1819.
AMARANTHUS. *Amaranthus*, formed from *amaranthos* and *eidos*, or from *α* and *μεγας*, and denoting incorruptible, because the flower being cropped does not soon wither, in Botany, a genus of the monocotyledonous class and order, of the *trianthria trigynia* of Gmelin’s Linnaeus, of the *miscellanea* of Linn. and *amaranthi* of Juff.; its characters are, that those species which have male flowers on the same plants with the females have a calyx, which is a five or three leaved perianthium, upright, coloured, and permanent, the leaflets lanceolate and acute; no corolla; the stamens have five or three capillary filaments, from upright patulous, of the length of the calyx, the anthers oblong and versatile; of those which have female flowers in the same raceme with the males, the calyx is a perianthium the same with the former; no corolla; the pistillium has an ovate germ, styles three, short and subulate; stigmas simple and permanent; the pericarpium is an ovate capsule, somewhat compressed, as is also the calyx on which it is placed, coloured, and of the same size, three-bent, one-celled, cut open transversely; the seed is single, globular, compressed, and large. Martyn reckons 29, and Gmelin 22 species. Those with three flowers comprehend, 1. *A. graecizans*, pellitory-leaved amaranth, with glomerules axillary, and leaves lanceolate, repand and obtuse. "The stem is a span high, smooth, grooved, and whitish, except at the base, where it is purplish; leaves smooth, green, and marked with lines; petiole very short; the glomerules in pairs, green, or five or five-flowered; and the calyx both of the male and female flowers is composed of three subulate, mucronate leaflets; a native of North America; cultivated in Chelsea-garden in 1723; flowers from July to September. 2. *A. albus*, white "with glomerules axillary, leaves roundish ovate, emarginate, and stem four-corrugated and simple." The stem is a span high, greenish white, decumbent and smooth; the leaves petioled, green, smooth, marked with lines, ending in an herbaceous, reflex, minute, whitish point; the petioles winged and channelled, and almost the length of the leaves; glomerules in pairs, sessile, and few-flowered; leaflets of the calyx oblong-lanceolate and whitish, with a green nerve, and at the end a subulate, herbaceous point; nearly related to the first species; a native of Pennsylvania, whence it was brought to Italy, introduced here in 1773 by M. Thouin; flowers in July and August. 3. *A. demissus*, "with spike very short with few flowers, leaves rhomb-lanceolate, and capillary not gaping;" the stem weak, filiform, decumbent, divided at the base into a few branches, green, except at bottom, where it is brownish, round, slightly decipitose and smooth; leaves green and smooth; petioles channelled and green; spike solitary, composed of only five or six flowers; no lateral glomerules; but a flower or two scattered in the axils of the leaves; the calyx five-leaved; leaflets diaphanous, white, oblong, and edged with green; dilignified from the rest by the capillary not opening transversely, but being entire. Its native place is unknown. 4. *A. polygonoides*, spotted-leaved A. blitum of Brown, Jamaica, and chenopodium of Burm. Zeyl. "with three-leaved glomerules, female flowers funnel-shaped, and leaves rhomb-ovate, emarginate." The stem is red and smooth; the leaves smooth and green; the petioles green and channelled; the glomerules axillary, with from six to eight flowers in each; the calyx of the female flower one-leaved and ventricose; the five segments spreading much, and transparent white; the capillus falling with the calyx when the seed is ripe; the calyx of the male-flower three-leaved, membranaceous and transparent; the leaflets oblong and obtuse, with a green nerve. This species varies in different situations, it resembles the second, but differs from it in having the stem round, and the calyx of the female flowers one-leaved and funnel-shaped; it is found wild by waysides and among rubbish in the tropical countries of Asia, Africa, and America, as in Jamaica, Guiana, Senegal, Guinea.
When in wrinkled, July. pairs, small by it; the colour is of kind the three-petal purple-coloured; it is a spike, native culture, Virginia simple branch it not its A. 1656 Tradefcant, the different 1731 of "of" ked, violet A. "with glomerules subspikspike, rounded, leaves elliptic, cuneate, and upright leaf." This species is a native of Virgina and Guiana; was cultivated in 1768 by Miller, and flowers from July to September. 14. A. trifis, round-headed A. "with glomerules in loose spikes, leaves subcordate-ovate, marginate, shorter than the petioles." This species is nearly related to the last, but may be easily distinguished by its upright stalk, more loose and slender spike, rhomboidal leaves, and five-leaved calyx: it is a native of China, Cochin, Ambon and Brail, and used as we do spinach; cultivated in 1759 by Miller, and flowers from June to August. 15. A. Blium, leaf A. or blite, "with glomerules subspikspike, three-leaved flowers, leaves ovate-retuse, and disfigured leaf." There are three varieties, viz. billium album majus, bl. majus rubrum, and bl. rubrum minus. This is a native of all Europe, except the very cold parts, Japan, &c. in cultivated grounds, on duaghills, banks, among rubbis, &c. 16. A. flavens, climbing A. "with spikes interrupted, compound, spiklets, bent in, leaves ovate, and stem weak." It resembles the foregoing species, and is a native of America. The species with five flowers are, 17. A. helicus, "with flowers in simple spikes, axillary, and glomerate, and leaves ovate, acute." It is doubtful whether this is a distinct species, or merely hybridous: it connects, in point of outward form, the three-flamed and five-flamed amaranths, varies much, and its native place is not known. 18. A. hybriit, clustered A. "with racemes decumbent, hipped, erect, and leaves ovate-lanceolate." Wildenow enumerates four varieties: 1. wholly green; 2. with a red stalk; 3. with the racemes reddish, the red green; 4. with red racemes. These differ in appearance, but are produced by the same feed. This species is found wild in Virginia and Arabia Felix; was cultivated in 1656 by Mr. J. Tradefnant, jun. and flowers from June to September. 19. A. flerius, "with racemes compound, erect, rigid, and leaves ovate, concave." This differs from the five-flamed species in its upright racemes propped close to the stalk, and the stiffness of the whole habit. Its native place is not known. 20. A. levis, "with racemes compound, erect, and leaves ovate, obtuse, and mucronate." It much resembles A. hybridus, but is distinguished from it by having the leaves blunt at the end, and being much smaller in stature, the stem never rising more than a foot high. 21. A. eruvin, various-leaved A. "with racemes decumbent, naked, patulous, and leaves lanceolate-ovate." This species varies, of a shining red colour, with a red stalk, with pale leaves, with a green stalk, with varied leaves, &c. When first cultivated in England in 1728, the stem was wholly red and smooth, the petioles, ribs, and nerves of the leaves underneath purple; the spikes purple, much spreading, and a little nodding. They were very beautiful for the first two years, but the seeds degenerated, and the plants had little beauty. It is a native of the East Indies and of China, and flowers from June to August. 22. A. hypochri-driaeus,
Amaranthus acutus, prince’s feather A. "with racemes compound, crowded, erect, and leaves oblong-lanceolate, and mucronate." This approaches very nearly in structure and variegations of colour to A. hybridus, and is distinguished from it, but not without difficulty, by the greater redness of the racemes, and sharpness of the leaves at the end, and by the base of the leaves running far down along the petiole; upon the whole, says Mr. Mutyn, it seems to be only a variety of that. It is a native of Virginia, and flowers from July to September; was cultivated by Miller in 1739, but is now become a common weed, frequently growing upon dung-hills, and abundantly scattering its seeds. 23. A. fanguinum, spreading or bloody A. "with racemes compound, erect, branches spreading and smooth, and leaves oblong and acute." The seeds were sent to Mr. Miller from the Bahama island before 1755, as an elegant plant, bearing fine flowers; and he describes it as growing three feet high, with purple flanks and leaves, the spikes short and swelling out in the middle; and at the extremity of the stalk arises a large cluster of spikes transversely, with one upright stalk in the middle; and those are of a bright purple colour at first, but become darker as the seeds ripen; it flowers from the middle of June to September. 24. A. paniculatus, "with racemes compound, branches spreading, pubescent, and leaves ovate-lanceolate." This differs from A. fanguinum in its pubescent branches, pointed calyces, clavate glomerules, and the whole habit; it is a native of America. 25. A. retroflexus, hairy A. "with racemes super-decompound, erect, branches pubescent, and leaves ovate waved." It approaches to the last species in the pubescence of the racemes, but differs in having green spikes, tomentose-fimbriate bracts, and leaves waved about the edges; it is a native of Pennsylvania, flowers from July to September, was cultivated by Miller in 1759, and is now become a common weed in many gardens near London. 26. A. chlorocephalus, "with racemes compound, nodding, and lanceolate leaves." It resembles A. retroflexus, but differs from it in its smooth stalk, lanceolate, flat leaves, glomerules in more dilated racemes, and in being much more slender; its native place is not known. 27. A. flavus, pale A. "with racemes compound, nodding, and leaves ovate-lanceolate." It differs from the last in the form and waving of the leaves, in the red lines on the stalk, in the red rachis of the flowers, and in the greater clofenes of the racemes; and from A. retroflexus, in having the leaves less waved, ovate-lanceolate, and much less obtuse, the stem at bottom and the petals smooth, and the colour in the stem, rachis, and veins of the leaves red. The flowers, notwithstanding the epithet flavus, are always green, and only turn yellow as the seed ripens; it is a native of the East Indies, and cultivated by Miller in 1768. 28. A. caudatus, pendulous A. or love-lies-bleeding; there is a variety, which is A. maximus, or tree A. the blitum maximum of many authors. This last is made by Mr. Miller a distinct species; it rises to the height of seven or eight feet; the spikes are seldom half as long as the other, which are 2½ feet, but much thicker. This degenerates gradually into the smaller; and the seeds, which are at first white, become red. It flowers in August and September, and was cultivated in 1803 by Mr. James Sutherland: it is a native of Perba, Ceylon, Guiana, Peru, &c. 29. A. frumentius, prickly A. "with racemes terminating, compound, and axillately." This varies, with the spikes and stem reddish; a native of the East and West Indies, Guiana, Guiana, &c.; in the former it is eaten as a green boiled with bafella cordifolia; it was cultivated in 1803 by Mr. J. Sutherland, and flowers from July to September.

The amaranths are annual, herbaceous plants, and most of the species are used as culinary plants in hot countries.

Culture of Amaranthus. Those most worthy of a place in the pleasure-garden are the 8th and 12th; but they are tender and require attention. They are usually sown in pots, with cocks-combs and other flowy plants for adorning court-yards, and the environs of the house. Next to these are the 23d and 28th sorts, for the ornamentation of the principal borders in the pleasure garden or parterres. The seeds of these should be sown in a moderate hot-bed, about the end of March; and when the plants come up, they should have air in mild weather. When they are fit for transplanting, they should be removed to another moderate hot-bed, and placed at six inches distance, watering and shading them till they have taken new root; afterwards they should have free air, and frequent but gentle waterings. In the beginning of June they should be taken up with large balls of earth to their roots, and planted either in pots or the borders of the pleasure-garden, shaded till they have taken root, and afterwards frequently watered in dry weather. The tree Amaranthus must be planted in a rich light soil, and if it is allowed room, and well watered in dry weather, it will grow to a large size, and make a fine appearance. The 21st is a tender plant, and should be treated like the 23d and 28th. The other sorts are sufficiently hardy to bear the open air, and may be sown on a bed of light earth, in the Spring, and when the plants are fit to remove, transplanted into any part of the garden, where they will thrive and produce plenty of seeds. The 23d and 28th sorts must be sown on a good hot-bed in February, or at the farthest in the beginning of March; and they will rise in about a fortnight; soon after which another hot bed must be covered with good, rich, light earth, about four inches deep; and the plants carefully raised and pricked out into this bed, at the distance of four inches every way, and gently watered. In the middle of the day let them be covered with mats from the heat of the sun, and raise the glasseys to give them air; the glasseys should be kept dry, for the moisture exhaled by the fermenting dung and perspiring seeds is very injurious. When the plants are firmly rooted give them air every day, more or less, as the weather is cold or hot. In about three weeks or a month these plants will have grown so as to meet, and must be removed into another hot-bed, with the same rich earth, about six inches thick; observing to take as much earth about their roots as possible, and to plant them at the distance of six or seven inches every way, watering them so as to settle the earth about their roots. In the heat of the day let them be shaded; refresh them often with gentle watering; and give them air according to the heat of the weather, and cover the glasseys every night with mats. In three weeks more, the plants will have acquired a considerable size and strength, and should be exposed more and more to the open air, when the weather will permit, and thus they will become sufficiently hardened to bear being removed into the places where they are to continue the whole season; but they should not be placed in the open air till after the first week in July, and this should be done, when the air is perfectly soft, and, if possible, in a gentle shower of rain. These plants, when grown to a good stature, perspire very freely, and should, therefore, be every day refreshed with water, if the weather be hot and dry. By this management fine amaranths may be obtained; and these plants, when properly reared, are the greatest ornament to a good garden, for upwards of two months in the latter part of the summer.

Amaranthus are very prolific. Willdenow says, that he sowed eight ounces of seed from one plant of A. caudatus. The seeds retain their germinating quality for several years, but continue longer in the ground than fresh seeds, which
AMARANTHUS. See ACHLYANTHES, CELOSIA, ILLECEBRUM, IRIS, and RIVINA.

AMARANTHUS helenus. See GNAPHALIUM.

AMARANTHUS malvinus. Vide, ind. 3. i. 52. f. C. C. This is also the true impatiens malvinus of Slose, Catal. p. 2. Jan. i.p. 56: the myriamus cavanum malvinus of Hill, part. p. 3, and cerebrites of Knorr. diff. tom. A. 51. f. 1. 2. - Linnæus describes it under the specific name of areola, as a mediterranean. See AREOLA.

AMARDIUS. In Ancient Geography, a river of Media, which discharged itself into the Caspian Sea.

AMARELLA, in Botany. See GENTIANA.

AMARGURA, in Geography, an island in the Southern Pacific Ocean, lying in S. lat. 17° 57', W. long. 175° 16' 54'. This was the first island discovered by Maurelle, in approaching the Friendly islands in 1781; he called it Amargura, i. e. bitter-ness, on account of his severe disappointment of obtaining refreshments from it; no landing place being found even for boats, and the island itself having a singular appearance of barrenness. In 1791, Captain Edwards coasted the north-west side of this island, observed much smoke upon it, and called it Gardner's island.

AMARICAE, in Ancient Geography, a people of Asia, in the interior part of Media, near the Mardi, according to Ptolemy.

AMARISCOGGIN RIVER, in Geography. See ANDESCOGGIN.

AMARISPPII, in Ancient Geography, a people of Asia, in Baorians, according to Ptolemy.

AMARNA, or AMARUSA, a town placed by Ptolemy in Harenia.

AMARULA, in Conchology, a species of helix, that inhabits the rivers and fresh waters in India's he Cell, imperator, or without unilabatus, oblong; whorls beft with fplinuous teeth. Linnaeus adds to this concise description, that the shell is black, without spots, the spiral flax fibrous, and the number of whorls either five or six, each armed along the upper edge with ten sharp spines: the aperture or mouth widely gaping and white, the exterior lip acute, the interior one thick. This shell is likewise defined by another author, buccinum tefla subvorta nigra; anfractuus furrum muri- catis; Mull. Hift. Vern. ii. p. 1371, n. 330, and is supposed to be the voluta flaviatilis of Rumpf. Muf. tom. xxxiiii. f. F. F. - Length from nine to nineteen lines.

AMARUMAYE, in Geography, a river of America, which rises in the Cordelier mountains, and after a course of four hundred leagues, joins the river of the Amazonas, in S. lat. 5°.

AMARUS, in Ichthyology, a species of the CYPRINUS, that inhabits the clear streams of Germany. Its specific character is taken from the number of bony rays in the pectoral and ventral fins, of which there are seven in each; as a secondary character the dorsal fin is said to contain ten rays, the anal eleven, and the caudal twenty rays. The head is small and cuneate or wedge-shaped, the eyes minute, with the iris red and yellow; the jaws equal, cover yellow. The body is sericulatus, fibrous and finely speckled with black; above the lateral line yellow, back greenish, chaly- bese-black near the tail. Upper fins reddish, lower fins greenish.

AMARYLLIS, derived either from the name of a shepherds' men, mentioned by Theocritus and Virgil, or from amaras or amari, pheasant, lilio-narces of Tournefort, in Botany, a genus of the hexandria monogyne class and order, of the natural order of ilia or lilaces, the fpathaceae of Linn. and nartiff of Jull.; its characters are, that the calyx is a fpath, oblong, obtuse, compressed, emarginate, gaping on the flat side and withering; the corolla has six petals, lanceolate, the nectarary has six very short scales without the base of the filaments; the lamina have six awl-shaped filaments, with oblong, incumbent, ridged anthers; the pistillum has a roundish, furrowed inferior germ, the style fiform, almost of the length and in the situation of the filaments, the stigma trifid and slender; the perispermium is a subulate, three-celled, three-valved capsule; and the seeds are several. The inflorescence of the petals, filaments, and pistil is very various in the different species of this genus; and the corolla in most of the species is rather hexapetaloid than six-petalled.

Gmelin reckons 27, Mr. Martin 29, and Wildenow 38 species.

Tho'fe with a one-flowered fpathae are as follow: 1. A. butus, yellow A. or autumnal narcissus, colchicum buteau-nana of Baalum, with an undivided obtuse fpathae, fpathic flower, bell-shaped corolla erect, shortly tubular at the base, and erect filaments, alternately shorter; the flowers feldom arise above three or four inches high; the green leaves come up at the same time, and when the flowers are pall, the leaves increase through the winter. This species recedes a little from the genus. It is a native of the south of France, Spain, Italy, and Thrace, was cultivated by Gerard in 1596, and flowers in September. 2. A. Pumilio, dwarf A. with two-leaved, one-flowered fpathae, corolla funnel-shaped, equal, segments revolute, and filaments bent in and alternately shorter. This is a native of the Cape of Good Hope, was introduced here in 1774, and flowers in November. 3. A. Amafoe, atamafoe lift, with fpathae bifid, acute, flower pedicelled, corolla bell-shaped, nearly equal, erect, shortly tubular at the base, filaments bent down and equal. The flowers are at first of a fine carnation colour on the outside, but fade till they are almost white; they appear at the end of May or beginning of June, and sometimes in August. This is a native of Virginia and Carolina, where it grows plentifully in the fields and woods, and was cultivated here by Mr. Charles Hatton in 1780. 4. A. formosia, jacobea lifty, so called, because some imagined that they discovered in it a likenes to the badge of the order of the knights of the order of St. James, in Spain, the lilio-narcissus and narcissus of others; with a fpathae undivided, flower pedicelled, corolla two lipped, nodding, deeply fpathed, filaments and pistil bent down. The flowers are produced from the fides of the bulbs, are large, of a deep red, and make a beautiful appearance; it is a native of America, first known in Europe in 1593, some roots of it having been found on board a ship, which had returned from South America. by Sion de Tovar, a physician at Seville; he sent a description of the flowers to Chiusus, who published a drawing of it in 1611, called by Parkinson, by whom it was figured in 1629, the Indian daffodil, with a red flower; cultivated in the Oxford garden in 1678, 5. A. tubiflora, with fpathae one-leaved, tubular, lished and one-flowered, and peduncle twice as long as the fpathae; found at Buenos Ayres, by Cormerston. 6. A. tubiflora, with fpathae one-flowered, two-leaved, corolla funnel-shaped, with a long tube; found in the sandy lands of Lima. 7. A. maculata, with fpathae one-flowered, two-leaved, linear, flower peduncled, filaments and styke bent down; found in Chili by Dombey. S. A. chilensis, with fpathae one or two-flowered, one or two-leaved, lanceolate, flowers peduncled, and leaves linear. The flowers, which are those of A. belladonna or reginae, are of a purple colour; found in Chili by Dombey. 9. A. elevata, with fpathae one-flowered, two-leaved, tubulate, and corolla club-shaped; native of the southern part of Africa.

The species with a two-flowered fpathae are, 10. A. reginae, Mexican lifty, "with fpathae, having about two flowers, pedicels divericating, corollas bell-shaped, shortly tubular, nodding, throat of the tube bifurcate, and leaves lanceolate, patulous;"
patulous;” the bulb is green, corolla scarlet, and at the bottom whitish green, the style red, the flowers large, of a bright copper colour, inclining to red: it flowered in Fairfield’s garden, at Hoxton, in 1728; and Dr. Douglas wrote a folio pamphlet upon it, giving it the title of *Elium reginae*, because it was in full beauty on the 11th of March, the queen’s birth-day: the roots were brought from Mexico, and therefore Mr. Fairfield called it Mexican lily, the name which it has retained: it flowers in the spring in a very warm house; it is in beauty in February, and in a moderate temperature of air, will flower in March or April. 11. *A. porpuracea*, purple flowered A. crinium speciosum of Linn. Suppl. “with spathes, having about two flowers, corollas somewhat erect, tubular at the bafe, throat of the tube smooth, and leaves linear-lanceolate;” nearly allied to the last: the corolla large, and of a blood-red purple colour; a native of the Cape of Good Hope, and introduced here in 1774. 12. *A. linearis*, crinium lineare of Linn. Suppl. “with linear leaves, bell-shaped corollas, two and narrower segments;” the flowers are large and white; found at the Cape of Good Hope. 13. *A. egyptris*, Barbadoes lily, A. dubia of Linn. Amoen. Acad. “with spathe having about two flowers, pedicles erect, shorter than the spathe, tube filiform and horizontal, border spreading, open obliquely and curved upwards, and throat hairy;” a native of the West Indies; introduced by Dr. W. Pitcairn in 1778. 14. *A. reticulata*, flat-ribbed A. “with spathes having about two flowers, corollas tubular at the bafe, and nodding, throat of the tube smooth, scape compressed, leaves oblong and attenuated at the bafe;” distinguished by the transverse veins of the petals and smoothness of the throat; a native of Brafia; and introduced by Dr. E. W. Gray in 1777. 15. *A. tatarica*, “with spathes having about two flowers, corolla sub-compaundated, and deeply six-parted, segments superior, very narrow, inferior obtuse acuminate, and leaves linear, longer than the scape;” found in Siberia.

The species with a many flowered spathe are, 16. *A. Belladonna*, Belladonna lily, “with corollas somewhat erect, six-petalled, petals flat, scape compressed, leaves sharply channelled, bluntly keeled, and very smooth.” This species differs from the A. reginae, by having the the edges of the petals waved, and not reverting at the tip: was first brought to England about 1712, from Portugal, abounds about Florence, and sold under the name of Narcissus Belladonna; usually flowered in England about the end of September or beginning of October, and the stem rises upwards of two feet in height; in a favourable season, and, when scented from frots, high winds, and heavy rains, will continue in beauty a month or longer, and is an ornamental plant. when other flowers are scarce; a native of the West Indies, on shandy hills, by the side of streams. 17. *A. vittata*, superb or riband A. “with flowers pedicelled, corollas wedge-tunnel shaped, the rachis of the outer felled to the edge of the inner petals, scape round, and filigmas grooved.” It is striped with red on a white ground, whence its name vittata or riband A.; in perfect bloom, it deferves the name of superb, given to it by Aiton, its stem rising to the height of three or more feet, and producing from two to five beautiful flowers; usually blooms in April or May; is probably a native of the Cape; and introduced into England by Mr. W. Malcolm, in 1769. 18. *A. fulata*, fiddle-leaved A. or crinium, “with corollas peduncled, erect, fix-petalled, scape compressed, of the length of the umbel, leaves flat, pressed to the ground, about the edge fiddle-shaped, white, cartilaginous and crenate.” It is a native of the Cape, and introduced here in 1774, by Mr. F. Maffon. 19. *A. ornata*, cape coast lily or A. “with flowers fefile, corollas tubular at the bafe, tubes longer than the spathes, and border, curved, segments of the border oblong, awned, lowest segment divaricate and concave.” It is a native of Guinea, probably cultivated by Lord Petre, in 1749, and flowers with us in June and July. 20. *A. longifolia*, long-leaved A. “with flowers pedicelled, 12-20 in a spathe, corollas tubular at the bafe, tube curved, short, segments of the borders lanceolate, obtuse, leaves broad subulate, channelled, and flaccid at the tip.” It is a native of the Cape of Good Hope, introduced in 1773, by Mr. F. Maffon, and flowers in July. 21. *A. montana*, “with many-flowered spathes, leaves linear-fusulate, petals alternate, mucronate, flaminus and fyle erect;” or, according to Willdenow, “with bell-shaped equal corollas, segments alternate, awned, flamines and fyle ftraight, and twice shorter than the corolla, foliose fcape and linear leaves.” This is a native of the higher parts of Mount Lebanon. 22. *A. seytnica*, Ceylon lily, Javan tulip of Ramphasia, “with many-flowered spathe, corollas reclining, tube fihiform, very long, and segment uncinate.” This is a native of the East Indies. 23. *A. revoluta*, revolute A. “with flowers pedicelled, corollas tubular, at the bafe, tube fihiform, short, curved, leaves linear, narrow, channelled, long, flaccid from their origin.” It is a native of the Cape of Good Hope, introduced here in 1774, and flowers in September. 24. *A. latispora*, crinium latifolium of Linn. Miller, and Rheed, “with many-flowered spathe, flowers pedicelled, somewhat reclining, tubular at the bafe; and leaves oblone-lanceolate.” It is found in the sandy foil of the East Indies. 25. *A. aurea*, golden A. “with flowers pedicelled, somewhat erect, corollas tunnel-form club-shaped, almost fix-petalled, segments linear, lanceolate, flamines and fyle ftraight, leaves linear, erect, channelled, with a reflex, smooth margin.” It is a native of China, introduced in 1777, by Dr. Fothergill, and flowers in August and September. 26. *A. orientalis*, broad-leaved A. Africa. “with many-flowered spathe, flowers pedicelled, fix-petalled, considerably shorter than the pedicels, irregular, germ wedge shaped and angular.” It is a native of the Cape of Good Hope, whence Mr. Miller received the roots which succeeded in the Chelsea garden; in the Kew catalogue, said to be introduced in 1707, by Mr. W. Malcolm. 27. *A. farrinosa*, ffilium fabricae of Douglas, who published a description of it in 1755, Narcissus of others, Guernfey lily, so called by Mr. Ray in 1665, “with petals linear, flat, flamines and pipil ftraight, longer than the corolla, filigmas parted and revolute.” The bulb is an oblong fheroid; the leaves are dark willow green; the number of flowers is commonly from eight to twelve, and circumference of each about seven inches; the corolla, in its prime, has the colour of a fine gold tiffie wrought on a rose-coloured ground, and when it begins to fade, it is a pink; in full sunfheine, it seems to be fudded with diamonds, but by candle-light the specks or flangues appear more like fine gold dust; when the petals begin to wither, they assume a deep crinm colour. The flowers begin to come out at the end of August, and the head is usually three weeks in gradually expanding. This beautiful plant is a native of Japan, and has been long naturalized in Guernfey. It is said to have been brought from Japan to Paris, and cultivated in Morrins garden before 1634. It was cultivated at Wimbledon, in England, by general Lambert, in 1659, and in 1664 became more common: it does not seem to have been in Holland before 1695. The plants are reputed to owe their origin in Guernfey to the shipwreck of a vessel returning from Japan, probably before the middle of the 17th century. The bulbs, it is said, being call on shore, took root in that sandy soil, and produced beautiful flowers, which engaged the attention of Mr. Hatton, the governor’s son, who sent roots to several of his friends. A variety of this found
found at the Cape of Good Hope is described by Jacquin, with many-flowered fpatha, corollas very patent, and reflex at the apex, filaments and pistil somewhat straight, longer than the corolla, and leaves uniform-linear. 28. A. marginata, with oblong revolute petals, filaments and pistil somewhat straight, longer than the corolla, linguiform leaves preflled to the ground, cartilagineous-marginate; or, according to Jacquin's description, with a many-flowered fpathe, corollas very broad, and reflex at the apex, erect pedicels, sublinguiform and prostrate leaves, terminated with a margin coloured, and undulated towards the apex. This is a native of the Cape of Good Hope. 29. A. turco-flora, with oblong, revolute petals, filaments and pistil somewhat straight, and longer than the corolla, with leaves stiff, linear-eniform and calcinated; or, according to Jacquin, with many-flowered fpathe, revolute, undulated corollas, erect pedicels, and leaves sublinear, widely channelled, and subfoliolated. This is a native of the Cape of Good Hope. 30. A. undulata, waved fflower African A. with linear channelled, waved petals, filaments and pistil bent down, shorter than the corolla, and oblitate figma. The flowers have no foecit, and expand from November to the beginning of January: a native of the Cape of Good Hope, introduced about 1767, by John Blackburn, cfl., and flowers here from April to June. 31. A. radicata, snow-drop leaved A. with lanceolate, waved petals, filaments and pistil bent down, diverging, twice as long as the corolla, and oblitate ligula. The native place of this species is unknown, cultivated by Miller in 1758, and flowers in June. 32. A. humilis, with three or four-flowered fpathe, lanceolate, fbringent-petalated petals, waved-reflex at the apex, with the lowest divaricated, the flaments and pistil ascending, shorter than the petals, and leaves linear, obtuse, smooth, naked and flat; or, according to Jacquin, with few-flowered fscapes, patent petals, the lowest divaricated, and leaves linear, obtuse, and flat. It much resembles the next species, but the scape and leaves are twice less; a native of the Cape of Good Hope. 33. A. flexuosa, with many-flowered fpathe, petals lanceolate, fbringent-petalated, waved-reflex at the apex, the lowest divaricated, the flaments and pistil ascending, shorter than the petals, and leaves linear, somewhat obtuse, concave, and pubescent dotted; or, according to Jacquin, with many-flowered fpathe, patent-petalated, the lowest divaricated, and linear, pointed leaves. The younger leaves are marked with white pulches; the more adult pointed, and when dry the points vanish; a native of the Cape of Good Hope. 34. A. radulara, with many-flowered fpathe, petals lanceolate, fbringent-petalated, flat, the lowest divaricated, the flaments and pistil ascending, of the length of the petals, with veins elliptico-ovate, preflled to the ground, and roughly pulished; a native of the Cape of Good Hope. 35. A. fl-botata, with many-flowered fpathe, corollas bell-shaped, shortly tubulose, segments, flat, reflex at the apex, flaments and pistil ascending, and the leaves elliptico-ovate, erect, and marginated; or, according to Jacquin, with many-flowered fpathe, corollas bell-shaped, equal, and reflex at the apex, sub ovate leaves, and frilated on the back; a native of the Cape of Good Hope. 36. A. eripa, with few-flowered fpathe, petals very patent, oblong, obtuse, and waved, flaments divaricated and shorter than the corolla, straight style, and leaves linear-siliform, and lax; or, according to Jacquin, with few-flowered fpathe, petals very patent and crisp, and leaves linear and very narrow. The flowers are very small; a native of the Cape of Good Hope. 37. A. f7ierria, with many-flowered fpathe, corollas patent and flat, a very short tube, flaments unequal, divaricated, shorter than the corolla, straight style, and leaves linear and erect; or, according to Jacquin, with many-flowered fpathe, very patent petals three, alternate, and barbated below the middle; a native of the Cape of Good Hope. 38. A. cirsium, crinum calpium of Pallas, with many-flowered fpathe, bell-shaped corollas, very short tube, flaments erect, longer than the corolla, and leaves lanceolated and waved; found near the Capfish Sea, in the beginning of Spring. 39. A. firalis, with fpathe two-leaved, few-flowered, peduncles filiform, very long, and leaves subulate. I. Heritier. This species was discovered by Bruguier in sandy grounds near the Cape of Good Hope. 40. A. cinnamomeum, with many-flowered fpathe, corollas sub-hexafluous, lanceolate, waved, flaments and pistil erect, shorter than the corolla. L'Heritier. This species is allied to Haranthus; was found by Bruguier at the Cape of Good Hope. 41. A. alta, with flowers declining, and leaves lanceolated. Forsk. Fl. Asg. Arab. p. 209. Martyn. Gymnus Linnaeus. Willdenow. 

Culture and Propagation. Most of these species have very beautiful flowers, and merit the attention of the botanist and florist. The first, or yellow natural A. is very hardy, and increases by offsets. The reason for transplanting these roots is from May to the end of July, when the leaves are decayed. They will grow in any kind of soil, but will thrive better in a friable, light, dry soil, and a warm situation, and will keep flowering from the beginning of September to the middle of November, provided that they escape severe frosts; and a succession of flowers will spring from the same root. The third, or Atamian lily, may be propagated by offsets from the bulbs, and will thrive in the open air on a dry soil, and in a warm situation. The 4th, or Jacobaea lily, is propagated by offsets, which are taken off every year; and the best time for shifting and parting the roots is August. They should be planted in middle-sized pots, and they will produce flowers two or three times in a year, and from March to September, when the roots are vigorous. The 10th, or Mexican lily, is less hardy, and must be placed in a warm flower, or the pots should be plunged into a hot-bed of Tanner's bark, and may be increased by offsets. It flowers usually in the beginning of Spring and makes a fine appearance in the flower. The 16th, or Belladonna lily, is cultivated by preparing a border near a wall, with a south-well aspect, about five feet wide; and for this purpose the earth should be removed to the depth of three feet, six inches of rotten dung laid at the bottom, and covered to the depth of about twenty inches, with light garden mould; the roots should then be placed at the distance of six inches every way, and covered over with light sandy earth, so as to bury the upper part of the roots about five or six inches; and in the Winter the border is to be covered with rotten tanners' bark to the depth of three inches, in order to guard against the frosts; and in severe frosts mats or straw should be laid over the leaves, to prevent their being killed. Thus managed, the roots will greatly increase, and produce flowers every year, which make a fine appearance during the month of October. The green leaves will abide till June, and then decay, after which the roots should be transplanted. The 17th species may be easily propagated by seeds. The 20th may be treated in the same manner as the Jacobea lily; will increase by offsets; and usually flowers in Winter, when the pots are placed in a moderate flower; and as there are few flowers in Winter in the open air, it is on this account the more valued. The 26th must be placed during Winter in a flower of moderate warmth, and left watered than the Jacobea lily. The 27th, or Guernsey lily, has been cultivated for many years in the gardens of Guernsey and Jersey, whence the roots are sent to most parts of Europe. The bulbs are commonly brought over in June and July, and they should then be planted in pots filled with fresh, light, sandy earth, mixed with a small quantity of very rotten dung, placed in a warm florarium.
a warm situation, and occasionally refreshed with water. About the middle of September the stronger roots will flewer their red-coloured flower-stem; and then the pots should be removed into a situation where they may have the fell benefit of the sun, and be sheltered from strong winds; but not placed under glass, or too near a wall, which would draw them up, and render them less beautiful. When the flowers begin to open, the pots should be put under shelter, so as to be secure from too much wet, but not kept too close or too warm. The flowers will continue in beauty for a month; and though without scent, their rich colour entices them to the field rank in the flowerery tribe. After the flowers are decayed, the leaves will be shed through the Winter, and they will be best sheltered in a common hot-bed frame. The roots should be transplanted every fourth or fifth year, toward the latter end of June, and planted into fresh earth. The offsets, planted in separate pots, will in three years time produce flowers; these roots will furnish a stock, which will supply flowering roots without the trouble and expence of obtaining them from Guernsey; and the roots preferred here will flower more strongly than those that are usually brought from thence. In order to preserve a large number of these roots without pots, a bed may be prepared in a well-sheltered part of the garden, by mixing a third part of fresh virgin-earth from a pasture ground with equal parts of sand, of rotten dung, and sifted lime rubbish. Of this, when it has been well incorporated, there should be made a bed about two feet thick, raised in dry ground four or five inches above the surface; and if the ground be moist eight or nine inches higher. In this bed the roots should be planted, about the beginning of July, about six or eight inches amidst each way; and in the Winter, when the frost sets in, covered with mats and straw; but in the Spring the covering may be removed, and during the Summer kept clear from weeds, and the earth occasionally stirred; and every year, when the leaves are decayed, a little fresh earth should be sifted over the beds, in order to encourage the roots. Here the roots may remain till they are strong enough to produce flowers, and then removed to pots, or suffered to remain in the same bed to flower. The roots of these plants often flower twice in the compass of three years; after which the same root will not flower again in several years, but only the offsets from it. The 22d, or Ceylon lily, is tender, and must be treated like the Mexican lily. It flowers usually in June and July, and sometimes the same root will flower again in Autumn; and if the pots are plunged into a bed of tanners' bark, the roots generally flower twice every year; but the flowers are not of long duration. The 24th may be increased by offsets from the roots, or by the bulbs which succeed the flowers; and it must be treated like the Cithara. The bell-time for transplanting the roots is about the beginning of August, when the leaves are quite decayed. Martyn's Miller.

AMARYLLIS. See Hypoestis Stellata.

AMARYLLIS Ciliaris. See Hemantthus Ciliaris.

AMARYLLIS diffusa. See Hemantthus tomentarius.

AMARYLLIS umbella. See Cyrtanthus obscurus.

AMARYNTHUS. In Ancient Geography, a small island of Euboea, according to Steph. Byz.; but, according to Strabo and Pausanias, a small place in the island, famous for a temple of Diana, where she was worshipped, and hence called Amarynthia.

AMAS, a mountain of Peloponnesus in Laconia, according to Pausanias, near Las and Gythium.

AMASENUS, La Toppia, a river of Italy. Also another river of Italy, which ran into the Liris.

AMASIA, in Biography, a professor of Greek and Latin at Bologna, and secretary to the senate, was born at Udine, in Friuli, in 1480. Paul III. invited him to Rome, made him preceptor to his grandson Alexander Farnese, and employed him on several embassies to the emperors of the empire and the king of Poland. He taught rhetoric at Bologna with an annual salary of 300 crowns, and at Rome, where he was much esteemed for his learning, and had a pension of 600 crowns a year. He translated Pausanias, that translation was corrected by Sylvius, and Xenophon's Expedition of Cyrus the Younger. He also wrote a volume of "Onstia", and "Scholas duas de Raymoni Inlinucendi." Two books, in which he shews that the Latin tongue is preferable to the Italian, were never printed. Huetius, "de claris Interpret," represents him as a great admirer of perspicuity and politeness of style, and says of him that he enlarged what was too concise, abridged what was too prolix, and elucidated obscure passages. He died about the year 1552, and left one son, named Pomplinius, who taught Greek at Bologna, and translated two fragments of the 6th book of Polybius. Gen. Dict.

AMASIA, in Entomology, a species of Papilio in the nymphales section. Wings indented, of a green colour, with a row of black spots along the margin of the posterior pair; under-side marked with ocellate spots. Found in Surinam. Fabricius.

AMASIA, a species of Phalara, of the Asina family. Wings varied with cinereous, and whitish, with a fulvous streak; lower-ones yellow, with two black bands, the outer one interrupted. Abbatt Inf. Georgica, by Dr. l. nich.

AMASIA, in Ancient Geography, a district or division of Anatolia Nothia, or Asia Minor, in Asiatic Turkey, bounded in the north by the Euxine Sea, on the east by Armenia, on the west by Anatolia Proper, and on the south by Caramania and Abduinia. The capital of this country is Amasia, called by the Turks Amos and Amazeh, which is an ancient town, situate among mountains, three miles distant from the river Iris, or Caulimack, and the residence of the governor of Cagherbag. It has been customary for the eldest son of the Grand Signior to reside here till he is called to the throne. The city was formerly the seat of the kings of Cappadocia, and some remains of its ancient magnificence are still existing. It gave birth to the famous geographer Strabo, and in Christian times it has been the see of an archbishop. Its wine and fruits are excellent. It is on leagues south of the Euxine Sea, and 200 miles south of Constatinople. N. lat. 40° 31'. E. long. 48°.

AMASIA, or AMASIA, in Ancient Geography, a town of Germany, supposed by some to be the present Embden, and by others Marburg. It was near this town that Druus vanquished the Bructeri.

AMASIS, in Biography and History, king of Egypt, was of plebeian extraction, and by his meritorious services obtained the confidence of Apries, his sovereign, whom he succeeded in the throne, B. C. 569, and soon after put to death. Upon his accession he was affianced in the exercise of his public duties, devoting his mornings to business, and his evenings to social amusement. Under his reign Egypt was singularly prosperous and happy, and is said to have contained 20,000 populous cities. For the preservation of order and the encouragement of industry, he enacted a law which required every person to inform the governor of the province once a year how he earned his living, and those who were not able to give a satisfactory account of themselves were punished with death. To the Greeks he was a great friend, inviting them into Egypt, and granting them places where they might erect altars and temples to their own
own deities; and it is said that he was visited by Solon; he also married a Greek woman. Such was the liberality of his disposition, that he contributed a thousand talents of alum to the Delphians for their relief when their temple was burnt, and he granted to the Greeks several valuable donations. In his own country he erected several magnificent buildings, and at a very great expense enriched the principal temples with gifts and ornaments. Amasis was the first person who subdued Cyprus, and extorted tribute from its inhabitants. The choice of his reign, however, was very different from its commencement and progress. Having by some means or other, probably by refusing to pay the same homage and tribute to Cambyses which he had been accustomed to render to Cyrus, incurred the displeasure of the Persian sovereign, Cambyses prepared to invade Egypt, and derived effeminate subservience from Phanes of Halicarnassus, who commanded the Greek auxiliaries in the pay of Amasis, and who, having been his ally and friend, joined Cambyses against him. Thus defeated by a prudent and valiant general, and by a powerful ally, and apprehending the formidable invasion of Cambyses, Amasis was rescued from the evils that threatened him, and that beclouded the closing scenes of his life, by death, B.C. 525, after a reign of 44 years. His dead body was embalmed, and deposited in a sepulchre which he had built for himself in the temple at Sais. The reign of his son and successor, Psammetichus, was short and calamitous; and the victorious Persians, after his defeat, capture, and death, took the body of his father Amasis from the tomb, mangled it in a shocking manner, and burnt it. Thus terminated the ancient splendour and liberty of Egypt. Herodotus. Diodorus Siculus. Un. Hist. vol. i. p. 314-323. Rollin's Anc. Hist. vol. i. p. 92-101.

AMASIS, in Ancient Geography, a species of Phalena, of the Bombyx family. Wings deflected; anterior pair whith, streaked with black, posterior pair yellow, with black spots. Abdomen black, belted with red. It is further described as having the head and thorax whitish, with black spots. The red or farrineous marks that encircle the abdomen are five in number, and the three black streaks on the anterior wings are angular. A native of Surinam. Fabr. Ent. Syll.

AMASIA, in Ancient Geography, a river of Germany, the present Ems.

AMASONIA, so called from Amason, a traveller into America, in Botany, a genus of the dorylaimis angiospermia class and order. Its characters are, that the calyx is a perianthium, one-leaved, bell-shaped, semi-spinuous, acute, equal, and permanent: the corolla is one-petalled, tubulous, longer than the calyx; border spinuous, sub-equal, spreading, and small; the stamens have four filaments at the upper side of the corolla, and longer than it, bending in at the end, two of them fleshy, the anthers oval and incumbent: the pistil has an ovate germ, style in the situation and form of the flaments, figmas two and thorp, no perianth. The seeds are ovate, one-celled nut, of the same length with the calyx. This agrees with the Tullgala of Athilet in every thing except the fruit, which, according to that, is a drupe, longer than the calyx one-celled, and containing two small hemispherical one-celled nuts. There is one species, viz. A. erecta. It is a native of Surinam, with an herbaceous stem, three feet high, round and fimbri: the leaves are alternate, petiolate, remote, elliptic-lanceolate, felterate, and scabrous: the flowers in a simple terminal raceme, a foot long, with about three flowers on a pedicle: the bracteas ovate, sessile, a little longer than the flowers, which are yellow, nodding, and grow all on one side of the flalk.

AMASEA, in Ancient Geography, a town of Peloponnesus, in Achaia.

AMASSI, a people of the Asiatic Sarmatians.

AMASTRA, a town of Sicily, the same with Ameltrata.

AMASTRIS, now Amstron, a town of Asia Minor, in Paphlagonia, upon a small island which joined the peninsula Selimus to the continent. It was built by Amastir, the wife of Lyrumneus, who gave it to his wife Arsinoe, and by her the government of it was entrusted to Hercules. Soon after it became very considerable, and put itself under the protection of Arisdarzaneus, the son of Mithridates. When the Romans carried their arms into Asia, Amastris was taken by Triarius, the lieutenant of Cotta. From the Romans it passed to the Greek emperors: it was afterwards taken by the Venetians: from them it became the possession of the Turks; and, having lost its commerce, it is now almost annihilated.

AMATA, in Entomology, a species of Papilio, in the section Danae Candeli, with round fulvous coloured wings, bordered with black on the upper side; beneath greenish; is found in India. Linn. Syll. Nat.

AMATARIA, a species of the Phalena, of the Goniota family, that inhabits Europe. The wings are angular, of a pale brown, slightly speckled, with an oblique darker-waved streak, and a straight purple line across the middle. It is produced from a green larva, with yellow rings, that feeds on the leaves of oaks. Limnæus. Don. Brit. Insects, tab. 33. fig. 2.

AMATEUR, in the Arts, is a foreign term introduced and now passing current amongst us, to denote a person understanding, and loving, or practicing, the polite arts of painting, sculpture, or architecture, without any regard to pecuniary advantage. Such have been found in the revivals of painting, &c. in most countries. Amateurs who practiced were never perhaps in greater number or of superior excellence than at present, and those who delight in and encourage the arts have been the means of raising them in this country to that eminence to which they are arrived. It is to be regretted, however, that the great works of former ages, collected by amateurs in this kingdom, are not so accessible to our professors as they are in foreign countries, which would tend to accelerate the progress of the arts, and that the encouragement given by these amateurs is in general upon too limited a scale.

It may occasion some surprise to the next generation, that Royal Patronage has not routed to emulation in this particular more of the noble amateurs who surrounded the throne, and induced them to encourage the greater works, as they do such as are of an interior nature; for this our reputation in historic art would be elevated so as to be equal, if not superior, to that of any of the neighbouring nations, and even to rival the fully celebrated pictures produced in the 14th and 15th centuries, and our sculptors might be equally esteemed with those of ancient Greece or Rome.

AMATEUR, in Music, is equal, in French, to the term Dilettante, Ital. implying a lover and cultivator of music, not professionally, but for his amusement—a gentleman performer. In the Encyclopedia Methodique we have a long article on the subject, by M. Guinguier, in which he divides les Amateurs into three classes, which he describes in the following candid and fair manner. "The first is composed of such as are born with delicate organs and much sensibility to the beauties

...
ties of music, and who, not having had leisure, inclination, or the means of cultivating their natural propensity, continue through life to cherish their passion for the art; eagerly attending all concerts and musical dramas; and, finally, by frequent and impartial parallels, dictated by nice and accurate discrimination, becoming, for times, better judges of composition and performance than trained professors, poetified neither of taste nor impartiality.

"The second class comprehends those who have had the means of developing, and confirming by study, the gifts of nature, and who have fulfilled their dispositions into talents. Of these the number is at present considerable. Music is become so interesting a part of a good education, and vocal and instrumental music have made so great a progress, and are so generally cultivated, that there are few private concerts in which more talents are not displayed by amateurs of both sexes than the most celebrated professors poifled in France 20 years ago. Concerts entirely composed of gentlemen and lady performers are not uncommon; but perfoms at all difficult are much disfigured if the principal parts at least are not guided by able profiirs.

"The third clafs is the most numerous and the most dis-tinguished, though they are less ambitious of shining than the second: it is composed of amateurs, who, not content with learning to read and execute music, have tried to penetrate into the secrets of the art, and enable themselves to account for the pleasure they receive, by analysing their sensations and studying the theory of music, to enable themselves to judge more accurately of the practice, and to unite intellectual pleasure with that of sense and the heart. Matters are fortunate who have such for judges, where their knowledge is incorporated with natural feeling and candour; and still more happy, a thousand times, the true amateur, who has neither the rage of decision, nor the arrogant pretentions of settled rank; who, knowing the arcana and refinements of the art, discovers and tells beauties unknown to vulgar hearers; who, preferring his primitive sensibility, enlightens it by meditation and study; and who finds himself impelled, both by judgment and feeling, to treat with regard the artist to whom he owes his pleasures, without a distinction of nation or party.

AMATH, or Ancient Geography, a town of Syria, called by the Greeks Emefa.—Alfo, a town of Phœnicia, near Gidara, the fame with Emefa.—Alfo, a town of Calis- fyrus, called by the Greeks Ephiphanias.

AMATHA, a country of Arabia.—Alfo, a town of Phœnicia, probably the fame that was founded by the 11th son of Canaan, called Chamati in the Book of Genesis, and by the Septuagint Amatha. According to Josephus, it was the capital of the Amathitans, and fame have supposed it to be the fame with Emefa.—Alfo, a place of Judea, in that part of it that was allotted to the half-tribe of Manasseth, on the coast of Jordan.

AMATHIEL, a people of Arabia Felix, according to Pliny.—Alfo, a people who inhabited the Land of Promise before the Israelites, and who occupied part of the tribe of Nephthali, towards Mount Liban. These people were vanquished by the Israelites, and retir'd into Phœnicia, where they built Amath, or Emath, on the banks of the river Orontes. According to Josephus, they fent forth a colony, who built the town of Amath, near the lake of Gennesareth.

AMATIFEA, in Entomology, a species of Papilio, in the Nymphulites fection, that inhabits South America. The wings are angulated, brown, with white spots; a red band, and undulated black line. Linna. Syd. Nat.

AMATHO. See AMATO.

AMATHUS, or AMATHOS, in Ancient Geography, Vol. II.

AMATUUS was a town of the southern part of the island of Cyprus, near Lyceus, between Curium and Citium to the east. It was founded by the Phœnicians, and owed its celebrity partly to the fertility of the adjacent country, and partly to the temple and worship of Venus in this place. Strangers, it is said, were facilitated on her altar. The goddess was displeased, and punished the inhabitants by changing the men into bulls, and by depopulating the women of their modely, so that they prostituted themselves without shame. Agreeably to this opinion, Ovid reports that the first constellations appeared in this town. The statue of Venus in this place was that of an hermaphrodite. The statue was allegorical; and probably the men sacrificed to her in female habits, and the women to those of males. There was another temple in this place, as we are informed by Pauly-Barnes, consecrated to Venus and Adonis. Amathus was afterwards called Limassol; but it is now utterly destroyed.

AMATHUS was also a town of Peloponnesus, in Laconia, according to Strabo.—Alfo, a river of Peloponnesus, in Messenia, called Panisu.—Alfo, a town of Palæline, beyond Jordan, on the coast of Mount Abaran, ruined by Alexander Jannaeus.

AMATUS, one of the epithets of the isle of Cyprus, and the inhabitants were called Amathysti, from Amathus above mentioned.

AMATI, ANTON and Hieronymo, in Biography, two brothers, celebrated instrument makers in Cremona, renowned in 1662. Nicolo Amati, the son of Geronimo, was living in 1682. All these were such admirable fabricators of violins, as to render valuable every instrument that was supposed to come from Cremona. See Stradusius and Stein.}

AMATILLAN, in Geography, a town of Mexico, in the province of Guatimala; 10 miles S.E. of Guatimala. N.lat. 14° 20'. W. long. 90° 20'.

AMATIQUE, a sea-port town, at the mouth of Guanaceu river, which discharges itself into the Amatique gulf, or gulf of Honduras, in the province of Vera Paz, in Mexico. The inhabitants are chiefly logwood-cutters, and on the south of the gulf is a tract of land, called Amatique land. The gulf is formed by the peninsula of Cape Three Points, and that which lies between it and Dulce gulf, and between these it runs far into the land. N. lat. 15° 23'. W. long. 89'.

AMATISSA, Amsis, in Ancient Geography, a small river of Gaul, which runs from the S. E. to the N. E. eastward of Ambacian, and discharges itself into the Loire.

AMATIUE, in Geography, a river of North America, in New Spain, which discharges itself into the Pacific Ocean, upon the confines of the province of Guatamala.

AMATIKINAK ISLAND is, with Ulak, the largest of the third group of islands between Asia and America.

AMATO, a town of Naples, in the province of Calabria Ultra, on a river of the same name, 7 miles S.E. of Nicaloro. AMATO, or AMATHOS, anciently LAMETUS, a river of Naples, which spreads itself over a large flat, in 50 different channels, and would overflow a great extent of country if its discharges were not restrained by high cliffs on each side of its bed. Its waters are of a muddy white colour. It discharges itself into the Ion, three miles south of St. Eufemia, on the west coast of Calabria Ultra.

AMATORIUS, in Anatomy, an appellation given to those muscles of the eye, which give them a cast sideways, and assist in that particular look, by some called ogling. When the abducens and the recti act together, they give to the eye this oblique motion.

AMATORIUS, in Ornithology, a species of the Parus genus, of a deep blue slate colour, with a longitudinal spot in the
the middle of the wings, half rufous, half yellow. — It is the
mating amorous of the Puffin, and _aureus tupaia_ (pars amo-
rous) of Latham. The length is five inches and a quarter, biil
two thirds of an inch, black on the back, tip orange.

This bird inhabits the northern parts of Asia, and is re-
markable for the affection each fox shows the other. When
paird in cages it exercises are feebly interrupted; a cir-
cumstance that has impoed the emphatic names of ama-
tarius, amorous, and amorous upon this species, to differ-
guith it from others of the genus genus.

AMATRICE, in Geography, a small town of Naples, in
Abruzzo, with the title of a principality.

AMATTA, or Brasilia, a town of South America, in
the country of Brazil, and government of Fernambuco.

AMATTA, or BAIA, or KANG, ISLAND, an island in the Southern Pacific
Ocean, discovered by Captain Cook, in 1774, about 11 or 12 leagues distant from
AMAMOON, N. N. W. It is about five leagues in
circuit, considerably elevated, and probably has a volcano;
It is inhabited, but not very fertile. Between this and an-
other island, called Oghao, is a fale channel, about two miles
bread, without any founlings.

AMAUROSIS, in Surgery, a privation or obscurity of
light, from _amazone_, more commonly named _Gutta Sil-
nera_. This disorder is either complete, when total blind-
ness exists, or incomplete, when vision is not perfectly
destroyed. It is distinguished from the _glaucoma_ or
_Cataract_, in as much as the latter is a disease of the crys-
talline lens, whereas the former is generally seated in the
optic nerve. Amaurus may be produced by various causes,
and admits of different modes of treatment; but the confi-
deration of these particulars is referred to the article gutter
fera. See _Amblyopia_ and _Disopia._

AMAXIA, in Ancient Geography, a town of Asia Minor,
in Cilicia Trachea or Cilicia Montana.

AMAXITUS, a borough of Asia Minor, in the Troas,
and territory of the Alexandrians. In this place there was
a temple of Apollo, in which the priest Chryses, mentioned
by Homer, is reputed to have sacrificed.

AMAXOBII, a people who according to Ptolomy, in-
habitcd the interior parts of Scythia, in Europe. Their
name, derived from _amos_ or _amos_, a chariot, refers to the practice
which prevailed amongst these people and other Tartarian
nations, of placing their tents on carriages for their more
caly removal from one place to another. See _Hammoxobi._

AMAYA, in Geography, a town of Spain, at the foot of
a rocky mountain, in the county of Leon, four leagues
from Aquilar do Campo.

AMAIN, in Scripture History, the eighth king of
Judah, was the son of Jona, and succeeded his father in
his 25th year, A.M. 3165, B. C. 830. He adhered to the
worship of the true God, but not without a mixture of
idolatry; and therefore, he is said (2 Chron. xxx. 2) to
have done "that which was right in the sight of the Lord,
but not with a perfect heart." We are further informed
(Ch. xxx. 3, 4.) that, after his accession to the throne, he
put to death the murderers of his father, and in conformity
to the humane requisition of the Mosaic law, (Deut. xxiv.
16,) he preferred their children alive. With a large army,
formed of his own subjects, and other hired troops from
Israel, he marched against the Edomites, who had revolted
from Judah, in the reign of Joram, about 54 years before;
but having disinfected the Israelite auxiliaries, he led forth
his own people to battle, and defeated the enemy in the
valley of Salt, with great slaughter. The auxiliaries on
their return ravaged the country, killed 3000 men, and
carried off a great booty, as a compensation for the advantage
which they expected to have derived from their expedition
against Edom. Amaziah, after his victory, took home
the gods of the children of Seir, and paid them divine
honours. Preferring on his success, and imagining himself
to be invincible, he sent a hostile challenge to Josiah, king
of Israel, expressed by the words (2 Chron. xxx. 17.) "Come,
let us look one another in the face." Josiah, by the fable of
the cedar and thistle, endeavoured to diffuse him from his
hostile purpose; but he peremptorily, and the adverse armies met
at Bethlehem, where that of Amaziah was routed, and he him-"self taken prisoner. Josiah led the captive king with him
to Jerusalem; and having made a breach in the wall, he
entered the city, plundered the temple and royal palace,
and then returned to Samaria. After this disastrous event,
the reign of Amaziah was prolonged 15 or 16 years; but a
conspiracy having been formed against him at Jerusalem, he
fled to Lachish, where his enemies overtook and effaced him,
A.M. 3165. B. C. 810. 2 Kings, ch. xiv. 2 Chron.

AMAZON, in a General Seife, denotes a bold, courageous
woman, capable of daring and hardy achievements. See
Amazons infra.

AMAZON, or the river of the Amazons, called also
Maranon, in Geography, a river of South America, is
one of the largest rivers in the world. Its source is in Peru,
in a lake near Guanero, about 30 leagues from Lima, where
the Maranon rises; and at the head of the river Napo, near
Quito; its first division in Peru is from south to north; it
afterwards runs a course from west to east, of about 3000
miles, across South America, and receives near 200 other
rivers, many of which have a course of 5 or 600 leagues,
and some of them not inferior to the Danube or the Nile.
These rivers run down with amazing impetuousity from the
eastern declivity of the Andes, and uniting in a spacious
plain, form this immense river. The chief of them, from
the south and south-west, proceeding from the mouth west-
ward, are Arauaya, Paratina, Madeira, Eurus, Ulyat,
Ucayali and Ucagiri rivers. From the north and north-west,
advancing from its mouth, are Parma, Negro, Yupuru, Iba
and Napo, which last rises near the town of Archidano,
about 150 miles eastward of Quito. The Amazon is inter-
spersed with a great number of islands, which are too often
overflowed to admit of culture. It falls into the Atlantic
Ocean, almost under the equator, by several channels, and
its breadth at its mouth is 150 miles, and at the distance of
1500 miles from hence it is 30 or 40 fathoms deep. In the
rainy season it overflows its banks, washing and fertilizing
the adjacent country. M. de la Condamine, who made a
voyage down this river in 1743, found its descent in a straight
course of about 1860 miles, to be about 1020 English feet,
or 65 inches in a mile. The tides are perceptible at 600
miles from its mouth, but at an elevation only of 50 feet.

Bevides Orellana, who made this voyage from motives of
ambition, and de la Condamine, who was promoted to it from
a love of science, Madame Godin des Odonais, undertook it
in 1769, from conjugal affection. The narrative of the
hardships which she suffered, of the dangers to which she
was exposed, and of the difficulties which befell her, is one of
the most singular and affecting stories in any language, and
exhibits in her conduct a striking picture of the fortitude
which distinguishes the one sex, blended with the sensibility
and tenderness peculiar to the other. Lettre de M. Godin

à M. de la Condamine.

AMAZONA, in Ornithology, a species of Alcedo, first
described by Dr. Latham, in his Syn. Av. Sup. p. 110,
under the name of Amazonian Kingsfisher. It inhabits
Cayenne, and is about thirteen inches in length. The colour
above is glossy green, beneath white, paling backwards in
a ring
ring to the nape; the sides are variegated with green; the wings and tail spotted with white. These particulars constitute the specific character: it may be further added, that the bill is three inches long, narrow, straight, and black; the under mandible yellow at the base; the thighs mottled with green, and the breast clouded with the same; tail feathers green, spotted on each side of the web with white, except the two middle feathers which are paler than the rest; legs black.

AZAMON, a species of Embiriza, described by Linnaeus and Gmelin. The general color is brown, crown of the head fulvous, vent whitish. It inhabits Surinam, and is about the size of the titmouse. The underside of the wings white at the base.—Buffon calls this L'Amazon, tom. iv. p. 354, and Latham gives it the English name of Amazon's Dunting.

AMAZONE, in Sculpture, a very fine antique flute, in Parian marble. It was about two hundred years at the Villa Mathe, upon Mount Coelius, at Rome; from whence it was removed to the museum of the Vatican, by pope Clement XIV.; and is now in the gallery of antiques at Paris. There is also a beautiful statue of a queen of the Amazons at Wilton; represented in a warlike action; being on one knee; as under a horse, defending herself in battle. Her shield is in the form of a half moon; behind the lower part of which, the sculptor has executed a horse's foot; in order to illustrate the attitude. This statue was executed by the celebrated Cleomenes.

AMAZONIA, in Geography, a large country of South America, 1400 miles long, and 900 miles broad, is situated between the equator and 26° S. lat., and bounded on the north by Terra Firma and Guiana, on the east by the Atlantic Ocean and Brazil, on the south by Paraguary, and on the west by Peru. This country was first discovered by Francisco Orellana, about the year 1541, who, in a bark, manned with 50 soldiers, was borne down by the current of the river Napo into the channel of the Maragnon; and who, after making frequent descents on both sides of the river, sometimes feizing by force of arms the provisions of the fierce savages, feasted on its banks, and sometimes procuring a supply offood by a friendly intercourse with more gentle tribes, reached the ocean. This bold and magnanimous adventurer pretended to have discovered along the banks of this river, nations so rich, that the roofs of their temples were covered with plates of gold; and he described a republic of women so warlike and powerful, as to have extended their dominions over a considerable tract of the fertile plains which he had visited. From this community of warlike women, who, with arms in their hands, opposed his passage, he called the country Amazonia, or the land of the Amazons, and he gave the name of Amazon to the river, which had formerly been denominated Maragnon.

The Spaniards have made several attempts to plant this country, but always met with so many difficulties and obstructers, as to render their designs abortive. The Portuguese have some small settlements on that part of the coast which lies between Cape North and the mouth of the river Amazon; but these excepted, the natives are in the sole possession of the whole country. The air in this country is cooler than might be expected, considering its situation in the middle of the torrid zone; which is owing partly to the heavy rains, which cause the inundations of the rivers for one half of the year, and partly to the cloudiness of the weather, so that the sun is obscured, during the greatest part of his day above the horizon. The fair season is about the time of the foliages, and the wet or rainy season is about the equinoxes. The soil of Amazonia is very fertile, and produces corn, grain, and all kinds of tropical fruits; besides a variety of timber, as cedar, Brazil-wood, oak, ebony, iron-wood, logwood, and other dying woods; and also cocoa, tobacco, sugar canes, cotton, cassava root, potatoes, yams, farfariila, guams, rafials, ballians of various sorts, pine apples, guavas, bananas, &c. The forests abound with wild honey, and also with tigers, wild boars, buffaloes, deer, parrots, and game of various kinds. The rivers and lakes afford an ample supply of fish, sea-cows, and turtles; but the alligators and water-serpents render fishing a dangerous employment. The trees, fields, and plants, are verdant throughout the year. The natives are of good stature, with agreeable features, long black hair and a copper-coloured complexion, and are very different from the natives of Africa, in the same latitude, on the opposite side of the Atlantic. Condamine says, that they have a taste for the imitative arts, especially sculpture and painting, and that they frequently excel in mechanical proficiencies. They spin and weave cotton cloth. Their houses are built with wood and clay, and thatched with reeds. Their arms, in general, are darts and javelins, bows and arrows, with targets of cane or fish skins. The several nations, on both sides of the river Amazon, which are very numerous, are governed by chiefs or caciques; for it is observable, that the monarchical form of government has prevailed almost universally, in both ancient and modern times, in a rude and uncultivated state of society. The regalia, by which the chiefs are distinguished, are a crown of parrot's feathers, a chain of tiger's teeth or claws, which hang round the waist, and a wooden sword. They are all idolaters, and worship the images of their ancient heroes; and in their various expeditions they carry their gods along with them.

As to the Amazonian race, if it ever exiled otherwise than in the imagination of the original adventurer Orellana, or in the exaggerated reports of travellers and voyagers, it is now wholly extinct; and probably the notion was at first fuggled by the activity and courage which the females of this country exerted, in the defence of their privileges, against the encroachments of foreigners.

AMAZONS, in Geography and History, denote an ancient nation of warlike women, who founded an empire in Asia Minor, upon the river Themadon, along the coasts of the Black Sea; and who are said to have formed a state out of which men were excluded. What commerce they had with that sex, was only with strangers, whom, after occasional intercourse at stated times, they put to death; hence, as Herodotus informs us, they have been called Eorputa, or murderers of their husbands. They also killed all their male children, or, as some authors say, broke their legs, or disjointed their knees, and thus rendered them incurably lame, by luxations, as Dionysius Siculus, Hippocrates, and Galen affirm, that they might be the more easily reduced to a state of dependence and slavery. Moreover, they nursed their females, and trained them up to war; and that they might ufe their arms more readily, and be more fit for the combat, they cut off, or feared with a plate of hot braff, their right breasts, apprehending that there would be otherwise some impediment in the use of the bow. Hippocrates and Galen allow that this fact was reported; but they allege, that this operation was performed, not on account of any impediment in the use of the bow, but to render the right arm stronger by an addition of aliments, as that which would have gone to the breast would be thus restrained to the arm. In reference to the excision of their breasts, Pentheus, one of
of their queens, is represented by Virgil, Æn. lib. i. v. 492.

“ Aurea subracenis excrse cingula mameae.”

From this last circumstance it is, that they are supposed to take their name, e. c. from the privative *a* and *μαμα*; *mamma*, breach.

Others have suggested, that the amputation performed on the breasts of the females was invented by the Greek etymologists, in order to explain the name of the nation. Others again have conjectured, that the name was derived from the Circassian word *mazwa*, the *moun*, which is said to have been a favourite deity among the mountaineers of Caucasus, in the vicinity of which the Amazons were settled. Dr. Bryant (not in the foot) traces the etymology of the appellative to *ezm*, the *fiat*, which was the national object of worship.

Some have maintained, that the description of the Amazons, given by the ancient writers, is purely allegorical; the amputation of one of the breasts signifying, that the female only was nourished by the mothers; and the killing of the boys denoting, that they were committed to the care of strangers.

It is, however, a point that has been controverted, even among the ancient writers, as well as the moderns, whether such a nation as the Amazons are described to be, have ever existed. Strabo, Pausanias, and others, absolutely deny it; whilst, on the contrary, Herodotus, Panuon, Dio-

Herodotus, in his history of the Scythians (lib. iv. c. 110. p. 330—332. ed. Walfeling.), informs us, that the Greeks, who had obtained a signal victory over the Amazons, near the river Thermodon, were carrying off the females that had escaped the slaughter in ships into their own country. While they were at the Amazons carried against them, and killed all the men whom they had on board; but being unacquainted with the art of navigation, even with the use of the rudder, sails, and oars, they were driven by the wind and tide to the precipices of the Palus Moesitis, in the territories of the free Scythians. Here they went inshore, and marching up into the country, they seized the first horses they found, and began to plunder the inhabitants. The Scythians unacquainted with their language, sex, and dress, took them at first to be youths; but after a skirmish or two, in which some of them were taken prisoners, they found that they were women. Accordingly all hostilities ceased, and they formed connections with them as their wives. But when the Scythians invited these women to accompany them to their own country, they declined accepting the invitation; alleging, that they had been always used to draw the bow, dart a javelin, mount a horse, and such warlike exercises, to which they supposed the Scythian women were altogether unaccustomed, and that they could not consent to exchange their military mode of living for a life of ease and indolence. They therefore exhorited their husbands, if they still retained the same conjugal affection for them, to visit their parents and friends, and to return with the several portions assigned them. They complied with the advice; and upon their return, were informed by their wives, that since they had deprived them of their parents, and committed several depredations in that country, they thought it much fitter to fix their habitation on the other side of the Tanais. This scheme was approved and executed. After three days march to the east of that river, and three more northward from the lake Moesitis, they arrived and settled in the country of Sarmatia, where they continued, says Herodotus, to his time. Hence, continues

the historian, the wives of the Sarmatians pursue their ancient mode of life, hunting on horseback either alone, or in the company of their husbands, marching with their armies, and wearing the same dress with the men. The Sarmatians used the Scythian language, corrupted by the Amazons, who had never learned to speak it correctly. Their marriages were attended with this peculiar circumstance, that no virgin was allowed to marry till she had killed an enemy in the field, and therefore some of them were old before they married, according to the requisition of the law.

From Diodorus Siculus (lib. ii. c. 45. p. 156—158. ed. Walfeling.), we learn, that there was formerly a nation who dwelt near the river Thermodon, in which women governed and conducted all their military expeditions. Among these, one excelled all the rest in strength and valor. By her an army was assembled, and trained up in military discipline, &c. as to subdue some of the neighboring nations. Her fame increasing with her success, she styled herself the daughter of Mars, and ordered the men to spin wool, and to perform the domestic services of the women. She promulgated laws, which required the women to engage in warlike exercises, and the men to remain at home in an inoffensive condition, and to be employed in the manual offices. The male children that were born were debilitated in their legs and arms, so as to be unfit for war; and the females had their right breasts amputated, so that they might be no impediment to them in fighting; and hence, says the historian, this nation obtained the name of Amazons. The queen, distinguished by her military skill, built at the mouth of the Thermodon a large city, called Themispeira, and adorned it with a famous palace. In her warlike expeditions she maintained strict discipline and order; and thus reduced to subjection all the neighboring nations, as far as the river Tanais. Having finished these exploits, she closed her life in the field like a hero, and fell in a battle, in which she had displayed singular courage. She was succeeded by her daughter, who equalized her value of her mother, and in some respects surpassed her. She caressed the young women to be trained to hunting in early life, and also to military exercises. She instituted feasts and sacrifices to Mars and Diana, which were the deities of her race; she built temple to the above-mentioned deities, and gained the love of her subjects by her mild and gentle government. She afterwards reduced a great part of Asia, and extended her conquests as far as Syria. The succeeding queens of the same race acquired renown by their government, and greatly enlarged the dominion of the Amazonian nation. The fame of the Amazons continued for several ages, till at length Hippolyta was vanquished and captured by Heracles, the son of Jupiter and Alcmene; and by degrees the Amazonian name became totally extinct. The last queen of the Amazon was Penthesilea, who assisted the Trojans, after the death of Hector, and was slain by Achilles. So signal and extraordinary were the character and exploits of this queen, and others of the Amazonian women, that Diodorus acknowledges, that in later ages, the relations of them have been regarded as fabulous.

Diodorus elsewhere (viz. lib. iii. p. 220.) mentions another race of Amazons, much more ancient than those of Pontus, in the vicinity of Thermodon. These inhabited the western parts of Libya; they were under the government of men; and as long as they continued single, they performed the duty of soldiers in the field; and after a stipulated period they associated with the men, and bore children;
but the magistracy and all public offices were retained by the females, and the men were employed in domestic offices, and were altogether subject to their wives, who would not allow them any participation of authority in the state, or any concern in military affairs. Their females had their breasts feared, that they might not be any hindrance to them as they grew up, and engaged in martial exercises. One of the principal queens of this nation was Myrina, who is supposed to have lived in the time of Orus, the son of Isis, and to have conquered Africa and the greater part of Asia, but was at last slain in Thrace.

Justin (ex Trog. lib. ii. cap. 4.) traces the origin of the Amazonian republic in Scythia. About the time of the first eruptions of the Scythians into Asia, in the reign of Scophoris, king of Egypt, two princes of the royal blood, named Hylinos and Scoloplytus, were compelled by an adverse faction to retire into Cappadocia, and there married their wives and families. By the assistance of the youths they brought with them, they obtained possession of Thermopole, on the river Thermodon, whence they made incursions into the adjacent nations for several years, till at last they were all treacherously murdered. Their wives, partly from revenge and partly from a dread of slavery, put themselves under the conduct of some of their chief heroines, and prepared for a bloody war with the murderers. In order to give full scope to their fury, they renounced all future marriages, and destroyed those of their husbands, who had escaped the slaughter; and then proceeded with such vigour and such success against their enemies, as totally to overthrow them, and to compel them to sue for peace. One of their first regulations was, that they should yearly have a month's intercourse with each other, for the propagation of their species; after which they went to their respective homes in their own way, deprived them of their right breasts, that they might be no obstruction to them in drawing their bow; and as for the boys, they either killed them, as Justin says, or disabled them for the future. And the mothers would bequeath to them their fathers, according to Herodotus and others. These surprising exploits were achieved under the government and conduct of two queens, Lympato and Marphesia, who pretended to be the daughters of Mars; and who, having extended their conquests into Asia, built cities there. The former of these females was left behind, with an army to secure their conquest, and the latter, on her return home, with her spoil, was surprized and cut off, with the rest of her female warriors, by some bands of barbarians. After a succession of female queens, Pentheilea is said to have come to Troy for the alliance of Priamus, as we have already mentioned. This queen, it is added, was the inventor of the battle-axe, and was killed by Pyrius, the son of Achilles. Another of their queens, named Tomyris, had a bloody encounter with Cyrus, king of Persia; and the famous queen Thaliestris had an amorous intercourse with Alexander the Great. Under this last queen it is said, that the Amazonian kingdom and race were ultimately destroyed.

Quintus Curtius (De Rebus Gestis, A. M. lib. vi. c. 5. tom. i. p. 400. ed. Snakenburg.) has given a particular account of this intercourse between Thaliestris and Alexander. He says, that the nation of the Amazons were settled upon the borders of Hyrcania, and that they inhabited the plains of Themiscyra, near the river Themodo. Thaliestris, their queen, who governed the whole country between Mount Caucasus and the river Phasis, being desirous of seeing Alexander, sent messengers to request an interview with him. Having obtained permission to visit him, the advanced with 300 of her female warriors; and when she approached his presence, she leaped from her horse, with two javelins in her right hand. The apparel of the Amazons, says Curtius, does not cover the whole body; but the left side is naked to the breast, and the skirts of their garments, which are tied up in a knot, reach below the knees. Their left breast is preferred, that they may suckle their female offspring; but the right breast is feared, that they may the more easily bend the bow, and shoot their arrows. Thaliestris, after observing Alexander for some time with an undaunted countenance, was disappointed, as his personal appearance did not correspond to the ideas she had previously formed of him, from the report of his signal exploits. When the king offered her, whether she had any thing to desire of him, Thaliestris without hesitation replied, that she wished to have children by him, and that she was worthy of the honour of giving heirs to his dominions. The female she would refuse for herself, and the male should be delivered to him. When Alexander interrogated her, whether she would accompany him in his wars, she declined, alleging, that she had left her kingdom without a guardian. Alexander, after renewed solicitations on her part, and a delay of 13 days, complied with her wishes; and Thaliestris returned to her kingdom.

Plutarch, in his life of Pompey, (Oper. tom. i. p. 678.) says, that the Amazons inhabit those parts of Mount Caucasus, that lie towards the Hyrcanian sea, that they are separated from the Albanians by the Getaic and Leges, and that they annually, for two months, accompany these people, and cohabit with them near the river Thermodon. They then retire to their own habitations, and live apart for the rest of the year. In his life of Thecus, (Oper. tom. i. p. 13.) Plutarch, after reciting some particulars relating to the history of the Amazons, acknowledges, that the accounts of them which had been preferred were partly fabulous and partly true. The arms of the Amazons were bows and arrows, javelins, and a kind of battle-axe, denominated the axe of the Amazons, the invention of which is ascribed by the elder Pliny to their queen, Pentheilea. On medals, the bull of the Amazons is usually armed with a small two-edged axe, called lironnis or fiduris, borne on the shoulder, and a buckler, in the form of a half moon, by the Latins called pelta, on the left arm. Hence Ovid's description of Ex Pont.

"Non tibia Amazonia est pro me fumenda securis,
Aut excisa lavi pelta gerenda manu."

And Virgil, speaking of the queen Pentheilea in Æneid.
lib. i. v. 490, says,

"Ductit Amazonidum lunas agmina peltis."

Besides the Amazons of Africa, which formed the most considerable body of these female warriors, and those of Mount Caucasus, near Colchis and Albania, and likewise near the Pelus Moeitis, of whom we have already given an account, Polyanes speaks of Amazons in India, who are also mentioned by Nonnus. They likewise occur in Æthiopia. They at one time, says Dr. Bryant, possessed all Ionia; and there were traditions of their being at Samos, and in Italy, where they had a town in Messapia, towards the lower part of the country, called Amazonia. Even the Athenians and Boeotians were of the same family; hence it is said, that Cadmus had an Amazonian wife, when he went to Thebes, and that her name was Sphinx. The Ciehians and Iberians, as well as the Cimmerians and Moeites, according to this learned writer, were Amazons; and so were all the Ionians, and the Atlantians of Mauritania. Philostratus,
in his Herodicus, mentions Amazonians on the Danube, and in Lucius Florus we read of German Amazons.

Among the ancient writers, who consider the peculiar history of the Amazons as fabulous, we have already mentioned Pseudo-Plutarchus, who was complimented for his distinguishing understanding, by the appellation "of περίδρατος," and who gave it no credit. Strabo also, although born at Amathus, in Cappadocia, an Amazonian region, could obtain no evidence to connote the history. He says, (lib. vii. tom. n. p. 576.) that many legendary stories have a mixture of truth, and most accounts admit of some variance. But the history of the Amazons is uniformly the same: the whole a monstrous and absurd detail, without the least appearance of probability. For who can be persuaded, that a community of women, either as an army, or a city, or a state, could subsist without men? and not only feebly, but make expeditions into other countries, and gain the sovereignty over kingdoms; not merely over the Ionians and those who were in their neighborhood, but pass the seas and carry their arms into Europe; to accede to this were to suppose, that nature varied from her fixed principles; and that in those days women were men, and men women. It may be added, that if such a people really existed, some traces of them would have been found, either in Iberia and Albania; or in the country upon the Thermodon, where they are supposed chiefly to have resided. But Procopius (De Bell. Goth. lib. iv. c. 3. p. 570.) says, that there was no mark, no tradition to be observed concerning them.

Among the moderns, who have maintained the existence of Amazons in ancient times, we may mention M. Petit, a French physician, who published a Latin dissertation, in 1685, in order to establish the fact. This dissertation contains abundance of curious inquiries, relating to their habit, their arms, the cities built by them, &c. Dr. Bryant (Analytical Ancient Mythology, vol. iii. p. 457, &c.) explodes the account of the existence of such a nation as fabulous; and he says, that the whole of this strange history has been owing to a wrong etymology of the appellation Amazon. The Greeks, who were fond of deducing every thing from their own language, imagined, that by the term Amazon was signified a perfon without a breast. This perfon they inferred to be a female; and, in consequence of it, as the Amazons were a powerful people, they formed a notion, that they were a community of women, who subsisted by themselves, and every absurdity, with which this history is attended, took its rise from the above-fated misconception. They did not consider, that there were many nations of the Amazons widely separated from each other; nor did they know, that they themselves were of Amazonian race. Dr. Bryant is of opinion, that the Amazons were in general Cuthite colonies from Egypt and Syria; and as they worshipped the sun, they were called Azoines, Amazones, and Alazones, which are names of the fame import and bear reference to the national object of worship. To this purpose Potamanius (lib. iii. p. 274.) mentions Apollo Amazonus, who was worshipped in Laconia. The most noted of them inhabited the region of Pontus, near the river Thermodon; and they were also called Chalybes, and Aylbes, and occupied part both of Cappadocia and Armenia, being situated near Sinope, and extending towards Celycis. They are mentioned by Homer (IIiad. lib. v. v. 826.) among the allies of the Trojans. One of the principal cities of these Chalybes, besides Sinope, was Amilia, or as Pliny expresses it more justly (lib. vi. p. 303.) Amazon, and he mentions a mountain near it of the same name. These people had different titles in the countries where they settled, and often in the same region; and therefore their history has been confused. They were called not only Amazons, but Syri, Aflvii, Chaldae, Mauri and Chalybes, and were still further diversified. They were the fame as the Ionians, and in consequence of it, they are said to have founded the chief and most ancient cities in Ionia, and its neighborhood. Accordingly the coin of the cities in Asia Minor, and particularly of those in Phrygia, Ionia, and Mityla, has often an Amazon for its device. The Amazons, according to the learned writer now cited, were Arctis, and one of their chief cities was called Sarcopolis, who came from Egypt, and worshipped the sun, and Selene, the chief deity of the country, from whence they came. They are told by Herodotus of Egypt, not as he conceives from killing their husbands, because, according to their history, they had not any, but from their worship; and this name was given to their priests. It signifies a priest of the sun, or Orus; and their priests used to sacrifice strangers, who accidentally came upon their coasts, and hence they were styled, "Apeironian," murderers. The Egyptians, it is alleged, admitted the firlam among their military instruments of music, and made use of it when they went to war. The same practice prevailed among the Amazons, who worshipped the Isis of Egypt, and made use of her fulam, when they engaged in battle. The Amazons of Colchis and Armenia were not far removed from the Minyae, near Mount Ararat, and were of the same family. They were Arctis, as we may learn from the people of Pontic Theba, and followed the rites of the ark, under the name of Meen, Baris, and Iona. Hence it is, that they have been represented with solar shields; not that they were of a solar shape, but the lunette was a device taken from their worship. It was the national emblem, which was painted upon their shields; whereby it is said of them, "xticks bellantur Amazonum amis." The Amazonian shield approached nearly to the shape of a leaf, as did also the shields of the Gothic nations; and upon these shields they had more lunettes than one; and from them the cullum was transmitted to the Turks and other Tartar nations. One of the most extraordinary circumstances in the history of the Amazons is their invasion of Attica. They are represented as women, who came from the river Thermodon, in revenge for the insult offered them by Hercules, who had plundered their country. Their attack is described as violent; and the conflict for a long time doubtful. At last, having lost many of their companions, they were obliged to retreat and entirely to leave the country. Of this invasion the Athenians pretended to have had many evidences; they exhibited the tombs of the Amazons, who fell in the contest; the place of engagement was called Amazonium; and near it was an ancient pillar, said to be erected by this people. But the history abounds with inconsistencies, though Plutarch (ubi praefat) seems to credit it, and addsuces several circumstances, with a view of establishing its certainty. Such a people, however, as the Amazons, had certainly been in Attica; the Athenians, as well as the Boeotians, were in a great measure defended from them. The rites to which Plutarch refers, in proof of hostility between the Amazonians and Athenians, afford no conclusive argument to this purpose; because they consisted originally in offerings made to the deity, from whom the Amazons derived their name. He was called Azoion, and Amazon, and was the same as Ares, the sun. They worshipped both Ares and Harmonia, changed by the Greeks to a feminine Harmonia; and in consequence of this worship, the Amazons were said to be the offspring of those deities. Hence it is, that the wife of Cadmus was said to be Harmonia; for the Cadimans were undoubtedly
undoubtedly Amazonians. What became of these female warriors after their repulse from Attica, the Grecians have not historically ascertained. Some say that they retreated into Magna Graecia, and founded the city Cletis. Icocrates (in Panegyr. p. 95.) acknowledges, that none of them returned into their own country; and Lydias (Fusc. Orat.) says, that their nation was wholly ruined by this expedition, that they lost their territories, and that they were no more heard of. Upon which Piatarch (ubi supra) observes, that we must not wonder, when transcriptions are of such antiquity, if history should prove contradictory and obscure.

The Amazonians are said to have always fought on horseback, (Arifopha. Lyd. hist. v. 680.) and yet the use of cavalry was not known in Greece, till long after this era; for, according to Homer, the Asiatic nations at the siege of Troy were equally unacquainted with this advantage. As for the tombs, which have been adduced as evidence of this invasion, they were probably high altars, raised in ancient days. The whole of this history relates to old rites and customs; and not to any warlike expedition. The pillar, called Amazonium, indicates, that the Amazonians might have been once in this country, and that they probably erected it; but this was the object to which they paid their adoration, as they lived in an age, when statues were not known. Such a one the Argonauts are said to have found in the temple of Arez, when they landed upon the coast of Pontus, and made their offerings to the deity, thus described by Apollonius, (Argonaut. lib. ii. v. 174.) according to the English translation of the original—

“Now to the grove of Arez they repair, And while the victims bleed, they take their stand Around the glowing altar, full in front Of a fair temple. Here of ebon hue Rifes in air a lofty antique Stone. Before it all of Amazonian name Bow low, and make their vows.”

That these supposed tombs were altars, is also inferred from their situation in the middle of the city, and in many different places. Every circumstance of this invasion is attended, says our author, with some absurdity. It is owing, we are told, to the injustice of Hercules, who stole the girdle of Hippolyte, and attacked the nation, of which she was queen, so as quite to ruin it. The Amazonians, thus defeated and weakened, and not able to withstand their next neighbours (see Diod. Sic. lib. iv. p. 229. tom. i. p. 262.) determined to wage war with the Greeks, and particularly with Thessaly. They began their march, but instead of proceeding directly to Greece, they purposed a contrary route, passing north-east in order to arrive at the south-west, and ranging round the whole Euxine sea, by Mount Caucasus and Colchis, to the Cimmerian Bosphorus, and traversing many hills and rivers, they at last arrived at Athens, pitched their camp in the precincts of the city, close to the Acropolis, fought a severe battle, retired, and not being able to return home, were dispersed and annihilated. And yet so far is this female history from terminating, the Amazonaz are introduced again by the poets, Homer, Virgil, &c. at the siege of Troy, and are to be met with in the wars of Cyrus. Some ages after, in the time of Alexander, an interview is said to have passed, as we have already related, in which the queen of the Amazonas makes proposals to that monarch about sharing, for a night or two, his bed. And even in the time of Pompey the Great, during the Mithridatic war, they are supposed to exit; for after a victory gained by that general, the Roman soldiers are said to have found many boots and buckles, which Dion Caius (in Bell. Mithrid.) thinks were undoubtedly Amazonian.

Such, says Bryant, after a long and learned detail of various particulars, of which the above is merely a concise abstract, was the credulity of the ancients about one of the most improbable stories that was ever feigned; and this learned writer concludes upon the whole, “that the Amazonians were a manifold people, and denominatd from their warlike people, and denominatd from their bond.” They were some of the Titanic race, who settled in Colchis, Ionia, Hellas, and upon the Atlantic in Mauritania; they were also to be found in other parts, and their family characteristics may in all places be traced. They were the same as the Cadians; and the structures which bore their names were not erected to them, but were the work of their own hands.”

Ludpoulos, says Plato (Mencken, vol. ii. p. 299.), led the Amazonians, when they invaded Attica; and he is supposed to have been the principal person who introduced the rites and mysteries, which were observed by the Athenians. His sons were the pritites, who officiated at the temple of Ceres in Eleusis. From all circumstances it is concluded, “that what has been represented as a warlike expedition, was merely the settling of a colony, and those who had the conduct of it were Amazonians, who had been represented as women. And so far is probable, that there were women among them, who officiated at the religious ceremonies which were instituted.”—Among barbarous nations women have often combated by the side of their husbands; but it is almost impossible, says Mr. Gibbon, (Hist. vol. xi. p. 48.) that a society of Amazons should ever have fubstituted either in the old or new world.

Later geographers and travellers speak of Mingrelian and Georgian Amazonas; Amazons in America, in Monomotapa, in the Philippine islands, in Denmark, &c. John de los Santos, a Portuguese capuchin, in his description of Ethiopia, mentions a race of Amazonas in Africa; and Eneas Sylvius gives us a very precise account of a republic of real Amazonas in Bohemia, which lasted nine years, founded by the valour of a young woman, called Valaska. That there have been females of singular talents and very extraordinary firmness and resolution, in all ages and in all nations, no one can dispute; and if we compare the warlike genius of the Scythian women in general, and more particularly that of the Sarmatians, in whose neighbourhood the Amazonas are said to have lived, with the occasion which is reported to have given birth to their strange kind of government, namely, the treacherous murder of their husbands, and their being in danger of becoming a prey to their murderers, and in a strange country; we may incline to give some credit to the brave and masculine method which they took to fave themselves from slavery, and to revenge the slaughter of their husbands. The Scythian, as well as the Celtic women, were anciently held in great esteem and veneration, for their skill in divination above the men, infomuch that the latter are upbraided by ancient authors for suffering women to assist at and direct their councils and to have even presided in their courts of judicature, and other assemblies; in which their judgment was reckoned decisive, because they were supposed to be divinely inspired. Being, therefore, inured to council, execution, and warlike exploits, exasperated by the barbarous brutality of their husbands, and rendered, as it were, desperate by the prospect of impending slavery, we need not wonder, that they should adopt effectual means of inflicting vengeance, and of defending themselves; and, with this view, that they should
A M A

should select one or two of the strongest and most valiant to lead them in an offensive war against their enemies, and that they should carry it on with courage and constancy, and of course with such animating success. And if their warlike temper, their government, customs, valour, conduct, and achievements, have been exaggerated beyond credibility, it may be alleged, that this has been done with respect to other nations, governments, and conquerors, which have attracted general attention, and of which it would be absurd to reject as altogether fabulous on that account. The fame allowance should be made in both cases: and this is much more reasonable than to suppose that the various historians, who have given an account of them, have been guilty of forgery or of too great credibility.

The true history of the ancients, and even of the modern Amazons, has, without doubt, been blended with much fable, with many marvellous and improbable, not to say altogether incredible relations: but the testimony upon which it is transmitted to us deferves regard, and it would manifest a degree of scepticism, which, applied to other cases, would be not only unwarrantable, but dangerous and pernicious, altogether to defraud it. The empire of the Amazons was certainly of a different kind from that which properly belongs to the female sex. "The empire of the woman," says Rouf- feau, "is an empire of lofiefs, of address, of complacency. Her commands are careless; her menaces are tears." "The character of the ancient Amazons," says Dr. Johnson, "is rather terrible than lovely. The hand could not be very delicate that was only employed in drawing the bow, and bradilising the battle-ax. Their power was maintained by cruelty: their courage was deformed by ferocity; and their example only shews, that men and women live side by side." The Amazons were applied, in a figurative sense, to bees, because among these insects the females alone are commonly supposed to bear sway.

Aridotle, treating of the breeding of bees, approves himself ignorant of their sex; and therefore, willing to keep up the prerogative of the males, he calls their governor βασιλεύς, rex, in which he has been followed by the generality of authors.

An ingenious writer of our own country, takes the liberty to strain the ordinary signification of the word rex, and in such places translates it queen, this being an Amazo- nian, or female kingdom.

Mr. Warder has published a work under the title of the True Amazons, or the Commonwealth of Bees.

A M B

AMAZONIAN, something relating to, or resembling Amazons.

AMAZONIAN, or female kingdom, is particularly used for a feminine one, or that wherein the females alone bear rule.

AMAZONIAS, in Antiquity, denotes a drefs formed in imitation of the Amazons.

Marcia, the famous concubine of the emperor Commodus, had this appellation Amazonian, because she charmed him most in a habit of this kind.—Hence also that prince himself engaged in combat; or at least intended to engage, in the amphitheatre, in an Amazonian habit; and of all titles the Amazonus was one of those he most delighted in. In honour either of the gallant, or his mitres, the month of January was also denominated Amazonus. Some also apply Amazonian habit to the hunting drees worn by many ladies among us.

AMAZONIUS is an appellation given to a kind of pafl, or troche, anciently used against risings of the stom- ach, and vomitings. The ingredients of which it is com- posed, are smallage, anise-seed, wormwood, myrrh, pepper, cyperus, opium, and cinnamon.

AMAZONIUS, in Entomology, a small species of Scel- rarius, found in Surinam. It is telficous, with two black marks on the thorax, and a brown callus on the exterior margin of the wing-cases. Linn. SYL. Nat.

AMB, in Botany, a name by which some authors have called the magna Indica, or Max-go-tree, called also amabilis, and ambe.

AMBAE, in Topography, denotes a kind of jurisdic- tion, or territory, the possession whereof has the administra- tion of justice, both in alto and bajo; or of what is called in the Scots law a power of pit and gallows, i.e. a power of drowning and hanging.

In some ancient writers ambacht is particularly used for the jurisdiction, government, or chief magistracy of a city. The word is very ancient, though used originally in a sense somewhat different. Eumius calls a mercenary, or slave hired for money, ambachtis; and Caesar (De Bell. Gallic. vi. 14.) gives the same appellation to a kind of dependents among the Gauls, who, without being free, were attached to the service of great lords.

AMBAGES, in Rhetoric. See Circumlocution.

AMBAIBA, the name of a tree in Brasil, called by the Indians, ipica. Ray's Hill Plant. See CECOPIA.

AMBATINGA, the name of a tree, whose leaves are so rough that they may be used to polish hard wood. Ray's Hill Plant.

AMBAPAYA. See CARICA.

AMBARVALIA, in the Materia Medica, a name by which some have called mulk feed.

AMBARES, in Geography, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Bourdeaux, five miles north-east of Bour- deaux.

AMBARVALIA, in Antiquity, a feast, or ceremony, among the Romans, celebrated annually, in honour of the goddess Ceres, in order to procure a happy harvest.

At these feasts, they sacrificed a bull, a fow, and a sheep; which, before the sacrifice, were led in procession thrice around the fields; whence the feast is supposed to have taken its name: from the Greek, to walk, or to run. But though others write it ambargaha, and ambarlka, and deduce it from ambir urken, to run round the city.

From the beasts offered in sacrifice, the ceremony was also called SUBEPAIALIA.

Some will have the ambarevalia to have been held twice a year: the first time towards the end of January, or, as others think, in April; and the second time in July, or as Rufinus imagines, in August; at the time when the harvest was ripe, maturis frugibus. Which opinion is the more probable, in that Ovid, who, in his Fasti, describes the feasts of the first six months of the year, from January to June inclusive, says nothing of the ambarvalia.

The sacrifice offered on this occasion was hence called ambarevalia facrum, and bowla ambarevalia.

The ambarevalia were of two kinds, public and pri- vate.

The private were those solemnized by the masters of families, accompanied with their children and servants, in the villages and farms out of Rome. They walked three times round the grounds, every one being crowned with leaves of oak, and singing hymns in honour of Ceres. After the procession, they went to sacrifice.

The...
The ambrosial carmen was a prayer preferred on this occasion; whereof we have the formula preferred in Cato.

"De re rustica." c. 142.

The public ambivalia were those celebrated in the boundaries of the city; and in which the twelve fractae arvalia officiated pontifically, walking at the head of a procession of the citizens, who had lands and vineyards at Rome.

The prayer, or formula, here used, as it is given by Feetus, in loco: "peffalus," was avertis sermum, marvin, tabem, nembulam, impetiginem, pofetatum. Virgil has described the ambivalia in the first book of his Georgics, v. 343, &c.

Some make a quinquennial as well as an annual ambivalia, the one performed every five years, the other once a year.

The priests who chiefly officiated at this solemnity, were called fractae arvalia.

AMBÆRVALIS flos, in Botany, a name given, by some authors, to the pratylo, or milkwort.

AMBASSADOR. See Embassador.

AMB AZAC, in Geography, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Limoges, 10 miles north-east of Limoges. The place contains 2793, and the canton 7543, inhabitants; the territory includes 101423 kilometres, and 7 communes.

AMBE, in Anatomy, a superficial jetting out of a bone.

AMBR, or AMB, in Surgery, an instrument employed for the reduction of a dislocated shoulder, especially when the head of the os brachii rete in the axilla. Various improvements have been made in the construction of the ambit since Hipocrates's time; but its use is rarely wanted, as a dexterous surgeon can generally replace the shoulder bone by more simple means. See Dislocations.

AMB EEZES, AMBOIZES, or AMBOIZES, in Geography, an island of Africa, in the Atlantic Ocean, near the coast of Benin. N. lat. 4° 15'. E. long. 10° 50'.

AMBELL, in Botany. See Nymphæa.

AMBELÀNIA. See Willughbeia.

AMBER, Hæmatos, Gr.—Eclètrum, fuccinum, Lat.—Succin, caratæ, ambre jaune, Fr.—Bernsteïn, ayzfeïn, gis Frimfeïn, woofch-amber, Ger.—Glefinum, ancient German, according to Play.—Börnfein, ræf, gis, Sweed.—Bernfeen, Dan.—Succina, ambra gialla, Ital.—Enyékö, Hung.—Junctar, Ruff.—Sæal, Egypt.—Bitumen fuccinum, Werner.

The colour of amber is generally some shade of yellow, as wine yellow, wax yellow, honey yellow, hyacinth red, yellowish white; it is also found occasionally green or brown. It occurs amorphous, and in detached pieces. It shining, or little shining, with a waxen lustre. Its fracture is conchoidal, and when broken it flies into indeterminate not particularly sharp fragments. It is commonly transparent, more rarely semi-transparent or translucent. It is brittle, and its sp. grav. varies from 1.055 to 1.1.

By rubbing, it readily becomes electric. When applied to a lighted candle it takes fire,放s considerably, but does not run into drops, and exhales a white smoke of a pungent penetrating odour.

It is sometimes confounded with copal and honey-stone, but may be distinguished from each without much difficulty. Copal is softer than amber, and when inflated melts into drops. Honey-stone is much weaker in its electrical properties, and when laid on a hot coal becomes white.

The only proper mines of this substance that are as yet known, are in Prussia, near the sea coast. They are worked in the usual way by shafts and galleries to the depth of about a hundred feet. The amber is imbedded in a stratum of fossil or carbonated wood, and occurs in nodules from a few grains in weight, to three or even five pounds: specimens also are occasionally met with consisting of the wood penetrated by veins of amber. The upper and under strata are sand and sandstone. Amber is also found along the whole shore of the German sea, and on the south coast of the Baltic. The projecting eastern shore of England too, and the coast at the entrance of the channel from the north affords many specimens. Rounded nodules have been occasionally met with in the beds of gravel near London. It is not, however, exclusively, though principally a northern product: the coast of the Adriatic sea and the Sicilian shores furnish a small quantity, and occasionally pieces have been dug up near Sidone in Provence.

The property of amber, when rubbed, to attract hair, straw, and other light substances, was first observed by Thales one of the Greek philosophers, who on this account attributed a certain kind of life to it; and from the Greek name of amber, electron, is derived the modern term electricity, being the science of an important class of facts, the first known of which was the attracting power of amber. On this account, and also from the real beauty of the substance, it was held in high estimation among the Romans, who made it into bracelets, necklaces, and other articles of female ornament. Those pieces that contained insects, &c., then as at present were the most valued, and we meet with many allusions in the Roman poets to this circumstance; thus Martial says,

"Cum Phantomea formica vagatur in umbra,
Impleuit tenuem fuccina gutta fremam."

They also held the idle opinion, which till lately was generally received among us, that a collar of amber tied round an infant's neck, would enable it to cut its teeth with safety.

When amber was more in request than it is now, as an ornament, and an article of Materia Medica, great attention was paid to it by the Prussian miners, and many experiments were made by the artificers to remove its defects, and improve its beauty. The coarser and smallest pieces were called flandlein or feahlug, those that were a little larger and cleaner had the name of sirinis or varnish amber, and the larger and better pieces were called, from the particular works to which they were applicable. Of the transparent ambers the most valuable was the bright golden yellow, of the opaque varieties the most esteemed were the flaky, or fealy. Methods were devised, especially by Gottlieb Samuelson of Brellin, of making opaque amber transparent, and of tinging it red, blue, violet, green, and white. Most of these secrets have perished with the inventors, but the two following were the usual methods of rendering amber transparent. First, by surrounding it with sand in an iron pot, and cementing it with a gentle heat for forty hours, some small pieces being occasionally taken out to judge of the progress of the operation. Secondly, which was the most usual method, by digesting and boiling the amber about twenty hours with rapsseed oil, when it became harder and clearer; linseed oil has not the desired effect. Amber, however, thus clarified, is always harder and less electric than in its natural state. The value of amber depending on its size, numerous attempts, but constantly without success, were made to fold together or melt down several small pieces, so as to convert them into one large piece.

The origin of amber has exercised the imagination of poets and chemists from the days of ancient Greece to the present; nor is it worth while to enter into an examination of any of these opinions, except those which are held by modern inquirers. Amber is by some considered as a proper mineral bitumen analogous to petroleum, perhaps originating

Vol. II.
AMBER, liquid, and balsam of. See BALSAM.
AMBER, in Geography, a river of Germany, in Bavaria, which rises two leagues from Tachsen, and joins the Her, near Landshut.

AMBER BY, is situated on the peninsula of Yucatan, in the bay of Honduras, and lies north of Ascension Bay.

AMBERED, or myrrh scented, is a seed that is somewhat like the millet, of a bitterish taste, and brought dry to us from Martinico and Egypt. The Egyptians use it internally, as a cordial, to fortify the heart, stomach, and head, and provoke flux.—It gives a grateful scent to the breath, after eating; but it is not proper for those who are inclined to vapours.

AMBER TREE, in Botany. See ANTHOSTERIUM.
AMBER BOL, See CERATOPTERUM.
AMBERG, in Geography, a city of Germany, in the circle of Bavaria, and Upper Palatinate, 32 miles north of Ratibon, and 32 east of Nuremberg. It is the capital of the duchy and residence of the elector's governor; it is seated on the river Vils, which runs through it, is well fortified, and is the largest place in the Upper Palatinate. It has an electoral palace, a cathedral, and a college of Jesuits. It is said to have been railed from a village to a town in 1297; and was taken by the Imperialists in 1703. On a mountain near it stands the pilgrimage-church, called Mary's-help, and in its vicinity is an iron-mine, which furnishes it with a considerable trade. N. lat. 49° 25'. E. long. 11° 55'.

AMBERH, a mountain of Sweden, in East Gothland, about two Swedish miles from Wadstena. Its height is so considerable, that from the summit of it a person may see 50 churches. Upon this mountain is a flat stone, under which one of the ancient kings is said to be interred. Antimony is found in this mountain near the Wetter-lake.

AMBERGER, Christopher, in Biography, an eminent painter of portrait and history, was born at Nuremberg, and refuted at Augsburg, where he died in 1552. He was a disciple of Hans Holbein, whom he imitated so exactly, that his pictures were sometimes taken for those of his master. He principally excelled in portraits, and acquired great reputation by his history of Joseph, in 12 pictures, and by the portrait of Charles V, for which the emperor paid him three times as much as he expected, besides a present of a rich chain of gold and a medal. Amberger was also an engraver, though his works are not specified. Pilking-ton and Scott.

AMBERGREASE KEV, in Geography, an island in Hanover Bay, on the east side of the peninsula of Yucatan, in the bay of Honduras. It runs along the mouth of the bay, and is seventy miles in length, but very narrow.

AMBERGRIS, from amber and grist, AMBER CAST, Anthospermum, in Natural History, a light, indissoluble, greyish, variegated substance, fluffy and fragrant with a gentle heat, and used as a perfum and a cardiel. Its colour is grey, brown, or yellowish brown, spotted with black; its hardness and consistence are those of wax; its specific gravity from 1.02 to 0.926, so that it swells both in water and refined spirit; its fracture is earthy and ragged, and exhibits bones of fish or beaks of birds; it has scarcely any particular taste, and unles heated, or much handled, very little smell; but in such circumstances its odour is very fragrant, resembling that of burning amber, and to most persons agreeable. It softens between the fingers, melts in a small degree of heat like wax; in a stronger inflames, and if pure, leaves no residue; cold water has no effect upon it, but to boiling water it communicates its smell, and being partially melted, falls to pieces. It is scarcely affected by spirit of wine, which dissolves it sparingly with the assistance
Ambergris.

affinice of a boiling heat, or fat oils; but by the essental, as that of turpentine, it is disdolved almost entirely, and by ether most perfectly. It has been found soluble in caustic fixed alkalis, still more so in oil of vitriol, and precipitable by water. Distilled it yields an aqueous phlegm, a brown-coloured acedulous spirit, a deeper coloured oil, at length, a thick balsam, and as some say, a volatile salt, leaving a black smelling residuum. The spirit, oil, balsam, and salt, are similar to those obtained from amber; but the oil is of a more grateful smell. Its chemical products resemble those of bitumen, among which some have ranked it.

It is found on the sea-coasts, floating on the surface of the sea, adhering to rocks, or thrown out upon the shores, in several countries; as along the southern and eastern parts of Africa, Madagascar, the Maldives, some parts of the Mediterranean, and in the West Indies, about the islands of Bermuda and Jamaica, and the Bahama islands, also on the coasts of Carolina, and the western coasts of Ireland. It is likewise said to be found on the coasts of Norfolk, and the islands of Orkney. It has also been found in the stomachs of whales, of various sizes and shapes. We have several instances in authors of large pieces of this matter, one of the largest that has been known in Europe was bought by the Dutch East India Company, of the king of Tidore, for 12,000 dollars, in 1649, and lent to Amsterdam in 1684, and kept in its horn for some years. It was almost round; measured two feet in diameter, and weighed a hundred and eighty-two pounds. The great duke of Tuscany offered fifty thousand crowns for it. We are told, however, that one was taken up, near the cape of Good Hope, which weighed three hundred pounds; and another, if we may credit the relation, fifteen thousand pounds. Phil. Trans. No 263. No 232.

There has been a great variety of opinions among naturalists with regard to the origin and production of this substance: to rehearse them all, would make a volume. Klobius recites eighteen, to which we could add half as many more. The principal may be reduced to these which follow.

1. Some take it for the excrement of a bird, called in the Madagascan language afchibibuch, and by the Maldives Ana-cangriugafusi; which being melted by the heat of the sun, and washed off the shore by the waves, they say, is swallowed up by whales, who return it back in the condition we find it.

2. Others, and particularly many of the orientals, imagine it springs out of the bottom of the sea, as napheba does out of some fountains. — They add, that the only springs of it are in the sea of Ormus, between the Arabian and Persian Gulfs. Eridisi, who is of this opinion, in the fifth climate of his Geography, mentions pieces of ambergris on those coasts, weighing a full quintal. Paludanus and Linchotten also speak of it as a sort of bitumen, gradually working up from the bottom of the sea and hardening in the sun.

3. Others take it for a sea-mushroom, torn up from the bottom by the violence of tempests; it being observed, that ambergris is never found but during the south-well monsoons, after storms.

4. Others assert, that it is a vegetable production, issuing out of the root of a tree, whose roots always shoo toward the sea, and discharge themselves into the sea. This account we have in the Philosophical Transactions, from one of the Dutch factors at Batavia; and the same is confirmed by Mr. Boyle. Others take it for a kind of wax or gum, which diffils from trees, and drops into the sea, when it congeals, and becomes ambergris. Mr. Magellan mentions an undoubtedly vegetable ambergris, gathered from the trees by M. Asplet, and examined by Roulle. Cronstett's Mineralogy, p. 458.

5. Others suppose it a spungious kind of earth, which the working of the sea washes off the rocks, where, being lighter than water, it floats.

6. Others maintain, that ambergris is made from the honey-combs which fall into the sea from the rocks, where the bees have formed their cells. This opinion seems to have something of experience on its side; several persons having seen pieces that were half ambergris, and half plain honey-comb; and others, again, having found large pieces of ambergris, in the middle of which, when broken, they discovered both honey-comb and honey. But the error of this hypothesis may be detected by chemical experiments; as honey likewise admits of a solution in aqueous methyl, but refists the most highly rectified spirit of wine.

7. Others are of opinion, that it is a bituminous matter; that it is at first liquid, and runs into the sea: and that it is there condensed, and reduced into a mass. To this purpose Mr. Neumann, chemist to the king of Prussia, after an ample recital of all the different opinions advanced by others, gives us his own; which is, that ambergris is a bitumen, issuing out of the earth into the sea; at first of a viscous consistence, but hardening, by its mixture with some liquid napheba, into the form wherein we find it. Phil. Trans. No 453. No 454. Neumann's Traité is of the same opinion.

This opinion has been considered as the best founded, and strengthened by this circumstance, that ambergris is found in the greatest quantities in the sea, about the island of Madagascar, where the subterraneous parts are supposed to be implicated with bituminous matter.

The pieces are frequently seen composed of divers fragments, laid one over another, with stones and other bodies included therein, and the fragments are sometimes full of little shells, which seem a species of concha anatifera; whence it may be conjectured, that the ambergris has originally been in a fluid state, or, at least, that it has been dissolved and in that state has formed itself afresh, and enveloped such bodies as happened to be in its way.

Neumann gives the chemical characters of this bitumen, and its analysis, by distillation. He distinguishes the sopplications of ambergris, and observes, that it is totally soluble in oils and vinous spirits, and that it yields the same product, as amber. See the particulars and the proofs of this in Neumann's Works, p. 239. &seq.

S. Dr. Boylston, and Mr. Dudley, in the Philosophical Transactions, assert, that the ambergris is a true, animal concrete, formed in balls, in the body of the male spermaceti whale, and lodged in a large oval bag, over the testicles, at the root of the penis. Phil. Trans. No 385. and 387. vol. xxii.

It is certain the whale-catchers have divers times found ambergris in their spermaceti whales, and that chiefly in the large and older sort; and it is from the information of Mr. Atkins, and other whale catchers, that Mr. Dudley chiefly drew his account. But it is added, that it is not one spermaceti whale in an hundred that is found to have ambergris, and that it is found only in the male. To this account it has been objected, that ambergris is frequently found in females as well as in males; and that the backs of the lepia, which are so constantly found in ambergris taken out of the whale, could not have been absorbed from the intestines by the faeces or lymphatics, and collected with the ambergris in the above mentioned bag.

9. Others have approached nearer to the truth, who represent ambergris as the excrement of a cetaceous fish; because it has been sometimes found in the intestines, and sometimes
Ambergris.

Sometimes in the faces themselves of such animals. Notwithstanding this suggestion, it was long thought, that ambergris, after having been swallowed, and in some mode or other changed in the stomach and bowels of the whale, from which it was obtained, was afterwards found among its excrements. But the real animal origin of ambergris has been satisfactorily ascertained by Dr. Swediar, in the Philosophical Transactions, vol. lxxii. art. 15.

In the accounts given of ambergris by various writers we have been told, that claws and beaks of birds, feathers of birds, parts of vegetables, shells of fish, and bones of fish, have been found blended with it. But Dr. Swediar, after examining many fragments of this substance, found no such materials mixed with it; and though he allows that such may occasionally occur, yet the black spots which he discovered in the various pieces, found in the sea or in the whale, that were examined by him, appeared upon accurate scrutiny, to be the beaks of the Sepia olivacea; and he apprehends, that these beaks were mistaken for claws or beaks of birds, or for shells. From the existence of these beaks in ambergris he infers, that this substance in its original must have been of a very soft or liquid nature. In order to investigate the true nature of this substance, he premised, that ambergris has been found upon the sea or sea-coast, and also in the bowels of whales; but he observes, that it has never been determined, whether the ambergris found in these different situations be of the same kind, and possessed of the same or similar properties. He alsolugается as a subject of previous inquiry, whether ambergris is found in all sorts of whales, or only in a particular species; whether it is constantly to be met with in those animals; and if this be the case, in what part of their body it is to be found. In discussing these subjects of examination, Dr. Swediar consulted the most intelligent persons concerned in the spermacei whale fishery, or in procuring and selling ambergris; and from their information it appeared, that this substance is sometimes found in the belly of the whale, but only in that species which is called the spermacei whale, and which seems from its description and delineation to be the phystcher macrocephalus of Linnaeus. The New England fishermen, having been long apprised that ambergris is to be found in the spermacei whale, conclude, that whales of this species frequent these seas where ambergris is found. They naturally expect to find ambergris in the spermacei whales which they catch; but they are generally disappointed. Whenever they took a spermacei whale, they observed, that it constantly not only vomits whatever it has on its stomach, but also generally discharges its feces at the same time; and if this circumstance occurs, they seldom find ambergris in its belly. But whenever they discover a spermacei whale, male or female, which vomits torpidly and sickly, they commonly find ambergris, as the whale in this state vomits its feces upon being hooked. They likewise generally find it in the dead spermacei whales, which they find floating upon the sea. Besides, those whales which yield ambergris have a morbid protrusion, or a kind of gathering, in the lower part of the belly, in which, when it is opened, they find ambergris. The whales, that yield this substance, are not only torpid and sick, but always leaner than others; and hence it is inferred, that a larger collection of ambergris in the belly of the whale is a source of disease, and probably sometimes the cause of its death. As soon as a whale, that is torpid, sick, or emaciated, or one that does not die before it is hooked, is caught, they immediately cut the protrusion already mentioned, if there be any, or rip open its bowels from the orifice of the anus, and find the ambergris, sometimes in one lump, sometimes in different lumps, generally from three to 12 and more inches in diameter, and from one to 20 or 30 lbs. in weight, at the distance of two, but mostly of about five or seven feet from the anus, and never higher up in the intestinal canal; which, according to their description, is probably the inteninum cecum, lithestro mistaken for a peculiar bag formed by nature for the secretion and collection of this singular substance. That this is the intestinal canal is certain, because they constantly begin their incision at the anus, and find the cavity every where filled with the faces of the whale, which, from their colour and smell, it is impossible for them to mistake. The ambergris found in the intestinal canal is not so hard as that which is found on the sea or sea-coast, but soon hardens in the air. When first taken out, it has nearly the same colour, and the same unpleasant smell, though not so strong, as that of the mere liquid dung of the whale; but, on exposing it to the air, it gradually not only becomes greyish, and its surface covered with a greyish dull like old chocolate, but it also loses its disagreeable smell, and when kept for any long time, acquires the peculiar odour which is so agreeable to most people. In considering whether there be any material difference between ambergris found on the sea or sea-coast, and that found in the bowels or among the dung of the whale, Dr. Swediar refutes the opinion, that ambergris found in whales is of an inferior quality, and therefore of much less value in piece. Ambergris, he observes, is valued on account of its purity, lightness, compactness, colour and smell. On the different coals pieces of ambergris are found of a very inferior quality; and those found in whales are of a superior quality; and different pieces in the same whale, are, according to the above specified test, of greater or less value. When ambergris is first taken out of the intestines of the whale, it has nearly the same smell with that of the liquid excrements, and also the same blackish colour; and it is found of different degrees of compactness, but never so liquid as the natural faces of that animal. After being taken out and kept in the air, all ambergris becomes harder and whiter, and gradually loses its smell, and assumes such an agreeable one, as that in general has which is found swimming on the sea, and therefore the goodness of ambergris seems rather to depend on its age. By being accumulated after a certain length of time in the intestinal canal, it seems even then to become of a white colour, and less heavy, and to acquire its agreeable smell. The only reason why ambergris floating on the sea generally polishes the above mentioned qualities in a superior degree is, because it is commonly older, and has been longer exposed to the air.

It is more frequently found in males than in females; those pieces that are found in females are generally smaller, and those in males seem constantly to be larger and of a better quality; and therefore the high price in proportion to the size is not merely imaginary on account of its rarity, but in some respect well-founded, because such large pieces appear to be of greater age, and possess the above mentioned qualities in a higher degree of perfection than smaller pieces.

It is known, continues our author, that the Sepia olivacea, a little fish, is the confant and natural food of the spermacei whale, or phystcher macrocephalus. Of this the fishermen are so well convinced, that whenever they discover any recent relics of it swimming on the sea, they conclude that a whale of this kind is or has been in that part. Besides, the spermacei whale, on being hooked, generally vomits up some remains of the Sepia. Hence it is easy to account for the many beaks, or pieces of beak, of the Sepia that
that are found in ambergris. The beak of the fepia is a black horny substance, and therefore paffes undigested through the lomachs into the intestinal canal, where it is mixed with the feces; after which it is either evacuated with them, or, if these latter be preternaturally retained, form concretions with them, which render the animal sick and torpid, and produce an obligation, that terminates either in an abscess of the abdomen, or becomes fatal to the animal; whence, in both cases, on the bursting of its belly, that hardened substance, called ambergris, is found swimming on the sea, or thrown upon the coast.

From the circumstances above related, and from having observed the above-mentioned piece of fepia in all fragments of ambergris of any size, Dr. Swediar concludes with great probability, that all ambergris is generated in the bowels of the phyfeter macocephalus, or fpermaceti whale, and then mixed with the beaks of the fepia octopoda, which is the principal food of that whale. He therefore defines ambergris to be the preternaturally hardened dung or feces of the phyfeter macocephalus, mixed with some indigetible relics of its food.

Many of the preceding observations, with regard to the production of ambergris, have been confirmed by the examination of Alexander Champion, Esq. a principal merchant concerned in the Southern whale fishery, and of the captain of a ship, employed by him, in the said fishery. This ship brought home about 360 ounces of ambergris, which the captain took out of the body of a female fpermaceti whale, on the coast of Guinea. This was observed to proceed from the fundament of this fhip, and whilst they were cutting the blubber, a piece of it was seen to swim on the surface of the sea. Some of this subfufu was observed in the fame paffage, and the reit was contained in a small bag, a little between the paffage, and communicating with it. The whale seemed fickle, and very old. The fpermaceti whale, it was observed, feeds almost wholly on a fih called fquids; and when the whale is dying, throws up a quantity of fuid, something white, and sometines in pieces. The bills of the fuid were found, fome in the inside, and fome on the outside of the ambergris, flicking to it. The fpermaceti whale, when fruck, voids her excrement; and if she does not, it is confecrated that she has ambergris in her. It was concluded by the intelligent captain, who communicated this information to the council of trade and foreign plantations, that ambergris is most likely to be found in a tucky fis; and that it is the cause or the effect of some disorder. The whole quantity of ambergris found in the whale, of which the above account was given, was 362 ounces Troy, and it was sold for £96. 9s. 4d. per ounce; half of it having been bought for exportation to Turkey, Germany, and France, and the other half having been purchased by the druggists in town. Phil. Trans. for 1791. vol. xxxi. art. 2.

Ambergris is of confiderable ufe among perfumers, who melt it over a gentle fire, and make extracts, effences, and tinctures of it. It is one of the moft agreeable perfumes. The leaff apt to diforder weak conftitutions, or fuch as are liable to be offended by fubflances of that fpecies. It would be of more ufe in phyfick too, were not its smell apt to occa- fion vapours.

There is a preparation, however, recommended by Hoffman, which is said not to be attended with thefe ill confe- quences. The preparation is made in the following manner: Let the spirit of rofe, perfectly dephlegmated, be, not only once, but twice, at leaft, drawn off from the falt of tartar, which is burnt, or calcined, in a vehement fire. By this means there is produced a spirit, which, by its penetrating quality, enters into the inmost fubflance of the ambergris, and so separates and resolves its oleous conftituents. This, we are affured, will not excite conceptions and agitation in a weak body, as does the common preparation of ambergris, which is made with a mixture of muff or cift. Hoffman. Observ. Phyf. Chem. lib. i. c. 18.

Ambergris enters into the composition of many cordial, fudorific, and alexiteriac waters. But its chief virtue consists in its antitiphomodic and fudorific qualities, familiar to those of mufk and califor, and its power of relieving certain hysterial, convulsive, and other nervous affections. It may be taken inwardly from half a grain to ten or twelve grains, or more; for as to doses, there can be no fixed rules about remedies and difeafes of these kinds. Dr. Lewis fays, that taken internally, from two or three grains to a fepule, it is accounted a high cordial, corroborant and antitiphomodic; and with this view it is prescribed by Riferius, in hypochondriacal affections. Dr. Swediar observes, that we cannot expect any medicinal effects from this fubflance in doses of two or three grains, but that it should be administrated in the quantity of as many fepules for a dose; though even then it could not be expected to produce any great effect, as he himself took 30 grains of pure unaculated ambergris in powder at once, without any fensible effect. A failer once took half an ounce, and found it a good purgative. The faculty of Paris directs a tincture to be drawn by digefting two fepules of ambergris in two ounces of a highly rectified spirit, impregnated with rofe. They have also a compound tincture made from the fame quantity of ambergris, with half as much muff, ten grains of cift, fix drops of oil of cinnamom, and four drops of oil of rhodium, digefted together in four and one-half ounces of a spirit impregnated with rofe, and orange flowers. This compound tincture is a very high perfume; and a few drops of it will give a fine fcent to a large proportion of inodorous matter. In preparing thefe tinctures, the spirit fhould be made to boil or fimmer with it first, that this ingredien may be completely diffufed before the more foluble ones are added. The orientals are faid to look upon it as an aphrodisiac, and fuppofe that the frequent ufe of it contributes to longevity. In Asia and part of Africa, amber- gris is ufed not only as a perfume and a medicine, but as an article of cookery; in which it is added to dishes in lieu of allifpe. A great quantity of it is bought by the Mecca pilgrims, probably to ufe it for the purpofe of fumigation and sacrifice, as the Catholics ufe frankincenfe. With us it is ufed by the perfumers to fcent pillars, candes, balls, bottles, gloves, and hair-power; and it is mixed with po- matums for the face and hands, either alone or compounded with muff &c.

Ambergris is very commonly counterfeited and adulterated. The first generally conifits of mufl, cift, torax, laudanum, and aloes wood, mixed together; the latter of a large quan- tity of bullock's blood, duly flavoured with mufl and cift. It is one of the moft agreeable perfumes; but mufl be proportioned fo sparingly, as that while it improves the smell of what it is added to, its own may not be perceived. It may be known to be genuine by its fragrant fcent, when a hot needle or pin is thruf into it, and its melting like fat, of an uniform confiance. Whereas the counterfeit will not yield such a smell nor prove of such a fat texture. One thing, however, is very remarkable, that this drug, which is the moft sweet of all the perfumes, fhould be capable of being refeembled in smell, by the preparation of one of the moft odious of all fcent fubflances. Mr. Homberg found that a veffel in which he had made a long digestion of the human feces, acquired a very strong and perfect fcent of ambergris, inofmuch that any one would have thought a great quantity of
of essence of ambergris has been made in it. The perfume was so strong and offensive, that the vessel was forced to be removed out of the laboratory. Mem. Acad. Roy. 1752.

AMBRIEUX, in Geography, a town of France, in the department of the Ain, and chief place of a canton, in the district of Belley, 14 leagues north-north-east of Lyon. The place contains 1276 and the canton 7275 inhabitants. The territory comprehends 105 kilometres, and 5 communes. N. lat. 4° 47' 58", E. long. 5° 15'.

AMBERING is used, by some writers, to denote the giving a scent or perfume of amber to any thing. This is otherwise called amburing. Dr. Hooke mentions an extraordinary method of amburing in infantum, i. e. with a small quantity of amber, and other refigtities, encumbraving a hundred or a thousand pounds of sugar, or the like, so as the first matter still remains unaltered, to be used again. Hooke's Phil. Collec. N° 4.

AMBERT, in Geography, a town of France, in the department of Pay de Dunois, and chief place of a district, situated on the riviere Dore, 104 leagues south-east of Clermont. It has a manufacture of cambks and woollen stuffs, and also of excellent paper and playing-cards, &c. The place contains 5926, and the canton 16356 inhabitants. The territory includes 265 kilometres and 8 communes. N. lat. 4° 37', E. long. 3° 30'.

AMBETTUWAY, in Botany, the local name of a tree, the leaves of which are said, when boiled in wine, to create an appetite, and used by the people of Guiana, for that purpose.

AMBIA, in Ancient Geography, an episcopal city of Africa, in Mauritia.

AMBIANI, a people of Gaul, in Belgia Secunda, mentioned by Caesar, Strabo, Phiny, and Ptolemy. They were situated between the Morini to the north, the Atrebati and Veromandui to the east, the Belovacii to the south, and the Caleni to the west, and had the sea on the north-west. Their principal river was Samara, and their capital Samarobriva, which afterwards took the name of the people. These people were distinguished among the ancient Belgians. We learn from Caesar that afterwards furnished 5000 men for the siege of Alenya, and their cavalry are much commended.

AMBIANUM, now Amiens, the capital of the Ambiani.

AMBIBARI, a people of Gaul, in Belgia Secunda, mentioned by Caesar, Strabo, Phiny, and Ptolemy. They were situated between the Morini to the north, the Atrebati and Veromandui to the east, the Belovacii to the south, and the Caleni to the west, and had the sea on the north-west. Their principal river was Samara, and their capital Samarobriva, which afterwards took the name of the people. These people were distinguished among the ancient Belgians. We learn from Caesar that afterwards furnished 5000 men for the siege of Alenya, and their cavalry are much commended.

AMBIDRAN, a people placed by Ptolemy in Norica.

AMBIDEXTER, compounded of amb, both, and dexter, right hand; by analogy to the Greek, δεξιός, which signifies the same; one who uses both hands alike, the left as well as right, or in cases where only the use of one is necessary.

Women, according to the observation of Hippocrates, are never ambidextrous. But this is denied by some moderns, who give inferences of the contrary; though it is owned, they are but few in comparison of those that are found in the other sex. It may be imputed to education and habit, that men as well as brutes are not all ambidextrous, there being no difference of right and left in the nature of things. Nurses are even forced to be at some pains to ensure the infants under their care to forego the use of their left hand. How far it may be our advantage to be deprived of half our natural dexterity, may be doubted. It is certain there are infinite occasions in life, when it would be better to have the equal use of both hands. Surgeons and ocultists are of necessity obliged to be ambidextrous; bleeding, &c. in the left-arm or left-ankle, and operations on the left-eye, cannot be well performed but with the left-hand. Divers inferences occur in history, where the use of the left-hand has been cultivated preferably to the right. But by the laws of the ancient Scythians, people were enjoined to exercise both hands alike, without partiality either for the right or left; and Plato enjoins ambidexterity to be observed and encouraged in his republic. In the Grecian armies their more distinguished officers, their pilkemen and halberdiers, as those who formed the first line of their battalions, were to be able to fight indifferently with the left hand or right. We find it mentioned in Scripture, that, on an extraordinary occasion, the single tribe of Gad produced 700 brave men, who fought with the left hand as well as the right; and the Roman historians affirm us, that they had gladiators who were trained up to the same exercise. An ingenious French writer is surprised, that among all the modern refinements in the art of war, none have thought of restoring the ancient practice of forming ambidexters, which, it is certain, might be of considerable service in the way of stratagem. In performing on keyed instruments, the harp, the dulcimer, and such as have a separate part for each hand, ambidexterity is necessary. On the piano forte, organ, harpsichord, or clarichord, two right hands are so necessary, that a child rigidly prohibited the use of the left hand in the common offices of life, can never have a powerful left hand in performing on the instruments just mentioned; but in rapid divisions, fugues, and imitations, the clumminess with which difficult passages are performed with the left hand disgraces the player and injures the composition. In the serious studies and practice of the student on the piano forte intended for the profession, it might be necessary for him perhaps to try to execute all kinds of feeble passages, flesh, beats, and trills with the left hand, till they can be played with so much ease and brilliancy, that a distant hearer, out of sight of the instrument, shall not be certain which hand has been employed.

AMBIDEXTER, in Law, denotes a person who takes money from both of the contending parties to aid them in their cause. In this sense the word may be applied to a judge, juror, a solicitor, or the like. The penalty on a juryman, if it be unfavourable to his client, is to forfeit decies tantum, ten times as much as he receives.

AMBIEGNA, in Antiquity, an appellation given to a victim, which was surrounded, or attended at the time of offering it, with other lesser ones. In this sense the word is also written ambigui. We read of ambigae once, used in sacrificing to Juno: which were sheep, having brought forth twins, and offered up with two lambs fattened on either side.

ABIENT, formed of ambire, to encompass, a term applied to such things as encompass others round about; called also circumambient bodies. The whole body of air, because it encompasses all things on the face of the earth, is often by physical writers called, by way of eminence, the ambient, or ambient air.

AMBIERLE, in Geography, a town of France, in the department of the Rhone and Loire, and chief place of a canton, in the district of Roanne, eight miles north-west of Roanne.

AMBIGENAL hyperbola, in Conics, a name given by Newton in his "Enumeratio Linearum tertii Ordinis," to one of the triple hyperbolas, E G F (Plate I. Conics, fig. 1.) of the second order, having one of its infinite legs, as E G, falling within the angle A C D, formed by the asymptotes A C, C D, and the other leg G F falling without that angle. See Hyperbola.

AMBIGU denotes a kind of mixed entertainment, where-
in both flesh and fruit are served together; so that it seems doubtful whether to denominate it a mere collation, or a meal.

AMBIGUA, in *Genusology*, a species of *Bulla*. Shell somewhat tapering, slightly compressed, pale flesh colour, with two remote bands, one broad and brown, the other blue. Gmelin. Country unknown. It is uncertain whether this shell belongs to the Linnean genus, in which Gmelin places it.

AMBIGUA, a species of *Phalera*, of the notula family. Thorax smooth; wings deflexed, greyish, speckled with black; behind the middle a black streak. Inhabits Austria; and is produced from a larva with a brown head and body, variegated with furrugineous and brown. Lower wings whitish, with a black spot in the middle. Fabricius.

AMBIGUOUS, something dubious, obscure, or which may be taken in different senses. See Equivocal.

The word is formed of *amb*o, both, and *ago*, I drive; q. d. that which keeps the mind wavering, or in suspense, not knowing which side to choose. The answers of the ancient oracles were always ambiguous. An anonymous writer has published a dictionary of ambiguous words. *Lexicon Philosophicum de Ambiguitate Vocabulorum*. Francoff.

1597. 410.

Ambiguity is occasioned either by a wrong choice of words and the use of equivocal terms, or by an improper arrangement of them. Ambiguities of the last kind are neither where the arrangement leads to a wrong sense, or where the sense is left doubtful. Dr. Campbell expresses the former by the term equivocation, and appropriates that of ambiguity to the latter. See Elem. of Criticism, vol. ii. p. 50–54. and Campbell’s Philosophy of Rhetoric, vol. ii. p. 26–38. See Perspicuity.

AMBIL, in Geography, one of the smaller Philippine islands, with a volcano, near the island of Leuan.

AMBILATRI, in *Ancient Geography*, a people of Gaul, suppos’d by Martin to be the same with the Ambilatres, who are called by Corfuus Ambilatres. Sampson places them in Britain, towards Lamballe.

AMBILICIT, a people of Norica, according to Tolemy.

AMBISINA, a town of Spain, assigned by Tolemy to the Murgoz.

AMBISONTI, or Ambissontes, a people so called by Pliny, and placed by Tolemy in Norica.

AMBIX, or figuratively, denotes the perimter, or the line or sum of all the lines by which it is bounded.

Isaac Volius has a particular inquiry concerning the ambit, or circumference of ancient Rome. That of the city he makes to be 601 miles, or *mile passa*, and that of the city and suburbs together 72 miles, exceeding ancient Babylon, whose ambit was only 68 miles.

AMBIX, ambitiosus, called also angiperitus, was particularly used, in *Antiquity*, to denote a space of ground to be left vacant between one building and another. By the laws of the Twelve Tables, houses were not to be built contiguous, but an ambit or space of 2½ feet was to be left about each for fear of fire. This was usually a thorough-fare, but sometimes not. For when Rome was crowded with houses, these interfiles were only left between some houses. Nero, after the dreadful fire which happened in his time, restored the ancient mode of building houses separate from one another.

Tacit. Annal. xvi. 43.

The ambitus of a tomb, or monument, denoted a certain number of feet, in length and breadth, around the same, within which the sanctity assigned to it was limited. The whole ground wherein a tomb was erected was not to be separated from the common ipsis; for this reason, it was frequent to inscribe the ambit on it, that it might be known how far its sanctity extended: thus, *in sents pedes toti*, in agnem pedes toti.

AMBITIANVS, in *Ancient Geography*, the place in which Caligula was born, and in which, according to Pliny, there were altars erected in honour of the prince. Claudius makes it the village of Capella, near Coblenz. M. d’Anville places it on the Rhine, between Confluentes on the north, and Baadberic on the south.

AMBITION, in Ethics, is that passion which prompts men to value or to seek any kind of eminence or distinction, as well as to avoid degradation and reproach. It is a kind of compound of admiration and desire, and becomes either a virtue or a vice, honourable or disgraceful, useful or pernicious, according to its direction or degree. The opinions of others concerning us, when expressed by words or actions, are principal sources of happiness or misery. The pleasures of this kind are usually referred to the head of honour; the pains to that of shame; but as it is most convenient to have a single word, to which we refer both pleasure and pain of this class, Dr. Hartley selects ambition for this purpose. He defines the several particulars which pertain, under the influence of ambition, with to have known to others, or concealed from them, in order to obtain praise or dispraise, under four heads; viz. external advantages or disadvantages, of which the principal are finelaces, riches, titles, and high birth, with their opposites, rags, poverty, obscurity, and low birth; bodily perfections and imperfections, of which the chief are beauty, strength, health, and the other, deformity, imbecility, or an infirmity of the body or the mind; the last, such as weakness, memory, invention, wit, learning, and their opposites, folly, dulness, and ignorance; and moral qualities, i.e. virtue or vice. This ingenious writer investigates, in conformity to his improved theory, the affections by which the pleasures and pains of ambition are produced. Observations on Man, § 2. prop. 95. p. 253, &c. Ed. 1791.

The Romans erected a temple to Ambition; and this was the divinity to which they offered the greatest number, or at least a very considerable number of sacrifices. It was represented with wings on its back, and naked feet, to express the extent of its desigins, and the promptitude with which they were executed. "A being of the nature of man," says an elegant historian, at the close of his account of the Byzantine princes, "endowed with the same talents, but with a longer measure of existence, would call down a flood of pity and contempt on the crimes and follies of human ambition, so eager, in a narrow span, to graze at a precocious and short-lived enjoyment. In a composition of some days, in a period of some hours, 600 years have rolled away, and the duration of a life or reign is contracted to a fleeting moment; the grave is ever before the throne; the felicities of a criminal is almost instantly followed by the loss of his fortune; and our immortal reason surives the 600 princes of beings who have passed before our eyes, and faintly dwells on our remembrance. The observation, that in every age and climate ambition has prevailed with the same commanding energy, may abate the prudence of a philosopher; but while he condemns the vanity, he may search the motive of this universal defect to obtain and hold the sceptre of dominion." Gibbon’s Hist. vol. ix. p. 10.

AMBITIONI, in *Ancient Geography*, a people of Galatia.

AMBITUS, among the *Ancient Roman*, the act of soliciting, or making intercessi, for offices or honours.

The candidates, in this cafe, went about the city, and into all publick places and assemblies, to beg votes; which
was called ambitiō; from om, in the ancient Latin, signifying circum, about, and ire, to go.

Among the Romans, it differed from ambitiō, as the former lies in the 2d, the latter in the mind. Ambitus was of two kinds, one lawful, and even laudable; the other infamous. This first, called also ambitus popularis, was when a person offered his services to the public, frankly, leaving it to every body to judge of his pretensions as they found reasonable. This kind was not prohibited by any law, but always approved and practised by the best and greatest men.

The means and instruments here made use of were various: 1. Amici, or friends, under divers relations, including cognati, affini, natali, camarali, consocii, tribales, clientes, municipi, sodales, collegae. 2. Nomenclator, or the calling and saluting every person by his name; to which purpose the candidates were attended with an officer, under the denomination of interrex, or nomenclator. 3. Blenda, or obliging persons by serving them, or their friends, patrons, or the like, with their vote and interest on any other occasions. 4. Prenotio, the shaking every hand by the person, offering him his service, friendship, &c. 5. Alfubitationes. 6. The toga candida, worn loose. 7. Beneficentia, the distributing largesses, cæsariæ, &c.

The second kind was that wherein force, caressing, money, or other extraordinary influence was made use of. This was held infamous, and severely punished, as a source of corruption and other mischiefs. This kind of ambitus was at one time the great trade of Rome, and demanded a constant supply of great sums of money. Tully assigns this as the cause of the high rate of interest, and tells us that it had raised it from 4 to 8 per cent. Siberyx was come to the pitch of 807.30l. per tribe: and there being no less than 35 tribes, it is obvious how expensive this corruption was grown. It is also well known where it ended. Several laws were made against it; as the Lex Aelia, or Calpurnia; A. U. 686, Aucilla, A. U. 672, Biboia, A. U. 571, Emilia, A. U. 675, Cornelia, A. U. 672, Caesilia Diaia, Fabia, Julia Angilia, Julia Cæsaria, Licinia, A. U. 658, Maria, Patella, A. U. 597, Pompeia, A. U. 701, Taulla Vetus, A. U. 900.

In the year of Rome 521, the use of the toga candida was prohibited. In the year 597, the candidates were forbid to go to the markets and meetings in the neighbouring towns. In 571, severe penalties were laid on the givers of largesse. In 594, this was made punishable by banishment. In 692, by the lex Aucilla, it was enacted, that if a candidate presented money to a tribe, and did not pay it, he should be exempt, but if he did pay it, he should be obliged to pay to every tribe a yearly fine of 5000 sesterces as long as he lived. In 697, heavy fines were imposed. By the lex Tullia, made in the consulship of Cicer, the candidates were forbidden to befall any combats of gladiators on the people, to make any publick feasts, or to cause themselves to be followed by a crowd of clients for two years before they offered themselves for any place. A senator, who was guilty of a breach of this law, was punished with ten years banishment; others were fined, and rendered incapable of any dignity for ever.

Ambitus was not only practised at Rome and in the forum, but in the meetings and assemblies of other towns in Italy, where numbers of citizens were usually found, on account of trade and buffines. The practice ceased in the city from the time of the emperors, because polling was not then to be had by counting the people, but by favour from the prince. Persons who had causes depending practised the same, going about among the judges to implore their favour and mercy. They who practised this were called ambitiose. Hence we also meet with ambitiōsa decreta, and ambitiōsa juxta; used for such sentences and decrees as were thus prepared by the judges, contrary to reason and equity, either gratuitously or for money.

Ambitus, in Moys, a name sometimes appropriated to signify the particular extent of each, or mode of grave and acute.

Ambivareti, in Ancient Geography, a people of Belgium Gaul, placed by Cesar beyond the Meuse. Martin places them between the Scalid to the west, and Moza to the east; and to the south of the Menapii, near the situation of the present Brabant.

Ambix, in Ancient Writers, denotes a vessel of glass or shell. Hence the origin of the word ambitus, which sometimes also called by the word ambitus.

Ambivada, in Ancient Geography, a town of Asia Minor, in Phulia, according to Stephan. But in Case, according to Strabo, who says, that the wine of Ambivada was useful in medicine.

Ambivatu, in Geography, one of the Molucca islands, is the smallllest of those that are subject to the governor of Amboina, and distant three leagues from Bumia.

Amble, Ambling, in Horsemanship, a peculiar kind of pace, wherein a horse's two legs, of the same side, move at the same time.

The ambling horses change side at each remove; two legs of a side being always in the air, and two on the ground at the same time: an amble is usually the first natural pace of young colts, which, as soon as they have strength enough to trot, they quit. There is no such thing as an amble in the manage; the riding-matters allowing of no other paces besides walk, trot, and gallop; their raison is, that a horse may be put from a trot to a gallop, without hopping him; but not from an amble to a gallop without hopping, which lasts time, and interrupts the junctures and cadence of the manage. This movement, which is very laborious to the horse, and in which he ought not to be indulged, except in smooth ground, is very easy to the rider; it has not the hardness of a trot, because the hind leg moves along with the fore one, and creates no resistance to the motion. Connoisseurs say that horses which naturally amble never trot, and that they are much weaker than those which have no such movement.

Colts, indeed, often assume this mode of moving, when forced to go quick, and when they have not strength enough to trot or to gallop; and even good horses, after being fatigued, or when they begin to decay, are apt, when pulled, to amble spontaneously. The amble may, therefore, be regarded as a motion occasioned by weakness or defect. But there are two other movements assumed spontaneously by weak or decayed horses, which are still more defective than that of the amble, and they are known by the name of broken amble. The one is a motion between walking and ambling, and the other between trotting and galloping. Both proceed from great fatigue or weakness in the loins, and are conspicuous in many of our hackney and polo-horses.

There are various practices and methods of discipline for bringing a young horse to amble; some choose to hold him in his foot-pace through new-ploughed lands, which naturally inures him to the iltrade required in the amble. But its inconveniences are, the weaknesses and lameness that such disorderly toil may bring on a young horse.

Others attempt it by sudden hopping or checking him in the checks when in a gallop, and thus putting him into an amazed, between gallop and trot, so that loosing both he necessarily stumbles upon an amble. But this is apt to spoil a good mouth and rein, and expels the horse to the danger of a hoof-reach, or fine strain, by over-reaching, &c.
"Others prefer ambling by weights as the best way; and to this end some overload the horse with excessive heavy shoes, which is apt to make him interfere or slide short with this hind feet. Others fold leaden weights about the fetlock patterns, which are not only liable to the mischiefs of the former, but put the horse in danger of incurable strains, cutting of the coronet, and breeding of ring-bones, &c. Others load the horse's back with earth, lead, or the like mally substance; but this may occasion a fawing of the back, over-slaing the irits, &c.

Some endeavours to make him amble in hand before they mount his back, by means of some wall, smooth nail or rail, and by checking him in the mouth with the bridle handle, and correcting him with a rod on the hinder hoofs, and under the belly, when he tends faile. But this is apt to drive a horse to a desperate phrenzy before he can be made to understand what they would have of him, and to rear, sprawl out his legs, and to make other antic postures, which are not easily quitted again. Others think to effect it by a pair of hind shoes, with long spurs or plates before the toes; and of such length, that if the horse offers to trot the hind-foot beats the fore-foot. But this occasions wounds of the back-finews, which often bring on an incurable lameness.

Some attempt to procure an amble by folding fine soft lift it raibout his gamsels, in the place where he is gardened for a stilt-lamein, and turn him thus to grafs for two or three weeks, and afterwards take away the lift. This is a Spanish method, but disapproved; for though a horse cannot then trot but with pain, yet the members must be fufferers; and though the amble be gained it must be slow and unprofitably, because attended with a crining in the hind-part. In effect, ambling by the trammel, as practised by us, appears the nearest to nature, and best and most artificial way.

There are divers errors, however, usually practised in this method; as, that the trammel is often made too long, and so gives no stroke, but makes a horse shake and shuffle his feet confusedly; or too short, which makes him volt and twitch up his hind feet to suddenity, that by custom it brings him to a running-bant, from which he will scarcely ever be recovered. Sometimes the trammel is misplaced, and, to prevent falling, put about the knee and the hind hoof. In which case the beast cannot give any true stroke, nor can the fore-leg compel the hind to follow it; or if, to evade this, the trammel be made short and straight it will prefix the main finew of the hind-leg and the flashy part of the fore-thighs, so that the horse cannot go without halting before and cringing behind.

As to the matter of the trammel fore to make it all of lether, which is inconvenient, in that it will either stretch or break, and thus confound the certainty of the operation. In a true trammel the side ropes are to be so firm as not to yield to a hair's breadth; the holc soft, and to lie so close as not to move from its first place; and the backband flat, no matter how light, and to depend from the illet fo as not to gall.

When the horse, by being trammelled on one side, has attained to amble perfectly in the hand, it is to be changed to the other side, and that is to be likewise brought to rule.

When by this changing from one side to another with a half-trammel, the horse will run and amble in the hand readily and swiftly, without snappering and tumbling, which is ordinarly done by two or three hours labour; the whole trammel is to be put on, with a broad, flat, backband, and both sides trammelled alike. See Trammel.

This pace is now generally difpersed, and not admitted in the regular system of the Manege.
are seen from a great distance at sea. On one side of this long and lofty ridge of mountains, which extends fifteen leagues inland, is the sea, and on the other a flat country, abounding in ponds and marshes. Here is also a lake fifteen leagues long, and of the same breadth, that contains several small islands. The people that inhabit these mountains are called Ambohitimenses.

AMBOINENSE, in Conchology, a species of Cardium. This shell is rather oblong, white, with blackish spots, and the ribs very convex. It inhabits the shores of Amboyna, is about an inch and three quarters in length, and the ribs are usually about twelve in number.

AMBOINENSIS, in Ornithology, a species of Certhia that inhabits Amboyna; it is of a cinereous colour above, beneath green, head and neck yellow, breast red, and wings black. Gmelin's Linn. This bird is remarkably brilliant and glossy, the length is about two inches and three quarters, bill half an inch long, and yellowish, and the edges of the wings and quills yellow.

This is the Tioxi, or Kakopot of Seba. Muf. or Avia Amboinensis; and Polytmus Amboinensis of Brillon. Dr. La-tham calls it the Amboina Creeper, observing, that "both Edwards and Buffon say, that humming-birds are peculiar to South America, and that none are found on any part of the old continent. It is most probable that the three half-mentioned (viz. the Mæsar, Indian, and Amboinan creepers) may belong to the creeper genus on our better acquaintance with them; which is the more to be supposed, as the whole description has been taken from Seba, who lived in an age not sufficiently enlightened in these matters.

AMBOINENSIS, a species of Psittacus, or parrot. It is of a fine scarlet, with a blue back, and a green spot in the wing. Gmel. Linn. This is the Phutaca Amboinensis cocinea (red Amboyna parrot) of Brillon, and Lori Perruche tricolor, (three-coloured Lori parrot) of Buffon, as well as the Perruche rouge d'Amboine, Pl. enl. of the latter author.

The length of this bird is fifteen inches and an half; the bill red, with a black tip; the head, throat, neck, and under parts scarlet; back, rump, upper tail, lesser underwing coverts, and the edge of the wings fine blue; under tail coverts violet in the middle, surrounded with red; the two middle tail feathers nine inches and an half in length, and of a violet brown; the exterior feathers decrease gradually in length, the outer one on each side being only four inches and an half long, and is distinguished from the rest by having the interior margin red. The legs and claws are red. It is a native of Amboyna, as its specific names imply.

AMBOINENSIS, a species of Turdus, rather bigger than a lark; it inhabits Amboyna, and is remarkable for its fine fingering, and for flitting up its tail, which reflects on the back in the breeding season.—The colour is ferruginous or reddish-brown, beneath yellow; the secondary quills feathers from the base to the middle yellowish, tail cuneiform or wedge-shaped, and fulvous beneath. Gmel. Linn. Seba calls this Aicula Amboinensis cinerea. It is the Merula Amboinensis of Brillon, Le Merle d'Amboine of Buffon, and Amboina thraup of Latham.

AMBOISE, George D', in Biography, a French cardinal and minister of state, was born of an ancient and noble family in 1465. As he was a younger son he was defined for the church, and at the age of 14 obtained the bishopric of Montauban. He was appointed almoner to Lewis XI. and raised by Lewis XII., to whole interef, whilst he was duke of Orleans, he attached himself, and for whom he suffered imprisonment, to the archbishopric of Narbonne, which he changed for that of Rouen. In the situation of lieutenan general, under the duke of Orleans, who was governor of Normandy, he was instrumental in restoring justice and order to that province. Upon the accession of Lewis XII. he was made cardinal and prime minister, and acquired popularity by diminishing the impots. After the conquest of the Milanese in 1499, he recovered the people who had revolted to their allegiance. As the pope's legate in France he attempted the reformation of the ecclesiastical orders, and promoted it by his own example; for he held only one benefice at a time, and devoted two thirds of the revenue of his archbishopric to the relief of the poor and the repair of religious edifices. He aspired to the papacy with a view of more effectually accomplishing his schemes of reform, but he was counteracted and outwitted by the Italian cardinals. As a minister of state he contributed so much to the welfare of the nation, that he was honoured with the appellation of "the father of the people." For the purpose of reforming the courts of judicature, and supplanting partiality and bribery in the administration of justice, he caused to be compiled a new code of regulations, and exercised his authority in Normandy, where he was governor, in reducing them to practice. The disappointment of his views with regard to the papacy, induced him to recommend a war with the Venetians, to whom he conceived it was owing. Conscious of some errors and faults into which his ambition had led him, he expressed his concern in the review of his conduct to an infirmary brother, who attended him at the convent of the Celestines, at Lyons, where he was taken ill, in the prosecution of his journey for the Venetian war.—"Brother John! I why have not I been all my life-time brother John," He died in this place, A.D. 1510, in the 50th year of his age. During the whole of his administration he caused the sciences and trade to flourish. He was a munificent patron and encourager of literature; and such was his general conduct in the various stations which he occupied, and especially as prime minister, that he was as much beloved by the people as by his master. Gen. Dict.

AMBOISE, Francis D', was the son of a surgeon to Charles IX. of France, and maintained by his liberality in the college of Navarre, where he studied rhetoric and philosophy. In 1572 he was made solicitor of the French nation, and afterwards applying to the study of the law, became one of the best advocates of the parliament of Paris. From this employment he was advanced to that of counsellor in the parliament of Bretagne, and then to be a matter of requets and counsellor of state. He published several pieces chiefly of a poetical kind, and others containing an account of his travels into various countries. He took great pains in collecting the MSS. of Abelard, and he prefixed an apologetical preface to the edition of 1616. His two brothers, Adrian and James, arrived at considerable literary and professional eminence; the former as an ecclesiastic and the latter as a physician. Gen. Dict.

AMBOISE, Ambosia, or Ambacis, in Geography, a town of France in the department of the Indre and Loire, and chief place of a canton, in the district of Tours; situated at the confluence of the Loire and Amance. The place contains 5100, and the canton 14,415 inhabitants; the territory comprehends 322½ kilometres and 16 communes. It has two parishes churches, four convents, and a hospital; and near it is a large castle seated on a high rock, and difficult of access, in which are thrown the statues of Charles VIII. and of his consort Anne. In this place the protestants confirmed in 1560, and the civil war commenced in 1561, and here it is said the name of Huguenot had its origin. In the castle of this town Lewis XI. instituted...
AMB

situated the order of St. Michael, in 1467; and Charles VIII. was born in 1470, and died in 1498, at Ambofie, N. lat. 47° 24' 51", W. long. 5° 39' 7".

AMBOISES, see AMBEZEEES.

AMBON, a town of France, in the department of the Morbihan, three leagues S.E. of Vannes.

AMBOUM, in Natural History, a term used by some old writers, to express the prominent tubercles on certain lones.

AMBORA, in Botany. See MITHRABEAE.

AMBOTE, in Geography, a town of Poland, in Samogitia, on the river Warwana, 28 miles north-east of Mednik.

AMBOTEN, a town of the duchy of Courland, eight leagues south of Goltingen.

AMBOLUE, valley of, a province of Madagascar, is situated somewhat more northward than 23° south latitude, at the mouth of the river Manampao, which waters the whole valley. In this valley flounders a large town of the same name. The country produces abundance of plants and fruits, particularly yams, and the céfame herb, whose seeds yield by expression the oil called menachil; the oxen and cows are very fat, and their flesh excellent. There is also iron mines. Near the town of Amboule is a fountain of hot water, within 20 feet of a small river whose sand is almost burning. The water of this fountain is said to boil an egg hard in two hours, and to be a sovereign remedy against the gout. The inhabitants of the country are employed in different preparations of iron and steel, which they obtain from their own mines, and forge darts and various other instruments, with considerable skill. The voadviziri, or chief governor of the country is honoured with the title of great lord, or rabetan; and he is the richest and most powerful of the chiefs in this country. He exercises sovereign authority, and absolute power; but in times of public disaffections his subjects often assemble in great numbers, seize his person, and threaten him with death, unless they are relieved; and this he does, by issuing orders for distribute provisions among them. The people are represented as licentious, dishonest, and indolent. Mod. Un. Hist. vol. xi. p. 404.

AMBOURNAY, or AMERONAY, a town of France, in the department of the Ain, and chief place of a canton, in the dioces of St. Rambert. It is situated in the road from Lyons to Geneva; has a parish church, a hospital, and an abbey of Benedictine monks, founded about the year 830; nine leagues north-east of Lyons, and one mile and an half north-west of St. Rambert. N. lat. 46° 1'. E. long. 5° 16'.

AMBOUTNOSSI, a small island on the coast of Madagascar, near the bay of Gaetemboule; and also a river of the same name.

AMBOY. See PERTH-AMBOY.

AMBOYNA, one of the Molucca or spice islands, in the Eastern Indian Ocean, lies in S. lat. 4° 25', and E. long. 127° 25'. This island is about 60 miles in length from north to south, and is divided on the west side, by a large bay into two parts or peninsulas, one of which, being about 12 leagues long, and two and a half broad, is called Heto; and the other about five leagues in length, and one and a half broad, is called Leytimoa. On the eastern side is another bay, with a bad harbour, where the Portuguese erected their chief fortresses Victoria. The town of Amboyna, which is the capital of the island, is nearly built, and stands near the south-west extremity. As the island is subject to frequent earthquakes, the houses generally consist only of one story; but the state-house is a more lofty edifice of two stories. The face of this island is beautiful; as woody mountains and verdant vales are interspersed with hamlets, and enriched by cultivation. The soil is chiefly a redish clay, but in the vales it is blackish and sandy. The chief produce of the island, in consequence of the restrictions imposed by the monopolizing avarice and defopitum of the Dutch, is cloves; and the clove-tree grows to the height of about 40 or 50 feet, with spreading branches, and long pointed leaves. Some of these trees, that are situated in deep sheltered vales, yield annually thirty pounds weight, and the chief crop is from November to February. The Dutch governor, in order the more effectually to secure this monopoly, makes an annual progress through the three islands, for the purpose of enforcing the observance of existing treaties, and of preventing the culture of cloves beyond the limits to which it is restricted. About twelve years ago, indeed, nutmegs were allowed to be cultivated in Amboyna, because Banda did not supply a sufficient quantity. The growth of indigo is prohibited, lest the natives should become rich and turbulent; but the sugar and coffee are excellent, and among many delicious fruits, which the island produces, is the mangifere of Hindostan. Cattle, grain, &c. are imported from Java, and they have a variety of curious woods, but these are chiefly brought from Ceram. The plants of the island have been described by Rumphius. The principal animals are deer, and wild hogs, and among their birds is the cassowary. Amboyna, with its dependencies, contained in 1798, when it was taken by the English, 45,252 inhabitants, of whom 17,813 were protestants; the rest were Mahometans, except a few Chinefs, and savages. As this is the next settlement to Batavia, with respect to wealth and importance, the Dutch are tolerably polished; but the natives are still rude and unacquainted. They resemble the other Malays, and when intoxicated with opium they will commit any crime. Their dress is a loose shirt or frock of cotton cloth; the men wear large whickers, and leave a little hair upon the chin; the women tie the hair in knots; wives are bought of their fathers, and if they prove barren, the marriage is dissolved. Their houses are made of bamboo canes and fago-trees; they sleep on mats; and their weapons are bows and arrows, javelins, feymets, and targets; and their chiefs are called Rajas.

The islands that are immediately subject to the Dutch governor of Amboyna are ten, comprehending an extent of about five degrees of longitude, that of Amboyna being farthest to the south; these islands are Ceram, Ceram-Lavut, B visc, Amba, Manipa between Bouro and Ceram, Kelang, two leagues north-east of Manipa, Bonva farther north, Orna two leagues east of Amboyna, Homimoa, a league east of Orna, and Roufa-Laout, a league south-east of Homimoa. The three last islands are denominated Uli-afers. The culture of cloves is restricted to these three islands, and Amboyna; but they formerly grew in all the islands, more especially in Ceram. Amboyna is the capital of this rich commerce, and the Dutch have taken care to destroy all the clove-trees in the adjacent islands, and it is said that even in Amboyna, when the harvest is very large, part of the produce is burnt. Soon after the fruit is gathered from the tree, the cloves are collected and dried on hurdles before the fire; and thus their natural and beautiful red colour is changed into a deep purple or rather black, to which their being sprinkled with water probably contributes. The reason assigned for this sprinkling is to prevent the worm from getting into the fruit; but it has been generally supposed that the true reason is to add weight to the
the cloves. The cloves are carefully gathered by the hand; and the produce is very different in different seasons; but at a medium of seven years it has been estimated at a million of pounds.

Amboyna was first discovered by the Portuguese adventurers Diego d’Abreu and Ferdinand Magellan, about the year 1515, and taken possession of in 1564; it was conquered by the Dutch about the year 1605; but it was some time before they became complete masters of the whole island. The English were at this time in possession of several factories, that were protected by the Dutch arms, but differences having arisen between the English and Dutch colonists, they were terminated, or rather suspended, by a treaty concluded in 1619 between Great Britain and the States General of the United Provinces. In consequence of this treaty, the English lived in security at Amboyna; and enjoyed one-third part of its clove, whilst the Dutch were in possession of the other two-thirds. In the year 1622, fresh occasions of differents arose; these were referred to the council of defence established at Jactara, in the island of Java; and the council, not being able to decide to the satisfaction of all parties, the fate of the cake was transmitted to Europe to be settled by the East India Companies of both nations, or, in the last resort, by the king of England and the States General. During the deliberations in Java and Europe, the diffidence at Amboyna increased, and the Dutch contrived, by a feigned plot, to get possession of the whole island. This plot, as it was pretended, was confederated by two foldiers in the Dutch service, one a Japalnese, and the other a Portuguese, who, upon a ground of suspicion, trivial and even imaginary, had been put to the torture; and, by the testimony of these two unhappy wretches, confirmed by that of an English prisoner who was also sentenced to the rack, the English were accused of being confederates in a conspiracy against the Dutch settlement. Upon this extorted confession, the English were feized; some of them were imprisoned, and others loaded with chains and confined on board the ships in the harbour; and their books and property were seized. By a process of varied torture of the most savage kind, the governor and his cabinet contrived some of the wretched sufferers, after pretending their own innocence and total ignorance of the pretended conspiracy, to acknowledge the truth of charges that were altogether unfounded. Some were racked, drenched with water, and scorched with fire; others were compelled to swallow such quantities of water as caused their bodies to be distended to more than twice their usual dimensions, and then made to diggory, by violence, the water which they had swallowed; and others were confined by burning them gradually from the soles of the feet upwards. But humanity shudders at the recital of such acts of barbarity. Of those who escaped or survived this savage treatment, ten Englishmen, with one Portuguese, and eleven Japalnese were executed, though all of them pretended their innocence with their expiring breath. The day following that of the execution was spent, by order of the governor, in public rejoicings and the takings of fire for signal an escape and deliverance from a pretended conspiracy, and for the iniquitous extirpation of their rival traders. That the conspiracy was a mere pretence on the part of the Dutch for gaining the sole possession of the island, is evident from various concurren circumstances. They had, at this time, a garrison of 300 men in the fort, and several other garrisons in the island; whilst the number of the English did not amount to 20 persons, who were unprovided with arms and ammunition for effecting the purpose with which they were charged. The English had not one vessel in the harbour, whereas the Dutch had eight ships near the town. When the boxes of the factors were opened, and their papers ruffled, no trace of any such conspiracy could be discovered; and, besides, the sufferers on this occasion profited in avowing their innocence. The English factory was withdrawn from the island; and the Dutch governor retained the effects that had been seized, amounting, as some say, to the value of 400,000 pounds. When the English council at Jactara demanded justice, the conduct of the governor was vindicated, and his proceedings were declared to be just and indisputable necessary; and from all the subsequent proceedings of the Dutch, it sufficiently appears, that the plot was of their own invention, and that their object was to monopolize the whole trade of the Spice islands; for, after the catastrophe at Amboyna, they seized all the English factories in these islands, and dispossessed the English, to their incredible loss and damage. When the news of this transaction reached England, and sufficient proof was adduced of the treachery and cruelty of the Dutch, it was natural to expect that reparation would be demanded and obtained. If, indeed, King James I. had acted with becoming spirit, and made proper representations to the States General, justice would probably have been done; for such atrocious villanies could not have been abetted by any civil community. But James submitted to the national injury even without requiring satisfaction, and contented himself with merely telling the Dutch ambassador, “That he never heard nor read a more cruel or impious act, than that of Amboyna.” But he adds, “I forgive them, and I hope God will, but my son’s fon shall revenge this blood, and punish this horrid massacre.” Charles I. finding remonstrances, letters of requell, and memorials ineffeetual, was preparing to increase his shipping, and to call the Dutch to an account; but he was prevented from accomplishing his design by the civil war which ensued. Cromwel, in this instance, avenged the wrongs of the British nation; for among the conditions on which he gave peace to the Dutch, in April 1654, it was inferred, “That they should deliver up the island of Poloneez in the East Indies,” which they had taken from the English in the time of King James; and where they had acted a tragedy similar to that at Amboyna, “into the hands of the English East India Company; and pay a good sum of money (300,000/) for the old barbarous violence exercised to many years since at Amboyna, for which the two last things could never obtain satisfaction and reparation.” The Dutch, however, have long retained unaltered possession of this island.—But both Amboynas and Banda were taken without resistance in February and March, 1796, by the English admiral Rainer; however they have been restored to their Batavian masters by the treaty with France in the year 1801. Mod., U. Hilt. vol. viii. p. 288—301. vol. ix. p. 70. Alfatc Regisfer for 1800. p. 200.

AMBRA, or ABRA, Cape, in Geography, sometimes called Cape Natal, is the north point of Madagascar island. S. lat. 12° 15’. E. long. 49° 10’.

AMBRACIA, in Ancient Geography, was one of the most considerable cities of Epirus, and situated in the territory of Thesprotia, near the mouth of the river Arachthus or Arethusa, and the gulf to which it gave its name. It was built, according to Polybius, (lib. iv.) by Ambraz, son of Thesprotus; probably when the territory of his father had been ravaged by the Dryopes, and afterwards by Hercules; and thus the origin of the Ambracians is traced to an era about 50 years before the last war of Troy. Strabo (lib. vii.)
(lib. vii.) says, that Ambracia was the work of Tolgus, the son or the brother of Cypleus, who was tyrant of Corinth, and lived about 620 years before the Christian era. A colony from Corinth under the conduct of the Etonians arrived in Epirus, and delivered the Ambracians from the tyranny of Phaeacus, and reduced them into subjection to himself: and Aritudes informs us, that they drove away Periander the son of Cypleus, and recovered their ancient liberty, for it was originally a free city. It was afterwards reduced by the Achaic kings of Epirus, who chose it for the place of their residence. In processes of time, the Etonians made themselves masters of it, and held it till the year before Christ 180, when they were subdued by the Romans, who found at Ambracia a great number of pictures and statues belonging to the magnificent palace of Pyrhus.

At this time it was a place of great strength, defended on one side by the river Arachthus, and on the other by steep and craggy hills; and it was surrounded by a high and thick wall, about three miles in circuit. It was vigorously beleaguered by the Romans and their allies, the Epirotes, under the conduct of the Roman confidant Marcus Fulvius, and as bravely defended by the Etonian garrison. It was at length compelled to capitulate; and Fulvius was presented with a crown of gold, which is said to have weighed 150 pounds. Paulus Emericus also deprived its inhabitants of their privileges and effects. Livy (lib. xxxviii. c. 4) has given a particular description of Ambracia. It is now reduced to a small place of Turkey in Europe, called Ambraea, on the lower part of the gulf of Larta in the southern Albania.

AMBRACIUS SIRUS, the gulf of Ambracia, now the gulf of Larta, was situated between the country of the Molossi in Epirus, to the north, and Acarnania to the south, and communicated with the Ionian Sea, by a strait called that of Actium.

AMBRARIA, in Botany. See Antho spermaum.

AMBRAS, or OMBRAS, in Geography, a town of Germany, in the county of Tyrol, four miles east of Innsbruck.

AMBRAYET, a river of Hindostan, which runs into the Cauvrey, eight miles east-north-east of Carroor.

AMBREDA, thus they call the sable or factitious amber, which the Europeans use in their trade with the Negroes on the coast of Africa, and particularly on the river Senegal. There are some large and red pieces of it, a thousand of which making twenty ropes of strings weigh three pounds. There are others small, and also red, which weigh but two pounds and a half.

AMBRES, in Geography, a small town of France, situate on an eminence, in the department of Tarn and diocese of Caftres.

AMBREBURY, or Ambersbury, a town of England, in the county of Wilts, pleasantly situate in a small valley on the banks of the Upper Avon, and consisting of two streets. The town is indifferently built, and has all the appearance of decay. Whether it derived its name from Ambrosius' consecrated stone, as Toland supposes—from its neighbouring monument, Stonehenge, being erected by Aurelius Ambrosius, who is supposed to have been slain near this place—or from Ambri, a Britth monk, who founded a monastery in this place—it is not easy to determine. In former times it was a place of importance. Some have supposed that, when the Britons retired to the general Gergael at Stonehenge, Ambrebury might have been used as a resting-place, or place of Assembly, and that Ambri founded a monastery here for the benefit of future devotees. At this town a nunery was founded by Eifrida, widow of King Edgar, in expiation, as it has been said, of the atrocious and unpro

voked murder of her son-in-law, Edward the Martyr, at Corfe Castle. Queen Eleanor, widow of Henry III., retired to Ambrebury, took the veil, and died a nun in 1201; and her grand-daughter Mary, the sixth daughter of Edward I. followed her example, and in company with 13 children of the English nobility retired hither, and took the veil in 1285. The nuns belong to this monastery, after its dissolution, and in process of time, became the property of the Assisbury family. To the west of the river Avon is a camp, occupying the whole summit of a hill, which has been generally attributed to Velopius; but an ingeniour tourist suggests that it is the camp, or town, often mentioned in the old British writings under the name of Casor Caradac. It is constructed in the shape of a square figure, with a very deep valum towards the west; and to the east it overlooks the town. The road passing from Ambrebury to Warminster is cut through the rampart of this fortification. The market of this town is on Friday; and it is distant from London 78 miles.

AMBRI, in Ancient Geography, a name given by Julius to a people of India, who lived upon the banks of the river Acenues. The Ambri are, according to M. d'Anville, the same as the Oxymri.

AMBRIERE, in Geography, a town of France, in the department of Mayenne, and chief place of a canton in the district of Mayenne, in the department of Mayenne. The place contains 2,234, and the canton 14,077, inhabitants; the territory includes 16,541 kilometres, and 10 communes. N. lat. 48° 24'. W. long. 0° 44'.

AMBRIZ, or AMBRIS, a river of Africa, in the kingdom of Congo, which springs from a lake in the eastern mountains of Tonda, and runs westward into the ocean between the mouths of the Luherda and Loze. It runs by the town of St. Salvador. Its course is rapid; its channel deep, and large; and its waters muddy. S. lat. 7° 10'. E. long. 12° 25'.

AMBRACHOS, in Ancient Geography, a country of Africa, in Marmaria, according to Ptolemy.

AMBRONAX, a town or borough, placed by Ptolemy in Paphia.

AMPROGI, DOMINOLO, in Biography, an Italian artist, flourished in 1653, and painted history and landscape. He was the disciple of Brizio, and, as an engraver, he is said to have executed some prints on wood in Chiare-Seuro. One of his engravings is "a woman seated in a triumphal chariot with two flamebeaux and a serpent, conducted by Neptune." Strutt.

AMBROMA, in Botany. See AEROMA.

AMBRONES, in Ancient Geography, a people of Gaul, known in the Cimbri war. They were probably the ancestors of the Ligurians, and had possessions to the north and south of the Po. They invaded the Roman territories, as Plutarch (in Marco) informs us, in conjunction with the Cimbri and Teutones, and were defeated with great slaughter by Marius, about 103 years before Christ. Their wives, who were waiting the issue of the engagement, seeing their husbands flying and the Romans pursueing, armed themselves with axes, and, gnashing their teeth, fell furiously on the pursuers and the pursued, without distinction. Headlets of their own defence, they threw themselves upon the combatants, seized their swords, and endeavoured to snatch away their bucklers; but when their rage was exhausted, they offered to capitulate on this single condition, that their honour should be preferred. When this condition was denied, these unfortunate women, being reduced to despair, first killed their children, and afterwards themselves, not one of so great a multitude remaining alive.
AMBROSE Island, in Geography, a small island of the Baltic, under Osel, seven leagues south-east from Dzenfiefs, and eight leagues north-west from Round Island. See ARENSBURG.

AMBROSA Island, is situated on the coast of Chili, in South America, on the Pacific Ocean. S. lat. 26° 49'. W. long. 82° 35'.

AMBROSE, of Alexandria, in Biography, the friend of Origen, flourished about the beginning of the third century. He was descended from a good family, affluent in his circumstances, and distinguished by his intellectual accomplishments and Christian virtues. According to Jerome he was a Marcionite, but Euch. calls him a Valentinian; and he was convinced of his errors by Origen, about the year 321, in consequence of which he became a deacon of the church, either at Alexandria, or at Caesarea, where Prototetus was presbyter. To both these persons Origen inscribed his book on Martyrdom, and he dedicated to Ambrose many of his other works, which were published at his desire and charge. Origen and Ambrose lived on terms of the most intimate friendship; they were alike indefatigable in their application; and Ambrose alluded Origen by procuring him notaries, and amanuenses, who copied his works, and to whom he occasionally dictated. Origen represents his friend, as a person eminent for his piety and for his diligent study of the Scriptures. Although Jerome reports that Ambrose was blamed by many for making no provision at his death for Origen, who was not only poor but likewise far advanced in years, Tillmont suggests this apology for him, that he knew his friend's mind, and that Origen chose to be poor, and to live in a state of dependence upon Providence. Some say that Ambrose died, with his friend Prototetus, as a martyr, in the persecution under Maximus, about the year 355; but the dedication of Origen's eight books against Celsus flew, that though he died before Origen, yet he lived to the year 250, or near it. Ambrose had a wife named Marcella, by whom he had several children; and he is commended by Origen as true Christian and a faithful wife. Lardner's Works, vol. ii. p. 447. Cave's H. L. vol. i. p. 122.

AMBROSE, St. bishop of Milan, descended from a noble family of Romans, was born in Gaul, as some say, in the year 333, but according to others, in 340. His father, at the time of his birth, was prefect of Gaul, and resided at Arles, the capital of Gallia Narbonensis. The son, after passing through the studies of a liberal education, attained, by the regular gradation of civil honours, the station of Confular of Liguria, a province which included the imperial residence of Milan. In the exercise of this government, he manifested a degree of wisdom and equity which obtained general esteem. At the age of 34, and before he had received the sacrament of baptism, a circumstance occurred which served suddenly to transform him from a civil magistrate to an ecclesiastical governor. His mother, and his sister Marcellina, both women of distinguished piety, had trained him up not only in habits of virtue, but with an early bias towards the religious system of the Catholic church. Thus previously disposed, he was prepared for availing himself of a dispute concerning the succession in the episcopal see of Milan, which had been produced by the death of Auxentius, who had been the leader of the Arian party in the west. In a tumultuous contest between the Arians and Catholics for supplying the vacancy, Ambrose presented himself to the assembly, and by an eloquent speech recommended a peaceable election. At the close of his address, a child exclaimed—"Ambrose is bishop!" The voice of the infant was regarded by the faithful multitude as a miraculous suggestion, though others might more naturally have inferred that it was the result of contrivance on the part of Ambrose or his friends. But the expedient, however, was effectual, and Ambrose was immediately elected by acclamation. The civil magistrate expressed great reluctance in complying with the public choice, and recourse to a variety of singular expedients to divert the multitude from perceiving in the appointment. The emperor Valentinian was at length solicited to confirm and enforce the election; and as the talents and character of the bishop elect were well known to him, he very readily interposed. Ambrose submitted to his authoritative injunction, and, after baptism, was ordained to the episcopal office. The ecclesiastical historians, acquitting the bishop and his friends of art and intrigue, and considering his opposition as real, represent the choice as "a divine election," and "the peculiar work of God." But the traces of human contrivance were much more discernible in the whole conduct of this business than those of a divine operation; and it will not be easy to exculpate the bishop himself from all concern in the plot.

Unprepared as Ambrose was, by the habits and occupations of his former life, for the new office that was devolved upon him, the active force of his genius soon qualified him to exercise, with zeal and prudence, the duties of his ecclesiastical jurisdiction. With this view, he bestowed his money upon the poor, settled his lands upon the church, with the reserve of a life-interest in favour of his heirs, and committed the care of his house and family to his brother. Thus disengaged from secular concerns, he commenced a course of theological study with Simplician, presbyter of Rome, and devoted himself to ecclesiasticalibus. In 357 he was obliged, by the irritated of the Goths and other northern barbarians, to retire to Illyricum; but the invaders were soon defeated by the Roman emperor, and Ambrose and the other exiles were allowed to return home. The prevalence of the Arian doctrine furnished ample occasions for the zealous exertions of Ambrose. Having written a treatise concerning the Trinity, for the establishment of the faith of Gratian, he was less successful in his attempts for converting the younger Valentinian, Gratian's colleague in the empire. The instructions of his mother Juliana, who was an avowed Arian, counteracted the arguments of the orthodox prelate. Ambrose, by his influence with Gratian, prevented the assembling of a general council, which he had agreed to convene; and probably fearing that the sentiments of the whole body of Christian bishops would be favourable to Arianism, he withheld the decision of the dispute to be referred to an assembly of the western clergy. Here the two "rotten heretics," as he called the two Arian bishops, Palladius and Secundianus, might be easily silenced. Accordingly a synod, consisting of 32 bishops, was held at Aquileia in 381, and Ambrose presided. Palladius very properly demurred against the decision of such a partial assembly, and it terminated with Ambrose's election of the two obnoxious bishops from the episcopal office. The orthodox prelate was no less zealous in his opposition to the followers of the ancient pagan religion than in his efforts for suppressing Arianism. The leader of the pagans was Symmachus, a wealthy and eloquent senator; and in the year 384 he was employed to prepare and present a petition for re-erecting the Altar of Victory to its ancient place in the hall of the senate; and the public funds for the support of the seven veiled virgins, and their religious ceremonies. To the talents of Symmachus were opposed those of Ambrose, who addressed a letter to Valentinian, in reply to the pleas of this petition; and he concludes with observing, that it was
was a debt which Christian princes owed to their faith, not to give countenance to heathen rites. Ambrose prevailed, and the petition of Symmachus was rejected.

The Arians were at this time a more formidable body to the intolerant bishop than the pagans. They were supported by the young emperor Valentinian and his mother Julitta; and they concurred in demanding from the bishop the use of two churches, one in the city and the other in the suburb of Milan. The bishop peremptorily refused; alleging, that though the palaces of the earth might belong to Cæsar, the churches were the houses of God; and that, within the limits of his diocese, he was the lawful successor of the apostles, and was the only minister of God. The privileges of Christiandom, temporal as well as spiritual, were confined to the true believers; and Ambrose was satisfied in his own mind that his own theological opinions were the standard of truth and orthodoxy. He therefore declared, that it was his firm purpose to die a martyr rather than to yield to the impious persecutor, by delivering up the temple of the Lord into the hands of heretics. Julitta deftined the refusal as an act of disloyalty and rebellion; and as the defined to perform her public devotions on the approaching festival of Easter (A.D. 385), Ambrose was ordered to appear before the council. He obeyed, accompanied by a tumultuous crowd of people; and the affrighted ministers of Valentinian, instead of pronouncing a sentence of exile on the bishop, humbly requested that he would interpose his authority to protect the person of the emperor, and to restore the tranquillity of the capital. Notwithstanding the tumult and clamours of the people, the bishop persisted in his refusal, and the court proceeded to the exercise of power. Orders were given to the officers of the household to prepare, first, the Palatine church, and afterwards the Basilica, for the immediate reception of the emperor and his mother; but it was found necessary to defend them by a strong guard from the insults of the people. The Arian ecclesiastics, who ventured to throw themselves in the streets, were exposed to the most imminent danger of their lives; and Ambrose had enjoyed the merit and reputation of rescuing his personal enemies from the hands of the enraged multitude; but while he laboured to restrain the effects of their zeal, the pathetic vehemence of his sermons continually inflamed the angry and seditious temper of the people of Milan.

The character of Eve, the wife of Job, of Jezebail, of Herodias, were indecently applied to the mother of the emperor; and her desire to obtain a church for the Arians was compared to the most cruel persecutions which Christianity had endured under the reign of Paganism. The prelate was supported, not only by the populace, but by the most respectable citizens; and the court, finding violent measures to be ineffectual, had recourse to the milder method of persecution, and solicited Ambrose to restore peace to his country by a timely compliance with the will of his sovereign. He resolutely replied, "if you demand my patrimony, which is devoted to the poor, take it; if you demand my person, I am ready to submit; carry me to prison, or to death, I will not resist; but I will never betray the church of Christ. I will not call upon the people to succour me; I will die at the foot of the altar rather than desert it. The tumult of the people I will not encourage; but God alone can appease." In his sermons he affected the exclusive power of the catholic bishops over the churches, and expressly denied the right of the emperor even to the use of a church for himself. Valentinian and his court were not disposed to submit to this ecclesiastical tyranny. An attempt was made for feizing the Basilica; and a body of Goths, urged by their Arian principles and ferocious spirit, advanced towards the church. On the threshold they were met by the bishop, who, thundering out a threat of excommunication, asked them, by what authority they presumed to invade the house of God? Superstitious terror held the barbarians in suspense: and the emperor was persuaded to leave the cathedrals in possession of all the churches of Milan, and to dissemble, till a more convenient season, her intentions of revenge. The mother of Valentinian, however, could never forgive the triumph of Ambrose; and the royal youth uttered a passionate exclamation, that his own servants were ready to betray him into the hands of an infidel priest. This temporary triumph of Ambrose was succeeded by an edit of general toleration in favour of those who professed Arianism, and by a sentence of excommunication, enjoining the prelate to leave Milan, and to cluse the place of his exile as well as the number of his associates. This sentence was refilled by the bishop, and his refusal to obey it was supported by the unanimous concurrence of his faithful people, who guarded his person and his palace. He devised various expedients for securing and increasing their attachment. By his bounty to the poor he formed a train of indigent persons; by introducing into Italy from the east the alternate or repromonitory plaudits, he aided the public devotion; and by alluding to exciting characters and circumstances in his discourses and commentaries upon the scriptures, he increased the popularity which was annexed by his profession of the times to his religious and episcopal character. Pious frauds and pretended miracles served only to augment the effect and elevation with which he was regarded by the credulous multitude. The contending prelate was fortunately directed by a dream to the discovery of the remains of two martyrs, Gervarius and Protasius, which had been under the pavement of the church for 300 years. Two perfect skeletons were found, with the heads separated from the bodies, and a plentiful effusion of blood. These holy relics were presented with solemn pomp, to the admiration of the people; and many miracles were wrought on the bodies and diseased persons who touched them, and one recovered his sight by touching the bier on which the bodies were deposited with his handkerchief. Ambrose appealed to these miracles in his sermons, and the people believed them to be real. The incredulity of the Arians, and the decision of Julitta and her court, were reproached and condemned; and the miracles were attested not only by Ambrose himself, but by Augustine, and Paulinus, who were then resident in Milan. Dr. Cave, relying on these testimonies, expresses his firm belief of their reality, and says, "that God suffered them to be wrought, at this time, on purpose to confront the Arian impieties." Such were the talents of Ambrose and the general estimation in which his character was held, that his affinity was repeatedly solicited in times of public exigence and danger; and it ought to be recorded to his honour, that he surrendered his private resentment to the public good, and served his country with fidelity and ardour. After the assassination of Gratian in 383, Ambrose was deputed by Valentinian on an embassy to Maximus, and contributed by his authority and eloquence to check the ambition of the tyrant, to dissuade him from passing the Alps, and thus to protect the peace of Italy. In 387 he undertook the same office; and if the council of Milan had availed themselves of the information given them by Ambrose on his return from an unsuccessful embassy, they might have been guarded against the perjury of Maximus, and Italy might possibly have escaped the defection which soon followed. The conqueror, however, entered Milan in triumph; Julitta and her son Valentinian fled precipitately.
ceptately from the country, and put themselves under the protection of Theodotus, the emperor of the East, in the post of Thebailonica; but Ambrose remained resolutely at his post, and during the depredations of a victorious army, humanly ordered the church-plate to be sold, and the money to be distributed among the unfortunate sufferers. After Theodotus had restored Valentinian to the kingdom in 388, he received information that the monks and populace of Callinicum, an obscure town on the frontier of Poesia, had tumultuously burnt a Jewish synagogue. The magistrate of the province had ordered the bishop, by whose invitation the synagogue had been burnt, either to rebuild it or to repay the damage; and his order was confirmed by Theodotus. Ambrose renounced; representing the toleration of the Jews, as the perfection of the Christian religion; boldly declaring, that he himself, and every true believer, would as eagerly dispute with the bishop of Callinicum the merit of the deed, and the crown of martyrdom; and lamenting, in the most pathetic terms, that the execution of the sentence would be fatal both to the fame and salvation of Theodotus. Besides this private admonition, he publicly addressed the emperor from his pulpit, nor would he content to offer the oblation of the altar, till he had obtained from Theodotus a solemn and positive declaration, which secured the impunity of the bishop and monks of Callinicum. After an interval of five years, and at a distance from Ambrose, his spiritual guide, Theodotus, tolerated the Jews, and condemned the destruction of their synagogue. How different were the feelings and conduct of Theodotus and Ambrose on another occasion! The tolerant emperor, incensed by the conduct of the populace at Thebailonica, who had murdered Botheric, and several of the principal officers of his army, and irritated by the sagacity of his minister Rufinus, issued a general order for the massacre of the inhabitants. The promiscuous carnage continued three hours, without discrimination of strangers or natives, of age or sex, of innocence or guilt; the most moderate accounts flate the number of the slain at 7000; and it is affirmed by some writers, that more than 15,000 victims were sacrificed to the manes of Botheric. "A foreign merchant, who had probably no concern in his murder, offered his own life, and all his wealth, to supply the place of one of his two sons; but while the father hesitated with equal tenderness, while he was doubtful to clime, and unwilling to condemn, the soldiers determined his fate, by plunging their daggers at the same moment into the breasts of the wretched youths." Ambrose, on the other hand, though unyielding and intolerant on occasion of the slightest religious differences, heard the relation of the massacre with horror and anguish; reproached Theodotus with the enormity of his crime; admonished him not to receive the holy eucharist with hands that were still polluted with the blood of an innocent people; and implored him in his approach to the church of Milan, declaring to his sovereign in the tone and language of an ambassador from heaven, that private censure was not sufficient to atone for a public fault, or to appease the justice of the offended deity. When Theodotus replied, that David, the man after God's own heart, had been guilty both of murder and adultery, the undaunted Ambrose rejoined, "you have imitated David in his crime; imitate then his repentance." After a delay of eight months, Theodotus was absolved and restored to the privilege of communion; but in the interval he appeared, stripped of the ensigns of royalty, in a mourful and suppliant posture, in the church of Milan, soliciting the pardon of his sins, and he signed an edict enjoining a space of 30 days before any sentence of death or confiscation, and its execution. After the affiliaction of Valentinian, A.D. 392, the empire of the West was usurped by the ignoble Eugenius; but Ambrose, with a laudable resolution, refused to enter into alliance with the usurper, and withdrew from Milan; but when the empire was regained by Theodotus, he generously interceded with the emperor for the pardon of the adherents of Eugenius. Ambrose did not long survive Theodotus, whose funeral obsequies he performed; but after a short illness, in which his mind was perfectly composed, and which afforded him an opportunity of declaring to his friends, "that he had not conducted himself so among them as to be either ashamed to live or afraid to die," he departed this life in April, A. D. 397.

Many fabulous particulars are related concerning Ambrose, which are not worth minutely recording, and which the allowable scepticism of the present age will not admit. Such are the stories of the swarm of bees that settled upon his face, when he was an infant in the cradle; of the paralytic woman, who was instantaneously cured, when he was praying by her bedside; of the two Arians, who having afflicted him, were instantly thrown from their horses and killed; of the globe of fire, which covered his head in his last illness, and illuminating itself into his mouth, left his face white as snow; and of the voice, which proclaimed in the hearing of a bishop, just as he was expiring, "arise, and hasten to him, for he is departing." These tales are gravely related by Paulinus, Dr. Cave, and others; but they will claim little credit. Of his general character, it will be sufficient to say, that his most partial advocates cannot acquit him of dishonest artifice, arrogance, and intolerance; and that his most prejudiced enemies cannot deny him the praiseful firmness in avowing his sentiments, and firmness in the performance of his ecclesiastical offices, liberality to the poor, generosity in his conduct towards his enemies, and zeal in the cause of humanity. With energy of mind he combined a great degree of tenderness and sympathy, and in his general conduct he was virtuous and amiable, except on occasions when he was moved by professional ambition or religious bigotry. As a writer, many of his sentiments will now be thought absurd, trivial, or ludicrous; his style is coarse and affected, and somewhat resembling that of Seneca. "Ambrose," says Mr. Gibbon, "could do better than he could write; his compositions are defective of taste and genius; without the spirit of Tertullian, the copious elegance of Lactantius, the lively wit of Jerome, or the grave energy of Augustin." The writings of Ambrose are numerous; but many of them are little more than transcripts from the Greek fathers, particularly Origen. Their chief object is to maintain and establish the faith and discipline of the Catholic church; or recommend perpetual celibacy as the summit of Christian perfection. One of the most valuable is his book "De Officiis," intended to explain the duties of Christian ministers, formed on the model of Cicero's "Offices." In his "Commentaries on the Scriptures," he chiefly follows the absurd method of allegorical interpretation; his "Epistles" throw much light on the history of his life and times. The most accurate and complete edition of his works is that of the Benedictine monks, in two volumes, folio, in 1688; reprinted in 1699. Ambrose appears to have received all the books of the New Testament, which we receive, without any other. For in his works he does not pay any particular regard to the writings of Barnabas, Clement, or Ignatius, or to the recognitions, or constitutions. Hence we may reasonably conclude, that these writings were not esteemed of authority by himself.
himself, or other Chrllians at that time. Cave's H. L. vol. i. p. 261. Gibbon's Hist. vol. v. p. 38–78. Lard- 

AMBROSE, a monk of Camaldoli, was born at Portico, near Florence, studied Greek under Emmanuel Chryfolos, at Venice, and entered into the order of Camaldoli at the age of 14 years. He was made general of the order in 1431, after having lived in it 30 years; at the council of Basil, to which he was deputed by Eugenius IV., he defended the authority of the papal see; at the councils of Ferrara and Florence he displayed equal ardour against the Greeks: and at Florence he was employed to draw up the articles of union between the Latin and Greek churches. The Greek oration, which he addressed at Ferrara, in 1437, to John Paleologus, emperor of Constaninopole, was much applauded. He was much esteemed by Cosimo de' Medici, who had his letters collected into a volume, that has been kept in the library at Florence; and by Paul Jovius, he is represented as a person who united piety with good humour, and who was so free from envy, and from a spirit of contradiction, that when he endeavored to reconcile Fuggerius with Lau- rentius Valla, he declared to them, that they acted neither as true men of letters nor like Christians, since they disregarded the dignity of the sciences by their vitriolic writings. Am- brose died, on his return from the council of Florence, in the year 1439, and his remains were deposited in the oratory of Camaldoli, without any epitaph or ornament. He collected a very large library in the convent of St. Mary de Angeliis, where he left behind him several transla- tions of Greek authors; such as those of Dionysius Areo- pagita de Caelesti Hicercarchia, Manuel Calecis against the errors of the Greeks, Palladius's Life of Chryfolon, Anchora of Gaza's Theophrastus, S. Ephrem's Sermons, Diogenes Laerius's Lives, &c. He also wrote, "Hodiurporicon," or a Journey through Italy, in 1431, to visit several monas- teries and nunneries of his order, and to correct their abuses; published in 4to. in Florence, in 1681; and "Le- tters," above-mentioned, which have been inserted in the third volume of Marten's and Durand's "Veterum Scrip- torum et Monumentorum Collectio." Paris, 1722, fol. some of which contain hints concerning the lives and char- acters of the learned men of his time. Gen. Dict. Cave's H. L. vol. ii. p. 155.

AMBROSE, ISAAC, an English Presbyterian divine, was the son of a clergyman, and descended from the Ambroses, of Ambrose-hall, in Lancashire. In 1621, he was admitted into Brazen-nose college, in Oxford, where he took a degree of bachelor of arts; and he afterwards took holy orders, and officiated in the church of England, but he obtained no preferment. In 1641, he left the establishment, joined the Presbyterian party, took the covenant, and preached first at Gartham, and afterwards at Palfon, in his native county. His zeal against the established clergy re- commended him to the office of assistant to the commissi- oners for ejecting such as were called candalous and ignorant min- isters and school-masters. It was his custom to retire for a month every year into a hut in the woods for the advantage of solitude and religious meditation. He anticipated his death for some time before it occurred, and took leave of all his friends at their own houses. He then died suddenly, as it is supposed, of an apoplexy, in 1634, at the age of 72. His works, written in the truly puritanical style and spirit, are numerous. They are entitled "Prima, Media, et Ultima; or Regeneration, Sanctification, and Meditations of Man's Misery and God's Mercy, &c." 1682 and 1685, Lond. "Looking upon Jesus," 1659, 4to. Lond. "War Vol. II. with devils, ministration of and communication with angels," printed with the former. Biog. Brit.

AMBROSE, St. CUL OF HEAVEN, in Geography, lies on the west coast of Africa, south-west of the Cape of Good Hope. The St. is long. 15°.

AMBROSE.—St. Amphiboe in the West, by the Italians called al nemo, is an order of religious, confirmed in 1431, under the rule of St. Augustin.

The monks of St. Amphiboe al nemo wear the image of the faint engraven on a little plate, and make use of the Ambro- 

sian office.

In the province of Berry, in France, the titled cultus of St. Amphiboe is also given to the canons regular of St. Aug- 

tine, because their abbey at Bourges is dedicated to St. 

Ambroise de Cahors.

AMBROSIA, in the Heathen Theology, &c. a delicious kind of food, on which the gods were supposed to feed.

The word is compounded of the primitive particle α, and άβρος, mortals, because it rendered those who fed on it im- mortal, or because it was the food of the immortals.

Lucretius, pulling the poetical gods, tells us, that ambrosia and nectar, of which one is the meat, and the other the drink of the gods, were not so excellent as the poets describe them; since these deities would leave them for blood and fat, which they come to suck from the altars like flies.

But though the ambrosia is commonly represented as the solid food of the gods, by way of contradiction from the fluid, which was called nectar; yet the apppellations are sometimes inverted, and the name ambrosia given to the drink of the deities, as that of nectar to the meat.

Wedeeus has a dissertation on ambrosia and nectar, wherein he shews, that the term is sometimes used to denote honey, sometimes wine, sometimes perfumes, and particularly ambergis; sometimes the method and ingredients for em- 

balming and preserving dead bodies from putrefaction, and sometimes also for a plate of unchangeableblessing or immortality.

AMBROSIA is also a splendid kind of title given by some phycicians to certain aetherialpompositions of extraor- 

dinary virtue. In this sense ambrosia, αμβροσία, amounts to much the same with <i>αμβροσία, θεομορφία</i>, as being supposed to conducte to immortality. This name was particularly given to a famous antidote of Philip of Macedon against all poisons, bites, and stings of venomous creatures, as well as many internal diseases.

AMBROSIA is also used for a pure spiritus kind of med- 

dicine, artfully extracted from the gros elementary parts of a Lody, and which being administered in the smallest dose is of confiderable virtue, and may be taken without disgust or inconvenience. In this sense ambrosia amounts to much the same with what we otherwise call quintessence. Nic. Abr. Trammes has a treatise on the preparation of these ambrosia. Ambrosiopea, Ludg. Bat. 1628, 2mo. Francof. 1630. 4to.

AMBROSIA is also used by some of the Ancient Writers to express what they judged to be the food of the bees.

This substance is by some taken to be a gros or solid honey, and is contradistinguished from the liquid or puer- 

tar, which is denominated nectar.

The ambrosia will not keep, and, if not speedily spent, corrupts and turns sour, making what is sometimes called comb, or flowing, or, after the Greeks, ἱονάσκει; highly offensive and pernicious to the hive. See Pain des Abeilles.

AMBROSIA, in Antiquity, denotes a feast celebrated in Ionis, and in almost all the countries of Greece, in honour of Bacchus, at the time of vintage.

The ambrosia were also denominated ebon and lament.

They
They were held in the month called Lenaeon, consecrated to Bacchus.

Amphrosia, in Mythology, the daughter of Atlas, was one of the Heroes.

Ambrosia, in Botany, a genus of the monotypic genus Parietaria (Parietaria monogyna, Gmelin) class and order of the natural order of Convolvulaceae, and Caryophyllaceae of Jullien; its characters are as follows. Male flowers compound: the calyx is a common, one-leaved, flat perianthium, of the same length with the florets; the corolla compound, uniform, tubular, equal, and hemispherical; the proper, one-petalled, tubulous, funnel-shaped, erect, quinquelabiate (trifid, lamin.) the stamens have very small filaments, anthers erect, parallel and acuminated; the pistil has a filiform style, of the length of the filaments, stigma orbiculate and membranaceous; the receptacle common, scarcely any, naked. Female flowers, below the males, doubled: the calyx is a one-leaved, acuminated, entire, permanent perianthium, the belly five-toothed, and one-flowered: no corolla; the pistil is a germ ovate, in the bottom of the calyx, filiform, of the same length with the calyx, stigmas two, stigmatic, long, and divericate; the pericarpium a fuscous nut, formed from the calyx hardened, one-celled, not opening, crowned with the five acuminate teeth of the calyx; the style filiform and round. There are five species, viz. 1. A. trifida, trifid-leaved A. "with three-lobe ferrate leaves." There is a variety, B. A. gigantea inodora, fol. asperis trifidiis. Ray. Hill. This species is a common annual weed in North America, growing often eight or ten feet high, and in a rich moist soil, spreading out into many branches; the flowers are more conspicuous than those of hemp: cultivated in 1669 by Mr. C. Bobart. The fort common in gardens has three-lobe leaves; but the larger variety B. has the lower leaves five-lobe. 2. A. elation, tall A. "with leaves pinnatifid, racemose panicked, terminal, and smooth." This is an annual, herbaceous plant, from two to three feet in height, upright, and branched; male flowers more numerous, approximating and nodding; the female flowers fewer, sessile, from three to five, aggregate: a native of Jamaica, in barren, sandy, rocky situations, by river sides, in the southern part of the island; flowers there from February to June; with us in July and August; cultivated in Kew garden by Mr. S. Doody, in 1665. It has the appearance and taste of wormwood; and the seeds have been imported from Virginia and Carolina, as well as from the West India islands. 3. A. artemisifolia, margin-toothed A. "with bipinnatifid leaves, the first leaves at the origin of the branches quite entire;" differs from the second in having the spikes of the flowers axillary; the racemes are lateral, and not terminal as in the preceding species; the primary item about a foot high, is more diffused, and the branches four feet long; a native of North America; cultivated, in 1759, by Mr. Miller. 4. A. maritima, see A. "with pinnatifid leaves, spikes solitary, hairy and fistulose;" rises about two feet high; the leaves, when handled, emit a strong odour; the spikes of the flowers are axillary; the spike does not fit on a long peduncle as in the preceding species; grows naturally in Cappadocia, Tuscany, and the county of Nice, on sandy shores; cultivated in Kew garden in 1750. 5. A. arboriforme, tree A. "with pinnatifid, bifurcate leaves, racemes solitary and terminating, and item shrubby;" a native of Peru, grows to the height of 10 or 12 feet; the spikes and flowers are produced at the extremities of the branches, and the female flowers grow in small, separate clusters. The fifth species of Gmelin’s Linnaeus is A. sinpleiifolia, with simple, lanceolate leaves, and axillary, subfoliaceous leaves. Walt. Fl. Carol. p. 231.

Ambrosia.—The seeds of the first species, sown in Spring, will remain till the following Spring; and when the plants come up, they may be transplanted into another and another hot-bed, allowing to each plant a square distance of three or four inches, watering and shading them till they have taken root, and afterwards exposing them to the air in warm weather, and well watering them: when the plants are pretty strong, they should be taken up with balls of earth to their roots, and planted in large pots filled with light earth, towards the latter end of May they should be placed abroad with other hardly, annual plants; they will flower in July, and their seeds will ripen in September. The third fort may be cultivated in the same manner. The seeds of the fourth fort should be sown in a warm border in Autumn; and when the plants are large in the Spring, they should be transplanted into a warm border of poor ground; the bell method for obtaining good seeds, is to plant some of them in heme-rubbit; the plant has not much beauty, and is admitted into gardens merely for variety. The fifth fort may be propagated by cuttings or seeds; if the former are used, they should be planted in a shady border in any of the summer months, and frequently watered, in four or five weeks they will have good roots, and should be taken up and potted; this fort is hardly enough to admit of being exposed to the open air in Summer, and in Winter, if it be sheltered in a common greenhouse, it will live several years; the seeds that are sown in the Spring will seldom come up the same year, but those which fall, or are sown in Autumn, will come up the following Spring. Martyr’s Miller.

Ambrosia. See Artemisia and Cochelearia.

AMBROSIA, in Ornithology, a species of Hesperus, or swallow, that inhabits Bengal, and frequents particularly strong of ambergris. It is of a greyish brown colour, bill blackish, legs brown. Gmel. Linn. Syll. The length is five inches, and an half, bill half an inch, the plumage dark as on the head and quills, and the tail very forked. This is the hisardne riparia Bengaleensis of Brissin. Av. v. 158. No. 13. L’Hirondel ambrée de Buffon. Ort. vi. p. 612.; and ambergris swallow of Lath. Gen. Syn. iv. p. 568.

AMBROSIA. It is uncertain whether this should be considered a distinct variety of the preceding species, or merely a sexual difference. Dr. Latham describes it as “cineraceum subtilis cinero-alba, cauda elongata maximo forciata;” (Ind. Orn. tom. ii. 572.) general color inclining to grey, beneath cinereous white, tail long, and greatly forked; its length is five inches. This was observed in the collection of Sir Joseph Banks, Bart. after the former had been described, and was published in the supplement of the Gen. Syn. It is supposed to inhabit China.

AMBROSIANA, or office, denotes a particular office or formula of worship, used in the church of Milan, which is sometimes also called the Ambrosian church.

The denomination takes its rite from St. Ambrose, archbishop of Milan, in the fourth century, who is usually supposed to have been the author of this office. Yet some are of opinion the church of Milan had an office different from that of the Roman and other churches of Italy before the time.
time of that father. In effect, till the time of Charlemagne, each church had its several office; and when in after-days the pope took upon him to impose the Roman office on all the other churches of the West, that of Milan sheltered itself from the imposition, under the name and authority of St. Ambrose; from which time the phrase Ambrosian rite has obtained, in contradistinction to the Roman rite.

The public library of Milan is also called the Ambrosian Library.

We also meet with the Ambrosian chant, or long.

AMBROSIAN CHANT. There are few writers on ecclesiastical music who do not speak of the Ambrosian chant, and of its being different from the Gregorian; but no satisfactory account has been given of their specific difference; nor was I able (says Dr. Burney) in hearing the service performed at the Duomo in Milan, (where he was for the first time present in all its purity), or by a perusal of the Missals, or other books on canto fermo published in that city, to discover any considerable deviation from the plain long used in the service of other cathedrals in France or Italy, where the Gregorian chant is said to be the only one that is in use. The truth is, that there are no vellages of the Ambrosian chant remaining, sufficient to ascertain its peculiar character. The fragments of it that Dr. Gafurius has inserted in his Pratica Musicae are very suspicious, not only as they have a much more modern appearance than even the ancient Gregorian chants that are come down to us, but on account of the number of modes in which they give them, which amount to eight; whereas all writers on these subjects agree in saying that St. Ambrose only used the four authentic modes, and that the four plagals were added afterwards by St. Gregory. Those who pretend to know the difference between the Ambrosian and the Gregorian canto fermo, tell us, that it is louder, higher, and of greater compass—fortior, durior, et magis extensia; but this conveys nothing to the mind of a musician as to the difference in the melody of the two chants. See Gregorian Chant, Canto Fermo, and Plain Song.

AMBROSIN, in Middle Age Writers, denotes a coin struck by the lords or dukes of Milan, wherein was represented St. Ambrose on horseback, with a whip in his right hand. The occasion of this coinage is said to have been a vision of that saint, who appeared to the Milaneze general in 1339, during the time of a battle.

AMBROSINIA, so named in honour of the two brothers Bartolomeo and Hyacintho Ambrosini, for 32 years professors of botany at Bologna, in Botany, a genus of the class and order of gymnandria polyandra of Miller, monandria monandra of Schreber, polyandra monogynia of Swartz, and polyandra polygynia of Ginian of Linnaeus, of the natural order of pipe-rice, and aroids of Jussieu: its characters are, that the calyx of the males is a fopathe, one-leaved, convolute, convolute at the base, and converging at the tip, partition membranaceous. (Spadix Bats), divided into two cells communicating at top, i.e. corolla; the stamens have no filaments; the anthers are very many, solitary, within the hinder cell of the fopathe, in the upper part of the partition, digested in a distinct order; the stamens are two, roundish, concave, at the base of the anthers. The calyx of the female is a fopathe common with the males; no perianthium; the pistillium has a germ in the anterior cell of the fopathe, and the lower part of the partition, solitary and roundish; the style cylinrical, shorter than the fopathe; the stigma obtuse; the pericarpium a roundish one-celled capsule; the seeds are very many, ovate and netling. There is one species, viz. A. Bats, ariforun of Monifon, Ray, and others, a native of Sicily near Palermo, first found, described and figured by Boccon, requiring the protection of a green-house, and capable of being increased from the root.

AMBROSIUS, Aurelianus, or Aurelius Ambrosius, in Biography and History, a famous general, and afterwards king, of the ancient Britons, was of Roman extraction, and is supposed to have been the son of one of the kings elected by the Britons after the Romans had left the island. He was educated at the court of Aldern, king of Armorica, and sent over at the request of the Britons with 10,000 men under his command, to affult them against the Saxons, whom Vortigern their king had invited into Britain. His successes in this expedtion was so considerable, that, after the death or abdication of Vortigern, Ambrosius, probably king of the Damnonii, in consequence of the death of his father, was elected to the pependrenship of sovereignty of all England; which supreme office he exercised with great honour to himself and benefit to his subjeets. During his reign, and under his direction, the famous Arthur obtained several victories, and was eminently successful in retaining the progress of the Saxons among the Northern Britons. Ambrosius, after distinguishing himself by his valour on several occasions, and by his zeal, as it is said, in regulating the affairs of the church, died at Winchester, according to the report of Geoffrey of Monmouth, of poison, administered by a Saxons disguised as a physician, and hired for the purpose by one of the sons of Vortigern, or, according to the more generally received opinion, was killed in a battle fought in 508., against Cerdic, one of the Saxon generals. Geoffrey of Monmouth pretends that Ambrosius built Stonehenge, near Salisbury, in commemoration of 300 British noblemen, who were massacred by the Saxons. Interesting Polydore Virgil says, that this edifice was erected by the Britons as a monument to their general Ambrosius, on the place where he fell in battle, to perpetuate the memory of the illustrious services which he performed for his country. But both these stories are rejected as fabulous by the best antiquaries, though they are by no means agreed as to the true origin of this building. Biog. Brit.

AMBREY, the place where arms, plate, vessels, and every thing belonging to house-keeping, were formerly kept. Hence, probably, the ambrey at Westminster was so called, because formerly set apart for that use; or rather, from ambroyery, a house adjoining to an abbey, in which the chariots were laid up and distributed to the poor. The word is still used in Scotland, in the same sense.

AMBRYM, or Ambain, island, in Geography, one of the New Hebrides in the south Pacific Ocean, Slat. 16° 9' S. Long. 165° 34' W. It has a volcano, and is about 50 miles in circumference.

AMBrysus, or Ambryssus, in Ancient Geography, a town of Greece in the Phocide. M. d'Anville places it between two chains of mountains, west of Lebadea, and north-west of Anticyra. It is called by Pausanias Amphyrrus. This town was separated from Delphi by Mount Parnassus; and it was fortised by the Thebans, in their war with Philip of Macedon. Near it was a temple of Diana Diaitynna, to which the inhabitants paid peculiar homage. Her statue was of black marble. Pausan. lib. x. c. 36.

AMBUBAJE, in Antiquity, a kind of wanton minstrels about Rome, who lived by playing on the flute, dancing in places of resort, and prostituting their bodies for hire.

Authors speak as if there had been a regular college, or community of ambubajes, and that these were the same with
what were otherwise called *tiline*. Thus Horace, fat. i.
speaks of

“...Ambubajarium collegia, Pharmacopoea...”

Some suggelt that the ambubaj was one, of the male kind, only dispensed in the habit of women.
Antiquaries have been greatly divided about the ambubaj: some hold them to have come to Rome out of Syria; others suppose them to have been Roman women, though clothed by a name of Syriac origin.

Torquatus, Tummus, and Pulianus, derive the name from ambu, or am, an old Latin preposition, denoting circum, about, and bait, a delicious place near Naples; and maintain, that the ambubaj were a kind of pageants, who frequented the baths of that city. Cruquius is of a different opinion, taking the word ambubaj to have been used for ambubaj, and primarily to denote a feller of ambubaj, as a herb mentioned by ancient naturalists. These fellers of ambubaj, being a kind of empires, their name became afterwards applied to all charlatans, and quacks.

Others say, that ambubaj is a Syrian word, and that in the Syriac language, it denotes a flaut, or the sound of a flute. From Juvenal it appears, that Syria was famous for furnishing the bell players and musicians. Thus he says, fat. vi. 67.

“...Jam pridem Syria in Tiberim defluxit Orontes,
Et linguam, et mores, et cum tibicinum chordas
Obliquas, neeun gentilia tympana fecit,
Vexit et ad Circum jufias profare puellas.”

Suetonius exhibits the emperor Nero as attended by these Syriac women, and Roman pageants at table; thus, “Cunctatbat non unguem—inter feceorunm totius urbis, et ambubajarnque minilera.” The followers of the profession of female flute-players became so numerous and so licentious at Rome, that their occupation was prohibited in the Theodorian code; but with so little success, that in the time of Julianus, as we are informed by Procopius, the feller of the empress Theodora, who was a flute player, or tibicina, appeared on the stage without any other dress than a flight scarf thrown loosely over her. These performers even became so common in all private entertainments, as well as at public feasts, where they frequently obtruded themselves, uninvited, that towards the close of this reign their profession was regarded as infamous, and utterly abolished.

Hoffman has a discourse on the ambubaj.

AMBUBELIA, in Botany, a name given, by some authors, to wild succyry.

AMBUELLA, or AMBOILLA, in Geography, a country of Africa, in the kingdom of Congo, between the lake of Aquelond and St. Salvador.

AMBULANS, in Entomology, an insect of the Podura genus, described by Linnaeus; it is white, with an extended tail, and lives amongst moths. This is the “Podura terrestris nival,” of Degeer Text. vii. p. 53. n. 6. tom. iii. f. 5.

AMBULANS, a species of Cryptoccephalus, one of the new genera, adopted by Gmelin in the Linnean arrangement, from Geoffroy and Fabricius. This insect is a native of Germany, is black, shining, and has the wing-cases punctured. Fab. et Gmel. It approaches Cryptoccephalus elongatus, very nearly, and the antennae of both species are serrated, but the thorax of the latter is rufous above, and deep, which in the former is black.

AMAVANT, or AMBULATORY, a name formerly given in France to those commissioners or clerks of the king’s farms, who had no settled office, but visited all the offices within a certain district, to see that nothing was done in them against the king’s right, and the interest of the farm.

AMBULANT is also used to denote those brokers at Amsterdan, or exchange agents, who have not been sworn before the magistrates. They transmit brokerage bundles, but their testimony is not received in the courts of justice.

AMBULATION, or walking. See Exercise.

AMBULATION, in Physics, is used by some for the spreading of a gangrene or mortification.

AMBULATORY, in Entomology, a species of Lamin, figured by Petiver, Gazap. tab. 37. fig. 6, and described by Fabricius. The anterior part of the thorax is armed on each side with two spines, and the body is clouded with circitous and chafnatt. It is properly a cernbax of Linneas. See Lania.

AMBULATORIUS, a species of Ichneumon, with a yellowish scutellum, and spotted thorax, the second joint of the abdomen ferruginous brown, the margins of the others white. This insect is very rare, it inhabits Great Britain, and was first described by Fabricius in the Species Insectorum, from a specimen in the cabinet of Sir Joseph Banks, Bart. The species was known to Linnaeus, and his last editor Gmelin has adopted the above Fabricius specific character. The head of this creature is black, the antennæ yellow beyond the middle, the thorax is black, with a yellowish line in the anterior part, and a spot of the same colour before the base of the wings: the abdomen is black, except the ferruginous or second joint, and the white margins of the third, fourth, and fifth.

AMBULATORY, formed from ambulate, to walk, a term anciently applied to such courts, &c. as were not fixed to any certain place; but held sometimes in one place, and sometimes in another. In opposition to stationary courts.

The court of parliament was anciently ambulatory; so also were the courts of king’s bench, &c.

We sometimes also say, in a legal sense, a man’s will is ambulatory to the time of his death; meaning, that he has it always in his power to revoke it.

AMBULIA, in Botany, a genus of the duynamia angioperina class and order; the essential characters of which are, that the calyx is quinventated, the corolla tubulose, quadrid, with unequal segments; and the capsule pentagonous, single celled, and single-seeded. There is one species, viz. A. monosperma of Gmelin, or A. aromatica of Linnæus, which represents the calyptrium as polypermerous. This plant, particularly described by La Marcé, (Encyc. tom. i. p. 18.) grows in Malabar, in a sandy and watery soil, and appears to be annual. All its parts have a sweet and aromatic smell, resembling that of pepper, when it is green. Its taste is bitter; and it is administered in a decoction, for allaying fevers, and in four milk in cafes of vertigo. La Marcé suggests that it is the mangle-nari of Rhed, and the tercinthiana of Rumphius.

AMBULLI, in Mythology, a name given at Lacedæmon to Jupiter, Minerva, Calter, and Polux, where they had altars before a large portico, in which the inhabitants were accustomed to walk. They are said to have derived their name from *aphoros*, delay, because it was thought that those deities had it in their power to retard the instant of death.

AMBULON, in Botany, a tree which grows in the island
of Ambrustus, in Entomology, a species of Phalaena of the notus family. Thorax eroded; wings incumbent, grayish-brown, with three yellowish bands, an annule in the middle, and an undulated streak behind. —This moth is produced from a naked brown larva, with white lines. The antennae are ferruginous, white at the base, head, and thorax reddish gray. Posterior wings white, tips brown. Inhabits Austria, on Lichens parichum Fabricius.

AMBLER, or Ambuscato, in Surgery, a solution of continuity, caused by the application of heated substances. See Burn and Scald.

AMBUSTUS, in Ornithology, a species of Falco. The body is pale tawny, front of the head between the eyes and bill naked, cere large, legs bluish. Gym. Lin. This is the tawny vulture of Brown and Latham. The bill is dully, short and thick, cere large, and beak with bristles, the chin bearded with a tuft of long slender feathers: head, neck, breast, belly, and thighs, pale tawny; covert of the wings intermixed with brown; tail dirty white, with brown bands: legs slender, bluish claws, long and slightly bent. The length of this bird is two feet four inches; it inhabits Falkland Islands.

AMBY, in Geography, a town of the Afnurid Netherland, in the province of Limburg, opposite to Maastricht, and on the east side of the river Meuse.

AMBUVA. See Birei Broun.

AMCITCHE, one of the Fox islands in the North Pacific Ocean. N. lat. 53° 22'. E. long. 178° 14'.

AME, soul, is made a musical term by the French, for feeling and expression. As to its effect in the aires tendres of their old music, it degenerated into over-charged tenderness, displeasing to all ears but their own.

AMEA, in Botany, a name given, by the natives of Guiana, to a plant which they use in bleeding at the nose, drying and powdering the leaves, and humming up the powder. It seems to be of the family of the plant called poincirivis, by Sir Hans Sloane, in his Jamaica Catalogue. Its leaves are large and atated, and of a beautiful green, even when dried. Phil. Transl. N° 232.

AMEDABAD, in Geography. See AMHEDABAD.

AMEDAN, a town of Persia in the province of Taberlan, 20 leagues S. S. W. of Amol.

AMEDEL, Amedani, in Ecclesiastical History, formed of the Latin amans Deurn, q. d. lover of God, or rather of amans Deus, beloved of God, a congregation of religions in Italy, instituted in 1430.

The Amedani wore a grey habit, and wooden shoes, had no breeches, and girt themselves with a cord. They had twenty-eight convents, and were united by Pope Pius V. partly with the Cistercian order, and partly with that of the Scolonci, or wooden-shoe warriors.

AMEDEUS, in Biography, a monk; was bishop of Lausanne about the middle of the 12th century. His "Sermon in praise of the Virgin Mary," printed at Bâle in 1557, and at Antwerp in 1630, are included in the Bibliotheca patrum. Dupin.

AMEDAGUR, in Geography, a country or Soubail of Hindostan, bounded on the north by Candeish and Malwa,
on the west by the Gatte or Balagat mountains, on the south by Beijpour or Vihanpour, and Tellngana, and on the call by the province of Barar.

AMENAGUR is also a capital of the above Souabh, now called Dowatabad, situated at the foot of the Balagat mountains, 105 miles N.W. of Vihanpour, and 62 E. of Poona. This city has been generally placed 59 miles S. E. of its true position. N. lat. 17° 6'. E. long. 74° 32'. See AHNENAGUR.

AMED. See DIABERIS.

AMEENABAD, or MINNABAD, a town of Hindoostan, in the country of Lahore; 30 miles north of Lahore. N. lat. 31° 30'. E. long. 72° 30'.

AM-EIS, a town of Germany, in Carinthia, on the Drave, five miles W. S.W. of Lavamund.

AMELIA, in Zoology, a species of Lacerta, having a verticillated long tail, thirty abdominal scales, and a kind of collar consisting of a double wrinkle beneath. Lit.

The amelina inhabits America. Dr. Shaw says it is principally found in South America, but that it is said to occur in some parts of Asia and Africa. "This creature varies considerably in colour, but is commonly blue or bluish green above, with somewhat irregular variegations of black and white, which are sometimes disposed in streaks, and sometimes in spots or patches; and commonly in such a manner as to leave several white, or pale blue round spots scattered on different parts of the body and limbs; the under parts are dusky, with more or less of a bluish cast, and often marked here and there with small whitish spots."—Dr. Shaw. Zool.

AMELANCOURT, in Botany. See CHIONANTHUS and MESELUS.

AMEL, see ENAMEL.

AMELANDT, in Geography, an island in the German Ocean, about four leagues long, and one wide, situated about two leagues north from the main of Frisia. N. lat. 53° 30'. E. long. 6° 14'.

AMELBARÉN, a town of Germany, in the circle of Westphalia and bishopric of Munster, six miles south of Munster.

AMEL CORN, in Agriculture, the same with SPLIT-CORN.

AMELIORATING SUBSTANCES, in Agriculture, are such, either of the animal or vegetable kind, as, when applied to land, render it more fertile and productive.

AMELIORATING CROPS, are such as are supposed to improve the lands on which they are grown. Most of those plants which have a large stem and flabby leaf are thought to render the soils on which they are produced more fertile. Carrots, turnips, artificial geries, and many other green vegetables, are in general considered as ameliorating crops; but it is probable, that all sorts of vegetables, carried off the land, are in some degree or other exhausters of the soil; and that green crops, such as have been just mentioned, are only left so, than such crops of grain or other vegetables as contain large proportions of gluten, or vegetal-animal matter in their compositions. The improvement of lands, therefore, by what are termed ameliorating crops, in a great measure probably depends either upon the culture, which the ground receives while they are growing, and the returns which they make to it in the way of manure, after decaying, or being consumed by animals, or from their taking up only such sorts of matters as are not necessary to the succeeding crop.

AMEL, in Botany, Karetta-Amelopodi of Rheed, Malab.

is a tree about seven feet high, with a slight stem, and white wood, covered with brown bark. The leaves are opposite, ovate-lanceolate, pointed at the ends, thick, entire, soft, smooth, glossy, of a blackish green above, and greenish below. The flowers are white, and grow at the summit of the branches, disposed in short panicles, and corymbiform. Each flower has a corolla with five oval-pointed petals, opening in a star, thick, white above, and fluted with red lines below; the stamens are five, a little longer than the petals, white, withered anthers, and an ovary with a pubephy lyle, forked at its summit. The fruit is a roundish capsule, of a brownish green colour, glossy, with three cells; but Rheed does not mention its seeds. This tree grows on the coast of Malabar, in sandy-flour soil. It is always green; flowers all the year, and produces mature fruit about the month of August. The decoction of its leaves in water is recommended as a sovereign remedy in colics. Its leaves and roots, boiled in oil, furnish a topic which is said to be efficacious in relieving large tumours. Rheed mentions another species of Amel, which he calls Katto-valuta amolea, somewhat smaller than the former, but little differing from it in other respects; it grows in the mountainous and uncultivated parts of Malabar. La Marec, Encycl. tom. i. p. 129.

AMELIA, in Geography, a county of Virginia, in North America, situated between the Blue ridge and the tide waters, having Cumberland county to the north, Prince George county to the east, and Linnensburg county to the south and west. Amelia, including Nottoway, a new county, contains 18,097 inhabitants, of whom 11,037 are slaves.

AMELIA ISLAND, lies on the coast of East Florida, in America, about seven leagues north of St. Augustine, and very near Talbot island on the south, at the mouth of St. John’s river. It is thirteen miles long, and two broad, is very fertile, and has an excellent harbour. Its north end lies opposite to Cumberland island between which and Amelia island is the entrance into St. Mary’s river, in N. lat. 30° 52'. W. long. 67° 23'.

AMELIA, an ancient AMELIA, a small town of Italy, seated on a mountain in the duchy of Spoleto, and the residence of a bishop, holding immediately of the pope, fourteen miles south of Todi. N. lat. 42° 33'. E. long. 13° 25'.

AMELIUS, GENTILIANUS, in Biography, a Platonic philosopher, was born in Tuscany, chiefly resided at Ape- ma in Syria, and flourished about the year of Christ 263. Having been instructed in philosophy by Lyfian- chus, he became the disciple of Plotinus, and continued with him at Rome 24 years, viz. from the year 246 to the beginning of the year 269. His talents and taste were so similar to those of his master, that he was soon admitted into his friendship, and employed by him in resolving questions proposed by his disciples, and refuting the objections and calumnies of his enemies. Here he commenced an intimate acquaintance with Porphyry, who, during the last six years of his residence at Rome, was his fellow disciple and companion, and who represents him as the most illustrious and laborious of all the disciples of Plotinus. He made large collections from the lectures and disputations of the school, and in a work of his own, consisting of 40 books, he refuted Zosprimus, a Christian heretic, who confounded the doctrines of the gospel with those of the philosophers. He also vindicated his master from a charge of plagiarism, in a treatise " On the difference between the Doctrine of Numenius and that of Plotinus." His works, amounting,
AMELLOIDES, in Botany. See Cineraria.

AMELLUS, a genus of the fragarias polygama super-
flua class and order; of the natural order of composite oppo-
stofoles, and eorymbifera of Joffic: its characters are, that
the common calyx is imbricate, roundish, (scales linear,
preffed close) the compound corolla is radiate, corollots her-
maprodite, very many in the dife, females very many in
the ray, proper of the hermaprodite tubules; one fertile,
female ligulate, lax, two or three-toothed; the fima in
the hermaprodites, have five capillary, short filaments, an-
other cylindrical and tubulous; the pelcillum in the her-
maprodites has an obovate germ, iyile filiform, of the length
of the filaments, fignias two, and filiform; females very
like the hermaprodites; no percarpium; calyx unchanged;
seeds to the hermaprodite lobular, obovate; down capi-
mary, to the females very like the others; the receptacle
chaity. Olb. The teeth in the corollots of the ray are
fearcely vifible. Martyn reckons two; Gmelin and La
Marck three, fpecies. 1. A. Lycbithis, traving A. verbenia
altered of Linn. fpec. edit. 1. chrysantherum Afric-
um of Breyunius, "with leaves opposite, lanceolate, obtufe,
downy, peduncles one-flowered." This fpecies rifes from
two or three feet high, fending out branches on every side,
terminated by flower-flaks, each supporting one violet-co-
loured flower, with a yellow disc, fhapcd like thofe of the
after, and appearing in July or Auguff. The down is vil-
lofe with few rays; a native of the Cape of Good Hope;
cultivated in Kew Gardens, by Mr. Miller, in 1768. 2.
A. umbellatus, umbelled A. solidago villofa, &c. of Brown
Jam. "with leaves opposite, three-nerved, downy underneath,
flowers umbelled." This fpecies has herbaceous, upright,
simple round hairy flems, two or two and a half feet
high; the leaves at first radical, petioled, wedge-shaped at
the base, somewhat decurrent and ferrate, nervcd,
smooth, dark green, white and foft beneath; the flem to-
wards the top generally divided into three branches, each
of which is subdivided into many small flower branches,
forming a fort of umbel; the umbellules have from three to
eight flowers, with linear leaflets, the peduncles an inch
long, each subtending one large yellow flower; the fcales of
the calyx lanceolate, membranaceous, and hoarty; the
feeds obovalical; the down feffile and hoarty; the recep-
tacle bifurte. It has the habit of tufliffoe, and would be
of that genus, if the down were filipitate, and the receptacle
naked. It is connected with the first fpecies by the mildly
chaffs between the florets. It is a native of Jamaica, in
the rocks, woods, and mountains, and flowers there in
Summer. 3. A. tendifolius, fefnder-leaved A. amellus cru-
ticulus, "with alternate linear leaves, and one-flowered
branches." This fpecies is about fifteen inches high; its
flem is woody, and divided at the bottom into cylindrical
branches, hairy, leafy, and generalliy simple; the leaves
one line and a half long, and one line and a half broad, are
straight, linear, soft, pubescent and alternate, the flowers
terminating, the branches are solitary, and resembhe of
the flf fpecies in their form and colour; the fcales of
their calyx are ftraight, very acute, hairy, and almost equal
to one another; the receptacle contains small seeds. The
account of this plant was communicated by M. Sonnerat
to La Marck. It was found at the Cape of Good Hope.
Its wood is yellow. 4. A. carolinianus of Gmelin, "with
opposite, subbifaciate, bifacciate leaves, the peduncles
double, one-flowered and axillary." Walt. Flor. Carol.
p. 213.

The first fpecies is a perennial plant, and may be easily
propagated by cuttings, planted in the shade in the Summer
months, and well watered. The plant should be taken up
with beds of earth, and put in pots, fo as to be sheltered in
winter, under a common frame or in a green house, with plenty
of air in mild weather. The second species may be propagated
by seeds fown on a hot-bed in spring; two or three of
the plants, when they are fit to be removed, should be
planted in pots, and plunged into a hot bed of tan, fo as
to get ripe seeds in the autumn, otherwise the plants will
require a flove in winter. Martyn's Miller.

AMELLOIDES. See Calea and Ericgeron.

AMELUS. See Angelii. See Aster.

AMELOT D.E LA HOUSAYE, ABRAHAM NICHOLAS,
in Biography, was born at Orleans in 1634, and formed
under the president of St. Andre, ambafador at Venice,
who employed him as his secretary. His manner and his
writings were alike as his actions; and as he never rose much
above indigence, he was often indebted to the liberality of
his friends. The events of his life are little known; and
he died at Paris in 1700, in the 7th year of his age. His
writings are numerous, and attractea notice, as he wrote
with freedom on political fubjefts. The principal of
his works, which were written in French, are the following:—
"A Tranflation of Father Paul's History of the Council of
Trent," 4to. 1696, well received, and highly recommended
by the afcertors of the liberty of the Gallican church,
now greatly superuced by that of Courayer; "A Tranflation
of Machiavel's Prince," 12mo. with notes, vindcating that
writer from the charge of having taught afaffination and
poifoning; "A Tranflation of Grattian's Courier," 12mo.
with moral and political reflections; "A Tranflation of the
Annals of Tacitus," with valuable notes of a pofitual kind;
12mo. printed in 1714, with "An Inquiry into the original
Liberty of Venice, translated from the Italian," which gave
great offence to the Venetian fiate; "The Morals of Ta-
citus," extracted from his Annals, 12mo. a work that has
been much read; "Meroirs, Histotical, Political, Critical,
and Literary," a polifhewn work, abounding with fati-
nal anecdotes. Amelot was at one period of his life con-
fined in the Baffle; but the causc of his imprisoned is not
now known. Possibly fome of his free political fritings

AMELOTTE, DENIS, a priech of the Oratory, and a
famous writer among the Roman Catholic, was born at
Saintes, in 1605, ordained priech in 1632, and maintained a
great correpondece with the fathers of the Oratory. He
published at Paris, in 1643, a life of Charles de Gendron,
second superior of that congregation, which contained reflec-
tions
tions on the famous abbey of St. Curat, that
ferred the
ment of the gentle
him to write a libel against the author; but deans ample retaliation, so that he did them greater prejudice than the whole body of Jesuits. The work which principally
to be mentioned is, "The French Translation of the
New Testament," with Annotations, in 4to, 8vo, printed
in 1668, 1697, and 1678. He last object in this translation
was to find expressions more proper and elegant than those
of the former versions, and with this view he obtained the
assistance of Mr. Courant, a protestant, well skilful in the
French language, but ignorant of Greek and Latin, so that
in turning a page he perverted the true sense of the text,
or encumbered it with, for want of being able to consult
the original. In the preface to the first edition he boasted
that he had confecrated the manuscripts of the Vatican, and many
others, but afterwards he confessed that he had never seen
any of them. He also wrote "An Abridgment of Divinity;"
"A Catechism for the Jubilee;" "A kind of Christian
Manual;" (Journee Chrétienne) and "A Harmony of the
Gospels" in 12mo, published in French, in 1669, and in
Latin in 1672. Amelot entered into the congregation of
the Oratory in 1632, and continued with them till his death

AMEN, a scriptural and ecclesiastical term, used as the
conclusion of all solemn prayers, &c., and signifying so be it,
or fait.

The Hebrews had four kinds of amen. That just men
tioned they called amen paf, which was accompanied with
the greatest attention and devotion; in this sense the word
has passed into almost all languages, without any alteration.

Some authors are of opinion, that the word amen is
formed of the initial letters of these words, Adonai, Molach
Neeman, Dominus Rex Fidelis; an usual expression among
the Jews when they would give weight or function to any thing
they said. In effect it is known that to express the words
Adonai Molach Neeman, in the ordinary
way of abbreviations; the rabbins only take the initial
letters, which, joined together, are really the letters of the
word שمس amen.

On the other hand, there are some of their Cabalists, who
according to their usual manner of finding a hidden meaning
in words, which they call notarigion, out of the letters of the
word amen form the whole phrase Adonai Molach Neeman.

Yet it is certain also that the word amen was in the
Hebrew tongue before ever there were any such things as cab-
bala or caballists in the world, as appears from Deuter-
onomy, chap. xxvii. ver. 15.

The primitive of the word amen is the verb amen, which,
in the passive voice, signifies to be true, faithful, constant,
&c. Hence came the noun SHN amen, which signifies
truth. And, lastly, of this noun amen they made a kind of
affirmative adverb, which, when placed at the end of any
phrase, or proposition, signifies, so be it, be it true, I acqui-
sire in it, &c., Thus in the passage above cited from Deu-
teronomy, Moses ordered the Levites to cry aloud to the
people, Curful be he that makes any graven or molten image,
&c., and all the people shall say amen, i.e. yes, may he be
cursed, we define, we agree to it. But at the beginning of
a phrase, as in several passages of the New Testament, it
signifies truly, verily. When it is reddoubled, or repeated
twice together, as is always done by St. John, it has the
effect of a superlative; agreeably to the genius of the He-
brew tongue, and her two daughters, the Chaldee, and Sy-
rine. — In this sense we are to understand amen, amen, also

The Evangelists usually prefer the Haranew word
amen, in their Greek amen, though St. Luke sometimes
renders it by amen, truly, or amen, certainly.

AMENABLE, or AMINABLE, from the Fr. aminable,
or amin, land, is applied to four laws books to a woman,
who is supposed to be gone to her husband.

It is likewise used to signify a right or power of bringing
persons before a particular jurisdiction; thus, we say, a
peron is amenable before such a court, or magistrat.

AMENANUS, in Ancient Geography, a river which passed
by Catana.

AMEND, or AMENDE, in the French Cafpons, a mulct,
or pecuniary punishment, imposed by a sentence of the
judge; for any crime, false prosecution, or groundless ap-
pel.

AMENDE HONORABLE, denotes an infamous kind of
punishment, used in France; &c., on traitors, paricides, fa-
crilegious persons, and other heinous criminals.

It consists in this, that the offender is delivered up to
the common hangman; who, having stripped him to his shirt,
and put a rope about his neck, and a wax taper in his hand,
leads him to the court, where he is to be hung by the God,
the king, the court, and his country.

Sometimes the punishment ends here; and sometimes death,
or the galleys, are added.

The phrase amenbe honorable is also used by way of allusion,
where a person is condemned to come into court, or into the
presence of some person injured, and make an open recantation
ask pardon, &c.

AMENDMENT, in a general sense, a change made in a
thing for the better.

Amendment amounts to much the same as with modification,
reformation, correction, &c.

Amendment, in Agriculture, is more particularly used
for a manure laid on the ground, to fatten or enrich it.

Amendment, in a literary sense, is used to denote the
corrections and other alterations made in the posterior edi-
tions of books. In this sense, amendments are also denomi-
nated emendations.

Amendment, in Law, the correction of an error com-
mited in a process, and discovered after judgment.

If the error be committed in giving judgment, viz. if a
wrong judgment be given, then they cannot amend it; but
the party aggrieved must bring his writ of error. — However,
where the fault appears to be in the clerk who wrote the
record it may be amended. Terms de Ley, 32.

At common law there was little room for amendments
for, says Britton in a treatise, published in the name and by
the authority of the king, probably about the 13 Edw. 1.,
because the law statutes therein referred to are those of
Winchelfer and Weltinmiler the second, the judges are to
record the paroles or plasas, deduced before them in judg-
ment; and king Edw. 1. granted to the judges to make record
of plasas pleaded before them, but prohibited their making their
own record a warranty for their own wrong, and raising
their rolls, amending them, and recording them contrary to
their original enrolment. So rigidly was this statute observed,
that when justice Engham, in the same reign, was induced
from motives of mere compassion for a poor man, who was
fined 13s. 4d. to erase the record and to make it 6s. 8d.,
he was fined 500 marks. With this, it has been said, a
clock-house was built at Weltinmiler, and furnished with a
clock; but the true use of the invention and use of clocks
in this country, which did not take place till about 100
years afterwards, or about the close of the 14th century,
falls in this story. There were, however, some cases, that were amenable at common law. Original writs were not amenable at common law; for if the writ be not good, the party may have another; judicial writs may and often have been amended. 8 Rep. 157. Whatever at common law might be amended in civil cases, was at common law amenable in criminal cases, and so it is at this day: resolved by Holt, Ch. J. Powell, and Powis J. 1 Salk. 51.

Formerly the suitors were much perplexed by writs of error brought upon very light and trivial grounds, as mispellings and other mistakes of the clerks, all which might have been amended at the common law, while all the proceedings were in paper; for they were then considered as only in * fieri,* and therefore subject to the controul of the courts. But when once the record was made up, it was formerly held, that by the common law no amendment could be permitted, unless within the very term in which the judicial act for record was done; for during the term the record is in the breast of the court; but afterwards it admitted of no alteration. But now the courts are more liberal; and, when justice requires it, it will allow of amendments at any time while the suit is depending, in trampling the record be made up, and the term be past. For they at present consider the proceedings as * in fieri,* till judgment is given; and therefore, that, till then, they have power to admit amendments by the common law; but when judgment is once given and enrolled, no amendment is permitted in any subsequent term. Stat. 11 Henry IV. c. 3. Mistakes are also effectually helped by the flatates of amendment and * jeofails,* so called, because when a pleader perceives any slip in the form of his proceedings, and acknowledges such error ("Jeofail or J'ait faille"), he is at liberty by those flatates to amend it; which amendment is seldom actually made, but the benefit of the acts is attained by the court's overlooking the exception. Str. 1011. These flatates are 12 in number; and by these all trifling exceptions are so thoroughly guarded against, that writs of error cannot now be maintained, but for some material mistake attainted. See Com. Dig. tit. Amendment.

By Stat. 14 Edw. III. c. 6. no procefs shall be annulled or discontinued by the misprison of the clerk in writing one falsable or one letter too much or too little; but it shall be amended; and by Stat. 9 Henry V. c. 4. it is declared, that the judges shall have power to make these amendments, as well after as before judgment, as long as the record in process is before them. This statute is confirmed by Stat. 4 Hen. VI. c. 3. For further enlarging the authority of the courts the statute 8 Hen. VI. c. 12 gives power to amend what they shall think in their discretion to be the misprison of their clerks in any record, process, and plea, warrant of attorney, writ, pannel, or return. There are only two flatates of amendments, viz. 14 Ed. III. Stat. 1. c. 6. and 8 Hen. VI. c. 12. and 15; the rest are reckoned to be flatates of * jeofails,* and not of amendments. As these flatates only extended to what the jujclives should interpret the misprison of their clerks, and other officers, it was found by experience, that many just cases were overthrown for want of form, and other failing, not aided by flat. 8 Hen. VI. c. 15; though they were good in substance; and therefore the flatates of * jeofails* were made. By Stat. 32 Hen. VIII. c. 30. it is enacted, that if the jury have once pass'd upon the issue, though afterwards there be found a * jeofail* in the proceedings, yet judgment shall be given according to the verdict. The Stat. 18 Ediz. c. 14. ordains, that after verdict given in any court of record, there shall be no stay of judgment, or reverse, for want of form in a writ, count, plaint, &c. or for want of any writ original or judicial; or by reason of insufficient returns of sheriffs, &c. By Stat. 21 Jac. I. c. 13. if a verdict shall be given in any court of record, the judgment shall not be stayed or reversed for variance in form between the original writ or bill and the declaration, or for want of averment of the party's being living, so as the peron is proved to be in life; or for that the * verba facit* is in part mis-awarded; for mifnomers of jurors, if proved to be the persons returned; want of returns of writs, so that a panel of jurors be returned, and annexed to the writs; and for that the return-officer's name is not set to the return, if proof can be made that the writ was returned by such officer, &c.

The Stat. 16 and 17 Car. II. c. 8. called in 1 Vent. 1000. an omnipotent act, and made perpetual by Stat. 22 and 23 Car. II. c. 4. enacts, that judgment shall not be stayed or reversed after verdict in the courts of record at Westminster, &c. for default in form; or because there are not pledges to prosecute upon the return of the original writ, or because the name of the sheriff is not returned upon it, for default of alleging and bringing into court of any bond, bill, or deed, or of alleging or bringing in letters testamentary or of administrations; or for the omission of vis and armis, or contra pacem, miflying the Christian name or surname of either party, or the sum of money, day, month, or year, &c. in any declaration or pleading, being rightly named in any record, &c. preceding; nor for want of the averment of hoc parasus est verificare, or for not alleging prout patet per recordum, for that there is no right visiere, if the cause was tried by a jury of the proper county or place; nor shall any judgment after verdict, by confession, cognovit alesionem, &c. be reversed for want of mifericordia or capiatur, or by reason that either of them be entered, the one for the other, &c.; but all such defects, not being against the right of the matter of the suit, or whereby the issue or trial is altered, shall be amended by the judges;—though not in suits of appeal, of felony, indemments, and informations, on penal flatates, which are excepted out of the act.

By Stat. 4 and 5 Ann. c. 16. all the flatates of * jeofails* shall extend to judgments entered by confession, nil dicit, or non sum innotanis in any court of record, and no such judgment shall be reversed, nor any judgment or writ of inquiry of damages thereon shall be stayed for any defect which would have been aided by those flatates, if a verdict had been given, so as there be an original writ filed, &c.—By Stat. 9 Ann. c. 20. 5. 7. this act and all other flatates of * jeofails* are extended to writings of * mandamus* and informations, in the nature of a quo warranto: the flatates of amendment and * jeofails* not being confirmed to extend to criminal proceedings, or on penal flatates in general. Buck. N. P. 325. 2 Mod. 144. But a * mandamus* may not be amended after return. 4 Term. Rep. 699. The Stat. 5 Geo. I. c. 13. ordains, that, after verdict given, judgment shall not be stayed or reversed for defect in form or substance in any bill or writ, or for variance therein from the declaration, or any other proceeding.

By the foregoing flatates, from 14 Edw. III. c. 6. to 8 Hen. VI. c. 15. the faults and mistakes of clerks are in many cases amenable; the misprison of a clerk in matter of fact is amenable, though not in matter of law. Palm. 258. If there be a mistake in the legal form of the writ, it is not amenable; the negligence of the clerk shall be amended, but his ignorance in the legal course of original writs is not amenable. 8 Rep. 159. A party's name was mislaken in an original writ; and it appearing to the court that
that the curtor's instructions were right, the writ was amended in court; and they amended all the proceedings after. 2 Vent. 152. Cro Car. 74. If a thing which the plaintiff ought to have entered himself, being a matter of substance, be totally omitted, this shall not be amended; but otherwise it is, if omitted only in part and unintentioned. Danv. Abr. 346. By the common law a writ of error, returned and filed, could not be amended; because it would alter the record; but now by flat. 5 Geo. 1. the writs of error, wherein there shall be any variance from the original record, or other defect, may be amended by the court where returnable.

When the award of a writ of inquiry on the roll is good, the writ shall be amended by the roll. The court cannot amend to make a new writ, or to alter a good writ and adapt it to another purpose, &c. only when the writ is prima facie bad. Mod. Cal. 263. 316. Annals 367. A declaration grounded on an original writ may not be amended, if the writ be erroneous; though if it be on a bill of Middlex or a latitat, it is amendable. 1 Lill. Abr. 67. A plaintiff may amend his declaration in matter of form, after a general issue pleaded, before entry thereof, without payment of costs; if he amend in substance, he is to pay costs, or to give imparence; and if he amend after a special plea, though he would give imparence, he must pay costs. 1 Lill. 58. A declaration in ejectment laid the demurr before the time; this was not amendable, because it would alter the issue and make a new title in the plaintiff. 1 Salk. 48. A demurrer may be amended after the parties have joined in demurrer, if it is only on paper. Style. 48. For the amendment of a plea, in paper or on record, &c. see flat. 4 Geo. II. c. 26.

As to the amendments of records, &c. an issue entered upon record, with leave of the court may be amended; but not in any thing material, or that shall damage the record. 1 Lill. Abr. 61. A record may be amended by the court in a small matter, after issue joined, so as the plea be not altered. Danv. Abr. 338. If on a writ of error a record is amended in another court in affirmance of the judgment, it must be amended in the court where judgment was given. Hard. 505. Where the record of nisi prius does not agree with the original record, it may be amended after verdict, provided it does not change the issue; but a record shall not be amended to attain the jury, or prejudice the authority of the judge. A general or special verdict must be amended by the notes of the clerk of affize in civil causes; but not in criminal actions. 1 Salk. 47. The issue roll shall be amended by the impalance roll, which is precedent; but a roll may not be amended after verdict, where there is nothing to amend it by; though surpluage may be rejected, and fo make it good. Cro. Car. 92. 1 Sid. 135.

A mistake of the clerk in entering a judgment was ordered to be amended. Cro. Jac. 351. Hutt. 41. A judgment may be amended by the paper-book, signed by the master. 1 Salk. 50. At common law, the judges may amend their judgment of the same term, and by statute of another term. 8 Rep. 156. 14 Edw. III. If judgments are not well entered, on payment of costs, they will be ordered to be done fo. When judgments are entered, it is said that the defects therein being the act of the court, and not the misprision of the clerk, are not amendable. Golib. 104. Mistakes in returns of writs, fines, and recoveries, by mutual affent of parties may be amended. Judgment shall not be stayed after verdict, because an original wants form, or varies from the record in point of form, which are amendable. 5 Rep. 45. After verdict given in any court of record, there shall be no flaw of judgment for want of form in any writ, or insufficient returns oftherife, variance in form between the original writ and declaration, &c. Stat. 32 Hen. VIII. 18 Eliz. 7 Geo. I. c. 13. The plea may be amended by the judge's notes. 1 Will. 33. 2 Stra. 1797. For amendments in informations by the attorney general, see 4 Term. Rep. 477, 8. Amendments are usually made in affirmance of judgments, and seldom or never to destroy them; and where amendments were at common law, the party was to pay a fine for leave to amend. 3 Salk. 26. Jacob's Law Dict. by Tomlin, art Amendment. Blackf. Com. vol. iii. p. 407.

Amendment of Bills in Parliament, means some alteration made in the original draught; and we read of amendments of amendments, amendments of returns of representatives, &c.

In cases of wrong returns, so reported by the committee of privileges and elections, and voted by the house of commons, it is usually ordered, that the returns be amended by the returning officer, according to the directions of the house, without filing a new writ.

Amendments ought always to be in so many from whence the thing to be amended originally proceeded, though the directions for the amendments came from the other house. Hakew. Mann of Parl. Bills, p. 167.

AMENDOLARE, in Geography, a town of Italy, in the kingdom of Naples, and province of Calabria Citra; fourteen miles north-east of Caffano.

AMENDUS, in Ancient Geography, a town of Caria, suppos'd, by Marti, to be Myndus.

AMENEBURG, in Geography, a town of Germany, in the circle of the Lower Rhine, five miles east-south-east of Marburg, 48 north-north-east of Mentz.

AMENIA, a town of Asia Minor, belonging to the Chalybes, who inhabited the eastern part of Pontus.

AMENIA, in Geography, a thriving township of Duches County, New York, in America, six miles from Sharon, in Connecticut; containing 3578 inhabitants, of whom 383 are electors.

AMENORRHOEÆ, formed of à priv. μορ, the menstru, and πυ', to flow, in Medicine, is an ability or deficiency of the menstrual excretion in women, between the age of thirteen and forty-seven. See Menstrue, Obstruction, and Cholosis.

AMENTACEOUS, in Botany, a term applied to the flowers of certain trees and plants, which are composed of a vast number of oplices, or anthéæ, hanging down in form of a rope, such as the hazel, &c. See Catkin.

AMENTICÆÆ, denote one of the classes of plants in Linnaeus's natural method of classification; and they are such as bear catkins. 

AMENTIA, in Medicine, is that deficiency of memory or reasoning which constitutes an Idiot. This lamentable malady is placed, by Dr. Cullen, under nervous diseases affecting the mind; because the mental deficiency is generally the most prominent symptom. In many instances, however, the bodily defects are equally conspicuous, and we may conclude that the cause of the disease is always to be traced to some imperfect organization of the body, particularly the brain and head.

A degree of mental imbecility is sometimes observed to follow violent fevers and apoplectic attacks; and this is the only kind from which we expect a patient to recover.

In these cases the return of mental power is observed to be proportionable to that of the corporal functions; and therefore
therefore to be promoted by the means employed in the
treatment of these diseases.

AMENTUM, in Antiquity, a leathern thong fastened
about the middle of a dart, or javelin, whereby, after calling
it at the enemy, it might be drawn back again to the owner.
The amement served also to increase the force of the strike;
for which reason, some of their great men refused to use it,
as confiding wholly in the natural strength of their own
arms. Amement denoted also a leathern string or latchet
that bound their bandoliers.

AMEN, in Botany, see CATNIP.

AMENY, in Geography, one of the Laccadive islands,
with to the Indian Sea. N. lat. 11° 37'; E. long.
7° 30'.

AMER, a river of Germany, which runs into the Neckar,
one and one-half mile call of Tubingen.

AMERADE, a kind of officers among the Saracens,
answering to the governors of provinces among the Euro-
peans.

The name is originally the same with that of emir.

AMERBACH. John. in Biography, a learned printer,
was born at Reutling, in Sweden, and acquired great reputa-
tion in the practice of his art at Brafl. The works of
Augustin were very correctly printed, for the first
1526. He began an edition of
Jerome, but died, in 1515, before it was finished. We are
indebted to Amerbach for the introduction of the beauti-
ful and useful Roman type instead of the Gothic
and Italian.

AMERICAN, or AMERICANISM, from Fr. Merci,
In Laws, a pecuniary punishment imposed upon the offenders,
at the discretion of the court; frequently also called mifer-
cordia.

In the new Terms of the Law, amercement is said to be
properly a penalty asfleld by the peers or equals of the party
amerced, for an offence done; for which he puts himself
upon the mercy of the lord.

There is this stated difference between fines and amerc-
ements: that fines are punishments certain, and determined
by some statutes; but amercements are arbitrary impositions,
proportioned to the fault, and wholly at the mercy of the
court.—Manwood, in his Foref Laws, makes another differ-
ce; as if an amercement were a more easy and merciful
penalty, and a fine a more sharp and grievous one. If amerc-
ements were too grievous, release might be made by an
ancient writ called modera mifercordia.

Fines also are imposed and asfled by the court; amerc-
ements by the country; and no court can impose a fine, but
a court of record; other courts can only amerce. C. Rep.
31. 41. A town shall be amerced for the escape of a mur-
derer in the day-time: and if the town be walled, it is said
it shall be subject to amercement, whether by day or night.
3 Inst. 53.

By the statute of Magna Charta, c. 14, a freeman is not
to be amerced for a small fault, but proportionable to the
offence, and that by his peers. 6 Hen. III. c. 4.

Before this period amercements were often excessive, and
they were imposed on a thousand different occasions, not
only for real crimes, but for trivial or imaginary offences,
and on the most frivolous pretences; of course they were
the sources of infinite vexations to the subjects, as well as of
great riches to the sovereigns of England. They fell heavy
not only on the common people, but upon the greatest pre-
lates, and most powerful barons of the kingdom. This gave
occasion to the above-mentioned article of the great charter,
and to the rules founded upon it, which enacted, that no
man should have a larger amercement imposed upon him
than his circumstances or personal estate would bear; saving
to the landholder his contention or land, to the trader his
merchandise, and to the countryman his wainsage, or team
and instruments of husbandry. In order to ascertain which,
the great charter also directs, that the amercement,
which is always inflicted in general terms ("fit in mifer-
cordia") shall be left, ponent, or reduced to a certainty, by
the oath of good and lawful men of the neighbourhood,
which method of liquidating the amercement to a specif-
com sum was usually performed in the superior courts by the
affidavit or amercement of the coroner, a sworn officer
chosen by the neighbourhood, under the equity of the
statute Westm. 1. c. 18. and then the judges extorted them
into the exchequer. But in the court leet and court baron
it is still performed by afforcers, or fators sworn to affeer,
that is, tax and moderate the general amercement, accord-
ing to the particular circumstances of the offence and the
offender. Amercements imposed by the superior courts on
their own officers and ministers were afferced by the judges
themselves; but when a pecuniary mulct was inflicted by
them on a stranger, (not being party to any suit,) it was
then denominated a fine; and the ancient practice was,
when any such fine was imposed, to inquire by a jury, quan-
tum inde rei dare velabat for annum, falsa fassificatione fini,
et uxoribus et libertum suorum. And since the difafe of such
inquests, it is never usual to affele a larger fine than a man is
able to pay, without touching the implements of his liveli-
hood; but to inflict corporal punishment, or a limited
imprisonment, instead of such fine as might amount to imprini-
sonment for life. Hence it happens that fines in the king's
court are frequently denominated ransoms, because the pen-
alty otherwise falls upon a man's perfon, unless it be re-
demned or ransomed by a pecuniary fine; according to an
ancient maxim, qui non habet in crunnenaut iuit et corpore.
Yet, where any statute speaks both of fine and ransom, it is
held, that the ransom should be treble to the fine at least.

A court leet can amerce for public nuisances only.
1 Saund. 135. For a fine and all amercements in a court
leet, a diftre is incident of common right: but for amerc-
ement in a court baron, ditfres may not be taken but by
prescription. 11 Rep. 45. When amercement is agreed on,
the lord may have an action of debt, or diltrain for it, and
impose the ditfres, or sell it at his pleasure; but he cannot
imprison for it. 8 Rep. 41. 45.

There is also amercement in pleas in the courts of the
record, when a defendant delays to tender the thing demanded
by the king's writs, on the first day. Co. Litt. 116. And in
all personal actions without force, as in debt, detinue, &c.
if the plaintiff be non-suited, barred, or his writ abate for
matter of form, he shall be amerced; but if on judicial
proceeds, founded on a judgment and record, the plaintiff
be non-suited, barred, &c. he shall not be amerced. 1 Nelf.
Abr. 260. And an infant, if non-suited, is not to be

Amercement royal, is used by fome to denote a pecuniary
punishment laid upon a Sheriff, coroner, or such-like officer
of the king, by justices, for some offence or abuse in his
office.

AMERI, in Botany. See INDIGOER.

AMERIA, in Ancient Geography, a district of Armenia,
mentioned by Strabo (tom. ii. p. 835.) situated in the vicinity
of Cabrara, in which was a temple of the moon Pharnac-
us, a number of priests or Heroes, and a sacred territory,
the fruits of which were appropriate to the pontifice. The

O 2
month Pharnaces, which was the deity denominated Lu-um among the ancients, was held in such veneration, that the oath by the fortune of the king and of the mount Pharnac-ces, was called the royal oath.

Ameria, now Asis, a town of Italy, south-west of Spoleto, founded, according to Cato, 975 years before the Persian war, or 1115 years B.C. Angulius established a col-ony in it. The celebrated Rothis is said to have been a native of this city. The whole of its territory was assigned by Angulius to the veteran soldiers.

Ameria, in Geographia, a town of Afiatic Turkey, in Natolia, 72 miles call of Kutaja. N. lat. 39° 25'. E. long. 5° 35'.

AMERICA. General History of. Throughout the his-
tory of the world no event more curious, in the eye of the philo-
osopher, has happened than the discovery of the new con-
tinent, which, with its surrounding seas, forms a com-
plete hemisphere of our planet, wherein of the ancients knew
no more than a hundred and eighty degrees of longitude,
which might even, by a slight deduction, be reduced to a
hundred and thirty; for, such is the error of Ptolemy, that
he shoves back a hundred and forty-eight degrees and more
the eastern mouth of the Ganges, which, according to a-
stronomical observations, taken by the moderns, is settled at
about a hundred and eight: thus manifestly giving an over-
plus of forty degrees of longitude in the statement of
Ptolemy, who seems to have had no notion of any of the
parts beyond what we denominate Cochinchina, which
consequently forms the eastern boundary of the world, as
known to the ancients, as our first meridian is the boundary
of the world to the west.

To pretend that the Phoenicians and the Carthaginians
made the voyage to America is an opinion truly ridiculous,
and no better supported on authentic documents than the
flories related in our times of the pretended navigations of
the Chinefe towards the shores of Mexico. It is well
known, from inquiries made at Pekin, that the work whereby
in some traces of these navigations to the latitudes of
Mexico were supposed to be found, is a romance to the full
as grofs as the fictions related by Aelian, (Hist. Diver-s.
lib. iii.) in regard to an imaginary country, entirely full of
gold, and which has seemed to have a complete conformity
with Peru, in the eyes of several of the learned, whose
judgment was extremely confined. Notwithstanding what
Vollus is pleased to say, in his commentaries on Pomponius
Mela, and M. Huct, in his defcription on the commerce of
the ancients, where he cites the Anuhi Orinus, which
nobody knows, it is certain that the Chinefe never took
long voyages; and that in 1330 they had not any notion
whatever of the island Formosa, which is at no greater dis-
tance than eighteen leagues from their coast. If they had
been in the practice of making long voyages, their igno-
rance in geography would not be so prodigious as it actually
is at present, to such a degree that they have never been
able to lay down the map of China: accordingly, whenever
they wanted a map of China, they have been obliged to
employ Europeans, whose performances we are well ac-
cquainted with, and know them to fall very far short of what
positive geography has a right to demand concerning to vail
a region as Asia.

If any people in Europe in reality did frequent some
parts of the coast of North America prior to the era of the
navigations of Columbus and Vespuccius, it must have
been the Icelawders and Norwegians; since it cannot be di-
puted that both the one and the other of these people had
before the fifteenth century formed settlements in Green-
land, which should at present be reckoned as a part of the
new continent. But here, we cannot avoid observing, that
we should never have been able to discover the centre of
America, if no other way had been found for penetrating
thither, than that of Greenland, by reason of the huge bul-
hes of ice which at once prevent any great progress within land,
and from making any considerable advances towards the pole.
Besides, the danger to be encountered in these high lat-
tudes, the exerise severity of the climate, the want of
many species of sufficiance, and the little hope of meeting
with any treafures to counterbalance the arduous enterprise,
would have been enough to dishearten the most intrepid
navigators. Christopher Columbus, however, in 1492, dis-
covered an easy passage; and, when we perceive him push-
ing up as far as the 25th degree of north latitude, to fetch
that call wind which commonly prevails between the trop-
pics, and afterwards proceeding in near a straight line to
the island of St. Domingo, we are almost tempted to be-
lieve that he had a previous inclination of that track; and
therefore, the Spaniards, with a degree of ingratitude alto-
gether monstrous, endeavored to deprive that great man,
because he was not born in Spain, of the credit of his dis-
covery, by publishing on this occasion the follle puierce and
contradictory fables. The truth of the matter is, that Co-
nubus substituted to be guided by one of his brothers,
named Bartholomew, who was a geographer by profession;
and in drawing his maps of the world, such as they were able
to make them at that time, he was perpetually alfirmed,
that of three hundred and sixty degrees of longitude, only
a hundred and eighty at molt were known; and, of course,
there remained as much of the world to be discovered as
had already been found out: and as it seemed by no means
probable that the ocean could extend, without any interrup-
tion, over one entire hemisphere, he maintained, that by
keeping conftantly to the well from the Canaries, they must
infallibly come either to islands or to a continent. And in
fact so it turned out. They first came to islands, and then
to a continent, where every thing wore the face of such ex-
tral defolation, that one cannot reflect upon it without
amazement. It is by no means our intention here to follow
the ancient flories, in which, to the credulity of childhood
has been added the dreams of daguage. In these accounts
whatsoever we meet with favours of the marvelous; nothing
is examined into: it shall be our bubisifs, therefore, to
devour at communicating to the reader clearer notion and
juftier ideas.

Among the various populations dispersed throughout the
forests and deserts of this newly discovered world, it is not
possible to point out above two that had formed any fort of
political society, the Mexicans and the Peruvians, and even
their history is stuffed with fables. Besides, their popula-
tion must have been much lower than has been flated, since
they had no iron instruments for felling the trees, nor for
filing the ground; they had no animal fit for drawing the
plough, and the construction of the plough itself was even
unknown to them. It is cally conceived, that when the la-
bour of the field must altogether be done with an wooden
yovel, and by the hand, it is impoffible to lay out much ground in
agriculture: and without a regular agriculture, wherein the
labour of animals concurs with that of mankind, no people
can become numerous in any part of the world. It is,
however, very surprifing, that at the time of its discovery
America possessed scarcely any animal fitted for tillage: the
ox and the horse were unknown, as well as the afe, which
was anciently employed in culture by several nations of our
continent, as in Bactica and Lybia, where the lightens of
the foil, says Columella, (De Re Rust. lib. vii.) enabled
this animal to supply the place of horses and oxen. It is
commonly thought that the American bison might have
been serviceable in tillage; but the bison being of a rude
untractable nature, it would have required a long series
of generations to tame him gradually for the purposes of hu-
bondry. Now this is what no one ever thought of in
America, where the people are both less industrious and
less inventive than the inhabitants of our hemisphere: their
laziness and indolence particularly struck the more attentive
and fagacious observers. In short, the stupidity they evince
on certain occasions is such, that they fiorn, according to
the expression of M. de la Condamine, to live in eternal
infancy. (Voyage far le fleuve des Amazones.)

At the same time no irregularity has been noticed in
our outward organs, unless we chide to except the abso-
lute defect of a beard, and of that down which persons of
both sexes should have on the chin, after arriving at
the age of puberty. It is in vain to affirm that the germ
of this soft down is destroyed or eradicated, since at a very
advanced age, here and there some flattered hairs of it
grow, which they commonly pluck up with their thumbs
and fingers. Their flaxen hair differs not from that of others
of our species in the temperate zones; for beyond the arctic
circle, the tribe of Esquimaux or Inuits, though of American
descendant, is composed of only short people; because
the action of the extreme cold is hostile to the complete
expansion of the members; and the cafe is nearly the same
with the inhabitants of Greenland, which is known to have
been originally peopled by hordes of American race, of
which the perfect agreement between the language of the
Greenlanders and that of the Esquimaux leaves no room to
doubt.

Nothing but a blind fondness for the marvellous could have
occasioned the propagation of such absurd figments as
those relating to a gigantic race, found on the Magellanic
shores, now customarily denominated Patagonia. The most
sensible navigators, as Narborough, (Voyage to the South
Seas,) who have had communication with the Patagonians,
describe them to be of the ordinary stature of mankind,
living by small troops in those immense regions, where the
English, who traversed them from one extremity to the
other, from Cape Blanco to Buenos Ayres, saw not an
inch of ground cultivated, nor the least trace of tillage;
so much that the difficulty of finding the means of subsis-
tence must have been exceedingly great, prior to the time of
the discovery, and while there was not a horse inexistence,
since the flesh of that animal is at present almost the sole
nourishment of the Patagonians who occupied the midst
between the river de la Plata, and the 45 th degree of south latitude. Such is the extreme indolence of
these savages, that they devour the very animals by means of
which they might clear their deferts, and at length put
an end to that miserable mode of existence in which they are
not a jot above the level of the beast, under the guidance of
infinit alone.

We shall not, as has been hitherto done, reckon among
the particular and distinct races, those Blafards that are
found in numbers by no means considerable at Colia Rica,
and the ilhumin of Darien, (Wafer's Description of the Ilh-
um of Darien, and Coreal Voyages, tom. i.) this being
only a defera, or an accidental interation in the tempera-
tment of the parents who produced these diseoursed in-
dividuals, who are known to bear a great analogy with the
white negroes, or the Dondos of Africa, and with the
Kakenalakes of Asia. The diltemper in which these symmp-
toms originate attacks more or less all the black or extremely
swarthy people in the hottest climates of the globe. The
pygmies, spoken of in an account translated by M. Gomb-
ervolle of the French academy, the himantopodes, or fa-
vages having the inflection of the knee turned backwards,
and others that have but one leg, may be ranked in the
fame class with the Amazonas, and the inhabitants of El
Dorado, among the absurdities which some travellers have
been weak enough to believe, and vain enough to publich.
All the monstrous people that have been seen in the New
World, were rendered fo by artifices; such as those that
have the head completely round, and are called bow1-head,
those who have it flattened, and are denominated plajoce-
phali; in short, such as have it conical, or lengthened out,
and are flyked macrocephali. Among a naked people, where
the garments cannot be affected by fahions, they influence
the body itself, and produce those various deformities
which have been noticed among the savages, some shorten-
ing their neck, others piercing the cartilage of the nose,
the hips, the balls of the cheeks, others lengthening their
cars, or curving their legs to swell by means of a figure
above the ankle.

It is not known, and it will ever be a matter of difficulty
to trace the true forces of the veneral disease with which
the Americans were afflicted in the West India islands, the
Caribbees, at Florida, in Peru, and throughout a great part
of Mexico: on this subject several curious conjectures have
been thrown out, some of them insufficiently ridiculous.
It has been pretended, that the flab of the fish intoxicated
the curum-ape, and the flesh of the game killed with
arrows poisoned with a species of wooodbine, called woorara,
produced this contagion among them. But the ancient
wild people of our continent poisoned in the same manner
their hunting weapons, without any conseqences in the
least degree prejudicial to their health and it is a well-
known fact, that the fishes killed in the ponds with the coc-
cula orientalis officinarum, and that the fowls slain in some
districls of the Alps with knives rubbed over with dle de
napel, afford a very wholesome nutriment. Besides, in the
island of St. Domingo, where the veneral disease was ex-
tremely rife, the ufe of poisoned darts was not in practice as
among the Caribs and several tribes on the Terra Firma. Neither
is it true, that the fling of a serpent or lizard of the iguan
tribe, or that the human flesh eaten by these anthropophagi,
engendered the veneral virus in the blood of the inhabit-
ants of the New World. The hypothesis of M. Affrig, as
flated in the last edition of his great work "De Morbis Vene-
reis," borders far more on probability than the fanciful opin-
ions just mentioned; though this hypothesis of that fa-
mous physician is by no means generally adopted. We
shall content ourselves with observing, that the veneral dif-
feblue may have been a morbid affection in the temperament
of the Americans, like the scurvy in the countries of the
north: for, after all, we are not to imagine that this dilem-
per made the fame ravages in America as it did in Europe
some time after its transplantation.

The almost total want of culture, the valt extent of the
forets, the immense tract of country, the waters of the rivers
exuded from their beds, the infinite number of swamps and
lakes, together with the holt of infects which are a natural
consequence from all these, rendered the climate of America
infalubrious in certain parts, and much colder than it
might otherwise be expected, confiding the relative la-
itude of its territory. The difference of temperature in
the two hemispheres, under the same paralles, has been esti-
nated at twelve degrees, and by a closer calculation, it
might
might even be fixed at some degrees more. Now, these local causes operating conjointly must have had an influence on the constitution of the indigenous people, so as to produce some alteration in their faculties: accordingly, it is only to a want of penetration that we can ascribe the little progress they had made in metallurgy, the flint of all sorts, as that without which the others fell, as it were, into a lethargy. It is well known that nature has not denied iron mines to America; and yet no nation of America, neither the Peruvians nor the Mexicans, possessed the secret of forg-}

mg that metal; whereby they were deprived of many conveniences, by rendering it impossible for them to make regular bars of timber in their forests, and to restrain the rivers within their beds. Their hatchets of stone could not enter the trunks of trees, except by the application at the same time of fire to them: so that they were forced to convey away all the parts reduced to coal, in order to prevent the flame from coming at the root. Their procress was nearly the same whenever they wanted to make barrels of a single piece, or cauldrons of wood for boiling their victuals, by afterwards casting in red hot flounces; for comparatively but few of the savages had the art of making vessels of clay. The farther these methods were from perfection, the more time they required in the practice: therefore, in South America it was often observed, that men were employed for two whole months in felling three trees. To conclude, it will be easily imagined, that the more stationary populations, as the Mexicans and the Peruvians, notwithstanding the want of iron, had acquired a degree of industry greatly superior to the mechanical skill polished by such as were dilered by families, like the Wopons, where they have not sufficient resources, says Dr. Bancroft, for procuring the mott necessary apparel clothing; and it is only with the reticulication found in the cocoa nut, or with some bark of trees, that they cover the organs of generation. Natural History of Guiana.

Hence we are not to be surprized, that the New World contained so few inhabitants at the time of its discovery: for the savage life is repugnant to the multiplication of the species beyond what we should at first sight imagine: since the saws the savages cultivate the soil, the more ground they want to live upon. In the northern tracts of America districts of forty leagues have been travelled over in all directions, without meeting with a single hut, or perceiving the smallest vestige of a habitation. After a march of nine or ten days, keeping always the same course, the traveller has perhaps come up to a petty horde, or rather a family, separated from the rest of mankind, not only by mountains and deserts, but also by its language differing from all known tongues. Nothing more strongly proves the little communication then subsisting between the Americans in general, than the incredible number of dialects spoken by the different tribes of savages. Even in Peru, where social life had made some faint advances, a great variety of languages was nevertheless found, reciprocally incompre-}

hensible or unintelligible, and the emperor could not give his commands to the greater part of his subjects, except by means of interpreters. It naturally occurs on this occasion, that the ancient Germans, though distributed like a
d spouse in populations, separated by vast deserts, yet spoke only one mother-tongue; and a person might, before the Augustan age, as well as at present, make himself tolerably well understood by means of the Teutonic, from the centre of Belgium, to the banks of the Oder: whereas, in the New World, we need only, says Acosta, to cross a valley for hearing another jargon. De procur. Indorum fabul. The depopulation was perhaps still greater in the more southern parts of America than in the north, where the forests had usurped every thing; so that much of the great game might propagate, and fulfill themselves in them, and at the same time afford nourishment to the hunters; whereas in the Magellanic countries there are plains upwards of two hundred leagues in extent where no wood is seen, but only bushes, bristles, and noxious weeds. (Beichreich. von Patagonia.) Whether it be that the quality of the briny or acid waters found there is repugnant to the propagation of forests, or that the ground there secretes deppositions of gravelly and flaky fulminances, from which the roots of large trees can derive no aliment. In short, for forming some idea of the defoliation of the Magellanic regions, it will suffice to say, that the English, carried into slavery by the Patagonians, have often travelled, in the train of their barbarous makers, for a whole fortnight together, before they came up with a few miserable huts covered in with horti hides. In the village that has been figured the capital of Patagonia, and where the grand caicce refused, they could reckon in 1741, to more than fourscore persons of both sexes. Ifon's Voyages. Bifides, in the southern degrees of latitude, there are few lands, one part whereof is marshy, and the other annually overflowed, because the rivers and torrents, which have not channels proportionate to their volume of water, deluge the country to immense diluvions on the accss of the rainy season in the torrid zone. From Sierra Lita to the extremity of the mission of the Misses, about the sixteenth degree of south latitude, through a space extending upwards of three hundred leagues, are found either these swamps or those lands where the inundations frequently drive the inhabitants up the mountains: accordingly there were seen but few, and they spoke thirty-nine languages, not one of which had any affinity with the rept. Relation de la Mission des Misses.

It is thought that the entire population of the New World, at the time of its discovery, might be forty millions; which falls short of the sixteenth part of the total amount of the human species, upon the computation of those who give to our globe eight hundred millions of individuals. Yet it is supposed, that in dimension the new continent is nearly equal to the old one: however, it is of confection to observe, that the calculations of Tempelman, Struyek, and several others, in regard to the surface of America, reduced to square miles, are not entitled to much confidence, as the geographical maps are still too defective for such an operation; and it would scarcely be believed, that all the known maps contain an error of almost a hundred leagues in the longitude alone of some stations of Mexico, as that longitude has been lately determined by an eclipse of the moon. But this is not all, for much as there is a tract of country beyond the Sioux and the Alenepolos; the commencement whereof towards the west is not known any more than where it terminates towards the north.

M. Buffon had already observed, that some Spanish authors must have been guilty of great exaggerations in what they relate concerning the number of persons who, according to them, were found in Peru. But nothing more completely proves that these writers have exaggerated, than what we have mentioned of the small quantity of ground rendered productive in this country, where Zarate himself agrees, that there existed only one place that had the aspect of a town, and that town, says he, was Cuzco. (Hist. of the Conquest of Peru, book i. chap. 5.) Nay, to long ago as the year 1510, the court of Spain law, that, to remedy the depopulation of the conquered provinces in America, no other
other means were left than to transport negroes thither, where the regular traffic began in 1516, and call enormous sums: it is even computed that each African brought to the island of St. Domingo came to upwards of two hundred ducats, or more than two hundred chequins, at the rate that the Genoese merchants charged for them. The Spaniards have, doubtless, contrary to their own interest, destroyed a great number of Americans, both by the labour of the mines and by atrocious depredations; but it is no less certain, that countries whither the Spaniards never penetrated, as the parts adjacent to Hudson's Bay, are still more desert than others that fell under the yoke of the Caffians.

We now conceive how great the difference in the fifteenth century, between the two hemispheres of our globe. In one, civil life was but just commencing; literature was utterly unknown: the very names of the sciences had scarcely been heard: the generality of trades were wanting: tillage was in its rudest stage as hardly to defray the name of agriculture, since neither the plough nor the harrow had been invented, nor any animal trained to draw them: reason, which alone can dictate equitable laws, had not yet cauifed her voice to be heard: human blood was shed upon the altars; and even the Mexicans were full in some respects anthropophagi; an epithet that may also be extended to the Peruvians, since, by the confession of Garcilasso, who is by no means prone to exaltate them, they fed the blood of children on the canes, or sacred bread, if that name may be applied to a paife, kneaded, so as for fanatics to eat it in a kind of temples by way of honouring the deity of whom they had no knowledge. In our continent, on the other hand, societies had so long been formed, that their origin is almost lost in the darkness of antiquity, and the discovery of forged iron, so necessary and so unknown to the Americans, has been in use among the inhabitants of our hemisphere from time immemorial. For, though the processes employed for obtaining the malleability of a metal so flubborn in its mineral state be very complicated, yet M. de l'Estoile has clearly proved that the several ores, at which writers have pretended to fix this discovery, are to be regarded as fabulous. Letters fur la Chine.

It is impossible here to enter into a regular analysis of the systems proposed for explaining the caufes of this difference between the two parts of the same globe. It is a secret of nature, on which the human mind becomes more and more confused in proportion as it obstinately determines to fathom it. Nevertheless, those physical vicissitudes, the earthquakes, the volcanoes, the inundations, and peculiar catastrophes, whereof we, who live in the calm of the elements, have not a very accurate idea, may have had some influence in its production; and it is well known at present that the most violent shocks of earthquakes, which are sometimes felt throughout the whole extent of the new continent, communicate no succussion at all to ours. Had it not been for the private advices received from different parts, we in Europe should never have known that, on the 4th of April, 1708, the whole tract of America was shaken: whence we may infer, that ancient dreadful calamities may have happened, whereof the inhabitants of our hemisphere, so far from feeling them, have not had the flighted intuition. Neither should we, following the example of some of the learned, apply to the New World the prodigies found in the Timaeus and the Critias of Plato, concerning the Atlantick fink by a torrent of rain that lasted only four and twenty hours. The basis of this tradition was brought from Egypt, but Plato embellished or disfigured it by a number of allegories, some philosophical and others puerile; such as the victory obtained over the Atlantides by the Athenians, at a period when Athens was not yet in being; these anachronisms occur so frequently in the writings of Plato, that it certainly was not without reason that the Greeks themselves accused him of being unacquainted with the chronology of his country. Athen., lib. vi. cap. 12 & 13. The great difficulty is to know whether the Egyptians, who were no mariners, and consequently could be but little versed in positive geography, had any accurate knowledge concerning a large island or a continent situated beyond the pillars of Hercules. Now it must be owned that this is not probable; but their priests, while studying cosmography, might furnish that there were more portions of land furthered in the ocean than they had knowledge of. The left they knew, from the total want of navigation, the more natural it is that they should have fallen on this conjecture; and especially if it could be shewn that prior to the navigation of the earth performed in Egypt by Eratosthenes, under Eusthenes, the priests had already an idea of the actual dimensions of the globe. However this be, their doubts and their surmises concerning the existence of some large tract of country, had no more relation to America in particular than to all other lands with which they were unacquainted; and the limits of the ancient world, precisely as we have fixed them, remain invariably the same.

That the cataclysm, or inundation of the Atlantid, rendered the sea beyond the straits of Gibraltar so muddy as to make it un navigable, as Plato affirms, is flatly contradicted by all experience from the voyage of Hanno to our own times. And yet M. Géfner, whose erudition is universally acknowledged, thought that the isle of Ceres, spoken of in a poem of very high antiquity, attributed to Orpheus under the title of Ἀτλαντίσκε, was a fragment of the Atlantis: but this isle, which is described by its forests of pines, and particularly by the black clouds which surrounded it, has no where been found; so that it must have been swallowed up in the abyss subsequent to the Argonautic expedition, even supposing, contrary to all probability, or rather contrary to policy, that those Argonauts could have come from the Euxine into the Atlantic ocean, by conveying the ship Argo from the Bosphorus into the Vifula, to enable them afterwards to enter the Mediterranean by the columns of Hercules, as it is mentioned towards the end of that poem referred to Orpheus; whence we may conclude, that there has been no sparing of the marvellous, and that M. Géfner might have been left credulous without any impeachment of his prudence.

If we find any where the well of us some traces of a continent converted into a multitude of isles, it is doubtful in the Pacific ocean; and we shall not here repeat what the President de Brofio has advanced on this subject in his work, in which he treats of the navigations to the southern parts.

As to those who pretend that the human race has only of late found its way to America, by crossing the sea at Kamtschitka, or the straits of Tichfuki, either upon the fields of ice or in canoes, they do not consider that this opinion, besides that it is extremely difficult of comprehension, has not the least tendency to diminish the prodigy: for it would be surprising indeed that one-half of our planet should have remained without inhabitants during thousands of years, while the other half was peopled. What renders this opinion least probable is, that America is supposed in it to have had animals, since we cannot bring those species of animals from the Old World which do not exiit in it, as those of the tapir, the glama, and the tajecu. Neither can we admit of a recent organization of matter for the hemisphere opposite to ours: because, independently of the accumulated difficulties in this hypothesis,
hypotheses, and which can by no means be solved, we shall observe, that the foill bones discovered in so many parts of America, and at such small depths, prove that certain species of animals, so far from having been recently organized, have been annihilated a long while ago. It is an incontestable fact, that when Christopher Columbus arrived there, there existed neither in the islands nor in any province of the new continent quadrupeds of the first magnitude: there was neither the doomed ncar, the camel, the giraffe, the elephant, the rhinoceros, the horse, nor the hippopotamus. Therefore the large bones that have been dug up have belonged to species extinct or destroyed some centuries anterior to the epocha of the discovery of that country; since the very tradition of them no longer subsisted among the natives who had not so much as heard talk of any quadrupeds of larger size than those found among them in 1492. Yet the molar tooth, in possession of the late Abbé Chappe, who died in California, was eight pounds in weight: as we learn from the extract of the letter addressed to the academy of Paris by M. Alzate, who affirms, that at Mexico is still preserved the bone of a leg, the knobb whereof is a foot in diameter. Some of the large species of the hippopotamuses, such as are found in Abyssinia and on the shores of the Zaire, produce grinders weighing upwards of eight pounds; and yet it may be doubted whether there be any elephants having legs that contain parts of such prodigious dimensions as those mentioned by M. Alzate, whole account, however, may not be absolutely exempt from exaggeration. The fame may be said of the dimensions given by Father Torrubia, in his pretended Gigantology, to some fragments of skeletons dug up in America, and which are at present pretty generally to be seen in the cabinets of Europe. The late Mr. Hunter, who made this subject his particular study, thought that they belonged to carnivorous animals; and it was not till after he had gone through a long course of comparative anatomy, that he delivered this opinion to the Royal Society of London. [Phil. Transact. for the year 1768.] But if this were true, nature must have acted upon a contrary plan in America to what she has followed in our continent, where all the terrestial quadrupeds of the first magnitude are frugivorous and not carnivorous. It is a mistake in Proper Alpinus and M. Maillet, to imagine that the hippopotamuses are farcophagous or carnivorous. The reason whereof seems to be the difficulty that carnivorous animals of the first magnitude would have had in finding fullness, and that at all times; whereas the vegetables immediately spryng up, and in such abundance, as to be more than sufficient for the nourishment of frugivorous beasts of the most enormous bulk: accordingly, the opinion of those who attribute these relues to zoophagous genera is scarcely probable. In vain were the savages who dwell on the banks of the Ohio interrogated concerning their notions about the huge bones that were found on the borders of that river in 1738; they threw no more light on the subject than the inhabitants of Siberia do on the discovery of the foill ivory of their country, which some of them consider as the spoils of giants, and others as the remains of an animal living under ground, which they call mammala, being more worthy of appearing in the mythology of the north than in the nomenclature of natural history. [See Tuite’s View of the Russian Empire, vol. i. p. 26.] Nevertheless M. Bertrand, that sagacious observer, who traversed Pennsylvania and a great part of North America, affurres us, that some savages, fixing on the place where the bones found in the Tidewater of the Blue Mountains, reaching from Canada to Carolina, said that it was not surprising to find shells about the Blue Mountains, since they knew that in days of yore the sea had surrounded them with its waters.

This relation is founded on the tradition universally diffused among all the tribes of America, from the Iroques of Canada as far as Mexico. They affirm, that in former times the low lands of their continent were submerged, which obliged their ancestors to retire to the heights. It is not without some degree of allowance that we read in Acosta, that in his time traces strongly marked of that inundation were still seen in several places: “Certe in novo orbe ingens cujusdam exsudationes non obscura monumenta a proxima notatur.” [De Natura Nov. Orb.] However this be, we are unable to explain how all the populations of America had so little commerce and connection with each other, as is proved from the multiplicity of languages in use among them, otherwise than by admitting that their manner of living by the chase or by the fishery not only prevented them from uniting, but even obliged them to retreat from each other. Accordingly, it has been seen, that when different tribes have come so near as to intercept the game, it kindles national wars, which only terminate in the destruction or the retreat of the weaker or less courageous tribe. Handfuls of men there dispute for the possession of immense defects, and the enemies are often at the distance of above a hundred leagues atonier: but a hundred leagues are nothing to hunters, who, in the search of game, or in the distant pursuit of it, always meet in some part or other. The difficulty of fixing boundaries, which is very great even among sedentary nations, is much greater among hordes who roam from forests to forests, and yet pretend to be the absolute proprietors of districts which they only run over.

Such nations as were really fishers, or ichthyophagi, existed only in the northernmost regions of the New World: for, though we find between the tropics savages who are much addicted to fishing, they nevertheless plant several feet of maize around their huts. But throughout America this culture, as well as that of the maize, was the busines of women, and the reason of it is very easy to discover; but little of it was cultivated, so that this employment was not regarded as the principal occupation. Many hunters have even been discovered, as well in the south as in the north, who followed no species of cultivation, living solely on game. As it happened that they were more successful at some seasons than at others, they could only preserve their meat by boiling it: for the nations dispersed towards the centre of the continent had not the slightest knowledge of salt; but almost all those who dwell in the torrid zone, and even at the extremities of the temperate zones towards the equator, made great use of pimento (capsicum annum) or other herbs as salt; and this they were taught by nature. We should here observe, that the physicians of Europe have generally been and are still in an error in regard to spices. In burning cliimes great and continual use of them is necessary to aid digestion, and relieve the bowels the heat which they lose by a too copious transpiration. Thus travellers inform us that those savages of Guiana, who sprinkle so much pepper over their viels, as to excoriate the tongues of persons not accustomed to it, constantly enjoy a more confirmed state of health than the other people of the country, as the Acouas and the Moroux, who cannot always procure pimento in sufficient quantities. Even in Europe we see how necessary this spice is to the Spaniards, who few white fields with it as we few barley: in short, it is well known that, in proportion as the heat of the climate augments, it has been found all over Asia and Africa that the consumption of spices has augmented in a proportion with the heat.

Among the hunting nations of the New World different componisns, to which we commonly give the name of nutritive powders or condenal aliments, have been discovered, which
which they expressly reduce to a small compass, in order that they may be able the more easily to convey them when they are to take refreshment for the safety of the game, which are in some places at a great distance from those in which they are in quest of them. Moreover, we gather, from various accounts, and even from some paffages in history, that the gentrality of ambulatory nations of our continent have had or still have similar practices: the savages of great Britain composed a kind of these paffes with karemyle, which is supposed to be the tubercules of the potato, called by the country folk wild vetches, though in fact it is a lathyrus. By swallowing a ball of this drug the Bretons were enabled to dispel with all other aliment for an entire day. [Dio Caius, in Sever.] The cafe is nearly the fame with the green powder, in use among the savages dispersed along the river Sulquehanna, which falls into Chesapeak Bay: it will suffice here to observe, that this substance is composed of torrefied maize, which forms the principal ingredient, roots of angeliae and salt. It may be conjectured, however, that these barbarians, before they had any communication with the colonies of Europe, employed no salt in the composition, as it cannot add much to the alimentary properties.

As to the method of procuring fire, it was the fame throughout the whole extent of the New World, from Patagonia to Greenland: that is, by rubbing pieces of hard wood against other very dry pieces, fo long and fo forcibly till they emitted sparks or kindled into a flame. It is true, that among certain populations to the north of California, they had the method of inflicting a kind of pivot in the hole of a very thick plank; and by the circular friction produced the fame effect with that above mentioned. [Mueller, Reife und Entdeckungen von den Russen.] It should seem as if it were not a custom, or, if the expression may be allowed, the innate industry of man, that taught him this practice: for that, on this supposition, what some accounts relate concerning the inhabitants of the Maranes, the Philippines, Los Jordenas, and the Amicaus, who were ignorant, as they pretend, of the secrecy of procuring fire, must be entirely without foundation. And if we find similar facts in the geographers of antiquity, as Pomponius Mela, in regard to certain tribes of Africa, it is necessary we should know that this author drew his information from the relations of Eu-adoxus, whom Strabo describes as an impostor, who, in order to have it believed that he had doubled the Cape of Good Hope, takes the liberty of telling abundance of falsehoods. It appears, from the history of China, and particularly from the custom still subsisting among the Kamthadases, the Siberians, and even among the Russian peasants, that the method of causing wood to take fire by friction must have been common in our continent prior to the knowledge of fire and of pyrites: the heat felt by savage man in his hands on rubbing them taught him the art.

As there were in America a very great number of petty nations, of whose fome were more deeply sunk in barbarism than the rest, and in a total ignorance of all that constitutes the rational animal, it is extremely difficult to distinguish accurately the customs adopted only by some particular tribes from the practices generally followed. There are travellers who have thought that none of the savages of the New World had the smallest idea of incest, at least in the collateral line, and that brothers indiscriminately married their sisters, or cohabited with them without marriage; which gave occasion to some persons to imagine that both the physical and moral faculties of those savages must have undergone an alteration, since it is thought that it is with mankind as with domestic animals, whereof some become haunted by incessant copulations; a circumstance that has pointed the necessity of mixing in caring for the races, for the purpose of maintaining the vigour and perpetuating the beauty of them. It is evident, from experiments recently made on a single species, that the degeneracy is greater and more rapid by a succession of copulations in the collateral than in the direct line; a refutation which certainly would not have been expected. However, according to the letters of Lattes and Guimara [Muller, Histoire des Sauvages & Histoire d'Oranook], it is certain that there existed several tribes in America, among whom marriage was not contracted even in the third degree of parentage; so that it cannot be said the conjunctions which we term illicit, or incestuous, were in general practice there, as they undoubtedly were among the Caribs and several others. Garcilasso likewise relates [Histoire des Incas] that the grand caciques, or the emperors of Peru, by a curious sort of polygamy, married their sisters and their cousin-germans at the same time. He adds, indeed, p. 68, tom. ii. that this custom extended not to the people; but it is a fact that seems to us almost impossible to explain. However, we ought not to give implicit faith to all that we read in Garcilasso touching the legislation of the Peruvians; besides, he agrees that, among the hordes of this country, where the authority of the grand cacic or emperor was unsettling, as among the Antis, "marriage was unknown, when nature inspired them with desire; chance gave them a mate, taking whatever woman they met; their daughters, their fillers, their mothers, were indifferent to them; these last, however, were more excepted. In another canton," he adds, "the mothers kept their daughters with extreme care, and when they married them, elles les destinaient en public de leurs propres mains, pour montre qu'elles les avaient bien gardees." [Tom. i. p. 14. This last custom, if true, would appear still more astonishing than the incest, which must have really been in vogue among the petty hordes, composed of not above 150 persons, such as are at present seen in the forests of America, than among the more numerous tribes; and especially if we reflect on the multiplicity of languages reciprocally unintelligible, which prevented these petty hordes from procuring wives from their neighbours. It should here be remarked, that what we have mentioned on the subject of the degeneracy that may arise from incessant copulations to the human race, as well as to several species of animals, is nothing more than a bare supposition. The truth is, that we are not at present, nor are likely soon to be, sufficiently informed on a subject of such importance, for being able to speak on it with confidence; for it would be to no purpose here to cite the example of some nations of antiquity, particularly that of the Egyptians, whose laws, which are thought to be the best known, are often the least understood. The Greeks, who wrote on the history of Egypt after the death of Alexander, might easily have confounded the foundations of a foreign code, adopted under the dynasty of the Lagides, with the foundations of the national code, wherein we, who have made it our particular study, have not been able to find any satisfactory proof of the law that is conjectured to have existed there prior to the time of the conquest of the Macedonians; but a more ample discussion of this matter would here be certainly out of place. What convinces us, however, that we ought not to insist on the necessity of crossing the races in regard to mankind, as we do when speaking of the domestic animals, is, that the Circassians and the Mingrelz constitute a people who never mingle with any other, and with whom the degrees of consanguinity that prevent marriage are extremely con-
trested; and yet their blood is generally known to be the
bell in the world, at least in the fair sex; and it is by no
means credible that the men there are as ugly as is pretended
by the Chevalier d'Arvieu, in his Voyages an Lévant, whose
testimony is in direct opposition to M. Chardin, who had
been upon the spot, whereas M. d'Arvieu never was. On
the other hand, the Samoyedes, who intermix with the
Laplanders nor with the Russians, compose a people ex-
tremely mean and ill-favoured, and absolutely bearded, al-
though we know, beyond all doubt, from the observations of M.
Klinghätt, that the Samoyedes never contract incestu-
ous marriages, as has been affected by some writers who have
been very ill informed.

In the climate of America there may exist some particu-
lar cauæ why certain species of animals are smaller than the
analogous races of our continent; such as wolves, bears,
lynxes, and some others. It is likewise in the qualities of the
soil, of the air, of the nourishment that Mr. Kemp thinks we
should seek the origin of that bafardiment which follows
among the cattle transplanted from Europe into the English
colonies on the main land, from the fortieth degree of lati-
tude to the extremity of Canada. [Hist. Nat. & Civ. de la
Pennsylvanie.] And the same thing is observed in the nor-
thern parts of Russia. As to savage man, the confusions
of food, and the little inclination he has to labour with his hands,
renders him less robust than we should be disposed to believe,
were we ignorant that it is the habit of work that principally
fortifies the muscles and nerves of the arm, as the habit of
hunting enables the Americans to sustain long marches; and
it was probably this that determined M. Fourmont to give
those nations the appellation of running nations, [Réflexions
Critiques,] though they neither run nor hunt, except when
forced to it by the mors preying necessity. For while they
have any provision of flesh preferred by broiling after their
manner, they remain day and night lying at length in their
huts, which necessity alone ever forces them to leave; and it
is well known at present, from repeated observations col-
lected in different regions, that all savages in general have so
great a propensity to idleness, that it forms one of the char-
acteristics that most distinguish them from civilized people.
To this shameful vice must be added an infatuated thirst for
spiritsuous or fermented liquors, and then we shall have a
tolerably just idea of all the excelles whereof these barbarians
are capable. Tho' who imagine that extreme intemper-
ance in drink prevails only among people situated in cold
climates are much mistaken; since we learn from all accounts,
that in the hottest as well as in the coldest climates, the
Americans are as furiously addicted to intoxication, as of-
ten as they can find an opportunity, and they would find
an opportunity if they were less indolent. But, as they cul-
tivate maize and manioc only in very small quantities, the
primary subsistence from which inflammatory liquor is ex-
tracted is frequently wanting to them; for we know that the
couin, the pivoré, the chicha, and other factitious beverages
of that nature are mostiy drawn from the flour of maize and
caffeine. The hordes that absolutely cultivate nothing at all,
as the Mocos, the Patagonians, and numberless others, em-
ploy roots, blackberries, and other wild fruits, for giving a
taste to the water, and communicating to it an inebriating
quality; which is very easily done by means of the ferme-
tation which comes on of itself. It is supposèd that the
cold and phlegmatic temperament of the Americans conducts
them more than other men to those excelles, which may be
termed, with M. Monteféliou, a national intoxication: the
liquors, however, which they brew themselves are not by far
so destructive to their health as the brandy sold to them by
the Europeans, making as much havoc among them as the
small-pox, which the Europeans likewise carried with them
into the New World, where it is particularly fatal to each
of the savages: so naked, because their epidemics, and their
mucous texture being always exposed to the air become thick,
and their pores are filled more closed by the greedy and oily
coouons with which they libate the whole body, to defend it
from the fumes of the infects, swelling in multitudes, be-
ond all imitation, in the llevels and uncultivated places:
and it is the perfection they undergo from the manigaines
and mafleces that has also taught them the use of smoking
tobacco.

The ancient accounts talk much of the extreme old age to
which the Americans attain; but it is now well known that
these exaggerations have been inserted in these narratives, and
have probably given encouragement to that ridiculous im-
potent that appeared in Europe under the name of Hulta-
zo, attempting to pass for an American aged 500 years
old. It has been remarked by us, and Dr. Bancroft has
made the same observation at Guiana in 1765, that it is impos-
sible to know exactly the age of savages, because some are
totally incapable of numerical numbers, and with others the
numerical words are scarcely carried as far as three; they have no
reguiers, nor any thing that can supply the place of them;
and, for want of calendars, they are often ignorant not only
of the day, but even the year of their nativity. In general
they live to the usual term with the rest of the species, at
least in the northern countries: for the heat between the
tropics, by exciting a continual perspiration in the body,
there abridges the course or the dream of life. Nothing is
more true, however, than that almost all the American
women bring forth without pain and with extreme facility;
so that it scarcely ever happens that any die in childbirth,
or from the consequences of it: histories relate, that before
the arrival of Pizarro and Almagro they had never heard
of midwives at Peru. Hence it has been surmised, that this
effect was only owing to a particular configuration of the
organs, and likewise to that want of sensibility observed
among the Americans, of which striking instances are found
in the relations of travellers. Almost 200 years had elapsed
before the method employed by the female savages for facili-
ting the umbilical cord of their children came to our know-
ledge: it is a great mistake to pretend that they tie it, and
then to add that it is a practice pointed out by nature to all
the nations in the world. They do not tie it, but apply a
burning coal to it, which carries off one part, and the other
shrive up to such a degree that it can never afterwards
open. If nature has taught a method of procès in this re-
pect, it must be confessed that it is a difficult matter to dif-
tinguish it from those which she has not taught.

Among the Americans very few individuals have been
found maimed or deformed from their birth; and the rea-
son is, because, like the Lacedæmonians, they had the barbarity
to destroy such children as by a vicious organization, or
some natural deformity, were incapable of procuring them-
selves a livelihood from the fishery or the chase. Besides,
as the savages have no arts, to neither have they the deceives
incident to artizans, and never diveterminate their limbs in raing
edifices or managing machines. The long journeys that
pregnant women are obliged to take, sometimes occasion
them to miscarry, but it seldom happens that the violence of the
movement maims the infant in the womb. The absolute
deficiency of all kinds of domestic cattle, and of course the
total want of all milky diet, is the reason that the American
women keep their babies a long time at the breast; and that
when they are delivered of twins, they sacrifice that which
appears to them the weakless of the two: a montrous prac-
tice, but introduced among petty roving nations, where
the
the men never take any burden that might encumber them in the chase.

Nothing is more surprising than the observations that are found in the memoirs of some travellers concerning the stupidity of the American children they have attempted to teach. Mungarre tells us: [Comment. ad Hist. Brasiliæ] that, in proportion as they approach the term of adolescence their capacities seem to contract. The miserable fate to which we know, that education is reduced in the colonies of South America, that is to say, among the Portuguese and Spaniards, might induce us to suppose that the ignorance of the masters may be sufficient to occasion that of the scholars; but we have not seen that even the professors of the university of Cambridge in New England have yet formed the minds of any young Americans, so far as to enable them to produce them in the literary world. We shall here only remark, that, in order to ascertain how far the intellectual faculties of the native Americans are extensive or confined, we ought to take their children while yet in the cradle, and conduct their education with great gentleness and patience; for after these children have contracted, during a number of years, the barbarous or savage manners of their parents, it is extremely difficult to efface from their minds those impressions that have struck the deeper root from their being the first. Besides, the experiment should not be confined to two or three subjects, but extended to a great number, since even in Europe, out of such multitudes of children as are put to study from their earliest years, such a small number of reasonable men are obtained, and a still smaller of enlightened persons. Is it, however, from a few merchants of America, from a few adventurers, guided in all their actions by the most forlorn avarice, that we are to look for these arduous attempts? Alas, we should form no such expectations.

There would be no need to mention the Creoles, as their history is not necessarily connected with that of the natives of the new continent, were it not expedient to observe, that, even granting that Thomas Gage and Coreal, or the traveller who has borrowed this name, have grossly exaggerated in their accounts of the imbecility or rather brutalization of the Spaniards born in the West Indies; [Descrip. & Voy. aux Isles occident.] it is nevertheless true, that the Creoles have been generally supposed to have undergone some alteration from the nature of the climate; and that being a misfortune and not a crime, Father Féjoo ought to have been a little more candid in what he has written in his justification, since it should seem that he never would have thought of vindicating them had he not conceived that the glory of the Spanish name was concerned. Such prejudices, however, are unworthy of a philosopher, in whose sight the glory of all the nations in the world should be as nothing, when put in the balance against truth. Readers of any penetration will easily perceive that it was neither to envy nor to any private resentment against the Spaniards that what has been seen of the alteration brought on in the temperament of their Creoles is to be ascribed, since to the full as much has been said of the Europeans, established in the North of America, as any one may convince himself by reading the history of Pennsylvania, which we have already had occasion to cite. If the Creoles had written works capable of immortalizing their name in the republic of letters, they would not have been in want of the pen and the inflated style of Jerome Féjoo to make their apology, which they alone could, and they alone ought to have done. Neither was it from want of time that they neglected it, since Coreal, who has depicted them, as we observed, in such unfavourable colours, failed for America in 1666. In short, the farther the culture proceeds in the interior of the New World, by draining the morasses, by felling the timber, and clearing the woods, the more also will the climate change and soften; which is a necessary consequence, observable from year to year; and that we may here fix exactly the period of the first observation made in this respect, we shall remark, that in the last edition of the Recherches philosophiques pour les Américains, there is a copy of a letter, by which it appears, that so long ago as the year 1677, this change of climate was already perceived, at least in the English colonies, which every one knows to have been the most pertinaciously bent on tillig and ameliorating the ground, on which the savages bestowed hardly any care; they expected all from nature, and nothing from their own industry. It is certainly a grand mistake to suppose that the abundance of game, of fish, and of fruits obtained without culture, retarded the progress of civilized life throughout almost the whole extent of America; to the northern point of Labrador, and all along the coasts of Hudson's bay, from Munk harbour to Churchill river, the fertility is extreme and incredible. Now, the small bands of the human species that have been met there, are as savage, if not more, as those that roam at the centre of Brazil, of Guiana, and all along the Maragnon and the Oroonoko, where they have found more alimentary plants, more game, more fish, and where the ice never prevents fishing in the rivers. On the contrary, it appears, that the possession of a grain so easily raised and multiplied as the maize, might have induced the Americans, in some provinces, to leave off the ambulatory life, and forgo the chase, which renders the heart of man hard and pitiless. It is, however, very certain, that some of those tribes who possessed the feed of the maize, were full anthropophagi, as the Caribs of the main land, who were seen in 1704, to eat the flesh of the Maroons that had revolted against the Dutch, in their settlements on the Berbice. (Natursgeschichte von Guiana, § 161.) Nevertheless it is known to be a fact, that these barbarians, of whom we are now speaking, cultivate not only the maize, but also the piafs, myfo paradisicus, and unhappily they are not the only ones among the Americans, who, without being compelled to it by any species of death, have defiled their tables, by serving on them pieces of human flesh, roasted on large wooden spits, or boiled in marabouts.

There is no difficulty in supposing that some travellers may have exaggerated the number of these man-eating hordes; but it is undoubtedly true that they have been found in the north, in the north, and between the tropics. The Atacamas of Louisiana, who, in 1719, ate up a Frenchman, named Charleville, dwell at the distance of more than eight hundred leagues from the district of the Caribs, in huts between the shores of the Essequibo and the Oroonoko; and then, again it is necessary to make an immense journey into the continent to arrive at the Encavellados or long-haired blacks, who likewise roast their prisoners; so that this species of barbarism is common to such nations as cannot have borrowed their manners from one another, nor have been corrupted to such a degree by the force of example.

It is not surprising that, in the immense quantity of particular supplies by the accounts concerning the religions practices of the Americans, some falsehoods should have slipped in, whereas some are already perfectly known, and others will be so in proportion as travellers shall become more enlightened than the generality have hitherto been of those who have spoken of the different parts of the New World; monks and people who had no pretensions to philosophy, in any sense that this term can be understood, have taken upon them to write things that sensible persons have repented that they
they ever read. We shall only illustrate this observation by one fact which will suffice for enabling the reader to form a judgment on many others. It has been affirmed that several savages of the southern provinces worshipped a ground or pumpkin; now let us examine how the matter stands. Just as the pretended foreseers of lands and the use of a magical drum which they beat in order to drive the devil whenever they think fit lodged in the belly of a little person whom they have not been able to compute among their ordinary remedies; so some savages in America employ a gourd, which, after extracting the pulp, they fill with pebbles; so that on shaking it a noise is produced that may be heard to a considerable distance during the night. It is natural enough that the savages who are not initiated into the jugglery, should entertain various fancies concerning this mysterious instrument, not unmixed with some degree of dread; accordingly they do not venture to touch or even to approach it; and this is the whole of the affair about the adoration of the gourd. It is to no purpose to interrogate their barbarians on the subject of practices so grofs, and many others infinitely more superstitious; the poverty of their language, of which the dictionary might be comprised in a single page, forbids all explanation. We know that even the Peruvians, though united in one sort of political society, had not yet invented terms for expressing either metaphysical beings, or the moral qualities which most distinguish mankind from brutes; as justice, gratitude, and mercy. Those qualities were in the number of things that had no name; virtue itself had none in that country on which so many exaggerations have been bestowed. Now, among the petty wandering hordes, the paucity of words is still incomparably greater, to such a degree that every species of elucidation on matters of morality and metaphysics is utterly impossible.

They are certainly mistaken who imagine that among savages religion is extremely simple, extremely pure, and that its corruptions increase in proportion as the people make farther advances in civilization. The truth is, that both savages and civilized people equally plunge into horrid and cruel superstitions, when not under the restraints of found reason; and, if even the profecution of Christianity was unable to prevent the Spaniards from afflicting their brethren to the glory of God, in the grand square of Madrid, it is a plain proof how necessary it is that the reasonable service of Christianity should be well understood. Now, it would be flying in the face of our own judgment to imagine there is much philosophy among savages, who likewise celebrate aute da fir in their way, and indeed unhappily to a great excess among the Antis, where were found huge earthen vases filled with the dried carcasses of children, who had been sacrificed to statues; and they were sacrificed in this manner, whenever the Antis celebrated an act of faith. As to those who among the savages of America are called hoyéés, faméteyés, peux, angekottés, jowan, isèhantangui, and enemus, they should more properly be denominated physicians than priests, as they are generally called; it is true, they are wont to accompany the medicines they administer to the sick, with fantastical practices, which they think adapted to calm or to expel the evil principle, to whom they seem to ascribe all the disorders that attack the human body. Instead of idly reasoning on the theology of these pretended priests, it would be acting far more wisely to engage them by presents and a generous treatment to communicate to us the characters of certain plants whereof they make great use in their medicaments; for we are not acquainted with the fiftith part of the vegetables that some of these practitioners in pharmacy carry always about them in little bags, and in which the whole of their medical knowledge consists. But the missionaries, who considered these American jugglers as their rivals, persecuted them with fury; and even whenever they have occasion to mention them in their relations, they dwell on them with abuse, which distinguishes us as much as the barbarous dulness of the style in which these accounts are written, and the prodigies, manifestly false, which they affect to be true. There has been no want of millionaires in America, but we have rarely seen among them enlightened and charitable men, taking a sincere concern in the welfare of the savages, and employing some means to reduce them. It may safely be advanced, that properly speaking, it is only the Quakers who have settled in the New World, without committing crying acts of injustice and shocking enormities. As to the Spaniards, had we no information from other quarters, we might be tempted to believe that Las Casas was striving to palliate their crimes, by rendering them absolutely incredible. He has the assurance to say, in a treatise entitled De la destrucción de las Indias Occidentales por las Castellanas, and inserted in the collection of his works, printed at Barcelona, that in forty years his countrymen massacred fifty millions of Indians. This, however, is a gros exaggeration; and the reason of his committing it to paper was, that Las Casas wanted to establish in America an order half-military and half-religious; his ambition afterwards led him to aspire to being grand master of this order, and so to raise a prodigious tribute in filter from the Americans. To convince the court of the utility of the project, which would have been useful only to himself, he swelled the number of murdered Indians to that extravagant amount.

Nevertheless, it is an undoubted fact, that the Spaniards caused a great number of savages to be torn to pieces by large hounds and a species of muliffs or bull-dogs, brought into Europe about the time of the Alains; they likewise occasioned the death of vast numbers more of these poor wretches in the mine, in the pearl-fisheries, and under the weight of burdens that could only be transported on men's shoulders, because throughout the whole extent of the eastern coast of the new continent no bend of burden or of draught was found; and it was only at Peru that any glamas were seen. In short, they exercised innumerable cruelties on the caciques and chiefs of hordes whom they suspected of having concealed any silver or gold; no discipline was observed in their small parties, composed of slaves, and commanded by men who deferred capital punishment for their crimes, and had most of them been taken from the drags of the people. It is an indisputable fact, that both Almagro and Pizarro could neither read nor write. These two adventurers were at the head of a hundred and forty foot-soldiers, a number of bulldogs, and a monk named La Valle Viridi, whom Almagro afterwards cauded to be best to death with the butt end of a mufket, in the island of Puna. Such was the army that marched against the Peruvians; as to that which went to the attack of the Mexicans, under the conduct of Cortes, it consisted of fifteen cavaliers and five hundred infantry at the utmost. Now we may form some idea of the horrors these few hundred and thirty-nine murderers must have committed at Peru and at Mexico; we may likewise get a notion of the ravages committed in the island of St. Domingo. But it is an infit to common sense to assert that they slaughtered fifty millions of inhabitants. Those who give credit to such extravagant affections, doubtfulls, have no proper conception of so great a number of mankind; all Germany, Holland, the Low Countries, with France and Spain taken together, do
...do not at the present day contain fifty millions of people. Yet if we except the interior of Spain, the earth there is tolerably well cultivated, and that by the labour of females, combined with that of the husbandman. In America nothing was cultivated by the labour of animals; accordingly we see from the journals of the Spaniards themselves, that it frequently happened that they marched for five or six days in Peru without coming to a single habitation. In the expedition to Canela, we are told by Juraba, that they made no use of their swords but in leveling the bris and brambles, to clear their passage across the most frightful defile that can be imagined. In the heart of Paraguay and Guiana, whither the little Spanish armies never penetrated, and of course committed none of the ravages that have been imputed to them, at first only forests were discovered, and afterwards forests again or petty tribes were found, often at the distance of a hundred leagues from one another. It is apparent from all that the Jesuits have published concerning the establishment of their missions, how difficult it was to bring together savages in countries more extensive than France, and where the land is better than in Peru, and not inferior to that of Mexico. If we would obtain an idea of the state of the New World at the time of its discovery, we must doubtfully study the accounts, but at the same time we should employ a more discernment and a critical severity for removing the falsehoods and prodigies with which they swindle; compilers without taste or judgment, pick up all they find in the journals of travellers, and thus form disgusting romances, which have but too much increased in our days, because it is much easier to write without reflecting than with care and meditation.

The thinnest of the population of America, and the want of courage in its inhabitants, are the true causes of the rapidity of the conquests made there; one half of the world fell, as it were, in an instant, under the yoke of the other. Those who pretend that fire-arms alone decided the victory, are greatly mistaken; since with those arms it has never yet been practicable to subdue the centre of Africa. The ancient Batavians and the Germans were for the most part naked; they had neither helmet nor cuirass; they had not even iron enough for barbing all their javelins; yet those men, supported by their valour, often fought with advantage against soldiers in coats of mail, helmets, and in short armed with instruments no less murderous than the pium of the Roman infantry. If, therefore, America had been peopled by natives as warlike as the Germans and Batav, even or eight hundred men would have never conquered from them two empires in a month. Nor can it be denied that the band commanded by Pizarro was supported by auxiliary troops, since, at the battle of Caxamalca, the Spaniards alone engaged the army of the emperor Atahualpa, and the event proved that Pizarro had no need of auxiliary forces.

It is not to be denied that by a local disposition extremely remarkable, all the great rivers, namely, La Plata, the Maraguan, the Oroonoko, the river of the north, the Missisippi, the St. Lawrence, have their mouths at the easter shore, where the Europeans must make their first landing; so that by going up these rivers they penetrated without difficulty into the heart of the continent; whereas the situation, as is well known, is quite different of Peru and Mexico, that is to say, on the western shore; and they cannot otherwise be attacked than by troops already fatigued by the long marches they have made in the interior of the country.

Whatever was the cause of it, the New World was such a desert, that the Europeans might have established themselves there without destroying any tribe of the natives; and, as they would have given the Americans iron, arts, trades, barbels, oxen, and kinds of all the other domestic animals at which they were deliterate, that would have been in some sort a compensation for the spoil of which they would have taken possession. Some civilians are known to maintain that the hunting tribes of America were not the right owners of the soil; because, according to Grotius and Launenbach, the property of a country cannot be acquired by hunting in it, by cutting wood or drawing water there; nothing but the precise demarcation of limits, and the intention of cultivating, or culture already begun, can establish the possession. We take the liberty, however, to differ widely from this opinion, and think that the hunting nations of America were well authorized to assert that they were, as has been observed above, the absolute owners of the soil; because, in their method of living, the chase is equivalent to culture; and the construction of their huts is a title against which Grotius, Launenbach, Titius, and all the civilians of Europe, cannot be appealed to without rendering the apppellant ridiculous. It is allowed, that in places where there was already some sort of culture, the right was still more incontrovertibly founded; and it is exceedingly hard to conceive how it could ever come into the head of pope Alexander VI. to grant, by a bull of the year 1493, the whole of the continent, with all the islands of America, to the king of Spain. Yet he did not think he was disposing of uncultivated and uninhabited regions, since he specifies in his donation both towns and castles, civitates &ca. in perpetuum, tenore presentium, donamus. It may be replied, that this act was only ridiculous; yes, it is precisely, because it was ridiculous that it ought not to have been made, to avoid giving room to weak minds to imagine that the sovereign pontiffs have contributed as much as lay in their power to all the depredations and to all the massacres that the Spaniards have committed in America, where they cited this bull of Alexander VI. whenever they poignarded a cacique and usurped a province. The court of Rome should have solemnly repealed this act of donation, at least after the death of Alexander VI.; but unfortunately we cannot find that it ever thought of taking this step in favour of religion.

Another remarkable circumstance is, that some divine maintainers, in the 16th century, that the Americans were not men; and it was not merely the want of a beard, and the nudity of the savages, that led them to adopt the sentiment, but the accounts they received concerning the anthropophagi, or the cannibals. This is manifest by a letter still extant of Lullus: the western Indians, says he, have nothing of the reasonable animal except the milk; they fearfully know how to speak, and are not acquainted either with honour, or modestly, or probity; no ferocious animal is so ferocious as they; they devour one another, tear their enemies into morsels, suck their blood, and always have enemies; for wars are eternal among them, and their vengeance knows no bounds. The Spaniards who frequent them, continue he, become infamously as perverses, as malicious, as atrocious as themselves, whether it be from the force of example, or whether it proceeds from the influence of the climate: adeo corrupuntur illi mores, sive id accidit exemplo incolarum, sive egni natura. There is no reason, however, to think that the climate has any influence in this matter; since we have already observed, that in the hottest countries, as under the equator, and in the coldest, as beyond the fifty-third degree, we have alike seen barbarians devour their prisoners, and celebrate in horrible fongs the memory of their ancestors, who feasted in like manner at similar banquets.
in regard to the first people of America, and whence they came to recite the various opinions that have been advanced would lead us greatly beyond our purpose. The subject has been copiously and elaborately investigated by the abbe Clavigero and Dr. Robertson, and we may reasonably content ourselves with the result of their inquiries. The latter, after recapitulating and discoursing the most plausible opinions on the subject, comes to the following conclusions: 1. That America was not peopled by any nation from the ancient continent, which had made any considerable progress in civilization; because, when America was first discovered, its inhabitants were unacquainted with the necessary arts of life, which are the first effects of the human mind toward improvement; and if they had ever been acquainted with them, for instance, with the plough, the loom, and the forge, their utility would have been so great and obvious, that it is impossible they should have been lost. Therefore the ancestors of the first settlers in America were uncivilized, and unacquainted with the necessary arts of life.

2. America could not have been peopled by any colony from the more southern nations of the ancient continent; because none of the rude tribes of these parts possessed enterprise, ingenuity, or power, sufficient to undertake such a difficult voyage; but more especially because that, in all America, there is not an animal, tame or wild, which properly belongs to the warm or temperate countries of the eastern continent.

In short, from these and several other arguments, he thinks it reasonable to conclude, that the progenitors of all the American nations, from Cape Horn to the southern limits of Labrador, from the similarity of their aspect, colour, &c. migrated from the north-eastern parts of Asia; and that the nations that inhabit Labrador, Esquimaux, and the parts adjacent, from their likeness to the American nations, and their resemblance to the northern Europeans, came over from the north-westerly parts of Europe. His Hift. of America, vol. ii, p. 22, &c.

On the other hand, the abbe Clavigero, a native of America, and a later writer than Dr. Robertson, is of opinion, that there remains no other solution to this intricate question than by admitting an ancient union between the equinoctial countries of America and those of Africa, and a connection of the northern countries of America with Europe on the east and Asia on the west; so that there has probably been a period since the flood when there was but one continent. The beasts of cold climates passed over the northern illimuses which perhaps connected Europe, America, and Asia; and the animals and reptiles peculiar to hot countries passed over the illimuses that connected South America with Africa; for, from various reasons, he is induced to believe, that there was formerly a tract of land uniting the eastern part of Brazil to the westerly part of Africa; and that all the tract of land may be sunk by some violent agitation of nature, leaving only some traces of it in that chain of islands whereof Cape de Verd, Fernandez, De Norona, Ascension, and St. Matthew islands make a part; and also in those numerous sand-banks discovered by different navigators, and particularly by de Buache, who founded that sea with great accuracy. These islands and sand-banks may probably have been the most elevated parts of that immerged illimuses. In like manner it is probable, that the north-westerly part of America was joined to the north-easterly part of Asia by a neck of land which has been sunk or washed away; and the north-easterly parts of America to the north-westerly parts of Europe, by Greenland, Iceland, &c.

On the whole, we cannot but believe that the quadrupeds and reptiles of the New World passed thither by land, and by different routes, from the old continent. All other suppositions are subject to enormous difficulties; and, though this be not without force, yet they are not altogether unmountable. The most formidable is the supposition of an earthquake, so violent as to submerge a tract of land of more than 1500 miles in length, which, according to our hypothesis, united Africa and South America. We do not, however, ascribe this stupendous revolution to a single shock; it may have been effected by a succession of earthquakes. It is well known that these convulsions are common in the climates where we suppose these illimuses to have been. Neither is it impossible, nor even improbable, that such an effect should be produced by earthquakes; nor is illimitation any means delusive of examples to our purpose. The earthquake that was felt in Canada, in 1665, overturned a chain of freestone mountains upwards of 300 miles in length, converting the whole of that immense tract into one entire plain. And how prodigious must have been the convolution occasioned by those extraordinary earthquakes recorded in the histories of America, when the world was thought to be on the verge of dissolution!

It may farther be objected to this system, continues the abbé, that if bears traversed by land from one continent to the other, it will be a easy matter to affix a cause why some species passed thither without leaving a single individual behind them on the old continent; and, on the contrary, that some entire species should remain in the old continent, and not a single individual of them emigrate to America. But this objection operates with equal force against every other opinion, excepting that which employs angels in transporting beasts. Supposing, however, that it did not, we have a satisfactory answer to it. All the quadrupeds of the earth are not yet known; we cannot, therefore, affirm how many are in the one which are not in the other continent. The knowledge of the best informed zoologists is very imperfect, and they differ among themselves. The count de Buffon enumerates only two hundred species of quadrupeds. Bomare, who wrote a short time after him, makes them amount to 265; but to say how many more there may be, and of what kinds, until we have explored the interior regions of Africa, a great part of Tartary, the country of the Amazons, the wild territory west of the Mississippi, and various other unexplored and extensive countries, which, together constitute a great proportion of the entire globe, would be mere conjecture. No argument, therefore, can be inferred from the difference of the animals in the two continents against our system, till the animals in these unexplored regions shall have been examined. Abbé Clavigero's Hift. of Mexico, vol. ii. diff. 1.
We have dwelt the longer on this article, as it must be highly interesting to every inquisitive mind, and the discussion of it is blended with much useful information.

**AMERICA.** In Geography, or the New World, or the West Indies, is one of the four quarters of the globe, bordered by the ocean, discovered by Christopher Columbus, a Genoese, in 1492, and delineated America, from America Velutina, a Florentine, who landed, in 1496, on that part of the continent, situated to the south of the equator; after which it fell principally under the dominion of the Spaniards, the English, the French, the Portuguese, and the Dutch. It is divided into north and south by the gulf of Mexico and the Straits of Panama. North America, as far as it is known, extends from the 11th degree of latitude, or 7° 30′, as marked in the map of Lazzarzi, to the 57th, or, as others state it, to the 72d. Its principal countries are Mexico, California, Louisiana, Virginia, Canada, Newfoundland, the islands of Cuba, St. Domingo, and the Antilles. South America reaches from the 14th degree of north to the 60th degree of south latitude, or, if the limit of Magallanes be the limit, to the 54th; its countries are, Terra Firma, Peru, Paraguay, Chili, Terra Magellania, the Brazils, and the country of the Amazons. America, in length from N. lat. 72° to S. lat. 54°, comprehends 1263, or 7560 geographical miles, or in British miles about 8560. The greatest breadth of South America from Cape Blanco west, to that of St. Roque east, is 45°, or 2850 geographical miles; but in the North, from the promontory of Alaska to the most eastern point of Labrador, or even Greenland, a third part must be added. Supposing the breadth of North America to be 3840 geographical miles, the average breadth will be about 3360 geographical miles, or nearly 4000 British miles. This extensive continent lies between the Pacific ocean on the west, and the Atlantic on the east, and is said to contain upwards of fourteen million of square miles.

**South America.** The population of which is estimated at about 12,000,000, is an extensive peninsula, connected with North America by the istmus of Darien, and divided between Spain, Portugal, France, Holland, and the Aborigines, as follows:

<table>

The climate of Terra Firma, especially in the northern parts, is extremely hot and sultry during the whole year. From the month of May to the end of November, the forest, called Winter by the inhabitants, is almost a continual succession of thunder, rain, and tempests; the clouds precipitating the rain with such impetuosity, that the low lands exhibit the appearance of an ocean. Great part of the country is of consequence almost continually flooded; and this, together with the excessive heat, so impregnates the air with vapours, that in many provinces, particularly about Papayan and Portobello, it is extremely unhealthy. The soil of this country is different; the inland parts being exceedingly rich and fertile, while the coasts are sandy and barren. It is impossible to view, without admiration, the perpetual verdure of the woods, the luxuriance of the plains, and the towering height of the mountains. This country produces corn, sugar, tobacco, and fruits of all kinds; the most remarkable is that of the maizamulito tree: it bears a fruit resembling an apple, but which, under this appearance, contains the most subtle poison. The bean of Carthagena is the fruit of a species of willow, about the bigness of a bean, and is an excellent remedy for the bite of the most venomous serpents, which are very frequent all over this country. Among the natural merchandise of Terra Firma, the pearls found on the coast, particularly in the bay of Panama, are not the least considerable. An immense number of Negro slaves are employed in fishing for these, and have arrived at a wonderful dexterity in the occupation. They are sometimes, however, devoured by sharks while they dive to the bottom, or are crushed against the shelves of the rocks. This country was called Terra Firma, on account of its being the first part of the continent which was discovered, all the lands found previous to this being islands.

From the situation of Peru, which is within the torrid zone, one would suppose it to be uninhabitable; but the Andes, those lofty mountains, being on one side, and the South Sea on the other, it is not so prodigiously hot as tropical countries in general are; and in some parts it is disagreeably cold. In one part are mountains of a stupendous height and magnitude, having their summits covered with snow; on the other, volcanoes flaming within, while their tops, chafins, and apertures are involved in ice. The plains are temperate, the beaches and valleys hot; and lastly, according to the disposition of the country, its high or low situation, we find all the various gradations of temperature between the extremes of heat and cold. It is remarkable, that in some places it never rains, a defect supplied by a dew that falls every night, and sufficiently refreshes the vegetable creation; but in Quito they have prodigious rains, attended by dreadful storms of thunder and lightning. In the inland parts of Peru, and by the banks of the rivers, the soil is naturally very fertile; but along the sea-coast it is a barren land.

The climate of Chile is one of the most delightful in the world, being a medium between the intense heats of the torrid and the piercing colds of the frigid zones. Along the coast of the Pacific ocean, they enjoy a fine temperate air, and a clear, serene sky most part of the year; but sometimes the winds that blow from the mountains in Winter are exceedingly sharp. There are few places in this extensive country where the soil is not exuberantly rich; and were its natural advantages seconded by the indulgence of the inhabitants, Chile would be the most popular kingdom in America. Some parts of Paraguay, situated as it is, must be extremely hot by reason of the almost vertical influence of the solar rays; while districts must be pleasant and delightful. The heat is in some measure, however, mitigated by the gentle breezes, which generally begin at about nine or ten in the morning, and continue the greatest part of the day. Some tracts of the country are very mountainous; but in many others are found extensive and beautiful plains, where the soil is very rich, producing cotton, tobacco, and the valuable herb called paragua, together with a variety of fruits. Here are also extremely rich pastures, in which are bred"
such herds of cattle, that it is said, the buffaloes are the only part exported, while the thistledown is left to be burned by the ravenous beasts of the wilderness. Not long since a borie might be purchased here for one dollar, and an ox, chosen out of several hundreds, for a still more trifling sum.

The climate of Brazil, or Brasil, has been described by two eminent naturalists, Piso and Maregrave, who made their observations with a Philosophical accuracy, and describe it as temperate and mild, when compared with that of Africa; but, putting this circumstance chiefly to the refreshing winds that blow continually from the sea. The air is not only cool, but chilly through the night, so that the natives kindle a fire every evening in their huts. As the rivers in this country annually overflow their banks, leaving a foot of slime upon the lands; the soil here is therefore admirably rich. The vegetable productions are Indian corn, sugar-canes, tobacco, indigo, hides, ipecacuanha, balman, Brazil-wood, which is of a red color, hard and dry, and is chiefly used in dyeing, though not the red of the kind kind. Here is also the asafoetida, or asa in dyeing yellow, and a beautiful speckled wood employed in cabinet work. They have five different sorts of palm trees, fame curious ebony, and a great variety of cotton trees. This country abounds in horned cattle, which are hunted for their hides alone, 20,000 being sent annually into Europe. Deer, hares, and other game are likewise in great plenty. Amongst the wild beasts found here, are tigers, porcupines, guanouars, and a fierce animal somewhat resembling a greyhound; monkeys, sloths, and the topirallia, a creature between a bull and an aha, but without horns and entirely harmless; the flesh is very good, and has the flavor of beef. The country abounds with a numberless variety of fowl, both wild and tame; and among them turkeys, fine white hens and ducks: also plenty of fish, insects, and serpents.

Of Cayenne, the land along the coast is very low, and greatly subject to inundations during the rainy season, from the multitude of rivers which run down from the mountains with great impetuosity. Here the atmosphere is sultry, moist, and unwholesome, especially where the woods are not cleared away; but on the higher parts, where the trees are cut down, and the ground is laid out in plantations, the air is more healthy, and greatly tempered by the sea breezes. The soil in many parts is rich and fertile, producing sugar, tobacco, maize, fruits, and other necessaries of life.

In the months of September, October, and November, the climate of Surinam is unhealthy, particularly to strangers. The common diseases are erysipelas and other fevers, the dry belly-ache and the droopy. About a hundred miles within land from the sea, a quite different soil is seen, a hilly country, a pure, dry, wholesome air, where a fire sometimes would not be disagreeable. Along the coast the water is brackish and unwholesome, the air damp and sultry. The thermometer ranges from 75° to 95° throughout the year. A north-east breeze never fails to blow from about nine in the morning through the day, in the hottest season. As the days and nights throughout the year are very nearly of equal length, the air can never become extremely heated, nor the inhabitants greatly incomforted by the heat, as those who live at a greater distance from the equator. The fevers formerly were divided regularly into rainy and dry; of late years, however, so much dependence cannot be placed upon them, owing, probably, to the country being more cleared, by which means a free passage is opened for the air and vapours.

The air in Amazonia is cooler than might be expected, considering it is situated in the torrid zone. This is partly owing to the heavy rains which occasion the rivers to overflow for one half of the year, and partly to the haziness of the weather, which obscures the fine part of the time he is above the horizon. During the rainy season the country is subject to dreadful storms of thunder and lightning. The soil is extremely fertile, producing cacao-nuts, annato, plantains, and a great variety of tropical fruits; cedar, redwood, pison, ebony, logwood, and many other sorts of dying wood, together with tobacco, ipecacuanha, cotton, potatoes, balman, honey, &c. The woods abound with tigers, wild boars, buffaloes, deer, and game of various kinds. The rivers and lakes teem with fish. Here are also sea-cows and turtles; but the crocodiles and water-serpents render fishing a dangerous employment.

The climate is said to be much colder in Patagonia than in the north under the same parallels of latitude; a circumstance ascribed to its being in the vicinity of the Andes, which cloths it, and are covered with eternal snow. It is a most impossible to say what the soil would produce, it not being at all cultivated by the natives. The northern parts are covered with wood, among which is an inexhaustible fund of large timber; but towards the south it is said not to produce a single tree big enough to be of use to mechanics. There are, however, good piaulures which give food to incredible numbers of horned-cattle and horfes, first carried thither by the Spaniards, and since increased to an amazing degree.

North America, bounded on the east by the Atlantic, and on the west by the Pacific ocean, extends on the south to the vicinity of Panama; the province of Veragua being universally considered as part of North America. According to the maps of Lopez, a chain of mountains runs north and south, called Sierras de Caravagua, and terminates in the point of Angra; which, dividing the provinces of Panama and Veragua, forms a natural boundary between North and South America. Its northern limit is not precisely ascertained; but from 72° N. lat., ascertained as the northern limit, to 78.30', the southern boundary, there will be an interval of 6,250, or 3,870 geographical miles, from what more than 4,500 British. Its breadth is very different in different parts. Those parts of North America not inhabited by Indians or Spanish, are Xew England and the United States, of which the States, excluding Greenland, belong to Denmark.

The remaining part forms the territory of the fifteen United States; the particular countries and provinces whereof are exhibited in the following view:

North America. In History. America was originally peopled by uncivilized nations, who lived mostly by hunting and fishing. The Europeans who first visited these shores, treating the natives as wild beasts of the forest, which have no property in the woods where they roam, plumed the standard of their respective nations wherever they happened first to land, and in their name claimed the country by right of discovery. Prior to any settlement in North America, titles of this kind were set up by the English, French, Spanish, and Dutch navigators, who came hither for the purpose of fishing and trading with the natives. Though as fast titles were, they afterwards became causes of contention between the European nations. The subjects of different princes often laid claim to the same tract of country, because both had discovered the same river or promontory, or because the extent of their respective claims was undetermined.

While the settlements in this vast uncultivated country were inconsiderable and scattered, and the trade of it confined to the bartering of a few trinkets for furs, a trade carried on by a small number of adventurers, the interference of chiefs produced no important controversy, either among the settlers or the nations of Europe. But in proportion to the progress of population and the growth of the American trade, the jealousies of the nations which had made early discoveries and settlements on this coast were alarmed; ancient claims were revived; and each power took measures to extend and secure its own possessions at the expense of a rival.

By the treaty of Utrecht, in 1713, the English claimed a right of cutting logwood in the bay of Campeche in South America. In the exercise of this right the English merchants had frequent opportunities of carrying on a contraband trade with the Spanish settlements on the continent. To remedy this evil the Spaniards resolved to annihilate a claim which, though often acknowledged, had never been clearly ascertained. To effect this design they captured the English vessels which they found along the Spanish main; and many of the English subjects were doomed to work in the mines of Potosi.

Repeated severities of this kind at length, in 1739, occasioned a war between England and Spain, which terminated in 1748 by the treaty of peace signed at Aix-la-Chapelle, in which restitution was made on both sides of all places taken during the war.

Peace however, was of short duration. The French policed Canada, and had made considerable settlements in Florida, claiming the country on both sides the Mississippi by right of discovery. To secure and extend their claims they constructed a line of forts from Canada to Florida. They had secured the important pass at Niagara, and erected a fort at the junction of Allegheny and Monongahela rivers, called Fort du Quesne. They took pains to secure the friendship and alliance of the natives; encroachments were made upon the English possessions, and mutual injuries succeeded. The disputes among the settlers in America, and the measures taken by the French to command all the trade of the river St. Lawrence on the north, and of the Mississippi on the south, excited a jealousy in the English nation, which soon broke forth in open war. This war was carried on with various successes, till a decisive blow, which proved fatal to the interests of the French in America, put an end to it in 1762. This was the defeat of the French army, and the capture of Quebec, by the brave general Wolfe. That hero was slain at the beginning of the action on the plains of Abraham, and M. Montcalm, the French commander, likewise lost his life. The loss of Quebec was soon followed by the surrender of Montreal to general Amherst, and Canada has remained ever since in possession of the English.

In 1763, a definitive treaty of peace was concluded at Paris between Great Britain, France, and Spain, by which the English ceded to the French several islands which they had taken from them in the West Indies, but were confirmed in the possession of all North America on this side the Mississippi, except the island of Orleans.

No sooner was peace concluded than the British parliament adopted the plan of taxing the colonies; and to justify their attempts, declared that the money to be raised was to be appropriated to defray the expense of defending them in the late war. The first attempt to raise a revenue in America appeared in the memorable stamp act, passed March 22, 1765, whereby it was enacted, that certain instruments in writing, as bills, bonds, &c. should not be valid in law, unless drawn on blank paper, on which a duty was laid.

Immediately as this act was published in America it raised a general alarm. The people were filled with apprehensions at an act which they supposed to be an attack on their constitutional rights. The colonies therefore petitioned the king and parliament for a redress of the grievances, and at the same time entered into associations for the purpose of preventing the importation and use of British manufactures until the obnoxious act should be repealed. This spirited and unanimous opposition of the Americans produced the desired effect; and on the 18th of March, 1766, the stamp act was repealed. The news of the repeal was received in the colonies with universal joy, and the trade between them and Great Britain was renewed on the most liberal footing.

The parliament, however, by repealing this act, so odious to their American brethren, by no means intended to lay aside the scheme of raising a revenue in the colonies, but merely to alter the mode. Accordingly, the next year they passed an act, imposing a certain duty on glass, tea, paper, and painters' colours; articles which were much wanted, and not manufactured in America. This act, as might reasonably have
have been stated after what had been said of the representation of the Americans, and created a general opinion to the contrary, so that the parliament, advisedly, in 1770, passed a tax on tea. Nevertheless, this tax, however trifling, kept alive the jealousy of the colonies, and their opposition to parliamentary taxation continued increasing from day to day.

It will be easily conceived that the inconvenience of paying the duty was not the only or even principal cause of the opposition; it was the principle, which, once admitted, would have subjected the colonies to unlimited parliamentary taxation, without the privilege of being represented. The right, abstractly considered, was denied; and the slightest attempt to justify the claim by precedent was uniformly repulsed. Nor could the Americans be deceived as to the views of parliament; for the repeal of the stamp act had been accompanied with an unequivocal declaration, that "the parliament had a right to make laws of sufficient validity to bind the colonies in all cases whatsoever."

The colonies, therefore, entered into measures for encouraging their own manufactures and home productions, and for retrenching the use of foreign superfluities, while the importation of tea was prohibited. In the royal and proprietary governments, and in Massachusetts, the governors and people were in a state of continual warfare. Assemblies were repeatedly called and suddenly dissolved; employing the time while sitting in flaring grievances and framing remonstrances. As if to inflame these discontentments an act of parliament was passed, empowering, that the governors and judges should receive their salaries of the crown; thus rendering them independent on the provincial assemblies, and removable only at the pleasure of the king. These proceedings, with many others of a similar tendency, could not fail to produce a rupture.

In 1772, the spirit of the Americans broke out into open violence. The Gaffee, an armed schooner belonging to his Britannic Majesty, had been stationed at Providence, in Rhode Island, to prevent smuggling. The vigilance of the commander irritated the inhabitants to such a degree, that about 200 armed men boarded the vessel under favor of the night, compelled the officers and crew to go ashore, and set fire to the schooner. A reward of $500 offered by government for apprehending any of the persons concerned in this daring act, produced no effectual discovery.

The resolution of the colonies not to import or consume any tea, having, in a great measure, deprived the English government of a revenue from this quarter, the parliament formed a scheme of introducing tea into America under cover of the East India Company. For this purpose an act was passed, empowering the company to export all sorts of teas, duty free, to any place whatever. The company departed from their usual mode of transacting business, and became their own exporters. Several ships were freighted with teas, and sent to the American colonies, and factors were appointed to receive and dispose of their cargoes.

The Americans, determined to oppose the revenue system of the English parliament in every possible shape, contrived the attempt of the East India Company to evade the resolution of the colonies, and dispose of teas in America, as an indirect mode of taxation, sanctioned by the authority of parliament. The people assembled in various places, and, in the large commercial towns, took measures to prevent the landing of the teas. In Massachusetts they in like manner viewed the tea as a vehicle of an unconstitutional tax, and as inseparably associated with it. To avoid the one they resolved to destroy the other. About 17 persons, drest as Indians, repaired to the tea ships, broke open 542 chests of tea, and, without doing any other damage, discharged their contents into the water.

No sooner did the tidings of this destruction of the tea reach Great Britain than the parliament determined to punish that devoted town. A bill was brought in and passed, to "discontinue the loading and unloading, landing and flitting of goods, wares, and merchandize at the town of Boston, or within the bounds thereof." This act, passed March 26, 1774, and called the Boston port bill, threw the inhabitants into the greatest consternation. The town of Boston passed a resolution expressing their sense of this oppressive measure, and a desire that all the colonies would concur to stop all importations from Great Britain. Most of them entered into spirited resolutions on this occasion, to unite with Massachusetts in a firm opposition to the unconstitutional measures of parliament.

But the port bill was not the only act that alarmed the apprehensions of the Americans. Determined to compel the province of Massachusetts to submit to their laws, parliament passed an act for "the better regulating the government in the province of Massachusetts." The object of this act was to alter the government as it stood on the charter of King William, and to make the sheriffs and judges dependent on the king, and removable at his will and pleasure.

The act was followed by another, which ordained, that any person indicted for murder, or other capital offence, committed in aiding the magistrates in executing the laws, might be tried by the governor, either to any other colony, or to Great Britain, for his trial. This was shortly after succeeded by the Quebec bill, which enlarged the bounds of that province, and granted many privileges to the Roman Catholics. The view of this act was to secure the attachment of that province to the crown of England, and prevent its joining the colonies in their refusals to the laws of parliament.

All these steps, however, far from intimidating, rather exasperated the Americans, by confirming them in their former apprehensions of the evil designs of government, and furred only to unite the colonies in a more determined opposition. A correspondence of opinion, in respect to these acts, produced a uniformity of proceedings in the colonies. The people generally concurred in the proposition for holding a congress, in order to concert measures for the preservation of their rights. Deputies were accordingly appointed, and met at Philadelphia on the 26th of October, 1774.

Preparations now began to be made to oppose by force the execution of these acts of parliament. The militia of the country were trained to the use of arms; and great encouragement was given to the manufacture of gunpowder, and measures were taken to obtain all kinds of military stores. At Lexington the first blood was shed in the war; a war which feved America from the British empire. Here was opened the first scene of the great drama, which, in its progress, exhibited the most illustrious characters and events, and closed with a resolution equally glorious for the actors, and important in its consequences to mankind.

In July, congress published their declaration of independence, which separated America from Great Britain. This grand event took place 28.4 years after the discovery of America by Columbus; 166 from the first effectual establishment in Virginia, and 156 from the first establishment of Plymouth in Massachusetts, which were the earliest English settlements in America.

On the 30th of November, 1782, the provisional articles of peace and reconciliation, between Great Britain and the American states, were signed at Paris; whereby the former acknowledged the independence and sovereignty of the United
United States of America. These articles were ratified by a
definitive treaty, September 7, 1783. Thus ended a long
and arduous conflict, in which Great Britain expended near a
hundred millions of money, with a hundred thousand lives,
and gained nothing. America endured every cruelty and dis-
tress from her enemies, lost many lives and much treasure,
but delivered herself from a foreign dominion, and established
a rank among the nations of the earth. Holland acknow-
lledged the independence of the United States of America on
the 19th of April, 1782; Sweden February 5, 1783; Den-
mark the 23rd of February; Spain in March, and Russia in
July, of the same year. On the 30th of April, 1789, George
Washington was inaugurated president of the United States
of America, in the city of New York.

Hitherto the deliberations of the Union have been marked
with wisdom, and the measures they have adopted have been
productive of great national prosperity.

To conclude, the United States, and indeed all parts of
North America, seem to have been formed by nature for the
most intimate union; as it may truly be affirmed, that no part
of the world is so well watered with springs, rivulets, rivers,
and lakes, as the territory of the United States. By means
of these various streams and bodies of water, the whole
country is chequered into islands and peninsulas. The fa-
cilities of navigation render the communication between the
gates of Georgia and New Hampshire far more expeditious
and practicable than between those of Provence and Picardy
in France, Cornwall and Caithness in Great Britain, or Gal-
licia and Catalonia in Spain. The canals opening between
Suquehanna and Delaware, between Patuxent and Eliza-
beth rivers, in Virginia, and between the Schuylkill and Su-
quenna, will form a communication from the Carolinas to
the western counties of Pennsylvania and New York. The
improvement of the Patomak will give a pallage from the
southern lakes to the western parts of Virginia, Maryland,
Pennsylvania, and even to the lakes. From Detroit to Alexan-
dria, on the Patomak, 607 miles, are only two carrying places,
which together do not exceed the distance of 40 miles. The
canals of Delaware and Chesapeake will open the communi-
cation from South Carolina to New Jersey, Delaware, the most
populous parts of Pennsylvania, and the midland counties of
New York. Were these, and the canal between Ashley and
Cooper rivers, in South Carolina, the canals in the northern
parts of the state of New York, and those of Massachusetts
and New Hampshire, ill opened, and many of them are in
great forwardness, North America would thereby be con-
verted into a cluster of large and fertile islands, communicating
easily with each other, at little expense, and in many in-
fluences without the uncertainty or danger of the seas.

From the numerous competitions in every branch of bu-
niness in Europe, success in any pursuit may be looked upon
in the same light as a prize in a lottery. But the cafe is widely
different in America. Here is room enough for every human
talent and virtue to expand and flourish. This is so invariably
truethey are generally believed there is not an infirmity to
be bound of an invidious, frugal, prudent European, with
other manners, who has not been successful in business in that
country.

American Earth Nut, in Botany. See Arachis.
American Grifts. See Acrostis.
AMERICANA, in Entomology, a species of Chryso-
mbella that inhabits America; a variety of it is found in the
south of France. The general colour is greenish gold, with
five fangunieous red lines upon the wing cæsae. Fab. &
Gmel. "Feeds on the lavandula. A red spot on the head is
a secondary distinction of this species.

AMERICANORUM, a species of Apis, described by
Fabricius as a native of North America. It is harry and
black; anterior part of the thorax yellow; abdomen yellow,
black at the end. Fab. Spec. Inf. Ous. Fabricius, in
his last work, "Entomologia Systematica," gives the apis
americanorum precisely the same specific character as he had
previously assigned to apis africana, so that at present they
are both described as "hirsuta nigra, thoracis dorso flavo,
abdomine virgente: Segmento primo flavo." To increase
the confusion, the latest editor of the "Linnæan Syl. Nat."
Gmelin, adopts the same error; apis africana, p. 2780, and
apis americanorum, p. 2784, and the description in the Spec.
Inf. of Fab. is only added as a synonym to the latter. It is
probable they are both the same species.

AMERICIMA, in Zoology, a name given by some early
naturalists to a small kind of lizard found in Brazil. The
precise species is uncertain; it is said to be very small; not
above three fingers breadth long, and of the thickness of a
fian’s quill. Its body appears square; its whole back is
covered by deep grey scales; its head, legs, and sides with
brown ones; and its tail with blue. It is very glosy, the legs
extremely slender, and it is generally esteemed poisonous.

AMERIGO, or AMERICUS VESPUCELLUS. See VES-
pucci.
AMERIMNUN, or AMERINNON, in Botany, a genus of
the diophila decandria claus and order, of the natural
order of papilionaceae or leguminosa; the characters of which
are, that the calyx is a one-leaved perianthium, tube bell-
shaped, five-toothed, the teeth sharp; the corolla paphilone-
cus, standard with an oblong claw, roundish heart-shaped,
expanding and convex, wings lanceolate, shorter than the
standard, and keel short; the flamina have 10 filaments con-
joined, anthers roundish; the pistillum has a germ pedicelled,
oblong, compressed leafy, varicoce, with lateral veins, within
woody, not gaping; cells disposed longitudinally within;
the seed solitary, kidney-shaped, thicker at the base, appended
at the top. There are two species, viz. 1. A. BROWIUS,
"unarmed, with leaves petioled, alternate, subcordeate-ovate;
racemes compound, axillary, and lateral.
"This shrub rises commonly to the height of ten feet, and supports itself on other shrubs. It is a native of Carthage, Jamaica, and
Dominio. 2. A. oblonga, prickly A. or Jamaica ebony,
pierocarpus felliiholos of Lin. p. busblos of Murray and
Aston, afpalathus ebucus of Lin. Spec. and Reich. brya
Browne Jamaic. Spartium arborefrons of Miller and Sloane;
"spiny, with leaves fiddle, aggregate, obvate-oblung, and
peduncles two-flowered. This is common in Jamaica and
several other parts of the West Indies, where the wood is
cut and sent into England under the name of ebony, the
name the true ebony is a native of the cataruus country, and of
a different genus. This wood is of a fine greenish brown
colour, and admits of polishing well, so that it is much valued
by the instrument makers; and it is of a very hard durable
nature. Dr. Browne says, that the trunk seldom exceeds
three or four inches in diameter; that the slender branches
being very tough and flexible are used for riding switches,
and kept at all the wharfs about Kingston to scourge the
refractory slaves.

This species may be propagated by seeds procured from its
native country. The seeds should be sown in pots filled with
light fresh earth early in the spring, and plunged into a hot
bed of tanners’ bark, or placed in an under pots. In about six
weeks the plants will appear, and being very tender should be carefully
treated; air should be admitted to them in warm weather,
and they should be often refreshed with water. In five or six
weeks more they should be transplanted into separate pots
filled with light rich earth, and plunged again into the hot-
bed, shading them from the sun till they have taken root;
they should then have air every day in warm weather, and
water once in two or three days, and in cold nights covered
with glass. In this hot-bed they may remain till autumn,
when
when they should be removed into the sloe, and plunged into the bank bed. Those whose roots have filled the pot should be removed into those of a larger size. In winter the plants should be kept warm, and have but little water, especially in cold weather; and then leaves, when they contracts with, should be cleared by washing them with a sponge, otherwise the plants will not thrive. Their tall plants will not live in the open air in the country, even in the summer. But; they might therefore be cultivated in the flower or flower bed, and allowed much air in summer when the weather is warm, and when they have acquired strength, they may be exposed for three months in a warm situation in the summer.

AMERSFORT, a city of the Netherlands, in the province of Utrecht, situated in a fertile and pleasant country on the river Ems. The objects most worthy of notice in this town are the town-house, the triangular grand palace, the public walks planted with trees, and the great church dedicated to St. George. In its vicinity is the mountain called Amersfort berg, on which trees are planted in a kind of vista, which reaches to Utrecht. The Ems becomes navigable at this town; and all the goods formerly brought out of Germany by Hoefn wagons, and confided to Amsterdam, were shipped at this port. A manufacture of dimity and bombazine has been established in this place. Its trade in beer, rum, and tobacco is now decayed. It is 11 leagues east-north-east from Amsterdam, and 52 1/2 north-east from Utrecht. N. lat. 52° 12'. E. long. 5° 4'.

AMERSHAM. See AGBRODESHAM.

AMERTHUA, or AMERTHA, in Ancient Geography, a village of Upper Galilee, mentioned by Josephus, who fortified it against the Romans, probably the same as Meroth, which terminates Upper Galilee westward.

AMES, Joseph, in Biography, an industrious antiquarian, was originally a ship-chandler in Wapping, and acquired a reputation at an advanced period of life by his study of antiquities. His "Typographical Antiquities," or Historical Account of Printing in England, with Memoirs of our ancient Printers, and a Register of the Books printed by them from 1471 to 1600, with an Appendix concerning Printing in Scotland and Ireland to the year 1749, 4to, is a book well known and often cited. This work was considerably augmented, both in the memoirs and number of books, by Mr. William Herbert, and printed in three volumes, 4to, in 1785, Mr. Ames also published in 8vo, "A List of English Heads engraved and mezzotinto;" and he drew up the "Parentalia" from Mr. Wren's papers. He was secretary to the society of antiquarians, and died in 1759. Nichols's Anecdotes of Bowyer.

AMES, William, an English divine, and a famous controversial writer, was descended from an ancient family in Norfolk, and was born in 1576. He was educated at Christ's college, Cambridge, under Mr. William Perkins, from whom he probably imbibed the Calvinistical and puritanical sentiments that distinguished his writings. Whilst he was fellow of his college he preached a sermon about 1610-11, in which he inveighed with great vehemence against cards and dice, as the invention of the devil. By this mode of preaching he gave such offence, that he withdrew from the university in order to avoid censure. In the same year he published his "Puritanus Anglicanus," in which he contradicts the principles and conduct of the puritans against those of other persons with a spirit and language equally illiberal and offensive. No other alternative remained, according to his statement, but either to suppress episcopacy, or to bring back the pope from hell. Mr. Ames, long after leaving Cambridge, removed to Holland, and officiated as minister to the English church at the Hague. In 1615, he began his controversy with Grevinchovius, minister at Rotterdam, on the doctrines of election and reprobation, and it was continued from the press. The reputation he thus acquired induced the flates of Friesland to invite him to the theological chair in the university of Franeker; and he continued in this respectable situation for twelve years. In 1618, he attended the synod of Dort, and from time to time communicated information to the ambassador of king James of the debates of this assembly. From Franeker he removed to Rotterdam, where he preached to a congregation of his own countrymen; and where, after being for some time afflicted with an ailment, he died in 1633. In the last year of his life he wrote his "Frucht Sünd gegenlarz Ceremonien," but it was not published till after his death.

He was esteemed a learned divine, an excellent casuist, a rigid Calvinist in doctrine, and a zealous advocate for the reformed form of church discipline. His writings were numerous, both in Latin and English; most of them were printed abroad; and the principal of them, besides those already mentioned, are the following: "Defunction Socillica," of N. Grevinchovius and G. Ameling, 8vo; "Difputatio Altera," 8vo. "Conciles ad Cunctationem Hancigenum," 12mo. written against the Arminians; "Defuncta Theologica," 12mo. "De Incarnatione Verbi," 12mo. against the Socinians; "Bellarminus censuratus," 8vo. against the Papists; "De Conftentia," 12mo. and in English under the title of "A Treatise on Conference," 4to; "Antientiologia," 12mo. against the Remonstrants; "Demonstratio Logica," 12mo.; "Difputatio Theologica," against Maffy; "Technometria," 8vo. on the purpose and bound of Arts; "Reply to Bishop Morton on Ceremonies," and other tracts in the same controversy; "Christiane Catacheces Sacrophilia," and "Lectiones in Pflamnos Davidos," 8vo. a pithy and learned work, dedicated to the magnificence of Rotterdam by Hugh Peter, the colleague of Ames in the English church of Amsterdam. Neal's Hist. Purit. vol. i. p. 579. Bosc. Brit.

AMESTRA, in Ancient Geography, a river of Africa in Numidia.

AMESTRATUS, a city of Sicily, called Mantissa by Ptolemy, Ministrat by Diodorus Siculus, and Amastira by Silius Italicus; now Milletta, in the Val di Demona, on the river Hales. The inhabitants are called Ciceria (in Verrum) Amestrati. It was a strong fort of the Carthaginians, besieged by the Romans for seven months with great loss, and, after another siege, taken and razed.

AMESTRIS, in Entomology, a species of Papilio, with angular indented wings, above black, with rufous and blue mottled marks; beneath obscure. Tab. & Gmel. —Indus Asia. The interior wings are black, with two rufous spots, and two blue spots in the middle of each; behind those a streak of reddish lunules, which terminates in two white spots at the anterior margin, and along the external margin a streak of blue mottled marks. Underside entirely brown, waved with black flecks, and a row of cincinnous points. Fabricius.

AMETHYST, in Mineralogy. This stone was well known to the Greeks and Romans, from whom it obtained the
the name amethyst, from a and μεθύς, non winifus, because, according to Pliny, its colour was similar to, but not so deep as that of wine; hence, by the abrid doctrine of sympathies, it came to be esteemed as an antidote against drunkenness.

There are two kinds of amethysts, the oriental and common.

The oriental amethyst is of a reddish or yellowish violet colour; and in hardnecfs, in the form of its crystals, and in shorf in every physical and chemical property, except that of colour, is the same as the ruby, the sapphire, and oriental topaz, being a mere variety of Corundum. It is a rare gem, and is very seldom brought to Europe. By being heated it loses its colour, and becomes perfectly transparent, and of great brilliancy, so as to be scarcely distinguished from the diamond; so nearly indeed does it resemble this precious stone, as to be occasionally substituted for it in jewellers work. De Boot, in his Historia Gemmarum, mentions an amethyst, thus rendered colourless, estimated at 360 rix-dollars, which being cut to the same pattern, and set in a familiar manner as a diamond of the value of 20,000 gold crowns, so nearly equalled it in lustre that he could not tell the difference between them.

The common amethyst is crysallized Quartz, or rock crystal, tinged naturally of a full violet colour; its properties and characters will therefore be mentioned under the article Quartz. The common amethyst, like the oriental, loses its colour in the fire, but at the same time spoiled by being rendered of an opaque white, owing to a multitude of minute cracks. The best European amethysts come from the vicinity of Carthagena in Spain.

To imitate the amethyst in pale or glass, take ten pounds of clear glafs or palle, made without manganese, and fuse it down with one ounce and a half of black manganese, and one dram of zaffer. The process recommended by Porta is one dram of Manganic to one pound of frit. Nerli's receipt is totally erroneous as to the proportion of colouring matter. He recommends to each pound of glass an ounce of colour composed of eleven parts manganese and one part zaffer, which would produce a deep black glafs. Weidenhau Handbuch der Mineralogie. De Boot. Hist. Gemmarum, lib. ii. c. 32. Pini. Hist. Nat. lib. xxxvii. c. 40. Nerli. Art de la Verrire. c. 48. Handmaid to the Arts, vol. ii. p. 368.

AMETHYST, in Heraldry, signifies the purple colour in the coat of a nobleman, which, in gentlemen's escutcheons below that degree, is called purpure, and in those of sovereign princes, Mercury.

AMETHYST, or amethyst, so called from the amethystine colours of the flowers, in Botany, a genus of the diandra monogynia calas, of the natural order of vericatia and labiate of Julicifus; the characters are, that the calyx is a perianthium one-leafed, tube bell-shaped, angular, semiquinquefolia, subequal, acuminate and permanent; the corolla is one-petalled, ringlet, longer than the calyx, border five-parted and subequal; upper lip erect, rounded, concave, two-parted, gaping, lower three-parted, the fides rounded, erect, shorter, the middle quite entire, concave, the length of the upper lip; the lamina have filiform form, divided under the upper lip and longer than it, anthersimple and roundish; the stigirum is a quadrifid grum, style base of the flaments, ligulas two and acute; no pericarpium, but the calyx becomes more bell-shaped and spreading; the seeds are four, fewer than the calyx, obtuse, and angular within. There is one species, viz. A. carlina, mountain upright A, which is a native of the mountains in Siberia, from whence the seeds were sent to the Imperial garden at Petersburg, and in 1759 to Chelsea garden, where the plants ramiylly produce seeds.

It is annual, and hath an upright flaxk, which rises about a foot high, and towards the top pots out two or three small lateral branches; these are garnished with small trifid leaves, faved on their edges, and of a very dark green colour; at the extremity of the branches the flowers are produced in small umbels; these are of a fine blue colour, as are also the upper part of the branches, and the leaves immediately under the umbel; so that though the flowers are small, yet from their colour with that of the upper part of their flaks, the plants make a pretty appearance during their continuance in flower.

If the seeds of this plant are sown in Autumn, or are permitted to scatter, the plants will come up early in the following Spring, and these will flower in the beginning of June; but those sown in the Spring will not flower until July. The best time for sowing is Autumn. The flowers have an agreeable smell.

When the plants come up they will require no other care than to keep them clean from weeds, and where they are too close to thin them, for they do not thrive when transplanted; the seeds, therefore, should be sown where they are to remain.

AMETHYSTINE is applied, in Antiquity, to a kind of purple garment dyed of the hue of amethyst.

In this fane amethystine differed from Tyrian, as well as from Carthusian purple, being a kind of medium between both.

AMETHYSTINA, in Entomology, a species of Chrysopoeia. Above blue violet, beneath green and violet. Shells with scattered hollow dots.—Thorax large, antennae short and black. Fabricius.

AMETHYSTINUS, in Conchology, a species of Venus, described by Argenville; it is of an ovate shape, and violet colour, with perpendicular lines; about two inches in length, and nearly the fame in breadth.—Native place unknown. Gmelin.

AMETHYSTINUS, in Entomology, is likewise the specific name of an insect of the Apis genus; it is nearly naked, black, wings violet. A native of the East Indies. Fabricius.

AMETHYSTINUS, a species of Carabus, that inhabits Cayenne; the wing-cafes and abdomen are blue; the head and thorax shining, bronze.—The antennae are hairy, serrulated at the base; wing-cafes streaked. Fabricius.

AMETHYSTINUS, in Ornithology, a species of Trochilus, or humming bird, found in Cayenne; its colours are chiefly green gold variegated beneath with grey and brown; throat amethystine blue; tail forked. Gmelin. Size of the red-throated humming-bird, T. Colubris. Linna.—Trochilus amethystinus is le petit oiseau-ronche à queue fourche & l'améthylle, of Buffon, and amethystine humming-bird of Latham.

AMETZ, in Geography, a town of France, in the department of Meffel, and chief place of a canton in the district of Longwy, three leagues west-north-west of Thionville, and three south east of Longwy.

AMEVILLE, a town of Savoy, in the valley of Aosta, near the Doria, two miles west of Aosta.

AMEWYLL, a populous town of America, in Hunterstown county, New Jersey; containing 5201 inhabitants, of whom 283 are slaves.

ANGAILA, or Angailah, in the Materia Medica of the Ancient, a name given by Avicenna and others to a plant sometimes called acantha Aralicia, and Amicantha by the Greeks; the roots of which were called bunon, and much used in medicine by the Arabian physicians.

The angaila, called also facalin, or sathal, is described as a prickly herb, having roots like thefe of the cyrus, formed of several joints or roots. They were used in flomachic and cardiac compositions, and were chosen by their lightness and good smell.

AMGINSKAIA, in Geography, a town and fortress of Russia, situate on the river Amba, 100 miles south-east of Yakutsk.
AMHARA, a kingdom of Abyssinia, situated between the two rivers Bafilo and Gelten, occupying almost the central part of the country; and having Beg-mder to the north, to the west the Nile and the kingdom of Gujam, to the south Walaka, and to the eastward Angot, about N. lat. 11° and E. long. 59°. The length from east to west is about 120 miles, and its breadth somewhat more than 40. It is a very mountainous country, full of nobility: the men are reckoned the handsomest as well as the bravest in Abyssinia. With the ordinary arms, the lance and the shield, they are thought to be superior to double the number of any other soldiers in the kingdom. The dignity of this province derives accession from the high mountains of Gelten, or the grally mountain, on which the king's sons were formerly imprisoned, till they were purified and murdered there in the Adelen war. Ludolf enumerates 36 provinces in this kingdom. The Amharic dialect was substituted for the ancient Ethiopic or Geez, in common use and conversation; after the restoration of the royal family from their long banishment in Shoá. This was denominated the king's or royal language, because it was introduced by the sovereigns of the country, when they were called to the government from their exile in the rocks of Amhara, and extended in the court and camp over the whole kingdom. With the function of this origin and authority it obtained an ascendency over all other dialects, and even over the ancient Ethiopic language itself. It differs from the Ethiopic both in construction and grammar; and seven new characters were added to answer the pronunciation of this new language, which is very difficult both to be written and learned. But no book was ever yet written in any other language but the Geez. Although the Amharic dialect be the court language, the Ethiopic retains its original dignity, not only in their books, but in their worship, and also in the king's letters patent, and commissions which are dispached in his council. Mr. Bruce says, there is an old law in the country, handed down by tradition only, that if any one should attempt to translate the holy Scripture into Amharic, or any other language, he should have his throat cut after the manner in which they kill kine, his family should be sent into slavery, and his house razed to the ground: and the act of this law was a great obstacle to his obtaining those translations of the Song of Solomon, which he proposed as specimens of the different languages of those distinct nations. The dialects of the neighbouring kingdoms, though they differ from one another, approach the nearest to the Amharic.

Ludolf has written a short essay towards a dictionary and grammar of the Amharic. See Ludolf's Hill. Æthiop. p. 78. and Bruce's Travels, vol. i. p. 425.

AMHERST, one of the Magdalen isles in the gulf of St. Lawrence.

Amherst, a county of Virginia in North America, lies between the blue ridge and the tide waters, on the north of James river, and contains 13,703 inhabitants, including 536 slaves.

Amherst, a township in Cumberland county, Nova Scotia, situate on Chignécat bason, on the south side of La Planche river, and on the rivers Napan and Macou. The town was settled by North Irish, Yorkshire, and New England people.

Amherst, the shire town of Hillborough county in New Hampshire, is a town of some note, formerly Souhegan West, and was originally granted from Massachusetts. It has 2,906 inhabitants, and was incorporated in 1762. The Aurean academy was founded here in 1790. This township was formerly much infested by wolves, but they were driven away with dismal howlings by incessant firing of guns and beating of drums for a whole day, and they have never since done any mischief in the town. Amherst lies on a northern branch of Souhegan river, which falls into Merrimack river, and is 600 miles west of Portland, and 53 north-west of Boston. N. lat. 42° 54'. W. long. 71° 37'.

AMHURST, Nicholas, in Biographia, an English poet and political writer of the eighteenth century, was born at Marden in Kent, received his grammatical education at Merchant Taylors' School, and removed to St. John's college, Oxford, whence he was expelled for misconduct. He attributes his expulsion to the liberality of his sentiments, and his attachment to the principles of the revolution and of the Hanoverian succession. Hence he took occasion to satirize the learning and discipline of the university of Oxford, and to expose the character of some of its most respectable members, in a poem, entitled "Oculus Britanniae," and published in 1724, and in his "Tertius Filius," a work blending satire and lewdness with a considerable portion of wit. It had been an ancient custom in the university, at public acts, for a person under the denomination of "tertius filius," to mount the rostrum, and divert a crowd of spectators with a merryonation in the Fescennino manner, interspersed with secret history, raillery, and sarcasm, as the circumstances of the time supplied matter; and on this custom the title of this latter work was founded. It was originally written in 1721, came out twice a week in periodical papers, and contained fifty numbers. When Mr. Amherst quitted Oxford he settled in London as a writer by profession. He first published a volume of Miscellanies on a variety of subjects, both sacred and profane. He afterwards published a poem, entitled, "The Con- vocation," in five cantos, which is a kind of satire against all the writers who had opposed Bishop Hoadly, in the famous Dangerous controversy. He also translated Mr. Addison's Resurrection, and some other of his Latin poems. But his principal literary undertaking was the political paper called "The Craftman," which was written against Sir Robert Walpole's ministry, and was carried on for a number of years with great spirit and success. In the execution of this work, and in the effect which it produced, he was assisted by Lord Bolingbroke and Mr. Pitteney, and probably by other leaders of the opposition. In 1737 there appeared in this publication an ironical letter, ridiculing the fact that had just passed for licentious plays, in conformance of which Mr. Amherst was arrested and confined, but the prosecution was dropped. He was at length totally defeated by his party, when they made their terms with the crown: and his death happened soon after, viz. in April, 1742. We shall close this article with Mr. Ralph's reflection on the subject. "Poor Amherst! after having been the leader of his party for the best part of twenty years together, was as much forgotten in the famous compromise of 1742 as if he had never been born! And when he died what is called a broken heart, which happened a few months afterwards, became indebted to the charity of a bookseller for a grave, not to be traced now, because then no otherwise to be distinguished than by the frequency of the turf, borrowed from the next common to cover it." This anecdote furnishes an instructive lesson to men of literary talents, and teaches them to form, as the basis of their prospects of reputation and happiness, a character for integrity, differentiation, and virtue. Biog. Brit.

AMÁ, in Ichthyology, a species of salmon, briefly characterized by Linnaeus, as having the lat ray of the dorsal fin longer than the tail, "pinne dorfa heiiopolioris radio ultimo longiore." Linna. — Country unknown.

AMIABLE, a species of Ameiotic, in Arithmetic, denote pairs of numbers which are mutually equal to the whole sum of each others aliquot parts. Such are the numbers 284, 220, the aliquot parts of which, with their sums, are as follows, viz.
Of 220, 1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110,—
their sum is 284.

Of 284, 1, 2, 4, 7, 14, 28, 56, and their sum is 220.

The second pair of amicable numbers are 17, 56, and 18, 16, which have the same property.

The third pair of such numbers are 93, 175, and 43, 75, 95. Schlooten, § 9, of his "Exercitationes Mathematica," found out these three pairs, and called them amicable numbers; though the properties of such numbers had been before treated of by Rudepuss, Des Cartes, and others. Schlooten, after Des Cartes, gives the following rule for investigating these numbers. Assume the number 2 of some power of 2; such that if 1 be subtracted from each of these three following quantities, 4r, 8 times the assumed number, 6 times the said number, and 18 times the square of the same number, the three remainders may all be prime numbers; then the half prime number being multiplied by double the assumed number, the product will be one of the amicable numbers sought, and the sum of the aliquot parts will be the other. Thus, let \( a = 2 \), and \( n \) be some integer number, such that \( 3^a - 1 \) and \( 6^a - 1 \) and \( 18^a - 1 \) be all 3 prime numbers; then will \( 18^a - 1 \times 3^a \) be one of the amicable numbers; and the sum of its aliquot parts is the other.

AMIANTHINITE of Kirwan, in Mineralogy. See Strehlstein.

The colour of amianthus is generally greenish or silvery white, approaching to mountain green, more rarely yellowish white, olive, or leek green, ochre yellow, or pale flesh red.

It occurs usually amorphous, but sometimes in small separate bundles. Its lustre varies from glittering to slightly shining, and is either weak-pearly or silky.

Its fracture is fine, and for the most part also flint, and even fibrous, rarely curved. It flies, when broken, into long splintered fragments.

It is found usually slightly transparent, but often opaque. It is soft enough to be scratched by the nail, and is considerably elastic. It has a soft, somewhat greasy feel.

The specific gravity of amianthus, according to Mufchenbroek, is 2.444. According to Brillin, before it has absorbed water, it varies from 0.9086 to 2.3134; after absorption it is from 1.5662 to 2.3803.

This mineral is principally met with in pot-tome and serpentine rocks, either diffused through them as a constituent part, or accumulated in their clefs and crevices unmixed with any other substance. The Tarentaise, in Savoy, furnishes the purest and most beautiful. It is also met with in Corsica, the Isle of Elba, and Crete; near Zobitz in Saxony, Salberg, and Swartwick in Sweden; in Cornwall, and the Isle of Anglesea in England, and at Portsay in Scotland.

A filament of the Tarentaise amianthus, when exposed to the flame of the blow-pipes, melts into an opaque globule, which becomes dark-coloured by the continued action of the flame. It diffuses quietly in borax and microcosmic salt, and effervesces with carbonated soda. If exposed in an earthen crucible to a high heat it melts into a dense scoria, firmly adherent to the bottom of the vessel, of a yellowish white colour, but almost white where it is in contact with the crucible, which last is in some degree penetrated and corroded. The surface of this scoria is overpread with crystalline needles crossing each other in all directions, or radiating from a common centre; similar angular crystals are diffused through the substance of the mass. These needles are a little thicker than a hair, and when viewed by a magnifier, appear perfectly transparent, of a quadrangular, prismatic figure, whose angles and faces are remarkably brilliant and well defined; whereas, the filaments of the amianthus, in its natural state, are much too fine to allow of their form being determined even by a very powerful lens. This scoria, on exposure to a greater heat, changes into a green glass, incapable of crystallizing, and which, in a short time, pales through the crucible. A specimen of greyish white amianthus afforded Mr. Kirwan, at 162 30.5 Wedgewood, a greenish black, perfectly compact glass. A specimen of amianthus from Greenland, according to Klaphroth's experiments, being included in a charcoal crucible, and exposed to the full heat of a porcelain furnace, fused into a scoria of a dirty pearl grey, covered externally with small grains of iron; its fracture showed a dull, finely porous texture, inlaid with separate, glossy particles.

The action of the mineral acids on amianthus is very feeble; the nitric and sulphuric take up no more than three or four per cent.; the nitro-muriatic, in the proportion of ten parts to one of the fonn, dissolves about 12 per cent. satisfactorily of lime, magnesia, and a little barytes.

Carbonated potash, even afluxed by ignition, is equally indifferent with the acids in decomposing this substance. The Tarentaise amianthus, mixed with four parts of pure salt of tartar, and ignited for two hours, only afforded 12 per cent. of matter soluble in sulphuric acid.

The real solvent of this refractory mineral is caustic potash, as appears from Bergman, who, by mixing equal parts of amianthus, carbonated potash, and charcoal, and igniting them for two hours, obtained a mass perfectly soluble in nitro-muriatic acid. This eminent chemic was not, indeed, aware that the addition of charcoal rendered his alkaline caustic, the reason of his using charcoal being to decompose the fulminate of barytes, to which he attributes the extraordinary refracto-

The Tarentaise amianthus, according to Bergman, is composed of

It is rather singular that sulphated barytes should have been found in the Tarentaise amianthus, as this earthy salt does not once occur among the analyses of the Swedish or Austrian
Anbrian specimens, or among those of albites, flectite, and other minerals that have the nearest analogy to the amiantus; it is therefore greatly to be wished that some able enquirer, in possession of the modern improved means of analysis, would undertake the examination of this mineral.

Amiantus is often confounded with the more flexible kinds of Asbestos, to which it bears a near resemblance in external characters and chemical composition. Its fibres are, however, for the most part, more distinct and flexible than those of albites; it is more fusible per se, and is considerably less acted upon by acids.

The fibrous texture of amiantus, its incombustibility, and the little alteration that it undergoes even in a strong heat, were early noticed, especially among the eastern nations; and methods were found out of drawing the fibres into thread, and afterwards weaving it into cloth; this, when dried with grace or other inflammable matter, was burned by throwing it into a bright fire; the flames were burnt out, and the cloth was then removed, but little altered in its properties, and of a dazzling white; hence it obtained from the Greeks the name of Amphion, (undeciled.) In the rich and luxurious times of the Roman empire, this incombustible cloth was purchased at an enormous price, for the purpose of wrapping up the bodies of the dead previously to their being laid on the funeral pile, that the ashes of the corpse might not be scattered and mixed with those of the wood. This practice was indeed probably confined to a few of the richest families, but of its reality there can be no doubt, especially since a funeral urn was discovered in 1792 at Rome, near the Porta Neva, in which there was a ferris and other calcined bones, together with a quantity of ashes inclosed in a cloth of amiantus nine Roman Pains long, and about seven palms wide. This interesting relic of antiquity was deposited, by order of pope Clement XI. in the Vatican library.

The difficulty of burning the dead occasioned the manufacture of amiantus cloth to be neglected, and at length entirely forgotten in Europe; but though it has ceased to be an article of necessity or luxury, yet the method of its preparation has occasionally attracted the notice of travellers, and occupied the time of the curious. Marco Polo affirms, that in the east the mineral is generally bruised in a mortar to separate the fibres, and, being washed till the water comes off clear, is dried and then manufactured as flax or wool. Cambia, of Rome, in 1601, and then Mahudel, after many trials, published the following as the best way of preparing the incombustible cloth. Having previously steeped the amiantus in warm water, divide its fibres by gently rubbing them with the fingers, as to loosen and separate all the extraneous matters, then pour on repeatedly very hot water, as long as it continues to be in the leaf discoloured. Nothing will now be left but the long fibres, which are to be carefully dried in the sun. The bundles of threads are to be carded by very fine cards, and the long filaments thus obtained are to be steeped in oil to render them more flexible. A small quantity of cotton or wool is to be mixed, and by means of a thin pin the whole is to be drawn into thread, taking care that the amiantus may in every part be the principal material. The cloth being then woven in the usual manner, is to be placed in a clear charcoal fire to burn off the cotton and oil, when the whole remaining tissus will be pure white amiantus. The shorter fibres that are incapable of being woven have been sometimes made into paper; the Proceeds of which is the same as that employed for common paper, except that a greater proportion of pate or size is required: after having been once made red hot, however, the paper becomes bibulous and brittle. For written documents of great importance, it might be worth while to be at extraordinary expense for incombiustible paper and indelible ink; the former of these may be prepared from the longer fibres of amiantus, so as to be much less brittle than when the shorter ones are alone made use of; and for the ink the following receipt will be perfectly efficacious. Take one part of sulphur of iron (green vitriol) and two parts of alum, dissolve them together in warm water, and then add peradist as long as any precipitate takes place; boil the mixture, and filter it on a filter, allow the precipitate to drain after being washed with warm water, and, while yet soft, dissolve it in distilled vinegar; use this moderately concentrated for ink, and the characters, after combustion, will be of a yellowish brown colour, and sufficiently legible.

AMATUS, in Enomology, a Species of Hysteria. Wings entire, black, posterior margin yellow; head and tail red. Inhabits America. The antennae hooked, black: wings uniformly black, except the yellow margin, body black, head and tail red. Fabricius.

AMAZON, in Geography, lies on the coast of Brazil, in which the city of Santos is situated, and hence it is called the gulf or bay of Santos. St. Vincent's is in another part of the same island, and before there was good anchoring.

AMICABLE, benevolent, amicabilis, in Antiquity, are generally supposed to denote the feasts in the Roman courts, wherein the advocates were placed. Some think that these have but little title to the denomination of amicable, and therefore will have the word to be here used for the benches whereon the advocate, or those called justes paegettis, were placed.

AMICABLE compounder, amicabilis compositor, is used by some ancient law-writers for an arbitrator.

AMICABLE, or amicabile compander, among the French, is a person who acts the part of a common friend, to reconcile two merchants or traders who have disputes, or are at law together. He differs from the arbiter, in that, in order to make the two disputants agree, he often prevails upon both to give up some part of their right or claim, which an arbiter, who performs the functions of a judge, is not, it seems, at liberty to do.

AMICABLE Numbers. See AMIAL.

AMICABLE society. See Assurance.

AMICELA. See Alumium.

AMICITIA—Tunor in Amicitia, is applied in Aric Writers to land granted freely, and of mere good will, to be enjoyed at the discretion of the donor.

AMICILE, or Ad Laxtulas, now Portella, in Ancient Geography, a town of Italy between Terracina and Forcett.

AMICONI, Jacques, in Biography, a painter of history and grotesque, is supposed to have been born in the territory belonging to the republic of Venice, to have studied the art of painting for some years at Venice, and to have completed himself in his profession at Rome. The liveliness of his imagination,
imagining, the red Hen of his invention, and the freedom of
his hand, soon recommended him to the public esteem,
and he found encouragement and employment in most of the
courts of Europe. He is said to have polished many of the
accomplishments of a good painter; but though his merit in
many respects must be allowed, and his drawing is generally
correct, yet his colouring is much too cold, too pale, and,
as it is termed by the artists, too mealy. His compositions
are well known in this kingdom, and many of his pictures
are admitted into the collections of the first nobility; but
nevertheless few particulars of his life have been ascertained.

Pilkinson.

AMICTUS, in our Ancient Writers, the uppermost of
the fix garments, worn by priests; the others are alba, cing-
gulum, palla, amphinem, and planum. It was tied round
the neck, Ne inde ad lingam transita manducit; and covered
the breast and heart, Ne manuosa coeptis.

This garment is otherwise called ambulatio; sometimes
ambulatio, amalgamation, and humerole. In ancient English
writers it is called amict.

The amict is also worn by deacons, sub-deacons, and accli-
batini, when they officiate at the altar.

The priests and deacons, in some dioceses, wear amicts
on their heads from All-saints to Easter; though, by the
canons, they be expressly forbid to wear the amict without
some considerable occasion.

Mr. Thiers affirms, that the use of amicts was intro-
duced into the Latin church before the twelfth century.
Dom. de Vert maintains the contrary, chiefly from a figure
of St. Firmin, first bishop of Amiens, supposed to have
suffered martyrdom towards the beginning of the seventh
century, wherein he is represented in his pontifical habit,
with the amict on his head.

AMICTUS, in Roman Antiquity, denotes any upper gar-
mant worn over the tunica.

AMICUS, in Geography, a lake in the province of Cu-
mana, South America, whose waters run south-erly through
Parima river, into the Amazon.

AMICULATUS, in Conchology, a species of Chiton,
that inhabits the Kurile islands. Shells of eight valves, kid-
ney shaped, and very brittle. External covering a fea-
brown coriaceous membrane.—Length fix inches. Gmelin.

AMICULUM, in Antiquity, denoted an upper garment
worn by the women. The amiculum is said to have differed
from the palla; but wherein the specific difference lay does
not appear. An amiculum was also in use among the men.
This seems to have been the same with the ab寒us, or pa-
ulamentum.

AMICUS, or AMICONESOS, in Ancient Geography, an
island of the Red Sea, according to Ptolemy. Amicus was
the epiphon of Hercules among the ancients, and hence it
is said was derived the name of this island. This is prob-
ably the same with the Amicena of Steph. Byz.

AMICUS CURIS, in Laws. If a judge is doubtful, or
mislaken in matter of law, a lie-the-about may inform the
court, as amicus curiae. 2 Co. Inst. 178. Any one as amicus
curiae may move to quash a vicious indictment; for if there
were a trial and verdict, judgment must be arrested. Com-
berb. 13.

AMID AMID, in Geography, a ridge of mountains in
Abyssinia, lying behind the two ridges of Litchambara and
Afromada, commence behind Semien, in the south-west
part of the province of Maitha, and become high only from
the mountain of Adam; resembling in their shape the
former ridges, and embracing them in a large curve, like a
crescent. Between Amid Amid and the ridge of Litcham-
bara is the deep valley known by the name of St. George,
Romans, on condition of their paying to the king of Persia 50 talents. Upon the decline of the Roman empire, it reverted to the Persians; from them it was transferred to the Sraezens; and it is now possessed by the Turks. Amida assumes in modern times the provincial appellation of Diarbekr, and is also called by the Turks Kara-amdeh; the epithet kara being derived from the blackness of the rock which comprises the town and ancient wall of Amida.

AMIDA, in Mythology, a god worshipped by the Japanese, who has many temples erected to him in the island of Japan, of which the principal is at Jeddo. They suppose that he flourished many thousand years ago, and that after a life of voluntary mortification and austerity, and of signal miracles and exemplary virtue, extended to 4000 or 2000 years, he passed by a voluntary death to another estate, where he was advanced to the dignity of a god. The Japanese have such a confidence in their idol Amida, that they hope to attain eternal felicity by the frequent invocation of his name. One of the figures of this idol is represented at Rome.

Cano, the son of Amida, is likewise held in great veneration, and has a flatly temple near the city of Meaco, in which are 1000 images or statues of him, beautifully carved and regularly arranged.

AMID-SHIPS, a nautical term, denoting the middle of a ship, either with regard to her length or breadth.

AMIENS, in Geography, a city of France, and capital of the department of the Somme; before the revolution it was the capital of Picardy, and the seat of a bishop, the suffragan of the archbishop of Rheims. It is situated in a plain, on the river Somme, which passes through it in three distinct channels, that afterwards unite; and may be seen at a great distance, decorated with a number of lofty towers, among which the cathedral commands peculiar notice. This is an elegant Gothic edifice, beautifully proportioned and delicately wrought; and the nave is particularly admired. It has many other collegiate, parochial, and public buildings, and an academy of arts and sciences founded in 1750. It is defended by a citadel and ramparts, on which are planted trees, which form a pleasant walk. The river Somme is navigable to the town. The houses are well built in the old taste; and the number of inhabitants has been reckoned between 40 and 50,000. Tinfau (Statistical view of France,) estimates them at 40,289. Its 4 cantons contain 45,157; its whole territory includes 100 kilometres and 12 communes. The commerce of Amiens has been very considerable, particularly in woollen stuffs, camlets, and hags. It has also been famous for its soap-manufacture.

Amiens, in Latin Ambiani and Samarobriva, is a place of great antiquity. It appears from Caesar's account in his Commentaries to have been one of the principal cities of Gaul; he held a general assembly of the Gauls in it, and committed it to the guard of a legion. Cicero refers to it in several parts of his epistles as a place of note; and Ambianus Marcellinus (lib. xv. c. 27.) mentions it as "a city eminent among others." It was enlarged by the emperors Antoninus and Marcus Aurelius; and it was the place in which Contantine, Constant, Julian, and other emperors frequently resided. The cardinal of Amiens, comprehend- ing a great part of the territory of the Ambiani, and since called Picardy, was formerly conferred by the kings on the bishops of this city. Philip Augustus, in 1193, annexed it to the crown. The states of France were summoned at Amiens by Lewis XI. in 1264, on the appeal made to him by Henry III. and the barons of England; and the appeal was decided in favour of Henry. Charles VII. granted it to Philip the Good, duke of Burgundy, in 1435; and Lewis XI. reunited it to the crown in 1477. Amiens was taken by the Spaniards in 1507, by the following stratagem. Soldiers, disguised like peasants, conducted a cart, loaded with nuts, and let a bag of them fall just as the gates were opened. Whilst the men in garrison were busily employed in gathering up the nuts, the Spaniards entered in a body, and made themselves masters of the city. Henry IV. however, retook it in the same year. Amiens is distinguished as the native place of Voiture, Roland, Du Caugy, and Guicci. It has lately, viz. in 1802, acquired celebrity by the negociation, which terminated the war between England and France, and other belligerent powers, and by the signature of the definitive treaty, by the plenipotentiaries of the four contracting parties, Spain, Holland, France, and Great Britain, on the 27th of March, which established peace. Amiens is situated in N. lat. 49° 53' 20", and E. long. 2° 17' 56".

AMISTDES, in Commerce, cotton cloths which come from the East-Indies.

AMIGONI, Octavio, in Biography, a painter of history and portrait, was born at Brescia, in 1655, and was a disciple of Antonio Gandino. His expression, and taste of design, were very remarkable and very elegant; and his compositions, executed with a free, firm, and masterly touch, and with figures as large as life, were much applauded in several parts of Italy. Pilkington.

AMILICHUS, in Ancient Geography, a river of Greece, in Achaia, situating to the north-west.

AMILICITI, in the Chaldaic Theology, denote a kind of intellectual powers, or persons in the divine hierarchy. The amilici are represented as three in number, and constitute one of the triads, in the third order of the hierarchy.

AMIL, in Ancient Geography, a river of Mauritania, mentioned by Pline.

AMILOS, or Amilus, a town of Arcadia, to the north-west of Orchomone.

AMILPAS, in Geography, two volcanoes in the province of Guatimala, in New Spain, near the mountains of Soconusco.

AMINE, in Ancient Geography, a people of the Falklay, who, according to Arilitote, transported their vines into Italy, whence the expression amina vitis.

amina, in Geography, a small town of Africa, in Bar- bary, situating on the eastern side of the kingdom of Tripoli.

AMINUS, in Ancient Geography, a river in the southern part of Arcadia, which runs from north-east to south-east into the Helifius.

AMINARTE, a great officer in Spain, answering to the lord high-admiral in England.

AMINARTE, or Cassibaco Bay, in Geography, a large bay on the north coast of the illusius of Darien, and near the limits of North and South America. It is in the province of Veragua, on the north-west of the Toro channel and bay of Concepcion, from which it is separated only by a congeries of rocks, which lie in the ocean, near the coast. N. lat. 6° 5'. W. long. 82° 30'.

AMINARTE ISLANDS. See Almirante.

AMISENUS SINUS, gulf of Amisenus, in Ancient Geography, a gulf or bay of the Euxine sea, situating to the east of the mouth of the Halys, on the coast of the kingdom of Pontus; so called from the town of Amisus.

AMISA. See Ems.

AMISS Drawing. See Drawing.

AMISSA Lex. See Lex.

AMISSEN or MISSEREN, in Geography, a point on the gold coast of Africa, east of Carintane, between it and Dajou or Tagu, near the rough point. N. lat. 5° E. long. 1° 15'.

AMISTOWES, a town of Bohemia, in the circle of Konigingratz, 10 miles west-south-west of Bicezow.

AMISUS,
AMISUS, in Ancient Geography, a considerable city of Asia Minor, in the kingdom of Pontus, was situated on the coast of the Euxine sea, near the mouth of the Halys and Iris, founded by the Milesians, and peopled also by a colony of Athenians. It was at first a free city, like the other Greek cities in Asia, but afterwards subdued by Pharnaces, king of Pontus, and made the metropolis of his kingdom. Pliny says, that it maintained its republican and popular form, till it was conquered by the Persians; but Alexander restored its liberty, of which it was deprived by the king of Pontus. It was in extent the largest city of the kingdom, except Sibyris. Mithridates had a palace in this city, and it was adorned with temples and many magnificent buildings, when Lucullus took it. Its inhabitants were massacred by Pharnaces, the son of Mithridates; but it was re-taken by Caesar, and made a free city.

AMITERNUM, a town of Italy, north-east of Rome, in the country of the Sabines, situate, according to Strabo, on the declivity of a mountain, and having, in its time, the remains of a theatre and a temple. It was taken by Sp. Carvilius, in the year of Rome 460, and subdued to the time of the conquest between the Guelphs and Ghibellines, when it sunk under the town of Aquila, newly erected by the emperor. It was famous as the native place of the historian Sallust. Some remains of it are still discernible near S. Vittorino and the springs of the Arenus.

AMITHOSCUTA, a country of Arabia Felix, according to Pliny.

AMITENES, a people of Etruria, according to Pliny.

AMITTERE legem terrae, a law-phrase, signifying the forfeiture of the right of swearing in any court or cause; or the becoming infamous.

This is the punishment of a champion overcome, or yielding in the combat: of jurors found guilty in a writ of attainder, and of perjuries outlawed. Vide Glanv. lib. ii. and see the flat. 5 Eliz. cap. 9. against perjury.

AMIXOCORES, in Geography, a people of America, in Brazil, near the country of Rio-Janeiro.

AM-KAH, in History, a name given to a spacious palace in the palace of the great Mogul, where he gives audience to his subjechts; and where he appears on solemn festivals with extraordinary magnificence. His throne is supported by six large steps of mellow gold. It is vast with rubies, emeralds, and diamonds; and is estiuated to 660,000l.:

AM-LAK, in Geography, one of the Fox islands, at the distance of about 15 miles from ATCHAK, and nearly of the same size. It has a harbour on its south side. It lies in about N. lat. 52° 30'. W. long. 173° 30'.

AMALGODE, or AMALGODE, a river on the south-west coast of the island of Ceylon, between Barberin island on the north-west, and Regama point on the south-east, about eleven leagues distant. It is not navigable; it is known by a garden of cocoa trees.

AMLET. See OMELET.

AMLING, CARL GUSTAV AB, in Biography, a painter and engraver, was born at Nuremberg, in 1651, and learned the art of engraving from Francis de Poilly, whose style he imitated but never equaled. He chiefly excelled in portraits, and failed in historical subjécts. He was engraver to the duke of Bavaria, and died in 1702. Among his portraits are “ Maximilian Emanuel,” elector of Bavaria, a large upright plate, esteemed as one of his best; and among his historical subjécts are “the history of the emperor Otho,” from the tapestries at Munich, in 13 plates, and “the Four Seasons,” from the same tapestries. Strutt.

AMLWCH, in Geography, a small village in the island of Anglesea, adjoining to the mines of the Paris mountain, and raised into eminence by the works and wealth which they occasion. The two great proprietors of these mines, Lord Uxbridge and Mr. Hughes, have adorned this village with two elegant houses for their occasional residence, one called the Moon, and the other the Paris Lodge. The little port of Amlwch is placed in a small cove, among the cliffs, about half a mile below the village, and is admirably formed for receiving and arranging the several vessels which are employed in the copper and brass trade. It often also affords a safe haven to those ships, which, in their passage from Ireland, are driven to the north-east, round the point of Holyhead, and cannot make that harbour.

AMMA, in Ancient Geography, Lemna, a river of Switzerland, which runs into the Aar, near Soleure.

AMMA, a town of Asia, in the tribe of Ater; called, by Jerom, Amma.

AMMA, in Middle Age Writers, denotes a spiritual mother. In this sense, the word was chiefly understood of an abbe, or superior of a monastery.

AMMA, or HAMMA, from oura, urinatum, in Surgery, a technical term, denoting the bandage employed to牢固 Ruptures of Hernia. This important instrument will be more properly described under the article Hernia, which it

AMMAEA, in Ancient Geography, a town of Melopota-ecia, near the Euphrates, towards the Persian gulf, according to Ptolemy.

AMMADARA, a town of Africa Propria, in that part called by Ptolemy Numidia Nova.

AMMAENSIA JUGA, a name given by Pliny to the mountains of Lusitania.

AMMATTIA, a town of Asia, in Asyria.

AMMAN, or AMMA, a town of Asia, in Arabia; it was the principal town of the Ammonites, and called also Rabbath.

AMMAN, in the German and Belgie Policy, denotes a judge who has the cognizance of civil causes.

The word is also written amant. Thus it occurs in writers on the French officers, where it stands for a notary, or parochial officer, who draws acts or instruments.

AMMAN, JOHN CONRAD, in Biography, was born at Schaff- hausen, in Switzerland, graduated at Basel in 1681, and practised physic at Amsterdam, towards the close of the 17th and beginning of the 18th centuries. He applied himself with particular attention to the discovery of a method of teaching persons born deaf and dumb to speak; and from observing the motions of the lips and mouths of persons addressing them, to understand their meaning. In this art he attained great perfection, and many persons born with those defects, were restored to society, through his skill and perseverance. In the year 1692, he published an account of the proceeds by which he was effected, in Dutch, under the title of “Surdes Loquens;” and in 1702, in Latin, adding to the title, “De Differtatio de Loquela;” Opus, Haller says, vere aureum; no material addition having been made to his directions, which are now every where practised, by persons professing that art. The work has always been held in high estimation, has been translated into most of the European languages, and passed through numerous editions. Haller Bibl. Med. Prat. et Chirurg.

AMMAN, JOHN, son of Conrad, also doctor in medicine, settled in Peterburgh, where he gave lectures in botany. He published “Icones et descriptiones florium rariorum Rheniacarum,” Petropolii, 1739, 4to.
The figures were principally taken from a collection of dried specimens of plants, preferred at the Imperial academy, Petersburg. Eloy Dictionaire Hiltor. de la Med.

AMMAN, PAUL, was born at Briavay, August 1634. After finishing his school education, he travelled for improvement over various parts of Germany, Holland, and England. In October 1662, he was admitted doctor in medicine at Leipsic, and in succession, professor of medicine, botany and phytoogy in the same university, in which offices he acquired considerable reputation. He died, February 4th, 1761.

Hallier gives a long list of publications by himself, but his principal works are, "Ammanni parenese ad doocentes occupata," 1673, 12mo; "Praxis vulgarum Illethum sex decusibus Histiorum rararium, Franco," 1701, 8vo. For the titles of his other works, see Haller's Bib. Med. Prat.

AMMAN, or AMMON, JEST or ONONUS, a designer and engraver, was born at Zurich, in Switzerland, A.D. 1539, resided at Nuremberg, and died there in 1591. He was an indefatigable artist, and produced considerable merit as an engraver. The number of his designs and plates is very great. His engravings were chiefly on wood, and are much superior to those on copper. Although he does not manifest much invention, his figures are well proportioned; and his animals are touched with great spirit. His manner of engraving is said to have been neat and decided. Among his performances we may select his "Dea Fortuna," ornum liberum mechanicarim et fedentarum attim genus continens, &c." Franco, 1564, amounting to 115 prints, and exhibiting the different artists and tradesmen in their respective employments. He also engraved in wood some detached pieces, and on copper "The Illustrious Women," beginning with Eve; a set of "Figures of Warriors," 1590; "The Four Seafons and the Four Elements," 1599. Strutt.

AMMAN JOHN, an artist and book-keller, lived at Hanau, in Germany, about the year 1640. A set of small wooden cuts, representing "the Passion of our blessed Saviour," executed very much in the style of the former artist, and published at Amsterdam, with Latin versés, in 1623, is reckoned to possess a considerable share of merit. Strutt.

AMMANATI, Bartholomeo, a celebrated sculptor and architect, was born at Florence, in 1511, and studied sculpture in his native town under Bandinelli, and at Venice under Sansovino. He designed the porticoes of the Piti palace, and the bridge Della Trinita, at Florence, which is accounted one of the most beautiful works, since the revival of the arts. At Rome he built the palace Ruipoli, and the noble front of the Roman college. On his return to Florence he expended his wealth in building the church of San Giovannino, belonging to the Jefuits, in which he was interred. Ammanati's large work "La Citta," comprehends the designs of all the public buildings necessary in a capital city. He died either in 1580 or 1592. His wife, Laura Battiferi, was distinguished for her poetical productions, of which a collection was printed at Florence, in 1580. Now, Diet. Hist.

AMMANNIA, named by Houtou in honour of J. Amman, in Botany, a genus of the tetraneura monogynia clads and order, of the natural order of calyxactere and foliariz of Jullien; its characters are, that the calyx is a pteranthum bell-shaped, oblong, erect, with eight streaks and folds, quadrangular, eight-toothed, teeth alternate bent in, and permanent; corolla none, or four-petalled, petals vertically ovate, spreading, inserted into the calyx; the filament have filaments, (four or eight) brilly, the length of the calyx into which they are inserted, anthers twin; the pellium is a germ subovate, large and superior, style simple, very short, and stigma headed; the pericarpium is a munth, four-celled capsule (berry) covered with the calyx; the seeds are numerous and small. There are seven species, viz. 1. A latifolia, tharistia of Brown. Jamaica, sharparies of Southe Jamaica. 2. A. purpurascens, a broad-leaved A. "with calves half-clasping, square flare, and erect branches." This species pursue lines in the botanic gardens in Europe. 2. A. tenuis, long-clasping. The species are annual, and grow naturally in Virginia and Carolina; rable at a foot high, with red fuscous flanks, putting out side branches, opposite, round, and ample, the flowers are produced from the axils on the lower part of the branches, and toward the top in clusters, they have little beauty; cultivated in 1571, and preferred for variety. 3. A. bacaefera. A. verticillata of La Marek, cornelica verticillata of And. Spec. "with leaves sub-petiole, capsules larger than the calyx and coloured," it has four-toothed calyces. This native of China, and naturalized in Italy. It has little beauty, and is rarely preferred in gardens. 4. A. olifandra, eight-flamed A. "with sepals linear-lanceolate leaves, and flowers petal-bearing, and eight-flamed;" the petals are blood red; found in Koenig in the East Indies. 5. A. pinnatifida, pinnatifid-leaved A. "with petals procumbent, rooting, compressed, and leaves linear, pinnatifid." The flowers are small, corolla red, and capsules four-cornered; found by Sonnerat in the isle of Java. 6. A. decus, clustered-flower A. "with leaves lanceolate, attenuated at the base, leaf branching, flowers in bundles from the axils, and capsules two-celled." This species is annual, the calyx angular, petals pale-purple, filaments shorter than the calyx, anthers ovate and yellow, capsule ovate and two celled; a native of the East Indies; introduced in 1778 by Sir Joseph Banks; and flowers in July and August. 7. A. fangulina, "with leaves, half-clasping, cordate at the base, flowers sub-peduncled, eight-flamed, petal-bearing;" a native of Jamaica and Domingo.

Culture. The three first species must be raised from seeds on a hot-bed in spring, and afterwards removed to another hot-bed in order to bring them forward. When the plants have acquired strength they should be transplanted into pots filled with rich light earth, and placed under a frame, shading them till they have taken fresh root; they should then be placed in a glass case or flower, to ripen their seeds, for the plants are too tender to thrive in the open air in this country, unless the summer be very warm. The second foot, raised in a hot-bed, in the spring, and planted in a warm border, will perfect its seeds in the open air. The other species are flower-plants. Martyn's Miller.

AMMANN, in Geography, a town of Japan, in the province of Fida.

AMMATA, or AMMATHE, in Ancient Geography, a town of Atia, in Palestine, belonging to the tribe of Juda.

AMMER, in Geography, a powerful but infamous tribe of Arabs, who inhabit the province of Conimanza, in Africa, and who, contrary to the practice of their brethren, prostitute their wives and daughters. Shaw's Travels, p. 53.
AMMERCOT, a town of HIndooftan, situate in a sandy
defert, 138 miles north-east of Nifferpur, and 256 south of
Moulant. Fenulita reckons it about 100 cosses from Tatta.
In the Ayin Abaceer it is clas'd as belonging to the Nis-
ferpur division of the province of Sindy. N. lat. 25° 40'.
E. long. 70°.

AMMEREN, a town of Germany, in the circle of
Welfphalia, and duchy of Juliers, six miles eall-north-eall from
Ruremond.

AMMERSRI, a lake of Germany, in the circle of
Bavaria, 12 miles long, and from two to three broad, 85
miles west of Salzburg.

AMMESPACHT, a river of Germany, runs into the Erle-
bach, in the archduchy of Austria, on the borders of Stiria.

AMMI, formed from ami mus, in Botany, a genus of
the penantandagryne clafs and order; of the natural order of
umbellate or umbellifers; its characters are, that the calyx
has its universal umbel manifold, frequently of 50 rays,
the partial short and crowded, the universal involucres
of many linear, pinnatifid, acute leaflets, scarcely the length
of the umbel, the partial many-leaved, leaflets linear, acute,
fimple, shorter than its umbel, the proper perianthum
searclly apparent; the corolla universal uniform, with all
the flowers fertile, the prople of five index, heart-shaped
petals, of unequal fize in the ray, almost in the middle
of the disk; the stamens have capillary filaments. anthers
roundish: the gyniun has a germ inferior, styles reflex,
and stigmas obtuse: no papetiaum, fruit roundish, smooth,
small, frgeted, and bipartile: the seeds two, convex
and frgeted on one side, and flat on the other. Martyn reckons
three, and Gmelin four species. 1. A. major, common
bishop's weed, ammielatifon, "with lower leaves pinnate,
lanceolate and serrate, upper ones multiplid and linear." This
species is annual, and grows in vineyards, and fields, in the
southern parts of Europe, and in the East. There is a rel-
riety reckoned by Baubin a dilBfide species, under the
title of A. major taliiis plurimum incis, et nonulbil crisus;
but Mr. Martyn has raised this variety from the seeds of the
former. 2. A. cupicum, "with leaves papier-de-compound,
linear, and seeds nuicrurate." This is of the native of Dill,
green, stem smooth and frgeted; leaves tripinnate oblong,
smooth, and linear; umbels with ten rays; involucere five-
leaved; partial involucere seven-leaved; corollas white, equal
and five angled; fruit ovate and mucrurate on every side,
seeds frgeted with five sculptures, aromatic: found by For-
skahl in Egypt; annual, introduced in 1773 by John Earl
of Bute. 3. A. glaucofolium, dauceus petraeus glauceolus
of Baubin, perennal bishop's weed, "with the subdivisions
of all the leaves lanceolate." This has the appearance of a
variety of the frst species; is a native of the south of
France; described by Miller as a perennial plant, preferred
for variety, but having little beauty. 4. A. 1avrificum,
"with bipinnate leaves, the winged leaflets tried, the blt
connected in whisks with the common rib." La Marec has
referred to this genus, the dauceus vifjuga of Linnaeus,
and the ammi andehifolium, with oblong pinnate leaves,
the leaves multiplid and capillary, and the petioles camil-
ated; the dauce meoids of Hort. Reg. brought originally
from the Levant, and flowering in the beginning of
Autumn.

Cultwe. There is a fpecies is propagated by seeds fown in
Autumn in the place where they are to remain; in the
Spring the ground should be hoed and the plants thinned
as in the management of carrots, leaving them four or five
inches asunder, or in good ground at the distance of six
inches; after which they will require no further care, be-
ides being kept free from weeds. They will flower in
June, and the seeds will ripen in Augutt, and should be ga-
thered as they ripen, for they will soon shatter. The 3d
species will grow in any open situation, is very hearty,
and thrives bell in a mild soil. Martyn's Miller's Dict.

AMMI, or ammi annua rei, in the Materia Medica,
a kind of aromatic feed, the produce of the sion ammi of
Linneas, sometimes though lowly brought from the
Levant, and formerly used in medicine. The feed is small,
whence, according to Lemery, the name of the plant ammi,
from ammoris, small, birelled, of a greyish brown colour, somewhat
bitterish taste, and fragrant smell, approaching to that of
origanum. This seems to have been the ammi of Dioscorides
and Hippocrates. It is now very rarely prescribed. Thesefeed,
dilfled with water, yield a considerable quantity of a
yellowish effential oil, containing their whole smell and
flavour; the remaining decoction is pleasantly bitterish.
Spirit of wine carries off, in its evaporation, the odorous
principle of the ammi. These feeds have been recommended
as a Thomae, emmenagogue, diuretic, and an elegant
aromatic carminative.

AMMINUS MARCELLINUS, in Biography, a Roman
historian, a native of Antioch, where his family made some
figure, and in early life served several years in the army in quality of
protector domesticus, which was then an honourable post. In 350 he
accompanied Uricius, a general of the horde under the emperor
Constantius, into the East; and followed him in several expe-
ditions, from 350 to 379, in which he acquired military
reputation. He attended Julian in his Persian expedition in
367, and was, either at or near Antioch in 371, when the
co-;ipiracy of Theodorus was discovered in the reign of
Valens, and was a witness of the torments of many persons
whom Valens ordered to be put to death on that occasion.
It is not certain whether he obtained any higher rank in the
army than that of domestic protector. When he quitted the
army, he retired to Rome, and employed himself in writing
the history of the affairs of the empire, during a period of
three centuries. Though he was a Greek, he chose to write in
Latin: but his Latin, in the opinion of Vossius, indicates
that he was a Greek and a soldier. His history was divided
into 31 books, commenced with the reign of Nerva, where
Tacitus ends, and terminated with the reign of Valens.

The first 13 books, ending with the reign of Constauitus,
and containing a superfluous epitome of 2,577 years, are lost;
the last 18 books, now extant, begin with the 17th year
of Constauitus, A.D. 353, and conclude with the year 375;
tho5ome particulars of a later date are men-
tioned, from which we may infer, that the historian lived at
least to the year of Rome 1142, or A.D. 396. The style
of his history is reckoned harsh and verboce; but this de-
fect is amply compensated by the variety of information
which he communicates from his own personal knowledge,
and by the fidelity and impartiality of his relation. Mr.
Gibbon (Hist. vol. iv. p. 426.) represents him as "an
accurate and faithful guide, who has composed the history
of his own times, without indulging the prejudices and pas-
tions, which usually affect the mind of a contemporary."
Some have supposed that he was a Christian; but of this
there
there is no sufficient evidence. As he wrote under Christian emperors, he might not judge it proper to profess his religion unconditionally, and he might think it most prudent to be cautious in his reflections upon Christianity. Although he was a pagan, as is evident from the respect with which he speaks concerning the pagan divinities, and from his defence and recommendation of heathen auguries, and such methods of investigating futurities, he nevertheless manifests no animosity against the Christian religion; on the contrary, he bears honourable testimony to the plain and simple nature, and the equitable and gentle spirit of Christianity, to the moderation of some Christian bishops, whilst he condemns the severity with which some Christians treated one another, and to the firmness and fidelity of the Christian martyrs. Hence Molheim concluded that Marcellus and some other learned men about his time were neutrals; alleging, that they neither rejected the Christian religion, nor forsook the religion of their ancestors. But the influences already cited merely prove, that he was a faithful and candid historian. The remaining works of Ammianus Marcellus have passed through several editions; all of which have been superseded by that of Vulcius, printed in folio at Paris, in 1681. This edition was reprinted by Gronovius at Leyden, in 1693, with valuable notes. Valerii Prof. ad Amm. Marc. Fabric. Bibl. Lat. cap. xii. tom. ii. p. 98, &c. Lardner's Works, vol. viii. p. 464, &c.

AMMINIAEUS, in Botany, a name given by the old writers, to the grapes of a wild vine, common in the hedges of Italy, and some other places. They used to make wine of these grapes, which they mixed with other richer wines, and had in common use. Columella says, that this wine was first brought from the country of the Ammiens in Thessaly, and that the wine produced from its grapes was the first and most ancient known among the Romans. According to Macrobius, the Falernian wine was more anciently called Aminian. Some write the word tameina, instead of amminea.

AMMIRABEA or AMMIRASH, corruptly Marba, and Umarba, in Geography, a river of Africa, which has its spring on mount Magnar, one of the heads of the Atlas near the confines of Fez, which runs through the plains of Adachfon, where it has a beautiful bridge built by Abu'l Hascher, the fourth monarch of the Benimerins, and thence winding southwards and watering the spacious plains between Dukala and Temesfana, becomes wider in its approach to the ocean, into which it discharges itself, and forms a capacious bay, on the east side of Azamor. This river is fordable neither in Summer nor Winter, so that the inhabitants are forced to ferry their effects over it, by the help of barks, fastened to leathern pontoons, or over rafters. Its fish not only furnishes all that country; but is exported to Spain and Portugal.

AMMIRAGLIO, a small river of Sicily, anciently Orethus.

AMMIRALIS, in Entomology, a species of Cerambix found in Surinam. Thorax rather spinous; fourth joint of the antennae bearded, second spinous. Gmelin. General colour black; base of the wing cilia and sides of the thorax reddish.

AMMIRATO, Scipio, in Biography, an eminent historian of the 16th century, was born at Lecce in Naples, in 1531, and descended from a considerable family, which was expelled from Florence by the Ghibelines. He was originally designed for the profession of the law, and with this view went to study at Naples in 1547; but his taste for polite literature diverted his attention from this kind of study. His father was much offended, and withheld from him necessary supplies, whilst he visited Venice and Padua, so that he was obliged to return to Lecce, to take orders, and to accept a canonry which was conferred upon him by the bishop of this city. At Venice, whither he afterwards removed, his life was endangered by an intrigue; and at Rome he had a quarrel with the pope's usher, which obliged him to return to Lecce, where he founded the academy of the "Transformati." After many projects and wanderings in Italy, he at last settled at Florence, where in 1575, he was engaged by the Grand Duke Cosimo to write the Florentine history. Though he was of an inconstant and querulous temper, he continued in the possession of a canonry, and in the apartments provided for him by the duke for the remaining 30 years of his life. Here he died in 1621, and appointed the affidavit of his studies, Chirilphoro del Bianco, for his title; who, in conformity to his will, took the name of "Scipio Ammirato the younger." His "Florentine History," first published in 1626, contains the events of Florence from its foundation to 1574, and is much esteemed for its extent and accuracy. The second part was published by Ammiano the younger in 1641, who gave a new edition of the first part, with many additions.

Ammirato the elder wrote also genealogical accounts of the principal families of Florence and Naples, which were very favourably received; and he published "Discourses on Tacitus," with several essays, historical, moral, and political. He wrote arguments in verse, to all the cantos of "Orlando Furioso," and other pieces of poetry; but in this kind of composition he did not excel. Gen. Diat.

AMMITES, or HAMMITES, in Mineralogy, a species of lime-stone. See Roystone.

AMMOCETUS, in Ichthyology, an obsolete name given by Gmelin and some others, to the AMMODYTES of Linnaeus.

AMMOCHEA, from αμος, sand, and κεράς, I lay along, in the Ancient Physic, a kind of a remedy, or operation for drying the body, by lying along on warm sand, and having the body covered with it. Some prefer falt for this purpose to sand.

AMMOCHEUS, in Ancient Geography, a promontory of the island of Cyprus south of Salamis; whence, by corruption, is derived the modern name Famagousta.

AMMOCRYSYS, the same as golden sica, which see.

AMMOCHEYSUS, in Natural History, a kind of gem, supposed to be the same with the aonarine.

AMMONIDES, in Ancient Geography, a promontory of Cilicia, between Pyramus and Cydnus.

AMMODYTES, in Zoology, a species of Coluber, very nearly allied to the viper. It inhabits many places in the easter regions, and the mountainous parts of Ilyria; and hence it has been called vipera illyrica. The Linnaean specific character is taken, as in general throughout the genus, from the abdominal plates and fulcral scales which are 12—32. Its general description is sometines brown, sometines pale bluish, with a black dentated dorsal band; the dentations being turned backwards. Nofe terminated by an erect wart.

This species is said to be extremely poisonous, and, according to Matthiolus, proves fatal in the space of three hours.

AMMODYTES, in Ichthyology, the name of a genus in the Linzneen system, of which only one species has been hitherto discovered. The generic character is, head compressed, narrower than the body; upper lip doubled, lower jaw narrow and pointed: teeth sharp pointed. Gill mem-
brane of seven rays. Body long, square. Tail fin distinct. This species is Tobiasius Linneus. This species inhabits the sandy shores of the Northern seas, and is known by the name of tobian, tobis, fandalis, fandibz, and fand lanece. It is usually from nine to twelve inches in length, its general colour silver white, grecchif on the back.

The name is formed from ammons, sand, and even, a river, expressive the quality of this creature, to live into, or bury itself under the sand.

AMMON, or HAMMON, in Antiquity, an epithet given to Jupiter in Lybia, where was a celebrated temple of that deity under the denomination of Jupiter Ammon, which was visited by Alexander the Great.

There has been a great dispute about the origin of this name. Some derive it from amon, sand, because the temple was situated in the burning sands of Lybia; others borrow it from the Egyptian anam, a ram; as having been first discovered by that animal. Others have will Ammon to signify the fun, and the horns wherewith he is represented the fun-beams. To this purpose Macrobizobberes (Saturn. c. 13.) that the inhabitants of Egypt worshipped the fun as the only divinity and soul of the universe; and they represented him under different forms, according to the various appearances of this luminary; in his infancy at the winter solstice, in his youth at the vernal equinox, or in spring, in his maturity at the summer solstice, and in his old age at the autumnal equinox.

The word Ammon, composed of Am ucin, shining, according to Jabloniki (tom. i.) denoted the desired effects produced by the sun on attaining the equator, such as the increase of the days, a more splendid light: and, above all, the fortunate prelude of the inundation and abundance. Ammon is said to have been originally derived from Ham, the son of Noah, who first peopled Egypt and Lybia, after the flood; and when idolatry began to gain ground soon after this period, he was the chief deity of these two countries, in which his descendants continued. A temple, it is said, was built to his honour, in the midst of the sandy deserts of Lybia, upon a spot of good ground, about two leagues broad, which formed a kind of island or oasis in the sea of sand. He was esteemed the Zeus of Greece, and the Jupiter of Latium, as well as the Ammon of the Egyptians. In process of time these two names were joined, and he was called Jupiter Ammon. For this reason the city of Ammon, No-ammon, or the city of Ham, was called by the Greeks Diopolis, or the city of Jupiter. Plutarch says, that of all the Egyptian names which seemed to have any correspondence with the Zeus of Greece, Ammon or Ammon was the most peculiar and appropriate. From Egypt his name and worship were brought into Greece; as indeed were almost all the names of all the deities that were worshipped. "Bryant's Mythol. vol. i. p. 5.

However this be, Jupiter Ammon, or the Egyptian Jupiter, was usually represented under the figure of a ram; though in some medals he appears of a human shape, having only two rams horns growing out beneath his ears.

The Egyptians, says Proclus, in Timaeus of Plato, had a singular veneration for the ram, because the image of Ammon bore his head, and because this first sign of the zodiac was the preface of the fruits of the earth. Eusebius (Prap. Evang. lib. iii.) adds, that this symbol marked the conjunction of the fun and moon in the sign of the ram.

Jupiter Ammon, the object of worship in every part of Egypt, was honoured in a peculiar manner at Thebes; and the Greeks, from this circumstance, denominated it Diopolis. Herodotus, Diodorus Siculus, and Pliny have given particular descriptions of the magnificent temple of Ammon at Thebes; and although it was defaced and ruined by Cambyses, there still remain vestiges of its ancient grandeur. In this temple there was a statue of Jupiter Ammon. The Ethiopians came down the Nile once a year to worship this deity at Thebes, and they had a small portable temple of this deity, which they carried with them to their habitations and to those of the Libyans, for the purpose of celebrating prosperous events by feasts and dances. This association for religious exercises of the Egyptians, Ethiopians, and Libyans, continued under the reign of Theodotus the younger. The Greek mythologists did represent Bocchus, after his conquest of Asa, passing with his army through Africa, and reduced to dillets for want of water, when his father Jupiter, assuming the shape of a ram, led him to a fountain where he and his exhausted troops were refreshed with water; and in gratitude for this salutary relief they say, that he built a temple to Jupiter, under the name of Ammon, from amanus, sand, alluding to the sandy desert where it was built.

AMMON, or BEN-AMMON, in Scripture Biography, the son of Lot, was the father of the Ammonites, and lived about 1500 years before Chrlst.

AMMON, in Entomology, a species of Formica, with a double-spined thorax, petiolated quisma, and the two spines incurved. It is found in New Holland. Fabricius.

AMMON, a species of Scarabaeus, found in America. Thorax, with three teeth; a recurved horn on the head; wing-cases frilated. Linneus.

AMMON, in Ancient Geography, a city of Marmica, in Africa, which belonged to the Ammonites, according to Ptolemy; but Arrian says, that it was only a spot of ground in which the temple of Ammon was erected. It seems probable from Herodotus, (lib. iii. c. 25, 26.) that the Ammonites were a populous nation, and had a king of their own, though part of their territory could only be considered as a barren, sandy desert. From this ancient historian we learn, that Cambyses, having advanced to Thebes, in his way to Ethiopia, detached from thence a body of 50,000 men to lay waste the country of the Ammonites, and burn the temple of Jupiter Ammon; but that, after several days march over the deserts, a strong and impetuous wind blowing from the south, raised such a torrent of sand, as to overwhelm and destroy the whole army. Alexander the Great, about 200 years after this time, was more successful in his journey to that temple. Pliny places the temple of Ammon at the distance of about 12 days journey from Memphis, and mentions the Ammonite name of Egypt. Diodorus Siculus and Quntius Curtius (lib. iv. c. 7.) relate, that though this temple was surrounded by a sandy desert, yet its proper district abounded with trees bearing great plenty of fruit, and was ornamented with fountains. It had also several streets or villages in the neighbourhood of the temple, a cattle fortified with a triple wall, and near it a holy fountain, called the Fountain of the Sun, because the qualities of the waters varied wonderfully every 24 hours; being warm in the morning, cool at noon, warm in the evening, and scalding hot at midnight. Strabo (lib. xvii.) informs us, that, under the reign of Augustus, the vefles of the Sybilis, and the Tuscan divinations, had depreciated the reputation of the oracle of Ammon; and in the 14th century it was forgotten; though the Arabs assert, that the district, in which it was situated, was still inhabited, The Fountain of the Sun, described by Quintus Curtius, was nothing more, according to their account, than a hot spring, which seemed to be warmer in the night than in the day.

AMMON, in Zoology, a species of Ovis, or sheep, in
Gmelin's Linnean system; the character of which is, that the horns are large, in quadrupeds; four or five, and divergent, wrinkled on their inner surface, and fluted on the under side; and the neck has two pendant hairy wattles. This is the capita ammon of the Syi Nat. loc., or capra orientalis of Buffon, muflon et origio of Pissar, muflion, or muflion of Gmelin, muflion et tragulus Bellonii of Ray, tragulus, or muflon of Klein, capra capra cornibus aiutinis of J. G. Gmelin now, comp. der., ovis ferris, vulgo argali dicta of Pallas, musus of Buffon, specific barami of J. G. Gmelin, B. Opinion, barano der. or musus of Steller, das Wilds. sauf, et der wiekler der alten of Gmelin, thiech, orientalica in island of S. G. Gmelin, wild sheep of Pissar, and Siberian cervidae of Buffon. It inhabits, in small flocks, the rocky and declivitous tracts of the Alpine region in the centre of Altai, in Kamtschatka, the Kirg. islands, probably on the west side of North America and California, and more certainly on the highest mountains of Barbary, Saratia, Corsica, Greece, and the deserts of Tartary.

It is very wild, fast, and active, and fights violently with its horns, acquires its full growth in two years, and Eildom lives more than 14; the female produces one or two lambs in the month of March. The general colour in Summer is a brownish ash, mixed with grey on the upper parts of the body, and a whitish ash on the lower parts; in Winter the former changes to a rusty grey, and the latter to a whitish grey; the tail is very short, of a whitish colour, and brown on the tip; the hair in Winter is about an inch and a half long, which falls off in Spring, and in Summer the coat is very short; the ears are erect and sharp pointed; the eyes are large, and generally of a brown or blue colour; the horns, which arrive at their full size in three years, are whitish, angular, wrinkled transversely, large, close at their bases, and placed on the top of the head, rising at first nearly upright, reflected backwards, divergent, and turned downwards and outwards at their ends: those of the female are smaller and more hooked, but are sometimes entirely wanting; the horns of the old rams are said to grow to such an enormous size, that each of them weighs between 30 and 40 Ruffian pounds, and measures, with its curvatures, two Ruffian ells in length; the hind-legs are rather longer than the fore-legs, by which the animal is better adapted for running up hills than on level ground; the flesh fat and are esteemed great delicacies in Siberia; the Kamtschakians clothe themselves with the skins of these animals. Mr. Pennant distinguishes between the Corfican argali, or ovis ammon Europea, and that of Siberia; though the difference seems to consist chiefly in colour; the former being of a brown colour tinged with tawny on the upper parts, with a white mark on each side pointing to the belly. A specimen, brought from Corfica to England by Paoli, differed from the above in colour, having a large white spot on the front of the neck, and being black on the shoulders. In Corfica this animal is denominated Mufro. It is probable that the argali once inhabited Britain, as Boeclius mentions sheep in St. Kila larger than a be ox, with horns as big as those of an ox. In confirmation of this account, the figure of a mufon has been discovered in a piece of Roman sculpture, taken from Antoninus's wall, near Glaafs. Buffon says, that the mufon seems to be the primitive rock of all the different varieties of sheep.

The Kamtschakians have not attempted to domesticate the argali; but they spend the Summer in hunting them on the wild and precipitous mountains on which they feed. Sometimes they set bent cross-bows in the paths through which they expect the argali to pass, in such a position, that when the animal tends on a thing lying to the bow, the arrow is discharged and lodged in its body. Sometimes they employ dogs in the chase. The dog never overcomes the wild sheep; but while the sheep's attention is engaged by the dog, the hunter, without being observed, approaches near enough to seize it with a ball or an arrow. The Mongols and Tung'is attack them in a different manner. They take out a great number of hounds, and dogs, and endeavour to encompass the flocks by farreight; but this is not easily done, as they are so swift, and so cunning, that when they disinguish, either by sight or by smell, the approach of an enemy, they instantly make their escape.

AMMONIA, in Agriculture, a term applied to volatile alkali, a substance which has lately been found useful in vegetation. It is formed from the decomposition of all animal and some vegetable matters during the process of putrefaction. It has been suggested by Dr. Darwin, in his treatise on agriculture and gardening, that in the decomposition of water, which particles take place after being absorbed by the roots of vegetables, the hydrogen, by its union with oxide, produces ammonia, which may contribute to the maintenance of plants by its mixture with oils, and thus produce foams which become diffusible in water, and also by decomposing insoluble saline earths, as gypsum or metallic salts, as vitriol of iron, and by this means producing more soluble or innocuous saline matters in the soils.

AMMONIA in Antiquity, feasts celebrated at Athens, mentioned by Hefychus.

AMMONIA, of Volatile Alkali. Alkali volatile, Ammoniacae, Fr.—Alkali fluebiges; Harzflueigh, urinflueigh, fluebiges, Germ.

Under the article Alkali we noticed some of the peculiar properties of the volatile alkali whereby it is distinguished from the fixed. We shall, in this place, give a more particular account of ammonia, which requires considerable notice from its high importance as a chemical agent, and from the numerous researches which have been made into all its properties and combinations, with more success than perhaps it has fallen to the share of any other substance of equal value to the chemist.

As ammonia is never found native in an uncombined state, and is, in most cases, a product of various natural or artificial processes, we shall refer the reader to the articles Animal matter, Carbonat of ammonia, Muratt of ammonia, and salt of Hartsnop, for every thing that relates to the natural history of this alkali and its production in the large way as a manufacture, and shall here confine ourselves to the purely chemical description.

The volatile alkali (like so many other chemical agents) when perfectly pure and uncombined, is only known to us in the form of a gas; and, as it is the only one of the alkalis which is capable of assuming this form in any common degree of heat, the term alkali is, nay, by Dr. Priestley and many other chemists, is synonymous with amoniall gas. This gas has the following properties: It poiferates a most pungent smell, which, when strongly fumeled up the nostrils, provokes to vomiting, and gives a temporary sense of suffocation, owing to the contraction of the surfaces which it produces. To the taste it is highly stimulating and acid, and quickly corrodes the skin of the tongue and lips, so that it cannot be taken into the mouth in the undissolved form with safety. It is speedily fatal to animals that are immersed in it, and it extinguishes a taper; but the flame of this last is first enlarged, and becomes of a pale yellow colour. Ammoniall gas is, next to hydrogen, the lightest of all the gaseous bodies. Its specific gravity,
gravity may be reckoned about 0.735 (distilled water being 1.000) whereas atmospheric air is 1.25; or nearly twice as heavy as alkaline air. The absolute weight of 100 cubic inches of this gas at 30°, and 61° therm. is reckoned by Kirwan to be 18.16 grains. It is highly distilable by heat, and at a very high temperature is decomposed. It is also very rapidly and copiously absorbed by most liquids, especially by water, and hence it cannot be kept over water; but, for the purposes of experiment, it must be confined in well closed bottles or over mercury.

Ammoniacal gas is given out during the distillation of alkali almost every animal, and some vegetable matters, but it cannot in this method be procured sufficiently pure for chemical experiments. For this purpose the muriate of ammonia (or common crude sal-ammoniac) is the most convenient material for yielding the gas. This salt is readily decomposed by quicklime, which latter unites with the muriatic acid of the salt, and expels the ammonia in its purest and most caustic form of gas. The decomposition is so speedy, that a very pungent smell of volatile alkali is perceived merely on rubbing together these two substances. If one part of dry sal-ammoniac is mixed with two parts of well burnt lime (or less if the lime is good), put into a dry phial or earthen tube, and heated gently, the ammoniacal gas rises in great abundance, and may be directed by means of a bent tube under a jar full of dry mercury, where it may be preferred in the gaseous form for any length of time. Many of the metallic oxys, especially minium or litharge, will supply the place of the lime and expel the gas from the muriate of ammonia in very great purity. A still more simple method of obtaining the gas is to apply a gentle heat to the liquid or watery solution of ammonia, which expels from it the alkaline air that the water had previously been made to absorb at a lower temperature. It may be remarked that the discovery of ammonia in a gaseous form, as well as many of the most interesting properties of this alkali, is due to Dr. Priestley.

Ammonia, dissolved in water (forming the liquid ammonia of modern chemists, the fluid volatile alkali of former times, or the aqua ammonica pure of the London Pharmacopœia) is the form in which the caustic ammonia is the most familiar to us, and in which many of the properties of the alkali can be most conveniently examined. This pure should be perfectly transparent and colourless as water, should have the strong burning taste and pungent smell of ammonia, and should give no effervescence with acids. This latter tells delvers attention on account of the variety of volatile alkaline liquors that are prepared, all of which, except the aqua ammonica pure, contain more or less carbonic acid, and are much milder in all their sensible properties.

Ammoniacal gas is absorbed by water with great rapidity, and at the same time a considerable quantity of heat is given out from the gas, which is sufficient to raise the temperature of the water, and to be sensible to the hand. The same gas, when put in contact with ice, mixes it with apparently as much rapidity as if the ice were put into a fire, and is greedily absorbed, at the same time that considerable cold is produced. At a moderate temperature water may be made to distil nearly one third of its weight, or many hundred times its bulk, of this gas. The bulk of the water is so much increased by this process that it becomes specifically lighter than distilled water. Mr. Davy, in his experiments on this subject, (Researches into nitrous Oxyd, 1800,) found that at the temperature of 52°, 100 grains of liquid ammonia, holding in solution 9.502 grains of the alkali, gave a specific gravity of .9984. When perfectly saturated, 100 grains of the liquid alkali contained 3.57 grains of ammonia, which is still one-third of the weight of the water employed, and had the specific gravity of .8054. Other writers, however, make the specific gravity of saturated liquid ammonia as little as .8077. The gentle heat of a spirit lamp again expels the alkali in the form of gas, but the last portions require a longer ebullition before they can be made to quit the water. When liquid ammonia is exposed to a very intense cold, sufficient to freeze mercury, as Misses. Fourcroy and Vanquelin have observed, it becomes a grey semi-transparent mass, of the consistence of a very stiff jelly, and with scarcely any odour.

The liquid ammonia is prepared in two methods. That which is the oldest and the most usually practiced, is to mix together quick-lime, muriate of ammonia, and water, and to distil the mixture with a gentle heat. The London Pharmacopœia orders for the preparation of the pure liquid ammonia, two pounds of lime, mixed in two pints of water, and one pound of sal-ammoniac, which are to be mixed with six pints of hot water, and to be kept in a covered vessel till cold. The liquor is then to be distilled, and the first pint which comes over is the pure liquid ammonia. This liquor, however, is by no means saturated with the alkali, for during the heat, even of a gentle distillation, the solvent power of the water is much lessened. The most elegant and effectual way of preparing this liquor is to distil the gas from the dry materials; and by using the beautiful apparatus of Woulfe, to caufe the alkaline air to pass into cold water where the absorption is much more speedy; and if necessary, the increase of temperature produced by this absorption may be prevented by surrounding the bottles with ice. The proportions of the ingredients here used, may be two parts of lime mixed in as little water as possible, mixed with one part of dry muriate of ammonia and put into a retort for the production of the gas; and in the condensing bottles, about as much water as the weight of the sal-ammoniac employed. The liquid ammonia is known to be thoroughly saturated with the alkaline gas, when the bubbles pass through the water undiminished, and no further absorption takes place.

Many of the combinations of ammonia with different chemical agents are highly curious and important; but as most of them produce alterations which depend on the decomposition of this alkali, they will be better understood by the reader, if we first relate some of the multitude of facts by which the analysis of ammonia has been ascertained. The constituent parts of the volatile alkali are, hydrogen (or the basis of inflammable air), and azot (the basis of phlogisticated air), the proportions of these two substances are, about 20, in weight of the former, and 112 of the latter; and it may be remarked that this is the only simple combination of these two substances with which we are certainly acquainted. The proofs of this analysis we shall relate nearly in the order of discovery by the various eminent chemists who have thrown light on the subject.

Dr. Priestley was the first who remarked a very interesting change produced on alkaline air by means of electricity. For this purpose he confined a known portion of this gas in a jar over mercury, and passed a number of successive electric explosions and sparks. He found after every shock that the bulk of the confined air increased, and continued to do so till it had expanded to nearly three times its original bulk. The air was now much altered in its properties, for on letting up some water into the jar, scarcely any of the gas was absorbed, whereas before electrization every particle...
AMMONIA.

ticle of it would have rapidly united with this fluid. The

The gas was found to be highly inflammable, and exploded when

mixed with common air, in the same manner as the inflam-
mable air procured from iron by an acid. The gas likewise

after being a short time in contact with water had entirely

lost its alkaline smell. The colour of the electric spark

taken in the alkaline air was red, but white in the centre,

when any considerable explosion had been taken.

The same eminent chemist likewise found alkaline air to

de be decomposed by passing through a red hot tube, though

not so completely as by the electric spark. In performing

this experiment he found the tube, through which the al-
aline vapour had passed, lined with a black matter, and

the liquor collected after this distillation also became

with the same sub stance. This is probably owing to some
diffusion in the tube which admitted carbonaceous matter

from the hot coals, as we shall mention hereafter. Another

property of alkaline air, highly illustrative of its composition, is

the reduction of several metallic oysds which it effects

when they are heated in contact with it. Dr. Priestley

confined some litharge, or oysd of lead, in this gas, and by

heating it with a burning lens (a method of applying heat

of all others the most accurate), he revived the lead in its

metallic form, and a quantity of phlogisticated air remained.

The red mercurial oysd, or red precipitate, was heated in

the same manner, and the mercury was revived, and at the

same time a considerable quantity of water was produced

so as to run down in drops on the sides of the jar, which

before appeared perfectly dry. The red precipitate, how-

ever, gave out during this reduction a large quantity of un-

combined phlogisticated air, which appeared in the residu-

al air after the reduction was completed. This, in another

experiment with the same materials, united with some of

the inflammable air contained in the alkaline gas and caused

a considerable explosion. The antiphlogistic theory will

readily explain the production of water during the experi-

ment from the union of the oxygen of the red precipitate,

and the hydrogen of the ammoniacal gas; but this fact

more properly belongs to the subject of water and phlo-

giston.

These experiments were soon repeated by various che-
nists, and with similar results. Landriani found, that in

passing ammoniacal gas through a tube heated white hot,

the alkaline properties were entirely lost, inflammable air

was produced, and likewise a small portion of carbonic acid

sufficient to give a precipitate with lime water.

Van Marum, in his experiments on the effect of electrifi-
city on the gases, found the same results with ammoniacal

gas that we have just mentioned. Two cubic inches and

devn eighths of the alkaline gas were enlarged to four inches,

and the air was no longer absorbed by water, and was high-

ly inflammable.

Whilst the properties and composition of the volatile al-
kalies were made the subject of so much ingenious and suc-
cessful research by Dr. Priestley, they received full elucidation
by the labours of one of the most eminent of the French

chemists, M. Berthollet.

This excellent experimentalist found, that when the oxy-
genated marine acid is added to liquid ammoniun perfectly
cautious, a considerable effervescence takes place, and a quan-
tity of gas is collected from the two liquids, which, when

examined by the usual chemical tests, proves to be pure

azotic gas. At the same time the oxygenated acid loses its
peculiar pungent smell, and becomes converted into

simple marine acid. The explanation given of these phe-

nomena is, that the ammonia is decomposed by the oxy-

nated acid; the hydrogen of the alkali unites with the ex-

cess of oxygen contained in the acid, and forms a water,

which mixes with the acid; whilst the azot, the other con-
stituent part of the ammonia, appears uncombined in the

form of gas. The gas was found by Berthollet to be

azotic, both by the common methods of examination, and

by its forming nitrous acid when united with oxygen by

means of the electric spark, in the method that M. Ca-
vendish had discovered. The same decomposition takes

place if the oxymuriatic acid and the ammonia are used in

form of gas. See oxymuriatic acid.

This theory of the decomposition of ammonia was also

beautifully illustrated by the same ingenious chemist, in his

accurate and original experiments on the nature and prepara-

tion of fulminating gold. This will be given more at

length under the article gold; but it may be here men-
tioned that the fulminating compound is formed by precipi-

ting a solution of gold in aqua regia by the volatile al-
kalies. This precipitate consists of the metal of oxygen

which it acquires during solution in the acid, and of a par-

t of the ammonia employed to separate it from its menstru-

um, which is retained by the metallic oysd, and which gives

it the property of exploding in a very gentle blast. M.
Berthollet ventured to explode small and known quantities

of this preparation in copper tubes, and found the prod-

ucts to be water and azotic gas, and the oysd of gold

completely reduced. The ammonia therefore is here de-

composed, its hydrogen produces water with the oxygen

of the gold, and its azot is set at liberty in the form of

gas. Some other of the metals which have a weak affinity

for oxygen are reduced to a regulare state by means of the

volatile alkali, which is also decomposed in the process.
M. Berthollet also repeated Dr. Priestley’s experiment of

the analysis of ammoniacal gas by electricity, taking every

possible precaution in order to ensure an accurate result;

and the calculations deduced from it have been very gen-

erally acquiesced in, and confirmed by subsequent experi-

ments. For this purpose he passed a succession of electric

sparks through 1.7 cubic inches of ammoniacal gas till it ac-
quired its utmost degree of expansion, when it occupied 2.3 cubic

inches, a degree intermediate between the results of Dr.

Priestley and M. Van Marum. A certain quantity of this

enlarged gas was then detonated with a superabundance of

oxygen gas in Volta’s electuiometer, whereby water was pro-

duced and the azotic gas of the ammonia remained unal-

tered. Then (alluming the quantity of oxygen entering

into the composition of water to be the hydrogen, as

74 to 145, according to the calculations of M. Monge,

given in the Memoirs of the French Academy) M. Ber-
thollet estimates the proportions of the constituent parts

of ammonia to be 2.9, in bulk, of hydrogen, to 11 of azot,

or, in weight, (alluming the hydrogen to be eleven times

lighter than the azot) 150 grains of ammoniacal gas will

contain 121 grains of azot, and 29 grains of hydrogen.—

Journal de Physique for 1786.

The above are the principal facts which have been brought
to prove the decompositon of ammonia. A number of others,
equally important and curious, will throw light on the

mode of its formation from the union of its constituent

parts.

An accidental production of ammonia in circumstances

where it had not been expected had frequently been re-

marked by various chemists. Dr. Priestley, in his numer-

ous experiments on nitrous air, found by accident that when

iron filings had been long kept in a jar, and moistened with

a diluted solution of copper in the nitrous acid, a thick
AMMONIA.

A production of ammonia, in somewhat similar circumstances, is likewise particularly noticed by Mr. Hauffman of Colmar. (Journal de Physique for 1787.) He relates, that on mixing nitrous gas with phlogilificated precipitate of iron, a large quantity of the gas is absorbed, leaving only a small residue of phlogilificated air; and on adding caustic fixed alkali to the iron precipitate, a fume of volatile alkali is very perceptible, and a flame moistened with nitrous acid and held over the mixture also indicates the presence of ammonia by forming dense white fumes. Mr. Hauffman distinguishes accurately between the phlogilificated and the dephlogilificated solutions of iron, the former being formed by dissolving the metal in nitrous acid, or in the vitriolic without previous preparation; and the latter being a solution in vitriolic acid of iron which has previously precipitated from a nitrous solution, and is therefore fully dephlogilificated, or, as is now said, in the highest state of oxygenation. The same chemist employed the solutions of iron in various states, and found, that wherever nitrous gas was absorbed by the iron, a certain quantity of ammonia is also produced, which he also observes, probably remains in union with the vitriolic acid till it is displaced by caustic fixed alkali. The properties of this compound of nitrous gas and oxyd of iron will be examined more particularly under the article EUDIMETRY, as it is intimately connected with this subject.

Still further light was thrown on the curious phenomenon of the production of ammonia, by some interesting experiments of Dr. Aultin. (Philosoph. Transact. for 1788, vol. xlviii.) The composition of ammonia having been fully ascertained by the experiments of Prieflley, Berthollet, and others, Dr. Aultin attempted to produce the alkali by a direct union of its constituent parts. For this purpose he mixed inflammable and phlogilificated airs in different proportions, and added to them some of the acid airs in order to favour their combination, tried the effects of cold, of heat, of electricity; and lastly, he decomposed alkaline air, and endeavoured to reunite the identical parts, but in no instance could he succeed in forming ammonia from the constituent parts of this alkali, unless both were employed in a gaseous form.

Hydrogen and azot, however, are certainly the constituent parts of ammonia, and their refusal to unite when in the form of gas led Dr. Aultin to vary his experiments by mixing these substances together in such a manner that the hydrogen should be involved in an atmosphere of azotic gas just at the time when it was itself beginning to assume the gaseous form. This has with great propriety been termed the nascent state of a gas, and this experiment was suggested to Dr. Aultin by another very striking production of ammonia from nitrous acid and tin, which we shall presently mention. He therefore inclosed in a glass tube some azotic or phlogilificated air, and along with it some iron filings moistened with water, which last were known to yield inflammable air after standing together for some hours; and this air therefore in its nascent state, or at the infant of its formation, was in full contact with the azotic gas. To detect the precise quantity of ammonia he also inclosed in the tube some paper stained with the blue of the ind of the radish, which was turned to green by alkalis. In twenty-four hours he found the colour entirely green. Another test was also used to indicate the presence of ammonia, which was paper stained with a solution of nitric acid and copper; the green of which, in a few days, converted to blue, the proper colour of a solution of copper in ammonia. Dr. Aultin found nitrous air to effect a much more speedy production of ammonia when used instead of the azotic gas. Atmospheric air will also succeed, but requires a longer time than the azotic air, so that ammonia should always be formed whenever iron in contact with water-woods in the open air. In this formation of ammonia by the direct combination of its principles, it is necessary, as Dr. Aultin observes, that the hydrogen should be only in the nascent state when it comes in contact with the azot, for if it is already in the form of gas it cannot be made to unite with the azot in any form so as to produce ammonia.

We may here remark, that this mode of effecting chemical union between bodies which, when uncombined, are only known in the gaseous form, (such as oxygen, hydrogen, and azot) by presenting one to the other when in the nascent state, should always be kept in mind in experiments of research, as it may be the means of very important discoveries in this difficult part of experimental chemistry. Mr. Kirwan, in his valuable experiments on hepatic air, observed the formation of volatile alkali when this air was mixed with nitrous gas. At the same time fulprur is decomposed. Another very striking experiment on the formation of ammonia, which is easily made and seldom fails of success, is the following. Take some powder, or filings of tin or zinc, pour on them some moderately dilute nitrous acid, which will act on them with great vehemence, and the disengagement of copious red fumes. After a short time fire into the mixture some quicklime or caustic alkali, and a very strong pungent smell of ammonia will be produced. In this case the ammonia is formed by the decomposition of the nitrous acid and the water, this ammonia instantly unites with a portion of the acid, forming nitrated ammonia, and the lime again decomposes this ammoniacal salt by simple affinity, and by displacing the alkali from its union with the acid, causes it to assume the gaseous form and to become evident to the senses.

Before we quit the subject of the composition of ammonia, we shall make a few observations on the decomposition of nitrous gas and nitric acid in the experiments above related, whereby the volatile alkali is produced. In the simpler methods of forming ammonia, such as Dr. Aultin's experiments, the union of the nascent hydrogen with azotic gas, the affinities which operate in forming the alkali, may be supposed to be tolerably simple, but when the nitric acid or nitrous gas are used, the affinities appear to be extremely complex, and perhaps hardly made out with much certainty. It should be noted, however, that, along with the production of ammonia, there appears concomitantly a proportionate quantity of that singular gas discovered by Dr. Priestley, and called by him dephlogilicated nitrous air; and of late denominated nitrous oxyd by Mr. Davy, to whose highly ingenious "Researches" we are indebted for much important addition to this curious and difficult part of chemistry. It is a striking property of the nitrous oxyd to support combustion in a very eminent manner, and very similar to oxygen gas, although it contains a less proportion of oxygen, and more azot than nitrous gas, which
AMMONIA.

which is unfit for combustion. This resemblance to oxygen gas in the nitrous oxyd has milled some chemists in the nature of the air left after the formation of ammonia from nitrous gas and nascent hydrogen, who have supposed a production of oxygen, and have been obliged to account for it accordingly. 'To explain the changes that take place with moistened iron filings, confined in an atmosphere of nitrous gas, we must observe, that the new compounds, which we know are formed out of these materials, are ammonia, confiding of azot and hydrogen, and nitrous oxyd, composed of much azot and little oxygen. The iron likewise is rilled or oxygenated. The source of the hydrogen in the new products may be supposed to be some of the water decomposed, from which the metal, in rolling, has abstracted its other constituent part, the oxygen. The only source of the azot (allowed by the antiphlogistic theory) is the nitrous gas, which is composed merely of this principle, and of oxygen. But if merely a portion of the azot of the nitrous gas was abstracted from it, the remainder, by losing azot, would be a substance containing (proportionally) more oxygen than nitrous gas; whereas, the nitrous oxyd, which is this remainder, contains less. There must, therefore, be an additional method of getting rid of this excess of oxygen, in order to produce a satisfactory explanation; and the only substance that offers is the hydrogen of the water decomposed by the metal, which may be supposed to unite with enough of the oxygen of the nitrous gas to reduce it to the state of nitrous oxyd. Thus then, according to this hypothesis, the metal decomposes the water, the hydrogen fre at liberty by this decomposition unites with a small part of the azot of the nitrous gas to form ammonia, and with a greater part of its oxygen, to form water, and the residue of the nitrous gas is in that proportion and mixture which constitutes nitrous oxyd.

We shall not pursue this subject farther at present, as it will apply to all the cases of the production of ammonia by nitrous acid, and it may, perhaps, be thought too hypothetical to be further infilled on, though there are many similar examples to be met with, of very extensive and complicated affinities being set in motion by a single disturbance of the quiescent attractions of the constituent parts of any of the substances contained in the mixture.

Having now enumerated some of the leading facts by which the composition of the volatile alkali has been established, we shall proceed to mention some of the mixtures of ammonia with various chemical agents. It may be observed that though the combined volatile alkali is in the form of gas when pure, all its combinations are either solid or liquid, and hence every substance added to the ammoniacal gas causes an absorption of it where any chemical action takes place. However, the tendency to the aerial form is so far retained by ammonia in all its combinations as to render them volatile, and to weaken its adhesion for them, whenever the temperature is raised to a certain degree. The force of affinity which ammonia exercises is therefore remarkably weakened by heat, where the substance to which it is united is naturally fixed in the fire, and many of the ammoniacal compounds at a high temperature are totally decomposed, and entirely new products result from the operation.

No union takes place by any simple mixture of ammonia with oxygen, hydrogen, or azotic gases. Under particular circumstances, and by the agency of complicated affinities, these substances may however be mutually decomposed, and new compounds produced. Thus, ammoniacal gas passed over heated oxyd of manganite forms Nitrous Acid, as discovered by the ingenious experiments of Dr. Miller.

Ammonia unites with all the acids with very great ease and rapidity, forming with them very easily soluble salts. There will be particularly mentioned under the respective acids, but some of their properties may here be mentioned. The union of alkaline air with the acid gasses, as discovered by Dr. Priestley, forms some of the most striking and beautiful experiments which chemical facts furnish. If ammoniacal gas is passed up into a jar containing carbone acid there is a thick white fisume immediately produced, the two gasses by uniting lose their gaseous form, so that there is a complete vacuum suddenly made in the jar, containing the mercuriu mercury over which it is confined to rise and fill it entirely, a sensible quantity of heat is given out, and a number of minute crystals of carbonated ammonium lining the inside of the jar, is the product of the mixture.

With the nitric acid gas the appearances are exactly similar, only the white fisume is still more dense and copious, the heat greater, and the union more rapid. Crystalline feathers of mutiated ammonia are the result, and this furnishes one of the most striking influences of alteration in form, and in sensible properties, which two bodies may undergo by chemical affinity; for each of the ingredients when separate are in the state of an indivisible gas with a highly pungent smell, and, when united, a fentinous solid salt is the product. In making this beautiful experiment both the gasses should be confined over mercury; and, on account of the much superior specific gravity of the gas acid over the alkali, if the former is thrown into a jar of the latter, the white cloud will form slowly, beginning from the point of contact of the gasses; but if the alkali be added to the gas acid, it rises through it immediately, and the combination takes place with great rapidity.

The nitric acid unites with ammonia with great ease, and with the production of white fumes when the two substances are gaseous. The resulting salt Nitrat of ammonia possesses very interesting properties, which will be mentioned under that article.

It may be of use to know that the presence of ammoniacal gas, where it cannot conveniently be detected by the smell, will be readily known by holding a piece of glass rod or any other substance wetted with nitrous or nitric acid, over the part where ammonia is suspected, when thick white fumes will be seen to form around the acid.

Phosphorous will not unite with ammonia at a low temperature. In a red heat the alkali is decomposed, and phosphoricd hydrogen, and azotic gas are produced.

With sulphur, ammonia unites with some difficulty, forming the Sulphuret of ammonia, or Boyle's fuming liquor.

Charcoal and the volatile alkali do not unite in a moderate heat, but at high temperatures the alkali is decomposed, and, by particular management, that singular substance, the Prussic acid, may be formed.

The affinity of ammonia for the different acids is much weaker than that of the other alkalis, and several of the earths. In several solutions of earths or metals in acids, where the affinity of ammonia for the acid is only in a small degree greater than that of the earth or metal, only a part of the substance dissolved is precipitated by the addition of this alkali, and the solution retains the remainder, united with the ammonia, forming together an ammoniacal triple salt. Thus if to a solution of magnesia ammonia is added, part only of the earth is precipitated, and the remaining solution is an ammoniacal magnesia. Also the affinities of ammonia are much weaker by heat, owing to the great tendency to volatilisation which the alkali possesses.

Ammonia has a very striking property of reducing to the metallic state (either entirely or partially) the oxydes of the several metals. This is performed, as we have already mentioned
tioned in the intantne of fulminating gold, by a decomposition of the alkali, its hydrogen uniting with the oxygen of the metallic oxyd to form water, and its azot appearing uncombined in the form of gas. Thus, as M. Fournier has observed, (An. Chim. tom. 2 & 6.) if the black oxyd of manganese is mixed with liquid ammonia, and gentle heat be applied, the oxyd passes to the state of the white oxyd, (which is nearer the metallic state) and an effervescence with disengagement of azotic gas takes place. The red oxyd of mercury, treated in a similar manner, gives the same results, and the metal is left in the state of a black powder, which simple exposure to light and air will convert to globules of running mercury. This affords a ready way of clearing the surface of mercury that has been tarnished and oxidized by acid vapours.

Some of the most difficultly reducible metals, such as manganese or tungsten, are on this account well prepared for reduction by being previously united with ammonia.

The volatile alkali may be made to unite with oils, so as to form ammonical soaps; but this combination is less perfect than the fixed alkali soaps, on account of the impossibility of applying heat to promote union without driving off much of the alkali in the form of gas. The volatile oils are equally soluable in ammonia with the fixed, an example of which is that union of oil of amber with ammonia, which forms eau de luce.

A great variety of vegetable and animal substances are dissolved or decomposed by this alkali, which renders it of the highest importance in the analysis of animal and vegetable matters.

The uses of the volatile alkali are numerous and important.

To the chemist, as a reagent of very extensive utility, it is an indispensible requisite, as there is hardly a single analysis of mineral, vegetable, or animal matter performed (where at all complicated) in which ammonia is not largely employed.

In medicine this alkali is highly valuable, on account of its strong and diffusibly stimulating properties. When taken internally, its first effect is generally upon the throat and fauces, owing to its partial volatilization by the heat of the mouth. Every one is familiar with its use in relieving stings and stings when mixed up the nostrils, though from the great acrimony of the caustic ammonia, the milder form of the carbonated ammonia, or sal volatile is generally preferred. The strong and pungent stimulus which it gives to the system, when applied to the nostrils, renders it also one of the most powerful applications in many of the more serious affections of the vital powers. The pure liquid ammonia is much too acrid to be used by itself, even as an external application, but when mixed with oil it forms a very useful liniment for strains, indolent swellings, and any ccat in which a powerful stimulant is required. Simple agitation with oil will unite the two liquors into an uniform milky faponaceous liquid, in which the sensible properties of the alkali are only blunted and not neutralized. A peculiar use of the liquid ammonia largely diluted with water, and taken internally, is in checking the sadden and dreadful effects produced by the bite of venomous serpents.

Friedly on Air.—Journal de Physique for 1783, 6, and 7.
—Davy's Recherches, &e.

AMMONIAC. In Mythology, an appellation of Juno, to whom the Eleans sacrificed, alluding, perhaps, to Jupiter Ammon.

AMMONIAC, Gum. or, as it is sometimes, though improperly, called, ammoniac, is a concrete, gummy, re-

frous juice, which is said to ooze from a plant of the umbelliferous kind, as may be inferred from the seeds and pieces of such a plant with which it is intermixed. Ammoniacum

is very analogous to Galbanum, and the former, as well as the latter, is probably procured from a species of the Bubon. The feeds that are found among the tears resemble those of anethum or dill, except that they are larger.

Dioscorides says, it is the juice of a kind of feraula, growing in Babary, and that the plant which produces it was called agyphiis. Pliny calls the plant whence it flows metopion, and says the gum took its name from the temple of Jupiter Ammon, in the western part of Egypt, now the kingdom of Barca, near which it grew. At present it is brought here from Turkey, and from the East Indies.

The good ammoneum ought to be in dry drops, white within, yellowish without, easily fusible, resinos, somewhat bitter and nauseous, and of a very sharp taste and smell, somewhat like garlic. The white drops or tears are observed to change to a yellowish or brownish colour, on being exposed for some time to the air. It should not be mixed with any weakne, wood, bone, or sand; this, by the Greeks, was called δακρυα, fragment. The other, which is full of bone or sand, was called ἄκρυα, that is, mixture. It is purified from the seeds, with bones, &c. commonly intermixed with it, by softening or dissolving it in a little boiling water, pressing it, while hot, through a strainer, and then inflicting it to its former condition. For internal use the larger and finer tears, unpurified, are preferable to the common drained gum.

From an ounce of this gum, or in fix days may be dissolved by spirit of wine, or fix films two or three and a half may be dissolved by water. Neumann.

This gum softens by the heat of the fingers, and adheres to them. It is brittle when cold; it is easily melted in an iron spoon; applied to a candle it burns and fumes. The more milky grains are contained in it, so much the more excellent is its quality. If these only be selected it will require no purification.

Some say it served the ancients for incense in their sacrifices. It enters several medicinal compositions, and its principal virtue is that of resolving obstructions, in which intution it is frequently used in asthmas and difficulty of expiratory, in menstrual suppurations, and cachectic indispositions. In obstructions of the brea it is reckoned the most effectual of the aperient gums. It is most commonly taken in the form of pills; the dose is a scruple, or half a dram, every night or oftener; in larger doses, as a dram, it generally loosens the belly. In phthisical cases, where no injury is to be apprehended from a stimulus, this gum may be elegantly combined with oxymel of squills, distilled water, and syrup. Applied externally, it is sup-posed to diffuse hard indolent tumours; and for this purpose it enters into the composition of many plasters. Plasters formed with vinegar of squills, and with wine vinegar, have been employed for curing the fungus of the joints or dropy of the knee, and are said to have proved cffectual. Plasters of this kind applied to the head, and allowed to remain for fix or eight weeks, have removed the tums capitis. Dr. Cullen (Mat. Med. vol. ii. p. 369.) affirms, that he has feldom found the expectorant power of this gum very remarkable, and that the mischief arising from its heating qualities has more than counterbalanced the benefit obtained by its expectorant powers. He adds, that its efficacy in resolving indurated tumours is very doubt-ful, and that he has had no clear proof from experience of its having any such power.

Ammoniacum, triturated with water, diffuses into an emulsion, or milky liquor, lac ammoniaci, and in this form acts rather more powerfully than in the cold one of a pill. Simple penny royal water is common-
A M M

mostly used for this purpose, in such proportion, that four spoons of that, is two ounces, of the solution contain thirty grams of the gum. Some have distilled it in vinegar of spirits, and thus obtained a very powerful but impalpable expectorant. When these pulpy solutions are kept for some time they deposit a considerable quantity of tenacious matter, and become clear. Impregnated they yield an extract of no smell, and of only a weak bitter taste. In dilution no essential oil is obtained, and the distilled water is but slightly impregnated with the flavour of the ammonium.

In this respect ammonium differs remarkably from most of the other deodorant gums, as aspirina, galbanum, and fagapheum, which afford not only a strong distilled water, but an actual oil, containing the concentrated flavour of the gums. Lewis.

**AMMONIAC, falls in Chemistry and the Materia Medica.**

AMMONIACAL preparations, in Pharmacy. There are several pharmaceutical preparations, into which the volatile alkalies, under one form or another, enter as a principal ingredient. Of these the only one in which the alkali is employed in its caustic state is the aqua ammonica pure, (Pharm. Lond.) also called acetic spirit of ammonia, or spirit of ammoniaca with quicklime: (spiritus ammoniacus cum calcis viris), the methods of preparing which have been described under liquid ammoniacum in the preceding article. It may be observed, that though it is called a spirit it only consists of water, impregnated with pure ammonia, through the medium of dilution. The appellation “with quicklime” is added to distinguish it from the simple spirit of sal ammoniacus, which is prepared (from the dilution of muriated ammoniac in both cafes, but) with chalk, and is therefore not caustic, but carbonated, and effervesces with acids.

The several preparations of the Carbonat of Ammonia, employed in medicine, will be mentioned more particularly under that article and HARTSHORN. The principal are the prepared ammoniac, ammoniac preparatum, (Pharm. Lond.) Sal volatile, salt of hartshorn, which is the solid carbonat of ammoniac in its pure state, prepared for the most part by sublimation of some of the neutral ammoniacal salts with chalk.

Aqua ammoniac, (Pharm. Lond.) or spirit of sal ammoniacus, is prepared by distilling muriate of ammoniac, chalk, and water; and is in fact nothing but a solution of carbonat of ammoniac in water, effected by the medium of dilution, and perhaps containing a small portion of the caustic ammoniac, where the chalk is not perfectly mild. Sometimes this liquor is prepared with pearlash, or carbonat of potash instead of chalk. The effect will be the same upon the ammoniacal liquor, only when the pearlash is used, as it is always in a semi-caustic state, it will render the volatile alkali somewhat less carbonated.

Spiritus ammoniacus, (Pharm. Lond.) spiritus fallis ammoniaci dulcis, pure vulgaris. This differs from the preceding in being a real distilled spirit, as proof spirit of wine is the menstruum employed for the alkali instead of water. The term spirit is therefore, in the present London Pharmacopeia, very properly confined to the ammoniacal preparations where spirit of wine is employed; and the term eau or of ammoniac is adopted where this liquid is the solvant for the alkali.

The true spirit of ammoniac is made the basis of several powerful compound preparations, in which either an aromatic oil and water, or a tincture, is united with the alkaline spirit, according to the intention which it is to answer. Of the former kind is the spiritus ammonica comestibulorum, or ammoniac spiritus, prepared by diffusing bergamossemi effuse and oil of cloves in the alkaline spirit (either with or without the help of dilution); of the latter is the spiritus ammoniacus

.. in which a certain quantity of affaictus is dissolved in the spirit. The ammoniacal spirit is likewise made the basis of some tinctures, instead of simple spirit of wine, where the operation of the volatile alkali properly combines with that of the gum or resin dissolved in the tincture. For external applications in this water and the spiritus ammoniacus, and both caustic and effervescent, are employed according to the strength of the remedy required. The caustic solution makes, by much the most rapid and permanent union with oils, whence it is preferred in that delicate preparation, the Eau de Luce.

AMMONITE, or納土石.

The ammonite is a fossil univalve, many chambered shell, of a flattened spiral figure, containing many circumvolutions, which decreases in bulk gradually from the circumference to the centre; all the circumvolutions may be divided by the same horizontal plane, and therefore the whole of the spiral is visible on each of the flattened sides. From its resemblance to a man's horn, or rather to the compressed spiral horn with which the figures of Jupiter Ammon are generally represented, it has derived its common name. The vulgar consider it as a petrified snake; hence its appellation of snakebone, &c. He least reflection, however, ought long ago to have destroyed this error, if men in general were as capable of finding out differences as they are willing to see resemblances. A snake always coils himself up, so as to have his head in the centre of the spiral, and therefore the volume of the spires diminishes as they approach the circumference, whereas in the ammonite precisely the reverse takes place.

Ammonites are found of all intermediate sizes, between those which are scarcely visible to the naked eye, and a speciem in the British Museum, above three feet in diameter, and weighing about one cwt. The number of circumvolutions, however, is by no means according to the size of the shell; there are few perfect specimens which contain less than five, and hardly any that exhibit more than twelve. Of some the external surface is smooth, of others it is rugose, or flattened, or tubed, or toothed. In fact there seems to be included, under the term ammonite, a very large natural family of shells, agreeing in certain essential characters, but remarkably differing in others; not fewer than thirty different kinds have been found in the neighbourhood of Bath. Schuchzer, in his "Natur. historie des Schweizerlandes," enumerates 149 varieties, and Rofius has added to the catalogue nearly 300.

There are three species of fossil shells, which have been occasionally confounded with the ammonite.

The first of these is the nautilis, or fossil nautilus; and although the extremes of the two species are readily discriminated from each other, yet the intermediate varieties of the ammonitiform nautilus, and the nautiliform ammonites may without much impropriety be classified under either species. In general, however, the nautilus has much fewer circumvolutions, and these do not gradually increase in capacity from the centre to the circumference, as is the case in the ammonites; but the exterior volume is rapidly and largely dilated, so as to be of much greater dimensions than that which immediately precedes it.

The spurious ammonite, or umbilicate, in external appearance, has a great resemblance to the real ammonite, but totally differs in its interior structure by not being divided into cells or chambers.

The
AMM

The linnite is another spiral many-chambered shell, but may, without much difficulty, be distinguished from the ammonite, as its volutes are fewer, do not touch each other, and the exterior one approaches nearly to a straight line.

Of all the fossil shells ammonites are perhaps the most numerous and most generally diffused; they are found principally in calcarceous strata, and are the only organized remains that have been met with at very great heights: De Luc has discovered them on Mount Grenier, 7500 feet above the level of the sea: they also occur in marl, flate, indurated clay, and argillaceous sandstone. The internal cavities of the shell are usually filled with calcarceous spar; at other times the whole substance is penetrated with pyrite, and occasionally is met with completely agatized.

The race of animals, of which these are the remains, has probably been long extinct, no naturalist having met with living ammonites more than a few lines in diameter, and even these have been, for the most part, proved to be only nautilus. In the account of the ill-fated voyage of La Perouse is a memoir by Lamanon, describing a living ammonite, four lines in diameter, found in the Florida of a bonnet, caught in the South Sea between the tropics; but this supposed ammonite, from the figure and description, is probably a nautilus; the exterior volute is by much the largest, and the number of circumvolutions is only two and a half. It was, indeed, an opinion of Linnæus, that living ammonites, corresponding to all the fossil varieties, were still existing in the depth of the ocean; hence they have obtained the name of Pelagian shells: this, however, cannot be proved, and is rendered improbable for the following reasons: first, the shell of the ammonite is very thin, whereas those of animals that live at great depths is always thick. Secondly, ammonites are almost always found mixed with turbines, buceina, and other common shells, which, while alive, are now known to inhabit shallow seas, and are daily thrown up on every coast; the living ammonite, therefore, if still in existence, would probably be found in similar situations, and be occasionally thrown upon the shore, together with those shells by which, in a fossil state, it is commonly found to be accompanied.

AMMONITES, in Ancient History, the defendants of Ammon, took possession of the country called by their name, after having driven out the Zamzummas, who were its ancient inhabitants. The precise period at which this expedition took place is not ascertained; nor does history inform us to any great degree concerning the manners and customs of these people. They had kings, and were uncircumcised, (Jer. ii. 25, 26.) and seem to have been principally addicted to husbandry. They, as well as the Moabites, were among the nations whose face or prosperity the Israelites were forbidden to despise. (Deut. xi. 29, 30.) However, neither the one nor the other were to be admitted into the congregation to the tenth generation, because they did not come out to relieve them in the wilderness, and were concerned in hiring Balaam to curse them. Their chief and peculiar deity, in Scripture, called Moloch; and Chemosh was also a god of the Ammonites. Before the Israelites entered Canaan, the Amorites conquered a great part of the country belonging to the Ammonites and Moabites; but it was re-taken by Moses, and divided between the tribes of Gad and Reuben. Before the time of Jephthah, ante Chrill. 1188, the Ammonites engaged as principals in a war, under an anonymous king, against the Israelites. This prince, determining to recover the ancient country of the Ammonites, made a sudden irruption into it, reduced the land, and kept the inhabitants in subjection for 18 years. He afterwards joined Jordan with a design of falling upon the tribes of Judah, Benjamin, and Ephraim. The Israelites refilled the invaders; and assembling at Mizpah, chose Jephthah for their general, and sent an expostulatory message to the king of the Ammonites. (Judge, x. 15.) The king replied, that these lands belonged to the Ammonites, who had been unjustly dispossessed of them by the Israelites when they came out of Egypt, and exhorted Jephthah to restore them peaceably to the lawful owners. Jephthah remonstrated on the injustice of his claim; but finding a war inevitable, he fell upon the Ammonites near Arar, and defeated them with great slaughter. On this occasion the Ammonites loft 20 cities; and thus an end was put, after 18 years bondage, to the tyranny of Ammon over the Israelites beyond Jordan.

In the days of Saul (1 Sam. xi.) ante Chrill. 1075, the old claim of the Ammonites was revived by Nahash their king, and they laid siege to the city of Jabesh. The inhabitants were inclined to acknowledge Nahash as their sovereign; but he would accept their submission only on condition, that every one of them should confess to lose his right eye, and that thus he might fix a lasting reproach on Israel; but from this humiliating and severe requisition they were delivered by Saul, who vanquished and dispersed the army of Nahash. Upon the death of Nahash, David sent ambassadors to his son and successor Hanun, to congratulate him on his accession; but these envoys were treated as spies, and dismissed in a very reproachful manner. 2 Sam. x. This indignity was punished by David with signal rigour. Rabban, the capital of Hanun, and the other cities of Ammon, which refilled the progress of the conqueror, were destroyed and razed to the ground; and the inhabitants were put to death with circumstances of extreme severity. In the reign of Jehoshaphat the Ammonites united with their brethren the Moabites, and the inhabitants of Mount Seir, against this king of Judah; but their hostile attempts were refilled, and they were completely routed. They were afterwards overthrown by Uzziah, king of Judah, and made tributary, 2 Chron. xxvi. 5. But rebelling in the reign of his son Jotham, they were reduced to the necessity of purchasing peace at a very dear rate. After the tribes of Reuben, Gad, and the half tribe of Manasseh were carried into captivity by Tiglath Pileser, ante Chrill. 740, the Ammonites and Moabites took possession of the cities belonging to these tribes, and were reproached for it by Jeremiah. Ch. xxix. 1. Their ambassadors were exhorsted to submit to Nebuchadnezzar, in the typical language of the prophet, and threatened, on their refusal, with captivity and slavery. Ch. xxxvii. 2, 3, 4. The prophet Ezekiel, ch. xxxiv. 5.—10, denounces their entire destruction, and informs them, that God would deliver them up to the people of the east, and that the Ammonites should no more be mentioned among nations; and this punishment they were to suffer for insulting the Israelites on account of their calamities, and the destruction of their temple by the Chaldeans. This punishment is supposed to have been inflicted upon them in the fifth year after the taking of Jerusalem, when Nebuchadnezzar made war against all the people around Judea, A. M. 3420 or 3421, ante Chrill. 583. It is probable that Cyrus granted to the Ammonites and Moabites liberty to return into their own countries, whence they had been removed by Nebuchadnezzar; for they were exposed to the revolutions that were common to the people of Syria and Palestine, and subject, sometimes to the kings of Egypt, and sometimes to the kings of Syria. Polybius (lib. v.) informs us, that Antiochus the Great took Rabbath,
AMMONITIS, in Ancient Geography, the country of the Ammonites. It was a district of Arabia Deserta, extending from south to north to the coast of Paludis. The limits to the well and partly to the north were the river Jabbok, which ran, according to Josephus, between Rabboth-Ammon, or Philadelphia, the capital of Ammonitis, and Gerafa, and fell into the Jordan. They had also the river Arnon on the west, which divided them from the land of Gilead, or the tribe of Gad; on the south they had the Ishmaelites, on the west the deferts of Arabia, and on the north the hills of Gilead and Bashan. The territories of the Ammonites seem, according to the sacred historians, to have been anciently confined by the river Arnon and Jabbok; but their frequent conquests on their neighbours occasioned their boundaries to be in a state of constant fluctuation. Reland. Lib. i. p. 153—154.

AMMONIUS, in Biography and History, was general of Alexander Bala's troops, and accursed by Polybius Philometer of a design to poison him. In his attempt to cleave from Asia, in the disguise of a female drab, he was apprehended and put to death. A. M. 3369, ante Christ. 145.

AMMONIUS, a Peripatetic, was a native of Egypt, and flourished about 150 years before Christ. He was the disciple of Plotinus, and is frequently mentioned by him, without either commendation or reproach. He attempted to extend the authority of Aristotle beyond the limits of his own sect, by blending the Platonic and Stoic doctrine with the Peripatetic. He taught and died at Athens. Suicides. Fabricius. Brucker's Phil. by Entfild, vol. ii. p. 114.

AMMONIUS, Saccus, so called, as it is supposed, from his early occupation as a porter in the harbour of Alexandria, was an eminent Alexandrian philosopher, and flourished about the beginning of the third century. He was born of Christian parents, and was betimes instructed in the clerical school established at Alexandria. Under the Christian preceptors, Athenagoras, Pantanus, and Clemens Alexandrius, by whom this school was conducted, and who united Gentile philosophy with the Christian doctrine, he acquired a strong propensity towards philosophical studies, and became exceedingly defirous of reconciling the different opinions which at that time subsisted among philosophers. To him we must refer the complete constitution of the sect of the Eclectics, which had been first projected by Ptono, a Platonist. Porphyry affirms, that Ammonius passed over to the legal establishment, that is, apostatized to the Pagan religion. Eusebius and Jerome, on the contrary, affirm, that Ammonius continued in the Christian faith to the end of his life. But it is probable, that these Christian fathers refer to another Ammonius, who, in the 16th century, wrote a Harmony of the Gospels, or to some other person of this name, for they refer to the sacred books of Ammonius; whereas, Ammonius Saccus, as his pupil Longinus affirms, wrote nothing. Porphyry's testimony is more worthy of reliance than that of Eusebius, because he was nearer Ammonius Saccus than the Christian father, and he must have derived his information from his master Plotinus, who spent 11 years with Ammonius. Besides, it is not easy to account for the particular felated in this philosopher, without supposing that he renounced the Christian faith. It seems improbable that a Christian would have accepted the chair in a Pagan school, or would have been followed by disciples who waged perpetual war against Christianity. However, it sufficiently appears, that he was well acquainted with the Christian doctrine, and endeavoured to incorporate it into his system.

According to Hierocles, Ammonius was induced to execute the plan of an Eclectic school, by a desire of terminating the contentions which had long distracted the philosophical world; and he believes great praise on the institution of philosophy, which he established for this purpose; or with a view of evincing the harmony that subsisted between the doctrines of Plato and Aristotle in all the great and essential points, and introducing a system free from dispute. Ammonius had many eminent followers, both Pagan and Christian. He taught his select disciples certain sublime doctrines and mystical practices, and was called Sibylus, the heaven-taught philosopher. These mysteries were communicated to them under a solemn injunction of secrecy. Porphyry relates, that Plotinus, with the rest of the disciples of Ammonius, promised not to divulge certain dogmas which they learned in his school, but to lodge them safely in their pure minds. The circumstances accounts for the fact mentioned by Longinus, that he had left nothing in writing. Ammonius probably died about the year 243. Amongst these disciples who were admitted to the knowledge of his mysteries were Herennius, Origenes, Longinus, and Plotinus. The two former violated their promise by divulging the secrets of the school of Ammonius; in consequence of which Plotinus thought himself no longer bound by his promise, and became a public preceptor in Philosophy upon Eclectic principles. Porphyry. Vit. Plotini. Suads. Fabric. Bib. Graec. tom. iv. c. 26, p. 154, &c. Lardner's Works, vol. ii. p. 441. Brucker by Enfield, vol. ii. p. 63, &c. Ammonius, a Christian writer of Alexandria, lived about the year 220, according to Cirec, and though his time is uncertain, has been confounded by him and many other learned men with Ammonius Saccus. Eusebius mentions a person of this name, who was a presbyter of Alexandria, and suffered martyrdom in the Antonian persecution; and we might be apt to think this to have been the writer, if Eusebius had not been of a different mind. St. Jerom speaks of Ammonius as an eloquent and very learned man, who, among many excellent monuments of his genius, composed an elegant work of the content of Moses and Jesus, and invented the evangelical canons, which Eusebius of Caesarea afterwards followed. The former is quite lost; of the latter we are informed by Eusebius, that Ammonius of Alexandria has left us a gospel compoied out of the four with great labour, fubjoining to Matthew's gospel the confonant paffages of the other evangelists; and that he had compoied, in another method, ten canons, which are there subjoined. The evangelical canons, though they are reckoned among the works of Ammonius, may have been probably Eusebius's invention, whilst the harmony of Ammonius's might have suggested the design. Whether this harmony be still extant is a subject
a subject in dispute. Cave and Mill agree in supposing, that it is the larger of the two which we now have in Latin. Mr. Jo. James Wetten will not allow this work to have been composed by Ammonius, but thinks it the production of some writer since Eusebius. Dr. Lardner supposes this work to have been interpolated since it was first composed, and even the form of it to have been altered.

Ammonius, the Grammarian, lived in the fourth century, and, according to Socrates, the ecclesiastical historian, was a pupil of the grammarian Hellenicus of Egypt. He fled from Alexandria in 380, when the heathen temples were destroyed by order of the emperor Theodosius. Phoebus speaks of him as a great admirer of the Greek poets, and an indolent critic in the Greek language; and to him we owe a treatise on Greek synonyms, entitled "Περὶ οἰκονομίας Συμμετρικὴ." "On words of similar and different significations," in the form of a dictionary. It was first published in Venice in 1497, and afterwards at the press of Aldus, as an appendix to a Greek and Latin lexicon. published in folio, at Venice in 1524, at Paris in 1521, at Bâle in 1532, and annexed to Stephens's Theaurus in 1572, and to Scalap's Lexicon. Fabricius Bib. Græc. lib. iv. c. 26. tom. iv. p. 173. Ammonius, a Peripatetic philosopher, was the son of Hermias, flourished at the beginning of the fifth century, and taught at Alexandria under the reign of Anastasius. He was the disciple of Proclus, and the preceptor of Simplicius, Afelepius the Trallian, John Philoponus, and Damascus, by the latter of whom he is represented as superior to the other philosophers of his age, and particularly excelling in mathematical learning. His commentaries upon Aristotle and Porphyry are still extant. His commentary upon Arisotle's book "De Interpretatione," together with a Commentary on the Categories, was printed by Aldus in folio, at Venice, in 1503. An age out from this work on Providence and the foreknowledge of God, and free will of man, was published by Grotius, at Paris, in 1648, and at Amsterdam, in the third volume of his theological works, in 1679. His Commentary "In Hæcogen Porphyrii de quinque Præceptis" was printed by Aldus, at Venice, in 1500, and has passed through several editions. Fabric. Bib. Græc. vol. iv. lib. iv. cap. 26. p. 161.

Ammonius, Alexanderinus, an ancient sargone of Alexandria, called also Lithotomus, from having invented an instrument, a kind of file or saw, for breaking or dividing bones generated in the bladder, and which are too large to pass through the natural passages in their entire size. With what facility this art, (which is obscurely hinted at by Celsus) was practised, we are not acquainted. It has long since been lost, and the title Lithotomus, given to perfons cutting into the bladder, and extracting the bones through the wound. But those, Le Clerc observes, should rather be called Cytoplomiths. Hillebr. Bibl. Chirurg. Ammonius, Andrew, a native of Lucena, who settled in England in the beginning of the 17th century, and lived for some time in the house of Sir Thomas More, and afterwards in St. Thomas's college, not being in circumstances that allowed him a house of his own. At length he was appointed secretary to Henry VIII. and honoured by Pope Leo X. with a public character at the court of this prince; but his views of higher and more lucrative advancement were disappointed in middle age by his death, occasioned by the sweating sickness in 1517. He was distinguished by the intimate friendship and frequent correspondence that subsisted between him and Erasmus. Erasmus, in the humorous advice which he gives him as to the most effectual method of advancing his fortune, desired to satirize the usual methods that are adopted for this purpose. "In the first place," says he, "throw off all sense of shame; thrust yourself into every one's business, and show out whomsoever you can; neither love nor hate any one; measure everything by your own advantage; let this be the scope and drift of all your actions. Give nothing but what is to be returned with usury, and be complaisant to every body. Have always two things to your bow. Reign that you are solicited by many from abroad, and get every thing for ready for your departure. Shew letters inviting you elsewhere, with great promises." Erasms. Epiph. xiiii. lib. 8. p. 474. Erasmus (Epil. v. lib. 23.) thus laments his death. "How many of my companions have I lost! in the first place, Andrew Ammonius of Lucena: Good God! what a sprightly genius! of what a faithful memory! how noble was his soul! how free from envy and every meanness! when his own qualifications, and the applause of princes had opened him a way to the greatest affairs, he was suddenly snatched off before he was forty- five years of age, the loss of whom I cannot but lament, as often as I reflect how delightfully I was with his acquaintance!" What he writes to Erasmus in one of his letters, viz., that the burning for so many heretics had raised the price of wood, must be regarded as an hyperbole. Ammonius wrote some Latin poetical pieces. Gen. Dict.

AMMOSCHISTA, in Nature History, a genus of flies of a laminated structure, and splitting only horizontally, or into flat plates. The genus aumoschista are coarse, hard, and rough flies, of a very hoarse texture, and appearing something porous. They are considerably heavy, and composed of a large, coarse, and obtusely angular grit, surrounded, and in part held together, by a hoarse earthy spar. They are very soft, and friable in the mass, but much more so when reduced to small pieces. They make a violent effervescence with aqua fortis, and will not easily strike fire with flint.

The species of aumoschista are fix.

AMMUNITION, in general, signifies all sorts of war-like flies and provision, more especially powder and ball. The word is ammunis, which, according to Du Cange, was used in the corrupt state of that language for justissimum. Ammunition for small arms, in the British service, is generally packed in half hulks or kegs, each containing 1000 muskets or 1500 carbine cartridges. An ammunition wagon will carry 20 of these kegs or barrels, and an ammunition cart 12 of them. The cartouch boxes of the infantry are made of so many different plates and sizes, that it is impossible to say exactly what ammunition they will contain; but most of them can carry 60 rounds. See Cartridge. The French pack all their ammunition in wagons without either boxes or barrels, by means of partitions of wood. Their 12-pr. wagons will contain 14,000 musket cartridges, and their 4-pr. waggon 57 only 12,000 each.

Ammunition, or gun-powder, may be prohibited to be exported at the king's pleasure, by 12 Car. ii. cap. 4. fe&c. 13. By 1 Jac. ii. cap. 3. fe&c. 2. ammunition, arms, utensils of war, or gun-powder, imported without licence from his Majesty, are to be forfeited with treble the value. Such licence obtained, except for the furnishing of his Majesty's public stores, is to be void, and the offender to incur a prenominy, and be disabled to hold any office from the crown. Whoever is curious to know the quantity of ammunition necessary for the siege of a place, may consult the chevalier de St. Julian's treatise, De l'art de faire des mines, and the quantity requisite for the defence of a place, will be found in Sireux de St. Remy's Memoires d'Artillerie. See Artillery.

Ammunition-bread, flies, &c. what is provided for, and distributed to, the soldiers of an army or garrison.
Such an officer has so many rations of ammunition, bread, &c. 

*AMMUNITION CERT*, a two-wheel carriage with shafts; the sides of which, as well as the fore and hind parts, are inclosed with boards.

*AMMUNITION WAGON*, is generally a four-wheel carriage with shafts; the sides are railed in with rails and raves, and lined with wicker work, so as to carry bread, and all sorts of tools.

*AMNA*, in Physical Writers, denotes the water found in limy soils, and which is consequently tinged with a whitish colour, as in many places of England.

In this sense Paracelsus speaks of the medical virtues and uses of *aman*.

*AMNESIA*, in Medicine, loss of memory. It is sometimes a consequence of febrile diseases, generally receding as the patient gains his strength.

When it is the consequence of old age it can hardly be expected to be cured.

*AMNESY*, or Amnesia, from α, not, and ἀμνής, I remember; a kind of general pardon, which a prince grants to his subjects, by a treaty or edict, wherein he declares, that he forgets and annuls all that is past, and promises not to make any farther inquiry into the same.

The word is ἀμνής, ἀμνιᾶς; which was the name of an ancient law of this kind, passed by Thrasybulus upon the expulsion of the thirty tyrants out of Athens. Andocides, an Athenian orator, whose life is written by Pherarch, and of whom we have an edition of the year 1575, gives us, in his Oration upon Mysteries, a formula of the amnesia, and the oaths taken thereupon.

Amnesties are usually practised upon reconciliations of the sovereign with his people, after rebellions, general defections, &c.

Amnesty is either general and unlimited, or particular and restrained, though most commonly universal, without condition or exceptions; such as that which passed in Germany, at the peace of Osnaburgh, in the year 1648.

Amnesty, in a more limited sense, denotes a pardon granted by a prince to his rebellious subjects, usually with some exceptions; such was that granted by king Charles II. at his restoration.

Amnesty also, in a military sense, signifies the pardon granted by a sovereign to deferrers, on condition of their rejoining their regiments.

*AMNIAS*, in Ancient Geography, a river of Phaphagonia, that roes in the country called Domainis, north west of Germanieopolis, and discharged itself into the gulf of Amicus.

*AMNICA*, in Conchology, a species of *Tellina*. Shell somewhat heart-shaped and transfervely grooved with an obtuse protuberance. Limneus. This is an European shell, and inhabits pools and ditches; it is less globose than tellina cornea, but about the same size. Infuse blue, shining; out side whitish or yellow brown, with one or two blackish ribs. Young ones entirely white andpellucid.

*AMNIMODAR*, in Astrology, the planet that rectifies a geniture, or rather a method of rectifying a nativity, and finding the precise degree in the horizon at the time of an infant's birth, from the condition of the planet, which had the rule in the last preceding conjunction, or opposition of the luminaries. Vital. Lex. Math.

*AMNISOS*, or Amision, in Anatomy, the innermost membrand of the ovum, which contains the fatus and the waters.—The word seems to be derived from ἀμνός, a lamb; q. d. pellis agnia, lamb's skin. See Generation.

*AMNISOS*, liquor of the, chemical properties of. Although the analysis of vegetable and animal substances is as yet less satisfactory than that of inorganic matter, a multitude of improvements have, nevertheless, been introduced of late years into this branch of the science for which we are principally indebted to the French philosophers, Vauquelin, Berthollet, and Fourcroy, by abolishing the old method of analysis by fire, according to which all animal substances afforded the same results, and introducing in its stead the use of the simpler method, have been enabled to discover many peculiar products of animalization. According to the ancient mode, in which Neumann was so long and so fruitlessly employed, of destructive distillation, any animal matter was made to yield first an impure, faint-smelling phlogon, then an impure ammoniacal oil, after which a portion of concrete salt was sublimed, and there remained in the retort a spungy coal of difficult incineration, which, by burning in an open fire, was reduced into a white ash or caput mortuum. If this had continued to be the way of the alyth, we should have contented ourselves with giving an intimation of one as a specimen of the whole; but since a better method has been found out, it will be right to particularize, in their proper places, most of the modern analyses and experiments on animal substances, as, if not quite satisfactory, they are at least well deserving of mention, in a work like the present, and have already been applied to explain the rationale, and improve the practice of some of the most difficult and important among the arts and manufactures.

The liquor of the aminios is a fluid in which all the young of the mammalia are inclosed previously to their birth; and chemistry is indebted to Vauquelin and Buiwiva for an examination of this secretion, as afforded by the human female and the cow.

The first of these liquors presented the following properties. It has a mild faint odour, like that of all the white or colourless animal fluids. To the taste it is slightly saline. Its colour is a dilute white, owing to its containing some particles of a cæsous matter; by filtration, however, it becomes perfectly transparent. Its specific gravity is 1.005. By agitation it froths considerably. On being heated it acquires a semipumice like that of milk with a large proportion of water, at the same time a freedom is developed like that of boiled white of egg. It decidedly changes the colour of tinture of violets to green, and yet finely redens that of tournefol. Pottah occasions a flocculent precipitate, resoluble by a weak acid. The acids appear to have no other effect than that of clarifying it. Alcohol throws down a light precipitate, which, when dry, becomes brittle and transparent like glue. With infusion of gall-nut it yields a very copious brown precipitate. Nitrat of silver causes a white precipitate insoluble in nitric acid.

Hence this fluid appears to contain albuminous matter, similar to that of the blood; a mutistic salt, probably mutuated soda; and a small quantity of free or carbonated alkali.

When evaporated to dryness it leaves a residue no greater than 0.12 of the mafs. This, by lixiviation and evaporation, affords crystals of common salt and carbonated soda, and the remaining animal matter, on being burnt, exhales a fetid ammoniacal odour like horn, and leaves a few white ashes, composed of carbonated soda, and phosphat, and carbonat of lime.

The aminiotic liquor of the cow remarkably differs from the preceding.

It is of a brownish red colour; an acid bitterish taste; an odour approaching to that of vegetable extract; its specific gravity is 1.058; and it has a viscid consistence, like a solution of gum.
It reddens very decidedly the tincture of tournesol. It gives an abundant precipitate with urate of barytes; and, when treated with alcohol, a thick, clear liquid is formed, consisting of redish matter.

When submitted to evaporation a thick fume rises to the surface, and after being reduced to a quarter of its bulk, a number of long, thin needle-like crysalts are produced as the liquor cools; these being all deposited, and the matter further brought by evaporation to the consistence of honey, a fresh production of crysalts takes place; these, however, differ in form from the preceding, and are sulphate of soda.

The extractive matter being separated from the acid crysalts, and from the water which held them both in solution, by means of alcohol, affumes the appearance of a compact, adhesive cement; in colour reddish brown, and of a peculiar indefinable flavour. It is readily soluble in water, to which it gives a viscosity, and the property of frothing by agitation; in this respect it resembles animal mucilage, but differs from this substance in not forming a jelly, nor combining with Tannin. When exposed to the fire, it swells greatly, and gives out at first an odour of burnt mucilage, then of an empyreumatic ammoniacal oil, and finishes with the difengagement of prussic acid. The coaly matter which it yields is bulky, eaily incinerated, and affords a light white ash, composed of phosphated magnesia, with a white tint of phosphat of lime.

The concrete needle-shaped crysalts are brilliant, transparent, lightly red, reddening the tincture of tournesol. They are scarcely soluble in cold water, but readily so in boiling water, from which by cooling they are deposited in long slender needles. This acid combines without difficulty with the caustic alkalis, forming a very soluble salt, but will not decompose the carbonated alkalis, except affixed by heat. It is separated from its alkaline combinations by the mineral acids, in form of a white crystalline powder. It produces no change in the aqueous solution of the alkaline earths, nor does it alter the nitrates of silver, lead, or mercury. By heat it is destroyed, exhaling an ammoniacal odour, mixed with that of prussic acid, and leaves a fputy coal. It is different in its properties from all the known acids, and may be received into the modern nomenclature by the name of the ammoniacic acid. Annales de Chimie, vol. xxxiii. p. 269.

AMNISUS, in Ancient Geography, a small river in the island of Crete, mentioned by Callimachus, Apollonius, and Suidas.

AMNISUS, a port in Crete, probably at the mouth of the above-mentioned river, in which the Cretans pretended, according to Paufanius, that Lucina was born, and where this goddess had a temple and was worshipped. Strabo says, that Amnisus was the port of the town of Causus.

AMNITAE, an ancient people, who seem to have been the fame with the SANNITAE of Strabo, whom he places in a small island to the west of Gaul, and near the mouth of the river Loire. According to him, the women were a fort of Amazons, who allowed intercourse with men only once a year, and who offered sacrifices to Bacchus.

AMNON, a river of Arabia Felix, according to Ptolemy.

AMODOCI, one of the mountains which encompassed the European Sarmatians, according to Ptolemy.

AMOENUS, in Entomology, a species of CURCULIO, described by Fabricius as a native of New Holland; it is black with two white or white spots on the thorax, and live on the wing-cases.

AMOEBAEUM, in the Ancient Poetry, denotes a kind of poem, or composition, wherein two parties speak alternately in the same name of verbs, but so as that he who answers either goes beyond or contradicts the other.

The word is σφίδλην, signifying mutual or alternate. Hence also we meet with σφίδλην αμβικος. Such, e. g., are those of Pliny and Trajan.

AMOEBARI, a kind of ancient Spanish soldier, in great repute for their bravery. These are otherwise denominated by some writers, almaguaeviri.

AMOELAUS, in Ichthyology, a name of a peculiar kind of flat fish, somewhat resembling the sole, and called in some parts of England, the liveret. It is of a very slender, pellucid, and white body, never exceeds three inches in length, and is very smooth to the touch, being covered only with a number of very thin scales, which fall off on touching it. Its flesh is very finely textured, and requires very little dressing.

AMOK, a term signifying slaughter, and used as the exclamation of the Bokanese slaves in the island of Batavia. These slaves, who are brought from the island of Celebes, when irritated by ill usage, are exceedingly dangerous; as in this case they intoxicate themselves with opium, fall into the street, and murder every person whom they happen to meet. This is called running amok, this word being the cry of these desperate wretches. Some have supposed, that from this practice Steele borrowed the idea of the moblock club, mentioned in the Spectator.

AMOL, or AMU, in Geography, a town of Asia, in the country of the Ulbeeks, in Independent Tartary, seated on the Ghion, 115 miles west of Samarcand. N. lat. 39° 30', E. long. 64° 35'.

AMOMI, is used, by the Dutch traders, for what we otherwise call Jamaica pepper.

AMOUM, in Botany, a genus of the monandra monogynia class and order, of the natural order of feßilinे and ina of Jussieu, the characters of which are that the calyx is a perianthium one-leaved, cylindraceous and unequally trilled; the corolla is monopetalous and funnel-shaped, tube cylindraceous, border three-parted, parts oblong and spreading; the stamen two-leaved or two-lipped, lower lip inferted under the upper segment of the corolla, spreading, almost erect, entire or three-lobed; the staminal have no filament, except the upper lip of the stamary, smaller than the lower, and opposite to it, acuminate or three-lobed the tip; the middle or at the end of which grows longitudinally a large oblong anther, geminate, or divided by a longitudinal furrow into two which are one-valved; the pistillum has an inferior, oblong germ, stye filiform, drawn through the future of the antler, stigma turbinate, obtuse and ciliate; the pericarpium a fleshy capsule, ovate, three-cornered three-celled, and three-valved; the seeds are several, covered with a sort of arill aril. Obf. The in- florescence is in a spike, on a distinct spike. Willdenow enumerates 11, Martyn 12, and Gmelin, in his edition of Linneus, 20 species. 1. A. zinziber or zinziber, zinziber major of Rumph. zinziber of Bauhin, intific of Rheed, sciffner sister of Wild. narrow-leaved ginger, with a middle-sized (naked, G. and W. ) scape, ovate spike, (ovate scales, W.) and leaves linear-lanceolate, (ciliate at the tip, W.) The root is creeping by palmate, compressed, fleshy tubers, which become fbruous with age; the culm annual, two feet high, fingle, folid, and upright; leaves half a foot long, smooth, alternate, on short, embracing petioles; the scape separate, eight inches high, thick, round, fcaly, usually without leaves; the spike composed of large ovate, subfucibinate, coloured scale, half closing the flowers; calyx a small double, fpathie, corolla yellow with green with a long slender tube, the segments of the body conical, and nearly equal; stamary reddish brown, ovate, petal-shaped, winged on each side at the base, and somewhat shorter than the corolla; filament, or upper lip of the nec-
very filiform, placed on the corolla and shorter; anther ovate, clavate longitudinally, embracing the filiform style; stigma cylindrical, ciliate at the tip; capsule smooth, containing many oblong seeds. This species, cultivated here by Miller, in 1731, and flowering in September, is a native of the East Indies, and other countries of Asia, and is much cultivated there and in the West Indies. The dried roots furnish a considerable article of commerce from our West India islands; they are of great use in the kitchen and in medicine, and preferred green as a sweet-meat, are preferable to every other root. For the diastatic and medicinal use of ginger, see GINGER. 2. A. zeylanica, zygner haricifolium fylestre of Herr. lampium of Rumph. kentuckyans of Rheed, block iner of B. Winslow. 9. or zerumbet, with a naked scape, oblong, obtuse spike, pubescent scales, and leaves ovate and smooth at the margin. According to Murray, the A. zygner' more aptly distinguished from the A. zerumbet, by its narrow leaves, called enigma by Jacquin, than by the ovate spike, and the latter is more truly distinguished from the former by its broad leaves than by its oblong oblong spike, for the A. zerumbet has equally an ovate spike. This species has the tubers of the root much larger, round, twisted, thick, branched, horizontal, pale-coloured, with little smell and a bitterish taste, but not an ardent flavour like true ginger: culm four feet high, perennial, straight, round and solid like the preceding species; leaves lanceolate, large, smooth, petioled, embracing and ascending obliquely: the scape a foot high, dillint, thick, fealy and red; spike large, round, clofe, one-flowered, red scales; calyx a single acute spathe; corolla pale, with a long tube;nectary of the same colour, petal-shaped, very blunt, bifid, fastened to the throat of the corolla; filament flat, subulate, bent in, adhering to the hinder segment of the corolla, and nearly equal to it; another oblong, fastened to the middle of the filament; cultivated at Hampton Court, in 1698, and flowering with us from September to November, when the flakes perish like those of the true ginger; a native of the East Indies, Cochinchina, &c. and also in Otathea, and the other Society isles. This is used externally in the East in cataplasms and fomentations, but not internally, as spirit or medicine; though Gancis says, that it makes a better preserve with sugar than the other. 3. A. zedoaria, with a naked scape, loose cylindrical truncated spike, and ovate acuminate leaves. This is the A. latumine, with larger ovate acuminate leaves, and scape terminated by an oblong spike of La Mark, zedoaria longa of Bahu, zedoaria officinarum of Petr. zedoaria feua Indorum tamog of Cam. loz. kua of Rheed, zerumbem tommon of Rumph. and zittering iner of W. This species grows in Malabar, and other parts of the East Indies. The flowers have an agreeable smell; the root has an acid pungent, aromatic, and somewhat bitterish taste; its smell is strong, but pleasant; dried and reduced to powder it loses its acid taste, and it is formed into bread by the Indians in a time of scarcity. See ZEDOARY. 4. A. fylestre, paco cercos of Pifio, Brazil. zingiger fylestre major, &c. of Sloane, wild iner of W. great wild ginger, with a naked scape, spike elongated, with oblong ventricose bracts, and leaves broad-lanceolate. This does not differ from the second species, except that the floral rifes eight or nine feet high, that it has much larger leaves, and that, instead of the flowers and fruits being on the end of the same stalk, they are on another about three feet high, immediately springing from the root. It is a native of the wood of Jamaica; the root is warm and stimulates gently, and may properly administer as a stimulant and aperient. 5. A. minor, daasoka vulgo miaga of Kempter, japonifer iner of W. Japanaee ginger, with a very short scape, ovate capsule, and uniform acute leaves. This approaches very near to the A. cardamonum of Java, in having the spike of flowers distinct from the leaves, and ovate capsules, but differs from it in having the scape more falcate and shorter, not oblong and imbricate, the leaves uniform, and merely acute, whereas in the other they are obovate-elliptic, with a long bristle at the tip; they are also much shorter, not only about a span in length, but in the other they are often four feet long. In the leaves it much resembles A. zimber and A. zerumbet; but the spike of flowers is radial, with scarcely any scape. It is a native of Japan, where it flowers in September. 6. A. umbellatum, umbellate, Al. Madagascaricum, major, &c. of La Mark, schramhblattiger iner of W. narrow-leaved ginger, with a naked, very short scape, capitated spike, and linear-lanceolate leaves. The stem is eight or ten feet high, the pedal leaves are very narrow and linear-lanceolate, the scape very short, the spike globose, and tew-flowered, and the capsules ovate. It is a native of the marshes of the island of Madagascar. The seeds have a pleasant aromatic taste, and their smell is agreeable; and hence, says Geoffroy, some have called them grains of paradise; a denomination that more properly belongs to another species. 7. A. cardamonum, cardamomum, with a very simple and short scape, and alternate, loofe bracts, or with the spike radical, fleshy and obovate, and leaves obovate-elliptic and cuspidate, W. This species has thick fleshy roots, resembling those of the large flag iris, which in the Spring send forth many green red-like flanks, that rise to the height of seven or eight feet, garnished with very long narrow leaves, alternate and embracing; the flakes decay in Autumn, and new ones arise from the roots in Spring; the roots thrive and increase, but it has not yet produced flowers in England. In Malabar cardamom is an object of considerable commerce. The Indians also themselves make great use of it, mixing the seeds with their bread, under a notion that it facilitates digestion. See CARDAMOM. 8. A. willoinum of Louvre, globba cripta rubra of Rumphius, rather iner of W. with short righting scape, linear bracteis and villose fruit, or with very short, vagninated scape, roundish spike, and bractes lanceolate and longer than the flower. The smell of the whole plant is aromatic, mild, with a small degree of sharpness, the taste of the fruit, when fresh, sweeteat and pleasant. It is a native of the mountains of Cochinchina; the seeds are much valued by the Chinese, and used medicinally in China. 9. A. medium of Louvre, with spike cauline, branched; and fruit oblong, and broken, without a valve. In Gmelin's Linnaeus, A. medium is characterized as having an oblong three-cornered pyramidal coriaceous capsule and three valves. This species is a native of China, in the province of Yunnan, to the west of Canton. The seeds are used in agues, for culinary purposes, and for increasing the strength of odours in general. 10. A. minor, with a sub-globose, three-furrowed, coriaceous, valvelles capsule. Gmelin. 11. A. globifera of Louvre, with spike cauline, branched, and fruit globose, with an even surface; a native of the mountains of China and Cochinchina, and used in both countries medicinally, in disorders of the bowels, &c. 12. A. biculsum of Louvre, tijane-koa of Rheed, paco-ceilings of Maregrave and Pifio, with spike cauline, simple, rosetting, and fruit roundish and fimbriate; or with spikes foliose and spikèd, under side of the leaves fimbriate, and large flowers of a yellowish white colour; a native of Cochinchina, Malabar, and of Brazil, in woods. La Mark suggests that this species is the costus arboles of Linnaeus. 13. A. echinatum, ammonum 2. of Koenig, globba cripta viridis of Rumphius, flaccidier iner of W. with spike radical, sefili and subglobose, and capsules furrowed, echinated and globose;
A MO
A MO

globose; a native of the thick woods of India. 14. A. ripens of Somnerat, lectarii 1, of Rhode, enef of Herm. kriechender ingewer of W. with ramose decumbent scapes, and lanceolate leaves, W. or procumbent scapes, racemose flowers in the base of the spathes, and leaves lanceolate and acuminate on both sides; a native of the mountains of Malabar. 15. A. graminis paradoxi, grains of paradise, lectarii 2, of Rhode, paradies ingwer of W. with scape branching and very short. This species is little known. It is a native of Guinea, and of the Islands of Ceylon and Madagascar, and was introduced into Few Garden, in 1735, by Lee and Kennedy. See Grains of paradise. 16. A. galanga, MARANTA GALEA of Linnaeus, galanga of Rumphius, galangale, with cauline, erect spikes, subfloridious spathes, and capsule three-cornered-ovate, and smooth. The galangale has an horizontal, creeping root, composed of roundish, twilit, knotty tubers; culm perennial, upright, smooth and fix feet high, leaves ovate, lanceolate, narrow, smooth, upright, length, on embracing petioles, spike oblong; perianth inferior tubuliform, and blunting trifid; corolla superior, yellowish white, segments oblong-ovate, concave and nearly equal; ovary petal-shaped, roundish, emarginate, nearly equal to the segments of the corolla; filament linear, thick, green, grooved longitudinally, longer than the corolla; anther oblong, oblong, embracing a style longer than itself; stigma thick, emarginate; seeds roundish; the smell of the whole plant is aromatic, and it has a biting taste. Linnaeus has made the galangale a species of maranta, but Professor Martyn observes, that the corolla is not nugent, nor five-cleft, nor has two segments spreading, but all the segments, which are three in number, are nearly the same in size and figure. It is properly a species of amomum, as Bergius has made it. It is a native of China and Cochinchina, and is cultivated in both countries. The root and seeds are used there medicinally. See Galangale. 17. A. arboresum of Loureiro, with stem arboreous and calyce fruit. This is a tree about 10 feet in height, with many twilit, spreading branches. It has scarcely any taste or smell, and its use is unknown; the wood is very light, and not even fit for the fire; a native of the island of Sumatra, in a wood, on the easterly soil. 18. A. curcumum of Jacquin, with a scape, having loose spathes from the centre of the leaves. The limb of the corolla is fexfidi. Gmelin. See Curcuma. 19. A. globosa of Koenig, and Rumphius, with stalks solitary, very short scapes, ovate spathes, and leaves alternate, petiolated, bifaried, oblong and acuminate. Gmelin. 20. A. littorale of Koenig, with very short squamule scapes, ovate spathes, very numerous stalks, and leaves nodding at the apices. Gmelin. 21. A. Koenigii, with short scapes, corded spathes, and leaves elongated at the apex and twilit. Gmelin. 22. A. uliginosum of Koenig, with scapes erect-curved, ovate spathes, fingle flowers, with double bracts, and fstellfe leaves. Gmelin. 23. A. jasminum of Koenig, with solitary scapes, ovate spikes, imbricated bracts, and leaves subpetiolated and oblong. Gmelin. 24. A. sepalierrum of Koenig, with solitary scapes, ovated spikes, imbricated bracts, and leaves subpetiolated and oblong. Gmelin. 25. A. kenurus of Koenig, with short scapes, erect and oblong spikes, adpressed bracts, and petiolated leaves. 26. A. nigra of Gaertner, with a berry ovate-globose and fingle-celled, the bace of the corolla funnel-shaped and coronated. Gmelin. Of the several species above-mentioned, the 1st, 2nd, 4th, 7th, 8th, 9th, 11th, 12th, 15th, 16th, 17th, are mentioned and described by Professor Martyn. As to their propagation and culture, he observes, that they are tender, and require a warm floor to preserve them in this country. They are easily propagated by parting their roots, which should be done in the Spring, before they put out new shoots. In parting the roots, they must not be divided into small pieces, especially if they are designed to have flowers, nor should they be planted in very large pots. They thrive best in a light rich earth, such as that of the kitchen garden; and with this the pots should be filled within two inches of the top, and the roots should be placed in the middle of the pots, with their crowns upwards, and the pots should then be filled with the same earth; they should then be plunged into a hot-bed of summer's buds, and sparingly watered, till their stalks appear above ground, when they will admit of more moisture, especially in the Summer months; but in Autumn the watering must not be frequent nor plentiful, and during Winter very sparing. The pots must compactly remain plunged in the tan-bed, for if they are taken out and placed on shelves in the flower, their flowers often shrink, and thus their roots decay. By this management these plants have greatly multiplied, and the common ginger has produced roots, weighing five or six ounces; but the others have been near a pound weight.

In the Weel Indies the ginger thrives best in a rich cool soil; in a more clayey soil the root shrinks less in fielding. The land laid out for the culture of it is first well cleared and hoed, and then lightly trenched, and planted in March or April; it flowers about September; and when the stalks are wholly withered, the roots are fit to be taken up, which is generally done in January and February. Browne cited by Martyn.

Anomum. See Alpinia, Costus, Myrrhus, and Sisone.
Anomum Curcumum. See Curcuma.
Anomum Plunii. See Solarium.
Anomum, in the Materia Medica, a small and rich aromatic fruit, growing in branches like grapes, valued highly for its medicinal virtues. It is commonly clasped among the feeds.

The commentators on Pitsy and Dioecrates, have never been able to agree upon the ancient amomum, the generality of them seek it in fruits different from their. Some will have the roe of Jericho pass for it.—F. Camelli is positive he has discovered the real amomum of Dioecrates, and that it is the jugus or birca, or cherry, growing in the Philippine islands; the grains or berries whereby are worn by the natives about their necks, both on account of their agreeable odour, and of their supposed virtue in preserving from infection, curing the sting of the scolopendra, &c. Phil. Trans. No 248.

Scaliger is confident, that the amomum of the ancients was not a fruit, but the wood itself, which bore some resemblance to a bunch of grapes, and was particularly used in embalming of bodies, and hence, says he, the term Mummy was given to the bodies of Egyptians, embalmed with it. On this account, likewise, all medicines and unguents used in the embalming and preserving of dead bodies, were called amomia.

The ancient amomum was of divers kinds; but the Armenian was most esteemed. It was a hater, drier, and astringent; used as a narcotic to appease pain, cure poisonous bites, inflammation of the eyes, &c.

The true amomum of the ancients resembles the muvat grape, and grows like it, in clusters; it is about the bigness of a large chest-pea, or middling grape, round, membranous, and divided into three cells, which contain several brown angular seeds; the fruit, on being opened, appears to contain three of them. Ten or 12 of these capsules stand together, without pedicels, upon a woody stalk, about an inch long; each single capsule is surrounded with six leaves, set in form of a star; and the part of the stalk, void of fruit, is clothed with leafy scales; of a very strong aromatic taste and smell; the taste is warm and pungent, approaching to that of camphor, and the smell is quick, penetrating, and
and fragrant, resembling that of lavender, but more agreeable. In distillation they yield a large portion of a subtle yellow oil; the bulbs gave the same kind of flavour in a lower degree. These bulbs have long been a stranger to this country.

This fruit was brought from the East Indies; and makes part of the composition of Venice treacle: but the seeds of the amomum vulgare have been used instead of it; and cloves have been also employed as a succedaneum to it.

The modern amomum, used in the shops, under the denomination of amomum vulgare, or amomum officinarum, appears to be the seed of the fison or sum of the ancients, answering to what in English we call hard-baked paste.

It is esteemed a powerful diuretic, and good in nephritic cases. It is also commended as an aperient in general, and prescribed in obstructions of the liver and spleen, and in supplicative affections. The people in some parts of England bruise the seeds, and give them in warm ale, in colics; but those of caraway, or anise, are better. Lewis. See Sisinnium.

AMON, in Geography, a river on the coast of Guiana, well of Arwacas bay, is deep and navigable far into the country, and capable of containing a large fleet. It falls into the ocean about N. lat. 6°, and W. long. 5° 50'.

Amox, a river of Italy, which runs into the Adriatic, about three miles south of the Po.

AMONOSUCK, the Indian name of two rivers of America, in New Hampshire; the one called Upper Amonosuck, rises near the north end of the White hills, runs northerly about 15 miles to a carrying place of about three miles to Amadoggin river, thence it pursues the direction of southwest and well nearly 18 miles, and discharges itself into the Connecticut at Northumberland, near the Upper Coos; the other, called Great or Lower Amonosuck, rises on the west side of the White mountains, and falls into the Connecticut just above the town of Haverhill, in Lower Coos, by a mouth 100 yards wide. About two miles from its mouth it receives Wild Amonosuck, 40 yards wide, from Franconia and Lincoln mountains. This last river is subject to very sudden and impetuous floods.

AMONTONS, William, in Biography, an ingenious experimental philosopher, was the son of a lawyer, who, having moved from Normandy to Paris, and born in 1663. In very early life he was feized with a deafness, which deprived him in a great degree of the pleasures of social intercourse, and led him, for his relief and amusement, to apply with peculiar attention to the study of geometry and mechanics. From these studies he derived so much satisfaction, that he ceased to regret his defect of hearing as an evil, and declined, it is said, seeking any remedy. He also acquired the arts of designing, land-surveying, and building; and extended his researches to the sublime laws by which the universe is governed. He likewise directed particular attention to the nature and construction of barometers, thermometers, and hygrometers; and in 1687 he presented a new hygroscope to the royal academy of sciences, which was very much approved. In 1695 he published a book, in French, entitled, "Observations and Experiments concerning the Construction of a new Hour-glass, and concerning Barometers, Thermometers, and Hygrometers."

To the royal academy, of which he was a member in 1699, he read his "New Theory of Friction," by which he has admirably elucidated an important part of mechanics. He also discovered a method of conveying intelligence to a great distance, in a short interval of time, by means of signals, from one person to another, placed at the greatest intervals from which they could be seen with telescopes; somewhat in the manner of our modern telegraphs. He had a happy talent in devising and executing experiments; and he communicated a great number of observations on the various subjects of air, action of fire, barometers, thermometers, hygrometers, friction, machines, heat, cold, rarefaction, pumps, &c. to the royal academy, which are contained in the volumes of its memoirs, for 1699, 1699, 1702, 1703, 1704, and 1705. His character for integrity, modesty and candour, was no less distinguished than his philosophical genius. His elegy, by M. Fontenelle, is printed in the volume of the Memoirs of the Academy for 1705. In October 1705, an inflammation of the bowels occasioned his death at the age of only 42 years. Gen. Dict.

AMOOR, in Geography, a town of Hindostan, in the county of Guzerat, 51 miles north of Scurat, and 58 south of Ahmedabad.

AMOOR. See AMUR.

AMOPHILA, in Entomology, a new genus propounded by the Rev. Mr. Kirby for a new genus of hymenopterous insects, in the Transactions of the Linnaean Society, vol. iv. The species of this genus are vulgaris, hirufata, affinis, and argentea; the two first are described insects, vulgaris being sphex vulgare of Linn. and Donov. Brit. inf. and hirufata, sphex arenaria of Linn. and Fabr. The two others belong to the genus of spheges in the Linnaean arrangement by Gmelin also. See Sphex.

The essential character of Mr. Kirby's new genus Amopil
ia is, beak conic, inflected, concealing a bident, retractable, tubular tongue. Jaws forcipate, three teeth at the tip; antennae filiform in either sex, with about fourteen articulations; eyes oval; wings flat; sting pungent, and concealed within the abdomen. The Linnaean character of the sphex genus is not distinctly applicable to these insects Mr. Kirby has selected for his new genus, nor to many other exotic species; for the mouth of the Linnaean sphex has no tongue. Gmelin has corrected this error by dividing the genus into families, the first has no tongue, and the second is furnished with one.

AMOR, in Entomology, a species of Hesperia in the Fabrician's syltem. Wings three-tailed, brown; beneath the dill variegated with white, black and yellow, and a golden marginal stripe on the posterior wings. Fabrician. This is truly a Papilio of the plebeii rurales family in the Linnaean arrangement. It is the papilio triopaeus of Cramer, and inhabits the East Indies.

AMORA, in Geography, a town of Affa, in the Arabian Irac, situate on the Tigris, 150 miles south-east of Bagdad.

AMORANS, from AMOR, or APIS, in Literary History, a sect or order of genric doctors, or commentators on the Jerusalem Talmud.

The word is otherwise written amoris, amoratis, amorarum. The amorans are also called, by Scaliger, "philis"; by Alting, "amoratis", or spokes of sentences; by Bartoloccius, "ancretes", or "deceptantes", because they conferred and disputed together in a scholastic manner.

The amorans succeeded the mischmiic doctors. They flourished 250 years; and were succeeded by the fubans.

AMORBACH, in Geography, a town of Germany, in the circle of the Lower Rhine, 12 miles north-east of Heidelberg. AMORDI, AMARDI, or AMARRI, in Ancient Geography, a people of Scythia, according to Pline.

AMORE, in Ichthyology, the name of a tribe of fishes in Morsgrave's Hist. of Brazil, of which he describes three species. 1. The amore paxuma. 2. The amore guzze. And, 3. The amore tinga.

The amore paxuma, or Gobius pisonis, in Gmelin's Linnaean system, has a very broad head, and a very large mouth, but has no teeth. Its body is oblong, and its back and sides are of a dusky iron colour. Its belly,
belly, which is protubent, is white. Its skin is soft; and it has seven fins, besides the tail, which is rounded, at the end. Its flippers are firm and well-tailed.

The amoena is like the former, of an ablong figure; but it grows to fix inches in length. Its head is thick, its pils large, and its mouth is furnished with small teeth. Its eyes are small, their pupils are black, and there is a brown spot on the back. It has seven fins, besides the tail, which is long, and rounded at the end. This species is covered with somewhat larger scales, and is of a rusty iron colour, but somewhat paler on the belly than on any other parts.

The amoena is of the same shape with the former, but is much smaller, and is covered with whitish scales all over, spotted with brown spots. Its tail is brown, and waved with different degrees of that colour. All the three species are eaten, but the first is esteemed the best. They are caught about the American shores.

AMOREVOLI, ANGELO, in Biography, a celebrated tenor singer in the serious opera, was a native of Venice. In 1746 he was the principal tenor in the king of Poland's famous opera at Dresden under the direction of his then maestro di Capella, Hass. In 1742 he arrived in England with Monticella at the beginning of lord Middletown's regency, and remained here 2 or 3 seasons. He surpaas'd in taste and expression all the tenor-singers of his time. He died in 1782.

AMORGOS, in Geography, an island of the Archipelago north-west of Stampalia, which, in the time of Ptolemy (see H. N. liv. iv. c. 121.), bore the name of Amorgos, or Amorgus: more anciently it was called Hipera, and Patage, or Pataga, and, according to Steph. Byz. Patas, Pyliax, and Carcia, containing three principal towns, viz. Arceninos, Minos, and Egeialn. This island is not quite so large as Stampalia; its shores are less winding, and it has fewer capes and points, and of course fewer retreats to navigators. There are none along its eastern coast, which is very steep, and on its western shore there are not more than two tolerably commodious harbours or havens; the one to the north, is called Porto Santi Anna, and the other to the south, which is the ball, is denominated Porto Vathi. The inhabitants of Amorgo were formerly friends to the sciences and fine arts, but they are now devoted to ignorance and superstition. In the country, which gave birth to Simonides, the famous Greek poet, are now to be found no others than papas and calykers, without genius and without knowledge, and distinguished merely by their credulity. They show, in a small chapel, a vase, which they affirm to be a certain oracle, and which the ignorant confut. in order to ascertain the issue of a voyage or enterprise: the vase full of water is a sign of succors, but if it be almost empty, it announces ill fortune. The three ancient towns, Arceninos, Minos, and Egeialn, are now completely destroyed, their foundations are doubtful and there remains of a little town or village, built on an eminence, and monasteries, where miracles are the occupation and the principal revenue of the monks or calykers, who inhabit them. High mountains, and naked and steep rocks, occupy some parts of the island, and in other parts it presents fertile plains and valleys. The abundance of its wines, oil, corn, and fruits, was renowned; and though it still suffices, in a less considerable degree, it has to surmount the obstacles and difficulties of a bad administration. A few districts are still well cultivated, and yield rich harvests; olive trees furnish a tolerably large quantity of oil, in proportion to the extent of the territory; figs are good and common; and the corn is of an excellent quality. This species of large grape with oval seeds, and a succulent and perfumed pulp, called by the Greeks ex-egg, and in France rafin d'Alexandria, here becomes of a considerable size and very delicious. Agriculture retains, in some degree, its ancient prosperity; but the arts, as well as the sciences that direct them, are extinct. At Amorgos are no longer fabricated those rich silks, which, under the name of amorgia, were in great request, both on account of the fineness of their texture, and of the beauty of the colour with which they were dyed. The inhabitants, nevertheless, still apply themselves to dyeing; and they know how to give to their linen a red colour with ardel, a species of bichen which not only clothes the rocks of Amorgo, but also grows on threads of several other islands of the Archipelago. Amorgos is distinguished by the mildness and affability of its inhabitants, and by the beauty of its women, who attached to ancient habits, dignified themselves by the peculiarity of their dress. In this respect they resemble those of Nilo, and Argentaria; with this difference, that the women of Amorgos pass ashawl, or large yellow handkerchief, made of fine wool, over the forehead and the lower part of the face, twirt it round the head in the form of a turban, tie it behind, and suffer a long end of it to hang down the back.

To this island criminals were formerly banished; and thither Thubers exiled Venus Serena.

South of the island of Amorgos, and at the distance of about three leagues, is seen an uninhabited islet, which is called Amorgo Pode, or little Amorgo. The fame island and that of Naxia, or to the west of the former, are other islets equally unincultivated and uninhabited, some of which, covered with lentis (lenticus vulgaris of Turnfort) small cypresses-leaved cedars (cedrus baccata, folio cupreph, &c. of Turnfort) and other wild plants, serve for the feeding of the flocks which are kept on them; while the others, which consist of steep malleys of rocks, delitute of all verdure, are the abode of a multitude of birds of prey. Sannin's Travels in Greece, &c. c. xiv. p. 173-180.

AMORIS POMUM, in Botany. See SOLANUM.

AMORITES, in Ancient Geography and History, were a people descended from Amor (according to the Sepuviots) Hamori (1711717), according to the Hebrew) or the Emorite (in our version), the fourth son of Canaan, (Gen. x. 16.) who first occupied the mountains lying west of the Dead Sea. They also extend themselves to the eartl of the same sea, between the brooks Jabbok and Arnon, from whence they expelled the Ammonites and Moabites. This conquest of Sihon, king of the Amorites, is celebrated by the most ancient poem extant. Numb. xxi. 27-30. Numb. xii. 29, 30. Joshua, v. 17. Judges xi. 19, &c.

When Moses met messengers to Sihon, entreating a free passage through his country, he rejected his request; and marched out against him; but fulfilled a total overthrow at Jazer, and loft his whole dominion. Og likewise, king of Bashan, who confounded the cause of Sihon, and attempted to support the progress of Moses and his people, was vanquished, and fell in battle; and the whole kingdom was transferred to the Israelites. This conquest of the Amorites happened, A. D. 2553, ante Christ. 1451. The prophet Amos (ch. ii. 9) representing their gigantic stature and valour, compares their height to the cedar, and their strength to the oak. The lands possessed by the Amorites on this side Jordan were given to the tribe of Judah, and those which they enjoyed beyond Jordan to the tribes of Reuben and Gad. In Scripture, the name Amorite is often used for the Canaanites in general.

AMORIUM, a city of Asia Minor, which some authors place in Phrygia, but it was afterwards comprised in Galatia. It was in the territory of the Tolistobii, on the river Sangarius. After the 6th century it became an episcopal see, and at length the metropolis of the new Galatia. Michael,
AMO

Amorium, the emperor of Constantinople, was a native of Amorium; and this original fact of the imperial house was adorned with many privileges and immunities; nor was Constantinople itself of much greater value in the estimation of the sovereign and his court. Amorium gives denomination to a war which subsisted between the emperor Theophilus and the Caliph Motaffem, A.D. 858; when the emperor penetrated into Syria, besieged the ancient town of Sozopetra, the birthplace of the Caliph, took it, levelled it with the ground, and marked and mutilated the Syrian princes with ignominious cruelty. In revenge of this injury, Motaffem prepared to attack Amorium. The name of Amorium was inscribed on the shields of the Saracens, and their three armies were united under the walls of the city. Although the wise counsel of the emperor was resolved on the evacuation of the city, to remove the inhabitants, and to abandon the deserted buildings to the refutation of the barbarians. Theophilus determined to defend, in a siege and battle, the country of his ancestors.

The Greeks, in a previous engagement, were repulsed and vanquished; and the emperor vainly hoped, after this defeat, to deprive the fate of Amorium. But the invariable Caliph rejected with contempt his prayers and promises, and detained the Roman ambassadors to be the witnesses of his great revenge. The vigorous assaults of fifty-five days were encountered by a faithful governor, a veteran garrison, and a desperate people; and the Saracens must have raised the siege, if a doomecient traitor had not pointed out the weakest part of the wall, which was decorated with the statues of a lion and a bull. The vow of Montaffem was accomplished with unparalleled rigour; nevertheless in the siege of Amorium above 70,000 Molleans had perished, and their loshs had been revenged by the slaughter of 30,000 Christians, and the sufferings of an equal number of captives, who were treated as the most atrocious criminals. The Caliph's forces being distrietted for want of water, in their return to his new palace of Samaria, in the vicinity of Bagdad, the Christian prisoners rode upon some of them and murdered them; by which act the Caliph was so much exasperated, that he put to death 6000 of the Greeks who had been principally concerned in that commotion. On the bridge of the river Lamus in Cilicia, one day's journey westward of Tarus, 4460 Molleans, 800 women and children, and 150 confederates, were exchanged for an equal number of Greeks. They passed each other in the middle of the bridge, and when they reached their respective friends, they flung Allah akbar and Kyrie eleison. Many of the prisoners of Amorium were probably among them; but in the same year (A. Heg. 231.) the most illustrious of them, the 42 martyrs, were beheaded by the Caliph's orders. Gibbon's Hist. vol. x. p. 67, &c.

The medals of Amorium were bronze, gold, and silver; and Greek medals were struck in this city in honour of Trojan, Caracalla, Geta, and Vespasian.

AMOROSO, in Ital. Muf. implies tenderly; with affection and supplication.

AMORPHA, formed of a priv. and μορφή (form, in Botan.) a genus of the diaphilus decandria class and order, and of the natural order of pappilionaceae or leguminosae; its characters are, that the calyx is a perianthium one-leaved, tubulous, cylindrical and turbinated, mouth erect, five-toothed, obtuse, the two upper teeth larger than the others; permanent; the corolla composed of one ovate, concave petal, scarcely larger than the calyx, erect, inserted into the calyx between the two larger and upper teeth, and placed at the upper face of it; the stigma has filaments very slightly united at the base, erect, unequal in length, longer than the corolla, anthera simple; the pistillum has a roundish, germ, subulate style, of the length of the stamens, and simple stigma; the perforation is a lemma, lateral, reflex; larger than the calyx, compressed, more reflex at the tip, one-celled, and tubercled; the seeds are two, oblong kidney-shaped. There is one species, viz. A. flourifopta, bastard indigo. La Mure mentions a variety. 3. A foliola pellucida pannatis pellucidis glabrositis, which he figures may be a confant species.

This shrub grows naturally in Carolina, where formerly the inhabitants made a coarse indigo from the young shoots, which occasioned their giving it the title of bastard indigo. It rises with many irregular items to the height of twelve or fourteen feet, with very long winged leaves, in shape like those of the common acacia. At the extremity of the same year's shoots, the flowers are produced in long slender spikes, which are very small, and of a deep purple colour; appearing in the beginning of July. After the flowers are pale, the germen turns to a sharp pod, having two kidney-shaped seeds; but these do not open in England. They were sent to England by Mark Catesby in 1724.

This shrub, which Thunberg observed in the great island of Nipon belonging to Japan, is become very common in all the gardens and nurseries near London, where it is propagated as a flowering shrub, for the ornament of the shrubbery. It is generally propagated by seed, sent annually to England from different parts of America, which arrive in February, and are sown in a light soil; they may be also cultivated by laying down the young branches, which in one year will make good roots, and may then be taken off and planted, either in the nursery, or the places where they are designed to remain.

AMORTIZATION, or Amortisement, in Law, the act of turning lands into mortmain, i.e. of alienating or transferring them to some corporation, guild, or fraternity, and their successors.

The word is formed from the French amortir, to extinguijih. See Extinquitament.

The term is also used for the licence or privilege which the king or superior lord grants, to enable such a corporation, &c. to receive lands in mortmain; which otherwise they cannot do.—There is always supposed to be some fine or acknowledgment paid to the king, or the lord, in consideration hereof; to make them satisfied for several accidental fines and profits, which would have fallen to them in the common way, which are hereby cut off.

This practice was borrowed from the ancient Lex Popria, whereby it was forbidden to consecrate any land to religious uses without the consent of the people. See pro Dom. 49.

AMORY, Thomas, in Biography, a presbyterian divine, was born at Taunton in Somersetshire, A.D. 1700. Having finished his preparatory classical education under Mr. Chadwick, he commenced his academical studies at a respectable seminary for the education of dissenting ministers, under the tuition of Mr. Stephen James and Mr. Henry Grove. In 1723 he began to officiate as an occasional preacher; and removed to London to pursue a course of philosophy under Mr. John Eames, an eminent tutor among the dissenters. In 1725 he became the colleague of his uncle Mr. Grove, in the department of classics and natural philosophy; and at the same time he preached occasionally at Hull Bishops, and some other places in the neighbourhood of Taunton. From the year 1730 to the year 1759, he was pastor of a congregation at Taunton; and in 1738 he succeeded Mr. Grove, and became sole tutor of the academy under his care. As a minister and tutor he was much respected and esteemed, on account of his
his comprehensive knowledge, unimpeachable integrity, and exemplary moderation. In 1759 he removed to London, to the great regret of his friends at Tamworth, but principally with a view of more advantageously settling his family; and accepted an invitation to become colleague with Dr. Chandler, and afterword preacher to the congregation at the Old Jewry; and at the death of Dr. Chandler in 1766, he was chosen to succeed him as joint-pastor with Mr. White. His real merit entitled him to a greater degree of popularity than he experienced in the metropolis; but though his talents were not of such a nature as to command a numerous audience, he was distinguished by the respectful and cordial attachment of many judicious and liberal friends. In 1768 he received the honour of the degree of doctor in divinity from the university of Edinburgh; an honour to which his talents, learning, and character justly entitled him. He was morning preacher to the congregation at Newington Green, in connection with the celebrated Dr. Price, of whom a particular account will be given in the course of this work; and he was also appointed one of the six preachers at the Merchants' Lecture at Salters' Hall, and a trustee of the charities of the late Dr. Daniel Williams, whose library contains a valuable collection of books, and is, under its present regulations, daily improving both in extent and utility. He retained his faculties, and his capacity of usefulness, to his death, which happened in the year 1774. His funeral sermon was preached by his intimate friend Dr. Flexman; who, after an intercourse of more than 50 years, declared, "that their friendship had never once been interrupted by dispute or darkened by a frown." Dr. Amory left a widow and six children, one of whom was for many years an eminent banker of the city of London. The subject of this brief memoir, as the writer of it can testify from personal acquaintance, was distinguished by a found judgment and amiable disposition. His piety and benevolence were eminent features of his character, and were fo intimately blended as to command respect and esteem from all who knew him. In the more advanced period of his life, his studies were chiefly directed to subjects of theology and ethics. His sentiments, with respect to some of the principal disputed points, coincided very nearly with those of Dr. Samuel Clarke; his mode of preaching was judicial, practical, and devotional: and though he did not the attribute, he approved himself to the feasible and candid.

AMOS, in Scripture Biography, the third of the twelve minor prophets, in the order of the Hebrew Scriptures, but the second in the order of time, was the son of a shepherd, and, though probably born in the territories of Israel, re-

tired to Tekoa, a village of the tribe of Judah, about five miles from Jerusalem. Under Uzziah, and Azariah, king of Judah, whose reign commenced in the 27th year of Jeroboam II. king of Israel, B. C. 804, Amos began to prophesy; but the precise year is not ascertained. Archbishop Newcome dates the commencement of his prophetic office in the year 823, B. C.; but Falconer in his "Chronological Tables," assigns it to the year 807, B. C. His first predictions were delivered at Bethel, whence he was driven back to his own country by Amaziah, the high priest of Bethel, who accused him before Jeroboam. These occur in the seventh chapter; and the others were pronounced in Tekoa, whither he retired after his banishment from Bethel. His two first chapters contain his prophecies against Damascus, the Philistines, Tyrians, Edomites, Ammonites, Moabites, Judah, and Israel; and the evils he threatened refer to the invasions of Salmonaz, Tiglath-pileser, Sennacherib, and Nebuchadnezzar. Amos also foretold the calamities that would befal the kingdom of Israel, after the death of Jeroboam II. who was then living; the death of king Zecchariah; the invasion of Israel by Phut and Tiglath-pileser, kings of Assyria; the captivity of the ten tribes, and their subsequent restoration. He remonstrates against the prevalent iniquities of Israel, their effeminacy, avarice, and obduracy with regard to the poor, the splendor of their buildings and the delicacy of their tables. He reproves the children of Israel for their pilgrimages to Bethel, Dan, Gilgal, and Beersheba, which were the most famous at that period, and for sacrificing to the gods of these places. The style of Amos is characterized by its simplicity, and by frequent allusions to pastoral life. Jerom (Proem. Comment. in Amos,) referring to the words of St. Paul, calleth him rude in speech, but not in knowledge. Suceeding writers, on the authority of this ancient father, have represented him, as if he were quite rude, and deficient of all the beauties of composition. But a very competent judge has given a very different opinion. Let any one, says bishop Lowth, (Prælectiones de Sacra Poëth. præf. xii. p. 285,) who has sufficient discernment and candour for forming a just judgment, from the writings of this prophet and not from the man, turn over the volume of his predictions, and he will pronounce, that our shepherd prophet is not a whit behind the chief of the prophets.

The time and manner of the death of Amos are unknown. It appears (2 Chron. xxxvi. 22. Is. i.) that Amos was the father of the prophet Isaiah, and of the family of Albur, (1 Chron. ii. 24.) from whose son Tekoa derived its name. Calmet and many others, however, have thought that Amos the father of Isaiah, was a different person, and of royal rank; but there seems to be no sufficient reason for this opinion.

AMOS, or AMUS, in Ancient Geography, a city of Asia Minor, in Caria. Steph. Byz.

AMOTAE, in Geography, a town of South America in Peru, situated near Tumbez, on the coast of the South Sea. The adjacent country, watered by a fine river, is highly improved.

N

AMOUS,
AMP

AMOUR, a town of France in the department of Landes, and chief place of a canton in the district of St. Sever, five leagues both of Tartas, and four leagues and a half south-west of St. Sever. The town contains 1721 and the canton 11,935 inhabitants; the territory includes 1824 square miles and 866 leagues.

AMOVING, in Latin, the act of removing or expelling a person from his place, office, or the like. We have statutes for removing papists out of London and Wollminton, and ten miles round the same. 1 W. and M. cap. 9.

AMOUR, William de St. in Topography, a French cedelaste of the 13th century, was born at St. Amour, in Franche Comté, and became canon of Beauvais, and doctor of the Sorbonne. He distinguished himself in the controversy of 1278 between the Dominicans and the University of Paris. The Dominicans claimed two professorships in the university; but the secular doctors refused their claim, and passed a law, refusing persons of the regular order to one. The dispute was referred to the court of Rome, and Amour was an able and zealous advocate in favour of the university. In a book Concerning the perils of the law Times, he attacked the whole mendicant tribe, and attempted to prove, that the prophecy of St. Paul relating to the pernicious times (2 Tim. iii. 1) was fulfilled in the establishment of the faiths of this order. The book was condemned by pope Alexander IV. and the author was sentenced to perpetual exile from France. Upon the accession of Clement IV. Amour returned to Paris, and in a collection and enlargement of his works, renewed his attack on the character and conduct of the mendicants. By favour of this pope, who respected his talents and merit, he remained un molested till his death in 1272. The mendicants reproached him as a heretic; but by the doctors of the Sorbonne he was highly respected. His spirit and eloquence against idleness and hypocrisy, amassed by humility and facility, justify the panegyric of Molinist, who represents him as “a man of true genius worthy to have lived in better times, and to have adorned a more enlightened age.” His works were published at Paris, in 4to, by Condé, in 1672, but the editor concealed his name, and the place of publication under the figulatory inscription, Conlantiae ad fontis bonae fidei apud aliothophilos. Cave H. L. tom. ii. p. 303. Molinist. Eccl. Hist. vol. iii. p. 202.

AMOUSHE, Raël, in Geography, the Battel of Edirih, a large cape formed by the mountains of the Shenooah, on that part of the sea-coast of Africa, called the Western Province or the province of Tlemfan. At a small distance is the Mere el Amouche, or port of Amouche, which is very safe in weathers winds. Shaw’s Travels, p. 20.

AMOF, an island on the south-west coast of India, where the English East India Company had once a factory, since removed to Canton. It lies west from the nearest part of Formosa island, somewhat more than 3° of longitude, and from the south-east point of China, which is called from Macao, about north north-east. The port of Amof has been described as one of the most convenient and safe harbours in India, on account of the road which is formed by that island between it and the continent, and it is so deep and large as to be capable of receiving 1000 ships of the greatest size, and of protecting them from every wind. N. lat. 24° 30'. E. long. 118° 45'.

AMPARES, a jurisdiction under the archbishop of Plata, eastward of that city, in the empire of Peru; abounding in grain and cattle.

AMPANA, in Botany, a name given in the Hortus Malabaricus to a genus of plants, since described by Linnaeus, under the name of Borassus.

AMPASA, in Geography, a small country and kingdom of Africa, on the coast of Zanguebar, between the line and Mendi. It has a capital of the same name; the king is a vassal of the Portuguese. S. lat. 1° 30'. E. long. 60° 20'.

AMPATRES, a people of Madagascar, on the southern coast between Carambolii and Caneceii, who live in the midst of forells and habit in by plunders.

AMPELS, in Botany, the vine. See Vine.

AMPELLIS, in Ornithology, a genus of birds in the Linnean Syllem, belonging to the order Passeres. The characters of this genus are, bill short, convex, upper mandible long and, somewhat incurvated; each mandible notched. Niphus covered with bristles. Tongue acute, cartilaginous, bifid. Linn. & Gmel. Dr. Latham’s generic character of ampeles is somewhat different, viz. bill short, convex, beading towards the point; near the end of the upper mandible a small notch. Niphus hid in the bristles. Middle toe connected to the outer at the base.

Gmelin describes eleven species of this genus, carinates, carinules, cyana, cocinea, cinainga, criptata, gavialis, maxna, pampadoras, tefra, and vorticuata, which see.

AMPELITES, or candle-coal. See Coal.

AMPELLA, or AMPILLA, in Geography, a city and seaport in Guatimalguil, in that of Mexico, 330 miles south-east of the city of Guatemala, which carries on a brisk trade in cochineal, cocoa, hides, indigo, &c.

AMPILON, in Ancient Geography, a colony of Miltians, in Arabia Felix, transported thither by the Persians.

AMPELOS, or AMPHILUS, a promontory of the island of Samos, to the west of that island, and opposite to that of Tecriis. Amphelos was also a promontory of Macedonia, according to Polonius, in the country called Parana; probably near the mouth of the Axios. Amphelos was also a town of Italy, in Liguria.

AMPULUSIA, or AMPULUSIT, a promontory of Mountanis Lingisana, not far from Tangis, mentioned by Strabo, Polonius, and Mela. It is denominated by the moderns Cape Scarpel. From Mela and Bochart it appears that Cottis and Ampulfitia were, in the Phenician and Greek languages, terms of the same meaning, and that they were deduced from the grapes with which that country abounded. Ampeleia was also a town and promontory of Crete, now called Capo Sovico. It was also a town and promontory of Macedonia, near the gulf of St. Anne, and now called Capo Canfira.

AMPERES, from verbs in both genders, in Antiquity, a kind of vessels, wherein each mariner brought two or three at the same time, one with the right hand, and the other with his left, answering to our scullers. This is also called arhipelium.

AMPEZO, in Geography, a town of Germany, in the country of Tyrol, ceded to Austria by the Venetians in 1505, 12 miles south of Bruneck.

AMPHANE is also a strong place of The Sally, probably the same that called by Scylax Amphineum.

AMPHAXITIS, a district of Macedon, in which was situated the city of Thessalonica.

AMPHEA, or AMPHEA, a town of Melfania, mentioned by Steph. Byz. and also by Pausanias, who places it in the vicinity of Lacoon.

AMPHAIRUS, in Mythology, a famous poet among the Pagans, was the son of Oileus, and great grandson of Mclampus, to whom part of the kingdom of Argos was assigned, as a recompense for some public service. In consequence of this division of Argos, Adrastus, its king, was overpowered by the party of Amphairus, and obliged to abandon the kingdom. Amphairus afterwards married Eryphila, the sister of Adrastus, and he was restored to the throne. During the preparations for the expedition against Therbus,
A M P

Thebes, Amphiaras, who poisefled the faculty of divina-
tion, was forewarned that he should lose his life in this war, and therefore he concealed himself, in order to avoid engaging in it; but his wife, being prevailed upon by a present of a gold chain, discovered the place where he was hidden, so that he was obliged to accompany the other princes, who marched against Thebes. The expedition was fatal to him; for the earth being split asunder by a thunder-bolt, both he and his chariot were swallowed up in the gulf. Pindar and Apollodoros mention this circumstance; and they ascribe the event to the kind interposition of Jupiter, who thus prevented the diabolism of his being killed by Petylemenes, by whom he was pursued. After his death he was ranked among the gods, temples dedicated to him, and his oracle, as well as the sports that were intituted in honour of him, were very famous. He was believed to excel chiefly in divining by dreams, and is said to have been the first who divided by fire. He left in charge with his children to put his wife to death, as soon as they were able to do it. Apol-
doros reckons him among the Argonauts.

AMPHIARTHROSIS, in Anatomy, a neutral or du-
hon kind of articulation; distinguished from the diarthrosis, in that it has no conspicuous motion; and from the synarthrosis, in its not being without febile motion.

The word is derived from συσς, both, and αφθανος, articulation, the amphiarthrosis being compounded of both the other forms.

Mr. Winslow cites, as specimens of this kind of articulation, the conjunction of the first rib and sternum by a single cartilage, and the connections of the vertebrae with each other by the intervertebral fibulæ.

AMPHIBALUS, in Biography, a monk of Carleon, who is said by some to have been a Roman by birth, and to have made his escape into Britain in the time of Duguellan's persecution. Others say, that he was born at Car-
leon, the metropolis of Wales, and that he was rector of the university of Cambridge. He was the preceptor of St. Alban, and instrumental in his conversion; and was crowned with martyrdom.

AMPHIBALLUS, Amphiballon, or Amphimall-
us, among Middle Age Writers, denoted a large marine, such as were the forerunners of the monks, which encompassed the body on both sides, (whence it was called amphiballus, from αμφι, and δαλλα, and amphiballon, from αμφι and μαλλος, a fleece of wool) and which was not barely thrown over the shoulders, like the toga. See CARACALLA.

AMPHIBIA, in Zoology, the third class of animals in the Linneus system, including those which possess, in a certain degree, the power of respiration, and are thereby enabled to live either in water or upon land. The characters assigned by early naturalists to animals of this class are, in many re-
spects, exceptionable; and those of Linnaeus are liable to some objections, as the writings of Count de Cepede, Mr. Schneider, M. Schoepff, and Dr. Shaw have proved in various instances; yet the Linnean arrangement is still adopted with some amendments, and upon the whole this is most ad-
vantageous, till this obscure tribe of creatures is more completely ascertained.

The amphibia are either naked, or defended by an exter-
nal covering; the skins of such as are denominated naked, are in general marked by soft, pitular warts; the coverings of the others are either horny shields, coriaceous integu-
ments, or scales. The lungs of the amphibia differ mate-
rially from those of other animals in the two preceding classes, mammals and fves, consisting in general of a pair of large bladders or membraneous receptacles, variously sub-
divided in different species; and the heart is furnished with one ventricle only. Some late physiologists have, however, ventured to assert, that the hearts of the amphibia are in reality double, or furnished with two ventricles, with a free or immediate communication between them.

In the Linnean arrangement, the amphibia are formerly divided into four orders, viz. 1. Reptila pedata, reptiles; amphibious animals, which breathe through the mouth by lungs only, and are furnished with four feet. 2. Serpentes apodæ, serpents; amphibious animals, breathing through the mouth by means of lungs only, and ditincture of feet, fins, and cars. 3. Mammalia, gliders; animals breathing by means of gills and lungs, and furnished with arms and claws; and 4. Amphipodes, breathing fishes, being placed in their natural order amongst the Pisces, under the title CHONDROPTERYGI; that order now in-
cludes the genera Aipigenus, Chiëma, Synurus, Reja, and Petromyzon; the Lophius genus is separated from the others, and arranged amongst the Pisces BRANCHIOPTERI.

The order of reptiles is divided into four genera, viz. Testudo, Draco, Lacerta, and Rana; and that of serpents into five genera, viz. Crocellus, Boa, Coluber, Anguis, Amphibia, and Caelia. This is the ar-
rangement of Gmelin, to which must be added the genus Siren; a kind of reptile, whose ambiguity of character induced Linnaeus to form the new order MEANTES. Lin-
aoc. Acad. vii. p. 31; et Syll. Nat. vol. i. part ii. Add-
ded. Gmelin has configured this creature to the first genus of fishes, Murana; and Dr. Shaw refutes it to the Siren genus in the appendix to his Zoology, vol. iii. p. 4, Amph.

It may well be doubted whether this, and two other known kinds of the same family be complete animals, or only the larvae or first state of some lizards, as Dr. Shaw very judici-
ously suggests.

The new genera of serpents, not noticed by Gmelin, are Acrochordus, Hydus, and Langava.

Of the amphibia in general, it has been observed, that their bones are more cartilaginous than those of other animals, and many possess the singular power of reproducing their tails, legs, and other parts when destroyed; in this respect bearing some affinity to many marine insects, as crabs, lobsters, &c. Some are viviparous, or hatch the young ones in the eggs, internally, and bring them forth alive; others deposit their eggs, and hatch them afterwards. The eggs differ also, some are covered with a calcaneous shell, others with a tough skin resembling parchment, and many, as in the Rana genus, are perfectly gelatinous. Numbers undergo a metamorphosis, or call their skins; all are extremely tenacious of life, and, from their peculiar internal structure, capable of enduring a longer abstinence than any of the larger tribes of animals. During Winter many remain in a state of torpidity.

Very few of the reptile tribes are venomous; and of the serpents not more than one-fifth are known as such. Those creatures, therefore, which are naked, and without limbs, seem perfectly defenceless, but nature has armed the rept.
not only with the means of offense, but also with the most dreadful means of aggression; and the poisonous serpents, collectively, are undoubtedly the most hideous and formidable tribe of creatures known. The poisonous kinds are furnished with tubular fangs, which are perfectly distinct from the teeth, and situated upon a glandular vehicle on the anterior part of the upper jaw; in this vehicle the fatal fluid is secreted, and when the wound is inflicted, discharges its contents into the fangs, through which it ooze by the linear apertures on one

side,
side, and effects its malignant purpose. The jaws of the serpents are extremely dilatable, and the esophagus so lax, that they can swallow, without mastication, an animal twice or thrice as large as the neck.

**Amphiura.** Anatomy of. See Classification of Animals and Reptiles in Comparative Anatomy.

**Amphibious,** in Natural History, a term applied to those animals which live both on land and in water. In technical language it is confined to those creatures which constitute the amphibia of naturalists; in a general sense it includes the otter, seal, beaver, and various other animals of the mammalia tribe, who live on land, and occasionally go into the water in search of prey; the word being derived from the Latin amphius, both ways, and viv, vita, life; as living in both places.

Dr. Parloss, in an ingenious paper published in the Transactions of the Royal Society, after considering the economy of amphibia, divides them into two sections; first, such as enjoy their chief functions on land, but occasionally go into the water; and secondly, such as chiefly inhabit the water, but occasionally go ashore. Of the first kind he includes the phoca, otters, beavers, and some kinds of rats, frogs, and lizards, the hippopotamus and tæto; and all, which he observes, are capable of remaining for an inconsiderable length of time in the water, to collect their prey, but are compelled to rise to the surface to breathe, and return ashore to perform most of the ordinary functions of nature. The ball are but of two kinds, cels, or water-ferrets, or snakes of every kind.

Most of the amphibia forms, the caflor, or beaver, and other excepted, have peculiar provisions in their structure to fit them for such a various way of living; particularly in the heart, lungs, foramen ovale, &c.

In some of these animals, as the frog, tortoise, &c., the heart has but one cavity, with an artery to receive the blood coming out of it, and a vein to convey it thither. In others, the foramen ovale appears to be still open for the passage of the blood from the ventricle to the arteria ventosa, without the help of breathing.

In the caflor, described by the academicians of Paris, though the foramen was not found actually open, yet the marks of it appeared; and the cause of its closure might be well enough accounted for, by the animal's having been detained a good while in the water, by which the part, having been in diffuse, closed up. In the otter the case is different; there is no appearance of any thing like a foramen; and hence the necessity the creature is under of riling, from time to time above water, to take in air. Phil. Trans. No 124.

The structure of the feet of the caflor pronounces it amphibious at first sight, the fore feet being formed like those of terrestrial animals, who hold their food in their feet, e. g. squirrels, while the hind-feet are fashioned after the manner of river fowl, with webs or membranes between the toes, as the goose, duck, &c.

Some kinds of insects, in different climates, may be said to be amphibious. The dytiscus, notonecta, and napa, undergo all their transformations from the egg, larva, and pupa state in the water, and though furnished in the perfect state with wings, and consequently destined to live on land, seldom quit the water except in the evenings, and confinantly return to it when their flight is over: these are called water-boatles. Others remain in the water only in the first stages of their transformations, and would perish in their native element from the moment they become winged creatures, as is frequently observed of the libellula, ephemer, and phryganæ, and some of the myxus and culicæ; and amongst the latter the transformation of the species pipiens, common gnat, is a striking instance of this remark. In fact many of these creatures which are mistaken for aquatic worms, are no other than the larvæ, or pupæ of amphibious insects, which their parents deposit in the egg state, on the leaves and flake of plants, &c. that grow in the water; and those hatching insinuantly, remain in the water till they become winged insects.

Birds are in a much less degree amphibious. Amongst those which are denominated water-fowls, from almost constantly living on that element, the divers and corvorsants are capable of remaining a considerable length of time under water; perhaps nearly as long as the otter. Swallows would certainly well deserve the title of amphibious, if, as some have imagined, they paused the whole winter in a lake of torpidity under water.

Dr. Hunter observes, that, properly speaking, there are no amphibious animals; for that fish cannot live long without air, though much longer than men.

The term amphibious has been sometimes also extended to men, who have the faculty of living a long while under water. We have various instances of such amphibious men: the divers employed in the pearl-fisheries pollens this faculty in an eminent degree. Credibility itself is staggered at the story of a Calabrian monk, who once of the king of Spain to continue twice twenty-four hours under water; but it is believed that a Sicilian, named the Fiji-Color, by a long habitue from his youth, had so accomplished himself to live in water, that his nature seemed to be quite altered, so that he lived rather after the manner of a fish than a man. Kircher.

**AmphiCida, in Entomology, a species of Papilio.** Wings, indented, above brown, with a connected silk of cincuous waved with brown, beneath, tins grey with black marked nates. Fab. et Gmel.—This species inhabits Africa. Above, the base and margins are entirely brown; cincuous in the middle, with two large undulated waves, the first brown, the second black. Beneath, pale at the base with rufous spots, and undulated lines, apex grey with a row of lunate black marks. Fabricus.

**Amphiblestroides, in Anatomy, a tunic or coat of the eye, more usually called retina.**

The word is compounded of amphi, amphions, and nets, and opho, form, on account of its net-like texture: whence the Latins also call it retinosis.

**Amphibology, from amphi, amphious, and logos, discourse, or Amphibola, in Grammar, a fault in language, whereby it is rendered obscure, and liable to be understood in a double sense.**

Amphibology is chiefly used in respect of a phrase, as equi-vocal is in respect of a word.

Of this kind was that answer which Pyrrhus received, from the oracle, "Aio te, Adæcida, Romanos vincere po!" where the amphibology consists in this, that the words "te," and "Romanos," may either of them precede, or either of them follow the words "po! vincere!" indifferently. See Oracle.

The English language usually speaks in a more natural manner, and is not capable of any amphibologies of this kind; nor is it fo liable to amphibologies in the articles as the French, and most other modern tongues.

**Amphibrachys,** the name of a foot in the Latin and Greek poetry; comprising of three syllables, the first and last whereof are short, and that in the middle long.

The word comes from amphis, circum, and bres, brevis, q. d. a foot short at both ends, and long in the middle.—Among the Ancients it is also called tainius, and fœlius. Dion. l. ii. p. 475.

Such are the words ambris, abris, pateronis, Opis, &c.
Paulanius and Heroëtus, Amphicleia. The Amphictyons, in their decree against the Phocian cities, gave it the name of Ophiaca. This city belonged to the Dryopes, and was pleasantly situated to the left of the river Cephissus, and near Mount Òeta. Amphicleia was famous for a temple and oracle of Bacchus, who, under the character of a physician, pretended to cure all disordered persons that applied to him.

AMPHICTYONS, AMPHICTYONES, in Antiquity, the deputies of the cities and people of Greece, who represented their respective nations in a general assembly; having a full power to concert, resolve, and appoint what they should think fit for the interest of the commonwealth. They were empowered to employ not only the rigour of the laws, in the execution of their decrees, but even to raise troops, if it were necessary, to compel such as rebelled to submit to them.

The amphictyons very much reformed the states-general of the united Provinces; or rather, what in Germany they call the Diet of the empire.

Some suppose the word AMICTYON, to be formed of αμ, about, and χι, or χιετο, because the inhabitants of the country round about met here in council. Others, with more probability, derived it from AMPHICTYON, son of Deucalion, whom they suppose to have been the founder of this assembly; though others will have Acerius, king of the Argives, to have been the first who gave a form and laws to this body.

Androcles, in his History of Attica, quoted by Paulanius, (lib. ii. c. 8. p. 817.) informs us, that from the most early period, deputies from the neighbouring states assembled at Delphi, and that these deputies were, from that circumstance, called Amphictyons; and that consequently, in process of time, this became the prevailing denomination of that high court. According to this account, whether the author’s etymology be right or not, this was an original institution, deriving its establishment from neither Amphictyon nor Acerius, but existing from the earliest ages of antiquity. Dr. Doig (Edinb. Trans. vol. iii. p. 150, &c.) suggests, that as the Hellenes had founded the oracle of Dodona, they probably established also the oracle of Delphi. This oracle acquired great reputation, and the concourse of the people to the temple of Delphi was immense. Its situation was well chosen for this purpose; and it lay nearly in the centre of those petty tribes that afterwards formed the Amphictyonic association. These states, becoming jealous of the growing power of the oriental colonies, determined to hold their conventions at Delphi, in order to concert measures for their mutual security. Both its sanctity and central situation pointed it out as a place well adapted to this purpose. The Hellenic prelates of the temple, superior to the Barbarians in political capacity, would from every nerve to promote a scheme calculated to advance both their honour and their interest. Common sacrifices have, in all ages, been deemed an infallible sign of amity and concord, and also the means of maintaining and promoting them. The confederates would therefore assemble at Delphi to offer sacrifices, and to perform other religious rites on behalf of all the associated tribes. These would serve as an indissoluble bond of their federal union. The confederates, on this occasion, would present liberal donations, and thus greatly enrich the treasury of the temple. It must therefore occur to them, that it would conduce both to their honour and interest to appoint officers for superintending this treasure. Strabo says expressly, (lib. ix. p. 420.) that this was one of the ends of the institution of the Amphictyons. Hence it appears, that the original Amphictyons were a kind of wardens of the temple of Delphi, elected by the suffrage of the confederate tribes. In process of time another class of persons would naturally be added to the former, whose province should be to watch over the civil interests of the confederacy. These two classes of superintendents gradually coalesced into one, and both united in discharging the sacred and civil functions annexed to their office. A tribunal, thus formed and established, reflects immortal honour upon Greece, and demonstrates the wisdom and sagacity of the Hellenes, to whom its institution is ascribed by the ingenious writer above cited, and which he connects, in its origin, with the oracular establishment at Delphi. Had its members been always animated by a spirit of peace, of justice, and of good order, it would have rendered itself for ever respectable; and the associated states under its direction would never have become a prey to the defiled Macedonians.

This council was principally instituted with a view of uniting in the sacred bond of amity the several people of Greece that were admitted into it, and of obliging them, by that union, to undertake the defence of each other, and to be mutually vigilant for the tranquility and happiness of the country. The Amphictyons were also created to be the protectors of the oracle of Delphi, and the guardians of the wealth of that temple, and also to adjudge the differences that might arise between the Delphians and those who came to consult that oracle.

Authors give different accounts of the number of the Amphictyons, as well as the states that were entitled to have their representatives in this council; according to Strabo, Harpoeratios, and Suidas, they were twelve, from their first institution, sent by the following cities and states; the Ionians, Durians, Perrasians, Bœotians, Magnesiens, Achaens, Phthians, Melians, Dolopians, Èonianians, Delphians, and Phocceans. Each of these only reckoned eleven, instead of the Achaens, Èonianians, Delphians, and Dolopians, he only gives these three, the Thebians, Ètans, and Loerians. Lastly, Paulanius’s list only contains ten Amphictyons; namely, the Ionians, Dolopians, Thebians, Èonianians, Magnesiens, Melians, Phthians, Doriens, Phocceans, and Loerians.

In the time of Philip of Macedon, the Phocceans were excluded from the alliance, for having plundered the Delphian temple; and the Lacedæmonians were admitted into their place; but the Phocceans, sixty-eight years after, having behaved gallantly against Brennus and his Gauls, were restored to their seat in the amphictyonic council. Under Augustus, the city Nicopolis was admitted into the body; and, to make room for it, the Magnesiens, Melians, Phthians, and Èonianians, who till then had distinct voices, were ordered to be numbered with the Thebians, and to have only one common representative. Strabo speaks as if this council was exact in the times of Augustus and Tiberius; but Paulanius, who lived many years after, under Antoninus Pius, affirms us it remained entire in his time, and that the number of amphictyons was then thirty.

When the Lacedæmonians, in order to pass any decrees which they thought proper, were for excluding the Thebians, Argives, and Peloponnesians, Timæides (Plut. in Them. p. 122.) in the speech he made to the Amphictyons for preventing that design from taking effect, seems to inform us that there were at that time 250 cities which had the right of sending deputies to this council.

The members were of two kinds; each city sending two deputies, under different denominations, one called συνεχας, whose business seems to have been more immediately to inspect what related to sacrifices and ceremonies of religion; the other ἀντιπάραγοι, charged with hearing and deciding causes and differences between private persons. Both had an equal right to deliberate and vote, in all that related to the common interests of Greece. The former was elected by lot; the latter by plurality of voices.

Though
Though the amphictyons were first instituted at Thermopylae, M. de Valois (Mem. Acad. Bulles Lettres, vol. iii.) maintains, that their first place of residence was at Delphi, where, for some ages, the tranquility of the times found them no other employment than that of being, in we may so call it, church-wardens of the temple of Apollo. In after times the approach of armies frequently drove them to Thermopylae, where they took their station, to be nearer at hand to oppose the progress of enemies, and to order timely succour to the cities in danger. When they assembled at Thermopylae, they held their feasts in the temple of Ceres, near the mouth of the river Aepus. Their ordinary residence, however, was at Delphi.

Here they decided all public differences and disputes between any of the cities of Greece; but before they entered on business, they jointly sacrificed an ox, cut it into small pieces, as a symbol of their union. Their determinations were received with the greatest veneration, and even held sacred and inviolable.

The Amphictyons, at their admittance, took a solemn oath, the form of which is prefixed by Mechin (in Orat. p. 75) never to dwell any city of their right of deputation, never to avert its running waters; and if any attempt of this kind were made by others, to make mortal war upon him; more particularly, in case of any attempt to rob the temple of any of its ornaments, that they would employ hands, feet, tongue, their whole power, to revenge it. This oath was enforced by terrible imprecations against such as should violate it; c. gr. May they meet all the vengeance of Apollo, Diana, Latona, and Minerva; &c. their fruit produce no fruit, their wives bring forth nothing but monsters, &c. lose all their lands, be conquered in war, have their houses demolished, and be themselves and their children put to the sword.

The fixed times of their meetings were Spring and Autumn; the Spring meeting was called Euph在哪，that in Autumn Eust夏。On extraordinary occasions, however, they met at any time of the year, or even continued sitting all the year round.

Philip of Macedon usurped the right of presiding in the assembly of the Amphictyons, and of first consulting the oracle, which was called Pythian. From this time the authority of the Amphictyons began to decline; for he claimed the right of presiding even by proxy both in this assembly and in the Pythian games, of which games the Amphictyons were judges and agonothetes in virtue of their office. This Demosthenes reproaches him with in the third Philippic: "When he does not preside, we say, to him, ‘In your presence, you send your representatives to preside over us.’" After the conquest of Greece by the Macedonians, this tribunal was deprived of its influence. Augustus, too, made some new regulations with respect to the flaves, which were invested with the privilege of sending deputies to this council. Though it subsisted in the days of Paulianus, as we have already mentioned, it was probably of so little repute in the age of Strabo, that this geographer looked upon it as in a manner annihilated.

AMPHIDROMIA, from ἀμφὶ, and δρόμος, a course, in Antiquity, a feast celebrated the sixth day after the birth of a child, called diei luctibus, or lustral day.

AMPHIDRYON, in Biblical and Theological Writings, a veil or curtain usually drawn before the door of the lema in ancient churches.

AMPHIGENIA, in Ancient Geography, a town mentioned by Homer, situate in the southern part of Elis, comprehended by the ancients in Nemea. In this town was a temple of Latona; and the inhabitants pretended that their town had given birth to Apollo.

AMPHILOCHII, a town of Spain, in Gallicia, founded by Tenser after his return from the Trojan war; and so called, as Strabo informs us, from the name of Amphilochoi, one of his companions, now Orestes.

AMPHILOCHIA, a country of Arcadia, situate to the east of the Ambrian gulf, and watered by the river Iachus. The inhabitants were called Amphilytii, deriving their name from Amphilochoi, the son of Amphiaras, and their capital was denominated Aegora Amphilocheorum.

AMPHILOCHIA, a place of Peloponnesus, in Elis. Steph. Byz.

AMPHILOCHIUS, in Biography, a native of Candepolis, was appointed bishop of Iconium, the chief city of Lycisca, about the year 370 or 373. In his youth he studied rhetoric and practised law; but afterwards devoting himself to a religious life, he retired, with his friends Basil and Gregory Nazianzen, into a solitary part of Cappadocia, called Ozaja. After he was advanced to the episcopal office, he affiliated at the first general council of Constan- tinople in 381, and also at subsequent councils in 385 and 394, soon after which he died. His eminence may be inferred from the several letters written to him by Basil, and from the character given of him by Theodoret and others. Jerome joins him with Basil, Gregory, and others, who were equally skilful in secular learning, and in the sacred Scriptures. Of his zeal against the Arians we have ample testimony from Theodoret Exccl. Hist. (lib. v. c. 16) and Sozomen (lib. vii. c. 6) and others. Being very desirous of prohibiting Arian assemblies, and finding the emperor Theodosius remiss in complying with his wishes, he contrived to accomplish his object by the following expedient. Whilst he was in the palace with other bishops, who were paying their respects to Theodosius, he took no notice of his son Arcadius, who had lately been declared Augustus. When the emperor reminded him of this seeming disrespect, and recommended his son to notice, Amphilochus apologised by saying, that he had paid respect to him, and that was sufficient. The emperor was displeased, and said, that a flight put upon his son was an indignity to himself. You are angry, replied Amphilochus, with those who fly your son, and cannot endure it: persuade yourself then, that the God of the whole world is offended with those who blaspheme his only begotten Son, and hates them as ungrateful to their Saviour and Benefactor. This mode of reasoning produced the wished-for effect; and Theodosius soon afterwards, A. D. 385, forbade the assemblies of heretics. But this was not the only way in which the bishop manifested his dislike of heretics; and the law procured for this purpose, and dated July 26, A. D. 385, is still extant, which prohibits all heretics, particularly Eunomians, Arians, and Macedonians, to hold any assemblies of worship in public places, or private houses. He wrote a book against the Manichians, and another work, entitled, "Of Pseudepigraphal Books composed by Heretics," both which are lost. "If they had been extant," says Dr. Lardner, "I suppose they would have given me more satisfaction than the law of Theodosius, which affords not any argument:" nor was Amphilochoi to be commended, adds this mild and candid writer, for procuring that law. A few fragments are preserved of Amphilochoi's book "Concerning the Divinity of the Holy Spirit," and his "Synodical Epistle," edited by Cotelarius. The Latin poem, addressed to Selseus, and containing a catalogue of the books of the Old and New Testament, has been ascribed by many to Amphilochoi;
philochus; but others are of opinion, that it was written by Gregory Nazianzen; they allege that the style is his, and that we have no information that Amphilochoi ever wrote verse. The poem, however, affords evidence of the care and caution of the ancient Christians concerning books received as part of sacred scripture, and the rule of their faith. This and other pieces, probably forgeries, were published by Combetics at Paris, in 1644. Cave H. L. tom. 1. p. 251. Laudner's Works, vol. iv. p. 411, ccc.

AMPHILOCUS, in History and Mythology, the son of Amphiaras, was no less famous as a diviner than his father. He accompanied Amnemon, his brother, to the second war of Thebes, and assisted in killing his mother, according to his father's injunction. After the war of Thebes, he allotted Mopsus in building the city of Mallus in Chio, where he had an oracle; and it is said that he had an altar erected to him at Athens. The answers of the oracle at Mallus were given by dreams; those who came to consult it slept a night in the temple, and that night's dream was the answer required. Dion Cassius mentions a picture done by order of Sextus Condianus, and representing the answer he received from the oracle in the reign of the emperor Commodus. In the time of Lucian (in Philopoeud. tom. ii. p. 552.) Amphilochoi was regarded by the superstition and credulous multitude as a great prophet, and his oracle maintained its reputation. Gen. Dict.

AMPHIMACER, a foot in the Ancient Poetry, consisting of three syllables; the first and last whereof are long, and that in the middle short. The word is derived from the Greek ἀς, cirum, and μακεσ, longus, by reason both extremes are long.

Such are the words ἀσίνθη, ἀσίνθης, ἀσίννεσ, &c. This foot in the Greek is called tetracotis, and sometimes τετρακοτική.

AMPHIMACUS, in Entomology, a species of Papilio. Wings indented, above, black, with a broad bar of shining blue in the middle. Beneath, anterior wings white, posterior wings cincereous. Inhabits India. The body is black. Wings above entirely black except the interrupted bright blue that extends towards the anterior margin. Beneath, from the base to the middle of the wings white, variegated with brown marks; on the posterior pair behind a large white spot, and seven small brown ones, with whith pupils and circles along the posterior margin. Fabricius.

AMPHIMALLIA, or Amphimallum, in Ancient Geography, was a town of the island of Crete, according to Pliney, situate on the north side, and of Sydonia. It gave name to a gulf in the same part of the island. Sonnini supposes, that the Amphimallum of the ancients is that narrow gulf, which is now formed by Cape Malea on the west part, and Cape Trepolaris on the east, and which penetrates nearly two leagues inland. Others place the harbour of Amphimallum between Suda and Retumo, where is only a bad haven. Sonnini's Travels in Greece, p. 243 Olivier (Travels, vol. ii. p. 198.) informs us, that the ruins of Amphimallum are still visible half a league from the sea to the foot of the gulf of Suda. These ruins are now the foundation of a Greek monastery.

AMPHIMALLUM, from αμφι, and μαλλος, a fleece of wool, in Ecclesiastical Writers, amphihitham and amphiboum, from αμφι and βαλλω. See Amphiballus.

AMPHIMASCALOS, in Antiquity, a tunic or coat worn by the Greeks, with two short sleeves, so as to cover part of the arm to the elbow. In general the tunics of the men and women had not sleeves like these parts of modern dress. The coats of freemen were amphimascalos, or had two sleeves; those of slaves only one, and were called επαραμπασκαλος.

AMPHIMEDON, in Entomology, a species of Papilio, with wings uniformly brown, the anterior pair radiated with white: five connected red spots in the middle of the posterior pair, with white lunules. The body is large, brown; anterior part of the thorax variegated with three red lines. From Amboyna. Fabricius.

AMPHIMONE, a species of Phalaena, of the Bombyx family. Wings entire, pale ash-colour, with two black streaks, and a fulvous dot in the middle of the anterior pair. Described by Fabricius from a specimen in the cabinet of Sir Joseph Banks. Inhabits Terra del Fuego. The antennae are greatly pectinated, body hairy, two yellowish lines on the thorax, abdomen with black belt, a single straight streak on the posterior wings beneath. Fabricius.

AMPHINOME, a species of Papilio, with indented wings, above black, clouded with numerous blue marks: an oblique white bar across the anterior wings; beneath the lower wings radiated with red. A native of South America. Linnaeus.

AMPHINOME, in Mythology, one of the 50 Nereids, according to Homer.

AMPHION, in Entomology, a species of Hesperia. Wings entire, blue, margins black: beneath cincereous, with black ocellated spots; posterior wings, with red lined marks, black points, and golden characters. A native of Germany. Fabricius.

AMPHION, in Ancient History, the twin brother of Zethus, was the son of Antiope, the greatest beauty of Greece, by Epaphus, king of Sicily, or, as Homer says, by Jupiter. Having seized the crown of Thebes, in Sicily, from Lagus, the father of the unfortunate Oedipus, he called the metropolis of the Theban government, or at least the lower city, Thebes, in honour, as it is said, of Thebe, their aunt by the mother's side. Homer says, that to secure the crown which he had usurped, he inclosed the city of Thebes with a wall, fortified with seven gates, and a number of lofty towers at a convenient distance from each other. Homer, however, does not say a word of the miraculous powers of Amphion's music, nor of his building the wall, as fables reports, by the sound of his lyre. Pausanias and Plato convey in relating, that he acquired his musical reputation from his alliance with the family of Tantalus, whose daughter Nerissa, he had married; and both these authors say, that Amphion learned music in Lydia, and, bringing it from thence into Greece, was called the inventor of the Lydian mode. As to the effect of music in building the wall, we may observe, that he might probably captivate the people to carry on the work, by diverting them with the music of his harp, as well as persuade them by his eloquence, which contributed to induce them, though in a state of barbarity, to live feebly and harmoniously together. We learn from Horace (Ars Poetica, i. 391.) that Amphion, after the example of Horace, employed the united powers of music and philosophy in civilizing the Thebans.

"Silentes homines facere interpresque deorum/ Cadibus et vienis facio ductum Orpheus; / Dictus ob hoc lenire tigres rabidiformes leones./ Dictus et Amphion, Thebanum conditor arcis,/ Saxa movere lono testudinis, et precce blandanum./ Ducere quo velvet. Fuit late desperia quondam,/ Publica privatis fecernere, facra profanis;/ Concebait proibibere vaga: dare jura maritius;/ Oppida mollii: leges incidere ligno;/ Sic honor et nomen divinis vatibus atque/ Carminibus venit."

"The wood born race of men when Orpheus tamed,/ From aorns and from mutual blood reclaims,"
The priest divin was fabled to affume
The tiger's fierceness, and the lion's rage.
Thus rose the Thian wall; Amphion's lyre,
And soothing voice, the l'it'ming homes inspire.
Poetic wisdom marked, with happy mean,
Tubule and private, sacred and profane;
The wond'ring joys of lawless love supersed'd;
With equal rites the bonds of Hymen blest'd;
Plain'd future towns, and instituted laws;
So ver'e became divine, and poets gained applause."  

Francis.

AMPHIPAGUS, in Ancient Geography, a promontory of the island of Coronea, to the north west.

AMPHIPEUMAS, æffppæf³mas, among Ancient Physicians, a great degree of species or different respirations.  

AMPHIPOLES, from απ'd and πολ.'s city, in Antiquity, archons, or chief magistrates of the city of Syracuse.

They were first established by Timoleon, in the 100th Olympiad, after his expulsion of Dionysius the Tyrant. They governed Syracuse for the space of three hundred years; and Diodorus Siculus affirms us they subsisted even in his time.

AMPHIPOLIS, in Ancient Geography, a city of Macedonia or Thrace, which was an Athenian colony, on the river Strymon, which separated Macedonia from Thrace; but it is not certain on which side of the river it was situated. Pliny places it in Macedonia, but Sylacax in Thrace. Thus by the editors (ib. iv. p. 320.) reconciles this difference of opinion by observing, that it was washed on two sides by the river Strymon, which was divided from its mouth into two channels, in the middle of which the city stood, where its name Amphipolis. i.e. απ'd and πολ.'s; and on the side towards the sea there was a wall built from channel to channel. M. d'Anville gives another etymology of the name, and says, that it signifies a town belonging to two countries, viz. Macedonia and Thrace. The ancient name, according to Herodotus, (l. vii. c. 114.) and Thucydides (ubi supra) was Αμφιπόλις, or the τούτους; and it was called Ακρίς, Εύλιος, whence the Turks have formed Τιμπλιβ, Μύρικα, Χρηματίμας, Χρηματίβλεντας, Χρηματίβλεντας, Κρημπόλα, or Κρημπολίβια. The inhabitants were denominated Amphipolitani. Livy. It was founded thirty years after the defeat of the Perians in Greece; and Miltiades conducted a colony into it. Philip, king of Macedonia, drove the Athenians from Amphipolis, and permitted the inhabitants to form a republic. The Athenians, however, always considered it as belonging to them; and Baphodes, the Lacedaemonian general, took it from them. Nevertheless, Philip recovered it, and promised to relend it to the Athenians; but when he became master of it, he obtained a surrender of it by a treaty of peace.

AMPHIPOLIS was also a town of Syria, on the Euphrates; its Syrian name was Τέρμιδα. It was either founded by Seleucus, or enlarged and adorned by him; and he changed its ancient name. It is the same with the Thasius of Pliny.

AMPHIPPI, in Antiquity, those who practised riding on two horses, by jumping from one to the other.

The word is Greek, απ'dππολπία; they are sometimes also called ταπάρια ψάντα, and sometimes by corruption, επίτερον. The appellation was given to a sort of cavalry in the Grecian armies, who, for their convenience, had two horses a piece, on which they rode by turns, leading the other.

AMPHIPORÆ, from απ'd and πολ.'s, πρώτα, were ships which had prows at both ends, that no time might be lost in turning them, and also on account of the rapidity of streams, and narrows of channels.

AMPHIPROSTYLOS, or AMHIPROSTYLE, in Ancient Architecture, is characteristic of a particular kind of Temple, which had a Porch of four columns, crowned with a Pediment in front, and another of the same form in the back, front, or rear. The porch in front was denominated the Προοσα, and that in the rear the Ποιιασιον. The word is composed of απ'd both, προ before, and ποιιοι column, and signifies "columns in both fronts."  

Vitusnus, in the fifth chapter of his third book, describes seven species of temples differing from each other in the number and arrangement of their columns, of which the amphiprostyle is the third. It is distinguished from the first and second species, by having columns in both its fronts, and from the peripteral and pseudo-peripteral kinds, by having only four columns in each front, and more especially by not having any on the flanks. It is remarked by Sannazato that the Christians never made entrances in the rear of their temples with Porches or portries, similar to those in the front; and for this reason the French have no word to express the polis of the Latins, as distinguished from the pronaos, which they denominate the "Porch." The same remark is true with regard to the English, and probably to all other Christian nations.

AMPHISA, in Ancient Geography, a river in Greece in Melenia, which discharged itself into the Iapygia, according to Paulinius, l. iv. Melenia. c. 23.

AMPHISO, in Mythology, one of the nymphs called Oceania.

AMPHISBÆNA, in Zoology, the name of a genus of serpents in the Linnaean system, in some respects allied both to that of Anguis and Lacerta; like the Celia it is defective of scales, but its skin appears completely annulated, or marked with numerous circles that surround the body and tail. This is the Linnaean character of the genus, to which may be added that the body is equally smooth and cylindrical; and the tail obtuse, and scarcely to be distinguished from the head.

Gmelin enumerates five species of this genus, viz. fulgino£, varia, magnifica, flavus, and alba.

1. Fulgino£. Kings of the body two hundred; of the tail thirty. This species is white, variegated with black or dark brown, and the head is without spots.

2. Varia. Variegated with white, black, chestnut and grey.

3. Magnifica. Variegated with purple, violet, and yellow; head yellowish, and a purplish streak over the eye.

4. Flavus. Variegated with white and brown; head yellow.

5. Alba. Kings of the body two hundred and twenty-three of the tail fifteen. The head of this is accelerated on the fore-part, and narrowed into an obtuse front. Found near ant-hills. Gmelin has relied chiefly on Seba in determining the characters of these species; yet it may be doubted whether that authority is sufficient. The number of annular rings round the body and tail, and which Linnaeus considered as the best specific distinction, is only mentioned in two species, fulgino£ and alba; the characters of the others, being only taken from the variations in their colours, are not satisfactory. The five kinds mentioned by Gmelin are natives of America.

Dr. Shaw terms to have considered the three species, varia, magnifica, and flavus, as varieties of fulgino£; for he observes, that only two species of this genus, amosphedra, have hitherto been discovered, viz. alba and fulgino£.

A. alba is from fifteen to eighteen inches, and sometimes two feet in length; the colour white, but sometimes inclining to pale yellow or brown; the head very short, the eyes very small; the mouth of moderate width, the teeth short, strong, not very sharply pointed, and constricting a single row of about fourteen or sixteen in each jaw; the tongue very large broad, thick, flat like, and bind only at the tip, the surface of the
the bafe appearing scaly. This is found in woods preying on insects, worms, &c. It is a harmless animal, but it is said, that on handling it for some time the skin becomes affected with a slight itching, accompanied by small pustules, owing to an aeromonia moisture exuding from the animal. 

A. fuliginosa is rarely so large as the preceding species, which it resembles in its manner, and is equally harmless. The Count de Cepede observes, that above the vent is a row of small perforated papillae, similar to those in many of the lizard tribe. The skin of the amphibia is remarkably strong and tenacious, and of a smooth and glossy surface, and it is probable that they are enabled with great facility to perforate the ground somewhat in the manner of earth worms, in order to obtain occasional supplies of food. Dr. Shaw.

**Amphibia aquatica**, a name given by Bertrutius, Albertus, Genser, and other authors, to that long, slender worm, called by Aldrovandus and others, the *fute aquatica*, &c. This is the *Corolis aquatium* of Linnæus. See *Gor-dious*.

**Amphischis**, formed from *aqua*, about, and *sero*, shadow, in Geography and Astronomy, the people who inhabit the torrid zone.

They are thus denominated, as having their shadow turned sometimes one way and sometimes another, i.e. at one time of the year to the north, and at another to the south.

**Amphismila**, or *Amphismela*, an anatomical knife, edged on both sides.

The word is formed from *spiss*, string, on both sides, and *vuln*, knife.

**Amphissa**, called by Herodotus *Amphicla*, in Ancient Geography, the chief city of the Ozzolian Locrians, about 15 miles to the west of Delphi, situate on the river Evenus, and so called because it was surrounded by mountains, according to Steph. Byz., but Panuasia deduces the origin of the name from Amphissa, who had a monument erected to her honour in this place. On the summit of a hill near the town was a temple of Minerva, with her statue in bronze. The people of the country thought this was one of the spoils of Troy, but Panuasia represents it as an ancient Greek work. Amphissa was taken by the Phocians, and destroyed with the rest of the Phocian cities in the holy war, and when it was rebuilt, Panuasia says that it took the name of *Opilida*, if the houses of the Phocians, which is just to have been the name of a town of Magna Graeca, at the mouth of the Sagra, in the farther Calabria, situate between Locri and Caulonia, and now called *Rocella*; but some have doubted the existence of such a city.

**Amphitape**, in Antiquity, a kind of carpets, or clothing, having a felt warm kape on each side.

**Amphitheatre**, in Architecture, is an edifice of an elliptical form, consisting externally of two or more stories of open *Arcades* with a number of interior *Gal-laries* and arched passages, fulfilling and serving as communications to several ranges of seats, rising one over another round a spacious area, called the *Arena*, on which the combats of wild beasts and other spectacles were exhibited.

The word is derived from *ampst*, around, and *stator*, theatre, so that amphitheatre signifies a place in which the spectators, ranged circumferentially, saw equally well from every side. It was also called *astethion* by the Latins.

The history of amphitheatres, though it occupies no remote or extensive period of time, is intermingled from its peculiar connection with the manners of the ancient world, and those which succeeded it, the establishment of the Christian religion; the rife and splendour of these edifices being occa-

**fioned by the ferocious barbarity of the former, and their subliterate difeuse and run by the milder character of the latter. They are undoubtedly of Roman invention, in the latter ages of the republic; yet because the combats of *Gladiators* were, among other spectacles, exhibited on the *Arena*, their origin has been ascribed to the *Etrurians*, with whom it is said they were first edifices set apart for such combats, and with them descended from that people to the Romans. "Religion," we are told, "in *Etruria* prevailed at these games, and elevated amphitheatres." A sensation that is certainly unfounded. Among the Etrurian gladiatory combats were exhibited at feasts as well as at funerals, and probably they were no otherwise religious institutions than as the occasion made them so, like the foot-races and other contest with which the ancients honoured the dead. In the earliest times they were presented before the funeral pile, or at the tomb of the deceased, and afterwards in the squares and open places of cities, as we learn from Vitruvius, who informs us that the Italians made the intercolumns of their *Forums* more spacious than those of the Greeks, "because, by ancient custom, the shows of gladiators were usually given in the forum." This continued to be the practice of the Romans for upwards of 200 years after the introduction of those combats among them, from whence it may be inferred, that neither the Etrurians nor the Romans had any edifice like an amphitheatre till the period we have mentioned; and it is evident that such edifices were not so necessary for the exhibition of gladiatory combats, as to be religiously appropriated to them from time immemorial.

The Romans had an inordinate passion for spectacles of every kind, and especially for such as were fanguinary and terrible; a disposition which their rulers politically encouraged, as tending to preserve that unconquerable spirit which made them masters of the world. In the year of Rome 490, the first gladiatory combats were exhibited in that city not long after the successful termination of the Samnite war had extended the Roman dominion not only over Etruria, but the whole peninsula of Italy. And in the year 503 wild beasts were introduced among the public spectacles of Rome, by Lucius Metellus, who brought into the *circus* the elephants he had taken from the Carthaginians in Sicily. These two kinds of shows were so conjoined to the tale of the Romans, that they were soon converted into engines of political influence, and the candidates for popular favour vied with each other, in exhibiting them with the greatest splendour and expense. Gladiators were trained to fight as to a profession, and hundreds of them were compelled to butcher one another in the *forum*, while every savage animal that could be procured from the forests of Africa or Asia was brought to parade in chains, or be limited in the *circus*.

In the time of Pompey and Cæsar the combats of beasts were given with a magnificence which we read of with astonishment, though far inferior to those presented by the emperors; and it is to these combats that we owe the invention of amphitheatres, as the name of *theatre minatoria*, or the *theatre for hunting*, by which they were at first denominated, sufficiently proves. It was found that these spectacles could not be seen equally well from every part of such an extensive place as the circus, interrupted as the prospect was by the *Metae*; and other buildings on the Spina, nor could they be gazed on with the same safe and security as the combats of gladiators; for in the games given by Pompey the elephants made efforts to break down the barriers which confined them in the circus. These circumstances induced Cæsar, when not long after he entertained the people with similar
familiar games, to remove the mere, and to surround the arena of the circus with a ditch, i would probably suggested the expediency of constructing edifices, in which the people might enjoy their favourite diversions without intermission or danger. This purpose amphitheatres were peculiarly adapted to answer; and, being equally convenient for gladiatory shows, they afterwards became the common theatre of both.

It is believed that the first building like an amphitheatre was formed of those curious machines constructed by Caius Curio, one of the partisans of Caesar, for the games he presented at the funeral of his father. Curio erected two costly amphitheatres to be built of timber, in the usual semi-circular form, and placed back to back, in which he amused the people for several days with theatrical diversions till noon; when the scenery was removed, and the two theatres, with an immense crowd of people in each, were wheeled round till they met, and formed an amphitheatre, in which gladiators contended on the arena till evening. This information we have from the elder Pliny; who, although he applauds the invention, excites against the temerity of the man, who dared to place the governors of the world in such imminent danger. How this was accomplished we are not told, and how much the relation may have been exaggerated by Pliny, it is impossible to know, as the fact is not mentioned by any other writer; nor is it possible to determine whether this ingenious piece of machinery gave the first idea of an amphitheatre, or was itself suggested by some amphitheatre that had been previously constructed. Be this as it may, Drusus Caesar, a few years after, erected a hunting theatre of timber, called indeed an amphitheatre, because the seats were placed round it without faces, in which he exhibited both the combats of wild beasts and of gladiators. This edifice, from the words of Dio, above quoted, has a fair claim to be considered as one of the first fabrics of the kind.

From this time, during the reign of Augustus and the succeeding emperors down to Vespasian, many other amphitheatres of timber were erected in Rome and in the provinces; but not any of these, except one by Statius Taurus, in the time of the first-mentioned emperor, which does not appear to have been held in much estimation, as it was seldom used in the splendid processions subsequently exhibited; nor could it be entirely of stone, as it was destroyed by fire in the reign of Nero. The timber amphitheatres were sometimes only temporary structures, raised and taken down as occasion required, though some of them were fixed and embellished as permanent buildings. Augustus, whose policy induced him to encourage every public amusement that interested the people, is said to have constructed several. Caligula began one, but did not live to complete it. Nero, who delighted in gladiatorial combats, also erected an amphitheatre of timber, which was near a year in building. This is described by Tacitus as a sumptuous fabric, and capable of containing a great number of persons. In the time of Augustus, Herod of Judea built amphitheatres at Jerusalem and Caesarea. In the reign of Tiberius a large one was erected at Fidenza, a town in the vicinity of Rome, which suddenly fell while the games were exhibiting, when, according to Tacitus, upwards of 50,000 persons were either killed or dangerously hurt. There was another at Placentia, celebrated as the largest in Italy, which was burnt in the war between Vitellius and Otho.

Accidents like those at Fidenza and Placentia, both in theatres and amphitheatres, had undoubtedly been frequent in Rome, as well as in the provinces, and turned the public attention to structures that were safer from conflagration, and of strength sufficient to sustain the multitudes by which they were crowded. With regard to theatres an example had been given by Pompey, who first constructed a theatre of stone, and drew upon himself the censure of the hatriceis for thus luxuriously deviating from the simplicity of ancient practice. Statius Taurus, as already mentioned, had also erected a stone amphitheatre, though it appears to have been of little consideration; and Augustus, who, as it is said, intended to have constructed one of more ample dimensions in the centre of Rome, on the very spot where the coliseum was afterwards erected, did not carry his design into execution. This was referred for Vespasian and Titus; the former began the Flavian amphitheatre in his eighth consulate, which was completed by his son Titus, and is deservedly celebrated as a prodigy of building among the ancients. Martial is lavish in its praise, and Caillidorus affirms, that the expense of it would have built a capital city. At the solemn games exhibited when this fabric was dedicated, 5000 wild beasts, according to Eutropius, and 9000, according to Dio, were destroyed on its arena. When the hunting was concluded, the arena was suddenly filled with water, in which aquatic animals were made to contend; and afterwards a sea-fight was exhibited representing a conflict between the Corinthians and Corelyrians, whose wars are related by Thucydides. If Martial may be credited, people from every part of the world crowded to Rome to be present at these games. This stupendous pile has been, from time immemorial, called the Coliseum, according to some authors, from a colossal statue of Nero, which floated at a small distance from it; but more probably from its colossal size, when compared with other buildings.

The Flavian amphitheatre became the model of many others that were subsequently erected by the emperors, or by the people of different countries desirous of sharing in the diversions of the imperial city. Of these the most remarkable were at Capua and Verona in Italy, at Nimes in Languedoc, at Pola in Istria, and in Spain. The velluses of others are said to be seen at Alba, a small city of Latium, and at Otrocol, a city of Umbria; the remains of one are found near the Carigliano, formerly the river Lyon. At Pizzazzuli some of the arches and cells of another are still existing. There are velluses of one at the foot of Mount Caflin, near the house of Varro, and of one at Paelium in Lucania; of others at Syracus, Agrigentum, and Catania in Sicily; at Gortina and Ceratonia in Andia, and at Argos and Corinth in Greece. In France there was one at Arles, and one at Astin. The latter, it is said, consisted of four stories, like the coliseum. There are also velluses of amphitheatres in Britain, near Sandwich in Kent, at Caerleon in Monmouthshire, (the Itca Silurum of the Romans), and in other places.

But it cannot be supposed that all these amphitheatres could deferve to be named as edifices, when compared with the original model, "the Flavian Amphitheatre." Some were little more than natural valleys, with benches cut in the declivities of the surrounding hills like the amphitheatre at Corinth. In some places benches of stone were placed on the declivities of two hills, and the elipias completed by works of masonry at the extremities, like that of Gortina in Andia. Some were elliptical excavations with benches of turf, like that near Sandwich in Kent, and most of the Campanian amphitheatres (for such was the general rage for amphitheatrical diversions, that fearlessly any camp, or fixed military station, was without its amphitheatre of turf or timber). Some were partily excavated and partly constructed with masonry, like the amphitheatres of Paelium and Caerleon; some had their exterior circuit constructed of masonry, and the seats and flares of timber, like that of Pola
in Idris; while others arose on a similar plan, and with nearly the same ornamentations of architecture as the Flavian amphitheatres. Such were the amphitheatres of Capua, Verona, Nimes, and Antium.

In these various structures, the combats of gladiators and the battles of beasts continued to be exhibited for near 250 years, in which time an incredible number of beasts and men were destroyed, and not unfrequently were they sanctified by the blood of the early Christians, who were devoured at a glance, or compelled to fight, for the gratification of the Pagan populace. At length Providence ordained that Christianity should become the religion of the state, and its lenient spirit gradually changed the barbarous amusements of the ancient world for others more congenial to the humanity of its doctrines. In the year of our Lord 337, Constantine the Great prohibited by law the exhibition of gladiatorial combats in the colosseum, but they were not finally abolished in Rome till the reign of Honorius, who, in the beginning of the fifth century, banished all professional gladiators out of the country. This was occasioned by the murder of a monk named Thelemaucus, who, on some solemn day, was destroyed by the people, while he was exhorting them to desist from their fangorous diversions. The combats of wild beasts, however, continued both in the eastern and western empires for some time after these events, but gradually became less frequent and less magnificent, till in the course of the sixth century, they were everywhere totally abolished; and amphitheatres being utilized for these purposes, were, in a great degree, abandoned to the depredations of men and the injuries of weather. At Verona and other places, during the middle ages, they were sometimes used for judicial combats and for tilts and tournaments; but these customs having also past away, they have since fallen into general neglect, and consequent ruin.

It is not easy by a verbal description to convey an adequate idea of the construction of an amphitheatre, and the means by which such a number of persons could have entered and egressed without confusion; but, with the assistance of the sectional diagram in Plate 11. of Architecture, and an occasional reference to the plans and sections of such amphitheatres as yet remain, these particulars may be easily understood. We have already observed, that the exterior circuit consisted of two or more stories of arcades; these varied in number according to the extent of the amphitheatre. On the ground floor they opened to an equal number of arched passages and galleries, tending like radii towards the arena, and were intersected by two or more arched passages, or corridors, that surrounded the whole edifice, and gave an uninterrupted communication to every part. Sometimes in the middle of the fabric there was an intermediate gallery, which, like those in the ground floor, surrounded the whole, and served as a common landing-place to all the galleries that led to the higher galleries, as in the amphitheatre of Nimes; and sometimes each gallery had its direct landing, without any gallery of general communication, as in the amphitheatre of Verona. Of the radiating passages the four which were placed on the diameters of the ellipsis were usually made wider than the rest, and were also, by lateral arches, laid open to the adjoining passages on either side of them. Those two which were placed on the shorter diameter were the principal entrances, by which the emperor, the senator, and other dignified personages were conducted to their seats on the Podium. The other two led directly into the arena by large arched gateways, and were appropriated to the beasts and gladiators, who probably entered in some consecrational manner, that required more width and elevation than the ordinary inlets. These interior gateways still exist at the extremities of the ellipsis in the amphitheatres of Verona and Padua, and in the former interrupt the continuity of the lower benches. Through the other passages the different orders of the people passed to the galleries which led to their respective seats; and as every arch in the exterior circuit was numbered, and also the Curt, which separated the people into classes, in the manner we shall hereafter mention, every one knew the passage which would conduct him to the place assigned by the laws of the amphitheatre to his rank and condition. Those persons whose dignity entitled them to a seat on the podium passed forward to the florcat A, and ascended to the doorways that opened upon that distinguished place. Those of the Equestrian order, or of such rank as entitled them to a seat in the division of benches next above the podium, ascended by the staircases B; while the other classes made use of the staircase C, which arose to the floor of the intermediate landing or corridor E; and then either ascended by the staircase F to the second division of benches, or by the staircase D to the second exterior corridor, and from thence by the staircase G to the third division of benches, and higher still by other staircases in a different direction, to the third exterior corridor, which communicated with the uppermost division of benches. Those different staircases were respectively opposite to different arches, and approached by different passages, though, for the sake of perspicuity, we have represented them in a single diagram.

The doorways, which opened from the staircases and passages, were denominated Vestitoria. The number of these varied, according to the size of the amphitheatre, and the number of exterior arches. In the amphitheatre of Verona there were 60 of them, placed in four elliptical rows alternately over alternate radii, so that the first and third were on one radius, and the second and fourth on another. In the highest circuit there were 16, in the next to it 16, placed at equal distances, in the next to that 15, but not all at equal distances, as the Balconies over the great gates of entrance to the arena occupied the place of two at the extremities of the ellipsis; but the number was supplied by two over the shorter diameter, where otherwise there would have been but one. On the lower line there were 15 which opened upon the podium. The number of benches between the several ranges of vomitories was unequal, and probably was not determined by any positive rule. The benches were about two feet four inches broad, and one foot eight inches high. Before every range of vomitories one bench was omitted, which left a platform four feet eight inches broad, (having a wall on the ascending side three feet four inches high) which encompassed the whole, and served as a communication to all the vomitories on the same level. These platforms were called Precincts, and the fronts of the walls, which bounded them on one side, were denominated Beils. The latter were sometimes embellished with Mosaic work, and surmounted by Ballustrades, to protect those from falling, who were seated on the benches immediately above them. The podium was a platform that surrounded the arena, more spacious than the precincts. Opposite to every vomitory a flight of stairs, two feet six inches wide, descended from one precinct to the belt or balustrade of the other. In the top of the benches, and close to the edges adjoining to the stairs, small channels were cut, by which the rain-water or urine flowed from bench to bench, till it reached certain pipes or conduits that conveyed it to the drains below. As these stairs radiated from the uppermost bench to the podium, they, with the precincts, divided the whole interior concavity into wedge-like
like portions, in which the spectators were seated according to their rank. There were the Cunei, so frequently mentioned by writers, and which do not appear to have been well understood, has the term as been applied to very different parts of the amphitheatre. That the people both in the theatres and amphitheatres were placed in wedge-like divisions, we learn from various passages in ancient authors. Apuleius says, such spectators as could not get places on the marble benches, but stood in the passages or on the stairs, were "unxed," and Tacitus informs us, that when Nero placed soldiers in the amphitheatre to applaud his performances, they were distributed through all the "wedges," that every part might ring with applause. With regard to the laws by which the people were arranged in amphitheatres, our information is very imperfect; but we may presume the same regulations applied to amphitheatres and theatres, as far as the forms of the edifices coincided. We know that persons of the highest dignity had their places on the podium, and in the middle of one side of it was the emperor's Pavilion, called the Suggestum. Several of the wedges were alligned to the senatorial order, as the podium was not sufficiently spacious to contain all the senator and other dignified persons. Other Cunei were allotted to the Equesrian order, with whom the Tribunes, both civil and military, took their seats, of which the number was very great, as every man that had once filled the office retained the rank. The Liberti were cautiously excluded from these orders, and even the Legati were prohibited by Augustus from sitting among the senators, because some Liberti had been sent in that character. The married men had places distinct from the unmarried. The young men had their appropriate seats, and their tutors fat in other seats near them, that they might observe their behaviour. The attendants and official servants of dignified persons had seats constructed of wood in the higher parts of the building. The places for the veillats were on the podium, and the princes and ladies of high distinction frequently sat with them, but the front of the gallery, which rose above the gradations of benches, was especially appropriated to the women, where they sat on chairs, and the lowest order of the Plebeians stood behind them. These were the leading distinctions of rank and classes; but for popular accommodation different wedges were, in all probability, allotted to different tribes. The Cunei were all numbered as before mentioned; but it is a mistake to imagine that every man had his particular seat numbered and ticketed, for sometimes all the Cunei were filled, and the precincts, and stairs so crowded, that many persons who were entitled to places within certain precincts, were obliged to ascend to the gallery, and mingle with the plebeians behind the women. By such arrangements as we have specified, which relate chiefly to the Roman amphitheatre, and which undoubtedly were varied in the provinces, as the ranks and classes of people differed from those of Rome, all confusion and disorder were avoided. The general care of the amphitheatre was given to an officer named the Vollicus Amphitheatri, and the Cunei were under the direction of other officers, called Locarii. The strictest attention was exerted to prevent any one from occupying a place to which he was not entitled; and if a man was wrongfully compelled to quit a seat he had taken, he conferred himself as degraded and injured. See Plate VII. of Architecture.

The front of the podium, next the arena, was defended by strong netting, and rails of iron, armed with spikes, and also with strong rollers of timber which turned vertically, to prevent the hunted animals from leaping over. The emperor's pavilion was lined with felt, and otherwise highly embellished. The seats of the principal persons were covered with cushions, the marble benches in general with boards, and over all an awning of woollen of different colours, called the Velum, was occasionally stretched to protect the spectators from the sun and rain, which, by means of pulleys and cords, could be let down and drawn up at pleasure. These articles, which may be denominated the furniture, were almost the only combustible parts of the fabric, and in the Flavian amphitheatre they were, at different times, destroyed by lightning, and particularly in the reign of Marcellus, when so much damage was done to that building, that the public games were performed in the circus for several years after.

It has been asserted that amphitheatres had an underground story, consisting of numerous dens and cells, in which the beasts were kept for the games; but whoever considers the place which, on the ground story, was necessary for the ingredes and ereges of the people, and the difficulty of getting light, however small the quantity requisite, and of gaining convenient entrances to these subterraneous places, to pay nothing of the intolerable fench that the food and carcase such numbers of animals would occasion, will at least acknowledge this to be improbable. As the coliseum has not been examined to the foundations, we can pay nothing with certainty with regard to the subterraneous parts of that fabric; but the amphitheatre of Verona was cleared in many places by Maffei, and nothing found but drains (see Plate VIII. of Architecture), which received the rain and other waters conveyed from above by channels in the staircases. Among the piazzas, and under the stairs on the ground story, are many cells and rooms that were probably prisons for criminals condemned to fight, or be devoured, in which the beasts might occasionally be flabled; but there is nothing to justify a conjecture that animals were constantly kept there. On the contrary, we learn from a passage in St. Chrys. from, that the beasts intended for the public games were kept in the envions of cities, and Procopius makes particular mention of a spacious place in Rome called the Vivaarium, appropriated to that use. It appears, that Liplius and others were led to conjecture that animals were kept under the amphitheatre, by some passages in ancient authors, which describe them as coming from subterraneous places into the arena. But it was sometimes the practice to give novelty to the games, by erecting pieces of machinery on the arena, representing mountains, on which real trees were planted, and under them hidden caves were formed, from whence the animals rushed out to encounter the combatants, or to devour their victims. It was probably to these caverns that such ancient authors alluded, and not to any permanent caverns constructed under the amphitheatre.

Of the amphitheatres which merit particular notice, the coliseum stands foremost in order of time and in magnitude. It was an ellipsis, whose length was about 615 English feet six inches, and the shorter 510 feet. The longer diameter of the arena was about 281 feet and the shorter 176 feet, leaving a circuit for the seats and galleries of about 157 feet in breadth. The external circumference, when complete, was about 1770 feet, covering a superficies of about 246,051 square feet, or somewhat more than five acres and a half, and could barely be included in a parallelogram of seven acres. There dimensions are taken from Deltet, who appears to have examined the remains of this edifice with great care, and to have corrected many mistakes of Serlio and Fontana.

The external elevation of the coliseum consisted of three stories of arcades respectively embellished with columns of the Doric, Ionic, and Corinthian orders; and an inclined
**AMPHITHEATRE.**

**PILASTER** of the Corinthian order that ascended to the uppermost cornice. The first story of arcades was raised four Reps, or about three feet 6 inches, above the ground, and the bases of the columns stood on the pavement. In the two superior stories the Piers and columns were elevated on stylobates, or continued Pilasters, which served as PARAPETS to the corridors. The Pilasters were also raised on a stylobate, in which were the windows of an intermediate gallery, and in every second inter-PILASTER was another window that lighted the highest gallery. The building was crowned by a cantalifer cornice perforated with square holes, three in each inter-pilaster, through which the upright pieces of timber that supported the awning were fastened to a range of CorBELS about the middle of the pilasters. These several stories of columns and pilasters appear to have been continued, without break or interruption, round the whole external circuit; although on some media, engraved by Maffei, there is a representation of a Portico on one side, as if intended for the principal entrance. Whether this was ever executed, and in what manner, cannot now be ascertained; as there are no vestiges of such an additional structure, unless the mutilations over the central arch, on the side next the Imperial palace, may be considered in that light. Piranesi says, that in this place there was a bridge which communicated with the portico of Claudius. The height of the first story from the pavement to the top of the cornice is about 30 feet 6 inches, the second about 39 feet, and of the third about 38 feet, of the pilaster about 40 feet, and the whole height, including the Reps and blocking course, about 104 feet. See Plate IV. of Architecture.

On the ground plan the exterior circuit of the ellipse consisted of eighty open arches; the piers of which were about seven English feet, one inch broad, having three-quarter-columns in front of about two feet ten inches diameter; seventy-six of the arches were each about 3 feet 8 inches wide, and the four which answered to the four semi-diameters, about 14 feet two inches. These arches opened into a spacious double corridor, that encompassed the whole, from thence radiated eighty piazzas and staircases, which either led to two interior corridors and the arena, or ascended to the galleries and vornitories above. This double corridor is a grand and distinguishing feature in the plan of the coliseum. The first interior corridor was lighted by square apertures in the floor of the precipitation over it, and the corridor adjoining to the wall of the podium was probably lighted in the same manner. The second story had a double corridor over that on the ground story, connected by piazzas on the same level, with an interior corridor from whence flairs, on one hand, ascended to the second range of vornitories, and on the other to an intermediate corridor, which formed an Entresol or MEZZANINE-floor, over the interior circuit of the double corridor. In this mezzanine gallery, which was lighted by square apertures in the floor of the gallery over it, the flairs commenced that rose to the next story. The third story consisted of a double corridor, and must have contained the flairs that communicated with the galleries above, but it is too much in ruin to be accurately traced. In the interior wall are some windows, and the doorways or vornitories that opened on the uppermost conus of benches. The fourth story, in all likelihood, was that appointed for the women, and on the exterior wall there are vestiges of flairs that led to the fifth gallery, which we conjecture was that allotted to servants, and furnished with benches of timber. This gallery contained four staircases that led to a sixth floor, which was, perhaps, appropriated to those who managed the velum and had no other covering, and from this floor the four staircases continued to the parapet or blocking course, which crowned the exterior wall. These three upper floors were comprehended externally in the pilaster, but on their interior sides were finished so that we may, however, presume, that they were so constructed, probably of timber, as to give the least possible obstruction to the prospect, and perhaps nearly in the manner we have represented them in the perspective section, Plate V. of Architecture, which with the plans in Plate III. and the sections in Plate IV. will sufficiently explain the contraction of this edifice.

The exterior circuit of the coliseum is built of Travertine-flane, cramped together with iron without cement. The piers of the double corridor, the VouSOIRS of the arches, the heads of the partition walls and some BONDING of the front of the arches, are of the same kind of stone. The roof is of brick. The OFFSETS of the front walls are all made on the outside, so that its interior face is nearly perpendicular. Some of the internal walls have remains of ornaments in plaster, and in others they are lined with marble. The floors of the corridors are paved with small flat bricks and covered with a hard incrustation of STUCCO. The columns in the three floors and the pilasters are all of one diameter. The diminution of the columns commences from the third part of their height. In the first and second orders they are three-quarter columns; in the third order semi-columns; the VolUTES of the Ionic capitals, and the foliage and other embellishments of the Corinthian capitals, are only rough-hewn or BOSSED. All the mouldings except the imposts of the arches have the SOFFITS of their projections sloping upward or higher in front than rear, and in the same degree in the mouldings of the first order in those at the top of the edifice. This was frequently practised by the architects of antiquity, for the purpose, as many have conjectured, of giving the mouldings a greater apparent projection; but, as Deldogelius justly observes, if the mouldings have in reality their due projection, to make them appear larger is to make them appear false, and as the ancients in all situations gave the same degree of elevation, he thinks they had some other besides optical reasons for the practice. This edifice is not everywhere executed with exactness, many of the parts being out of level and larger in some places than others, perhaps the unavoidable conundrums of an immense number of persons working upon such an extensive building at the same time, and the unequal settling of so many piers, placed upon a foundation of seventeen hundred feet.

This amphitheatre, according to Jufts Lipius, was capable of containing 87,000 spectatones on the benches, in which number painted were added 23,000 for the galleries, staircases, and piazzas. But it will be found, that allowing two feet two inches each, and 21 inches each for each person, not quite so many as 50 thousand could be contained on the benches, with the addition of one floor of the gallery, and supposing all the precint and staircases to be filled. If the higher galleries were completely crowded, perhaps about 30,000 more might be added, in all about 80,000, a number sufficiently large without exaggeration.

A structure of such dimensions, and of such contrivance and ingenuity as that we have been describing, throws into obscurity the most magnificent works of the Greeks, and even when compared with the pyramids of Egypt, is more entitled to our praise, though less the object of vulgar admiration.
AMPHITHEATRE.

The pyramid, if it be considered as buildings, are the works of barbarous greatness, performed by ignorant labour, with little invention or ingenuity. The edifices could not have been constructed till the art of building had arrived at its highest perfection, and probably would never have been commenced if the arch had not been invented, and its powers determined both experimentally and mathematically some short space of time preceding. This, however, is conjecture. When this edifice was complete, its external aspect must have been strikingly grand, from its magnitude, its lofty, and simplicity of form; and the immensity of its interior concavity, especially when crowded with two or three persons, must have been in the highest degree imposing. Even now, when its benches and galleries are in ruins, and the arena filled with the accumulated rubbish of twelve centuries, its remains are contemplated with astonishment. Yet this magnificent edifice, if it was completed by Titus, was erected in two years and nine months, a wonderful example of the energy of the Romans! However, there is a tradition in Rome, that 15,000 men were employed upon it for ten years, which, if true, will place the time of its being completed far in the reign of Domitian, though it was certainly dedicated, and the first games exhibited within it, before the death of his brother. The coliseum has been pillaged greatly at various times, and most by Michael Angelo, who carried away near one half of the outward wall to build the Palazzo Farnese. Pope Benedict XIV. to stop these depredations, conferred on the ruins, and erected several altars, which on Fridays and Sundays were, before the French revolution, much frequented by devotes. A small building near the centre was furnished with accommodations for a hermit, who constantly resided there to guard the sacred relics from the rude hands of ignorance and impety, an office which we hope is still continued.

Of the amphitheatre of Verona only four arches of the external circuit were remaining at the beginning of the 18th century. They consist of three stories of unornamented rustic arcades, of which the two lower stories were embellished with rusticated pilasters and entablatures, assignable to no legitimate order. In the third story, there were no pilasters, but capitals are executed under the architrave, as if pilasters had been originally intended. On the top of the highest cornice there are two mutilated courses of rustici work, like the rest of the front, and the beginning of two plain pillars which has been superseded the commencement of a fourth story. The height of the three existing stories is about 90 English feet. The whole of the edifice was erected without any cement, the stones being nicely joined and secured by iron cramps, covered with lead. The longer diameter of the ellipse was 500 English feet. The shorter 450 feet. The arena was about 227 feet by 154. The exterior circuit was 1451 feet. The superstructures 204:930 feet, or four acres and nearly one third of an acre.

The exterior circuit was divided into 72 arches, opening into a single corridor, surrounding the whole fabric, from whence radiated 72 passages and flancases, intersected by two other surrounding corridors. The greatest part of these exist, and by consulting the plans and section in Plates VI. and VII. of Architectura, a clear idea may be obtained of their construction. The two grand entrances at the ends of the ellipse were considerably wider than the other passages, and nearly of an uniform width from one end to the other. The grooves in the jambs of the remaining external piers flew that the arches have been inclosed by gates; but whether this was the case at Rome and other places we know not. In the plan of the second story we find that the outward corridor was inclosed by eight staircases, which, rising on the concave passages, conveyed the spectators to the third corridor, and the uppermost segments. The benches of this amphitheatre, 45 in number, remain, but not in their original places, having been moved and altered; according to Maffei in the repairs, which the citizens of Verona, much to their honour, have from time to time made to this edifice. By contriving to make it occasionally useful as a place for public directions, they have preserved it from entire destruction. As we drew our general description of the precensions and curial, as well as many other particulars, from this amphitheatre, it is unnecessary to repeat them here.

In Plate VIII. of Architectura, we have represented the fewers made for the purpose of carrying off the water of the building. In the centre a well is observable which has no connection with the fewers, the use of which it is not easy to conjecture, unless it was intended to receive some mall or pool, erected for the purpose of supporting and working the velum. It is six feet wide and very deep. The time of building this edifice is unknown, some ascribe it to Augustus, and others to the emperor Maximilian, but Maffei supposes it to have been constructed by the citizens of Verona, during the reign of Domitian and Nero. The younger Pliny mentions a magnificent exhibition of gladiatorial combats at Verona, which gives probability to the conjecture of Maffei. About 50,000 spectators might have been crowded into this amphitheatre if the precautions and flancases, as well as the benches and gallery, were filled.

The elevation of the amphitheatre at Nimes consisted of two stories of open arcades and an Attic. The lower story is very lofty, the arches tall and narrow, extra-dosed, and separated by buttresses of two projections in the Gothic form, crowned by a Tuscan capital. A regular entablature encircles the building, and breaks in projection over every buttress. The second story is embellished with columns of the Tuscan order, seven diameters in height, over each of which the entablature breaks as in the order below. The arcades on this story were originally designed by a parapet that rose about three feet six inches above the floor of the corridor, formed of one large flat stone, with a sunk pannell, on which various designs were carved in bas-relief. On one which remains perfect, there is the representation of a combat between two gladiators. The reef have been removed and their place supplied by others of modern building. On the crown of the attic, directly over every pier, are two consoles, projecting 20 inches before the face of the wall, pierced with a hole about eleven inches diameter. Through this hole the pole which supported the velum was passed to the cornice, where it rested in a socket of the same dimensions and about fix inches deep. Other holes are found in the benches at corresponding intervals, in which other poles were fixed, and the velum extended by pullies from one pole to another, as represented in Plate II. of Architectura. This method of supporting the velum is more simple than Fontana's; but it makes only the upper ranges of benches, and leaves those where the perrons of highest rank were seated, exposed to the weather; yet if we conjecture rightly as to the use of the well in the Veronan arena, the velum might have been further extended by other cords attached to a mast in the centre. See Plates II. and IX. of Architectura.

The exterior circuit consists of 60 open arches, of which four at the extremities of the diameters are ornamented with
with pediments, and formed the grand entrances." The other 56 led to the passages and staircases, intersected by two corridors which encompassed the whole; one in the exterior of the building, and one near the wall of the podium which received light by iron grates from the arena. Another interior corridor or gallery, situated near the middle of the building, and nearly at equal distances of height between the two exterior flowers, forms the common landing of the staircases, and communicates both with the exterior gallery on the second story and the benches. The spectators ascended by 20 steps, each nine inches high and twelve broad, into the intermediate gallery, and by 20 more into the exterior one on the second story. There is a fifth gallery in the attic, which was approached by narrow stairs, wrought in the body of the wall, and probably intended for the velaria or servants who managed the velum. This amphitheatre had no covered gallery surmounting the benches and looking upon the arena, like those of Rome and Verona. All the radiating passages, as well as the four grand entrances, regularly decreased in height and width from the exterior corridor to the wall of the podium. It was the fame in the amphitheatre at Arles, as may be seen in the only passage remaining.

The largest diameter of this edifice, extending from east to west, is, according to Benouen, corrected by another account, about 148 English feet, the shorter diameter 338 feet, and the whole height 76 feet six inches. The superstructures were originally 32 inches in number, from 18 to 21 inches high, and from 18 to 24 in breadth. They were approached by three rows of vomitories, and were capable of containing about 1500 spectators. The flowers with which this fabric is constructed are of very small dimensions; sometimes cemented and sometimes fixed with iron cramps and lead. In several places the impost of the pier is a single stone, nine feet long, seven feet broad, and between two and three feet thick, and many of the stones, which form the benches, are eighteen feet long, two feet broad, and one foot eight inches high.

The vicissitudes of the amphitheatre of Nimes upon record, are so numerous that it is wonderful it should have been preserved so well as it now appears. In the year 472 it fell under the dominion of the Visigoths, who surrounded it with a ditch, built a castle within it, and converted it into a citadel. Part of the towers of the castle still remains; but the ditch was filled up in the 13th century. In 720 it was taken by the Saracens, who were driven from it in 737 by Charles Martel. After that time it was occupied as a fortress by the counts of Provence, who sustained a number of attacks in it, and built a church and a palace on the arena. The steep slope of the church is still in existence. In 1226 the knights, who then guarded the citadel, yielded it to Lewis the VIII., and in 1591 it ceased to be a fortress and was evacuated, though the houes continued. In 1533, that polished monarch Francis the First directed it to be cleared, which his subsequent misfortunes prevented from being done, and similar orders were given by the late unfortunate Lewis the XVI., but the work has not yet been completed.

Governor Pownall, who visited Nimes in 1757, says, that the amphitheatre was filled with houes arranged in streets, and looked like a little walled town. The galleries on the ground story and the intermediate gallery were converted into numberless miserable habitations, but the exterior gallery of the second story and that in the attic were perfectly unencumbered as in their original state. The date of this building is uncertain; but Mons. Menard conjectures it was erected by Antonine, which places it between the years 138 and 161.

What remains of the amphitheatre at Pula, in Istria, is a single elliptical wall of 72 arches, built on the declivity of a hill, having on the western side, which looked towards the sea, two arches arches, and on the opposite side only one arch. The wall,情形 being gradually lost in the slope of the hill. Above the arches there is an attic with a wall, with 72 windows, which surround the whole, and in it are grooves and corbels for the poles that supported the velum. At the haunches of the ellipses are four projecting buildings or towers, of two arches in height, having windows curiously filled with reticulated stone work in the attic, and doors and windows on every story towards the arena. The second story of the arches in these projecting buildings are closed up as high as the imposts, and the semi-circle is filled with upright mullions of stone, like the loopholes of an English barn. These towers have been called Counters by Serlio and others, but in all likelihood they were made for another purpose, as will be mentioned hereafter.

The whole of the exterior circuit of this edifice, excepting a very few yards of the parapet, was remaining when it was visited by Maffei, and appeared with extraordinary beauty when viewed from the sea. It was built with stones cramped together without cement. All the benches and other interior parts which were originally constructed of timber had long been destroyed. The larger diameter of the ellipse is about 416 English feet, the shorter diameter about 377 feet. The circuit about 1182 feet, the superstructures 1230/2 feet, or about two acres, and seven-eighths of an acre.

The Marquis Scipio Maffei, whole attachment to Verona, made him unwilling to believe that amphitheatres existed in other places, insisted on this inclosure, and pronounced it to have been a theatre only, assigning the slope of the hill to the benches for the spectators, and the opposite side which is nearly level, to the orchestra and stage. The two towers on the western side he supposed to have been constructed to represent the houses in the ancient scene, and the other two on the eastern side to have been built for the sake of uniformity only. All this appears highly improbable. The erection of such an extent of elliptical arches as half this inclosure, for the actors, would have been a waste of labour and expense to produce a work but ill adapted to its use, and if the towers had been intended to represent the fronts of houses, they would not have had doors and windows on both the upper stories, as well as the arches which gave entrance on the ground story; nor would such appendages have been erected on the opposite side for the sake of uniformity, when, in no point of view, they could be seen together. It is much more likely that the architect took advantage of the slope of the hill to place his benches on one side, and constructed them of timber on the other, and made the staircases to the higher ranges in the four towers, which conjecture renders them useful as well as uniform, on every side. It is said that villas of such staircases actually exist, but if they did not, the disposition of the apertures would justify the conclusion. There can be no doubt but the interior of this amphitheatre was filled with houses as high as the second story of arcades, and had a covered gallery on the attic story. If this be not admitted we may ask why was there a range of windows in the attic story, and for what use was the cornice or coping of the wall formed.
formed into a gutter, unless to receive rain water from a roof?

The amphitheatre of Paestum is one of those which had the area and part of the benches sunk below the soilage of the earth and the excavation, encompassed by other benches and an arched structure of stone. Next to Major's work on the ruins of Paestum, none the Italian work on the same subject, published at Rome in 1784, by the Rev. Father Paul Antonio Paoli, enable us to form a clear idea of its construction, or even the exact state of its remains, and it would not have merited particular attention if it had not been made the basis of an hypothesis respecting the origin and progress of those edifices, which, however simple and pleasing, does not appear to be true. The reverend father conjectures that the first public spectacles were given in small vales, and that the spectators beheld them from the declivities of surrounding hills. That afterwards, when they were exhibited in cities, excavations were made in the earth, and encompassed with benches of turf, upon which the people enjoyed their diversions without inconveniencing one another. That the greater the number to be accommodated the more they sunk the arena, and increased the surrounding slope; and finally, that they inclosed it with walls of masonry, and added other benches of stone till it was capacious enough to contain a vast multitude of spectators. This, he thinks, was the first method of forming amphitheatres, which the Romans improved into the magnificent structures we have been describing. The amphitheatre of Paestum he considers an example of this ancient method, and supposing the excavated part to be of great antiquity affords to the time of the Etruscans, and adopts the opinions which we have briefly controverted in the beginning of this article. But, however plausible this theory may be, if it depends on the antiquity of the Paestum amphitheatre, its probability will decrease in proportion as that antiquity becomes doubtful. The remains of this amphitheatre are indeed situated among temples, which are believed, though perhaps erroneously, to be very ancient; but it is difficult to believe that a city, which could erect such temples, would be content with a simple excavation for the place of its public amusements. As to the part which was built of stone, the arches at either end of the elliptical inclosure, prove it to be the work of a much later period; and if our conjecture be well founded that the invention of the arch and the first construction of stone amphitheatres were nearly coeval, if not reciprocally the causes of each other, the date of that part will be fixed in the reigns of the first emperors, when the fame of the coliseum and the passion for public spectacles spread through all the Roman provinces and tributary nations, and every country endeavoured to imitate in the manner belted suited to its population and riches the amphitheatre of Rome. But in whatever age the amphitheatre of Paestum was made, its form alone is no proof of its antiquity, as the amphitheatre of Carleon was formed in the same manner, and Britain might with equal reason produce it as an example of the earliest mode of forming amphitheatres, and from such evidence contend with Lucania or Etruria for the honour of the invention. The length of the Paestum amphitheatre was about 211 feet, its width 131 feet, the superfricis 71861 feet, or about three quarters of an acre.

In the five different amphitheatres which we have described, will be found the principal varieties of these edifices in a gradation that may be amusing to those who will take the trouble to examine them. The dimensions have been collected from the best authorities; and the calculations made and examined with care; but such is the difference among authors in this respect, that the more we have consulted the greater has been our uncertainty. Thus Beaumont gives the dimensions of the amphitheatre of Nimes as 738 by 333 feet, while Governor Pownall states them to be 460 by 333, and the difference between Fontana and Degodetz, with regard to the coliseum, is not less considerable. Who can wonder that the dimensions of the pyramids should appear to have remained doubtful from the days of Herodotus to the present, when we are uncertain as to the exact size of objects in a manner under our eyes.

The writers on amphitheatres, most worthy of regard are the learned Julius Lipius and the celebrated marquis Scipio Maffei. To the latter we have been greatly indebted, though we have not always adopted his opinions. Serino, who described the ancient buildings of Italy, about the middle of the 16th century, deserves more attention than he has received. His prints of the coliseum, though rudely executed, and in places, incorrect, preserve some particulars which later authors have omitted. The splendid work of Fontana on the same subject is very ingenious, but inaccurate, and full of improbable conjectures; we have, therefore, followed Degodetz in preference, who has trodden in the steps of Serino, corrected his errors, and supplied his deficiencies; but even the plates of Degodetz are in a few instances incorrect and inconsistent with one another. Governor Pownall's "Antiquities of the Provincia Romana of Gaul," and Augustus Beaumont's "Select Views of Antiquities in the South of France," furnish much information relative to the amphitheatre of Nimes and amphitheatres in general. "The Rovine della Citta di Petto," by Father Paoli, contains some amusing speculations which are rendered delightful by the amphitheatre of Carleon, as described by Giraldus Cambrensis, and that intelligent traveller Mr. Cox, in his "Tour in Monmouthshire." Numberless other notices may be found in writers on local antiquities that illustrate this subject; a subject equally interesting to the architect and the antiquary.

The amphitheatre is used by the French for the feats at the lower end of the theatre which arise above the parterre, opposite to the stage, and occupy the space of the front boxes and a part of the pit of an English theatre. They also give his name to an apartment appropriated to public scientific lectures and discourses, filled with seats, rising one above another, either in a rectangular, circular, or encompassing the whole room like the seats of an ancient amphitheatre. In the former case the scholars are in front of the lecturer; in the latter, he is placed in the central area, and surrounded by his scholars. Such schools in England are denominated theatres, as the theatre of the University of Oxford, the anatomical theatre at Surgeon's Hall, and the theatre of the Royal Institution, in London.

Amphitheatre, in Gardening, is a lofty terrace, ascended by flights of steps either straight or circular, supported by banks and slopes of turf in various forms, and used to terminate the view from an alley or an opening in a thicket. This mode of decoration is also employed to give regularity to the side of a hill, and to gain an easy ascent by means of slopes and platforms of turf to the summit. The banks and slopes are frequently embellished with flatten, fountains, vases of flowers, clipped yews, shrubs, and dwarf-trees, and sometimes behind these are planted trees of other size, such as pines and cedars. A terrace for gardening more conformable to the beauties of natural landscape, has nearly basified this kind of amphitheatre from England; but it is not uncommon in gardens on the continent.
AMP

AMPHITHURA, in Ecclesiastical Antiquity, a name given to the veil, or curtain, which divided the chancel from the rest of the church.

The word is αμφίθυρα, thus called, on account of its opening in the middle, after the manner of folding doors.

AMPHITREON, in Entomology, a species of Papilio. Wings indented, above black, with an unequal yellow band; beneath, on the posterior pair, a stripe of yellow dots, and blue lunulate marks. Limnæus. This is the Papilio Cambridius of Cramer. The body is large, and without spots; general color black, with an unequal row of yellow spots near the anal angle of the posterior, but not connected with it. Under side of the posterior wings black, with a stripe of seven large orbicular spots, and a streak of blue lunulate marks, terminating at the anal angle in a yellow dot; the margin fimbrious with yellow. A native of America. Fabr. 267.

AMPHITRITE, Ἀμφιτρίτη, from ἀμφίω, and τρίτη, third, in the Heaten Mythology, the wife of Neptune, daughter of Oceanus and Thetis, and goddess of the sea, sometimes taken for the sea.

There was a statue of Amphitrite in the temple of Neptune at Corinth, and another in the Isle of Tenos. Spanheim says, that she is often represented like a Syren, with the upper part of the body to the waist like a female, and the lower part with the tail of a fish instead of limbs. Amphitrite was the mother of Triton. Two Nereids were also called by this name.

AMPHITRITE, in Natural History, a genus of the Molusca order in the class of Vertebr. The body is protruded from a tube, and is annulated; peduncle warded; feelers acuminated, approximated and feathered; and it is defitute of eyes. Limnæus. The species of this genus are Renaformis, Pencillus, Ventilabrun, Ancrioma, Cistata, Chrysopectera, and Plumosa, which see.

AMPHITRYON, in Mythological History, the husband of Alcmena, was the son of Alceus, and the father of Hercules; but less distinguished by his own exploits than by those of Alcmena, which is of no great importance to recite.

AMPHODONTA, compound of αμφίω, and δόντη, tooth, in Zoology, a designation given to animals which have teeth in both jaws, the upper as well as under.

AMPHORA, in Antiquity, an earthen vessel, which served as a kind of liquid measure among the ancient Greeks and Romans.

It is called in Homer αμφοραί, from αμφίω, and φοραί, and by simcope, αμφορο-i, on account of its two handles for carrying. It is the same with the quadratales. But we meet with two kinds of amphora in ancient writers, the Italic and Attic.

AMPHORA, Italic, was that used by the Romans, and which is, therefore, sometimes called the Roman amphora. The Italian amphora was also called quadratales, and sometimes cadus. It contained 72 pounds of wine or water, 80 of oil, and 180 of honey.

The amphora was equal to 2 uræ, or 3 modii, 6 femidii, 8 rhenii, 48 sextaries, 96 semina, 192 quartaries, or 57,600 cubic, amounting to about 7 gallons one pint, English wine measure. Arbutnot.

The ancient amphora were either sēsile, i. e. such as would stand, or non sēsile, terminating in a sharp bottom. Of both which kinds, we meet with figures on ancient medals.

The amphora capitanea was the standard of this measure, which was kept in the capitol, to adjust others by.

Suetonius tells us of a man, who stood for the quattuor-

ship, and who drank an amphora of wine at one meal with the emperor Tiberius. Supposing the amphora to have been a cube of four feet each side, as Polian affirms it to have been, we may venture to say, that ten of the greatest drinkers on earth could not have emptied it. Dudder's computation is much more reasonable; he makes the amphora of wine amount to about 4½ gallons Paris measure.

AMPHORA, Attic, was that used by the Greeks, and therefore sometimes also called the Grecian amphora.

The Attic amphora was one-third part bigger than the Italic; so that as the latter contained 2 uræ, or 48 sextaries, the former contained 3 uræ, or 72 sextaries, amounting to about ten gallons 5½ pints English wine measure. This was called αμφορα, sometimes also αμφορεύς, and, by way of distinction from the Roman kind, μινχρῖς.

AMPHORA was sometimes also used as a dry measure, containing three bushels; the standard whereof was kept at Rome in the capitol, to prevent false measures.

AMPHORA is also used to denote the largest liquid measure in use among the Venetians. The amphora contains four luiros, seventy-five mydhe, or two boats, or muids.

AMPHORARIUM, in Antiquity, denotes that which is drawn or poured into amphore or pitchers, by way of distillation from vinum dolhare, or caaff wine.

The Romans had a method of keeping wine in amphora for many years, to ripen, by softening the lids tight down with pitch or gypsum, and placing them either in a place where the smoke came, or under ground. Colum. Re Rust. lib. i. cap. 6. Plin. Nat. Hist. tom. ii. lib. 23. cap. 1.

AMPHORITES, a kind of poetical contest, which obtained in the island of Ægina; in which an ox was given to the person who produced the best dithyrambic verses in honour of Bacchus.

AMPHOTEROPLON, among Civilians, denotes a kind of naval insurance, where the insurers run the risk both in the going out and return of a vessel.

In this sense the word ἄμφοτερος opposed to ἄμφοτερον, where only the voyage outwards is insured.

AMPHOTIDES, in Antiquity, a kind of defence, or armour for the ears, worn by the ancient Pugiles, to prevent giving their adversaries a handle by that part.

Authors have not been well acquainted with the nature and office of the amphotides. Some explain them as a fort of helmet for covering the nose and ears.

Fabretti first ascertained their real use, from the figure of a Pugil, which had amphotides over its ears joined by a piece coming over the forehead, and tied with strings under the chin.

AMPHRYSUS, in Ancient Geography, a town of Phocis, called Amphiros.

AMPHYSUS, or Ampyros, is also the name of a river of Phthiotis in Thessaly, which ran by the foot of Mount Othrys. Virgil, in speaking of this river, alludes to the time when Apollo, being a shepherd, guarded the herds of king Admetus, whence he is called "pater ab Amphryso," Georg. lib. iii. v. 2. This river is also mentioned by Callimachus, Apollonius, Ovid, and Lucan. Another Amphryus in Phrygia is mentioned by Pliny, to which was ascribed the property of rendering women barren.

AMPLA, in Conchology, a species of Voluta. Shell elongated, aperture large, lip acute, wreaths of the spire scarcely visible. Linnaeus.

AMPLEPIUS, in Geography, a town of France, in the department of the Rhone and Loire, and chief place of a township.
AMP

There is likewise a difference between the amplification and the proof; because the one serves to clear the point, and the other to heighten and exaggerate it; and therefore it requires a florid and beautiful style, consisting of strong and emphatical words, flowing periods, harmonious numbers, lively tropes, and bright figures.

There are two general kinds of amplification; the one of things, the other of words. The first is produced in divers manners: as, 1. By a multitude of definitions; thus it is Cicerio amplifies his history: Historia est fatis temporum, lux certatil, vita memoria, magistri vita, mundi vehiculi. 2. By a multitude of adjectives; of which we have a fine instance in Virgil's lamentations for Caesar's death, by enumerating the many prodigies and miracles that either preceded or succeeded it. Voxque parvae quaesitque saepe silentes ingenit, & simulacra multa tulentis miris sub obsoletis noditi: psuedique locuta, infrangunt inflant annos tergae deificunt: a sublimi illiary matem templi clar, araque fudiant. 3. By a detail of causes and effects, 4. By an enumeration of consequences. 5. By comparisons, similitudes, and examples. 6. By the contral of antithets, and by rational inference.

Amplification by words is effected fix ways. 1. By using metaphors. 2. By hyperboles. 3. By synonimia. 4. By splendid and magnificent terms; as that of Horace, Scandit creatae viribus nobis cura, nec turmas equitum relinquens, occis cerere, & agentis nimbose victa effus. 5. By periphrases, or circumlocutions. 6. By repetition. To which may be added, by gradation.

AMPLITUDE, in Astronomy, is an arch of the horizon, intercepted between the true east or west point, and the centre of the sun, or a star, at its rising or setting, so that the amplitude is of two kinds; ars or east, and or west. These are also called northern or southern, as they fall in the northern and southern quarters of the horizon; and the complement of the amplitude, or the distance of the point of rising or setting, from the north or south point of the horizon, is called the AZIMUTH.

To find the sun's or star's amplitude, either rising or setting, by the globe, see GLOBE.

To find the sun's amplitude trigonometrically; having the latitude and the sun's declination given. Say, as the cosine of the latitude is to the radius, so is the sine of the sun's or star's declination to the sine of the amplitude. Suppose, e. g. the latitude to be that of London, viz. 51° 32', and the declination 23° 28'; then cosine 51° 32', or 0.7993847; rad. or 10.000000 :: sine of declination 23° 28' or 0.600185: 10.000000 + 0.600185 = 0.7993847 = 0.600185, or the sine of the amplitude, or 39° 48'; and this is the same name with the given declination, viz. north, when the declination is north, and south, when the declination is south.

AMPLITUDE, MAGNETICAL, is an arch of the horizon, contained between the sun or star at its rising or setting, and the magnetic east or west point of the horizon, indicated by the magnetic compas, or the amplitude or azimuth compas; or it is the difference of the rising or setting of the sun, from the east or west point of the compas. For this purpose place the compass on a steady place, from which the horizon may be clearly seen, and looking through the light-vanes of the compas, turn the instrument round, till the centre of the sun, or other celestial object, may be seen through the narrow slit which is in one of the light-vanes, exactly in the thread which bisects the aperture in the other light.
fight-vane; and when the centre of the celestial object, whether rising or setting, is just in the horizon, pull the flag, in the side of the box, so as to stop the flag, and then read the degree of the card which stands just against the fidetrical line in the box; and this gives the amplitude required. In this operation allowance must be made for the height of the observer’s eye above the level of the sea. The difference between the magnetic amplitude, thus observed, and the true amplitude, obtained by the last article, is the variation of the compass. E. G. If the magnetic amplitude be observed by the compass to be 61° 47’, at the time when it is computed to be 39° 47’, then the difference 22° 0’ is the variation well.

AMPLUSTRA, in Conchology, a species of BULLA. Shell roundish; spire elevated, obtuse, banded with flesh colour. Inhabits Asia. Linneus.

AMPOSTA, in Geography, a town of Spain in Catalonia, situated on the Ebro, three leagues from its mouth, seven miles south of Tortosa.

AMPOTIS, variously figures properly the receds or cobb of the tide. But Hippocrates, who was of Cos, one of the Greek isles, and must have had many opportunities of observing the tides, very elegantly applies this word to the receds of humours from the circumference of the body to the internal parts.

AMPRACE, in Ancient Geography, a people whom Pliny places in Arabia Felix.

AMPRELITE, a people of Colchis, according to Pliny.

AMPSAGA, a river of Africa, on the eastern part of Mauritania Cofariensis, separating it from Numidia Propria, rises on Mount Auris, in the confines of the Atlas, and falls into the Mediterranean, ten leagues call of Jijel, or Lijjil. One branch of it, called Rummel, waters Cirta. According to Dr. Shaw, the Ampsaga is now called Wed el Kibbi, or the Great River, which corresponds with the signification of ampsaga; amplaga, in Arabic, denoting ample, or large.

AMPSALES, a town of Asia Minor, according to Ptolemy.

AMPSANCTI Vallis, or Lucus. See Moffetta.

AMPSANI, a people of Germany, conquered by Germanicus, according to Strabo.

AMPY, in Geography, the name given in Denmark to a lesser jurisdiction or district. The country is divided into several larger districts, called flits-amps, of which there are seven; four in Jutland, and three in the islands. Every flits-amps is subdivided into lesser districts called amps. A person of quality is generally chosen flits-ampsman, a pilot resembling that of lord-lieutenant in England. The flitsman, or under-governor of an amp, is generally a person of inferior rank, who resides in the principal town of his district, and is intrusted with the conduct of all public concerns. The pilot is generally given for life, as a recompense to those who have faithfully served the court. The flitsman is usually 400 crowns, and that of the flits-ampsman a thousand crowns; besides various exemptions and privileges.

AMPTHILL, a town of England, in the county of Bedford, pleasantly situate, near the centre of the county, between two hills. It has been of late years much improved, particularly by the erection of a handsome market-house. The principal streets are neat and regular, crossing each other at right angles. Near the middle of the town is an obelisk of Portland stone in which is a pump, built for the use of the inhabitants by the Earl of Upper Ossory; and west of the town is Ampthill park, his lordship’s seat, which is a superb edifice, containing a valuable collection of paintings, by several ancient and modern masters. The town has an almshouse and a charity-school. Its market is on Thursday; and its distance from Dunstable 12 miles, and from London 432.

AMSONIA, in Botany. See TABERNAMONTANA. Gmelin has made Amsonia a distinct genus, including two species, &c., 1. A. Tabernamontana, and 2. A. Ciliata. But Mr. Dryander observes, that the A. Tabernamontana of Walter, to which Gmelin refers, is certainly meant for TABERNAMONTANA AMSONIA of Linnaeus. The trival name is printed in Roman character; and he thinks it highly probable that Gmelin’s A. Ciliata is the same as TABERNAMONTANA AMPULLIFOLIA of Hort. Kew. Linnean Trans, vol. ii. p. 228.

AMPTRUARE, in Antiquity, denotes a kind of dancing performed by the chief of the fells, and answered with a correspondent motion by others in the chorus.

This is sometimes also called amphiurea; the answer of the chorus was particularly called redamtruares.

AMPUDIA, in Geography, a small place of Spain, in the country of Leon. In the time of the Goths it was a considerable city and bishop’s see; 12 miles north of Valladolid.

AMPUGNANI, a town of the department of Golo (island of Cortica) the county of which contains 4,143 inhabitants.

AMPULLA, in Antiquity, an oil vial or jug, with a large belly, used for unctions at the baths.

The word ampulla was also used for a drinking vessel used at table.

AMPULLA, among Ecclesiastical Writers, denotes one of the sacred vessels used at the altars.

The word is sometimes also written in English amphil. Ampulles were also used for holding the oil used in chrifnation, consecration, coronation, &c.

Among the ornaments of the churches we find frequent mention made of ampuls, or vials. In the inventory of the cathedral of Lincoln, we meet with ampuls of crystal, variously enriched with silver feet and covers: one containing a tooth of St. Christopher, another a tooth of St. Cecily, another a bone of the head of St. John Baptist. Dugdale, Mon. tom. iii. p. 272.

AMPULLA, Knights of St. Ampulla, belong to an order instituted by Clovis I. king of France; at the coronation they bear up the canopy, under which the ampulla is carried in procession. This ampulla, or sacred vial, with which the kings of France were anointed at their coronation, is said to have been brought from heaven by a dove, for the baptismal anointing of Clovis I. the first Christian king of France, A. D. 496, and dropped into the hands of St. Remigius, then bishop of Rheims, where it has been preserved ever since for the purposes of anointing all succeeding kings; and its divine denial is said to be confirmed by this miracle; that as soon as the coronation is over, the oil in the vial begins to wane and vanish, but is constantly renewed of itself, for the service of each new coronation. The Abbé de Vertot vindicates the truth of this miracle, in a dissertation written for this purpose; and Baronius says, that it was a miracle worthy of the apomophical times. Archbishop Hincmar, in the year 669, is the first voucher for the truth of this legendary tale. Justin’s Rem. on Eccl. Hist. vol. v. p. 320. Middleton’s Works, vol. ii. p. 184.

AMPULLA, in Conchology, a species of BULLA. Shell roundish, opaque, crown unmblicated. Linneus.—A most common species in the Indian, Ethiope, and American seas; about three inches in length; colour white, variegated with cinereous, black, brown, red, and blue, in spots and clouds. There are two, if not more, distinct varieties of this species;
Amputation.

The first, very oblong, opaque, dark, and scarcely an inch and a half in length; the second, transparently streaked, grey and black.

Ampulla, in Entomology, a species of gasterina, having blue claws without fangs; fourteen legs: hind thighs compressed and dilated. Fabricius. This is the cancer of Linnaeus. inhabits the northern ocean. Body almost white; proboscis incurved and sharp pointed. Tail of six leaves, last joint bifid.

Ampullaceae, in natural history, a name by which some authors have called a tribe of shells, which, in the Linnean arrangement, belong generally to the genus Voluta, or Becsekia; it is synonymous with concha, secohia, abum, and tonem. See Delium.

Ampura, in Geography, the name of a province in the kingdom of Peru, before its conquest by the Spaniards. The inhabitants are said to have worshipped two high mountains, because they furnished streams which fertilized the land. It is said to have been conquered by Viracocha, the eighth idol.

Ampurias, in Spain, a sea-port town of Catalonia, and the capital of a district called Ampurdam, in Catalonia, situated at the mouth of the Fluvi. It was once considerable, and a bishop's see, but is now a mean place; 1 5 miles east of Gerona, and 38 north east of Barcelona. N. lat. 42° 10'. E. long. 5°.

Ampurias, Castillo d', a little town of Catalonia, seated in a bay.

Amputation, in Surgery, is that operation by which a member is separated from the body. It differs from excision, in that the latter is cutting off a part of the body; whereas, the former is cutting it off.

Amputation is one of the most formidable and important operations in the whole art of surgery: although it is by no means the most difficult to perform. The skill of a surgeon is often much more clearly evinced, by saving a condemned limb, than by dexterously removing it: so that “the most expert operator,” as Mr. O'Halloran observes, “may not always be the best surgeon.” Nay, “to do justice to the sick and to ourselves, we must, in many cases, rather avoid than perform capital operations.” See Mr. O'Halloran's Treatise on Gangrene and Sphæclus; pref. p. 3-7. et seq.

"As to amputation itself, its indifferency of use, or, indeed, rather abuse, has been of infinitely greater detriment to mankind than service, must be admitted. We daily hear of sudden accidents that require amputation; and nothing is more common than to be informed, that the patient died in two or three hours after the operation. In sea engagements, where a limb is torn and shattered, death very soon follows mutilation; and after battles the recoveries bear no proportion to the deaths on this account.

"It was this great propensity to lopping off limbs,” continues our author, “that caused a complaint to be exhibited to Louis the XIVth, that his surgeons exaggerated the importance of their service by the number of mutilations only; and they were obliged to defend themselves from this aspersions before a prince, who wisely rated the lives of his subjects too high to suffer characters to be gained at their expense. In fact, it is not enough for a surgeon to know how to operate; he must also know when to do it.” Mr. O'Halloran computes that ninety-five patients out of an hundred ought to recover, where amputation is performed at a proper time, as well as in a proper manner; an acquisition highly honourable to surgery, and acceptable to humanity."

Historical Sketch of Amputation.

Although, from the earliest period of human existence, there must have been occasion for performing this operation, we have no decisive proofs from history that it was ever done by the father of medicine, Hippocrates. A. C. Celsius, who lived in the reign of Tibullus, and whose book De Medicina should be read by every surgeon, has left us a short description of the mode of amputating gangrenous limbs. It has been often remarked, that Celsius has left no instructions for securing the divided blood vessels; but it has not been commonly noticed, that in his chapter on wounds, he directs us to stop hemorrhages by taking hold of the vessels, then tying them in two places, and dividing the intermediate portion. If this measure cannot be adopted, he advises the use of a cauterising iron. Several hints are also to be met with in the writings of Celsius, from which it may be inferred, that the ligature of bleeding vessels was sometimes practiced in that early age; and this supposition is strengthened by a fragment of Archigenes, preferred by Cochin on the subject of amputation, where he speaks of tying or searing the blood-vessels. We are not, however, in possession of all the writings of medical authors prior to the time of Galen, and must therefore remain in doubt upon this point.

Celsius recommends amputation to be performed between the found and corrupted part of the member. The first incision was made with a knife down to the bone, but not over a joint; and some of the found flesh was to be cut off, rather than leave any of the gangrenous part. The muscles were then to be retracted, and cut close around the bone, to lay it bare; then we were to saw off the projecting bone close to the flesh which still adheres; afterwards the rough edges of the bone were to be made smooth, and the integuments brought over it as much as possible. It is somewhat extraordinary that Galen has neither mentioned this important operation, nor so much as once quoted the name of Celsius, who flourished about a century before him at Rome. If amputation proved often fatal in the days of Celsius, “fæpe in ipso operis,” as he tells us, it was owing to the want of some efficacious method of compressing the blood-vessels during the operation itself; for, although the ligature might, perhaps, be employed, they knew not the use of a tourniquet. See Tourniquet, Ligation, Cautery, and Hemorrhage.

The conciseness of the account left by Celsius renders it uncertain whether the edges of the skin were confined or not, so as to leffen the suppurating surface of the stump; but he evidently intended to preserve a large elevation of skin and muscle, in order to facilitate the cure. And as to the wound, so far as it remains exposed, he directs it to be covered with lint, and then bound over with a sponge dipt in vinegar. From the whole, then, it appears that the ancient Romans had tolerably correct notions of the art of healing. Paulus Egineta, about eight centuries afterwards, foggeled no improvement, except a broad fillet of cloth to retract the divided muscles during the time of sawing the bone: he recommended the application of hot irons, to sear the orifices of the bleeding arteries; and indeed, the early Greek practitioners were more disposed to use the actual cautery than the Romans.

The Arabian surgeons, who chiefly copied from the Greeks, made no material alteration in the mode of amputating; and were strangely inattentive to the advantage of the needle and ligature, which they well knew how to apply on other occasions. Perhaps this last affirmtion will be controverted; as a surgeon in Edinburgh has professed to tell the world, in two of his late publications, that the Arabian surgeons were ignorant of the needle and ligature for tying blood-vessels, and never used them otherwise, than by faying a wound just so much the closer and tighter in proportion to the
the bleeding." He says, "burning irons were used by the ancients, merely because they knew of no other means of sup-pressing the bleeding." Again, "In the times before Paré, not being able to take up an artery," &c.

We shall elsewhere have opportunity to treat of the Lita-
tures of bleeding vessels; and therefore can only observe, by way of anticipation, that those who (with Mr. John Bell) impute the first discovery of this practice to Ambrose Paré, are greatly mistaken, and not sufficiently familiar with the writings of the old surgeons, whether Greeks, Romans, or Arabsians. "It is not only entertaining but useful," says the late Dr. Hunter in his Commentaries, p. 62. "To see by what purports and steps an improvement was made; it gives clear ideas of the subject, makes a stronger impression upon the memory, shews the most probable road to improvement in similar inquiries, and raises emulation." But says he, "if a man writes freely upon any subject, without knowing what has been said by others, he vieues being made the object of ridicule or cenfire." Ibid. p. 60.

Guido de Cauliacco, who revived the languishing state of surgery in Europe during the 16th century, agrees with Avicenna and Albucasis, that it is better to cut off a morti-
ted extremity than to let the whole body perish. He ad-
vives, when the gangrene is near a joint, to separate the arti-
culation. In other cases he directs us to apply a tight lig-
ture on the edge of the healthy part as well as on the gan-
grenous part; cutting between them down to the bone, and then fusing through, with a retracter interposed. But some-
times Guido would wrap up a mortified limb, and allow it to fall off of itself; by which means he avoided the odium of am-
putating members that his patients might have thought cap-
pable of preservation. After the example of his predecessors, he had recourse to hot irons, boiling oils, and antiphon pow-
ders, to induce the hemorrhage; although he disapproves the practice of Theodoris and others, who gave narcotic remedies to prevent or mitigate the suffering of their patients.

Methods of amputating, somewhat like those of Guido, were used by Bartholomew Magnus, Velufins, and most surgeons in the 16th and 17th centuries; till Botalhis and Regius pro-
pounced to lop off the limb by a sort of guillotine, at one 
stroke, after the manner in which criminals, formerly of Scotland, and lately of France, were decapitated. This
summary treatment, however, caused so much contusion and splintering, that it was very soon opposed as unscientific and butcherly. The most important innovations made, about this time in amputating, were introduced by the celebrated Ambroise Paré, a French surgeon; to whose induc
ty, good sense, and skill, we are chiefly indebted for the abolition of cauterying instruments, and the general use of a needle and ligature to suppress the bleeding, after this operation.

Paré recommended to cut off the whole of the gangrenous part, if the limb be mortified; but to enroach as little as possible on the living flesh. At the same time he laid it down as a rule, not to leave a very long stump to an amputated leg; because the patient could more conveniently, he says, make use of a wooden leg, having the stump only five fingers long below the knee, than if much more of the flesh were to be preserved. In the arm, however, he left the whole of the living and healthy portion of the member, only separating the diseased part from the sound.

In preparing for amputation, he directs the fleshy and muscles to be drawn upwards, and bound tight with a broad bandage, a little above the part where the incision is to be made. This fillet was intended to answer a threefold pur-
pose: 1st, To afford a quantity of flesh for covering the bone and facilitating the cure; 2dly, To cleave the extrem-
ties of the divided blood-vessels; 3dly, To dull the patient's feelings, by pressure on the subjacent nerves. When this
firm ligature has been applied, Paré directs an incision to be made down to the bone, either with a common large scalpel, or a curved knife: then, by a smaller curved knife, we are carefully to divide the muscle or ligament remaining between the bones of the fore-arm or leg; after which we may proceed to faw off the bone, as high as possible, and to remove the apertures occasioned by the saw.

With the assistance of a curved pair of forceps, he drew out the extremities of the bleeding arteries, either by them-
Lelves alone, or with some portion of the surrounding flesh, to be firmly tied with a strong double thread. He now loosened his bandage, brought together the lips of the wound over the face of the stump, and kept them as close as he could, without actual fretting, by means of four stitches or futures. If the larger tied vessels should accidentally be-
come loose, he defines the ligature or bandage to be again palled around the limb; or elle, which is better, to let an afflant grip he limb firm with both hands, and press with his fingers over the course of the bleeding vessel, so as to stop the hemorrhage; then, with a square-edged needle about four inches long, and a thread four times doubled, the surgeon must secure the artery in the following manner:

Thrust the armed needle into the outsize of the flesh, half a finger's breadth from the vessel which bleeds, and bring it out at the same distance from the bleeding orifice; then round the vessel with the ligature, past it back again to within one finger's breadth of the place where it first entered, and tie a half knot upon a folded slip of linen rag, to prevent its hurting the flesh. Paré, by this means, says, the orifice of the artery will be agglomerated to the adjoining flesh so firmly, as not to yield one drop of blood; but, if the hemorrhage were not controlled, he contented himself with the application of antiliment powders.

The limb was afterwards treated according to the old plan, with "defenztive, reparative, and agglutinative." The first dressing was not removed for three or four days; but, when a suppuration came on, the "digestive, de-
terife, and mundificative remedies" were employed, until the ligatures might be safely removed, and exfoliation of the bone took place. As the surgeon saw proper, it was also recommended by Paré to halt the exfoliation by the actual cauterly applied to the extremity of the bone only; and to keep down fungous flesh by the use of burnt alum, blue vitirol, or red nitrate of mercury.

Thus did this famous surgeon endeavour, by his single example and principles, to exclude the barbarous use of hot irons in amputation. He says, he knew not of any such practice among the old surgeons; except that Galen recommended to us to tie bleeding vessels, towards their origin, in acci-
dental wounds, and he thought proper to do the same in cases of amputation; but in an apology at the end of his book, Paré has quoted, in his own defence, a dozen au-
thors, who employed or recommended the ligature before him; and he might have cited many more.

From the statement we have here given, it may be seen how far our best writers, of every country almost, have erred in ascribing the original invention of tying arteries to Ambroise Paré. Great merit, indeed, was due to him for the part he took in extending, and even reviving this incomparable prac-
tice; nay, it is not certain whether any one before him had ever applied the needle and ligature in similar cases, i.e. after amputation, but how very wide of the truth Mr. John Bell's recent account of this matter is, will appear to 
very person who will enquire into the facts themselves; for not only were needles and ligatures in use among the ancients.
AMPUTATION.

Woodall relates, that it was at this time no uncommon thing for criminals, who, in the East Indies, had their feet chopped off at the ankles, to get so well cured as to run on errands for their livelihood, after having put their stumps into large bamboo canes or reeds stuffed with cotton, &c.

Numerous applications, mechanical, chemical, and pharmaceutical, having been thought of to prevent bad and fatal hemorrhages after bleeding, it occurred to our countryman, James Young, that a more secure way of compressing the artery during amputation would be as follows: He placed a hard wad or bolster of linen cloth upon the inside of the arm or thigh, exactly in the course of the main artery; then, passing a towel or bandage around the member, he tied the ends together, and twisted them so very tight with a flick or button, as to stop the circulation through the blood-vessels. When the limb was amputated, he says, there was scarcely any bleeding, and the pain was greatly diminished by the compres. Before the dressings were applied, he advises to loosen the tourniquet a little, in order to observe where our care and allrigments are most wanted. This proposal is described in a curious and scarce book, published at London, A. D. 1679, entitled, "Curnis Triumphalis et Terribilis;" where may be likewise seen the first hint of the method of amputating with a flap, since claimed as a discovery by two continental surgeons, Verduin and Submorin; but whether or not these writers borrowed the suggestion from Mr. Young, is uncertain. As this mode of amputating is still very frequently practiced, and in many cases is unparalleled for its simplicity and advantages, we extract part of the author's original account, where he thus addresses his friend:

"Sir, I find by yours, that you are surprised with the intention I gave you, of a way of amputating large members, so as to be able to cure them per symphysin in three weeks, and without hourly and sealing the bone. I shall now entertain you with an account of the manner of this operation I would recommend to you, after I have told you that it was from a very ingenious brother of ours, Mr. C. Lovelam, of Exeter, that I had the first hints thereof. The ligatures and gips being made after the common manner, you are to put this dressing, or some long miliar-knife, to raise (following the leg) a flap of the membranous flesh covering the muscles of the calf, beginning below the place where you intend to make an incision, and raising it thitherward of length enough to cover the stump: having done so, turn it back under the hand of him that gipses, and as soon as you have secured the member, bring this flap of cutaneous flesh over the stump, and fasten it to the edges thereof by four or five strong stitches; having so disposed, clap a doffit into the inferior sort, that one padding may be open, for any bone or matter that may lodge between; but of that there seldom occureth any: then lay on a common defensive, &c. boil. fang. dracor. matric. terre sigil. cum alib. ovar. & acetum. and thereto girt it close with your cross bandage, and other compresse, after the usual manner; for the same way the defensive, &c. not only defends from accidents, as heat, pain, fluxion, &c. but gently compresseth the vessels, thereby contributing to the securing the amputation, and very considerably assists to the agglutination: the latter, "fidel. the compres figura, keeps the flesh firm and close to the ends of the divided vessels, confirms the coagulation, keeps the parts from cavity, and the blood from extravasation; and hinderers that deflux of humours which would otherwise destroy the intention of cure.

"In this fort of amputation, that manner of compressing the thigh by ligature, or the arm near the shoulder, which I have recommended in the foregoing discourse, is of excellent use; because thereby you may retain the delicacy of the blood, till by your dress and bandage you have so far secured the part as that it can receive no damage thereby.

"In this way of cure, phlebotomy, ileps ligature of the extreme parts, if need be, with what else may contemporaneously to the blood, hinder defluxion and maturation, and promote coagulation, though claimed against in that discourse, is in this case very useful and necessary.

"In the succeeding dressings, medicines healing per symphysin are to be used, and moni'ted them, perhaps, there are none better than those already mentioned, adding some powder of the roots of great compirse thereto; the doffitt, if you use any, may be left out the next dressing, or that following it.

"That this method hath cured such a stump in the three weeks, is a truth I can vouch with sufficient testimony; and I believe you will not much doubt it when you have perused this, and considered how easily and soon such large coagulation hath been made.

"I must not forget to intimate to you that this manner of dismembering, &c. is not to be made use of where the part hath been much injured, touched from fluxion, or otherwise vexed therewith, nor in members amputated for chronic caules; as cancers, fistulas, &c. of which the body is poor, or covered each by each, because in such digestion (which would destroy the motion) it is necessary to rectify and soothe the mistake, which it doth by draining off the matter of the dispoze more than ten fontanelles can do. It is also lef's unavoidable, for the course of nature that hath been dischared itself to long (as in a fistula), cannot of a sudden be obstructed without hazard of a mischiefous apolllamation; moreover, in such ill habits as those cases either cause or re-
AMPUTATION.

felt from, consolidation is difficult, if not impossible to be so suddenly performed, as this manner of cure requireth: the dyscrasia of the blood having destroyed or weakened its balance that it cannot expeditiously the work, which, if not speedily done, cannot be performed securely and firm; and in parts infamed and tortured by fluxion, or by concretion, it is easy to imagine there must be a discharge of that concrete matter, which cannot be, and yet the wound cured by sympathy.

"But in most of the amputations made at sea in fight, or on land in battles, or whatsoever acute accidents, such as wounds, recent lacerations require it, it may be done, and that with those advantages of the other way it rivals."

The author next enumerates eight very singular advantages with which this new method is attended, and then concludes his letter as follows:

"These are all the considerable advantages manifestly acquired by this new way: without doubt lice and trial will discover more, equal to them, and an abundance of lesser conveniences, which at present occur not to my consideration: these are enough to shew the novelty to be considerable and worthy of imitation: let them have with you this exceptional manifestation, that I am very ready to obey and serve you."

"Plymouth, Aug. 3, 1678. "JAMES YOUNG."

We thus have demonstrated, though it is not commonly believed, that what the French call "operation a l'anbeau," claimed as the invention either of Verdun or Sabourin, was put in practice by surgeons of Exeter and Plymouth before the year 1678. The different improvements and suggestions of more modern authors, will be noticed in our account of the amputation of particular members.

Of the Causes which may render Amputation advisable.

Previous to the time in which the needle and ligature were generally had recourse to, for securing the divided arteries after amputation, this formidable operation was but rarely ventured upon, by even the most enterprising surgeons; so that, we seldom read among the older authors of a limb having been amputated, from any other cause than a complete mortification. About the middle of the last century, however, the practice of inconsiderately taking off diseased members was so common, that several eminent surgeons attempted to prove it was never, or scarcely ever, absolutely needful. This opinion, although it originated from the belief that it was certain, was evidently wrong; since cases daily occur, in which, for want of amputation, patients must either inevitably die, or would only preserve their limbs at the hazard of dragging out a miserable existence, perhaps worse than death itself. Two general causes, at least, will therefore justify the performance of amputation: First, when the life of the patient is considerably endangered, by keeping his limb; secondly, when its preservation does not secure a more useful member than an artificial one.

The surgeon must know how to distinguish the circumstances in which the amputation of a limb is necessary, or may even be considered as a benefit; and in which, though it be delayed, or conceived to be unnecessary, the patient would run the risk of losing his limb or his life. To form a determination is no easy matter, and in many cases extremely difficult; especially as, in forming it, we have also to consider whether, by means of the operation, the patient's life or limb can really be saved. For in the cure of limbs that have been materially wounded, the event often depends upon the constitution of the patient, his age, and the air in which he lives; and it is rarely possible to form a sure prognostic at first, as the symptoms, from which it can be drawn, generally do not make their appearance till during the progress of the cure. Now, though it cannot be denied, that amputation has in many instances been performed when there was no necessity for it, it would be folly to imagine that it may in all cases be avoided. For there certainly are numerous diseases incident to the extremities, in which this operation is the only means of alleviating the sufferings of the patient, and even of saving his life.

1. A Caries of the Bones, whatever be its degree and magnitude, is not a sufficient reason for amputation in a young subject, at least not till every possible means have been tried for the preservation of the limb; but when the disease has spread very far, so that no benefit can be expected from the common milder remedies; and when the caries is become advanced, and combined with deep spreading ulcers in the surrounding soft parts, we have certainly no remedy left but the operation. However, even in this case, it would be necessary previously to examine, whether benefits were really to be expected from the operation; that is, whether the caries was confined entirely to the part, or, whether it had not spread itself already too far to admit of a cure.

2. When the bones of a limb have been entirely shattered by a Gun-shot wound, and all the muscles, ligaments, vessels, and nerves have been so lacerated by it, as to render the circulation of the blood into the fore-part of the limb altogether impossible, and that its death is altogether inevitable; farther, when a whole limb, or a part of one has been torn off by a cannon-ball, or by any other means, in such a manner that the bones are broken off into uneven splinters, and remain uncovered, and the muscles and tendons likewise are of unequal lengths, and at the same time very much torn and bruised; in both these cases the necessity of the operation is evident.

3. When a large Aneurism of long standing has destroyed the texture of the surrounding parts, and has produced a high degree of supputation, especially if it be in a joint, amputation is necessary, on account of the diseased state of the surrounding parts; for, on account of the aneurism alone, it would never be advisable. But it also becomes necessary when, after the operation for an aneurism has been performed, the limb does not acquire again its warmth and sensibility, but dies away. See the article Aneurism.

4. In compound fractures, let them have ever so unfavourable an appearance, amputation is never allowed, provided we are able immediately to procure for the patient all the requisite medicines, red, attendance, pure and wholesome air, and proper nourishment; for even in the most desperate cases a cure has sometimes been effected. But when, for example, in armies and fleets, every thing requisite for the cure of the wound is wanting, we are obliged to proceed to amputation; which must either be performed very soon after the injury has been inflicted (especially if the bones be shattered near a joint), or delayed until its most immediate effects and consequences, namely, the swelling, inflammation, and fever, have made their appearance.

5. In large wounds, combined with much Laceration and contusion, it is extremely difficult to determine the necessity of the operation, which, consequently, ought never to be performed immediately after the wound has been inflicted; but it is at most admissible afterwards, when the wounds suppurate so profusely as to exhaust the strength of the patient, or when they become gangrenous, or when a hemorrhage
hemorrhage is produced that can be stopped by no other means.

6. In white swellings, when the bones have become carious, the operation is always indicated; but good effects can only be expected from it when the disease is still merely or chiefly local. When it has already become general, or when it is the consequence of a serousous habit of the body, it is in the first case always, and in the second generally, unsuccessful.

7. In large swellings of the bones, that either endanger the life of the patient, or on account of their size, or from some other cause, become unbearable, the amputation of the limb is the only remedy that remains; provided there be no caufe present that renders it inadmissible.

8. Cancerous Sores, which, in some rare cases, attack the extremities, may indeed now and then be extirpated without amputating the limb; however, when the disease has already spread itself among the surrounding parts, and has attacked the bones and ligaments, the amputation of the limb, above the diseased site, may be of some benefit.

9. In other extensive and malignant ulcers, that do not arise from any inner and general cause, and which materially vitiate the whole mass of fluids, injuring the health, and, instead of yielding to the remedies that are employed, spread farther and farther, and become more and more obstinate, we are obliged to advise amputation, as the patient's life is actually in danger.

10. Incysted Tumours are sometimes very deep seated, or are even produced within the bone or upon the periosteum, and increase to a considerable size; so as by the preasure they occasion, to injure the texture of the surrounding parts, and not only to render the bones carious, but entirely to dissolve them. In such cases the operation may, under certain circumstances, be rendered necessary.

11. The extremities, and, according to Dr. Richter, most frequently the feet, are sometimes affected with a singular kind of tumour, the peculiar character of which has not as yet been accurately defined, but for which no remedy has hitherto been discovered, except amputation. The reader will find it described under the head of Oedema.

12. Sometimes also the distortion of a limb may be so considerable, and cause such great inconvenience, on account of its flattened, that the patient will rather lose the limb than remain longer in that condition. If we are not able to cure or relieve the distortion by any milder means, we may with propriety comply with the desire of the patient.

13. Finally, a gangrene may render the operation necessary; but that this is advisable in only a few cases, the reader will find maintained under the head of Gangrene.

When, therefore, it appears, upon due consideration of every circumstance, that the diseased limb cannot be preserved, and that the life of the patient can only be saved by immediately amputating it, the operation must be undertaken without further delay. Considered of itself, it is not so dreadful an operation by far as it formerly was, nor are its consequences so precarious and troublesome; and the cure is effected much more speedily, provided that, in performing it, all the rules prescribed by the present improved state of surgery are observed.

For performing the operation most of the following instruments are requisite:

1. Two straight knives, the blade of one to be from six to seven, and that of the other from five to six inches in length. The first of these is used in amputating the thigh, and the second for the rest of the limbs.

2. A small, narrow, straight knife, or catin, edged half way down the back, three inches and a half long, half an inch broad. This is used for cutting through the flesh between the two bones, in the forearm and leg, and for dividing the periosteum.

3. A fine sharp saw, for sawing through the bone. The blade may either be made of a steel spring, about ten inches long and half an inch broad; or of a wide steel blade, strengthened by a firm back, as represented in the plate of amputating instruments. The handle should be of a size proportioned to that of the blade; it also should be smooth, and without much ornament.

4. A small saw, made of a watch-spring, for separating splinters, and dividing the bones of the fingers, &c. The blade of this saw must be provided with a screw, by which it may be turned in either direction.

5. A small straight saw without a frame, for separating splinters in parts where the first saw cannot conveniently be applied.

6. A small pair of scissors, with long handles, for dividing membranes, ligaments, and tendons.

7. A pair of forceps, with a sliding button, for laying hold of the arteries; or, which will answer the purpose better, a tenaculum, with a light handle.

8. A tourniquet. (See the description of this instrument.)

9. A flip of parchment, eighteen inches long, and from four to five broad; it ought to have a slit as far as the middle, terminating in a circular hole. (See Retractor.) Its use is to draw back the muscles. We may also use instead of it, a broad leather strap, or a fillet of linen of the same shape.

10. Two tapes, half an inch broad, for tying round the limb, one above the other, under the place where we intend to make the incision. Still more useful for this purpose, especially when the limb is fat and flabby, are narrow leather straps with buckles, which hold the flesh firmer than the others.

But many surgical uses neither of them.

11. A quantity of adhesive plaster cut into slips.

12. Two fingle headed bandages, the many tailed bandage, or a woollen cap.

13. A number of pledges and compresses.

14. Lint, needles, and waxed thread.

General Rules of Practice.

In performing this operation the surgeon must be particularly attentive to the choice of the place where he should amputate; to the prevention of any violent hemorrhage during the operation; in cutting through the skin and muscles, to the finding of as much of those parts as is necessary for entirely covering the stump; in tying up the arteries he must be careful to spare the neighbouring nerves and other parts as much as possible; he must be attentive to the support of the external integuments, that they may not shrink back again after the operation; and, finally, to the subsequent treatment of the patient, till he is completely cured.

In general, a successful event depends upon the surgeon promoting, by every means in his power, a speedy union of the parts, or the healing of the wound without suppuration; the chief method by which this important point may be obtained, is by preventing all exposure of the wounded surface, and retaining the integuments in close contact with the subjacent bone, &c.

Ordinary Steps of the Operation.

Having determined on the propriety of amputating, and fixed the time in which it should be performed, we should prepare and arrange the necessary apparatus. Previously to commencing
commencing the operation, the surgeon will not fail to see every thing in the apartment that may be wanting, either for his own use or the patient's comfort. When the assistants have been properly instructed, a tourniquet is first to be placed over the main artery of the limb to be amputated, so as to stop the circulation entirely. On some occasions a tourniquet cannot be applied, and in such cases a careful person is to be appointed to the office of preventing the haemorrhage by other means. The limb being firmly secured, an incision is then to be made through the skin and cellular membrane, down to the muscles, by one circular stroke, except when the flap operation has been resolved on. The integuments are next to be raised, and turned back or drawn up from the muscles, more or less, according to the circumstances of the case, for the purpose of afterwards furnishing a covering to the face of the stump; in thus separating the integuments, we must have particular regard to the size of the limb. At the lower edge of the reflected skin and fat, the operator begins his second incision, carrying it through to the bone, in an oblique direction upwards, by holding his knife a little flinting. The retractor, if one be wanting, is now to be applied; and, by means of the double-ended caudal, the flesh, &c., is to be divided between the bones (in the fore-arm and leg). A small line of separation must also be made through the peritoneum, but it is not to be severed, for the entrance of the saw; after which the bone or bones will be divided, by slowly repeated long strokes with the saw, taking care not to make splinters. Having next secured the bleeding vessels, by ligature alone, and wiped away the coagulated blood, after slackening the tourniquet entirely, we finish, by bringing the lips of the wound neatly in contact, retaining them by crofs flips of good adhesive plaster, laying soft lint, &c. over the outside, in the direction of the edges of the wound, and bandaging the stump, with the ligatures hanging out at one corner. Thus may we frequently effect a cure in twenty or thirty days, by healing without suppuration, and without danger, after taking off the largest extremities; especially in quiet, airy situations, and with healthy young patients.

Amputation of the Thigh.

In this operation, the patient is to be recumbent on a table of the ordinary height. A common tourniquet must be applied as near as possible to the upper part of the thigh, immediately under Poupart's ligament, in such a manner, that the compres comes to lie straight upon the femoral artery: the fillet laid over it is to be screwed or twisted, by means of a short pick, over a piece of horn or leather placed on the opposite side, so tight, that not only no blood can flow through the large artery, but so as also to squeeze together all the muscular parts as closely as possible. A tourniquet of this kind (see the Plate of Surgery) prevents a haemorrhage, not only from the principal trunk of the artery, but also from all the lateral branches, and is therefore preferable in such cases to the screw tourniquet. Some surgeons, during the operation, never make use of a tourniquet, but have the artery strongly compressed by an assistant with his fingers and a cuffion.

It is a general rule, that we ought never to amputate more of the thigh than the disease absolutely requires; for the more of it we suffer to remain, the more useful the lump will be. Where the injury done to the limb is such, that only the leg is damaged up the knee, we amputate the thigh about a hand's breadth over the knee, in order to gain a quantity of skin sufficient for properly uniting the parts. The incision through the skin must be made at least three fingers breadth lower than the second cut, by which the muscles are divided. In order to hit upon the right measure, we must principally attend to the thickness of the thigh, for the thinner it is the more skin we must endeavour to gain; but it is in general better to have too much, than too little, of the integuments.

Two assistants, who stand at the head of the patient, hold fast his arms, and a third secures the found leg. The divided limb is held by two assistants in a horizontal position, with the knee moderately bent. One of these holds the limb, with both hands under the knee, firm and immovable: the other supports the thigh in the middle, holds it fast, and at the same time draws the skin tightly upwards. The operator now applies one of the small fillets to the place where he intends to make the first cut; namely, when the whole thigh is found close over the patella, and draws it very tight in an exact circle round the limb. With the assistance of this fillet the cut may be made more even and circular; and the fleshly parts, particularly the integuments, are prevented from shrinking and impeding the operation, being held fast and tenet at every point. This fillet, therefore, is of great and essential use in the operation, and ought certainly to be retained, though some may be inclined to reject it as imprudent. Due to apply a second fillet above the cut, as some do, is unnecessary. The operator, who stands on the outside of the limb, now cuts through the skin and cellular texture, with a straight, strong, and sharp knife, close over the upper margin of the fillet, in an exact circle, without cutting into the muscles. In performing this part of the operation, great attention is necessary, in order that the incision may not be made too superficial, or too deep, or even crooked. When the operator has divided the skin all round, but not the fascia lata, by this first cut, he next divides the fascia cautiously, by repeated cuts, without penetrating into the muscles; after which the skin may be more easily drawn back as far as he thinks proper. The skin is now to be retracted in an uniform manner, in order that the second cut may also be made exactly circular; the first assistant must, therefore, be well acquainted with the method of performing this operation.

When the skin has been drawn back full three fingers breadth (too much is always better than too little), the operator, using the same knife as before, cuts the muscles through down to the bone, close to the margin of the retracted skin, with a perpendicular, even, and circular incision. Some surgeons, however, cut through obliquely, by flinting the edge of the knife upwards. If the operator has acquired sufficient dexterity by practice, he will always be able to make this incision without carrying the knife twice round the limb.

"As it frequently happens, in amputating the thigh," says Prof. Murina (Neue Med. u. Chirurg. Beobachtungen, Berlin, 1796. 8. pag. 515), "after the circular incision through the muscles, though these are divided three fingers breadth higher than the skin, that the flexor-muscles of the leg contract more than the extensors, and thus, at times, produce a deformity of the limb, which occasions some inconvenience in wearing a wooden limb: this accident might be prevented, by keeping the patient's knee moderately bent, whilst cutting through the extensors, and extended whilst making the incision through the flexors. The incision will, nevertheless, be even and circular; and when performed in the above mentioned positions of the limb, will prevent any deformity of the limb, for the flexor-muscles of the leg contract with much more force, after the incision than the extensors; in order to avoid which, the former must be cut through at their greatest elongation, consequently when extended, and the latter when contracted. By this practice
AMPUTATION.

no time is lost, nor any additional pain given to the patient; and both the cure is more speedily effected, and the stump acquires a better form."

"Generally (says Dr. Richter in Medicin. u. Chirurg. Bemerk. &c. B. I. Gottingen, 1793, p. 232.) the flexor muscles contract with much greater force than the extensors after amputation of the thigh. They do the same during the progress of the cure also, and consequently, even in the most rapid cure, attended with no suppuration, the stump generally grows uneven at the bottom, which causes inconveniences in the application of a wooden leg." He accedes therefore to Prof. Murmann’s opinion, that the extensors should be divided higher and the flexors lower, consequent on the flit with the knee moderately bent, the second with the knee extended. This practice deserves, therefore, to be generally recommended.

According to Mr. Allan’s method, the knife ought to be conducted in a slanting direction, with the edge directed upwards, in form to a hollow cone; but few surgeons have any opportunity of acquiring the dexterity requisite for performing the operation in this manner, by practising it upon dead bodies; and it is not done by some of the most noted surgeons on the continent. Prof. Colenien (Tode Medicin. Journal, B. I. Copenhagen, 1793, p. 166.) does not make his incision in the form of a cone, but cuts through the skin at the requisite distance from the place where the bone is to be faved through. He next separates the skin from the muscles, as far as is necessary, in order to turn it back as the cuff of a coat. He next cuts through the flit, saws off the bone, binds up the vessels; and, lastly, draws down the retracted skin over the stump, and folds it together in such a manner as to make it form an oblong flit from above to below, out of which the ligatures of the vessels hang.

"To hold the knife obliquely (says Prof. Murmann in Neue Med. u. chirurg. Beobachtungen, p. 165.), with the edge turned upwards, in cutting through the muscles, so as to form a conical incision, is a refinement upon the operation, which it is equally difficult and unnecessary to practice."

"I am still of opinion," Dr. Richter remarks (Med. und Chirurg. Bemerk. B. I. p. 232), "that the operation by means of which Mr. Allan endeavours to make the stump itself hollow, is very difficult, if not entirely impracticable." He performed the amputation in the following manner: the incision was made three fingers breadth above the knee. An aifillant laid hold of the limb, with both hands, above the place of the incision, and secured the skin. By the first circular incision, the operator divided not only the skin, but also the cellular texture, as far as the external surface of the muscle; this must necessarily be done, if we wish to be able to draw the skin much upwards. When the cellular texture has not been completely divided, we shall generally find that it becomes tenes, whilst we are drawing the skin upwards, and thus prevents its being retracted so far as it otherwise might. Whilst, therefore, the assistant drew up the skin as much as possible, the operator made a second circular incision, close to the margin of the retracted skin, with which he again divided the cellular texture as deep as to the surface of the muscles, whereby the assistant was enabled to draw up the skin still much higher; so that now the upper margin of the skin was at least three full fingers breadth distant from the lower. The separating and turning back of the skin, according to Mr. Allan’s method, he considers as a very tedious and difficult operation. With the third circular incision he cut into the muscles along the margin of the retracted skin, not so deep as down to the bone, however, but only about half way through. He now directed this divided external layer of flesh to be drawn upwards, as much as possible, with the fit compres; and with a fourth circular incision along the margin of the retracted skin, he cut through the remaining flesh to the bone. The whole of the flesh was now drawn back with the fit compres so strongly, that the bone was laid bare the length of at least two fingers breadth, and could be sawed off to that height. When the skin and muscles were drawn down, the stump formed a conically excavated surface, at the upper part of which the bone lay so deep within the flit, that it could not be seen. After the vessels had been tied up, the stump was pressed together on both sides, so that the wound formed a flit in a straight direction from before to behind. The edges of the skin were so close to each other, that the wound resembled a very narrow slit. The skin was fastened together with adhesive plaster, and the flit and the stump were pressed together by pads of lint applied to both sides, and then confined by a bandage. The ends of the ligatures hung out at the lowell and pollelwr angle of the wound. Even on the fifth day, three quarters of the wound, from the top, adhered together, and were quite dry; the lowest quarter, out of which the ligatures hung, was still moist, but discharged only a very few drops of pus during the whole course of the cure. On the eleventh day the ligatures were separated, and the remaining small orifice closed in the space of a few days more.

When all the muscles have been cut through to the bone (whether we have recourse to Richter’s or Allan’s mode), the fit compres is applied; by means of which the remaining muscular parts are covered, and these are, at the same time, somewhat drawn back by the hands of the aifillant, in order that the operator may be able to use the saw with more freedom, and saw off the bones higher up. When this has been done, the periosteum is divided circularly, as high as possible, with a short, strong knife, and peeled downwards. The saw is now applied horizontally, and the bone sawed through. The operator saws slowly at first, but when the saw has laid proper hold of the bone, he moves it somewhat quicker; and, at the same time, the aifillants hold the limb rather high at the superior part, and low at the inferior, so as to bend it somewhat afunder, in order that the saw may not get wedged in during the operation. When the bone is nearly sawed through, the saw is again moved slowly and with short strokes, in order that the stump may become as smooth and even as possible. Should there still remain any small projection on the bone, this must immediately be removed.

As soon as this has been performed, the vessels are to be secured by ligatures. The principal trunk is first tied up, and if it be at the division of the artery, both branches are included in one ligature. For this operation a triple thread is used, which is fastened together with wax, so as to form a flat ligature, in order that the artery may be tied fast, without danger of its cutting through. This thread is inserted into a crooked needle; the artery is laid hold of, at its orifice, with a tenezium, or crooked sharp hook; it is then drawn forwards, and the needle being introduced under the vessel, in such a manner as at the same time to perforate the cellular texture on both sides, it is pulled through. The aifillant now holds the hook, whilst the operator takes hold of the ligature inflected under the artery, and ties it fast with a double knot, over which some surgeons make another single one, about two lines above the extremity of the vessel. The ligature is generally left of such a length, that it can be conveniently fastened upon the skin on the outside of the wound. Should we find it difficult to discover the trunk of the art
AMPUTATION.

When the tourniquet has been removed, the stump must be left exposed, upon which the pointing of the blood immediately discloses its oriice. In order to discover the oriice of the lateral vesfels, the tourniquet must always be quite loofened, that they may also be bound up in the manner already described.

As the adhesion of the parts, and the healing of the wound depend upon the blood being entirely stopped, it is necessary that all the lateral vefels which discharge any should be tied up; for which purpose the surgeon, when he has loofened the tourniquet entirely, wipes the stump with a wet fpounge, examines whether any of the branches discharge blood, and ties up those which do, be they never fo small. When no more blood is discharged, the stump is once more wiped with the fpounge, entirely cleansed from the blood, and the lips of the wound are brought together.

The ends of the ligatures, if there be many, ought to be distributed between both angles of the wound, that they may not form a thick bunch, and occasion inconvenience by their pressure. When every part of the operation has been performed in manner above directed, the adhesion will take place easily; but if the directions are not observed, it will sometimes not take place without much difficulty and pain.

The lips of the wound may be brought together in two different ways. Some prefs them together, on both sides, fo that the wound forms a perpendicular slit, which runs in a straight line from the fore to the back part of the thigh, and let the threads of the ligatures hang out of the lowermost and posterior angle of the wound. Others prefs them together, fo as to form a horizontal fllure: in this manner the flap may lie conveniently, and the fluids may still be discharged by the two lateral orifices of the wound, out of which the threads hang. By this method the flap also acquires a better form than when the fold is made perpendicularly.

When the lips of the wound are brought together in either of the abovementioned ways, they must be made to apply neatly to each other, and all the points of the sides of the wound brought into close contact. Whilft the surgeon holds them together in this manner, an affiant applies from four to six flips of adhesive plafters; then lays over the edges of the wound some loose dry lint, and covers this with a quantity of the fame fpafnum, fpread with a mild, healing ointment. The whole is finally secured with a long bandage, which is apied at the upper part of the thigh, and carried down in spiral folds round the limb to the bottom, where it is doubled round, and carried up again to the upper part: it is then doubled round, and brought over the fore side upon the wound from behind upwards; and these flaps are repeated over both sides of the thigh and over the wound, in such a manner, that one fold alfo always covers the other. The whole thigh is thus covered with the bandage. These folds are then b'cured by circular folds from below upwards, without crossing the bandage over the flap, as that would be an impediment to the adhesion of the wound; but by this method of bandaging, the retraction of the skin is prevented, and the adhesion promoted.

After the bandaging has been completed, the patient is placed in a convenient posture, and the thigh is laid upon a bolster, gently bent; for if laid horizontally, or even lower than the horizontal line, it not only causes pain to the patient, but the flexor muscles of the thigh constantly tend to bend it and bring it to the abovementiond position. If we attempt to counteract this tendency, by applying force to the limb, it becomes convoluted, and the adhesion is frustrated.

If no particular symptoms forbid it, the flrst dressings are suffered to remain on till the fourth, fifth, or flfth day; and when all this is still properly united, the adhesive plafters are nevertheless left in their places. The wound is cleansed from the impurities that have been discharged, and the limb is bandaged in the manner above described. If any of the plafters have broken loose, or the lips of the wound have separated at any part, the flatter is cut through over the wound, without pulling it off, and a new one, or if it be necessary, several are applied, in order to bring the separated lips of the wound into proper contact.

Instead of the circular bandage above described, some ad- vise the limb to be rolled with Loder's twenty-seven-tailed bandage, (D. Juft. Chr. Loder, Chirurg. Medium. Boohachingen, &c. Lib. i. Wimar, 1794, p. 14. Tab. i. fig. 4. 5;) in which case a circular bandage is firit applied to the upper part of the thigh, and carried down to the bottom in spiral folds, fo close to each other, as to prevent its retraction of the skin and muscles, but not to excite pain, or obstruct the circulation. The bandage is falleden with a pin at the lower part of the flump, leaving for future use a piece large enough for folding two or three times round the limb. After the whole of the bandaging has been performed as above described, the remaining part of the fliet is folded twice or thrice round the limb, fo that the prufure can be increafed or diminished at pleafure, and finally the twenty-seven-tailed bandage is applied.

While we apply the circular bandage, the tourniquet must be removed, but it must be again applied as soon as we have finifhed the bandaging of the limb, in order that we may be able immediately to stop any hemorrhage that may come on; for which purpose it fuit likewise be kept applied for several days after amputation has been performed.

When the patient has been put to bed, and a hooped frame laid over the flump, he fould immediately receive an opiate, in order to prevent involuntary fpasmodic motions of the flump. During the fift days after amputation, an affiant ought frequently to examine the thigh with great care, in order that if he fhould find blood to flow from any of the vefels, he may draw the tourniquet as tight as is neceffary to prevent any material hemorrhage, till proper affiduus can be obtained. If there eude only a small quantity of blood from the surface of the flump, it is unneceffary, on that account, to remove the bandages; but when the hemorrhage is confiderable, it can only be stopped by the application of ligatures: for were it even poifible to flop it by compreflion, this would ftrquate our principal aim, namely, the speedy union of the parts without fappuration. After we have flopped the bleeding, we must apply the bandages as before directed.

When every thing goes on according to our wish, the bandages are only renewed every two or three days, in order that we may not impede the uniting of the parts; but often, if the fappuration becomes more copious, or a new pain is perceived in the wound. Commonly about the tenth or ifth day, sometimes later, the threads of the ligatures may be drawn out by gently pulling them; frequently they grow loose and fall out of themselves. When the threads have been detached, the open angles of the wound are to be united nearly in the fame manner as before; after which the complete cicatrisation of the wound takes place in a longer or shorter time, but commonly in a week or a fortnight more.

To prevent inflammation, the patient fhould be strictly treated during the fift days after the operation, according to the antiphlogistic regimem; though this must be used with great caution in exhausted and debilitated constitutions, lest by too strict a regimen we might impair the strength of the body. When the pyrexia has abated, the patient is in a
AMPUTATION.

It is adopted by many as a general rule, that the amputation of the leg should never be performed just above the ankle, even though the disease be seated near the bottom of the limb; but always three or four fingers breadth under the knee: repeated experiments, however, have shown, that amputation may be successfully performed just above the ankle, and as near to them as the disease permits. The advantage of being able to use the knee-joint in walking is so great, that the surgeon should not deprive the patient of it. (See our account of the Flap Operation.) The objection, that a long stump is an incumbrance, may be removed by the use of an artificial foot. In order to promote the cure of those wounds, the projecting tendinous parts must be separated with the scissors. Mr. B. Bell conceives it to be better in every instance, where the circumstances admit of it, to amputate a little above the ankle than at the upper part of the leg: amputation immediately under the knee he rejects entirely, as the cure of the stump is always tedious in this situation, the bones thick, and the soft parts deficient. In such cases he prefers amputating above the knee, though his opinion cannot be unconditionally adopted.

When we are to amputate immediately below the knee, the patient is placed upon a table, and secured in the same manner as in the amputation of the thigh. Some are of opinion that the tourniquet should be applied a little above the knee, with the cushion upon the artery in the ham; but others apply it also in this operation immediately under Poupart’s ligament, or in the middle of the thigh, which is the preferable method. The foot and leg are secured by an assistant, who sits before the patient. A second assistant draws up the integuments towards the knee. The surgeon stands on the inside of the limb, and with his knife makes a circular cut through the skin and cellular sub stance down to the muscles; so that after as much of the integuments as will afterwards be necessary for covering the stump, has been separated in this manner from the parts beneath, the muscles and bones may be divided immediately below the part where the tendons and flexor muscles of the leg are inserted. When this has been done, the soft parts between the two bones must be divided with a two-edged knife (named a cuti)n, and the periosteum separated downwards. The skin and other soft parts must then be held fast to protect them against the saw, which is to be applied so as to cut through both of the bones together. When this has been done, and the vessels tied, the external integuments are drawn over the stump, and retained with adhesive plasters. During the course of the cure the practice is the same as after amputation of the thigh.

In separating the skin we must be very careful to separate it from the subjacent parts in such a manner as to have as much of the cellular substance attached to it. The more we deprive the skin of its cellular texture, the more lifeless it becomes, and the less fit for adhering speedily to the stump. As the skin also on the one part of the leg cannot be retracted with near the same facility as in other parts, for example, the thigh, where it lies upon muscels, while on the fore part of the leg; on the contrary, it is connected by a very dense cellular sub stance immediately to the periosteum, the assistant is always obliged to fold back as much of it as has been separated, before the division of the muscles can be attempted, in order that the surgeon may be able to separate them from the bone, and have as much of them as is requisite for covering the stump.

The reason why the surgeon is directed to stand on the inside of the limb in this operation is, that when the knee and foot are turned inwards, and the fibula raised, he may be able to saw through both bones of the leg together, which he cannot do when he stands on the outside. Finally, he must take care not to suffer the bone to break off, or should such an accident happen, he must remove the inequalities that may be produced by it. Many have advised, in amputating the leg, after the muscles have been cut through, to apply a ligature round both bones, in order to hold them fast, and the same has also been advised in the amputation of the fore-arm; but this can be of no advantage, for it will he better to hold both the bones fast with the band, and infer the forefinger between them, nearly under the spot where the saw is to go through, in order to prevent their coming into contact with each other.

When the leg is amputated immediately above the ankle, an artificial foot cannot easily be applied and secured upon the stump; the machine must be made heavier and thicker at the ankle, nor can the leg be made so equal in length and thickness as the other, as would otherwise be possible. When the stump is about nine inches in length from the knee, its dimensions are reckoned to be in every respect the most convenient.

Of amputating with a Flap.

In the old method of performing amputation, the cures were very tedious, and the health of the patients much impaired;
Amputation.

As it is very difficult to restrain the hemorrhage which may accidentally happen to supervene, after the flap has been applied in Mr. Young's manner, it being necessary for that purpose to undo the whole of the bandages, and separate the flap from the surface of the wound; moreover, as the flap does not always adhere uniformly over the whole surface of the lump, and the pain, inflammation, and tension which supervene, are sometimes much more violent than after the ordinary method of amputating, Mr. O'Halloran proceeded to define the lump and flap as two separate wounds for the first twelve or fourteen days; but afterwards, when the danger of bleeding is over, the symptoms subsided, and suppuration established, to turn the flap back over the surface of the lump, and secure it by adhesive plasters, compresses, and bandages, till a complete adhesion has taken place. It seems that one grand cause of failure in the success of the flap operation, as it was performed in France about a century ago, was "the monstrous hemorrhage," as Mr. O'Halloran expresses himself; and, according to their uncouth mode of conducting the operation, we almost agree with the late named writer, that "it was absolutely impossible for it to succeed." But we are surprized that Mr. Benjamin Bell, of Edinburgh, even in the new edition of his Surgery, should misrepresent the success of the present mode, so much as to deny its having cured "before the fourth week."

System of Surgery, vol. vii. p. 330, 7th edition: this is certainly an unfair and imperfect statement of Mr. B. Bell.

By Mr. O'Halloran's improvement the flap operation was rendered more safe and certain, but has not come into general use, as that which Mr. Alphonsin invented in the mean time deserves, in most cases, the preference. The flap may, under various circumstances, be employed with advantage. Where it is impracticable in the common way to cover the divided parts sufficiently, we ought always to cut out a flap of muscle or skin for that purpose; it is bell, for example, when we amputate the arm at the shoulder joint, or a finger, or toe.

It has also been preferred by some surgeons when the leg is to be amputated immediately under the knee, as the integuments are very thin at that part, and there is reason to suppose that the lump cannot be sufficiently covered by any other means.

It has not been the common practice to make a double flap, although this is at present done with very great advantage by the surgeons of the Liverpool Infirmary. Their method is (excepting for diseases of the feet) to take the flap from each side of the limb, in preference to above and below, as it affords a better outlet for any pus that may collect in the lump. Upon an average, we find, on making recent inquiry, the flumps are healed in about "eighteen days;" which is more than can be laid in favour of any other mode of amputating. The double flap likewise is free from the puckered appearance which remains after the single flap; and in a few weeks, we are informed, "the cicatrix can hardly be perceived." Our own experience with the flap operation, even in the metropolis, is much in its favour; so that whatever objections have been raised against it (when properly performed), we are strongly inclined to think they have been chiefly theoretical, and not founded on actual observation.

Amputation with a Flap immediately above the Knee.

This operation may be performed either with one or two flaps; but if it be done with only one, it succeeds best on the fore part of the thigh, as there is here a sufficiency of flapps for forming the flap and covering the bone; and as the matter thus falls off more readily when the flap is applied, and the patient laid down upon his back.

The patient being placed upon a table, and the tourniquet applied to the femoral artery below Poupart's ligament, an afieldant draws the skin firmly up, and retains it in that situation. Whilst this is doing, we ought to mark, with ink upon the skin, the circumference of the intended flap. The extreme angle of the flap should reach to the bottom of the thigh below the skin, which should be much dissected, in which case the flap must terminate where the dissection of the integuments commences. The base of the flap must be at the place where we intend to saw through the bone. Its breadth must be proportionate to the dimensions of the limb. If, for example, the diameter of a flump be twelve inches, a flap four inches and a quarter in length will be fully sufficient to cover it. But as some allowance must also be made for the quantity of skin and muscles that may be saved on the opposite side of the limb, by drawing them up before sawing the bone, a thirteenth inch thick will require a flap more than three inches and a quarter long, and in proportion to the size of the limb. The flap should be as broad at the base as the breadth of the limb will permit; and it should be continued nearly, though not entirely, of the same breadth, till within a little of its termination, where it should be cut circular, so as to correspond, as accurately as may be, with the back part of the circumference of the wound.

When now the surgeon has marked out the circumference of the flap, he must place himself on the outside of the thigh, apply the point of a straight double-edged knife to the outer side of the base of the intended flap, and pull it in to the depth of the bone; then, carrying the point close to the bone, pull it through the integuments on the opposite side of the mark. He must now carry the edge of the knife downwards in such a direction as to cut out the flap according to the figure marked out; but towards the end he should raise the edge somewhat from the bone, so as to make the lower part of the flap somewhat thinner than the base, whereby it will apply more accurately to the surface of the fore. The flap must be held by an afieldant, but the skin and muscles on the back part of the limb must, with one stroke of the knife, be cut down to the bone, about an inch lower down than where the bone is to be sawed. The muscles are then to be separated to this height from the bone, with the point of the knife, and all the soft parts must be drawn back with the flat compress, till the bone is sawed. Any splinters that may have been left are then to be separated, the arteries tied up, and the ligatures left hanging out at the edge of the flap.

The muscles and integuments must now be drawn down, and secured with a roller, as has been directed above, in treating of the amputation of the thigh with the circular incision. The flap may now be laid down over the surface of the wound, the coagulated blood having first been carefully wiped off with a sponge, and the flap may then be moderately secured to the stump with adhesive plasters and future. The under part of the flap should be covered with a large
A large pledget is spread with cerate, and a cushion of lint or tow laid over it. The whole should then be covered with crofts flaps of linen, and several turns of the circular roller. After the space of three or four days, or even longer, the dressings may be renewed. As soon as all the ligatures are removed, and the tension and pain have abated, the skin may be drawn over every part of the wound which before was not covered, and secured with adhesive plasters.

The method now described is generally to be preferred; but if, instead of effecting the cure by promoting a speedy adhesion of the parts, the surgeon deems it advisable, he will treat the flap as a separate wound according to O'Halloran's method: in which case, his correct mode of proceeding is as follows: The muscles and skin being brought down and secured with the roller, the whole surface of the flap is covered with a soft pledget spread on both sides with an emollient ointment. Upon this the flap is laid down, and another pledget of the same kind being laid over the flap, a cushion of lint or tow fiat, and a compact of soft linen are applied, and the whole is secured with crofts flaps of linen and a circular roller; but with no more pressure than is requisite for the security of the dressings. At the end of three or four days the dressings may be renewed in the same manner; and about the tenth or twelfth day, or whenever the tension and inflammation are removed, the ligatures may be taken out.

When now a proper suppuration is established, the flap may be applied to the stump. But previously, the matter must be wiped off from the surfaces of both forces, with a soft sponge, and these being brought into contact with the greatest exactness possible, they may be secured either with adhesive plasters or two or three futures.

Mr. Benjamin Bell, who prefers the latter method, advises us, that when, with a view to immediate adhesion, the flap is laid down directly after the operation, the pain, tension, and inflammation, which ensue, run too often high as to compel the surgeon to remove the dressings; whereas, when O'Halloran's method is adopted, the inflammation which ensues is very trifling, and the cure is accomplished even more quickly, than when the operation has been done according to the former method. We are however very much disposed to think the inflammation, etc.; is too often produced by tight bandaging or futures, in the cases where it falls of itself.

The operation with two flaps, according to Ravoton's method, is performed in the following manner: When the tumefaction has been applied, an assistant draws up the skin tight, and makes a circular incision through the skin and muscles at the lowermost part of the limb, with the edge of the knife turned obliquely upwards. A sharp-pointed knife is now pushed in on one side of the limb down to the bone, at the part where the bone is to be fow'd, and the under edge of the knife being turned obliquely outwards, the muscles are divided down to the circular incision. The skin and muscles on the opposite side of the limb are now divided by a similar incision, and with these the intermediate soft parts that may have been left are likewise cut through. When now the bone has been sawed, and the vei'ets tied up, the surgeon may either lay both flaps together immediately (as we recommend), or keep them separate for the first twelve or fourteen days, after which he may treat them in the manner above directed.

Of the Flap-Operation below the Knee.

This operation is performed nearly in the same manner as that above the knee; and the flap may be applied either immediately, or after the pain, tension, and inflammation are gone. Only we cannot here, as on the thigh, so commodiously cut out the flap on the fore part of the limb, as the leg has no muscles there. On that account all writers direct the flap to be cut out at the back part: though this is attended with a very considerable inconvenience. For when the flap has been cut out at the calf of the leg, it is fearfully possible, after it has been applied to the stump, to prevent the accommodation and retention of the pus, as it does not find a free vent below, and we dare not apply more than a very moderate degree of pressure to the flap.

Instead therefore of cutting the flap out of the back part of the leg, Mr. B. Bell advises us to it from the outside of the limb, where there is a sufficient quantity of muscles for the purpose, and where the flap can be no impediment to the discharge of the pus. He therefore performs the operation according to the following method: Let the point of the knife be entered on the outside of the ridge of the tibia, at the place where the bone is to be sawn, and after carrying it backward, in a direct line, to the opposite side of the sa/e of the flap, let the edge be carried down the line previously marked with ink as a direction for the form and length of it.

When we amputate immediately above the ankle, we must cut out the flap behind, as there is not a sufficient quantity of soft parts behind; but it is here to be repeated, what has already been observed, that the leg ought never to be amputated immediately above the ankle, as to have the stump too long for an artificial leg and foot being conveniently adapted to it. In an adult we ought therefore to form the flap about nine inches under the knee, if we wish to perform the operation in this manner.

Amputation of the Foot, Toes, and Fingers.

When the whole foot is diseased, we must perform the amputation in the manner above mentioned, above the ankle. This should also be done even where the joint itself is found, but all the rest of the foot diseased. Some, indeed, have advised to take off the foot at the ankle joint; but as, when this is done, an artificial foot cannot be applied, nor the stump covered with feithy sublimation, the amputation above the ankle is evidently to be preferred.

But when a considerable part of the foot is still found, we ought to endeavour to preserve it, and merely to remove what is diseased; and this should be our practice even where two of the metatarsoal bones only remain found; for the patient may still make good use even of a small part of the foot in walking, provided he wears a shoe well made, properly fluffed out, and with a strong unyielding sole. This may be done, especially when the bones on the inside of the foot, or those corresponding to the great toe, and those next it, are left. Very remarkable, therefore, is the case of Mr. Turner's amputating the foot at the middle. The operation was performed on account of a painful tumour, which extended as far as the middle of the metatarsoal; and it was thought unnecessary to amputate above the ankle. A double incision was therefore made, and in order to preserve as much as possible of the integuments, a small part of them situated above the tumour, was included in the first incision. As the integuments could not be drawn back to any considerable length, it was impossible to preserve so much of them as might have been wished. The foot was fow'd through at the upper part of the metatarsoal, the hemorrhage was easily stopped, and in the course of ten weeks it was completely healed, without any violent symptom having supervened.

When only single bones of the tarsals are diseased, these bones alone are to be taken out. When only one part of a bone
bone is diseased, this must be removed with the faw, chisel, or trephine, but not the whole bone taken away.

In every amputation as much skin as is sufficient for covering the wound must be faved; but this is particularly necessary in amputating any part of the foot, where bad effects are to be apprehended from friction in walking. As the skin of the sole of the foot is commonly very thick, the flap which is to cover the sore ought, if possible, to be taken from that part; for this will prevent the bad effects of friction upon the part, much more than could be done by the skin of the upper part of the foot which is thinner, and accustomed to friction or pressure.

In performing this operation, the patient is placed on a table, and the tourniquet applied, either below Poupart's ligament, or the upper part of the thigh, or over the knee, with a compress in the ham. The limb is secured by an affiant, and in sawing through the diseased bone, a piece of pasteboard, or a thin splint of wood, should be inserted between it and the contiguous found bone, in order to prevent the latter from the saw. When the diseased bone has thus been removed, and the arteries tied, the flap that has been faved is laid, with as much exactness as possible, on the fore, and secured with slips of adhesive platter, and a roller. If futures are employed, they ought to be inserted in such a manner as not to injure the tendons of the flexor and extensor muscles of the foot and toes.

In amputating the fingers and toes, we proceed in the same manner as with the larger extremities, and the flump must here also be covered with a flap. The skin is drawn back as much as possible, after which the skin and flesh are cut through with a straight bistouri, between the contiguous found fingers and the diseased one, in a straight line backwards, till somewhat above the joint, on both sides; the skin and flesh are also cut through above, round the joint; the finger is then bent towards the palm of the hand, and cut off from the out to the inside; the incision terminating at the fore part in such a manner, that still some part of the flesh is preserved for the purpose of being afterwards applied over the wound to facilitate the cure. When we only leave a single flap of integument on the finger, it has been recommended to let it be taken from below in labouring people, to afford a suitable flump for pressure; but, where beauty is more an object than use, we may take the flap of skin from above, as it will then scarcely occasion a visible scar after the cure.

In as much as we here speak of the flaps, in which the whole finger or toe is amputated from the contiguous metacarpal or metatarsal, we must also proceed in a similar manner when amputating only one or two joints; and if we find it necessary to tie an artery, we should do it by means of the tenaculum. The flap must be laid over the wound, and secured as accurately as possible with adhesive plasters, and moderate pressure with a roller. The objection which has been made that the union of the soft parts with the cartilage is precarious, is not founded in truth; for the skin unites with the cartilage, which covers the bone at the joint almost as readily as with other parts. It is therefore unnecessary that we should separate the cartilaginous surface of the joint with a small saw, as was formerly the general practice.

Amputation of the Arm and Fore-Arm.

This is performed in every respect in the same manner as has formerly been directed for the amputation of the thigh and leg. It should be remembered, however, that a long flump will be more useful in the arm than a short one. When we are to amputate at any other part than the joint, we may do it without cutting out a flap to cover the wound; for in these parts there is a sufficient quantity of muscles, cellular texture and skin, for covering the flump, if we draw back the skin, according to the directions formerly given, and first divide that, and afterwards the muscles. Should this not be practicable in certain cases, it would then undoubtedly be better to perform the operation with a flap.

Amputations in the Joint.

These operations have been recommended on the authority of a number of cases in which they have been performed. In such an operation we are directed to cut first through the skin, nearly over the joint, with a straight knife upon the upper or forefoot side, making a semicircular incision; we then open the capsule of the joint on both sides, and in doing this, we bend the limb (suppose it be the hand) in order to obtain room for cutting through the capsule all round, that we may the better be able to spare the cartilage of the joint. The rest of the operation and cure is conducted in the usual manner.

But though amputation at the joint is preferable to amputation above the joint, with the fingers and toes, and perhaps also with the hand, the application of the same practice to other joints, such as the elbow, knee, and ankle joint, must be attended with very great difficulties. For, in the first place, this method of amputating is in fact more tedious than the operation above the joint. It is also equally painful, and the hemorrhage equally dangerous; and as the soft parts in these joints are mostly aponerotic and tendinous, a favourable inunction and suppuration are not so likely to ensue. Besides it is very difficult at the elbow and ankle joint to saw off so much muscular substance and skin as are requisite for covering the bone at the surface of the articulation, on which account a tedious suppuration and exfoliation generally take place; and there is reason to apprehend, that we may afterwards be still compelled to amputate again above the joint, and saw through the bone.

We shall describe the operation, as it has been done at the hip and shoulder-joint by eminent surgeons.

Amputation of the Arm at the Shoulder Joint.

Though this operation ought never to be performed when we can accomplish our purpose by amputating below the shoulder-joint, it being always a hazardous operation yet we ought not to hesitate to undertake it, when abscesses in the joint, carries of the humerus extending to the shoulder, complicated fractures reaching as far as the head of the bone, bad gun-shot wounds, or a phænocus render it necessary. Mr. Bromfield has given the following directions for performing it; and he did it several times with success. See his Chirurgical Observations, vol. i. p. 247, et seq.

When the apparatus is ready, place the patient upon his sound side upon a table, and in a somewhat oblique posture, that the surgeon may have room to move freely. Let an affiant then compress the subclavian artery at the place where it passes through the scapular muscle, in such a manner that, by the relaxation of the first rib, the passage of the blood through the artery may be entirely prevented. In order to know whether the pressure be sufficient for this purpose, we have only to examine the pulse at the wrist.

The patient being properly secured by the affilante, and pressure made firmly on the artery, the surgeon begins his incision on the inner side of the arm, at the edge of the deltoid muscle, namely, at the place where the great pectoral muscle passes over the axilla, to be inserted into the os humeri. He cuts through the skin and muscles, carrying his incision downwards, and rather obliquely outwards, till he arrives a little
AMPUTATION.

The ends of the ligatures are then drawn to the outside of the arm, and the inner part of the flap let fall down in such a manner, as to fit into the semicircular incision. The surgeon then passes a large crooked needle in a thread through the inner flap, about an inch and a half under the upper and inner part of the wound, and carries the point of it through the skin of the wound in the same line, forming the interrupted future in the usual manner, in order to promote the speedy union of the parts. The same operation he repeats twice with the outer flap, then draws out the ends of the threads through the middle incision in the deltoid muscle, and lets them hang out till they come away spontaneously, which may be in about eight or ten days.

When the socket of the joint is not curious, the operator, before drawing out the ends of the vessels, is recommended (but, we think, very improperly) to separate the cartilaginous substance which lines its socket with a scalpel, and to cover the bone with dry lint, which is to remain there till it comes away of itself. He also makes use of dry lint when the socket of the joint and the adjacent bones are curious. Every long sinus that does not proceed perpendicularly upwards must likewise be laid open by an incision.

After the operation he covers the flap with a double piece of flannel, which he draws together with a needle and thread, in such a manner as to make it lie close upon the upper part of the shoulder, so that it cannot fall down. This he furtherSecures with other strips of flannel, from three to four fingers-breadth broad, and from 6 to 9 inches in length, according as the strength of the patient requires, leaving such a stripe of flannel on each side to the upper edge of the bandage; the foremost of which he carries behind over the back of the patient, and the hindmost forwards over his breast, so that they cross each other over the shoulder, and again on the opposite side at the axilla, after which their ends are brought back to the flap, and there secured with pins. Two other stripes of flannel are fixed on the inner and outer side, to the inferior margin of the flannel bandage on the flap, one of which is carried across the back, and the other across the breast at the lower part of the sternum; they are then made to cross each other at the axilla of the sound arm, then brought round to the shoulder, and crossed again; after which the end that was brought out under the axilla, and carried to the shoulder, is now passed along the lower part of the neck to the bottom of the flap. The other end is brought forwards, and secured to the bottom of the flap with pins.

Mr. Benjamin Bell advises us to perform this operation, after a method somewhat different from that of Bromfield; although he seems not to have done it himself. He directs us to place the patient upon a table of a convenient height, covered with a mattress and a blanket. Let him be laid upon his back, as near as possible to the edge of the table, and properly secured by assistants. Hemorrhage is guarded against by an assistant compressing firmly with his fingers and a cushion on the subclavian artery, as it passes over the first rib directly above the clavicle. The diseased shoulder is then made to project somewhat over the side of the table, and the arm is stretched out at nearly a right angle with the body, and supported by an assistant.

The incision is made exactly at the junction of the deltoid muscle into the humerus, in a circular form through the skin and cellular substance; the integuments are retracted about half an inch, and along their margin all the muscles are divided with a perpendicular cut down to the bone. All this is performed with the common amputating knife; the rest of the operation is performed with a strong round-edged scalpel. With this instrument a perpendicular incision is made.
made down to the bone, commencing at the acromion, and terminating in the former circular incision, so as to pass straight between the centre of the deltoid muscle and its outer edge, and end about an inch above, or rather on the outside of the brachial artery. A similar incision is made on the back part of the arm, commencing also at the acromion, and terminating in the circular incision. This should be at such a distance from the first perpendicular incision, that the two flaps formed between them may be both nearly of equal breadth. The brachial artery must be tied, as soon as it has been divided by the circular incision through the muscles; and any other anastomosing branches of arteries that may have been cut must likewise be tied in a similar manner. The two flaps must now be separated from the bone, care being taken not to injure the great brachial artery, in separating that part of the flap near which it lies. An assistant must then prevent both the flaps from being drawn forward, so as to bring the capsular ligament of the joint into view. Into this ligament an opening is now made, and the bone dissected, by dressing the arm backward. The operation is then finished by dividing the remaining part of the ligament.

Any arteries that may have been cut about the joint must be tied, and theligature suffered to hang out at the most depending part of the wound. When the parts have been cleared of all the congealed blood, the two flaps are laid together, in such a manner as to cover the joint as exactly as possible, and retained in this situation by one or two more ligatures. A pledget spread with emollient ointment is laid upon the joint, and over this a cushion of lint with a soft compress of lint. All this is secured by a flannel roller, applied so as to make only a moderate pressure, by which the flaps will be kept in contact with the parts beneath. The patient must, in other respects, be treated according to the directions formerly given. In the course of eight or ten days, Mr. Bell says, the ligatures will easily come away; but to avoid any risk from sudden hemorrhage, he advises an assistant to watch the patient for the first few days after the operation.

This method is undoubtedly more easy and simple than that of Bromfield: for the muscles are divided at once, down to the bone, with a circular incision; and not, as in Mr. Bromfield's method, first one muscle cut and then another. As the attachments of all the muscles to the humerus are removed by the arm being taken away, it is not necessary we should divide them with such fineness and caution; one ligature also upon the brachial artery is sufficient, if applied with the requisite care and attention by means of the tenaculum. Neither is it necessary to scrape off the cartilage from the acetabulum of the joint; for, as has been already observed, the soft parts will adhere to cartilage as readily as to bone.

Another method of amputating the arm at the joint was employed by Mr. Defaut, of Paris, which seems not only to be far more expeditious, but also less painful to the patient, and easier to execute than any other. The manner in which it is performed is as follows:

The patient being placed upon a chair, and the subclavian artery compressed by the finger of an assistant at the place where it passes through the scapular muscle, the arm is raised in such a manner as to form nearly a right angle with the trunk of the body. A two-edged scalpel, having a straight blade six inches in length, and half an inch in breadth, is thrust into the joint at the place where the long head of the biceps muscle enters it, and brought out again an inch below the axilla; in this manner the capsule of the joint is cut through forwards; and, at the same time, the knife is carried round the head of the os humeri on the same side of the arm, care being taken to keep it always quite close to the bone. By cutting downwards in this manner, all the fleshy substance is at once separated from finger-breadths below the joint, so as to form a triangular flap, in which the axillary artery and vein are contained. This flap is immediately laid hold of by an assistant, who holds it off from the bone, and compresses the vessels with his fingers. The arm is then bent a little backwards, the knife introduced again into the joint, the remainder of the capsule and ligaments cut through, and, by carrying the instrument downwards from the back part next the bone, and at the same distance from the joint as before, another triangular flap is formed similar to the former in shape and size. The arm being entirely cut out in this manner, the axillary artery and vein are tied as high up as possible.

When the acetabulum of the joint is quite free from disease, the cure is endeavored to be effected by reunion, for which purpose Mr. Defaut also conceived it to be unnecessary to scrape away the cartilage. The two flaps are now laid together, so as to fill up the socket of the joint, and the legs united by means of the interrupted future. Over the fleshy parts dry lint is applied, and over that a compress, in the form of a croul of Malta, spread with ointment; then again a round compress and two longuettes, which are all finally secured with a flannel roller. Under the axilla an oval piece of linen is applied, partly in order to refill the impetus of the blood in the axillary artery, and partly to prevent the fleshy parts more closely to the hollow of the scapula, with a view to facilitate the healing of the wound. The whole of these dressings are likewise secured with a roller.

The knife used in this operation must be sharp, and somewhat ground off on both sides, like a pair of scissors. The blade should not be made of too hard steel, lest it break during the operation; on the contrary it should be rather flexible, but at the same time tough, in order that when it is carried round under the head of the os humeri, it may apply the more aptly to the bone.

Amputation of the Thigh at the Hip Joint.

The proposal of this operation must at first strike a feeling mind with horror; and, indeed, it is so terrible as well difficult to perform, that many eminent men have thought it impracticable to be done with success. This opinion has even been advanced by Schnuckro, in his Vermifche Chirurgiliche Schriften, &c. B. i. p. 48. Berlin, 1776; where the author says, "He is persuaded that no patient on whom it may be performed can ever survive." He very properly diffuses us from relying on experiments which have been made on dogs, and from thence inferring, that similar trials will succeed equally well on the human subject; but Schnuckro ought certainly to have spoken with some degree of diffidence, after the publication of facts which seem to establish an opposite opinion to his own. That a person may actually survive this dreadful operation, will appear from what we shall presently relate for the reader's information.

The possibility of performing amputation at the hip joint with success, was discussed so early as the year 1739; and was maintained in a public thesis, at one of the medical schools at Paris, A.D. 1748. The members of the Royal Academy of Surgery at Paris, likewise believing that it was practicable, gave out the following prize question in 1756: "Dans le cas où l'Amputation de la Cuisse dans l'article par-voitait l'unique Ressource pour sauver la vie à un Malade, déterminer si l'on doit pratiquer cette Opération, et quelle serait la Meilleure la plus avantageuse de la faire?" but not being satisfied with the answer it met with, they again proposed the same subject for the year 1759. On the former occasion, twelve memoirs were received by the Royal Academy; on the
AMPUTATION.

I then turned the head of the femur out of the cæstulum, that I might with more ease and security accomplish the most important part of the operation, namely, the taking up the artery. From the foregoing description you will easily conceive that a flap about four inches in breadth, consisting of all the integuments with the artery included, was still undivided. This flap I grasped firmly between the fingers and thumb of my left hand, (my fingers on the skin side of it, and my thumb on the muscular) and cut it through immediately below my hand, and between three and four inches from the passage of the artery under the ligamentum tallopini.

The incision here was made from above downwards, first through the muscular part of the flap, and then through the fat, vessels, and skin. It was done in this manner that the skin might correspond with that which was divided by the first incisions, and that the edges of the wound, we cannot say a lump, might thereby be kept neat and uniform.

The next step was to secure the artery, which I effected by lashing a strong ligature round it with a needle, and getting one of my assistants to tie it up; such a compreßion being all the while made upon it by my left hand in the manner related above, as to prevent the loss of a single drop of blood, and the hemorrhage from the other arteries was full as inconsiderable as in any other amputation of the thigh. By laving a good portion of skin the wound was much more decent and feemly than you can well imagine; but, to my great mortification, I found not only the acetabulum carious, but also the adjacent parts of the uña immumata, to a very considerable extent. From her almost confluent cough, I was under the greatest apprehension that the artery would be forced open; yet no mischief ensued, and the ligature fell off at the fourth or fifth dressing: the aspect of the fore, in the mean while, giving us the most fanguine hopes of her recovery. But about the tenth or eleventh day her respiration became more difficult, expiratio cæsatur, her mouth and tongue were covered with aphthæ, and she died on the 15th day from the operation. The appearance of the fore, even to the half, was such as to give good reason to suppose that the immediate cause of death was the daily increase of the hectic symptoms, and that without the amputation the operation would have succeeded; I therefore had her opened, and our supposition was, I think, pretty strongly confirmed by the following phenomena. The lungs were almost totally reduced to matter, especially on the right side, in which there was scarcely a vestige of pulmonary substance remaining. The left lobe also was full of abscesses, and reduced to less than half the natural size. An abscess (commonly called the poa abscess) was likewise found on the right side, in the abdomen, which communicated, by a corroded opening with the acetabulum, with the joint.

I have given you an exact narrative of the circumstances of the case, the operation, and the event of it; at least, I do not recollect any other of consequence. I shall not comment farther upon it than just to observe, that the total destruction of the ligamentum rotundum by the suppuration within the joint, contributed greatly to the facility with which the operation was accomplished; for I imagine, if that ligament had been entire, the division of it would have been attended with perhaps considerable embarrassment; I think, however, it might be effected in a found joint.

With regard to the expediency of the operation, I am so much convinced of it in certain cases, that in such I shall not, for the future, hesitate to perform it when they occur.
AMPUTATION.

Concluding Observations.

It still remains for us to notice two proposals, one of which is directed to the prevention, the other to the improvement, of the operation of amputation. In cases of ferulous tumours, or as they are termed, white swellings of the joints; of collections of matter in the cavities of joints, which often follow upon simple inflammation; of gun-shot wounds and compound fractures of the joints; and, in the most simple, but, at the same time, penetrating wounds, a variety of nodid symptoms take place, which render timely amputation of the limb the only means by which the unfortunate patient's life can be saved. In these cases, when they affect the knee and elbow-joint, Mr. Park has proposed, instead of amputating the whole limb, as is generally practiced, another remedy, which consists in the complete extirpation of the joint, or rather, in the amputation of the extremities of the bones which form the joint, together with the whole, or at least the greater part of the capsular ligament, the cure is afterwards effected by means of callus, which occupies the place of the bones that have been fawn off, or the femur is attached to the Tibia by a synoves. But in the elbow, the humerus synoves with the radius and ulna, without the joint retaining any perceptible power of motion. With this view he made the following experiment:

Two inches above the upper end of the patella he made an incision, and carried it down to its lower extremity; he then placed the leg in an extended posture, and made a cross incision immediately above the patella, through the tendon of the extensor muscles, down to the bone, and nearly half round the limb, so as to form a right angle with the former incision. The lower angles which were formed by this incision, he widened so as to lay bare the capsular ligament, and took out the patella. The upper angles he likewise widened, so as to lay bare the head of the femur, and to enable him to pass a small knife across the posterior flat part of the bone immediately above the condyles, taking care to keep one of the flat sides of the point of the instrument close to the bone all the way. He then withdrew the knife, and introduced an elastic spatula in its place, to guard the soft parts during the sawing through of the femur. He then carefully dissected out the head of the femur that had been fawn off. The head of the tibia was then easily turned out; this he fawed off, and cut away as much as possible of the capsular ligament, leaving only the posterior part to cover the veils, which he found, upon examination, to be not only unhurt, but also that they were sufficiently covered with the remaining part of the ligament, and that, during the whole of the operation, they had been sufficiently far from the course of the knife. Although the wound had a formidable appearance, he saw no reason to doubt that nature would be able to repair the breach; as the limb below would not be deprived of its nourishment, and every healthy flesh-covered surface, both of bone and of soft parts, has a natural tendency to granulate.

The next operation he performed upon the elbow-joint. He made an incision, commencing two inches above the tip of the olecranon, and terminating at the same distance below it; he then raised the integuments, and endeavoured to separate the lateral ligaments from each other, in order that he might be enabled to draw the bones asunder. But as he found this to be difficult, he first fawed off the olecranon, whereby he loosened the joint to that degree, that he could easily draw it asunder, without being under the necessity of making a cross incision. He then turned out the lower end of the humerus, and fawed it off, and afterwards the heads of the radius and ulna. He does not, however, flatter himself that this method will prove equally successful in all cases; as, in some, amputation is indispensably necessary; for example, when the disease has spread too far, when the soft parts are too much injured, and the caries too extensive. In general, he thinks the operation is more to be recommended in cases of external injury than in ferulous affections.

The other proposal, which has Mr. Wrabetz for its author, refers to the amputating of limbs without the knife, by means of ligatures. Mr. Ploucquet (von der unblutigen Abtheilung der Glieder. Tuebingen, 1789, St.) describes it as follows: Take a flaxen, or rather a cotton cord, of thicknesses and strength proportionate to the size of the limb; lay it in spirit of turpentine, mixed with fine powder of tobacco-leaves, the seeds of the ruta, cantharides, and camphor; and after it has lain in this liquid for the space of twelve hours, apply it to the limb in the following manner. Draw back the skin as much as possible towards the found part of the limb, and apply it above the dissected part round some perfectly found part of the limb; draw it tight with a turn-stick, and secure the latter. About two inches above the cord rub a quantity of the above-mentioned mixture, till small blisters are raised, which must be opened and dressed with a drawing platter. By this application and by poultices the requisite degree of inflammation is promoted. As long as the cantharides are employed, the use of which is very beneficial to debilitated habits, the patient must drink mucilaginous liquors, with which cordials are to be combined, such as camphor, Peruvian bark, arnica, &c. and, at the same time, blood-letting and refrigerant remedies, especially nitre, are to be administered. As the cord sinks into the flesh, and grows looser, it must be tightened; and the crevice which it leaves above it must be filled up with a fine powder of Peruvian bark, camphor, and alum, in equal parts. This powder may also be made into a limenium with oil, hypericum, and rubbed into the above-mentioned crevice. That part of the limb which we wish to separate should be swathed in a cloth soaked in a mixture of a solution of alum, lime-water, and some aromatic spirit. Mr. Wrabetz has in one case succeeded in amputating the humerus according to this method, and affirms us, that he has often separated small limbs by means of ligatures; it is, however, a practice that cannot be recommended for imitation, although Mr. Marguet has endeavoured to demonstrate the advantages of this operation; for, on the one hand, his observations are too defective to prove anything, and on the other, the operation should only be attempted in a perfectly similar case.

For an account of the means of suppling defective members, see Limbs, artificial.

AMPUZITZA, in Geography, a town of Befarabia, 26 miles well-north-west of Ismail.

AMPYX, in Antiquity, a kind of golden chain, which served to bind the hair of the horses on the forehead. Homer describes by this ornament the fleeds of the god of war, calling them χέρσυκτιβο. The term was afterwards used more generally to denote a band or fillet, which formed a part of the drefs, and which encompassed the hair. It was sometimes encircled with gold and precious stones.

AMRAM, in Scripture Biography, was the son of Koath, of the tribe of Levi, and married Jochobed, by whom he had Aaron, Miriam, and Mofes. He died in Egypt, aged 137. Exod. vi. 20.

AMRAN, in Geography, a town of Arabia, 20 miles north-west of Sana.

AMRAPHEL, in Scripture History, was king of Shinar, and confederate with Chedorlammon, king of Elam, and two other
other kings, in making war against the kings of Sodom, Gomorrah, and the three neighbouring cities. The kings, who were in league with him, plundered these cities, and carried off many captives, among whom was Lot, Abraham's nephew; but Abraham pursued them, retook Lot, and recovered the spoil. A. M. 2092, B. C. 1912.

AMRAS, in Geography, a castle or palace of Germany, in the county of Tyrol, called by some writers Ars Ambrosiana, and also Ondera, and situate at the foot of a mountain, two miles south west of Innsbruck. In the heat of Summer it is a place of retirement for the arclidukes. It is famous for its collection of antiquities, gold medals, cameos and intaglios, most of which were sent to it by Charles V. On the walls and ceilings are many curious paintings, and one, in particular, of Noah's ark by Baffano, for which the grand duke of Tuscany is said to have offered 100,000 crowns. Here are also a library, a gallery full of bulbs, and many pictures of great value. N. lat. 47°. E. long. 11°. 40'.

AMRU, or ABRU, ED-AL-AS, in Biography and History, a famous Suraee commander, was the dubious progeny of Aai, of the tribe of Koreib, by a notorious prostitute. In his youth he was impelled by the passions and prejudices of his kindred: his poetic genius was exercised in satirical verses against the person and doctrine of Mahomet; and his dexterity was employed in the reign of faction, to pursue the religious exiles who had taken refuge in the court of the Ethiopian king. From this embly he returned a secret profyle, having renounced the worship of idols; and making his escape from Mecca with his friend Caled, he joined the fugitive prophet at Medina. His inpatience to lead the armies of the faithful was checked by the reproof of Omar, who advised him "not to seek power and dominion, since he who is a subject to-day may be a prince to-morrow." Amru, having acquired a high degree of military reputation, was the chief in Iraq, when Caled summoned all the Arabian generals to his assistance, in the siege of Damascus. In Paleflme, he served during the Caliphate of Omar, under Abu Obeidah, who was the commander in chief. On his arrival in this country he was informed, that Constantine, the son of the emperor Her- chius, lay encamped with a body of troops near Caesarea. As he was advancing towards the siege of this city, this prince deputed some Christian Arabs to reconnoitre the Moslem camp; when one of them was discovered, and cut to pieces. Amru was much offended, and issued orders that all spies should be brought to him for examination, before they were thus punished; alleging, that such spies might probably, in case of conviction, rather embrace Islamism than suffer death. About this time Constantine expressed a desire to have a conference with Amru. When the Arabian chief was introduced to the prince, he declined making use of a feast that was offered him, and took his place crofs-legged on the ground, after the Arabian manner, with his sword upon his thigh, and his lance laid across before him. Constantine made overtures for a pacification, but they were rejected with great insolence by Amru, who inflicted upon his paying tribute or embracing the religion of Mahomet. This conference closed with a declaration on the part of Amru, "that the Arabs were tired of living in their scourging defects, and were resolved to re-enter into the possession of the delightful country, which was the inheritance of their progenitors." Accordingly both parties prepared for action; which terminated in the capture of Caesarea by Amru, and the subjugation of all the maritime towns of Syria. A. D. 638. Upon the death of Obeidah, Amru assumed the chief command in Syria, in which, notwithstanding the opposition of Othman, he was confirmed by Omar. Determining to proceed to Egypt, he left his station at Gaza, and advanced forward at the head of only 4000 Arabs; but in his progress he was overtaken by a messenger from Omar, with instructions contained in a letter which he did not open, because he entertained some suspicion of its contents, till his tents were pitched within the territory of Egypt. "If you are still in Syria," said the ambiguous mandate, "retreat without delay; but if, at the receipt of this epistle, you have already reached the frontiers of Egypt, advance with confidence, and depend on the favour of God and of your brethren." After perusing this letter in the presence of his officers, he declared his ready obedience to the commands of the Caliph. After a siege of 30 days, he took possession of Faramah or Pelhium, and this key of Egypt, as it has been justly called, unlocked the entrance of the country, as far as the ruins of Heliopolis, and the neighbourhood of the modern Cairo. From Pelhium, he marched to the ancient Memphis, or Misrâh, the siege of which was protracted to seven months; and as the invaders were, by this delay, threatened with the inundation of the Nile, they formed the place and drove the remnant of the Greeks to their boats and the isle of Ronda. On this spot, the eastern bank of the Nile, recommended to the conqueror by its easy communication with the gulf and the peninsula of Arabia, he built a city called Foaft; and the contiguous quarters of Babylon and Foaft are confounded in their present decay, by the appellation of old Misrâh or Cairo, of which they form an extensive suburb. After this conquest, the Coptic Chrlstians, or Jacobites, negociated, by means of their governor, Mokawas, a treaty of peace and amity with Amru; agreed to pay a stipulated tribute; sworn allegiance to the Caliph, and promised an hospitable entertainment of three days to every Mussulman, who should travel through their country. Their patriarch Benjamin, at the earnest request of Amru, emerged from his desert; and, after the first interview, the courteous Arab affected to declare, that he had never converted with a Christian priest of more innocent manners and a more venerable aspect. In the march from Memphis to Alexandria, the lieutenant of Omar entrustted his safety to the zeal and gratitude of the Egyptians; and in every step of his progress, he could depend on a constant supply of provisions and intelligence. The fugitive Greeks were pursued to Alexandria, and the road thither was laboriously cleared by the victorious Saracens, in 22 days of general or partial combat. After a siege of 14 months, and the loss of 25,000 men, the city was taken A. D. 640. See Alexandria. During the progress of this memorable siege, Amru "was betrayed by his imprudent valour; his followers, who had entered the citadel, were driven back; and the general, with a friend and a flave, remained a prisoner in the hands of the Chrlstians. When Amru was conducted before the prefect, he remembered his dignity and forgot his situation; a lofty demeanour, and reftate language, revealed the lieutenant of the Caliph, and the battle-axe of a foilder was already raised to strike off the head of the audacious captive. His life was saved by the readiness of his fiate, who instantly gave his master a blow on the face, and commanded him, with an angry tone, to be flent in the presence of his superiors. The cedulous Greek was deceived; he listened to the offer of a treaty, his prisoners were dismissed in the hope of a more respectable emblamy, till the joyful aclamations of the camp announced the return of their general, and inspired the folly of
of the infidels." After the capture of Alexandria, the whole of Egypt soon submitted to the arms of the conqueror; and in the administration of it he balanced the demands of justice and policy. In the management of the revenue he disapproved the simple, but oppressive mode of a capitation, and preferred with reason a proportion of taxes, deducted on every branch, from the clear profits of agriculture and commerce. A third part of the tribute was appropriated to the annual repairs of the dykes and canals so essential to the public welfare. Under his administration the fertility of Egypt supplied the dearth of Arabia; and a string of camels, laden with corn and provisions, covered almost without an interval the long road from Memphis to Medina. The genius of Amru opened the maritime communication which had been attempted or achieved by the Pharaohs, the Ptolemies, or the Cæsars; and a canal, at least 80 miles in length, was opened from the Nile to the Red Sea. From Egypt, Amru extended his conquests to the neighbouring parts of Africa; but on the accession of Othman, he was superseded in his government of Egypt by Abdallah-ebn-Said. The dissipation of Amru was considered as a public loss, and even disposed the Egyptians to revolt. This change in the sentiments of the people induced Constantine, the Greek emperor, to meditate the reduction of Alexandria, and he readily effected his purpose. Upon this loss Amru was restored to his former dignity; and employed in the recapture of the city. After a vigorous resistance, on the part of the beleaguered, and great slaughter, he took it by storm; and though by his authoritative interposition he restrained the massacre of the inhabitants, he dismembered it, and utterly demolished all the walls and fortifications. After this exploit, he was again displaced by Abdallah, and recalled to Medina; but Othman found it necessary to avail himself of his influence in quelling a faction, which he was unable to effect.

Upon the accession of Ali, Amru joined the malcontents, and quitting his command in Palestine, arrived at Damascus, which was then the residence of Moawiyah, the competitor of Ali, and swore allegiance to him. When it was proposed to decide the difference between these two rivals by single combat, Amru persuaded Moawiyah to accept the challenge; but he declined it, and ascribed Amru's recommendation of it to selfish motives, and to his desire of obtaining the caliphate for himself. Notwithstanding this unjust suspicion, Amru maintained his attachment to Moawiyah, and served him in the business of the arbitration between these two competitors. See Ati. He also took possession of Egypt in Moawiyah's name, after having defeated Mahomet-ebn-Abubeker, Ali's governor, whom he took prisoner, and put to death in a barbarous manner. Amru was now considered of such importance, that he was one of the three confiditards, whom the right of the Kharijites determined to affilliate, with a view of refooming peace to the Saracen empire. Amru fortunately escaped; being prevented, by a fit of the colic, from attending in the mosque on the day when one of the confiditards went to kill him, but Kharijah, a friend whom he appointed to perform the office of Imam, as his substitute, was slayed by the confiditard, who maimed him for Amru, and fell down dead with the blow. In the year of the Hegirah 43, a.D. 663, during the caliphate of Moawiyah, Amru ended his days in the palace city, which he had founded on the banks of the Nile. Of him Mahomet is reported to have said, that there was not a Moslem more sincere and steadfast in the faith than Amru. He was justly esteemed one of the greatest men amongst the Arabs of the age in which he lived; distinguished by his quick apprehension, solid judgment, undaunted courage, and singular resolution, as well as his profound sagacity and penetration; always excellent in his advice, firm in his purpose and fpercy in its execution. The two first successors of Mahomet were not insensible of his merit. To his arms they were indebted for the conquest of Palestine; and in all the battles and sieges of Syria, he united with the temper of a chief, the value of an adventurous soldier. In a visit to Medina, the caliph wished to survey the sword which had cut down so many Christian warriors; Amru undeathed a short and ordinary fcytneyar; and as he perceived the surprize of Omar, "Alas!" said the modest Saracen, "the sword itself, without the arm of its master, is neither sharper nor more weighty than the sword of Pharezidak the poet." This saying is preserved by Poseck, and justly applauded by Mr. Harris, in his Philosophical Arrangements, p. 350. After the conquest of Egypt, Amru was recalled by the jealousy of the caliph Othman; but in the subsequent troubles, the ambition of a soldier, a statesman, and an orator, emerged from a private station. His powerful support, both in council and in the field, established the throne of the Omnanides; the administration and revenue of Egypt were restored by the grace of Mahomet to a faithful friend, who had raised himself above the rank of a subject; and in the possession of this lucrative dignity his life terminated. His dying speech to his children, in which he deplored the errors of his youth, and particularly his offence in latarizing Mahomet, is celebrated by the Arabsians as a model of eloquence and wisdom. Ockley's Hist. of the Saracens, vol. i. and ii. Mod. Un. Hist. vol. i. p. 315; &c. Gibbon's Hist. vol. ix. p. 475; &c.

AMSDEG, in Geography, a town of Switserland, in the canton of Uri, seven miles south of Altorf.

AMSDORF, Nicholas, in Biography, a Lutheran divine, was born at Meissen, in 1483. After studying at Wittenberg, he became a disciple of Luther, who appointed him minister of Magdeburg, and afterwards of Naumburg. He was distinguished by his opposition to the Roman Catholics, and by his controversy with Melanthon and his adherents, on the subject of good works; in the heat of which he extravagantly maintained, "that good works were an impediment to salvation." From this imprudent and unwarrantable expression, the flame of controversy received new fuel, and broke forth with redoubled fury. The tenements of Melanthon in opposition to those of Luther and his partizans, were ably defended by George Major, an eminent teacher of theology at Wittenberg; who, in 1552, maintained the "necessity of good works," against the extravagant affections of Amstorf; who died at Magdeburg in 1541.

AMSDORFIANS, in Church History, a sect of Protestant, in the 16th century; were so denominated from their leader Amstorf. They maintained, that good works were not only unprofitable, but even opposite and pernicious to salvation. Molinch's Eccl. Hist. vol. iv. p. 328.

AMSEGETES, in Antiquity, those whose grounds abutted on the highway. Vide Feit. de Verb. Signif. in voc.

The laws of the Twelve Tables decree, amsegetes vivam munianto.

AMSMOE, in Geography, an island in the German Ocean, near the west coast of Denmark. N. lat. 54° 40'. E. long. 20° 25'.

AMSTEL, a river of Holland, which passes by Amsterdam, and joins the Y or Wye.

AMSTELAND, a small district of South Holland, takes
AMSTERDAM.

AMSTERDAM, or Amsterdam, formerly called Amstel, i.e. the dam or dyke of the Amstel, the capital of Holland and of the United Provinces, is situated at the influx of the river Amstel from which it derives its name, into the arm of the sea, called Y or Wy, and which forms a port, capable of receiving a thousand large vessels, about two leagues from the Zuider sea. Although the Pampus, which is the only channel leading to it from the sea, is shallow, and ships of considerable burden are lightened before they can pass through it; and they are afterwards under a necessity of waiting for an easterly or north-easterly wind, in order to proceed through the Maasdiep into the North sea; yet upon the whole, its commercial situation is advantageous, on account of its easy connection with the other towns of the province, and its small distance from all the ports of North Holland, Friesland, Overcyst, and Gelderland. The soil, on which this city is seated, is marshy, and therefore its buildings are founded on oak piles, which gave occasion to the witticism of Ermans, "that in his country vast multitudes of people lived on the tops of trees." This circumstance restricted the use of coaches to great men and physicians, who paid a tax for this privilege; and goods are conveyed from one part of the town to another on sledges.

In the beginning of the 15th century Amsterdam was a very insignificant fishing town, containing a few huts that were the residence of persons engaged in this occupation; but its inhabitants were gradually multiplied, and the earth of Holland gave it the title and privileges of a city; nevertheless, till the year 1390, it was surrounded merely by a weak pallisado. At this time it was encompassed by a wall of brick, constructed by order of Mary of Burgundy, in order to defend it from the incursions of the inhabitants of Utrecht, who were frequently quarrelling with the Hollanders; but it was soon afterwards reduced to ashes. The people of Gelderland besieged it in 1415, but not successully in their attempt to take it, they set fire to the ships in the harbour. In 1420, the town-house of Amsterdam was attacked by a party of wild enthusiasts, under an anabaptist leader; but they were defeated by the citizens, and most of them were cut to pieces. Tumults of a similar kind were renewed by persons of the same description in 1533, (see Anabaptists,) and these were followed by a regular and deep-laid conspiracy against the magistrates of Amsterdam, with a design to wrest the government of the city out of their hands. Van Geelen, the head of these insurgents, marched his fanatical troop to the town-house, on the day appointed, with drums beating and colours flying, and fixed there his head-quarters. He was attacked by the burgsters; assisted by regular troops, and headed by several of the burgomasters of the city; and after an obstinate resistance, he was surrounded, with his whole troop, and they were put to death, in the fevered and most dreadful manner. In 1578, Amsterdam was besieged by the Hollanders, and after a resistance of ten months, capitulated; on this condition, among others, that the Roman Catholics should be allowed the free exercise of their religion. The condition, however, was not observed by the Protestants; for they drove the ecclesiastics, monks, and nuns, out of the city, broke the images, and demolished the altars. From this time Amsterdam became the general rendezvous of persons of all ranks and nations; and by them it was raised to that degree of splendour and magnificence to which it afterwards attained, and which it long continued to enjoy. The city has been frequently enlarged to accommodate its new accession of inhabitants; particularly in 1575, 1579, 1612, and 1675; and in 1675 it was extended by its present line, surrounded by a wall and a large ditch, 80 feet wide, and full of running water, and fortified on the land side with ramparts and 26 bastions, on each of which were afterwards placed a windmill. It has also eight gates towards the land, and one towards the water. The land side of the town may be easily monkeys. Amsterdam is intersected by several navigable canals, which divide the town into a number of islands, joined to each other by wooden and stone bridges, and which are connected with the Wy and the Amstel. These canals, on the side of which are generally planted rows of trees, serve the convenience of trade, and contribute to render the streets through which they pass clean and pleasant; though in hot and calm weather they occasionally emit fetid effluvia. Of these canals the principal is that called the Ammarrack, formed by the waters of the Amstel, which admits the influx of the tide, and it has on its side two large quays. It has also several bridges; the chief of which, next the sea, is called Pont Neuf, or the New Bridge; it is 600 feet long and 70 broad, with iron balustrades on each side; it has 36 arches, 11 of which are very lofty, and eight are shut up to include the yachts. This bridge affords a fine prospect of the city, port, and sea. The port is a mile and a half in length, and above 1000 paces in breadth; and it is filled with a multitude of vessels, the masts of which appear like a forest, and forming a kind of floating city. Towards the side of the Wy, or of the haven, the city is inclosed by double rows of piles, driven into the ground, and connected by large horizontal beams. Between these piles are openings, through which the ships pass in and out, and which are shut every evening at the ringing of a bell. The streets are generally narrow, but well paved, and the houses, which are built of brick or stone, have the air of neatness, peculiar to those of the Dutch. In the interior of the city there are agreeable walks, but the communication with the environs is chiefly by water; though there is a pleasant road to Oudekirk, through gardens and groves. The population of Amsterdam is estimated at 212,000 persons; and its commercial connections supply a very considerable, but fluctuating, accession of foreigners, who resort to this city from all nations, and are tolerated in their religious worship, though the government is restricted to persons of the reformed or Calvinistic profession. For persons of this profession, which is the established religion of the country, there are eleven churches, whose ministers are maintained by the state, and which are allowed the use of bells. The English have also had three churches; one for the Presbyterians, whose ministers have been paid by the magistracy; a second for the church of England, provided for by his Britannic majesty; and a third for the Brownists, who maintain their own ministers. These churches or congregations were formerly estimated to comprehend about a third part of the inhabitants. The Roman Catholics, who had about 27 places of worship appropriated to their use, amounted to another third part of the population; and the other third part included Jews, Lutherans, Arminians, Anabaptists, &c. The Jews had two synagogues, one of which, viz. the Portuguese, is the largest in Europe; and annexed to it are several
fearful school-rooms, in which children are taught the Hebrew language, and instructed in the Jewish religion. The most remarkable of the churches at Amsterdam is that called the New Church, and dedicated to St. Catherine. It is said to have been begun in 1408, or 1414, and not to have been finished for 100 years. The bell-tower, intended to be constructed before this church, and standing upon a great number of piles, is not yet completed. The pulpit is a curious 44-structure, and is adorned with various kinds of sculpture, particularly that of the four evangelists. The paintings in the glass windows exhibit, amongst other figures, the emperor Maximilian presenting an imperial crown to the burgomasters of Amsterdam, for the erection of the arms of the city. The organ has been much admired and extolled, on account of its size, and its powers of execution. It has a set of pipes that counterfeit a chorus of voices, and has 52 whole stops, besides half stops, with two rows of keys for the feet, and three rows for the hands. Its sound, when it plays, seems to resemble that of the human voice. The grate, by which the chancel is separated from the body of the church, is constructed of Corinthian bafia. The branches of the candlesticks are the richest in the seven provinces. In the church is a marble monument, erected to Admiral Ruyter, who was killed at Medina.

The largest and most latelv edifice, not only of Amsterdam, but of all the United Provinces, is the Stadhuis, founded in 1648 on 13,059 piles, and comprehending in breadth 282 feet, in depth 238, and in height 110 feet. On the front is a marble pediment, on which is a female figure in relievo, holding the arms of the city, seated in a chair, which is supported by two lions, and bearing an olive branch in the right hand; on each side are four Naiads, presenting her with a crown of palm and laurel, and two other maritine goddesses, offering her different sorts of fruit; there is also Neptune with his trident, accompanied with Tritons, a sea-unicorn and a sea-horse. Above are placed three statues in bronze, representing justice, strength, and plenty; and on the top of the structure is a round tower, 50 feet above the roof, adorned with figures, and an harmonious chime of bells, the biggest of which weighs about 7600 pounds; and they are made to play different tunes every month. The entrance into this edifice is by seven doors, intended to represent the seven Provinces. In the great hall are two globes, celestial and terrestrial, made of black and white marble, and inlaid with jasper and copper, 22 feet in diameter, and 60 in circumference. All the chambers are enriched with paintings, carvings, and gildings. Under the stadthoude is the treasury of the bank of Amsterdam, which is strongly secured, and entrusted to the care and inspection of the burgomasters, and opened only at the presence of one of them. In other vaults are the prisons for debtors and criminals, and also the guard-room for the citizens, in which the keys of the city are deposited every night. At the end of the great hall is the chamber of the schoppen or aldermen, where civil causes are tried; and there are also other apartments and offices of various kinds. In the second story is a large magazine of arms; and in the top of the building are fixed large cisterns of water, as a supply in case of fire, for the prevention of which the chimneys are lined with copper.

Another public building that deserves notice is the bourse or exchange, constructed of free-stone, and standing upon 2000 wooden piles. Its length is about 250 feet, and its breadth 140. The galleries are supported by 26 marble columns, upon each of which are the names of the people that are to meet there. They are all numbered; and there is a place fixed for every merchandise, under some one of these numbers. A superb staircase on the right hand of the gate leads to the galleries; on one side are several shops, and on the other a place in which cloths are sold. This exchange resembles that of London. The admiralty-office is in a house which formerly belonged to the princes of Orange. The arsenal for their men of war, 250 feet long and 22 feet broad, is in the harbour; and contains, on the ground floor, bullets, on the second the arms and ordnance, and on the third, smalls, pulleys, flags, &c. and many curiosities. The conservatory of water on the top of the building holds 1500 tons of water, which, in case of fire, may be distributed into 16 different parts, by leaden pipes. Near this edifice is the dock or yard, in which the men of war are built, and which is 528 feet long. The East India company occupy a large building, divided into several offices or apartments, which serve as magazines or warehouses for goods of various kinds. They have also a kind of arsenal, of considerable extent. The academy, called "the illustrious school," is also a good building; it was formerly a convent belonging to the nuns of St. Agnes; it is now devoted to instruction in Latin, the oriental languages, theology, philosophy, history, &c. The lawyers and physicians have likewise their schools. Besides these, there are several hospitals, or houses for the accommodation and relief of the aged, orphans, of sick persons, of persons infected with the plague, and of lunatics, &c. The principal houses of correction are the rapf-houde and spin-houde. In the former offenders are employed in sawing and rapping Brazil wood; and those who will not perform their task are placed in a cellar, into which the water runs, so that if they neglect to work the pump, they are exposed to the danger of being drowned. The spin house is appropriated to daubed women; in this they are employed in spinning wool, flax and hemp, and other work. The hospitals are maintained partly by voluntary contributions, for receiving which the poor's boxes are fixed in different parts of the city, and partly by taxing all public diversions. Those who have the management of the public charities are called, "deacons." The governors are selected from the most considerable persons in the city, and are nominated by the magistrates.

The places of diversion appropriated to the lower classes are called, "feul houdes," in which the amusements are music and dancing. To this city belong two suburbs, one at the end of the regulars, and the other extending as far as Overtoon, a village at a small distance, where boats that come from Leyden are forwarded over land upon wooden rollers.

Amsterdam is governed by a senate or council, called Vrouediep, and composed of 36 persons, who represent the whole body of the people, and are invested with the supreme power. Their office is for life, and the survivors supply vacancies occasioned by death. This senate elects deputees to be sent to the states of Holland, and appoints the chief magistrates, called "burgomasters," or "echevins," reenacting our aldermen. Their number is 12, and four of these are annually chosen to execute the office, and are denominated "burgomasters regent." Three are dismissed every year, and three new ones supply their places. During the term of the office of each, which is three months, they may be compared to the lord mayor of the city of London. To them it belongs to dispose of all offices, that become vacant during their regency. They have likewise the direction of all public works, which concern the safety, peace, and embellishment of the city. The keys of the bank of the city are in the custody of these magistrates.

The college consists of new burgomasters, who are judges
in all criminal affairs, without appeal; but in civil causes they may appeal to the council of the province. There are two treasurers, a bailiff, and a provost. The bailiff continues in office three years, and it is his business to search after criminals, to take care of their prosecution, and to superintend the execution of sentence. The provost is the head of the magistracy, and is supposed to be well versed in the laws; and it is his province to defend the interests of the city.

Amsterdam has in former times contributed to the public income tax above 5,000,000 beavers per day, besides the eels of beer, flesh, and corn, which amounts to above 1,600,000 a year; and this sum is more than the amount of the payments of all the other provinces; and yet Amsterdam bears the 8th rank in the assembly of the states of Holland, with this distinction, that as the other cities send two members, this sends four.

The militia of Amsterdam is considerable, and has usually consisted of 60 companies, each of which has from 200 to 300 men. From this service the Jews and Anabaptists are excluded, as they are not allowed to bear arms: but they are obliged to contribute to the maintenance of the city-guard, which is composed of 1,500 soldiers, and to the night-watch, who patrol about the streets, and proclaim the hour. Besides these, there are trumpeters on every church clock, who sound every half-hour; and if a fire happens, they ring the fire bells, and announce where it is. The trade of Amsterdam, before the late war, and the revolutions and changes that have attended it, was very great; and it was justly regarded as the magazine or store-house of Europe.

What alterations may take place in its internal government or foreign relations, in consequence of the peace that has been lately established, cannot now be ascertained. Amsterdam is distant 44 leagues from Brussels, 49 from Liège, and 112 from Paris. N. lat. 52° 22' 45". E. long. 4° 45' 30'.

Amsterdam, now called Tongataboo, an island in the South Pacific ocean, fail to have been discovered by Tasman, a Dutch navigator, in 1643. It was visited by Captain Cook, and other later navigators. Its extent is about 16 miles in length, and its greatest breadth about eight. It is about 64 leagues west of Middleburgh. S. lat. 21° 3' 9'. W. long. 174° 40'.

The shore of this island is surrounded by a coral rock, and its most elevated parts are not above six or eight yards above the level of the sea. Its interior parts are highly and universally cultivated, the whole island consisting of inclosures, with red fences, about six feet high, intersected with innumerable roads; and its plantations supply some of the richest productions of nature. It abounds with bread-fruit, cocoa-nut trees, plantains, bananas, flaxdocks, yams, sugar-canes, and a fruit like a nectarine, called by the natives "fighega." Caffirinars, pandangs, and wild fago palms appear here with their various tints of green, and barringtonia of the size of the largest oaks. As the coral rock, which forms the basis of this spot, is but thinly covered with mould, the bread-fruit does not thrive with the same luxuriance as at the Society islands; neither does this island afford an equal supply of water, though the ships were furnished with as much as they wanted from a pool to which they were directed by the chief.

The men and women are of the common European size; their colour is that of light copper; and they are well shaped, have regular features, and are lively and active. They have fine eyes, and in general good teeth even to advanced age. The women are merry and talkative; many of them are modest, and others of a different character. They swarm about the ships, without any covering, like amphilobous creatures; and were easily persuaded to come on board; though they would not stay after sun-fret, but returned to pass the night on shore with the other inhabitants, under the shade of the wood that lined the coast, where they had large fires, and were heard conversing together aloud during the whole night. Their hair is black, and worn short, excepting a lock on the top of the head, and a small quantity on each side. The men shave their beards close by means of two shells; and the hair of many was observed to be burnt at the ends, and burned with white powder, which was found to be lime made of shell or coral, which had tinged the hair; some used blue powder, and others an orange-coloured powder, made of turmeric. The dres of both sexes consisted of a piece of cloth or matting, wrapped round the waist, and hanging below the knees. From the waist upwards they were generally naked; and it seemed to be a custom with them to anoint those parts of the body every morning. The practice of tattooing, or puncturing the skin, prevailed amongst them; the men performed this operation from the middle of the thigh to the part above the hips; the women performed it lightly and only on their arms and fingers. The ornaments worn by men as well as women, are amulets, necklaces, and bracelets, the bone, shells, and heads of mother-of-pearl, tortoise-shell, &c. The women also wear on their fingers nuts rings, made of tortoise-shell, and occasionally pieces in their ears, about the size of a small quill. They have also a curious apron, made of the cocoa-nut shell, and composed of a number of small pieces, disposed as to form flars, half-moons, little figures, &c. and frizzled with beads and shells, and covered with red feathers, so as to produce an agreeable effect. They have cloth similar to that of Otaheite, but not so fine; and they have a method of glazing it, which renders it more durable, and capable, for some time, of withstanding rain. Their colours, which they procure from vegetables, are black, brown, yellow, purple, and red. Of matting they have different sorts, used for clothing, for bedding, and for fails to their canoes; they have also several kinds of baskets made of the same materials with their mats, or of the twisted fibres of the cocoa-nut, which they form of different colours, and add with beads made of shell or bones. They appear to be ingenious in designing and executing various articles of this kind. Their fishing implements are much the same with those of the other islands; their nets are formed of strong though slender threads. Although their disposition is friendly, they possess very formidable weapons; some of their spears being furnished with many bars. This island is often visited by the blood of human victims; nor do the ideas of property, which prevail among the inhabitants, prevent their feeding from strangers. The Millionaries, in their voyage, some of whom were left on this island, imparted useful arts to the natives; but the rats were found very destructive to the European plants. Thieves, with hogs, dogs, and guanos, were the only quadrupeds in the islands, till cats were left there in 1797. The morais are here called fatookas; and are constructed in the form of terraces, with high steps, and the material of which they are formed is coral. In the missionary voyage of 1797 there is an interesting map of this island.

Amsterdam, an uninhabited island in the Frozen Sea, near the west coast of Spitzbergen. This is also the name of an island in the Indian Sea. S. lat. 38° 42'. E. long. 76° 54'. (for an account of which, see St. Paul); and another in the Chinese Sea, between Japan and the island of Formosa.

Amsterdam, New, a name originally given by the Dutch to the city of New York, in America. Amsterdam
is also the name of a new township in Montgomery county, New York; containing 235 inhabitants, who are electors.

AMSTOTTEN, a town of Germany, in the arch-ducny of Austria, eight miles south-west of Ips.

AMTZITZ, a feigncy of the circle of Guben, in Lusatia, containing the market town of Amitz, with a citadel, and several villages.

AMTRUSTIO, in Ancient Charters, denotes a sworn or liege tenant, or vassal, of the ancient French or German kings.

The word is also written antryftia. Spelman derives it from the German ant, of the English tyrple.

AMTSZELL, in Geography, a town of Germany, in the circle of Swabia, eight miles east of Ravensburg.

AMU, or Amol, or Amu-Daria, called also Gihon, and said to be the Oucus and Baxuras of the ancients, a river of Independent Tartary, in Basharia, which formerly discharged itself by two channels or mouths into the Caspian sea; but these are become dry, and the stream has been diverted by art into the sea or lake of Aral. In the reign of Cyrus it was the boundary of the Persian monarchy, and some authors have supposed it to be the Araxes of the ancients. Its source is in the mountains of Paropamissus.

AMU. See Amol.

AMUDA, in Ancient Geography, a town of Syria, distinguished in the Notitia Imperii from Amida; but its situation is not known.

AMUDARSA, a town of Africa Propria, in the territory of Bizzarum, mentioned by Antonine, and placed by M. d'Anville north of Septinumica. It was an episcopal see. ALEOIR.

AMULET, Amuletum, formed from amuleïri, to remove, a kind of external medicament, to be worn about the neck, or other part of the body, for preventing or removing diseases. Such are quills of quicksilver, or arsenic, which some hang on the neck, or wear under the skirt, against the plague, and other contagious diseases; as also the bloodstones worn by others against hemorrhages; and that worn by the women of the East Indies to bring the menstru.

Amulets are also frequently no other than a sort of spells, or charms; consisting of quaint words and characters, supposed to have the virtue of warding off mischief, witchcraft, and disease, and to which credulity and superlition have annexed wonderful properties. Pliny makes frequent mention of them.

Perfons of all ages and nations have used them. The materials of which they were formed, the characters inscribed upon them, and the superstitious ceremonies with which they were prepared, were various. Amongst the ancient Egyptians they were very common, and those denominated abraxas were peculiarly distinguished. The Persians, having observed in Egypt the practice of suspending to the neck small cylinders, adorned with figures and hieroglyphics, adopted a similar custom, and instead of the Egyptian deities, they sublimed representations of subjects deduced from their history and theology, and annexed to them hieroglyphical characters, disposed in the form of a prayer, which, in the opinion, gave a secret virtue to these amulets. A similar practice prevailed also among the Ethiopians. The Jews confined in their efficacy for driving away diseases, and they are prohibited by the Mishna, unless they had been effected in the cure of least of three persons. Christians also in former ages had recourse to amulets, made of the wood of the crosb, or ribbands with texts of scripture written upon them, as preservatives against diseases.

AMU.

The Greeks called this kind of remedies φαντασμα, phantasia; σαμποντα, sampon, τανθρακας, tanthracas, βεσκας, and χαφας. The Latins call them amuleta, amuletum, punctula, &c.

Some think this word derived from amula, a small vessel with a little water in it, anciently carried in the pocket by the Romans, for the sake of purification and expiation. This last opinion appears the more probable, in that some amulets were made in the shape of little vessels, as appears from the testimony of Plinius, who observes, that pieces of amber, cut in form of little vessels, were hung about children's necks for amulets.

Amulets are by some considered as a natural species of talisman. Others rather make talismans a species of amulets. The bulla, worn by the ancients; the abxaras of the Basilians, &c. were also amulets. See Abraxas, Abracadabra, and Talismen.

The ancients made great use of gems for amulets; the whole East, according to Chilfort, wore a kind of Jasper for this purpose.

That species of amulets compounded of poisons, used as preservatives from the plague, are more particularly denominated semenba.

Under amulets, some also include medical or other substances fixed to brutes, or even plants, to preserve them from certain diseases and dangers.

Charms, words, scrolls, magic figures and numbers, make a large class of amulets, to which the Turks are still greatly devoted. Their amulets, called chaimalt, are little bits of paper of two or three fingers breadth, rolled up in pieces of silk, containing short prayers or sentences cut out of the Alcoran, with circles and other figures, in which they inscribe the name of Jesus, the figure of the crofs, &c. They hang them about their necks, or place them under their arm-pits, or in their bosom near their hearts, and especially when they go to war, as a preservative against the dangers of it.

The pope is supposed to have the virtue of making amulets, which he exercises in the consecration of Agni Dei.

Amulets are now much fallen from the reputation they were anciently in; yet the great Mr. Boyle alleges them as an influence of the ingred of external effluvia into the habit; in order to shew the great porosity of the human body.—He adds, that he is perfuaded none of these external medicines do answer: for that he himself, having once been subject to bleed at the nose, and reduced to use several remedies to check it, found the moes of a dead man's skull, though only applied so as to touch the skin till the moes was warm thereby, the most efciential of any. The same Mr. Boyle shews how the effluvia, even of cold amulets, may, in tract of time, pervade the pores of a living animal; by supposing an agreement between the pores of the skin, and the figure of the corpuscles. Bellini has demonstrated the possiibilidad of the thing in his last propositions, De Pecibus; and the like is done by Dr. Wainwright, Dr. Keill, &c. However, these are principally used at present by empirics, women, and credulous superstitious persons.

AMULET, in a more particular sense, is restrained to such medicines as do not operate by any physical virtue, or to those wherein there is no proportion between the cause and effect.

In this sense medicines, which operate by effluvia, odours, and the like, do not belong to the class of amulets.

In this sense also those essence-vesils worn by hysterical women on their breasts, called by the Greeks χαφας, &c.
AMU

and by the Latins domus pecoris, were not properly amulets.

AMULET is sometimes also applied, in a more extensive sense, to all medicines, whether internal or external, whose virtue or manner of operation is occult.

AMULET, in Cookery. See OMLET.

AT-ULETICS, in Medicine, is used by some writers for what is more frequently called an amulet.

Amulets amount in the main with what are otherwise called sumptuaries, and have been chiefly used in late times to flrop bleeding; such are the perfuors, tapis humeuris, dried roots, &c. also against warts, fistulae, &c.

Sir Kenelm Digby's sympathetic powder is one of the principal amulets in cafes of hemorrhages, and with many the amanita.'

AMUNCULA, in Ancient Geography, a town of Africa Propria, situated between the two Syrtides.

AMUND, in Ancient Writers, denotes a person free or discharged from tuition or wardship. The word is also written amund, anual, and aman; and is compounded of the privative a, and the Salon mundus, defence, tuition.

AMUR, or Anurun, in Geography, a river of Alasric Russia, or rather of Chinese Tartary, is formed of two rivers, Argoon and Shilka, and first takes its name on their conjunction in the Chinese territory, E. long. 121° 14', and discharges itself into the Pacific ocean, opposite to the island of Sakhalen, E. long. 145° 14'. N. lat. 53° 5'. The Shilka rises in the Yablonny mountains, E. long. 109° 14'. N. lat. 49°, being formed of the tributary streams, called Ingenia, Oonoa, and Netcha, filled by Netchinka, through the Nertchenko district, and joins the Argoon. The Argoon has its source in a lake upon the frontier that parts Ruffia from China, and forms the border all the way to its exit, in the Shilka. By the treaty of 1727 the Amoor belongs entirely to China; otherwise, the ship-building on the sea of Okhotick would be much facilitated to the Russians, as great part of their materials might then be brought by water, which are now conveyed by land at a great expense.

AMULO, in Biography, was born in France, and after having been deacon of the church of Lyons, under Agobard, was on his death raised to the archbishopric of that see in 841. He condemned the veneration that was paid to relics as an occasion of error and superstition; he also wrote a letter against Gotechaleus, and some other pieces upon Grace, Predellation, and Free-will; and "a book against the Jews," addressed to king Charles, the brother of the emperor Lotharius. Amulo, considering the time in which he lived, and his high rank in the church, was a man of distinguisued liberality and moderation; he was much esteemed on account of his talents and eloquence; and shared in an eminent degree the favor of Charles the Bald. He predeceased the council of Lyons in 843. His book against the Jews was published in 1050 by Father Chifflet, under the name of Rabanus Maurus. All his works, except this, were published by Eulze, with notes, at the end of his edition of Agobard, whence they were transferred to the Bibliotheca Patrum. Trithemius says, that Amulo was well skilled in the scriptures and ancient writers, very conversant in secular learning, famous for his knowledge of the Hebrew as well as Latin tongue, and of a quick and lively genius. Cave, H. L. tom. ii. p. 29. Mosheim, vol. ii. p. 322.

AMURACORY, in some Writers of the Middle Age, denotes a kind of Turkish soldiery belonging to the corps or order of janizaries.

They seem to be the same with those otherwise called Serapourit and Portadores.

AMURATH, or Morad, I., in Biography and History, Sultan of the Turks, was the son of Orchan, and the brother of Soyman, and succeeded his father, A. D. 1366. In pursuing the conquests of the Greek empire, he subdued without resistance the whole province of Romania or Thrace, from the Hellepont to mount Idaus, and the verge of the capital, and, made choice of Adrianople for the royal seat of his government and religion in Europe. He afterwards marched against the Sceldonian nations, between the Danube and the Adriatic, viz. the Bulgarians, Servians, Bosnians, and Albanians, and having vanquished their forces and warlike tribes, he converted them by a prudent institution into the firmest and most faithful supporters of the Ottoman greatness. Being reminded by his vizir, that, according to the Mahometan law, he was entitled to a fifth part of the spoil and captives, and that the duty might be easily levied, by blazoning vigilant officers at Gallipoli to watch the passage, he selected for his use the stoutest and most beautiful of the Christian youth, and educated many thousands of the European captives in religion and arms. This new militia was consecrated and named by a celebrated dervish, who, standing in the front of their ranks, stretched the sreeve of his gown over the head of the foremost soldier, and pronounced his blessing in these words: "Let him be called Janizaries, (yenghi cherti, or new soldiers); may their countenance be ever bright! their hand victorious! their sword keen! may their spear always hang over the heads of their enemies! and wheresoe'er they go, may they return with a white face!" Such was the origin of the Janizaries. By the assize of these troops, Amurath extended his conquests in Europe and Asia; and he succoured the emperor, John Palaeologus, against the Bulgarians. When a rebellion was concerted by the eldest sons of these two sovereigns against their fathers, Amurath punished his own son by depriving him of his sight, and inflicted on the same penalty being inflicted on the son of the emperor. After a protracted course of successes, Amurath was opposed by a formidable league of the Walachians, Hungarians, Dalmatians, Triballians, and Avars, under the command of Lazarus, prince of Servia. By the battle of Coffsra, Lazarus was defeated and taken prisoner, and the league and independence of the Sceldonian tribes were finally crushed. But as the victor walked over the field, viewing the slain, and triumphing in his successes, a Servian soldier killed from the crowd of dead bodies, and pierced Amurath, at the moment of his exultation, in the belly with a mortal wound. Others have attributed his death to a Croat, who is said to have labbed him in his tent; and this accident was alleged as an excuse for the unworthy precaution of pinioning, as it were between two attendants, an ambassador's arms, when he was introduced to the royal presence. Amurath died in the 71st year of his age, and 50th of his reign, A. D. 1389. His character has been highly extolled by the Turks, and he has been represented as mild in his temper, modest in his apparel, temperate in his mode of living, and a lover of learning and virtue: he was reproached, however, by the Molossians for his absence from public worship, and he was corrected for his negligence by the fumes of the mufti, who refused to admit his testimony in a civil cause. The sultan, it is said, profited by the reproach, and atoned for his fault by erecting a magnificent mosque at Adrianople, Gen. Dict. Gibbon's Hist. vol. xi. p. 444. &c.

Amurath, or Morad, II., succeeded his father Mahomet I., in 1422, at the age of 18 years. He reign commenced
meased with the capture and death of an impolite, who pretended to be Multapha, the son of Bajazet, and who was supported by the Greek emperor. He then invited Contantine; but his attention was diverted by the rebellion of Multapha, his younger brother, who was imprisoned and flung into the palace. In 1434 he restored the discipline of the Janizaries, and reformed the abuses of the Saphis, and in 1436 he laid waste the Isle of Zante, belonging to the Venetians. In the next year he invaded and subdued the Morea, and obliged the Grecian emperor to pay him tribute; and having taken Thesalonica, or Saloniki, he compelled the Venetians to make peace. In 1434 he suppressed the rebellion of Karamanogl; and when a war broke out between the Ottoman empire and the king of Hungary, in which the famous Hungarian general, John Huniades, gained several victories, Amurath crossed the Danube, and laid siege to Belgrade, but Huniades obliged him to raise it. He also invaded and subdued Servia, which was restored in the peace between Hungary and Poland; and on this occasion it was stipulated, that neither party should cross the Danube in a hostile manner into the dominions of the other. Amurath, having awed Karamanogl, who was renewing his attacks, into submisson, and granted him peace in compliance with the intrigues of his wife, found his dominions in a state of tranquillity; and formed a resolution of abdicating the Turkish throne. Accordingly, in 1443, at the age of 40 years, perceiving the vanity of human greatness, he resigned the empire to his son, Mahomet, and retired to Magnesia, where he joined the society of devouts and hermits, and adopted all their austerities and fanatic rites. If his motives in this extraordinary proceeding had not been debased by an alloy of superstition, we might have extolled his magnanimity. From this dream of enthusiasm, as it may be justly called, he was soon roused by the Hungarian invasion. Ladislaus, the king of Hungary, and his auxiliaries, invited by Karamanogl, the inveterate foe of the Turkish empire, penetrated into the Musulman territories, and Amurath, urged by the earnest intertreaty of his son, and the wishes of the people, determined to take the command of the army. Advancing by halcyon marches from Adrianople, at the head of 60,000 men, he met the Christians at Warna; and on the first onset the Turkish wings were broken; and Amurath perceiving the flight of his squadrons, despairs of his fortune, and that of the empire. During the heat of the engagement, a copy of the treaty of peace between himself and the Hungarian king, was displayed in the front of the ranks, and it is said, that the sultan in his distress, lifting his eyes and hands to heaven, implored the protection of the God of truth, and called on the prophet Jesus himself to avenge the impious mockery of his name and religion. Whilst the battle was in suspense, the young king of Hungary rushed forward in the confidence of victory, till his career was stopped by the impenetrable phalanx of the Janizaries. If we may credit the Ottoman annals, his horse was pierced by the javelin of Amurath; he fell among the spears of the infantry; and a Turkish soldier proclaimed, with a loud voice, ‘Hungarians, behold the head of your king!’ The death of Ladislaus was the signal of a total defeat. Ten thousand Christians were slain in the disastrous battle of Warna; and of the number was cardinal Julian Cefarini, distinguished by his talents and learning, and by a volatil genius, equally adapted to the school, the camp, and the court. The circumstances of his death are variously related; but it is believed, that a weighty incumbrance of gold impeded his flight, and tempted the cruel avarice of some Christian fugitives. However, it is allowed, that he fell a just victim to that pernicious caitiffy by which he quieted the mind of Ladislaus in the violation of his oath, and absolved him in the pope’s name from the guilt of perjury. The loss of the Turks, more considerable in numbers than that of the Christians, bore a smaller proportion to their total strength, and yet Amurath himself was not ashamed to confess, that his ruin must be the conquest of a second and final victory. This battle happened on the 1oth of November, A. D. 1444; and was followed by the retirement of Amurath a second time to the chancellery and devotion of private life. In 1445 he was again called forth to public service by an insurrection of the Janizaries, who filled Adrianople with rapine and slaughter. Having quelled this tumult, he turned his arms against the famous Scanderbeg, prince of Epirus, who had revolted; and followed him to Albania, at the head of 60,000 horse and 40,000 Janizaries. The conquests of the sultan were confined to the petty fortresses of Scetigrade; and he retired with shame and loss from the walls of Croya, the castle and residence of the Caffriots. Amurath, by the alternative of death or the Koran, converted all the Epirots to his own faith. The Hungarians renewed their invasion of the territories near the Danube; and Amurath fell in with them near Costova, the place where Amurath I. had been victorious. The refult of many partial but bloody actions was the route of the Christian forces, and the capture and imprisonment of Huniades, the supreme captain and governor of Hungary, in his retreat. Amurath returned to Adrianople; and having given up all thoughts of resignation, he married his son Mahomet to the daughter of the prince of Elbistan, and appointed him to the government of Asia Minor. By his disappointment at Croya, and the fatigues of his retreat, his last days were not only embittered, but probably shortened; for on his arrival at Adrianople he was seized with a disorder in his head, which terminated his life in the 47th year of his age, and the 50th of his reign. According to Cantemir, the historian of the Ottoman empire, he died 49, and reigned 50 years, five months, and eight days. According to this historian, “he was a just and valiant prince, of a great soul, patient of labours, learned, merciful, religious and charitable; a lover and encourager of the studious, and of all who excelled in any art or science; a good emperor, and a great general. No man obtained more or greater victories than Amurath; Belgrade alone withstood his attacks. Under his reign, the sultan was ever victorious; the citizen rich and secure. If he subdued any country, his first care was to build mosques and caravanserais, hospitals, and colleges. Every year he gave a thousand pieces of gold to the sons of the prophet, and sent 2500 to the religious persons of Mecca, Medina, and Jerusalem.” It should be considered, however, that cruelty and violence have been sanctioned by zeal in propagating the Mahometan faith; and that, in the hands of the Turks, theeyer was the only instrument of conversion; after all the abatements that ought to be made in the preceding panegyric, it is generally allowed that the moderation and justice of Amurath have been attested by his conduct. In the vigour of his age and military power, he seldom engaged in war till he was justified by a previous and adequate provocation; when victorious, he was disarmed by submissi on; and in the observance of treaties, his word was sacred and inviolate. Mod. Univ. Hist. Gibbon’s Hist. vol. xii. p. 156, &c. AMURCA, in Pharmacy, a medicine made of the refuse or remnant of expressed olives. A murca, being boiled in a copper vessel to the consistence of
of honey, becomes a drug of some use in medicine, being reputed an antiseptic and diuretic, and as such sometimes prescribed in ulcers, as well as against diseases of the teeth, eyes, \\

Hippocrates applies the term amurea to a cruste, immature, putrid state of the liver.

Some authors have also given the name amurea to the juice of fluid found in the Reseae facultaria.

AMUSKEAG FALLS, in Geography, are on Merrimack river, in New Hampshire, America, 10 miles below Concord, and seven below Hooksett falls. There are three of them, one below the other, so that the water falls about 60 feet in the course of half a mile. In the middle of the upper part of the second fall is a rocky island, in which are found several excavations or pits, by the circular motion of small stones, impelled by the force of the defending water, which are capable of holding several tons of water. A little below the falls is a bridge 566 feet in length, and 20 in breadth, consisting of 2000 tons of timber. N. lat. 42° 59'.

AMUTRIUM, in Ancient Geography, a town of Dacia, according to Ptolemy.

AMUY, in Geography, a town of India, beyond the Ganges, near the western bank of the lake Chamai, on the confines of the kingdom of Kanduana.

AMWELL, a village in England in the county of Herts, 21 miles north of London, and one south-west of Ware, in which is the spring of the New River, that supplies a considerable part of London with water. This river or canal was projected by Sir Hugh Middleton, in 1666.

AMY, in Law, the person next of kin to an orphan, or infant, who is to be intrusted for him; properly called prochein amy.

The word in French literally signifies friend.

AMY, alien, is a foreigner here, subject to some prince, in friendship with us.

AMYBUS, in Ancient Geography, an island of the Red Sea, supposed to be the same with Amicus, or Aniety Infula.

AMYCI Campus, a name given by Polybius to a plain in the midst of which runs the river Orontes, between Libanus and Anti-Libanus.

AMYCI Portus, was situated on the Thracian Bosphorus, north of Nicopolis, and south of Fanum Jovis. It derived its name from Amycus, an ancient king of the Brichri, who was killed in a combat with Polus, and on whose tomb was planted a laurel, Gr. Daphne, whence the port was called Daphnous portus.

AMYCLE, a city of Peloponnesus, in Laconia, situate south-west of Sparta, and near it. Although small, it was famous for its fruit-trees, so that it was called by Statius (Theb. ix. v. 769) 'virdes Amycle.' According to Polybius, the temple of Apollo in this place was the most celebrated in Laconia, whence it was denominated by Statius, "Apollo Nicola Amycle," and it was pretended that Leda, the mother of Castor and Pollux, resided in this place, whence Silvius Italicus, (lib. xi. v. 434.), describes it thus:

"Leda is venera victor Xanthippus Amycles.
Venus had also a statue in this place, executed by Gitiades. When this part of Laconia was attacked by the Romans, Q. Flaminius encamped near Amycle, and ravaged its territory; and the city was afterwards destroyed. In the time of Tarquiniius, there were some remains of its ancient magnificence.

AMYCLE was also a town of Italy, in Upper Calabria, said to have been peopled by a colony from Amycle, in Laconia, but its situation has not been ascertained; though, it is supposed to have been between Cagna to the south, and Terracina to the north-east. Pliny and Solinus say, that the inhabitants were so afflicted with serpents, as to be under a necessity of abandoning their dwellings. The Amicli were distinguished among the ancient poets by the epithet, "tire," or silent, because it was built by the Epaedemomii, who, having adopted the system of Pythagoras, recommended silence; or, according to others, because a law was enacted in this place, for the purpose of preventing false rumours, by which the people were alarmed, which prohibited any person from reporting the approach of an enemy; but this law was in the end the cause of the ruin of the city; for the Dorians arrived unexpectedly at the walls, and took the city. To this circumstance Silius refers, lib. viii. v. 536:

"—Quamque everti silentia, Amycle, &c."

AMYCLEI, a people of Africa, who, according to Dionysius Peirestes, inhabited Cyrenaica.

AMYCLEIAUM, a town and port of the island of Crete, according to Eutathius.

AMYDON, a town of Macedonia, upon the Axios, in Pzaonia, mentioned by Steph. Byz.

AMYGDALA, in Natural History, a species of Echinus, in the class mollusca of worms, so called, because in shape it resembles an almond.

AMYGDALAE, in Surgery, denotes superficial flesh growing at the root of the tongue.

AMYGDALAE, in Anatomy. See Almonds.

AMYGDALATE, an artificial milk, or emulsion, made of blanched almonds, &c.

AMYGDALAE, See Almond.

AMYGDALIS SIMILIS, in Botany. See Theobroma.

AMYGDALOID, in Natural History. See Toad-Stone.

AMYGDALUS, in Botany, a genus of the icefandria monogynia (polyandra monogynia, Gmelin,) chaff and order, of the natural order of pomaceae and rosaceae of Jullieu; its characters are, that the calyx is a perianthium, one-leaved, tubulous, inferior, quinquefald, deciduous, divisions spreading and oblique; the corolla of five petals, oblong-ovate, obtuse, concave, inserted into the calyx; the filaments have about 30, filiform erect, shorter by half than the corolla, inserted into the calyx, anthers simple; the pistilium has a roundish, villose, fimbriate, the length of the flaments and headed stigma; the pericarpium is roundish, villose, large drupe, with a longitudinal furrow; the seed is a nut, ovate, compressed, acute, with prominent futures on each side, reticulated with furrows, and dotted with small holes. Obs. the nut of the almond is covered with a dry skin; that of the peach with a small pulp. There are seven species. 1. Amygdalus, with all the serratures of the leaves acute, and the flowers sessile and solitary. There are two varieties, viz. the peach-tree, with downy fruit, and the
AMYGDALUS.

NECTARINE, with smooth fruit. For a particular account of both these, their varieties, and different qualities, and the method of their culture and propagation, see AMYGDALUS, in Gardening, infra. 2. A. communis, the almond tree, with the lower ferratures of the leaves glandulous, and the flowers sessile and in cypripets. Some reckon three varieties, viz.: a. A. fruticosa, the common or wild almond; b. f. vallisii, sweet or Jordan almond; and c. A. amara, bitter almond. Miller makes three species of the almond, viz.: 1. A. communis, or common A., cultivated more for the beauty of its flowers, than for its fruit; of which there are two varieties, one with sweet, the other with bitter kernels, which often arise from the fruit of the same tree. 2. A. dulcis or Jordan A., the nuts of which are frequently brought to England; these have a tender shell, and a large sweet kernel. The leaves are broader, shorter, and grow much closer than those of the common fort, and their edges are crenate. The flowers are very small and of a pale colour, inclining to white. These trees have been often raised from the almonds which came from abroad, and the plants have been found to maintain their difference from the common almond. 3. A. sativa, with short pointed leaves, flowers much smaller than those of the common almond, and white; the shoots of the tree smaller and joints closer than those of the common fort; and the tree is less hard, and should therefore have the advantage of a warm situation, otherwise it will not thrive. This fort flowers in the Spring, and rarely produces fruit in England. From an old tree, placed against a wall, with a south aspect, the fruits have been years been ripe, and well flavoured, but their kernels have been small.

Duhamel gives seven species and varieties of the almonds, viz.: 1. Common A. with a small fruit. 2. Sweet A. with a tender shell. 3. Bitter A. with a tender shell; a variety of the preceding. 4. A. with a small fruit, and a tender kernel: Amande-furtex,—and, with a still smaller fruit, amande-pitache. 5. Sweet A. with a large fruit. 6. Bitter A. with a large fruit, a variety of the preceding. 7. Bitter A. probably a variety of the first. He also mentions another, which he calls amandier-oilier, and supposed to have been produced from the impregnation of the almond, by the farina of the peach.

The common almond has leaves which resemble those of the peach, but the lower ferratures are glandular; they proceed from buds both above and below the flowers, and not as in the peach, from the ends of the shoots. Above are not below the flowers. The form of the flowers is not very different, but they usually come out in pairs, and vary more in their colour from the fine blush of the apple-blossom to a flowery white. The chief obvious distinction is in the fruit, which is flatter, with a coriaceous covering, instead of the rich pulp of the peach and nectarine, opening spontaneously when the kernel is ripe. The shell is not so hard as in the first species, and is sometimes tender and very brittle; it is flatter, smoother, and the furrows or holes are more superficial. This tree is a great object in some parts of Italy, and in the south of France, and there are large plantations of it in Provence and Dauphiné. It is common in China, and most of the Eastern countries; and also in Barbary, where it is a native. In the time of Cato it seems not to have been cultivated in Italy; for he calls the fruit nucis graces, or Greek nuts. With us it is valuable as an ornamental tree in clumps, shrubberies, &c. within view of the mansion; for it displays its delicate red-purple bloom in the month of March, when few other trees have either leaves or flowers. An almond-tree, covered with its beautiful blossoms, is one of the most elegant objects in nature. In a forward Spring, they often appear in February; but in this case, the fruit generally delirious them, and they bear little or no fruit; but when they flower in March, they seldom fail to bear plenty of fruit, very sweet, and fit for the table when green, but they will not keep long.

3. A. rumilla, persica africana, &c. of Herm. rugosa, A. persica nana, &c. of Pink, phyto persica amygdalus of Miller, double-flowered dwarf-almond, with leaves veined-wrinkled, or leaves lanceolate and double serrated, wild. The blossoms are smooth, two or three feet high, and dark-purple; the flowers are generally two in a bud and sessile; the calyx reddish; the petals charnate (acuminate, Reichard), red, longer than the tube of the calyx, filaments pale; germ and style subpilose at bottom; stig- stipes linear and very deeply serrate; varies with double flowers; and its native country is Africa. These shrubs make an agreeable variety amongst low flowering trees, in small wildernees quarters; the single fort flowering in the beginning of April, and the double commonly three weeks later. It was cultivated by Miller in 1731. 4. A. amara, A. indica nana of Pluck, and Miller, prunus inermis. &c. of Gmelin, Sibir, armeniaca pericirc folius. &c. of Amn. Ruth. common dwarf almond, with leaves attenuated at the base. The leaves are lanceolate, subulate, scattered, somewhat rigid, smooth, the ferratures very sharp and somewhat spinod, the stigmas linear, long and deciduous; the flowers very abundant on the twigs, appearing with the first leaves from all the buds, the calyx subobtuse and reddish; segments acute, green, and very finely serrate; petals of a fine rose-colour: flammus about 20, the inner ones gradually shorter; pilill very villose; fruit usually solitary, sessile, somewhat compressed, very hirsute, with a harsh yellowish wool, the fize of a hazel nut, which is of a sharp ovate form, yellowish-grey colour, and grooved at the futures; the kernel resembles that of the peach and colour in table; the wood hard, of a yellowish chestnut colour, and veined, but the trunk seldom an inch in thickness. It varies much in size; on the banks of the Volga, it is annually set on fire, and never rises to any height, but is low and shrubby, creeping very much at the root, and obstructing the plough. In Cheriton it scarcely attains a span in height, but in the Ukraine it grows a fathom high, as it does in gardens, where the leaves are broader, and sometimes five inches long. It blooms in April, when all the young shoots are covered with flowers of a peach-blossom colour, and makes a fine appearance among shrubs of the same growth. It is a native of the northern parts of Asia, abounds in Caluce Tartary, and is very common on the banks of the Volga, cultivated in New garden by Mr. Sutherland, in 1683. See AMYGDALUS INFRAS. 5. A. inca, hoary dwarf A. with leaves lanceolate, serrate, wrinkled, subfusillis, white tomentose beneath. It may be doubted whether this be not a variety of the preceding species. 6. A. orientalis, A. argentea of La Marek, silvery-leaved A. with leaves lanceolate, quite entire, silver, perennial, and petiole shorter. The flowers are small, and are not succeeded by fruit in England. It was found growing near Aleppo, whence the fruit was sent to the duke d'Ayen, in France, who raised several plants in his garden at St. Germain's, and sent some to Mr. Miller, who cultivated them at Chelsea, in 1750. It is a native of the Levant. 7. A. robbinsoniana, with leaves ovate, quite entire, and racemes, small, and subterminal. This is a large tree, with spreading branches, acuminate, waved, shining, and alternate leaves, white corolla, drupe about half an inch in diameter, and kernel like the common almond, in form.
AMYGDALUS.

From and small, a native of the wild woods of Cochinchina. For the culture and propagation of almonds, see AMYGDALUS in Gardening, &c. See Bearbium.

AMYGDALUS AETHIOPIUS. See Terminalia.

AMYGDALUS INDICA. See Terminalia.

AMYGDALUS, in Gardening, is applied to the almond, peach, and nectarine trees; the oblong, oval, or almond-shaped, as different species of which, have been given above. In order to render their culture and modes of propagation as clear and intelligible as possible, it may be proper to consider each of them separately.

1st. Amygdalus, almond-tree. This fort of tree is cultivated both for the advantage of the fruit, and as being admirably ornamented in shrubberies, plantations, and other descriptions of pleasure ground, from its coming into bloom early in the Spring. It is, however, less important in the former than the latter point of view, as the fruit is often liable to miscarry in this climate. All the species and varieties of this tree are deciduous, and of a hardy nature, thriving well in most common garden soils. Those of the tree kind frequently rise to fifteen or twenty feet in height, dividing in many spreading branches, which ultimately form beautiful heads, that are generally well adorned in the beginning of March with innumerable flowers, which continue in full bloom for a fortnight or three weeks, and are followed by the leaves, which are long and narrow, and the fruit takes its growth. This is downy, rather large, and of an oval form, consisting of a thick, tough, leathery substance that embraces an oblong nut or stone, in which the kernel or almond is enclosed, which is the only part of the fruit that is capable of being made use of.

The dwarf shrubby sorts of this tree do not, however, in general, exceed three or four feet in height, having slender limbs, which lend forth a great number of small branches near to the ground; and in the single-flowered kind various suckers are frequently sent up from the root. And in both the double and single-flowered almond tree, all the young branches are thickly beset with flowers in the Spring, which, from their having a fine pale red colour, and continuing some time in blow, are highly ornamental. The single-flower have their flowers coming out about the end of March, and the double kind in the beginning of April, each remaining about a fortnight in blow.

The sorts chiefly cultivated for use in this country, are, according to Mr. Forfyth, the tender-scaled almond, the sweet almond, the common or bitter almond, the sweet Jordan almond, and the hard-scaled almond. Those propagated only for ornament are the dwarf and the double-flowered almonds.

Methods of Propagation, &c.—These are either by budding them upon plum, almond, or peach flocks, or by fowing the flocns of the fruit. It is observed in the "Universal Gardener," that in the first way they much sooner form full and regular heads, and attain the state of flowering and producing fruit; and that if it be intended to continue the sweet-kernelled, or any other particular sort, it can only be effected with certainty by inoculation, as when raised from seed they are apt to vary, all the varieties often proceeding from the fruit of the same tree. This operation is generally performed about July or August, and may be done either for dwarfs, half, or full standards. Mr. Forfyth remarks, that the Spring after being budded they may be trained for standards, or let grow for half-standard's; but that the most common method is to bud them at such a height as the Icem is designed to be; and the second year afterwards to plant them out for good. If they are to be transplanted into a dry soil, it is recommended to be done in October, when the leaves begin to decay; but if into wet ground, in the month of February. Such as are budded on plum flocks are found to grow the best in wet foids, and those on almond and peach flocks in dry ones.

In raising trees of this kind from the flocns, it is best to plant them in the early Autumn or Spring months, as October and November, or February and March, being careful to chance the 2d half Summer's growth, drilling them in, in the bed of good light ground, two or three inches in depth. The plants appear in the Spring, and in the Autumn or Spring following, may be transplanted into the nursery, and put in rows for the purpose of being trained for standards, half standards, or dwarfs, according to the intention of the planter.

When it is intended to bud any of them with peaches or almonds, they will some of them be in a proper state for the operation; for dwarfs the 1st, and all of them the second Summer after transplanting; but for standards, in order to be trained with proper items, they should constantly have three years growth.

The dwarf sorts, besides being propagated by budding upon plum or almond flocks, may be easily raised by suckers from the roots, and by layers. The common method in pruning trees of this fort is, in the Spring, to shorten the 2d shoot from the bud to four or five eyes, in order that the trees may put forth lateral shoots in proper quantity, so as to form regular full heads. But it is advised by Mr. Forfyth, that when the young trees are brought from the nursery, they should never be cut till the young shoots begin to break. And, that, as after wet Summers, when the wood is not well ripened, hard Winters are apt to kill the shoots, they should in such cases be cut down to the ground, care being taken, to prune out all such crook shoots as rub against others, leaving the tree open in the middle, cutting the shoots about the fame length as for apricots, and in proportion to their strength. The cankery parts and decayed wood must always be wholly cut out and removed.

Whether made use of as standards or half-standards, it is recommended that they be planted in sheltered situations, which have a southerly aspect. In some cases it may be necessary to protect them by some fort of light covering, against the injury that may be expected from the frosts in February and March. Trees of this sort are also sometimes planted against walls and on efpaliers.

The fruit of the almond-tree, after being properly dried, may be preferred in either bran or fand.

2d. Amygdalus-Perfica, or peach-tree. Its native country is not known. It came to the Romans from Persia, as its Latin name, MALLUS PERFICA, indicates; and it has been cultivated from time immemorial in most parts of Asia; it has been adopted by almost every nation of Europe, and now flourishes abundantly in America, where it has been introduced by the Europeans. Of this tree we have only one distinct species, but there are a great many varieties, and by producing them from the seed or kernel, they may be almost indefinitely increased. But though they are capable of being greatly augmented in this manner, it is probable that but very few possess the necessary qualities, as nurserymen seldom cultivate more than twenty or thirty sorts. As in the cultivation of this sort of tree much experience is constantly required in walls or other suitable buildings, none but such as produce fine fruit should be attended to.

This sort of trees will grow to a considerable height as standards, but in order to produce and ripen fruit, requires the shelter of warm walls. They flower early in the spring.
AMYGDALUS.

in common, the flowers appearing before the leaves, mostly on the twigs of the preceding year, and either singly or in pairs along their sides. They are formed of five small petals, with many stamens in the middle, and a small round germen that becomes the peach.

The fruit is distinguished into two forts, the peach and plum, from the circumstances of the flesh or pulp quitting or adhering to the stone, as in the former it easily separates, while in the latter it adheres firmly.

There are various sorts of peaches that may be cultivated, but for small gardens Mr. Forbth recommends the following as the most suitable: the early avon, flaminia, the anjpeach, royal George, royal Kisington, noblest, early Newtoning, Halland, early purple, blanchard, sweet, the Catherine, the late Newtoning.

Against north and east walls he thinks the early avon, early Anne, early Mignon, royal George, red Magdalen, royal Kisington, noblest, graft mignon, and Milet's mignon are by much the best. In this method a regular succession of fine peaches, if it may, is conceived, be procured until the late sorts against the south and west walls come in. But late sorts should never be planted on a north or east wall.

Methods of Culture and Propagation.—It is observed by Mr. Forth, that peaches require a lighter soil than either pears or plums, and that a light, mellow loam is the most proper for them. Where the natural soil is a strong brick mould, inclining to clay, it will be necessary to take some of it away in first preparing the borders for the trees, in order to be mixed with some light mould, sand, or old lime rubbish. And in making them up, where the trees are to be planted, the earth should be taken out to the depth of three feet, and the breadth of four, and the soil worked well together with rotten leaves or street dung, and the above mixture, throwing them up as soon as convenient into rough ridges, to be exposed to the action of the frosts, and the influence of the atmosphere.

The borders, when it is intended to plant these trees against walls, should never be narrower than three or four feet, and when made six or seven feet, they are more proper. The most advantageous aspects for trees of this description, are those which have the most command of the south fun, but on an eastern or western aspect, they sometimes answer tolerably well.

Where the soil is wet, drains laid deep are recommended by Mr. Forth to be made across the borders, to draw the water from the roots of the trees. These may be filled with old bricks or floes at bottom, and above with gravel, having the depth of two feet of good mould upon the latter. And when water is retained after rains from the illines of the ground, the borders should be formed with suitable floes for the same purpose.

If the soil be a four, loth clay, he advises brick-bats to be thrown into the bottoms of the borders, and to be covered with lime rubbish, or the core from the screenings of lime, which should be then wittered, and, when nearly dry, well rammed to form a solid surface, and prevent the roots of the trees from penetrating the wet earth below, as well as to affix in taking off the water.

When water is permitted to flagmate near the roots of tender trees, in strong land, it is remarked, that it is certain to bring on the mildew, and thereby totally spoil them. They may, however, in some instances, be rescued by moving them to another aspect. All the French peaches, it is observed, are extremely liable to this disease on lands of the strong adhesive kind.

The propagation of peach-trees is accomplished either by setting the seed, or by budding upon plum-stocks. The fine varieties of this fruit have been mostly obtained in the full method, though it is tedious, and often attended with but little success, from the great tendency to deviate from the nature of the variety from which the seed was taken.

The manner of proceeding in this way is to sow or set the seeds, in beds of good mould, in small drills two or three inches deep, about October or November; or where this cannot be done, to preserve them in sand till February. They will be up in the Spring, and after one or two summers' growth, according to circumstances, they will be fit to be transplanted into the nursery, which should be done in rows, either in the Autumn or Spring months. After having remained about twelve months in this situation, some of them may be taken out, and planted against a palings or other proper fence, in order to be trained.

But the most certain method of propagation for preserving the variety, according to the authors of the "Universal Gardener," is that of budding, as by this means peach-trees are produced that afford fruit in size, colour, and taste, exactly similar to that of the tree from which the bud was taken. Before, in this way, the trees become much lower in a bearing state. Though peaches may be budded on different sorts of stocks as those of their own kind, the almond, the apricot, and the plum, yet the peach is always to be preferred for the purpose, as being more hardy and suitable for continuing the trees in a prosperous and full bearing condition. It is also more adapted to grow well in different kinds of soil. The muscle plum-stock is by much the best, where it can be procured.

Stocks for this use may be raised from the different varieties of plums, as well as from peaches, almonds, and apricots, by fowing the seed or floes in the manner that has been already described. The true muscle plum cannot, however, be produced with certainty in this way, as it is liable to great variety when raised by seed. The only mode of procuring it with certainty is by layers in the Autumn, or suckers from peach or other trees that are known to have been worked upon that sort of plum-stock. These are to be collected in October or November, or in the early Spring months, such being chosen as are about the size of the little finger; the knots of old wood adhering to the roots, and the side branches being then trimmed off, they are to be planted in rows two feet and a half distant, and the following Summer some of them will be ready to bud for dwarfs. For forming dwarfs, the most proper fixed stocks for budding upon are those from half an inch to an inch in thickness; but for half or full standards the stocks should be allowed to stand till the limbs are an inch thick at the bottom, and four or five feet in height. See Stock.

The best season for budding them is August, though some gardeners perform the operation in June or July; but when budded too early the buds are liable to freeze weakly the same season, and to be so greatly injured by the Winter, as to make but little progress. See Budding and Isolation.

As it is most necessary that trees of this kind are trained against some sort of fence, they should be principally budded to as for dwarfs, that their branches may come out low. Where the fences are high, they may, however, be budded for half or full standards, and trained accordingly. In performing this business, care should constantly be taken that only one bud be inserted into each fock, the head of which should remain perfect until the Spring; when about March, the whole of the buds should be cut out, in a sloping direction, just above the places where the buds were inserted. Shortly after this the buds most slowly out, producing each a strong...
cerst shoot, which by Autumn has generally attained a consisten
table height, and the tree have obtained their full date of
formation. They should therefore, in the early Aut
omn or Spring months, as October and November, or
February and March, be transplanted either against suit-
able walls, where they may remain, or against some fence
merely with the view of being properly trained before they are
finally planted out into their intended situations; but in
either case, in the Spring, they must have the first shoot
from budding headed down to a few buds or eyes, in order that
a proper supply of lateral shoots may be produced below.
In two or three years they are generally in a state to bear
fruit. See Planting down Trees.

Planting the Trees.—In cultivating this sort of tree, Mr.
For-
syth well observes, that such plants should be preferred as
have the strongest and cleanest forms; and if such as have
been headed down, and are of two or three years growth,
will bear and fill the walls much sooner than those
that have not been managed in this way. Where they have
only one item they are better than with two, as, in the latter
case, one of them must be cut off; for, if planted with both,
the middle of the tree would be left naked, and a large por-
tion of the wall remain uncovered. He is aware that it is
frequently the practice to chuse the trees with the smalllest
items; but, he thinks, they always afford weaker shoots than
the others.

The seasons of planting are either the Autumn or the
Spring. In dry, warm soils, October or November, as soon
as the leaves begin to fall, may be the best periods for this
but they may be used in most soils the Spring months,
as February and March, are to be preferred.

In whatever season the work is done, if the borders be
new, the ground should be well trenched before the trees are
planted; and where they are to supply the places of
such as have been removed, or where the trees have died,
the whole of the old roots should be carefully removed, and
fresh mould put into the place where the old tree was
removed from; the new earth being raised sufficiently above
the old, as where this is not the case, the trees are fre-
quently injured by being planted too deep. Where they are
not kept at first above the level of the old ground, Mr.
Forsyth says, they seldom thrive well. After the trees have been
planted, the roots should be well watered in order to settle
the mould round them, letting it remain in that state for
several days till the whole of the water has been taken up.
The earth is then to be well trodden round them, and the
holes filled up to the top. The fresh planted trees should
remain without being pruned until the Spring when planted
in the Autumn. The authors of the "Universal Gardener," however, advise, that trees of this sort, as well as most
others that are designed for walls, be planted out into their
permanent situations, when they are only of one year's growth
from the bud, and with their heads entire, as in this way
they may be more perfectly pruned and trained the two first
years, which are the chiet points in forming good wall-trees.

Where walls are to be immediately covered, trained trees
from the nursery mull, however, be procured, and of such
sizes as may be the most suitable to the views of the planter.
The proper distance of planting peach trees is about fifteen
feet from each other. Where the walls are high, half
or full standards may sometimes be planted between the dwarfs
to fill up the upper parts until the dwarfs grow up so as
to cover them. The general rule is, where the walls are
not more than six or eight feet high, to plant none but
dwarf trees at the distance mentioned above; but when they
are nine feet in height, half standards of three or four feet
item may be put betwixt; and when the walls are ten or
twelve, full standards of five or six feet item may be had re-
concile to, in order to cover the top parts; the lower branches
of the standard trees being annually removed, as the branches
of the dwarf trees advance, and the trees themselves at last
wholly taken away, to admit the dwarfs to spread over the
whole space.

In removing the trees from the nursery great care should
always be taken to preserve their roots as much as possible,
and that such parts as are bruised be cut away. The long
small roots may also be a little shortened. The trees are
then to be planted three or four inches from the wall, with
the buds outwards, and the heads inclining to the fence,
to which they should be immediately tied, in order to pre-
vent the winds from injuring them. When the ensuing
Spring proves dry, they should be moderately watered once
or twice a week, according to circumstances. See Planting
of Fruit-Trees.

When planted with their heads entire, they should be
headed down about March, when they just begin to bud.
This is done by shortening the first main shoot within a few
eyes of the bud, in a flopping direction next the wall, as before
directed. This must be done to all the trees that are to be
planted against fences, whether dwarfs, half, or full standards;
as by flopping their upward direction, it induces them to
send out lateral shoots near the parts where they are budded
from, which, by proper training, are formed into good trees.
Where this operation is then omitted they run up, leaving
the item naked to some height. The next thing is to at-
tend to the shoots that are made from the few eyes that
were left, rubbing such off close, as come out for-right,
either from the front or back of the branches, only retaining
those that are bent off laterally, which, about June, when
of sufficient length to be laid in, ought to be nailed well to the
fence, keeping them to it, without being shortened during
the Summer.

About November, when the leaves have fallen, or in the
March following, they should have their first Winter
pruning. This is to be performed according to the number of
shoots that have been produced from the heading down. If
there should be two shoots, one on each side, both of them
may be retained, being shortened to eight, ten, or more
inches, in proportion to their strength, to produce a further
supply of wood, nailing them horizontally to the fence.
When there are three shoots, the middle one, if not regularly
placed, or of too strong growth, should be cut out close to its
origin, the others being shortened and nailed as above; but
when of a moderate growth, and regularly placed, it should
be shortened and nailed in an upright direction. When there
are four shoots, they must be shortened as above, and trained
regularly two on each side; the principle to be chiefly
attuned to at this period of their growth, being that of keep-
ing the shoots of as equal a strength as possible, and of equal
number and regularity on each side; which is best accom-
plished by leaving only two or four good branches, to be
trained with exactness both to the right and left, as these
will supply others to cover the fence in an upright direction.
See Wall-Trees.

In the second year's pruning, during the Summer, all the
shoots that proceed from the upper or under sides of the
horizontal branches of the former year, are to be retained en-
tire and trained, the whole of the for-right shoots arising from
both the front and backs being carefully rubbed off as
nucleas, reserving all such as are regular to be trained in at
full length, as in Summer the shoots should, but in few in-
stances, be shortened.

7 The
The second Winter pruning may be performed about the same periods as the first, in which the branches are to be shortened as directed above, and kept in as much regularity and uniformity as possible, both in number and size, by removing such shoots as are weak. By constantly keeping the lowest branches the most extended, where there are five, six, or eight branches on a side, and these trained at the distance of four, five, or six inches from each other, every handsome trees will be formed, from which some fruit may be expected in the former following.

The trees being by these means brought to the proper form for bearing, they are to be pruned and kept in order by proper Summer and Winter pruning. It may be observed, that both the peach and nectarine trees constantly produce their fruit on the former year's shoots, or the shoots that are formed each Summer bear fruit the next; and that the same shoots seldom bear more than once, except sometimes, on very short casual lateral spurs; nor farther do the same shoots, after the first year, furnish a regular supply of successional bearing wood; it is most generally afforded by the year old shoots. Hence the great object in pruning is to procure an annual succession of young wood, in every part of the tree. This is principally effected by the shortening of each year's branches in the Winter prunings, as by this means they are made to afford both a supply of bearing wood and a crop of fruit.

The manner of pruning and training, so as to render these trees regular and uniform in their shape and appearance at first, has been already explained.

But the general Summer prunings chiefly consist in reforming the irregularity of the numerous shoots then produced, and training, to the wall at full length, in every part, an abundant supply of all the regularly placed ones as successional wood for the next year's bearing; and the general Winter prunings are intended to reform generally the branches and shoots of all ages, sizes, and situations, so as to render the trees healthy, beautiful, and productive. The times of performing these different prunings have been mentioned above. See Pruning of Fruit-Trees.

After the trees have been pruned they should be immediately nailed to the fences, and the bent methods to nail them as the pruning advances, that is, as soon as a tree is pruned to secure the branches by nails, before another is begun. In performing the operation care is to be taken that the branches be laid with order and regularity in a horizontal direction, having their extremities but very little higher than their bottoms, where there is sufficient room between the trees. And in other cases the degrees of obliquity should be as little as the nature of the situations will admit. Where more wood has been left than can be laid in, it must either be cut out altogether or down to an eye, for the purpose of a shoot the next year. See Nailing of Fruit-Trees.

Peach trees are very liable to be affected with the bloat, a disease in which the leaves are shrivelled, or curled up, and considerably thickened. This arises from insects and other causes, and is to be remedied by removing the leaves that are mottled defaced, and washing the trees in hot weather with water, by means of a garden engine, afterwards letting them be well irrigated with tobacco smoke, or sprinkled over with the powder of it. See Fumigation, and Diseases of Fruit-Trees.

As these trees come into blossom early, it frequently becomes necessary to protect them from the effects of the frost, in order to secure the fruit. For this purpose various means have been attempted, but those that seem the most effectual are either thin light mats nailed over them, or a strong open canvas. These should be nailed up in the evenings, and removed during the sunny part of the day. Or in severe weather they may be kept on the whole day.

From the fruit of these trees setting too thick, or in clusters, it often becomes necessary to thin them, which should always be done according to the vigour and strength of the tree, and the size of the fruit. Where the trees are strong, and the fruit small, they may be left thicker than where they are weak and the fruit large. In each case the largest, fairest, and those that are best placed should be left; and where the leaves cover the fruit too much, they should also be thinned away, by being pinched off. Trees of this kind, from the period of their being headed down, to their fifth or seventh year, may be considered in the stage of training, though in their second or third they will generally begin to bear fruit. When properly managed they are also much more durable than is commonly supposed, as they will continue thirty or forty years. It is likewise of much utility in the culture of peach trees, to dig a little dung occasionally into the borders in which they are situated, and to permit none but the smaller kind of garden plants to be grown about them.

Peach and nectarine trees are often cultivated in basins, frames, and hot walls, in order to obtain their fruit early. For these purposes the early sorts should always be procured. See Peach House, Forcing Frames, and Hot Walls.

The double blossomed and dwarf peach trees are mostly planted out in shrubberies and pleasure grounds, as beautiful or ornamental trees; the latter sometimes in pots, as being curious.

3. Amygdalus Nucipersica, or the Nectarine Tree. This is now generally considered as a variety of the peach, but the two trees cannot by any circumstances in their growth, wood, leaves, or flowers, be distinguished from each other with any degree of certainty. The fruits are, however, readily discriminated in all their different stages of growth, that of the nectarine having a smooth, firm cuticle, or rind, while in the peach it is covered with a soft downy substance. Besides, the pulp or flesh of the former is much more firm than that of the latter.

There are many varieties of the nectarine that may be cultivated; but those that chiefly deserve attention are the Fairchild's, the violet, the Ebrange, the Newtonian, the Roman, the Temple, and the Virmajo. The white nectarine may also be cultivated both for the goodness of its fruit, and as being a curious variety.

The culture and management of this tree is, in every circumstance, the same as that of the peach. It also requires the same sort of soil and situation. See Amygdalus Persica.

AMYLACEOUS, formed from "Amylum, starch," a term applied to the fine flower of farinaceous feeds, in which consists their nutritious part.

AMYLON, in Ancient Writers, a kind of aliment answering, as some apprehend, to our furnity.

The word is Greek, αμύλων, thus called, because made fine meal.

AMYLUM. See Starch.

AMYNTA, in Literary History, a beautiful pastoral comedy, composed by Tasso; the model of all dramatic pieces, whereon shepherds are actors. The Pastor Fido, and Fili di Siro, are only copies of this excellent piece.

AMYNTAE, in Ancient Geography, a people of Thebapots. Steph. Byz.

AMYNTAS, in Entomology, a species of Hesperia in the Fabrician family, with tailed wings; above blue, margin black; beneath cinerose with black points. Two ferruginous spots at the anal angle of the posterior wings. This is a small
AMY

a small insect, and inhabits Africa. Fabricius.—This is the Papilio Theolepis of Esper.

AMYNTICA empheia, in Pharmacy, defensive, or strengthening plasters.

AMYNTOR, properly denotes a person who defends or vindicates a cause. The word is amnatar, formed of the verb amnare, I defend or average.

In this sense Mr. Toland entitles his defence of Milton's life, Amnter, as being a vindication of that work against Mr. Blackhall, and others, who had charged him with questioning the authority of some of the books of the New Testament, and declaring his doubts that several pieces under the name of Chrift and his Apostles, received now by the whole Christian church, were supposititious.

Amyntor, in Entomology, a species of Hesperia.

Wings indented, tailed, black; a fulvous spot at the base, and yellow stripes at the tip. The wings are entirely black above, except the fulvous spots and yellow stripes beneath, yellow, with an arched black band; posterior end of the lower wings black with white dots. A native of India. Fabricius.

AMYOT, James, in Biography, was born at Melun in 1514, and rose from an obscure original to the high station of bishop of Auxerre, and great almoner of France. At the age of ten years he fell, for fear of chastisement, from the house of his father, who, as some say, was a currier; but according to Thuanus and others, a butcher; and being taken ill on the road, he was removed to the hospital at Orleans, where he was not only restored to health but charitably furnished with 16d. for defraying the expense of his journey home. This relief was required, on his subsequent prosperity, by a legacy of 1000 crowns to the hospital. He was afterwards a diligent student in the university of Paris, where he was maintained either by the industry of his parents or the charity of a lady, whose sons he attended at college; and at the age of 19 he attained the degree of Master of Arts. In 1537 he left Paris and accompanied the abbots of St. Ambroze to Bourges; and being recommended as preceptor to the children of William Bouchetel, secretary of state, he was thus introduced to the patronage of the princes Charles and Louis, Tutors of Francis I. who obtained for him the chair of public lecturer in Greek and Latin at the university of Bourges, where, for ten years, he read two lectures a day, one in Greek and the other in Latin. Here he translated the ancient Greek romance of Heliodorus, intitled, his "Ethiopic History, or the Loves of Theagenes and Charicles," which performance was much admired, and procured for him the abbey of Bellosana. At Venice, whither Amyot went in pursuit of preferment, after the death of Francis I. he was employed on a commission to the council of Trent, and having executed it with honour, he spent two years at Rome, prosecuting his studies, and ingratiating himself with those who were likely to serve him. By Cardinal de Tournon he was recommended to the king of France, and undertook the charge of educating his two sons in 1558. When the eldest of these pupils succeeded his father, under the name of Charles IX. in 1560, he immediately upon his accession to the throne, advanced Amyot to the dignity of great almoner, appointed him curator of the university of Paris, and conferred on him the honours and emoluments of the abbey of St. Corelille, and the bishopric of Auxerre. When the younger of his pupils, Henry III., came to the crown, Amyot was continued in his other offices, and in 1578 appointed master of the order of the Holy Ghost, then instituted. During the commotions and civil war which ensued, he remained in his diocese, and closed his life in 1593, in the 79th year of his age. In proof of the avverse, with which Amyot has been accused, and which enabled him to amass 20,000 crowns, it is alleged, that, when he was soliciting from Charles IX. another benefice, in addition to the lucrative dignities which he possessed, the king said to him, "How now, master ? you told me, if you had 1000 crowns a year, you would be satisfied: I believe you have that and more." —"True, sir," replied the bishop; "but appetite comes by eating." Of the learning of Amyot we have ample evidence in his translation of Heliodorus, and also of Plutarch's Lives, which is still held in high estimation in France; the first edition is that of Vaclofian, printed in 1573 and 1574, in 13 volumes, 8vo.; and Racine says of it, that this old translation possesseth a grace not to be equalled in modern language. As an apology for not complying with the request of those who wished him to write a history of France, he humorously urged, "that he loved his masters too well to write their lives." Amyot translated seven books of Dioctus Sicius, some Greek tragedies, and the pataulon of Daphnis, of which a beautiful edition, with plates, in 8vo. was published in 1713. His miscellaneous works were printed in 8vo. at Lyons, in 1613. Gen. Dict.

AMYRALDISM, in Ecclesiastical History, a name given by some writers to the doctrine of universal grace, as explained and asserted by Amyraldus, or Moses Amyraut, and his followers, among the reformed in France, towards the middle of the seventeenth century.

This doctrine principally consisted of the following particulars; viz. that God secures the happiness of all men, and none are excluded by a divine decree; that none can obtain salvation without faith in Christ; that God refuses to none the power of believing, though he does not grant to all his affiance, that they may improve this power to faving purposes; and that many perish through their own fault. Those who embraced this doctrine were called universalists, though, it is evident, they rendered grace universal in words, but partial in reality, and are chargeable with greater incon sistencies than the supralaparians.

Amyraldism is said to have been a system formed with a view of producing a reconciliation with the Lutherans.

AMYRAUT, Moses, in Biography, an eminent protestant divine, was born of a good family at Bourguet in Touraine in 1566. He was designed by his father for the profession of the civil law, which he afflictedly studied in the college of Poitiers; but preferring that of a divine, he applied himself to theology at Saumur in 1620, and obtained the professorship of divinity in the university of this place. With his two colleagues in office he lived in perfect harmony; and the three professors cordially concurred in their exertions for the credit of the seminary in which they prevailed. In 1631 he was appointed by the protestant synod at Charenton to present to the king their complaints concerning the violation of the edicts which had been passed in their favour; and being instructed not to deliver his address on his knees, which had been the usual mode, he was allowed to decline it, and the ability and address with which he conducted this business were admired by Cardinal Richelieu. His treatise "On Grace and Predestination," written at the request of a Roman catholic of rank, who was favourably disposed towards the protestants, excited much attention. This attempt, on the part of Amyraut, for reconciling the doctrine of predestination with that of universal grace, was violently opposed by the Calvinistic divines, and particularly by Du Moulin. Although Amyraut was enjoined silence with regard to these subjects of debate by the synod of Alem- son, he persevered in the contest; and such was, ultimately, his success, that the sentiments which he inculcated, and which
which nearly coincided with those of the Pelagians and Arminians, were received in all the universities of the Huguenots in France, and disseminated by the French protestants, who fled from the rage of persecution, through all the reformed churches of Europe. The talents, learning, and moderation of this able polemic, were much respected by the clergy and laity of all professions. His political opinions, which were favourable to the high pretensions of absolute monarchy, and which militated against those which were generally avowed by the Huguenots, and the advocates of religious liberty, served to recommend him to the particular notice and esteem of Cardinal Mazarin. In his Apology for the Protestants of France, published in 1647, he declares, that he will not pretend to justify the taking up arms against one's prince on any occasion whatever; and that he always believed it to be more much more agreeable to the nature of the gospel and the practice of the ancient church, to have recourse to no other arms than patience, tears, and prayers. In his book "On the Sovereignty of Kings," published in 1650, on occasion of the tragic death of Charles I, he expresses, in the strongest terms, his approbation of the doctrine of passive obedience. He excepted, however, those cafes of condescence, in which he regarded the authority of God as superior to that of man: and he so frequently refuted an order of the council of state, which required all the protestants to put out hangings before their house's Corpus Christi day, that the order was soon revoked.

Amyraut was eminently distinguished both by his writings and character. His moderation and candour secured the respect of persons of different sects; and his liberality to the poor comprehended alike the catholics and reformed, and it was so extensive, that he distributed in charity the whole salary of his ministry during the last ten years of his life. He died, much respected and regretted, in 1664, bearing testimony, in his last moments, to the truth and importance of those religious principles, by which the course of his life had been uniformly regulated. Gen. Dict. Monheim's Eccl. Hist. vol. v. p. 364, &c.

AMYRBERIS, in Botany, a name used by some authors to express the Barberry-tree. AMYRIS, a genus of the ordandria monogynia class and order, and of the natural order of terebinteae, Juliku. Its characters are, that the calyx is a perianthium, one-leaved, four-toothed, acute, erect, small, and permanent; the corolla consists of four, oblong, concave, and spreading petals; the stamens have awl-shaped, erect filaments, anthers oblong, erect, of the length of the corolla; the pistillum has a germ, superior ovate, style thickish, of the length of the stamens, and stigma four-cornered; the pericarpium is a drupaceous and roundish berry; and the seed is a round, shining nut.

Martyn, in his edition of Miller, enumerates 9, and Grisel, in his Linnaeus, 13 species. 1. A. elegantissima cornus of Plume, icere alba of Maregr. frutex trifolium of Cateby, with leaves ternate and pinnate, with five lobes, downy underneath. The height of this tree is about six feet; the leaves pointed, fluff, and shining; and leaves opposite on peduncles two inches long; at the ends of the branches grow four or five slender stalks, set with many very small white flowers, in a little corymb; the petals are inax at the tip. It has a small trunk, covered with a smooth, grey bark, and grows almost in the manner of a beech-tree. The fruit is of the size and figure of an olive, and the colour of a pomegranate, having within it an odoriferous pulp. A native of Carolina and Brazil. The rind of this tree is the Gum ELEMI, 2. A. fulva, with leaves teregate, corne, and acute. This is a erect, leafy shrub, from 2 to 15 feet high, according to the soil and situation, having a turpentine of a strong disagreeable smell: it is found plentifully about California in woods near the sea, and in flowers in August. 3. A. maritima, small, shrubby sweet-wood, with leaves teregate, crenulate, and obtuse. This is a dwarf shrub, yielding a juice like that of the former, but moreagreeable, and smelling like rue: the berry is of the size of black pepper, black when ripe, incoating a globular, brittle nut, in which is a white kernel. Swartz doubts whether the preceding he distinct species from this. It grows in very barren coppices, in a calcaneous rocky soil, both near the sea, and on the interior mountains of Jamaica, Hifpaniola and Cuba; and flowers from June to September. 4. A. Glycofera, balsam of Gymn, with leaves teregate, quite entire, and peduncles one-flowered, and lateral. This species is a shrub with purplish branches, having protuberant buds loaded with balfamic resin; the flowers proceed from the same buds by threes; the bracte minute and lightly bifid. It is doubtted whether this be distint from the next species. See Balsam of Gymn. 5. A. Opolsonum, balsam of Mecca tree, balsamum of Bellon, and Alpin, opobalsamum, or balsamum Judicium of Geoffroy, has pine leaves, and ellipse leaflets. See Balsam of Mecc, and Opolsonum. 6. A. toxifer, poison ash, cimfera of Linn. Hispanic, toxicon andro of Cateby and Miller, with leaves pinnate, and leaves petiolate and plane. Cateby describes his poison-wood as a small tree, with a light-coloured, smooth bark, the mid-rib of the leaf, as seven or eight inches long, and the pides as an inch in length; the fruit as hanging in bunches, shaped like a pear, of a purple colour, covering an oblong hard stone; from the trunk distils a liquid as black as ink, which the inhabitants say poison; birds feed on the fruit. It is a native of America. 7. A. pruniun, pruni Javanicum of Burm., tingulong of Rumph, with leaves pinnate, and leaves petiolate and waved. It is perennial, and a native of the East Indies. 8. A. ambrosiata, icada hepata of Linn. Guan, with leaves pinnate and petiolate, and panicules crowded and axillary. This is a tree, with a trunk 30 feet high, branching at the top, branchlets leafy and flowery; leaves alternate, with two or three opposite, ovate leaves on each side, ending in long points. Smooth, entire, on short-peduncles, gibbous at the base; flowers yellowish white, axillary, and corysmmed; petiole very small and four-toothed; petals lanceolate, spreading at the tip; filaments filiform, half as long as the calyx, inserted into the tube; germ, superior, subglobos, style cylindrical; stigma capititated, depressed and four-cornered; fruit ovate, oblique, four-celled, resembling that of the laurel; the nucleus involved in a brittle covering, four-celled, with four stones wrapped up in a vifid red pulp, having a balsamic smell and tarry, hardening into a grey resin, and used for burning as a perfume. The whole tree is very sweet.
sweet-scented, and yields a very odoriferous balm from the wounded trunk or branches, which is used in the dysentery; the dotte is one drawn in red wine; it is also used in houses and churches for burning as a perfume. It grows in the woods of Guiana, and by the sea-thore, flowering and fruiting in September. The Caribbce name is aramonoa, and the French arbre de l'Eveque. 9. A. balnsiniera, lucernum of Plak. Sweet amys, white candle-wood, or rosewood, with leaves two-paired. This grows to a considerable size, and is one of the most valuable trees in the island of Jamaica; the wood is white, and of a curled grain when young, but grows of a dirty, clouded ash colour with age, bearing a fine polish, and having a pleasant smell; it is heavy, and much esteemed among cabinet-makers. All the parts of this tree are full of warm aromatic particles, and may be used in baths and fomentations; the berries are oblong, and have the taste of the balm Copaiba. An infusion of the leaves has a pleasant flavour, is highly cephalic, strengthens the nerves, and is particularly reforlative to weak eyes. In Jamaica there are several species of amyris, the leaves and bark of which yield a fine balsamic juice; and if the body were tapped at the proper season, a thick liquor would trufudate, resembling that of the Gilead balsam, to which the taste of the bark and wood of the smaller branches bears a very exact relation. Dr. Wright apprehends that this wood, by distillation, would yield a perfume equal to the oleum rhodii. 10. A. kafos, with leaves ternate, ferrate at the tip, and dichotomous peduncles. Forik. Fl. Aeg. Arab. 11. A. balsamica, with leaves ternate, and pinnate, with five lobes, and flowers falcifolied and pentatetalous. Gleditch. Sehr. Berl. Naturf. 12. A. Zeylanica, with leaves pinnate, petiolated and smooth, racemes interrupted and axillary, and flowers involucrated and hexandrous. Koenig apud Retz. Off. Bot. 13. A. Guimana, with leaves pinnate, the pinne two-paired, and ovate-oblong, and racemose berries. Sloan. Hist. Jam. Gmelin’s Linneaus, and Martyn’s Miller.

AMYRIS. See XENIANA.

AMYRUS, in Ancient Geography, a town of Greece in Thessaly; its present situation is not known. There was also a river of the same name.

AMYSTIS, a river of India, so called by Arrian.

AMYTHAONIA, a district of Ellis, so called from Amythaon. Steph. Byz.

AMYTON, a town of Caria, according to Ptolemy.

AMYTRON, a town of Thrace, according to Hesychius.

AMYZON, a town of Asia Minor, in Caria, according to Strabo.

AMZEL, in Ornithology, the name of a bird found in the northern parts of Great Britain; but which is better known by the name of ring-ouzel. This is the Turdus torquatus of Linnaeus. See Torquatus.

ANA, in Commerce, the name of an Indian coin, in value somewhat more than one penny sterling.

ANA, ANAH, or ANA, in Geography, a town of Asa, in Arabia Deferta, situate on the Euphrates, in a pleasant and fertile country, which produces plenty of corn, olives, dates, oranges, lemons, pomegranates, figs, &c. It is under the government of an emir, tributary to the grand sifinor. It is the general resort of the robbers, who plunder the caravans that pass to and from Bagdad, Aleppo, Damascus, &c. 260 miles east of Damascus, and 300 north-east of Aleppo. N. lat. 32° 55'. E. long. 42° 4'.

ANA, ïïï, in Medicine, denotes an equal quantity of any things, whether in liquid, or in dry measure. Hence analcice proportio is used by some writers to signify the rate, or proportion of equality.
rebaptized. But we must not close under the same denomination those bishops of Asia and Africa, who, in the third century, maintained that baptism, administered by those whom they called heretics, was not valid; and therefore that such of them as returned into their churches ought to be rebaptized. Nor does it appear that there is sufficient authority to affirm, that the *Vindicta* and the *Mennonites* were precursors of the modern *Anabaptists*; though some of them adopted the practice of adult baptism.

It was not till a little after the time when the Lutherans separated from communion with the Remish church, that the *Anabaptists* began to make a noise in Germany. Storck, Stubner, and Munzer, were the first disciples of Luther, who, about the year 1521, were styled Anabaptists. But well knowing that their opinions were very different from Luther's doctrine, they availed themselves of his absence to disseminate them in Wittenberg, and had the address to over-reach the piety of Melancthon. Their principal purpose was to gain over the populace, and to form a considerable party. To effect this, says Bayle, they were indefatigable and active, each in his own way. Storck, wanting knowledge, boasted of inspiration; and Stubner, who had both genius and erudition, laboured at commodious explicatons of Scripture. Not contented with disseminating the court of Rome, and deriding the authority of consisitories, they taught, that men being entitled under the Gospel to equal liberty, could not be justly subjected to any civil power, nor erect supernendencies over each other; that, as all magistracy was an usurpation on Christlian freedom, no true Christlian could be either magistrate or subject, nor consequently pay any impost, give any oath, or bear arms; that violence and arms ought never to be made use of, excepting against princes, and people in power, from whom they were permitted to revolt, as from too many usurpers, who were to be pulled down, in order to erect the kingdom of God. They pretended that Christlians, being all free, equal, and independent, there ought to be no tribunal among them, nor laws, nor any distinction of property, but that every thing should be in common, nor any restraints with regard to the number of wives whom they might marry. In other respects they affected singular austerity, recommending jactations, fastings, and the utmost simplicity of apparel. Their fermons were, for the most part, declarations against the communion of the reformed; and they were incessantly exhorting everybody to join with them, who, as they said, were rent of God, to re-establish the kingdom of his Son. They made high promises to all who would unite with them to exterminate the impious, if this masse proved the epocha for the commencement of Christ's reign upon earth, when the just, meaning themselves, were to reign also, instead of the unrighteous usurpers of authority. They moreover affected to speak with a kind of contempt concerning exter nal worship, the sacraments, the ministry, and even the word of God, with a view to enhance the merit of the esaties, visions, and inspiration, to which they pretended, and on which they valued themselves. They dealt much in predictions, especially concerning the nearness of the last judgement; and, finally, to give a greater eclat to their party, they rebaptized all those who joined them; and to make their practice succeed, they taught that baptism administered to infants was void.

Munzer took the lead of this party; and, in 1535, assembled a numerous army of associates; but this insurrection was soon suppressed, and Munzer put to an ignominious death. Many of his followers, however, survived, and propagated their opinions through Germany, Swifterland, and Holland. In the year 1538 they formed a new community at Munster, under the direction of two Anabaptist prophets, John Matthias, a baker of Haarlem, and John Blockholdt, a journeyman tailor of Leyden. Having made themselves masters of the city, they deposed the magistrates, confiscated the estates of such as had clapped, and deposited the wealth they amassed together in a public treasury for common use. They made preparations of every kind for the defence of the city, and sent out emissaries to the Anabaptists in the Low Countries, inviting them to assemble at Munster, which was now dignified with the name of Mount Zion, that from hence they might be deputed to reduce all the nations of the earth under their dominion. Matthias, who was the first in command, was soon cut off in an act of frenzy by the bishop of Munster's army; and was succeeded by Blockholdt, who was proclaimed, by a special designation of heaven, as he pretended, king of Zion, and invested with legislative powers, like those of Moses. The extravagancies of Blockholdt were too numerous to be recited: it will be sufficient to add, that the city of Munster was taken after a long siege and an obstinate resistance; and Blockholdt, the mock monarch, was punished with a most painful and ignominious death. The *Baptists* in England and Holland, or, as they are there called, the *Mennonites*, are very different from those who first gave rise and name to the sect.

It must be acknowledged, that the first insurgents in Germany had been grievously oppressed; and that they took up arms principally in defence of their civil liberties; nor should subsequent extravagancies of violence be attributed to their religious principles, much less charged on their successors. The sequel of their history, and distinguishing tenets, may be seen under the article ANTI-PEDO-BAPISTTS, BAPTISTS, MENNOITES, WATERLANDIANS, &c.

ANABASIS, in Antiquity, the couriers who travelled on horseback, or in chariots, for the greater expedition. The word comes from the Greek *ánabasis*, mounting.

ANABASIS, in Botany, a genus of the *pamndia* elati and order, of the natural order of *babaraceae* and *atriplexes* of Jucieau: its characters are, that the calyx is a three-leaved perianthium, the leaflets roundish, concave, obtuse, and spreading; the corolla five-petalled, petals ovate, equal, less than the calyx, and permanent; the *fotamina* have filaments filiform, longer than the corolla, and anthers roundish; the *pilifnum* has a germ roundish, acuminate, ending in two styles, and obtuse stigmas; the *pervicu- trium* is a berry, roundish, surrounded by the calyx and di- luted; the *seed* is single and screw-shaped. There are four species. 1. *A. aptilis*, leaves *A. falloa* bacceera of *Gmel. Siber. kali bacciferum of Buxh. without leaves, and the joints emarginate. This is a perennial plant, and has been found wild on the shores of the Caspian. The berry, in a state of maturity, is large; it is red, the pulp is watery, and it dyes a yellow colour. *Gmelin* makes the anabasis ceteacea of Pallas and Gartner a variety of this species. 2. *A. falcifolia*, leafy *A. falloa* foliis incrassatis, &c. of *Gmel. and Pallas*, kali bacc. fol. clavatis of Buxhbaum, with leaves subclavate. It is seldom more than half a foot high; annual; found wild on the shores of the Caspian. 3. *A. tamarijefolia*, tamarisk-leaved *A*. with awl-shaped leaves and juiceless pericarps. This is a shrub with white branches, very smooth; a native of Spain. 4. *A. spinifolia*, thorny *A*. shrubby, branches without leaves, but full of spines; the native place of growth is unknown.

ANABASIS, in Medicine, the slake of a disease in its growth.

ANABASISUS, a name given by Pliny to a plant, which he calls alio *ephebra*, and describes as hanging down from
LANCICNINC, the mounting them yalaquity, the Ornithology, firrups, brown inns, species more the name Pifidia. kind place Ipecica Bill twenty vented. of It the fion mountains, U'lkrrs, office foot-boards gene by ANARLATUM, ANABIBAZON, AN...
calyx, one thicker, double the length of the others, lying on the germ in front, anthers roundish, in the longer filament large and fertile, in the rest small; the _pistillum_ has a germ kidney-shaped, obliquely emarginate in front, style subulate, bent in, the length of the corolla; stigma small, roundish, defrizzled, and concave; no _pericarpium_; receptacle fleshy, very large and obovate; the seed a nut kidney-shaped, large, at the top of the receptacle, with a thick shell, cellular within, and abounding in oil. The _calyx, corolla, and flamina_ of the male flowers as in the hermaphrodites; the _pistillum_ has either no germ, or one that is abortive. There is one species, _Anacardium occidentale_, acajuba occidentalis of Gartner, acajou of Píno, acajuba of Maregrave, caffuvinum of Rumphius, cachon of Merian, kapa-mava of Rheed, _anacardium frutescens_ ovato nuce reniformi, racemi terminalibus of Browne, Jamie. Cachew-nut, caffu, or acajou. The cachew is an elegant tree, 12 or 16 feet high, spreading much as it rifes, and beginning to branch at the height of five feet, according to Browne; and Long affirms, that in good soils it spreads to the size of a walnut tree, which it resembless in the shape and smell of the leaves: the trunk seldom exceeds half a foot in diameter; the leaves are coriaceous, subobovate, shining, entire, petioled, and factured alternately; the panicles corymbose, diisetc, and terminating, containing many small, sweet-smelling flowers, on an oblong receptacle, scarcely distinguishable from the peduncle; the corolla red, with commonly 10 flaments, one of which has no anther, but it has frequently eight or only seven all fertile; and there are sometimes female flowers entirely deficate of flaments. The fruit has an agreeable fubacid flavour, in some degree refringent; in some of a yellow, and in others of a red colour, which difference may be probably owing to the soil or culture. The juice of the fruit, fermented, affords a pleasant wine, and distilled, yields a spirit exceeding arrack or rum, and serves to make punch, and also to promote urine. The ripe fruit is sometimes roasted, and fliced, and thus used for giving an agreeable flavour to punch. The reftingrness of the juice has recommended it as a remedy in dropical habits. From one end of the apple proceeds the nut, which is kidney-shaped, inclosed in two shells, the outer of an ash-colour, and smooth, and the inner covers the kernel. Between these shells is lodged a thick, inflammable, and very caustic oil, which, incautiously applied to the lips and mouth, inflames and excoriates them. This oil has been successfully used for eating off ring-worms, canicular ulcers, and corns; but it should be very cautiously applied. Some of the females have used this oil as a cosmetic, in order to remove the freckles and tan occasioned by the scorching rays of the sun, but it proves fo corrosive as to peel off the skin, and cause the face to inflame and swell; but after enduring the pain of this operation for about a fortnight, their new skin, as it may be called, appears fair like that of a new-born infant. This oil also tinges linen of a rusly iron colour, that can hardly be got out; and when smeared on wood, it prevents decay, and might therefore serve for preserving houte timber and shipps bottoms. The fresh kernel has a delicious taste, and abounds with a sweet milky juice; it is an ingredient in puddings, &c. and is eaten raw, roasted, and pickled. The negroes of Brazil, who are compelled by their masters, the Portuguese, to eat this nut, for want of other fullcance, obtain relief from this involuntary use of it in various disorders of the stomatch. When the kernel is ground with cacao, it improves the chocolate; but if it be kept too long it becomes shrivelled, and loses its flavour and belt qualities. The milky juice of the tree, obtained by tapping or incision, will stain linen of a deep black, which cannot be washed out; but whether this has the fame property with that of the easter _anacardium_ has not yet been fully ascertained; for the infipidice juice of that tree is the best for be which is used for filling black in China or Japan. Phil. Trans. vol. xlix. part ii. p. 872. Lewis Comm. Phil. Techn. p. 329, &c. This tree annually transfiles from five to ten or twelve pounds weight of a fine semi-transparent gum, resembling gum-arabic, and not inferior to it in virtue or quality, except that it has a flight astringency, which may probably, in some respects, render it more valuable. It is a native of both Indies, e.g. Malabar, Ceylon, Brazil, Guinea, Jamaica, and the Caribbean islands; and was cultivated in Kew Garden in 1659, by the duchess of Beaufort.

**Culture.**—The cachew tree is easily raised in its native country from the nut; and it is of quick growth, bearing fruit in two years after it has been planted. But in England the plants are preferred with difficulty. They are easily raised from the nut supplied from America; and they should be planted in small pots filled with light handy earth, and plunged into a hot-bed of tenant's bark, which should be preferred from moiture. Fresh nuts will yield plants in about a month, and in two months these will be four or five inches high, with large leaves, but they seldom advance much farther in the fame year. The plants must be constantly kept in the fove, as they are too tender to live abroad in England, even in the warmestfavons. They should have little water in Summer, and in Winter, water once in a fortnight will be sufficient. When they are transplanted, the pots should be broken, that the earth which cleaves to their roots may not be disturbed; and they should then be put into larger pots, filled with light handy earth, and plunged into the hot-bed. They must not be removed oftener than once a year, and the pots should not be too large, for unless their roots are confined they will not thrive. With this management they may be kept several years, but they seldom exceed two feet and a half in height, and are seldom half as high. Martyr's Miller. Murray's Mat. Med. vol. iv. p. 413.

**Anacardium Oxirale.** See _Avisenna._

**Anacardium Officinale._ See _Semecarpus._

**ANACATHARSIIS, in Medicina, properly denotes a purgation by spitting; in which sense it stands contradistinguished from _catharsis_, or evacuation downward. In this sense is the word used by Hippocrates and Galen; agreeable to this Blafius refinns _anacathartico_ to expectoration. Only Blanchard, on what authority does not appear, extends _anacathartic_ medicines to all those which work upwards, by the glands of the head, whether vomitinges, fetiduates, or medicinalis.

**Anacatharsis is also a name given by civil lawyers to the _Basileon repetito Prefectionis_, made by order of the emperor Constantin Porphyrogenitus. It was thus called, as being a review or correction of the _Basileon._

**Anacathartic, among Divines, denotes the clearing up some obscure passage, by a spiritual or analogical interpretation.**

**ANACATHARTIC, from _an_, upward, and _katharein_, I purifie, is usually underdstood of a vomit, or a purging medicine that works upwards.**

**ANACEIA, an Athenian festival in honour of the Diocuri. It took its name from those deities, who were also called _Arkes_, and honoured with a temple called _Akomion_, _Anacuc._ The Anaces, Anacutes, and Diocuri have been thought by some writers to be the same with the Cabin of the ancient Carthaginians, but others are of a different opinion. However this may be, they were undoubtedly descended from the Anakins of Moesia; and Inachus was also of...
of this race, as his name imports. Some have supposed, that the appellation Anakites was given to those princes of the line of Abus, who had distinguished themselves by their heroic actions.

The sacrifices offered at that time were named θυσίαι, because those deities were θεοί, or strangers; and consisted of three offerings, which were called θυσίαι. Athenaeus mentions plays acted in honour of these deities.

ANACEPHALOÉYSIS, formed of θανατος, which in composition signifies θανατός, head. In Rhetoric, a reappearance, or a short and summary repetition of the heads of a discourse.

ANACHARIS, in Biography, a Scythian philosopher, was the son of a Scythian chief by a native of Greece, and flourished about 600 years before Christ. Having acquired an early acquaintance with the Greek language, he was enticed by his sovereign with an embassy to Athens; and in the full year of the 47th Olympiad, i.e. 592 B.C., he was conducted by Taxis, one of his countrymen, to the house of Solomon. Anacharsis availed himself of the opportunities which free and familiar intercourse with Solomon afforded him for gaining a wisdom: he was introduced to the society of the principal persons at Athens, and he was the first stranger upon whom the Athenians conferred the honour of citizenship. After the death of Solomon, and probably not before, Anacharsis left Athens, and travelled into other countries; and at last returned to Scythia, with a design of communicating to his countrymen the knowledge he had acquired, and of establishing among them the deities and the worship of Greece. But his attempts were ineffectual. Whilst he was performing sacred rites to Cybele, in fulfilment of a vow which he had made upon his way home, he was killed by an arrow directed against him, as report says, by the king's own hand; so that he fell a sacrifice to the envy and folly of his countrymen, who would not confound it to be instructed by Grecian wisdom. The phrase, "Scythian eloquence," was derived from the manly and nervous kind of language for which he was distinguished. He is said to have been the inventor of the anchor and potter's wheel, but these imitations were known before his time; however, he might have introduced the use of them among the Scythians. Of his ingenious sayings that are recorded, the following deserve to be mentioned: "The best method of teaching a youth sobriety is to let before his eyes a drunken man." "The vine bears three sorts of fruit: the bril, pleasure; the second, intoxication; the third, remorse." "An ape is by nature ridiculous; man, by art and study." To an Athenian of infamous character, who reproached him for being a Scythian, he said, "My country may be a disgrace to me; but you are a disgrace to your country." As he was one day considering the thickness of the planks of a ship, he cried out, "Alas! those who go to sea are but four inches distant from death." Being asked what was the most secure ship, he replied, "That which is arrived in the port." He often repeated, "That every man should be particularly careful to make himself master of his tongue and his belly." Being asked what was the best and what the worst part of a man, he answered, "The tongue." "It is much better," said he, "to have but one friend, if he be faithful to us, than a great number of those who are always ready to follow the change of fortune." He used to compare laws to spiderwebs; and to ridicule Solomon, who pretended to restrain the passions of mankind by pieces of writing. He observed, "That the prince who is wise is happy; and that that city is best wherein all things else being equal, virtue hath the better condition; vice the worse." The epithets that bear his name are probably spurious. Herodotus, lib. iv. Plut. Vit. Solon, apud Opera, tom. i. p. 80. Diog. Laertius, lib. i. tom. i. p. 64. Strabo, lib. vii. tom. i. p. 461. Brucker's Hill of Philos. by Enfield, vol. i. p. 124. The Travels of Anacharsis the Younger in Greece, by the Abbé Barthélemy, compiled in seven volumes, 8vo, with a volume of maps, &c. in 4to, is a work in high estimation.

ANACHIMOUS, in Geography, a province of the island of Madagascar, having on the east the river Manghara, which runs through it, the country of Manaroule on the south, on the west large and lofty mountains, and on the north the river Manghara and the country of Emragadra. This province produces great quantities of rice and yams, with plenty of cattle, and other necessaries of life, and is extremely populous.

ANACHIS, in Mythology, one of the four deities, to whom the Egyptians imagined the peculiar care of each person was committed at his birth: the other three were Dymon, Tyche, and Hercules. They were also called Dynamis, Tyche, Eros, and Anarches; i.e. Power, Fortune, Charity, and Necessity.

ANACHORESIS denotes a withdrawing from society, or retiring into solitude. The anachoresis was not allowed to persons before they had spent thirty years in the community.

ANACHORET, from ανακορην, I retire into a solitary place, a hermit or devout person, living alone in some defect, to be farther out of the reach of the temptations of the world, and more at leisure for meditation. Such were St. Anthony, St. Hilary, &c. Paul the Hermit was the first of the tribe of anachorists.

When many of the habitations of anachorists were placed together in the same wilderness, at some distance from one another, they were all called by one common name, laura, which, as Evagrius informs us, differed from a cenobium, or convent, in that a laura consisted of many cells divided from each other, where every monk provided for himself; but a cenobium was one habituation, where the monks lived in society, and had all things in common. Anachorists, popularly anachorists, were very numerous among the Greeks, confining principally of monks; who not caring for the fatigues and offices of the monastery, purchased a little spot of ground, with a cell, whither they retreated, and never appeared in the monastery again excepting on solemn days. These are sometimes also called effects or solitary.

They had their chapel, and after prayers applied themselves to the culture of their vineyards, olives, fig-trees, and the like, which afforded them provision for the year.

These anachorists only differed from the conventual monks, in that they had less intercourse with the world, and lived but in small bodies.

The anachorists of Syria and Palestine retired into the most obscure and unfrequented places; hiding themselves under rocks and mountains, without either tents or cottages, repelling wherever the approach of night happened to find them, and living on the spontaneous productions of the earth. This course of life they pursued, that they might avoid the view and the society of mortals.

There have also been anachorists in the West. Peter Damas, who was of the order of hermits, frequently speaks of them with great praise. He represents them as by far the most perfect sort of monks; holding them in much higher opinion and estimation than the canons, or monks residing in monasteries.

Many of these retire, with the leave of their abbots, and have an allowance from the monastery. The people, on account of their piety, present them with good sums of money, which they carefully hoard up, and at their death bequeath to the monastery they had belonged to.

ANACHORETA, in Entomology, a species of phalaena, of the bombyx tribe, which, till lately, was confounded with
with phalana curta, from which it chiefly differs in having a white streak across the brown spot at the tip of the anterior wings. Its specific character is, wings grey, with white streaks; at the tip a furruginous-brown spot, marked with a waved streak of white. Fabricius. Feeds on the willow and poplar in the larva stage. The larva is hairy, brown with a flesh-coloured stripe along the back; two elevated warts, and lateral dots of rufous colour. Inhabits Austria.

**ANANCHORITA**, in *Ecclesiastical Writers*, a name sometimes given to the cells of recluses.

By the ancient canons, no anachorita could be erected without consent of the bishop.

**ANACRONISM**, compounded of *aUCT, higher, and σκόπος, time*, in *Chronology*, an error in computatio of time; whereby an event is placed earlier than it really happened.

Such is that of Virgil, who placed Dido in Africa at the time of *Kneus*; though, in reality, she did not come there till 300 years after the taking of Troy. An error on the other side, whereby a fact is placed later or sooner than it should be, is called a *parachronism*; though this distinction is not commonly observed.

**ANACHTISMIS**, in *Natural History*, a species of *Echinus*, of the second order of *Vermes, Melissus*; it is heart-shaped, rather oblong, and somewhat conic, base flatish. Spaces and divisions ten; mouth fimbriate, surrounded with an elevated margin; vent oval, notched below. Klein and Linn. Found in a fossil state.

**ANACIUM**, in *Ancient Geography*, a mountain of Attica, on which was a temple of Callic and Pallas.

**ANACLASTIC**, *glæsus, virtus anachyclus*, a kind of fomorous phials or glases, chiefly made in Germany, which have the property of being flexible, and emitting a vehement noise by the human breath. They are also called vexing glases, by the Germans *vexier glaser*, on account of the fright and disturbance they occasion by their reflection.

The anaclastic glases are a low kind of phials with flat bellies resembling inverted funnels; whose bottoms are very thin, scarce surpassing the thickness of an onion peel: the bottom is not quite flat, but a little convex. But applying the mouth to the orifice, and gently inspiriting, or as it were fucking out the air, the bottom gives way with a horrible crack; and from being convex becomes convex c. On the contrary, upon expiring or breathing gently into the orifice of the same glas, the bottom with no left noise bounds back on its former place and becomes gibbous as before.

The anaclastic glases first taken notice of were in the castle of Goldbach; where one of the academists *Nature Curiosorum*, having seen and made experiments on them, published a piece expressly on their history and *phenomena*. Rolini Lentii Orbilibi Sebed. de Vitris Ancaphilicas. Vid. Ephrem. Acad. N. C. Dec. 2. Ann. 3. p. 489; lvq. Their figure may be seen in the book above cited.

They are all made of a fine white glass. It is to be observed in these, 1. That if the bottom be concave at the time of inspiration, it will burst, and the like will happen if it be convex at the time of expiration. 2. A strong breath will have the same effect even under the contrary circumstances.

**ANACLASTICS, or ANACLASTIC**, derived from *aUCT and κλασσω, I break*; that part of optics which considers refracted light, and is the same with what we more usually call *DYOPTICS*.

**ANACLETHERIA**, formed of *aUCT and κλασσω, I call*; in *Antiquity*, folkma feats celebrated in honour of kings and princes when they came of age, and took upon them the administration of the state, and made a solemn declaration thereof to the people.

**ANACLETICUM**, in the *Ancient Art of War*, a particular bruit of the trumpet, whereby the fearful and flying soldiers were rallied, and recalled to the combat.

**ANACLETUS, or CLETUS, of ANACLETUS, i.e. irrefrangible**, in *Biography*, a pope, reckoned by Roman Catholics the third; succeeded *Linus* as bishop of the church of the Romans; and, according to *Eusebius*, in the *auct. Eccl. lib. iii. c. 13. 15.* in the second year of the reign of Titus, or in 69, A. D. and governed that church 12 years. This bishop has been enrolled among the saints and martyrs, though there is no satisfactory evidence of his martyrdom.

**ANACLETUS** was also the name of a competitor for the popedom against *Innocent II*. It was the grandeur of a circumcised Jew, named *Peter* of Leon. When *Innocent II*. was acknowledged as successor to the papal chair by the emperor *Lotarius II*. upon the death of *Honorious II.* in 1128, *Roger*, King of Sicily, did homage to *Anacletus*, who was for some time master of Rome. After the defeat of *Roger*, upon whom he had conferred the title of king of Naples and Sicily, he was obliged to yield to his more fortunate competitor. He died in 1138, and his memory has been reproached with scandalous vices. Dupin.

**ANACLINOPAL**, from *anac. clock. I recline*, and σκόπω, *arms*, in *Antiquity*, a kind of wrestling, wherein the champions throw themselves voluntarily on the ground, and continued the combat by pinching, bitings, scratching, and other methods of offence.

The anaclinopale (or contradistensible) was the orthopale, wherein the champions were erect. In the anaclinopale, the weaker combatant sometimes gained the victory.

**ANACLITUS**, the denomination of those Britons, who are placed by most of our antiquaries in that district of Berkshire which is adjacent to Henley.

**ANACLINTERIA**, in *Antiquity*, a kind of pillows on the dining-bed, whereon the guests used to lean. The ancient triclinary beds had four *stola*, one at the head, another at the feet, a third at the back, and a fourth at the breast. That on which the head lay was properly called the Greeks, *ανακλίντορον*, or *ακλίντορον*; by the Romans *fatum*, sometimes *pleatus*.

According to other writers, anaclinteria is more properly understood of the backs of chairs whereon we lean.

**ANACOISNIS**, from *anac. clock. I communicate*, communicato, a figure in *Rhetorics*, when we consult the adversary, or appeal to the judges what ought, or could have been done on such an occasion.

Such is that of Cicero, *Quo pro Cunjente, ut in hoste domum tuam re- ducant, conti bominis et armatis, non modo limine telopea ediam tuam, sed primo adita vestibuloque probabere, quid aliamus?* Cicero pro Cestio.

**ANACOLOMA**, formed of *ανακολαω, conglobato*, in *Phyle*, denotes a limen or other medicine applied to the forehead, to stop or prevent delusions of the eyes.

*Anacolotoma* makes a species of medicines called *fronatulae*. The qualities required are, to be drying, cooling, thickening, altringent, conglutinant, &c.

To the class of anacoloma belong bran, manua, myrrh, terra firma, acacia, &c.

Junker describes an *anacoloma frontale* for stopping hemorraghes at the nose.

**ANACOLUTHON**, from *ανακολουθω, incoherent, among Ancient Grammarians*, denotes an incoherence, or a construction which does not accept. This is usually signified by the
the appellation of a figure which ought rather to be denominated an inaccuracy.

ANACONDA, in Zoology, a name given in the life of Ceylon (and adopted by some naturalists) to a very large and terrible snake, which, it is said, often devours the unfortunate traveller alive, and is itself accounted excellent and delicious fare. This creature is described as a species of rattlesnake, but it is far more probable that it is not of that genus. It is generally believed that rattlesnakes are altogether peculiar to the American continent; nor is there any known species of rattlesnake that corresponds with the description of this tremendous creature; the largest kinds, fearfully exceeding four, five, or at most six feet in length.

Perhaps the snake in question may be leo ceylanicus of Linnaeus, which it is known sometimes grows to the length of twenty or thirty feet, and is of such prodigious strength, that it is able to destroy almost any other animal. It is a species found in the Indian islands, and is eaten by the inhabitants.

ANACOPIA. See ABCHAS.

ANACREON, in Biography, a Greek lyric poet, was born at Teos, a sea-port of Ionia, and flourished during the reign of Polycrates, tyrant of Samos, at whose court he resided, in the first century before Christ. His fame was such, that Hipparchus, the son of Philatus, as we are informed by Ptolemy (in his hippocoon) sent a velvol of 50 oars to bring him to Athens. After the death of Hipparchus he returned to Teos, and afterwards removed to Abdera, the place of his youthful residence, where he died at the age of 85 years.

Report says, that his death was occasioned by a grape-juice, which choked him whilst he was drinking new wine. He was a professed voluptuary, and habituated to the unrestrained gratifications of wine and Venus—

"Quid, nihis cum multo Venus confundere vino
Præcipient lyrici Teia mufa Senis?"

His attachment to Cleobulus is recorded by Maximus Tyrius, (Orat. ii.) and the ardour of his passion for Bathyllus is mentioned by Horace. Epod. xv. v. 9.

"Non alter Samio dicant arbite Bathyllvo
Anacreaon Tetum,
Qui peripha cava telludine fluvem amorem."

Ælian (in his Var. Hist. lib. ix. c. 4.) has endeavoured to vindicate his character; but the charges against him are too well founded to admit of refutation. During his residence at Samos, Polycrates made him a present of 5 talents, equal to about 5625l. sterling. Unaccustomed to the possession of such a sum, he could not enjoy his usual repose, and he therefore hastened to restore it to the generous donor, alleging, that while he had so great a charge in his custody, he should never be able to write or sing again. The poems of Anacreon, that are extant, consist chiefly of Baccalian songs, and love-fonets. They are mostly composed in verses of seven syllables, or rather of three and a half feet; spondees and iambs, and sometimes anapests; and hence verses in that measure are sometimes called Anacreonics, or Anacreontic verses. The odes of Anacreon abound in suavity, sprightliness, and elegant fancy; they are sweeter, says Scaliger, than Indian sugar; and, according to Mad. Dacier, the chief beauty and excellence of Anacreon consisted in his imitations of nature, and in his following reason; so that he presented to the mind no images that were not noble or natural. The odes of Anacreon, says Rapin, are flowers, beauties, and perpetual graces; it is familiar to him to write what is natural and to the life; and he poetised an air to dedicate, gay, and graceful, that, among all the ancients, there is nothing comparable to his method, nor to the kind of writing which he pursued. He flows, adds this writer, soft and gay, diluting the joy and indulgence of his mind through his verse, and tuning his harp to the smooth and pleasant temper of his soul. The character of his writings is justly given by the God of Love, directed to speak by Mr. Cowley:

"All thy verse is softer far
Than the downy feathers are,
Of my wings, or of my arrows,
Of my mother's doves and sparrows;
Graceful, cleanly, smooth, and round,
All with Venus' giddle bound."

The authenticity of some of those poems, which have been disdained by his name, has been suspected, but they have been acknowledged by ancient writers; nor is it probable that imitations, composed at different times by different authors, should invariably retain the same style and dialect. Of these odes we have had translations in various languages. Of the original the best editions are those of Barne and Baauw; and the free versions of Cowley are the most approved English imitations. The odes of Anacreon have been lately, in 1801, translated into English verse, with notes, by Thomas Moore, Eq. 4to. Gen. Dict.

ANACRISIS, from anacris and ssus, I judge, among the Ancient Greeks, is used for a kind of trial or examination, which the archons, or chief magistrates of Athens, were to undergo before their admission into that office. The anaerifics was disdained from the pocmnica, which was a second examination in the forum. The anaerifics was performed in the senate-house. The questions were proposed to them who were considered their family, kindness, behaviour, estate, &c. Some maintain that all magistrates underwent the anaerifics.

ANACRISIS, in the Civil Law, denotes a search or inquiry into the truth by examination of witnesses.

ANACROSIS, in Antiquity, denotes a part of the Pythian song, wherein the combat of Apollo and Python is described.

The anaerifics was the first part, and contained the preparation to the fight.

ANACTON pedon, a festival held at Amphissa, the capital of Locris, in honour either of the Dioscuri, or of the Curetes, or Cabiri, about which authors are not agreed.

ANACTORIA, now Voncea, in Ancient Geography, a town of Acarnania, at the extremity of the peninsula, at the entrance of the gulf of Ambracia. Stephanus Byz. says, that it was founded by a colony of Corinthians. Augustus transported its inhabitants to Nicopolis.

ANACUIAS, in Geography, a people of America, in Brazil, on the borders of the country policed by the Portuguese, under the appellation of Capitania de Sergipe.

ANACYCLUS, fantolinoides of Vaillant, and cotula of Tournecourt, in Botany, a genus of the fynemea polygama family, composed of plants of the natural order of composite dicotyledons, and coromibera of Jullieu; its characters are that the calyx is common, hemispherical, and imbricate, with many ovate, flat sharp scales; the corolla is compound and radiate, with numerous hermaphrodite corollas in the disk, from five to ten females in the ray, scarcely higher than the disk; the hermaphrodites funnel-shaped, with a quinquefoil, spreading...
spreading border; females with a flattened tube, and an ovate entire border; the *flamina* in the hermaphrodites; filaments five, capillary, and very short; anther cylindric; *pillillum* a germ flattened, stigma bifid, in the hermaphrodites, with a membrane on each side, style, stilmform, of the length of the corolla, and two slender reflex stigmata in the florets; *pericarpium*, calyx unchanged; *seed* in the hermaphrodites solitary, oblong, compressed, naked, or downy; in the females with a very broad, membranaceous wing on each side, and emarginate at top, but without down; the receptacle chaffy, chafis obtuse with a point. There are four species. 1. A. *creticus*, *cretula* reticulata, &c. of Tournefort, Lantomiroides annua, &c. of Vaillant, taining ancyclus, "with leaves decumbent, linear, and foliolous divided and flat." 2. *A. oritulais*, chamaemelum orientale, &c. of Tournefort, *ealter a." with leaves compound, brilly, acute, and straight. These two species grow naturally in the islands of the Archipelago, whence their seeds were sent by Tournefort to the Royal Garden at Paris: their seeds have been also received from Portugal. They are low plants, with branches trailing on the ground. The first leaf has fine-cut leaves, like those of chamomile; the flowers are small, white, and grow single, with their head declining, like those of the common May weed. The second has leaves like those of the ox-eye; the flowers are white, and like those of chamomile. 3. *A. aureus*, chamaemelum luteum capitata *aphylo* of Bakhin, anthemis chrysanthenum of Loh. golden-flowered a, "with leaves bipinnate, roundish, hoary, and hollowed." This species is a native of the south of Europe and the Levant, and was cultivated here in 1739. 4. *A. sulcatus*, chrysanthenum valentinum of Clausius, pherulanthum lindsay, *flora* of Halai, chamaemelum tempulatum, flor colabathus aureos of Bar. "with leaves decumbent and linear, foliolous divided, roundish, and acute; the flowers flocculose." This grows a foot and a half high, sending out many side-branches; the leaves are finely divided and hairy; the flowers are single at the end of the branches, and are of a bright yellow colour, with a filervice, seedy calyx; they are as large as those of the ox-eye. It is a native of Spain and Italy; cultivated in 1656 by Tradescant; flowering in June and July.

**Culture.**—All these plants are annual; the seeds should be sown early in the Spring, in a border of light earth, where they are designed to remain, and need no other care that to be thinned and kept free from weeds; they flower in July and August, and their seeds ripen in September. Martyn's Miller.

**ANADARA**, in Conchology, a name by which some naturalists have distinguished the species of *Arca*, called antiqua by Linnaeus. Adan. Seneg.

**ANADAVADAEA**, in Ornithology, the name of a small bird of the East Indies, which has the beak of a chaffenich, and the feet of the lark. It is sometimes brought over to England alive in cages, and will live here very comfortably.

**ANADEMA**, formed of *anadema*, to be bound round, among the Ancients, denotes an ornament of the head, wherewith victors at the sacred games had their temples bound. Some confound the anadema with the diademis, worn by the ancient Perian kings. 

*Anadema* are also mentioned by ancient writers among the ornaments of the heads of women. 

According to some, *anadema* answers to what the Latins call *redimusculum*.

**ANADIPLOSIS**, *anadiplosis*; from *an*, again, and *di-****

**ANADROMOUS**, in Ichthyology, a term of distinction applied by some early naturalists to those migratory fishes that have their flitted times of going from the fresh-water to the salt, and afterwards returning back to the fresh-water again.

The word is derived from *an*, back, again, and *delta*, a course. Many of the fish genus are of this kind, and particularly *salarias*, or the common salmons, whose periodical returns from the sea to deposit its spawn in fresh-waters is well known. The method nature has appointed for their course of changes seems to be this: they are first produced from the spawn in fresh-water rivers; they live there till they acquire some strength and size, and then seek the salt-water to feed more at large; and, growing to their full extent, at which period they return to the fresh-water again to lay their spawn, that the young brood may have the same advantages which they had before, of being placed in fresh-water. Some ufe the word *cotanadromus* in the same fene.

**ANADUOMENE VENUS**, in the Cretian Mythology, answerfed to the *Sea-Venus* in the Roman, and was the appellation given to one of the chief deities of the sea. The moft celebrated picture in all antiquity was that of this goddess by Apelles; and the famous Venus of Medici is a *Sea Venus*.

**ANADYR**, in Geography, a river of Siberia, that rises in the country of the Tchuktehi, out of a lake (N. lat. 60° 20'. E. long. 175° 41') among the frontier mountains which are a continuation of Stanoevi-Krebet, and discharges itself into that part of the Eastern or Pacific Ocean, which is called the *Sea of Anadyr*, Anadyrskhain gulf, or bay of Anadyr. N. lat. 65°. E. long. 177° 34'. This river receives many streams, besides the brook “Yablona, which gives the name of Yablomei-Krebet to the range of mountains where it springs, but none of them are very large. Its bed is in general sandy, and its current by no means rapid; its channel is very broad, and contains a considerable number of islets, but of so little depth, that it can scarcely be crossed in any part with the common ferry-boats of that country, called *shitiki*, which are beaved together, have no iron in their construction, and draw no more than two feet of water.

From the source of the Anadyr to the brook Yablona, the country is mountainous and bare; below the Yablona are some trunks of meadow-land and some poplar trees; and on the mountains to the left, for at least 100 versts above Anadyrskoi-oitrog, are this woods of larch trees and dwarf Siberian cedars. The whole of the northern region, as far as the Anadyr, is in general defirute of standard trees, and has scarcely any pices fit for pulture; whereas,
whereas, south of the river, at no great distance, especially about the head of the main, the Peninns, and the Aklan, are forests of tall timber in abundance. From the Amadry to the Kokama and the Frozen Ocean, and throughout the whole country of the Tchukichi, no more forest has been discovered: the meadow shrubs scarcely shoot above a span high, as in the whole tract along the northern coast of Siberia. But so much the more frequent are the flats, overgrown with yellow and white mols, on which innumerable herds of wild rein deer feed pastoure. Tooke’s View of the Russian Empire, vol. i. p. 250.

ANA Gänkia Gulf, a bay of the Pacific Ocean, on the coast of Siberia, extending from Cape Apostol-Thad Bou. E. long. 17° 24’. N. lat. 61° 3’. to the bay of Saint Lawrence, E. long. 78° 14’. N. lat. 65°.

ANADYSKOLI, a fortified town of Siberia, on the river Amadry. E. long. 165° 14’. N. lat. 65°.

ANADYSIS, among Ancient Divine, denotes the ceremony of the emersion in Baptism.

In which sense are; stands contradistinguished from Ato, or immersion.

ANEA, in Ancient Geography, a town placed by Stephan. Byz. in Caria, opposite to the Isle of Samos, which took its name from one of the Amazons who was buried there; and which was the birth-place of Menelas, a peripatetic philosopher and celebrated historian.

ANADATEIA, in Antiquity, a denomination given to a silver flord placed in the aryzoplaus, on which the defendant or person accused was feated for examination.

The word is Ato, which imports impudence; but according to Justin’s correction, it should rather be Ato q. d. innocence.

The plaintiff or accuser was placed on an opposite floor, called Ato, or injury; here he proposed three questions to the party accused; to which positive answers were to be given. The first, are you guilty of this fact? the second, how did you commit the fact? the third, who were your accomplices?

ANÁRETA, in Astrology, a place in the heavens, at the which the Apétha arriving, an infant born at that time, is pronounced by astrologers in danger of death.

The word is Greek, and literally imports a ruin off.

In this sense, anáreta stands opposed to Apétha.

ANÁRETA, among the Greek Astrologers, amounts to the fame with what the Arabs call abanm.

ANAESTHESIA, anáesthesia, in Medicine, a privation of sense, or of the faculty of perceiving external objects. The species or degrees of this are Ato, habitudo, depravatio, &c. The sense of feeling may be injured by any thing that obstructs the nervous influence, or prevents its being regularly conveyed to the organs of touch, as prelure, extreme cold, &c. It may likewise be impaired by too great a degree of sensibility, when the nerve is not sufficiently covered by the cuticle or earl-skin, or where there is too great a tension of it, or it is too delicate. Whatever disorders the functions of the brain and nerves hurts the sense of touching; and hence it seems to proceed from the sense general caufes, as palsy and apoplexy, and requires a similar treatment. In a Ato, or defect of touching, which arises from an obstruction of the cutaneous nerves, the patient must be first purged, and then recourse should be had to such medicines as excite the action of the nerves, or stimulate the fyllem. For this purpose the spirit of hartshorn, either by itself or combined with effential oils, horse-radish, &c. may be taken inwardly; and the disordered parts may, at the same time, be frequently rubbed with fresh nettles, or spirit of salvolatile. Bliffs and inatiom applied to the bruised parts will likewise be of use; and also warm bathing, especially in the natural hot-baths.

ANÆTHETUS, in Ornithology, a name which has been sometimes given to a species of tern found in Java, and described by Brown. This is Sterna solidis Limnius, which see.

ANÍA, or Dar Beyda, in Geography, a town of Africa, on the wellest coast of Morocco, situate in one of the most beautiful parts of the kingdom, formerly possessed by the Portuguefe, and populous, but now a heap of ruins; 30 miles south-south-west of Salé.

ANAGADA, an island in the West Indies, so low as to be almost covered with high tides. N. lat. 18° 38’. W. long. 64° 18’.

ANAGALLIDASTRUM, in Botany. See Centneculius.

ANAGALLIS, derived from anagá, to laugh, because, as it is said, by curing the spine it disposes person to be cheerful, a genus of the pentaadia monegynia clas and order, of the natural order of roaceae, and fijnicarea of Jussieu. Its characters are, that the calyx is a pentatium five-parted, sharp, and more permanent, and divisions keeled; the corolla is shelf-shaded, border five-parted, divisions ovate-orbicular, with the claws connected; the filament have erect filaments, shorter than the corolla, thrapture below, anthers simple; the pistil is a globoso cerme, blyle filiform, lightly bending, and stigma capitata; the pericarpium is a globoso, one-celled capsule, opening transversely; the seeds are very many and angular; the receptacle globoso, very large, (fangofo, alveolate, and free.) Martyn enumerates 5, Willdenow 6, and Gmelin 8 species. 1. A. arvensis, A. flore phaeniceo of Ray, and A. mas of Ger. common or scarlet pimpemel, with leaves univalent, stem procumbent, and corolla finely notched; or with stem procumbent, leaves ovate-lanceolate, and segments of the calyx pierced; or, according to Dr. Smith, with leaves ovate, punctate underneathe, and stem procumbent. Dr. Smith reckons three varieties, viz. B. A. phaenicea, folis amplioribus ex adverfo quaternis of Ray; γ. A. farinosa of Ray and Gerard. A. corolla of Abbot, blue pimpemel; and B. A. teresfria flore albo of Ray. The root is small; the stem procumbent, very branching at the base, tetragonous, smooth, and foliace; the leaves opposite, (those of B in a rich foil being four) fefile, ovate, entire, smooth, and underneathe dotted with purple; the peduncles auxiliary, solitary, one-flowered, longer than the leaves; the calyx the calyx lanceolate, acuminate, membranaceous at the margin; the corolla deeply quinquidact, minutely ciliato, softly scarlet, with a violet mouth; the filament hairy and violet; the anthers yellow; the stigma obtuse and crenate; the capsule globofoe and diaphanous, (marked with five lines as if the stems of so many valves, but always separating transversely into two parts, Withering); the seeds angular, and heaped together; the flowers in the variety γ are blue, but Dr. Smith has perceived scarcely any other difference. Dr. Withering observes, that every part of this plant is singularly beautiful; and will amply repay the trouble of a minute examination. It is an annual plant, frequent in ploughed grounds and gardens, particularly in sandy soils, and flowers in June and July. The variety γ, female or blue pimpemel, grows wild in Sweden, Germany, and Swizerland and is found between Stockwell and Camb-berwell, near London, near Mitcham in Surry, and Hilton in Cambridgeshire, on Brecon-hill, in corn-field at the top of Overbury-wood in Worcestershire, at Dawlish in Devon-
shire, and between Bath and Bradford. Ray, Linnaeus, and others, take the blue pimpernel to be only a variety of the red. Haller, after Blair and Bochmer, and followed by Al-
lioni and Gilmel, considers it as a distinct species; observing,
that it is a taller plant, with smaller leaves and larger flowers;
that the calyx is more ovate, but the divisions of the calyx
are narrower, and the petals ferrate about the edge. Haller
mentions a blue form, with three and four leaves together.
The variety has been found in Cowley field. The blossoms
of the male or common pimpernel open about eight in the
dawn, and close in the afternoon; and from this circum-
stance it is denominated the shepherd's, or poor man's wea-
ther-gale. But with rain, or much moisture in the air, the
flowers either do not open, or close up again. Small birds
are very fond of the seeds; swine and goats feed on it, but
their food is bad (in the Amene. Acad.) to refine it, whereas
Schreber says, that sheep eat it readily. It was formerly
celebrated for its medicinal qualities, and given in maicael
cafe, and in the hydrophobia. It is now fallen into difufe,
thougl Lewis observes, that it is not wholly deftitute of me-
cinial powers; as the expressed juice of the leaves, on
being defperated by fettling, and then infpiffiated to the con-
fluence of an extract, affed the organs of fafe with a pung
famine afility; and therefore thofe herbs have some
claim to the refolvent and deftergent virtues ascribed to them
by fome writers, though neither a decotion, nor tincture
of them, nor their juice in its dilute state, and much lefs
their defilited water, can exert thofe virtues in any confiderable
degree. Murray has cited several cafes, adduced by Gelm, 
which favour the efficacy of the anagalis as an antidote to
the bite of mad animals. It has also been recommended as
affording relief in cancerous complaints. 2. A. monelli, upright
pimpernel, with leaves undivided, and erect stem. This is a
very beautiful, small plant, and produces a great number of
fine blue flowers in April and May. It is a native of Verona,
and cultivated in 1645 in the Oxford garden. 3. A. latifolium,
broadd-leaved P., with leaves heart-shaped, stem-clawing,
and stem comprifed. This is nearly allied to the firft species,
but diftinguished by its large broad leaves and comprifed
stem. It was fent to Mrs. Miller in 1750 from Spain, and
is a trailing annual plant. 4. A. linefolia, hair-leaved P., with
leaves linear, and stem erect. A native of Spain and Portu-
gal. 5. A. tenella, lyminocha tenella of Sp. Pl. Hudson,
Miller, and Dickfon; nummularia minor, bur purpurea
cent of Ray, Gerard, and Parkinson, bog P. or purple-flowed
fooe-flitre, or money-wort, with leaves oval and sharpish,
and creeping stem. This has the habits of lyminocha, the
corolla almost of cæruculins, but the stamina and froot of
the anagallus. It is not uncommon on wet heaths and turp
bogs in France, Italy, and England, in Suffolk and Stafford-
shire, is perennial, and flowers in July and Augulf. 6. A.
verticillata, verticilled P. with stem-leaves verticilled, and
stem erect. 7. A. pumila, dwarf P. with stem erect, and
leaves roundish, acute and fefile. It is annual and a native
of Jamaica in the high mountains and marufes.

Culture. — The four firft sorts being annual, are propagated
from seeds which should be foon fown after they are ripe. The
firft, though beautiful, is a common weed, and never culti-
ved except in botanic gardens. The second, third, and
fourth require being kepted from extreme cold. The fifth
is a bog-plant, and cannot be cultivated in gardens, but will
flourith well enough in pots of bog-earth plunged in water.
The sixth, if it be a different species, has not yet been cul-
tivated with us. Martyn's Miller. Smith's Flor. Brit. Wil-
denow. Gmelin's Linn.

Anagallis. See Centunculus, Evolvulus, Ly-
mincha, and Pedelota.

Anagallis Aquatica. See Graziola, Montia, Pe-
plis, Samolus, and Veronica.

Anagallis Cornulus. See Graziola.

Anaglyphia, in Ancient Writers, denote vefts, or
other things adorned with sculpture in buffa reliefo; and
hence the anaglyphic art is the art of carving, chafing, en-
graving, or imbiffed plate.

Anaglyphicus, or Anaglyphis, denotes that
species of sculpture wherein the trokes or figures are pro-
minent, or imbiffed; and is contradiftinguished from diagly-
phic, where the trokes are in lented.

The word comes from the Greek αναγλύφω, exculpo.

Anagnia, in Ancient Geography, a town of Italy, in
Laetium, south of Praenelle, the capital of the Hernici;
diftinguished among the ancients by the appellation of rich,
noble, and illustrious. It submitted, after a feeble refiftance,
to the Romans, and obtained the freedom of the city. It
was afterward by Drufus Cesar wall ed round, and its terri-
ory affigned to the veterans. It is now Anagni, about
thirty-six miles caile from Rome. N. lat. 42° 48'. E. long.
13° 45'.

Anagnoses, or Anagnismata, from aυς and γνωσεως, I know, in the Greek Church, denotes an ecclesiasti-
chal book, containing the lefions read at divine service in the
feveral fells, &c. of the year.

Anagnosta, or Anagnostes, among the An-
cients, denotes a kind of fervant retained in the families of
perfons of rank to read to them at meals.

These are called by the Greeks anagnosma, and by the Ro-
mans lectores; sometimes also a ludus.

Even private families who lived in any degree politely,
were not without this kind of literary fervants. Servius
makes mention of a female anagnosma, under the denomina-
tion of lectrix. Sometimes the matter himself performed the office
of reader. The emperor Severus himself read at table. Ma-
tial mentions one Ligurinus, who read his own poems at
inner to the great dignit of the guests.

Among the Greeks there were also anagnosai in their
theatres for public reading of the poets.

Some speec of the anagnosma, as a species of acroama,
from which, however, in propriety, they differed.

Cornelius Nepos relates of Atticus, that no acroama was
ever heard at his meals, but an anagnosma. He never supped
without reading, fo that the minds of his guests were not les
agreeably entertained than their appetites. The fame cuftom,
Eginhard oberves, was kept up by Charlemagne, who attable
had the histories and acts of ancient kings read to him. This
cuftom ceems to have been a reliche of that of the ancient
Greeks, who had the prajies of great men and heroes fung
to them, while at table. The ancient monks and clergy
kept up the like ufage, as we are informed by St. Au-
gulin. Sidonius praiies a man of quality in his time,
who, in this refpeet, lived a clerical life, though he was no
priest.

Bilbergius, and Th. Raynau, have difcussions expros
on anagnostes.

Anagnostes, John, in Biography, a Byzantine historian,
flourished in the reign of the emperor John Palaeologus,
and was prefent in Thessalonica in the year 1450, when that city
was besieged by Sultan Morad, and reduced under the Turk-
ish yoke. As he relates events that occurred two or three
years after that fiece, he much have lived at least to the year
1453. His work "De rebus Confiolantinopolitarum Ma-
deconicis," records the particulars of the fiece of Thessalo-
nica and its surrender to the Turks. This history was pub-
lished in Greek, with a Latin translation, by Allattius in 8vo,
at Cologne. A. D. 1653.

Anagnostic.
ANAGNOSTIC, in Middle Age Writers, is sometimes used for an epistle, or other writing.

ANAGOGIA, in Antiquity, solemn sacrifices to Venus at Ephes, in Asia, where she was honoured with a magnificent temple.

The name of this solemnity was derived, ανάγωγος, τό, ς, i.e. from returning; because the goddess was laid to rest in Asia, and returned to Africa at that time.

ANAGOGICAL, transplanting, something that raises the mind to things eternal and divine; the great objects of the next life.

The term is principally used in speaking of the diverse senses of Scripture. — The literal sense is the first, and natural sense: the mystical sense is founded on the natural sense, from whence it is taken by analogy or comparison, by similitude or resemblance of one thing to another; and is divided into several kinds.

Where it regards the church, and matters of religion, it is called the allegorical sense. Where it regards our morals, it is called the topographical sense; and where it regards eternity, or the life to come, it is called the apocalyptic sense.

ANAGOGY, ANALOGY, a rapture or elevation of the soul, to things celestial and eternal.

Anagogy, in a more particular sense, denotes the application of types and allegories of the Old Testament to subjects of the New; thus called, because the veil being here drawn, what before was hidden is exposed to open sight.

Some of the fathers place αναγωγή in opposition to ἀνακρίνεια.

Anagogy, in Medicine, denotes a return of humours, or the rejection of matter upwards, or by the mouth.

Anagogy amounts to the same with what is otherwise called anabol.

NAGOGY, αναγωγή, in Ancient History, denotes a loose education or discipline.

ANAGOMIRI, in Ancient Geography, mountains of Africa, placed by Ptolemy in Maramara. M. d'Avville places them west of the temple of Ammon.

ANAGRAM, ANAGRAMMA, formed from ανα, backwards, and γραμμα, letter, a transposal of the letters of a name, with a combination thereof in some new manner, so as to exhibit one or more words, either to the advantage or disadvantage of the person to whom it belongs.

Thus the anagram of Galenus is ἀγαλές; that of Logica, καλίγα; that of Alcides, χιλίατης; that of Edmondus Godfrey, I find murdered by rogues; or by Rome's rude finger die; that of Loraine, is alerion, on which account it was, that the family of Loraine took alerions for their arms. — Calvin, in the title of his Institutes, printed at Strasburg in 1539, calls himself Alcuminus, which is the anagram of Calvinus, and the name of an eminently learned person in the time of Charlemagne, who contributed greatly to the reformation of learning in that age. Barclay, in his Argenis, anagrammatizes Calvinus by a leaf creditable name Ufudata; and Rabelais, to be revered of the name Calvin, who had made an anagram of his name, found in that of Calvin, Jan. Col.

Such as keep close to the definition of anagram take the liberty to omit or retain the letter H, and that letter only; but such as stand up for the poetical licence, may hold sometimes to use E for Ε, V for W, S for Z, and C for K; and vice versa.

This way of writing was fearcply known among the ancients: Daurat, a French poet in the reign of Charles IX.
the keel. Martyn enumerates three species, which are hardy deciduous flowering shrubs. 1. *A. fàsitilis*, rhubarb bean trefoil, with leaves ovate and flowers axillary. This is the only species mentioned by Gmelin in his edition of the Linnaean System, and also by Willdenow. It grows wild in the South of France, Spain, Italy, and Sicily, and also about Smyrna. It rises to the height of eight or ten feet, and produces its flowers in April and May; they are of a bright yellow colour, growing in spikes, somewhat like those of the laburnum; the seeds are never perfected in this country, and therefore it is scarce in England; it was cultivated in 1750 by Mr. Hugh Morgan. 2. *A. cîria*, with leaves oblong, and racemes longer. This is a native of Can- dia, and some of the islands of the Archipelago, and is at present very rare in English gardens; it has longer leaves than the former, and flowers later in the Summer, so that it never produces seeds; and it is probably only a variety. 3. *A. inoîora*, with leaves pinnate, calyxes inflated and col-oured, legumes compressed and straight, racemes terminating and oblong. This is equal to a middle sized tree, with branches hanging down, and frequently fecond; leaves unequally pinnate, leaflets oblong, acuminate, smooth, and without smell; flower white; a native of the woods of Cochin-China. It is doubted whether Loureiro's anagryris foetida, found wild near Canton, in China, be the same with our European one.

**Culture.**—These plants may be propagated by layering down their tender branches in the Spring, thusing them in the same manner as the layers of carnations, and watering them in dry weather. By this management the layers will take root by the following Spring, and should be cut off from the old plants before they begin to put out their leaves, and planted in a warm situation.

If the plants are propagated from seeds, they will be much handier, and rise to a greater height. For this purpose the seeds should be sown in a moderate hot-bed in the begin- ning of March, or in a border of good rich earth, in a well-sheltered place, sitting over them about half an inch of fine mould, and covering them with a common frame, in order to protect them in severe weather. When the seeds are good, the plants will appear in a month after the seeds are sown; they should then be thinned out, and set in the open air, and removed into a sheltered situation towards the end of May. With this view the seeds may be sown in pots, and plunged in a hot-bed, because the plants will not bear transplant- ing till the following Spring; and it will be proper, during the two first Winters, to shelter them under a common frame, the glasses of which may be drawn off every day in mid land weather, that the plants may be thus prepared for being planted abroad, when they have acquired proper strength. They should be kept in pots for three years, and they will then be fit for removal to the places where they are to remain; the best time for which is about the beginning of April, just before they begin to put out new leaves. At this time they should be turned out of the pots with good balls of earth to their roots; and some of them may be planted against walls with warm aspects, so as to be secure from the frost; and others in warm situations, where by covering the surface of the ground about their roots with tanners bark in severe winters, and screening their heads with mats, they may be preserved for several years. In the fourth year from sowing these plants will begin to produce their flowers, and will con- tinue flowering every year, and they will be proper for intermixing with other flowering shrubs of the same growth in warm situations. Martyn's Miller.

**Anagryris.** See Cytisus laburnum.

**Anagryris, or Anagyrus; in Ancient Geography, a dif-
trict of Attica, in the tribe of Erechtheis, between Phalerus and the promontory of Sounion, to the call of Aëxoma. Some derive the name from a hero called Anagryus, who over- threw the houces in this district, because the inhabitants had destroyed a chapel that had been dedicated to him. Others say, that its appellation was derived from the feftid plant called Anagryis, which grew here, and which had the property of yielding a stronger smell the more it was handled; and hence arose the proverb, *Commoere Anagryis, or Anagy-
rum*, to bring a misfortune upon one's self.

**ANAHARATH,** a town of Judah, in the tribe of Issa-

**ANAITA,** a district of Asia in Armenia, situate upon the Euphrates. It is said to have derived its name from the goddes Anaitis, to whom the Armenians rendered peculiar worship. The Anaitic lake, mentioned by Pliny, was situate near this place, of which he says, that the bell reeds which were used in writing grew upon its banks.

**ANAPHTIS,** called also Tanais, in Ancient Mythology, a goddes held in great veneration by the Armenians. Strabo (lib. xi. tom. 2. p. 805) says, that the Armenians principally worshippd this goddes, and that the most illustrious per- sons of the nation dedicated their virgin daughters to her, who, after having been for a long time prostituted in her service, were given in marriage; none disdaining to marry them, but rather wishing it as an honor to be thus allied to them. Pliny (lib. xxxiii.) informs us, that when the temple of this goddes at Acilene was plundered by the Romans, under Marc Au- tory, her statue of maffy gold was carried off, and broken to pieces. A report prevailed, that the first man who presumed to touch the goddes, was struck with an apoplexy, and instantly fell down dead. Augustus, being at Bologna a long time after this event, and supposing with an old soldier who had shared the plunder, questioned him concerning the truth of the fact, and the soldier replied, "Czar, it is the god-
des Anaitis's leg you are now cutting for fupper, and all I have in the world I owe to her."

**ANK, in Scripture History,** the father of the Anakims, was the son of Arba, who gave his name to Kirjath-Arba, of Hebron. Josh. xiv. 15. Anak had three sons (Josh. xv. 14.) Shihibai, Ahiman, and Talmai, who, as well as their father, were deemed giants; and they with their posterity were denounced Anakims, and reputed as a fierce and warlike people, and also of extraordinary stature. To this purpose the Hebrews, who were sent to view the land of Canaan, returned with a report, that they found there the giants, the sons of Anak, in comparison of whom they were both, in their own light, and all in that of the Anakims, as grasshoppers. Numb. xiii. 33. When the city of Arba, the father of Anak, was allotted to Caleb, in the distri- bution of Canaan, he drove out the Anakims about A.M. 2550. Josh. xv. 13—15.

**ANALATIVA,** in Geography, a small island near the north-west point of the island of Ceylon.

**Analecta, in Antiquity,** the fragments, or offals of meat, which dropped from the table on the ground.

**Analecta** was also used for a servant appointed to gather up the offals of the tables.

In this sense the word is sometimes also written analecta. Satellius Quadratus, in the way of derision, advised Calvi- nius Sabinus, a man of great wealth, and much affection of learning, but with little memory, and lefs genius, to keep analecta, ut grammaticos habetur analectae; a phrase which has occasioned much dispute among critics and antiquarians.

**Analectis** is likewise, in a literary sense, used for a collec- tion of small pieces or compositions.

The word is formed of *analete,* to gather.

**ANALEMMA,**
ANALEMMA, in Mathematics, derived from αναλήμμα, transl. I take backwards, a plane, or projection of the sphere, on the plane of the meridian, orthographically made, by perpendiculars from every point of that plane, the eye being supposed to be at an infinite distance, and is the ca't or well point of the horizon. In this projection, the polar coördinates, and all its parallels, are projected into concentric circles, equal to the real circles of the sphere; and all circles whose planes pass through the eye, as the horizon and its parallels, are projected into right lines equal to their diameters; but all oblique circles are projected into ellipses, having the diameter of the circle for the transverse axis respectively.

The analemma was invented by John de Royas, a Spaniard. The advantages of this above the astrolabes of Ptolomy and Gemma Frisius, are, that all the lines proceeding from the eye are parallel to each other, and perpendicular to the plane of projection; consequently not only the equator is a right line, as in the astrolabe of Gemma Frisius, but all the parallels to the equator are so too; since, in virtue of the infinite distance of the eye, they are all in the same plane, as if their plane passed through the eye: for the like reason, the horizon and its parallels are also right lines. On the other hand, whereas in the two former astrolabes the degrees of circles converted into right lines become very small towards the centre, and large towards the circumference, they become here small towards the circumference, and large towards the centre: so that their figures will be no less altered in this than in the others. Add, that most of the circles here degenerate into ellipses, which are often difficult to describe. See Orthographic Projection.

ANALEMMA is also used for a gnomon or astrolab, consisting of the furniture of the same projection, drawn on a plate of brass, or wood; with an horizon, or meridian, fitted to it.

Its use is for finding the time of the sun's rising and setting, the length of the longest day in any latitude, and the hour of the day. The analemma is also of considerable use among Dialists, for laying down the signs of the zodiac, with the length of the days, with other matters of furniture, upon dials.

The most accurate treatise on the analemma now extant, was written by Ptolomy, and printed at Rome in 1562, with a commentary by F. Commandine. Since that time many authors, as Agullonius, Laquet, Dechales, Witty, &c. have written on the same subject.

ANALEPSIS, the restoration of a body wasted by disease, by the use of a nutritive diet.

ANALEPSIS is also used for the method of hanging a broken or dislocated member, especially the hand, in a sling. This operation to the arm is called analepseis; to the foot, tethis.

ANALEPTICS, derived of αναλεπτικά, in Medicine, restoratives; or remedies proper to reconstitute the body, when wasted or emaciated, either by the continuance of a disease, or by want of food.

This term is sometimes applied to stimulants, but more commonly to those substances which supply a deficient nourishment. As a term, however, says Dr. Cullen (Med. Med. vol. 1. p. 166), attended with some ambiguity, it should not be employed at all.

ANALIS, a specific name that occurs in several genera, both in the Linnean and Fabrician arrangement of Entomology.

ANALIS, a species of SCARABAEUS. It is black, with three equal tubercles on the head: ends of the wing ca³ses ferruginous-brown. Fabricius. Inhabits India.
which feline animal is analogous to man and brute.—Of attribution; where, though the reason of the common name be the same, there is a difference in its multitude or refeft thereto: in which feline healthy is analogous both to a man and an exercise. Of proportionality; where, though the reasons of the common name do really differ, yet they bear some proportion to each other. In this feline, the gills of fishes are laid to be analogous to the lungs in terrestrial animals; and thus the eye and the understanding are laid to bear an analogy to each other.

Reasoning by analogy may serve to explain and illustrate, but not to prove anything; and yet a great part of our philosophizing has no better foundation.

From a few data, a few points known and allowed, we reason by analogy, and deduce a number of others. It is thus that most branches of knowledge are extended to their present dimensions. There are but few things actually observed, few experiments made; and all the observations and experiments we have are only singular. Such an effect was found from such an individual body, under such and such circumstances. We infer, that what has been observed of one body under such circumstances, will, from the analogy and uniformity in the works of the Creator, equally hold in all other bodies of the same species under like circumstances. Thus, without having recourse to experience, we never hesitate to conclude, that the fruit of trees of the same species will have the same taste and properties. This has many times drawn us into great errors; it continues every day to lead us into new ones, and may be laid to be the source of most of the mistakes committed in pursuit of science. But nevertheless, while mankind extend their thoughts toward unknown and inaccessible objects, they have no other guide to direct their researches but the supposed correspondence between the objects they are acquainted with, and those which are the subjects of their investigation.

The analogy between the three kingdoms of plants, animals and minerals, has been the source of a variety of discoveries, either real or imaginary: hence it is we have learnt, that stones vegetate; that plants breathe; that the sap circulates in them; that generation is performed by eggs in the human kind; that the planets have their atmospheres, their inhabitants, their trees, their seas, &c. Indeed, if we will follow whither analogy, real or imaginary, will lead us, there is no end of science.

As to divine and supernatural matters, it is affecting we know nothing of them but by analogy; that is, by the meditation and application of these ideas we have of ourselves and other natural beings. Our ideas of God himself arise from this principle; we have no direct and immediate perception of him. The knowledge we have of the Supreme Being is only an observation of his works, and a reflection of the mind, which flows what power, wisdom, &c. appear necessary to enable him to produce them. Having no proper ideas of his perfections, we give them the names of those faculties of men, which we judge necessary.

It is natural to men (says Dr. Reid, in his Essays on the Intellectual Powers of Man, Eff. i. ch. iv. p. 52, &c.) to judge of things left known, by some similitude they observe, or think they observe, between them, and things more familiar or better known. In many cases we have no better way of judging; and where the things compared have really a great similitude in their nature, when there is reason to think that they are subject to the same laws, there may be a considerable degree of probability in conclusions drawn from analogy. Thus, we may observe a very great similitude between this earth which we inhabit, and the other planets. They all revolve round the sun, as the earth does, although at different distances, and in different periods. They borrow all their light from the sun, as the earth does. Several of them are known to revolve round their axes, and, by that means, must have a like succession of day and night. Some of them have moons, that serve to give them light in the absence of the sun, as our moon does to us. They are all, in their motion, subject to the law of gravitation as the earth is. From all this similitude it is not unreasonable to think, that these planets may, like our earth, be the habitation of various orders of living creatures. There is some probability in this conclusion from analogy. In medicine, phyists must, for the most part, be directed in their preceptions by analogy. The constitution of one human body is so like to that of another, that it is reasonable to think, that what is the cause of health or sickness to one, may have the same effect upon another. And this generally is found true, though not without some exceptions. In politics, we reason, for the most part, from analogy. The constitution of human nature is so similar in different societies or commonwealths, that the causes of peace and war, of tranquility and faction, of riches and poverty, of improvement and degeneracy, are much the same in all.

Analogy, reasoning, therefore, is not, in all cases, to be rejected. It may afford a greater or a less degree of probability, according as the things compared are more or less familiar in their nature. But it ought to be observed, that this kind of reasoning can afford only probable evidence at least, so unintellectual caution be used, we are apt to be led by it. For men are naturally disposed to conceive a greater similitude in things than there really is. E. G. Anatomists, in ancient ages, seldom dissected human bodies, but very often the bodies of those quadrupeds, whose internal structure was thought to approach nearest to that of the human body. Modern anatomists have discovered many mistakes into which the ancients were led by their conceiving a greater similitude between the structure of man and of some beast than there is in reality. By this, and many other instances that might be given, it appears, that conclusions built on analogy stand on a slippery foundation; and that we ought never to rest upon evidence of this kind when we can have more direct evidence.

Analogy reasoning may be of excellent use in answering objections against truths which have other evidence. It may likewise give a greater or a less degree of probability in cases where we can find no other evidence. But all arguments, drawn from analogy, are still the weaker, the greater disparity there is between the things compared; and, therefore, must be the weakest of all when we compare body with mind, because there are no two things in nature more unlike. There is no subject in which men have always been so prone to form their notions by analogies of this kind as in what relates to the mind. We form an early acquaintance with material things by means of our senses, and are bred up in a constant familiarity with them. Hence we are apt to measure all things by them, and to ascribe to things most remote from matter the qualities that belong to material things. It is for this reason that mankind have, in all ages, been so prone to conceive the mind itself to be some subtle kind of matter, that they have been disposed to ascribe human figure, and human organs, not only to angels, but even to the Deity. Though we are conscious of the operations of our own minds when they are exerted, and are capable of attending to them so as to form a distinct notion of them; this is too difficult a work to men, whose attention is continually solicited by external objects, that we give them names from things that are familiar, and which are conceived to have some similitude to them; and the notions we form of them are no less analogy.
the names we give them. Almost all the words, by which we express the operations of the mind, are borrowed from material objects. To understand, to conceive, to imagine, to comprehend, to deliberate, to infer, and many others, are words of this kind: so that the very language of mankind, with regard to the operations of our mind, is analogical. Because bodies are affected only by contact and prehension, we are apt to conceive, that what is an immediate object of thought, and affects the mind, must be in contact with it, and make some impression upon it. When we imagine any thing, the very word leads us to think that there must be some image in the mind of the thing conceived. It is evident that these notions are drawn from some similitude conceived between body and mind, and between the properties of body and the operations of mind. The influence of analogical reasoning from a suppos'd similitude of mind to body as a fruitful cause of error, with regard to our mental operations, may be illustrated by the following instance. When a man is urged by contrary motions, the one, on one hand, inviting him to do some action, the other, on the other side, forbidding it, he deliberates about it, and at last resolves to do it, or not to do it. The contrary motives are here compared to the weights in the opposite scales of a balance; and there is not perhaps any instance that can be named of a more striking similitude between body and mind. Hence the phrasing of weighing motives, of deliberating upon actions, are common to all languages. From this analogy some philosophers draw very important conclusions. They say, that as the balance cannot incline to one side more than the other, when the opposite weights are equal, so a man cannot possibly determine himself if the motives on both hands are equal; and as the balance must necessarily turn to that side which has most weight, so the man must necessarily be determined to that hand where the motive is strongest. On this foundation some of the scholastics maintained, that if a hungry as were placed between two bundles of hay equally inviting, the beast must stand still and starve to death, being unable to turn to either, because there are equal motives to both. This is an instance of that analogical reasoning that ought never to be trusted: for the analogy between a balance and a man deliberating, though one of the strongest that can be found between matter and mind, is too weak to support any argument. A piece of dead, inactive matter, and an active intelligent being, are things very unlike; and because the one would remain at rest in a certain cafe, it does not follow that the other would be inactive in a cafe somewhat similar. The argument is no better than this, that because a dead animal moves only as it is pushed, and, if pushed with equal force in contrary directions, must remain at rest; therefore the same thing must happen to a living animal; for surely the similitude between a dead animal and a living one, is as great as that between a balance and a man.

No author has made a more just and a more happy use of the analogical mode of reasoning than Bishop Butler, in his admirable treatise, entitled, “The Analogy of Religion, natural and revealed, to the Constitution and Course of Nature.” Instead of indulging in idle speculations how the world might possibly have been better than it is, or forgetful of the difference between hypothesis and fact, attempting to explain the divine economy with respect to intelligent creatures from preconceived notions of his own, this excellent writer first inquires, what the constitution of nature, as made known to us in the way of experiunt, actually is; and from this, now seen and acknowledged, he endeavours to form a judgment of that larger constitution, which religion discovers to us. If the dispensation of Providence which we are now under, considered as inhabitants of this world, and having a temporal interest to secure in it, be found, upon examination, to be analogous to, and of a piece with, that further dispensation, which relates to us as destined for another world, in which we have an eternal interest depending on our behaviour here, if both may be traced up to the same general laws, and appear to be carried on according to the same plan of administration; the fair presumption is, that both proceed from one and the same Author. And if the principal parts objected to in this latter dispensation be similar to, and of the same kind with what we certainly experience under the former, the objections, being clearly inconclusive in one case, because contradicted by plain fact, must, in all reason, be allowed to be inconclusive also in the other. This way of arguing from what is acknowledged to what is disputed, from things known to other things that resemble them, from that part of the divine establishment which is exposed to our view to that more important one which lies beyond it, is, on all hands, confessed to be just. By this method Sir Isaac Newton has unfolded the system of nature; and by the same method Bishop Butler has explained the system of grace, and, as Mr. Mainwaring (in the disputation prefixed to his volume of sermons, p. 123) expresses it, “formed and concluded a happy alliance between faith and philosophy.” Although the argument from analogy be allowed to be imperfect, and by no means sufficient to solve all difficulties respecting the government of God, and the designs of his providence with regard to mankind; yet surely it is of importance to learn from it, that the natural and moral worlds are intimately connected, and parts of one dependant whole or system; and that the chief objections which are brought against religion, may be urged with equal force against the constitution and course of nature, where they are certainly false in fact. This information we derive from the bishop’s work; the proper design of which is not to prove the truth of religion, either natural or revealed, but to confirm that proof, already known, by considerations deduced from analogy; and to answer objections against those truths, which are established upon their proper evidence. When objections are made against the truths of religion, which may be made with equal strength against what we know to be true in the course of nature, such objections can have no weight. The ingenious author has prefixed the following summary of the contents and plan of his work, which we shall here transcribe for the information of those readers who may be desirous of pursuing the investigation of subjects of this nature. “The divine government of the world, implied in the notion of religion in general, and of Christianity, contains in it—that mankind is appointed to live in a future state—that there every one shall be rewarded or punished; rewarded or punished respectively for all that behaviour here, which we comprehend under the words, virtuous or vicious, morally good or evil—that our present life is a probation, a state of trial, and of discipline, for that future one; notwithstanding the objections which men may fancy they have, from notions of necessity, against there being any such moral law as this at all; and whatever objections may appear to be against the wisdom and goodness of it, as it stands to imperfectly made known to us at present—that this world being a state of apoloagy and wickedness, and consequently of ruin; and the fene both of their condition and duty, being greatly corrupted amongst men, this gave occasion for an additional dispensation of Providence, of the utmost importance; proved by miracles; but containing in it many things appearing to us strange, and not to have been expected; a dispensation of Providence, which is a scheme or system of things, carried
or, analogy may be considered as a general or established usage, applied in similar cases to certain words, phrasing, or constructions not yet established. Or, analogy is only a particular usage, which, in certain cases, is inferred from a general usage already established.

Grammarians are divided into two parties. Some, with Sancius, contend, that the analogy or reason rules through all the parts, all the phrases and divisions of the Latin tongue. On the contrary, others, with Perizonius, assert, that there are many phrases, contrary to analogy and reason, derived all originally from the populace. Such, e. g. are, Nemo, homo, deorsum, vero, &c.

Varro and Caesar wrote expressly on the analogy of Latin words, but their works are now lost. Jac. Operarius has endeavored to supply that loss, by tracing the analogy of 20,000 Latin words. Tab. Bib. Lat. lib. i. cap. 10.

Analogies of conjugation, analogiae conjugationis, is not only when a verb is conjugated like another, but agrees with it in the quantity of the syllables.

Thus cherno is conjugated like ano, and clamabam pronounced like amabam.

Analogies of declension, analogiae declinationis, is not only when a noun, pronoun, or participle is declined like another, but agrees with it in respect of the quantities of the syllables.

Thus, e. g. mater is declined like pater, solans as amans, fons as trnus. So penamnur is pronounced as menamnur, and funeris as munemv.

Analogies of doctrine, among Critics, is one of the great rules to which regard is to be had in the interpretation of authors.

We are first to learn from the author himself the general system which he follows; and as no writer is to be easily supposed to contradict himself, our interpretation is to be so conducted, as that nothing be admitted which is contrary to, or tends to overthrow this system.

Thus, in interpreting an author who follows the Platonic scheme, we are to prefer a sense which is consistent with the Platonic doctrine to another which is contrary to it, unless there be some evident proof, that the author contradicts himself, or affects things which are inconsistent.

Analogies, in Rhetoric. See Comparison.

Analogies of faith, among Divines, denotes that relation which the several articles of faith bear to each other.

Analogies of faith stands opposed to tradition and authority, which is the great rule of interpretation among catholics. By this it is required, that whether we interpret Scripture, or explain the doctrines of Christianity, all our positions and explanations be consistent with the analogy of our faith, and those evident propositions deduced from Scripture.

Tortschius, Antonius, Tranckius, &c. have written expressly on the analogy of faith.

Analogies, in Medicine, is a certain relation or resemblance between diseases, in virtue whereof, we may reason and conclude from one to another, and treat them all much in the same manner: e. g. pleurisy being a species of inflammation, produced like inflammations of other parts, is to be treated like them, relaxing the foids, which are too much stretched, and giving free passage for the humours.

This method of deduction was called by the ancients medicina rationalis, or dogmatica, in opposition to the empirics, called also epilogism, which was conducted by appearances only without theory.

Analysis, derived from analyso, to resolve, in a general sense, the resolution of something compounded into its constituent parts.
The whole of the practical and experimental part of chemical science may be properly included under the art of analysis; a complete account of this, therefore, would require the enumeration of almost every known fact in chemistry; and the inferences and general deductions from these facts would comprehend all that is valuable in the philosophy of chemistry. To treat the subject thus fully would, however, be inconsistent with the plan of this work, and would be little satisfactory to the reader, except such a system of arrangement was adopted, as would admit of reference to any particular part without the necessity of confuting the rest. For these reasons we have thought it upon the whole most convenient to subdivide all that relates to the subject of analysis in the following manner.

For the general method of analysing animal matters, see Animal matter; of vegetable matter, see Vegetable matter; of minerals in general, see Mineral analysis; of mineral waters, see Waters, mineral.

The analysis of metallic ores will be treated of generally under Ore, and particularly under each metal.

Analysis, grammatical, is that employed about words, their etymons, homonyms, or various acceptations, synonyms, contractions, ufs, and the like.

Pafur has given a grammatical analysis of the difficult words in Heliac, &c. Sturmns has published a method of making the analysis of Latin words.

Analysis, in Logic, is a method of applying the rules of reasoning to resolve a discourse into its principles, in order to a discovery of its truth or falseness. Or it is an examination of such discourses, propositions, or other matters, by searching into their principles, and separating and opening its parts, in order to consider them more distinctly, and arrive at a more precise knowledge of the whole.

Analysis makes one great branch or species of method; and as it resolves a complex idea into its component principles, it is called also resolution. It is particularly used for the reduction of an imperfect syllogism to a perfect one. This is otherwise called reduction.

The order of the syllogism is contrary to that of the analysis, one beginning where the other ends. The two methods cannot always be used indifferently; the analysis is most proper for the discovery of truth, and synthesis for teaching and explaining it in a syllogistical way. Hence some call analysis the method of invention. See Method.

Analysis of ideas, that whereby an idea is resolved into the ideas of its ingredients, and the ideas of these again into simple ones, till at length we arrive at the most simple.

Analysis, in Mathematics, is proper the method of resolving mathematical problems, by reducing them into equations; and may be divided into ancient and modern.

The moderns are at some loss concerning the ancient analysis, i.e., concerning the art and method whereby the ancients resolved problems, and invented theorems. Some traces of their method are extant in Pappus, Apollonins, and Euclid; and Dr. Hooke suspects, that their analyses went backwards through almost all the same steps by which their demonstrations went forwards.

That this might often be the case, seems evident to any one who has studied Euclid with care. They have indeed left us no precepts of their art. This, like almost all others, must be acquired by imitation, and the excellent examples left us by the Greeks. Men of genius among the moderns, who had studied the works of the ancient geometers, have been thereby enabled to imitate them, and penetrate into their methods: the works of Huygens and Newton, and also the treatise of Conic Sections by Mr. Simpson; profes-

for of mathematics in the university of Glasgow; as also several parts of Mr. Maclaurin's Treatise on Fluxions, are evident proofs of this. Weigelius has endeavoured to retrieve the ancient analysis of Archimedes, from Euclid and other ancient geometers.

The ancient analysis, as Pappus has described it in his "Mathematicae Collectiones," lib. vi. p. 157, ed. Commandini, Paris. 1588, is the method of proceeding from the thing sought for granted, through its consequences, to something that is really granted or known; in which sense it is the reverse of synthesis or composition, that commences with the last step of the analysis, and traces the several steps backward, making that in this case antecedent, which in the other was consequent, till we arrive at the thing sought, which was assumed in the first step of the analysis. The principal authors on the ancient analysis, enumerated by Pappus (ibid supra) are Euclid in his "Data," "Porismata," and "De Locis ad Superficiem;" Apollonius, "De Sectione Rationis," "De Sectione Spatii," "De Tactionibus," "De Inclinationibus," "De Locis Planis," and "De Conicis;" Arithmus, "De Locis Solidis;" and Eutodokhes, "De Medias Proporcionem." Pappus himself, who has given many examples from the preceding writers, may be added to the above number. This analysis has also been cultivated by many of the moderns, as Fermat, Viviani, Chevalier, Snellius, Huygens, Simson, Stewart, Law. &c, and particularly by Hugo d'Omerique, in his "Analytica Geometrica," in which he has endeavoured to restore the analysis of the ancients. Sir Isaac Newton, as we are informed by Dr. Pemberton, ("View of Sir Isaac Newton's Philosophy," preface,) always professed himself a great admirer of the ancients, and even confounded himself for not following them more closely than he did. He also regretted his mistake at the beginning of his mathematical studies, in applying himself to the works of Des Cartes and other algebraic writers, before he had considered the Elements of Euclid with that attention which so excellent a writer deserves. He used to commend the laudable attempt of Hugo d'Omerique to restore the ancient analysis; and very much esteemed Apollonius's book, "De Sectione Rationis," for giving us a clearer notion of that analysis than we had before; and he particularly recommended Huygens's rule and manner. In the application of the ancient analysis for the solution of geometrical problems, strict rules cannot be laid down, nor any previous instructions be delivered, from which it may not be necessary to deviate. Some preparation is necessary in order to form a connection between the data and quæstia, which must be suggested to the mind of the analyst by a due consideration of the nature of the problem; and the skill of the analyst was manifested in discovering the most proper preceding operations, on which his analysis was to be founded. As an example we may give the 15th proposition of the 7th book of Pappus, p. 257. From the extremes of the base A and B (Plate 1. Geometry, fig. 14.) of a given segment of a circle, let it be required to draw two lines AC, BC, meeting at a point C in the circumference, which shall have to each other the given ratio of F to G. Pappus resolves this problem in the following manner: Analysis. Suppose the thing done, or that the point C is found: and draw CD a tangent to the circle. If then meeting AB produced in D. By the hypothesis AC : BC :: F : G, and AC : BC : DB ; DA : DB; which may be thus proved. DC touches the circle, and BC cuts it; and therefore by Euclid, lib. iii. prop. 35, the angle BCD = BAC, and the angle D being common to both the triangles DCA and DCB, these triangles will be similar; and consequently DA : DC :: DA : DB; and consequently DA : DC :: DA : DB. Moreover, DA : AC ::
Sir Isaac Newton, indeed, who well knew the advantages of analysis in geometry and other sciences, frequently lamented, that the study of the ancient geometry should be neglected and abandoned; and it must be allowed that the method employed by the ancients in their geometrical writings is more rigorous than that of the modern analysis; and though it be greatly inferior to that of the moderns, in point of dispatch, and facility of invention, it is nevertheless highly useful in strengthening the mind, improving the reasoning faculties, and accommodating the young mathematician to a pure, clear, and accurate mode of investigation and demonstration, though by a long and labourd process, to which he would reluctantly have submitted, if his talent had been vitiated, as it were, by the modern analysis. On this circumstance were principally founded the complaints of Newton, who feared, left by the too early and frequent use of the modern analysis, the science of geometry should lose that rigour and purity, which characterizes its investigations, and the mind become debilitated by the facility of our analysis. He was therefore fully justified in recommending, to a certain extent, the study of the ancient geometricians; whole demonstrations, being more difficult and operose, afford greater exercise to the mind, acclimating it to a closer application, extend its views, and habituate it to patience and resolution, so necessary for making discoveries. This, however, is the only principal advantage resulting from it; for, if we refer back to the method of the ancients, it is probable that performances of the most acute and comprehensive genius would have made few or insignificant discoveries, in comparison of those obtained by means of the modern analysis. And even with regard to the advantages attending investigations, pursued in the manner of the ancients, which is that of being more rigorous, it may perhaps be doubted whether this pretention be well founded. As for those of Newton himself, who conducted his demonstrations in the manner of the ancients, it is evident that he investigates his theorems by a method different from that employed in the demonstrations, which are commonly analytical calculations, disguised by substituting the name of lines for their algebraical value; and though it must be acknowledged, that his demonstrations are rigorous, it is no less true that they would be the same when translated and delivered in the algebraic language; and what difference can it make in this respect, whether we call a line $AB$, or denote it by the algebraic character $a$? Indeed, this last designation has this peculiarity, that when all the lines are denoted by algebraic characters, many operations can be performed upon them, without thinking of the lines or the figure. And this circumstance is very advantageous, as it relieves the mind, so that its whole energy may be employed in overcoming the natural difficulty of the problem itself. Upon a comparison of the ancient and modern analysis, the result seems to be, that the method of the ancients is the best adapted to the commencement of our studies, as it serves to form the mind, and to fix proper habits; and that of the moderns should succeed, and be fitted to extend our views beyond the present limits, and to assist in making new discoveries and improvements. Montucla Hitt. des Mathematiques, tom. 1. p. 166. p. 195. Ittoton's Math. Dict. tom. 1.

Analysis is divided by some authors into simple and compound. Analysis, simple, is that employed in solving problems reducible to simple equations. Analysis, compound, or complex, that which gives the expressions or solutions of problems in compounded equations. Analysis is further divided, with regard to its object, into that of finite, and that of infinite.
The advantage of the modern mathematicians beyond the ancients arises chiefly from the use of this modern analysis.

Analysis of powers, doth the resolving them into their roots. In this sense analysis amounts to the same with what we otherwise call evolution.

We find divers other kinds of analysis treated of by mathematical writers, as the analysis of indivisibles, &c. M. Leibnitz spoke of an analysis fines, different from the analysis of magnitudes.

The analysis of geometrical curves fithe their properties and internal constitution, their curvature, points of inflexion, station, retrogradation, variation, &c. In this analysis curves are usually considered as polygons, composed of an infinite number of infinitely little sides, but this supposition is neither accurate nor necessary, though it sometimes affords convenient hints for invention.

F. Reynau, of the Oratory, has given a large system of algebra, under the title of analysis. F. Callet censes it as not sufficiently methodical or systematical. The great divi-

sions and members are lost in the multitude of particular rules and methods.

Analysis, in Rhetoric, is that which examines the connec-
tions, tropes, figures, and the like, inquiring into the pro-
pition, division, parallel, arguments, and other apparatus of rhetoric.

Several authors, as Fregius and others, have given analyses of Cicero's Orations, wherein they reduce them to their grammatical and logical principles; strip them of all the ornaments, and additions of rhetoric, which otherwise disguise their true form, and conceal the connection between one part and another. The design of these authors is to have those admired harangues, just such as the judgment disposed them, without the help of imagination; so that here we may coolly view the force of each proof, and admire the use Cicero made of rhetorical figures, to conceal the weak part of a cause.

A collection has been made of the analyses formed by the most celebrated authors of the sixteenth century, in three volumes folio.

Analysis of Soil, in Agriculture. See Soil.

Analysis of Vegetables. See Vegetables.

Analysis is also used as a kind of syllabus, or table of the principal heads or articles of a continued discourse; disposed in their natural order and dependency.

Analytical are more scientifical than alphabetical indices; but they are less used, as being more intricate.

Analysis is likewise used for a brief, but methodical translation of the principles of a science; in which sense it is nearly synonymous with what we otherwise call a synopsis.

ANALYST, a person who analyses a thing, or makes use of the analytical method. In which sense analyst amounts to much the same with complicate or calculator.

Some refrain the word more peculiarly to denote a mathematician, who makes a great use of the algebraic method or calculus in geometry, in exclusion of the synthetic, or strict geometrical method.

In a sense not unlike this Dr. Berkeley, an ingenious writer, gives the title Analys to a book against the modern geometry, or doctrine of fluxions.

ANALYTIC, ANALYTICAL, something that belongs to, or parts of, the nature of analysis.

Thus we say, an analytical demonstration; analytical inquiry; analytical table, or scheme; analytical method, &c. The analytic method stands opposite to the synthetic. See Method.

ANALYTICS, ANALYTICA, the science or doctrine and use of analysis.

To the modern analytically principally belongs algebra; the history of which, with the several authors thereof, see under Algebra.

ANALYTIQUE, in Literary History, is particularly used to denote certain writings of Aristotle under this title.

Aristotle's Analytica consist of four books, two under the denomination of former, Analitique prior, and as many under that of later, Posterior. They belong to the class of his astronomical works. Fabr. Bibl. Græc. lib. iii. cap. 6.

Analytics is also used by some for a part of logic, which teaches to decline and conclude reasons, as grammar does words.

ANAM, in Geography, is called by the Portuguese Cochin-China, and befits its hollow curve along the coast, from lat. 14° to 17° 30'.

ANAMBRA, or JAMISIA, a large and populous town in the kingdom of Fantin, on the gold coast of Africa, where the English have a fort. The inhabitants are generally deceitful and fraudulent, and are very artful in dealing and counterfeiting their gold coin. Anambra is reckoned the most powerful town upon the whole coast. It is divided into two parts; one part inhabited by the fishermen of Elmina, the other by those of Fantin, who pay a certain duty to the brass for the liberty of purifying their occupation. The greatest inconvenience attending the situation of the English fort at this place, arises from the difficulty of landing from the flaps, as the shore is covered with rocks projecting into the sea, and the surf rises to a great height; and, on this account, those that trade here, are landed by means of canoes upon a sandy point, surrounded by a wall, which is built by the company, and rendered convenient by lodgings for the negroes under the cannon of the fort. The fort is adapted for making bricks; the shells upon the coast furnish excellent lime; and the country affords great plenty of timber. The adjacent country is mountainous, but the hills are at a distance from the town, serve as land-marks at sea, and being covered with trees, afford an agreeable prospect. The country is populous, and very rich in gold, slaves, and all the necessaries of life, but more particularly
particularly in corn; and the palm wine is excellent. Their opulence has rendered the inhabitants haughty and arrogant. In the woods of this country are found the most beautiful parrots, and a great variety of other birds. Fruits, roots, and vegetables of every kind abound, and are cultivated with little trouble. The English fort is a large edifice, flanked by two towers, and fortified towards the sea with two batteries; it is constructed of brick and lime cemented with lime. It stands upon a rock at the distance of 32 paces from the sea; it is mounted with 12 pieces of cannon, and 12 pateroceres, and defended by a garison of 12 whites and 18 blacks, under the command of the chief factor.

The natives formerly treated the English garrison with so much insolence, as often to block them within their walls, and frequently, if they disliked the governor, they sent him in a canoe to Cape Coast, with marks of the utmost contempt. The negroes of Fante are the most turbulent upon the coast. In 1701 they declared war against the English, and, assembling in a tumultuous manner, lit fire to the exterior building, and proceeded with their outrages, till they were dispersed by a discharge of the cannon from the batteries. The English, however, took their revenge, by laying the greater part of the town of Anamabon in ashes; and hostilities continued for some time, till at last the natives were obliged to sue for peace. The fort was abandoned in 1733, but again refounded by the English, who have maintained possession of it ever since.

ANAMANI, ANAMANES, or ANANES, in Ancient Geography, were friends and allies of the Romans, who inhabited Gadisipine Gaul, at the foot of the Apennines to the south of the Po, having Trebia to the west, and Tarsus for their principal rivers. In the extent of their country were found Placentia, Velitra, Florentia, and Julia Fidenis. ANAMARI, a people mentioned by Polybius, and placed in the vicinity of Marsilles.

ANAMASCA, or ANAMATA, a town of Lower Panama, and placed by M. d'Anville south of Acinum.

ANAMBRA, in Geography, an island in the Indian sea, off of Borneo. N. Lat. 2° 55'. E. Long. 160° 44'.

ANAMIM, the second son of Mizraim, Gen. x. 13. Broughton takes his descendants to be the Numidians, among whom he finds Anabhis. Others suppose that they were the Anasites of Ethiopia. But as they were the descendants of Mizraim, and must be sought for about Egypt, the opinion of Bocchor is more probable, who conceives them to be the Nomades, who lived between Ammon and Nafanomites; and were called Anamis, from Am, which signifies a sheep among the ancient Egyptians; as it does among the Arabians. For the Nomades fed sheep, as Herodotus informs us, and lived upon them, whereas, they abstained from eating cows or swine; and their garments also were of shear-linen.

ANAMIS, in Ancient Geography, a river mentioned by Arrian (cap. xxxiii.), and supposed to be the same with that which is called Andamis by Ptolemy. It belonged to Carmania. M. d'Anville places this small river on a chart, which forms the communication between the sea and the Persian gulf.

ANAMMELECH, in Scripture History, an idol of the Sephanites, who are said (2 Kings, xvii. 31.) to have built their children in honour of this deity and Adrammelech. These were the same gods with Moloch, to whom the same sacrifices were offered. The Jewish rabbins represent one in the form of a peacock, and the other of a peafowl; but they were probably only different names of Moloch, which was the sun: the addition of Addir, signifying magnificent or potent, makes Adrammelech or the mighty Moloch, and of Ana, denoting to answer, forms Anammelech, or the Occular Moloch. Dr. Hyde (Rel. Vet. Pers. cap. ii. p. 65) is of opinion, that Adrammelech signifies the king of the flock; Addir denoting great; and Ana being the name with pecus in the Persian language, and expressing the latter cattle, viz. the sheep and goats; Anammelech was of much the same significatory. These gods, he observes, had the care of the flocks; and as the riches of these people consisted in cattle, were made the objects of their worship. They were also celestia constellations, as he observes, which, as the people imagined, promoted the breed and growth of cattle. Others make Adrammelech the sun, and Anammelech the moon.

ANAMNESEIS, from ana and nanoos, I remember, in Ancient Writers, denote enumerations of persons who had behaved well in war, or on other occasions, reaped before the emperors of Constantinople, to put them in mind of bestowing suitable rewards.

ANAMNESTICS, in Medicine, are used by some writers to denote those signs which help to discover the pale face of a patient's body, in which tides it stands opposed to prognostics.

These are otherwise called remembarians.

Some have used this term for medicines that are supposed to improve the memory, or restore it when lost. But this is a general title, says Dr. Cullen (Med. vol. i. p. 166), which seems to have no foundation at all, or which, if it had, is too general, and would be very improperly employed.

ANAMOKA, or ROTTERDAM, in Geography, one of the Friendly islands, in the South Pacific Ocean. It is situated in S. Lat. 20° 15'; and W. Long. 173° 31', about 18 leagues distant from Tongataboo, or Amsterdam: which it resembles in its aspect. Its form is triangular, and none of its sides exceed the length of four miles. Its extent is also diminished by a large salt lagoon which almost cuts off its southern-eastern angle from the sea. Its coves are surrounded by small islets, sand banks, and reefs, by which is formed a harbour on the south-western side of the island, with anchorage in 10 and 12 fathom. The bottom being coral sand. It is well sheltered, but no fresh water is to be obtained near the shore. On the north-west side are two coves, to which are narrow passages for boats through the reefs. To the southward of there is a bank, free from rocks, with 20 and 25 fathom depth, one or two miles from shore. The coast rises nearly perpendicular, 15 or 20 feet from the sea, and the interior appears level, excepting some small hillocks, and a more considerable one toward the centre of the island. It is similar to Tongataboo in form and productions, but less cultivated, even in proportion to its size. It is, however, better furnished with water, though somewhat brackish, having a pond about three quarters of a mile from thelanding-place on the north-west side, of half a mile in circuit. This island was discovered by Talman, in 1643, and called Rotterdam. Captain Cook arrived at it in 1774. The thefts were more frequently committed here than at the founahsans islands of the group; the character of the women appeared also to be more licentious, and that of the men more daring. Some of the natives dilliminished themselves by their good conduct, and most of them behaved well, except when they were tempted to steal some of the novelties presented by their visitors. Capt. Cook returned to this island in 1777. Lieutenant Bligh, in the Bounty, anchored at Anamooka in 1789. Pith apples, which had been planted in the islands visited by Capt. Cook, were found here at that time in a flourishing state. Capt. Edwards twice visited Anamooka in 1791. No subseqent visit to this island has been made known. It is ranked by the natives amongst the smaller islands of their Archipelago.
which contains 5; larger than this. A disease of the leporous kind, which seems to be common to all the islands of this ocean, is said to prevail more at Angamala than in any other part of this group. The general disease, introduced here by the English, has made a lamentable progress. As wood is an article procured here by all the tribes, care should be taken to avoid an accident, which may occur in cutting a tree, called by the natives fallam. This is a species of pepper, and yields a milky juice that injures the eyes and skin of the workmen. 

ANAMORPHOSIS, composed of ann and po[gra], form, in Perspective and Painting, a monstrous projection; or a representation of some image, either on a plane or curve surface, deformed and distorted: which at a certain distance shall appear regular, and in proportion.

To make an anamorphosis, or monstrous projection on a plane. Draw the square ABCD (Plate I. Perspective, fig. 1.) of any size at pleasure, and subdivide it into a number of arcubes, or letter squares. In this square, or reticle, called the craticular prototype, let the image to be distorted be drawn. Then draw the line ab (fig. 2.) equal to AB; and divide it into the same number of equal parts, as the side of the prototype AB; and in E, the middle of it, erect the perpendicular EV, so much the longer, and draw VS perpendicular to EV, so much the shorter, as the image is designed to be more distorted. From each point of division draw right lines to V, and join the points a and S, by the right line a S. Through the points d, e, f, &c. draw lines parallel to ab; then will aed be the plane in which the monstrous projection is to be delineated; called the craticular eclipse.

Lately, in every arcube, or small trapezium of the space aed draw what appears delineated in the correspondent arcube of the square ABCD; by this means you will obtain a deformed image, which yet will appear in just proportion to an eye distant from it by the length of EV, and raised above it be the height VS.

It will be diverting to manage it so that the deformed image may not represent a mere chaos but some other image: thus, we have seen a river with its islands, warehouses, &c. marching along the side of it, so drawn, that when viewed by an eye in the point S, it appears to be the faithful face of man.

An image also may be distorted mechanically, by perforating it here and there with a needle, and placing it against a candle or lamp; and observing where the rays, which pass through the eyes' little holes, fall on a plane, or curve superficies; for they will give the correspondent points of the image deformed; by means whereof, the deformation may be completed.

Let the image, whatever it be, e. g. IHS, be drawn upon a cylinder of paper or pasteboard, ABCD (fig. 3); and the perforations being made as now described, place a candle G, behind the cylinder, and mark upon the ground the points corresponding to the perforations of the image, which will be distorted more or less, according to the position of the candle, or the plane, &c. Then, let the picture that is formed be an exact copy of this distorted image, and substitute a metallic speculum in the place of the cylinder, and let the eye of the spectator have the same position before the cylinder that the candle had behind it, the distorted image will, by reflection from the speculum, be reflored to its proper shape.

Anamorphosis, to draw the, or deformation of an image, upon the convex surface of a cone.—It is manifest from the former cafe, that here it is merely required to make a craticular éctype on the superficies of the cone, which shall appear to an eye duly placed over its vertex equal to the craticular prototype.

Let the base, or periphery, ABCD, therefore, of the cone (fig. 4.) be divided by radii into any number of equal parts; and let some one radius be likewise divided into equal parts; and through each point of division draw concentric circles; thus will the craticular prototype be made. With double the diameter AB, as a radius, describe the quadrant EFG (fig. 5.) so that the arch EG may be equal to the whole periphery: then this quadrant, duly folded, will form the superficies of a cone, whose base is the circle ABCD. Divide the arch EG into the same number of equal parts as the craticular prototype is divided into; and draw radii from all the points of division. Produce GF to I, so that FI = FG; and from the center I, with the radius IF, draw the quadrant IFK; and from I to E draw the right line IE. Divide the arch IF into the same number of equal parts as the radius of the craticular prototype is divided into; and draw radii through each of the points of division, from the centre I, meeting EF in 1, 2, 3, &c. Lately, from the centre P, with the radii, F 1, F 2, F 3, &c. describe the concentric arches. Thus will the craticular éctype be formed, the arcole of which will appear equal to each other.

Hence what is delineated in every arcole of the craticular prototype, being transferred into the arcole of the craticular éctype, the images will be distorted or deformed; yet an eye raised above the vertex of the cone, at a height equal to that of the cone itself, will perceive them in just proportion.

If the chords of the quadrants be drawn in the craticular prototype, and chords of the four parts in the craticular éctype, all things else remaining the same, you will have the craticular éctype in the quadrangular pyramid.

And hence it will be easy to deform any image, in any other pyramid, whose base is any regular polygon.

Because the eye will be more deceived, if from contiguous objects it cannot judge of the distance of the parts of the deformed images; therefore, the kinds of deformed images are to be viewed through a small hole; and when they are made to appear like the objects which they are intended to represent, by means of a mirror of any particular construction, these anamorphoses are said to be reformed. See Mirror.

The original author of this ingenious device is not known. Simon Stevinus first wrote upon it, without informing us from whom he acquired it. The principles of it are laid down by S. Vanzeland, in his "Perspective Conique et Cyllindrique," and Gasper Schottius, professing to copy Marius Butinus, in his description of this piece of artificial magic. Other methods more exact and geometrical than that above described, in which a lamp or candle was used, were afterwards invented, and rules laid down for drawing the requisite figures. Schottius quotes one of those methods from Butius, another from Hevigninus, and another from Kircher, which may be seen in his "Magia," vol. i. p. 162, &c. He also gives an account of the methods of reforming pictures by speculums of conical and other figures. The method given by Dr. Smith, (in his Optic, vol. i. p. 250.) is, without doubt, the best; and from this any person may easily make a drawing of the same kind. The same description answers to two mirrors, one of which, fig. 6, is convex, and the other, fig. 7, is concave. In order, therefore, to paint upon a plane a deformed copy, ABCDEKIHGF, of an original picture, which shall appear regular, when seen from a given point O, elevated above the plane, by rays reflected from a polished cylinder, placed upon the circle,
circle, hp, equal to its given base; draw from the point R, which is supposed to be directly under O, the place of the eye, two lines RA, RB, which shall either touch the base of the cylinder, or else cut off two small equal segments from the sides of it; as the copy is intended to be more or less deformed. Then taking the eye, raised above R, to the given height RO, somewhat greater than that of the cylinder, for a luminous point, describe the shadow arey, of a square acez, fig. 8, or parallelogram standing upright upon its base ae, and containing the paper required, any where behind the arc hp. Let the lines drawn from R to the extremities and divisions of the base a, b, c, d, e, cut the remotest part of the shadow in the points f, g, h, i, k, and the arc of the base in l, m, n, o, p; from which points draw the lines lA, mB, nC, oD, pE, k, as if they were rays of light that came from a focus R, and were reflected from the base hp, so that each pair, as lA, lR, produced, may cut off equal segments from the circle. Lastly, transfer the lines lA, mB, nC, oD, k, and all their parts, in the same order, upon the respective lines lA', mB', nC', oD', k, and having drawn regular curves, by estimation, through the points A, B, C, D, E, through F, G, H, I, K, and through every intermediate order of points; the figure ACEKH, so divided, will be the deformed copy of the square, drawn and divided upon the original picture, and will appear similar to it, when seen in the polished cylinder, placed upon the base hp, by the eye in its given place O.

The practical method of drawing these images seem to have been carried to the greatest perfection by J. Leopold, who, in the Leipsic acta, for the year 1712, has described two machines, one for images to be viewed with a cylindrical, and the other with a conical mirror. The person, who has this instrument, may take any point at pleasure, and whilst he goes over the outlines of it with one pen, another traces the anamorphosis.

By methods of this kind, groves of trees may be cut, so as to represent the appearance of men, horses, and other objects from some one point of view, which are not at all discernable in any other. This might easily be effected by one person placing himself in any particular situation, and giving directions to other persons, what trees to lop, and in what manner. In the same method it has been contrived, that buildings, of circular and other forms, and also whole groups of buildings, consisting of walls at different distances and with different positions to one another, should be painted so as to exhibit the exact representation of particular objects, which could only be perceived in one situation. Bettinus has illustrated this method by drawings, in his "Apotria."

In the cloister of the Minims, in the Place Royale, at Paris, there are two anamorphoses traced upon two of the sides of the cloister, one representing a Magdalen, and the other St. John, writing his gospel. They are so managed that when viewed directly, they appear like a kind of landscape, but from a particular point of sight they appear very distinctly, like human figures. These two figures were executed by Nicoleau, a Minim, who published a treatise, entitled "Thaumaturgus Opticus," in which he has described the manner of tracing anamorphoses on any surfaces. In vol. iv. of the Memoirs of the Imperial Academy of Peterburgh we have the description of a similar anamorphosis, by Mr. Lutman, in honour of Peter II., emperor of Russia. On the subject of this article, see Wolfius Elements Mathematicks, sect. vol. iii. cap. v. p. 89, &c. PrieiUey's History, &c. of Wales, &c. p. 93-96.

ANAMSAGAR, in Geography, a town of Hindostan, in the county of Vittapour, 51 miles east of Baldamy, and 71 south-east of Calgala. Vol. 17.

ANANAS, in Botany, by some called "anemos," and by others "jabana," and popularly the "pineapple." On account of the resemblance it bears to the cones of pines and fir, it is a species of Bromlia.

ANANAS, in Natural History, a species of Madelepora, in the fourth order of Verses, Zeophyta, the flares of which are angular, convex, and concave in the disk. This kind inhabits the Mediterranean and South American seas, and is often found in a scufi flate.

ANANCITIS, in Antiquity, a kind of figured stone, otherwise called synochitis, to which superstition ascribed a magical virtue in raisinp the shadows of the infernal gods.

ANANDRIA, in Botany, a species of Tussilago.

ANANES, in Geography, three small islands in the Cretian Archipelago, about three leagues south-west of the isle of Milo.

ANANISABATA, or ANANISBATTA, in Antiquity, a magical word inscribed on coins and other amulets, and supposed to have efficacy in preserving the wearer from the plague.

ANANTHOCYCLUS, in Botany. See Cotula.

ANANITOUR, in Geography, a town of Hindostan, in the Miyore country, 85 miles north-east of Chitteldoorg, and 150 north-north-east of Sarangapatam.

ANANUS, the Younger, in Biography, a Sadducee, was appointed high-priest of the Jews by Agrippa, the younger, about A.D. 60. Jofephus (Antiq, lib. xx, cap. 8, § 1.) represents him as fierce and haughty in his behaviour, and extremely restless and daring; and as belonging to the sect of the Sadducees, who were above all other Jews cruel in their judicial sentences. Upon the death of Festus the Roman governor, and before the arrival of Albinus, appointed to be his successor, Ananus called a council, and bringing before it James, our Lord's brother, and some others, he accused them as transgressors of the laws, and had them fined to death. Jofephus says, that many were offended at this proceeding. Some, he says, went running to meet Albinus, who was coming from Alexandria, and put him in mind, that Ananus had no right to call a council without his leave. Albinus approving of what they said, wrote a very angry letter to Ananus, threatening to punish him for what he had done, and king Agrippa took away from him the priesthood, after he had enjoyed it three months, and put in Jefus, the son of Damneus. Dr. Lardner infers from this circumstance, as well as others, that the Jews had not at this time the power of life and death. Works, vol. i. p. 81.

ANANUS, a learned Jewish Rabbi, who flourished about the year 760. He was denied the title of gaon or excellent, though a man of great learning, on account of some material error of which his doctrine was fullfed; and the suspicion appears to have been well founded, as he became the reiuer and chief of the Sadducean sect, which, after having been long almost extinct, became formidable to that of the Pharisees. Gantz Tzemach David, p. 725.

ANANDON PORTUS, in Ancient Geography, Santo Hespiote, an obscure port, which the author of the "Itinerarius Meritimus," commonly supposed to be Antouine, places between the Portus Herculis and Nicia. Clavier has confounded it with Aviho. M. d'Anville places it in a small creek, at the extremity of a small peninsula, to the east of Nicia, and forming to the west the Portus Diliuva, and to the east the Portus Aviho.

ANAPHEST, AMAPHESTUS, a foot in the Greek and Latin poetry, consisting of two short syllables, and one long, being the reverse of the dactyl.
The word is derived from ἀναφαίης, contr. ἀναφαιν, because in dancing this measure, the ground was thrashed in a contrary order from what it was in the dactyl. Whence the Greeks called it ἀναφαίης. Danae, ii. 42, 54.

Such are the words ἀναφαίης, ἀναφαιν, ἀναφαίης, ἀναφαιν, &c.

Hase Vellinga (loc. rais., Rhythms, p. 59) has said that the English have no perfect model in their language. But Dr. Dunlop (Hist. Music, vol. i. p. 79) observes, that the change is easily confounded by the mere mention of the words recommend and adjuration.

ANAPASTIC, or ANAPHETIC, sometimes is used in a

substantive sense.

Such is the ἀναφαίης ἀριστοφαίης, in Cicero, which is a

verse consisting of eight feet, as

"Asena ponti per frecta colches denique delatus adulter.

Vide Cir. in Orat. cap. 56. Fabri. Thef. in voc. Anaphefis.

This is otherwise called anaphefis εκενεωριος.

Anaphetic, in an adjective sense, something relating to or composed of anaphefis.

Anaphetic kind, genus anapheticum, is a sort of verse composed of pure Aristophanic or Parthenic anaphefis.

Anaphetic verses are either Aristophanic or Partheneic. Anapheticus Aristophaneum, called also Parthenaeum, consists of three anaphetes, and one long syllable, but so as that instead of the first two anaphetes, as many spondees may be used.

Its type stands thus:

\[
\begin{array}{cccc}
\text{1} & \text{2} & \text{3} & \text{4} \\
\hline
\text{5} & \text{6} & \text{7} & \text{8} \\
\end{array}
\]

- Venient cito secula quam jam
- Socius calor offa reviet
- Animatique fangevne vivo
- Habitacula prifina geget
- Lacrymam suspendite cunet
- Mors hect reparatio vita eft.

Pindaric Anaphefis admits, in the first place, either of an anaphet or a spondee; in the second, only of an anaphet; in the third, of an anaphef or a spondee; in the fourth, either of a spondee or a trochee.

\[
\begin{array}{cccc}
\text{1} & \text{2} & \text{3} & \text{4} \\
\hline
\text{5} & \text{6} & \text{7} & \text{8} \\
\end{array}
\]

- In summa pericula venturi
- Multos timor tpic mali mittit.

ANAPAUMENAE, in Ancient Geography, a fountain of Greece, in the Molossia, which was part of Epirus. It was situated near that of Dodona, and was also denominated "fons Jovis.

ANAPES, in Geography, a town of Flanders, one league from Lille.

ANAPHE, in Ancient Geography, an island of the Cretan sea, supposed to be one of the Cyclades to the east of Thera. Steph. Byz. says, that it was one of the Sporades. Its first name was Membliares, which it derived from Membracia, the Phocian, who, when his relations went in quest of Europa, accompanied her, and settled in the neighbouring island of Thera. It was afterwards called Anapha, a Phocian word, which, according to Bochart, signifies shaded and dark, an epithet given to this island, on account of its gloomy and thick forest. But the most commonly received opinion is, that it owes this name of Anapha to the Greek word ἀναφαίης, to appear, from the thunder having on a sudden occasioned it to rise from the bottom of the waters, in order to receive the fleet of the Argonauts, on its return from Colchis, when asailed by a tempest. The fable of antiquity is the history of the formation of this island, now called Nanto, which a volume could appear sufficiently above the sea, in the midst of a violent agitation of the atmosphere and the waves, which has happened to some other islands of the Archipelago. In memory of this event was built a temple, mentioned by Strabo, which was consecrated to Apollo Aeetes, or dazzling with light. Slight vellages of this temple still remain on the place which it occupied, in the fourth part of the island; and the marble of which it was constructed was taken from a very steep rock, of a terrifying aspect, on whose summit is now set a chapel, dedicated to our Lady of the reed: in modern Greek "parmia kalamotika." For a further account of the present state of this island, see Nanto.

ANAPHILYSTUS, a small maritime town of Attica, in the tribe of Anticles, very near Athens, towards the cape Calvin, and north-west of Cereon. It had temples of Pan, Ceres, Venus Colladies, and the goddesse called Genetylides. This place is now called Eleus.

ANAPHRAXA, ἀναφραξα, signifying repetition, in Rhetoric, a verbal figure, whereby one or more words are repeated in the beginning of several sentences or verses.

This is a lively and elegant figure, and serves very much to engage the attention; nor by the frequent return of the same word the mind of the hearer is held in an agreeable suspense till the whole is finished.

Such, e. gr. is this of the Psalms, "The voice of the Lord is powerful: the voice of the Lord is full of majesty: the voice of the Lord shaketh the wilderiffs.

"You do nothing," says Cicero to Catiline; "you attempt nothing, you think nothing, but what I not only hear but also see, and plainly perceive." This figure is frequently used by way of interrogation, which renders it not only beautiful, but likewise strong and nervous. Thus Cicero, at the beginning of the same speech: "Does neither the night-guard of the palace, nor the city-watch, nor the people's fear, nor the agreement of all good men, nor the meeting of the Senate in this fortified place, nor the countenances and looks of this assembly, all move you?" And in another of his orations: "What is so popular as peace, which seems to afford a pleasure, not only to beings endowed with sense, but even to inanimate nature? What is so popular as liberty, which even beaks as well as men feem to covet and prefer above all things? What is so popular as ease and leisure, for the enjoyment of which you and your ancedors have undergone the greatest labours?" Contra Rull. ii. c. 4. Ward's Oratory, vol. ii. p. 56.

ANAPHRAXA is used in the Ancient Medicine, for the rejection of matter by the mouth.

Hence also we meet with the term anaporphic, ἀναφορικος, used for those labouring under an hemoptysis, who bring up blood from the lower part of the mouth.

Anaphora, among Ecclesiastical Writers, denotes the host, or species offered in the eucharist.

Anaphora is also used to denote the rehearsing of a person's name from the diptych in the liturgy.

Anaphora is also a title given to those little Syriac liturgies, wherein are contained the prayers after the ευχλεμον πτοις. Ignatius, patriarch of the Maronites, enumerates forty of these anaphores.

Anaphora, in Astrology, denotes the second house, or that
that part of heaven which is thirty degrees distant from the
horoscope.

The term anaphora is sometimes also promiscuously ap-
pied to some of the succeeding houses; as the second, fifth, eighth, and eleventh. In this sense anaphora amounts to
the name with *epanaphora*, and stands opposed to cataphora.

**Anaphora** is also applied by some to the oblique ac-
fections of the stars.

**Anaphrodisia**, from αν and ἂφεδρος, *Venus*, de-
notes impotency in respect of venery. Some also use it for a
want of desire or inclination to the sex.

In this sense the academists *Nature Curiosae* give an ex-
traordinary instance of this kind in a person otherwise
94. See Impotency.

**Anaphus**, in *Entomology*, a species of *Papilio*, in
the division *Papilio Ursico*, that inhabits Surinam. It has
no tail, and is uniformly brown, except the apex of the
lower wings, which is yellow. Fabricius.—The antennae
are hooked at the end.

**Anaphysemata**, from αν and ψειδ, *I send forth,
in some Ancient Writers*, denote winds issuing from
underground, at the cliffs or apertures thereof.

These are sometimes called by later writers ἐρασαί.

**Anapalias**, from αν and παλαις, *I turn, in Sur-
gery*, the complete restitution of a broken bone, so that the
two ends meet, and close exactly together. This is the
name with what is otherwise called *diaphysis*.

Anapalias also signifies a restitution of the extended flesh.

**Anaplerosis**, in the general sense, denotes re-
plication. Anapleoritis is more particularly used to denote
that part of surgery whereby things wanting are supphed.

In which sense anapleoritis amounts to the name with what
we otherwise call application, or *prothesis*.

**Anaplerosis**, in the *Civil Law*, is a name which same
give to the four last books of Julianin's Code.

**Anaplerotics**, from αναπληταις, *I fill up, in Medi-
cines*, such remedies as incarnate and fill up ulcers and wounds
with new flesh.

Anaplerotics are the name with what we otherwise call
*incarnatives*.

**Anapodari**, in Geography, a river of the island of
Candia, which rises at Callk Bonifacio, runs near Cassel
Boulevard, and discharges itself into the sea between Cape
Matola and Cassel de Girapetra. The ancients called it Ca-
taractus.

**Anapodophyllum**, in Botany. See Podo-
phyllum.

**Anapuia**, in Geography, a province of Venezuela, in
South America, towards the mountains of St Peter, and the
source of the Buria.

**Anapus**, or *Anapsis*, in *Ancient Geography*, the name
of a river of Sicily, which ran from west to east at the distance
of about two miles from Ortygia, and somewhat less than a
mile and a half from Neapolis, and discharged itself into the
great harbour of Syracuse. This stream, which is only 24
feet wide, and 12 or 15 deep at its mouth, flows, in a terpen-
tine course, through a small extent of country, which, though
slightly elevated in its south and south-western side, on the
north and north-west confines of an extensive marshy plain.
This plain lying between the river and the city, is terminally
by two fens or moors, the one called Syrcas, where the city
was named, and the other Lyamela. Between the Anapus
and the promontory of Plinyrium, was situated the little
inlet of Olympia, surrounding the site of the ancient temple
of Jupiter Olympus, built upon an eminence, and bounded
on either side by the vast Lyamelian marshes, extending
from the head of the great harbour, half covered with
water in the vernal months, and exhalting under an al-
mot vertical sun, the most unwholesome and pestilential
vapours. To this river the ancients gave the name of
*Alpheus*.

Anapus was also a river of Illyria, which ran near
Liffus.

Anapus was also a river of Epirus, in Chaonia. Thucy-
dides reckons it from this river to Stroton, or Stratus, a
considerable place of Achaia.

**Anaquitio**, in Geography, a country or America in
Peru and in the province of Quito.

**Anaraci**, a people of Scythia, on this side the Ganges, according to Ptolemy.

**Anarchy**, people of Scythia, placed by Ptolemy be-
low the Agathyri.

**Anarchi Montes**, mountains of Scythia, forming
part of the chain of Imaus.

Anarchi, in Antiquity, a name given by the Athenians to
four supernumerary days in the year, during which they
had no magistrates.

The Attic year was divided into ten parts, according to
the number of tribes, to whom the presidency in the senate
fell by turns.

Each division consisted of 35 days; what remained after
the expiration of these to make the lunar year complete,
which, according to their computation, consisted of 354 days,
were employed in the erection of magistrates, and called
τριάδες, and ἀπεξήγησις.

**Anarchy**, derived from the Greek privative αν, and
αρχή, *principality*, the want of government in a nation, where
no supreme authority is lodged, either in the prince or other
rulers; but the people live at large, and all things are in
confusion.

All kinds of states are subject to anarchy. We read of
civil anarchies, ecclesiastical or spiritual anarchies, and even
anarchies in the republic of letters.

Anarchy is supposed to have reigned after the deluge,
before the foundation of monarchies. We find it obtain in
diverse parts, especially of Africa and America; e. g. among
the Illinois, who are observed by travellers to live in a per-
fected independency of any superior; among the Californians,
where every family makes its own laws as well as religion;
in Chili, where every master of a family is a king; in the
Marian islands, where neither prince nor law is known, but
every perfon governs himself according to his own will; and
to mention no more, among the Hottentots, where the only
semblance of government is, that in each neighbouring
the elder is the first in honour, and his advice chiefly fol-
lowed, not from any civil authority he is vested with, but on
account of his superior experience.

Some extend the idea of anarchy farther, so as to make it
comprehend all the more popular governments. In this
sense anarchy amounts to much the same with democracy.

Hobbes, in this sense, calls the Roman commonwealth an
anarchy.

It has sometimes been controverted which of the two is
best, a state of anarchy, or of tyranny and arbitrary power.
This controversy, however, does not appear to be of any
great use; it is of little purpose to determine which is best,
for a state of anarchy, naturally, may, neccisarily, pave the
way for despotism; and confusion is always the parent of
oppression.

**Anarchy** is also applied to certain troublesome and
disorderly
diforderly periods, even in governments otherwise regular. In Germany, the interval from the election of Richard, duke of Cornwall, to that of duke Rudolf of Lorraine, is commonly called the anarchy, or interregnum.

In England, the period between the death of Cromwell and king Charles's Restoration, is commonly represented as an anarchy. Every month produced a new scheme or form of government. Enthusiasts talked of nothing but annulling all the laws, abolishing all writings, records, and regillers, and bringing all men to the primitive state. No modern nation has been more subject to anarchies than Poland: where every interval between the death of one king, and the election of another, was a perfect picture of confusion, in so much that it became a proverb among that people. Poland is governed by confusion.

The Jewish history presents numerous instances of anarchies in that state usually denoted by this phrase, that in those periods there was no king in Israel, but every man did that which was right in his own eyes, which is a just picture of an anarchy. The first anarchy we read of in that commonwealth, is that which ensued on the death of Josiah, who leaving no successor, the government devolved on the elders of the tribes, who ruled each according to his own will. After the death of these elders the anarchy became complete.

ANARGYRI, in Ecclesiastical History, is an appellation given to certain saints in the Greek church, who having been physicians, gave not only their advice but their remedies gratis. They are also called argyropotes.

ANARGYRUS, from α and αργυρος, money, in Ancient Writers, denotes a person without money, though otherwise sufficiently accommodated with land and other effects.

In a like sense we sometimes also meet with the word anargyria, used by lawyers for the condition of a person without ready money.

Mart. Phil. Fabricius has a dissertation De Exceptione Anargyriz.

ANARHAPHE, from α and αρματος, futurus, in Surgery, denotes a kind of future or retraction of the upper eye-lid, when relaxed and hanging over the eye.

This is by some also called futura blepharica, by others abbreviatio, contradictio, collection, or suppeso superioris palpebro.

It is used in the phlegmen, peñis, or eolysis; where the sight is obliterately by a prolapus of the part, or the eye-lid itself is too thick befit with brightly hairs both within and without.

ANARHICHAS, in Ichthyology, a genus of the order Apodes. The head is obtuse, fore teeth in each jaw conic, large, divergent, fix in number or more grinders in the lower jaw, and palate rounded. Six rays in the gill membrane. Body roundish, tail sin distat. Linn. Gmel. — The species of this genus are Lupus, Minor, and Pantherinus, which see.

ANARIA, in Ancient Geography, Ischia, an island south-east of Baia. Augustus gave it to the inhabitants of Neapolis, in exchange for the island of Capraza. It was also called Pytheus.

ANARIACA, a town which, according to Strabo, was near the Caspian sea. It is suppos'd to have been situate between Albania and Hircania.

ANARIS MUNDI PRIMUM, was situated, according to Ptolemy, in the island of Taphrosana.

ANARIUM, a town of Asia, in Greater Armenia, according to Ptolemy.

ANARIPI, a people placed by Ptolemy in Germany.

ANARKHION, in Byzanz, a name given by some of the ancients to the plant called by others lychnis agris, and by others antirrhinum. Pliny tells us, that this plant reflected wax, that it had scarce any root; that its flower was the colour of the hyacinth, and its fruit resembled the nose of a calf. It is from this resemblance that we at this time call the plant colocynth. Dioscorides says, that it was like the amagallis.

ANARES, or ANARTI, in Ancient Geography, a people who inhabited the north-west part of Dacia, according to Caesar and Ptolemy.

ANARTHRA, from α and αρθρος, joint, in Natural History, a class of naked insects, distinguished from all others by having neither wings nor limbs. To this class belong all kinds of worms and leeches.

ANARTOPHRACITI, in Ancient Geography, a people placed by Ptolemy in Sarmatia, adjacent to the Ombrones, in European Sarmatia.

ANAS, now called Guadiana, a river of Spain in Baskica. ANAS, in the Linnean system of Ornithology, the name of an extensive genus of birds, of the order Anseres, and known in England by the general names of Swans, Geese, and Ducks. The Linnean character of this genus is taken from the form of the bill and tongue; the bill being convex, obtuse, and the edges of both mandibles befit with lamel-lated teeth; the tongue ciliated and obtuse. Linn. Gmel. To this concise generical distinction some authors add, that the bill is strong, broad, depressed, and commonly furnished at the end with an additional piece or nail; nostrils small and oval; tongue broad, and fringed at the edges, near the base; toes four in number, three being placed before, and one behind, and the middle one longest. Latham. Gen. Syn.

The species of this genus, according to the late authorities of Linneus, Latham, Gmelin, &c., are —

Amer. teal
Cacumen, ruddy goose
Cineria, ash-coloured, or log-gered head goose
Circia, summer teal
Clangula, golden-eyed duck
Clypeata, shoveller
Coromandelana, Coromandel teal
Cofeculae, Chili goose
Cricca, common teal
Cripfe, crested duck
Curvirostra, curve billed duck
Cyanus, Chinese goose
Cynus, wild or whittling fowl
Domiatic, Damietta duck
Difors, blue-winged teal
Dispar, western duck
Domestica, common tame duck
Dominica, St. Domingo duck
Dominian, Dominican duck
Erythrops, Bermalm goose
Erythropolis, crimson-billed duck
Falcata, falcated duck
Perina, pochard, or red-head ed goose
Ferruginea, ferruginous duck
Fornicata, Baikal teal
Gyphala, tufted duck
Huecida, Mexican pochard
Pufa, velvet duck
Eufa, brown duck
Calocikula, Chinese teal
Ooamis.,
Gambuka, spur-winged goose
Gaitoir, Gannair duck
Georgica, Georgia duck
Glaciaria, long-tailed duck
(Latham)
Glocis, grey-headed duck
Gloetemis, binnaculated duck
Gmelini, Russian teal
Grandis, great goose
Hina, Hina teal
Hylomitra, harlequin duck
Hylida, Hybrid fawn
Hyemalis, long-tailed duck
(Edwards)
Hyperborea, snow goose
Jacquini, chenuet-coloured duck
Jamacensis, Jamaica shovel
India, barred-headed duck
(Iatham)
Icelandica, Iceland duck
Kagolka, Kagolka duck
Kuckwxula, Kuckuxula duck
Labradoria, pied duck
Leucophala, white-headed duck
Leucoptera, bufflo goose
Lurida, bird duck
Madagascanfa, Madagascar teal
Magellanica, Magellanic goose
Malacoikeous, soft-billed duck
Manillavis, Manilla teal
Marilla, scap duck
Margra, ural duck
Melanoccephala, black-headed fawn
Melanotes, black-backed goose
Melanura, black-tailed duck
Mexicana, Mexican duck
Minuta, minute duck

ANASARCA from ανασαρκα, in Medicine, a sort of universal dropsy, wherein the whole or consideral part of the body is flouted or bloated with watery fluid.

This distemper is sometimes also called anasarca, sometimes diaplastia, sometimes diapharism, sometimes aquas inter calorem, or interitus, because the humour spreads itself through the flesh. Serenus Samonius elegantly calls it lymphaticus error; Albusca calls it a droppy by infiltration.

Preternatural collections of water in any part of the body, except the urinary bladder, are called Dropsies. Some of these are confined to particular cavities, and take their name from that of the cavity, as, hydrothorax, or a droppy in the chest; sphenitis, a droppy of the esophagus, &c. but anasarca may take place in any part of the body where there is cellular membrane. Dr. Cullen places it in his third class, Ca- chexia, order, Intemofusitus, aquosus, and admits several species of it, depending on the remote cause. The most usual and general Cause of anasarca is debility, whether induced by fatigue, or watching without lying down, by hemorrhage, by crepitant fever, or by deficient or watery food. It is sometimes believed to arise during pregnancy, from the pressure of the uterus on the veins which return the blood from the lower extremities.

The Efferal Character of this disease is founded on the swelling being pale, soft, and leaving a pit after preressure with the fingers.

Symptoms. As anaeractive affections differ much in degree or severity from a slight swelling of the feet and ankles to-wards night, to a general diffusion of water throughout the cellular membrane of the whole body and extremities; so the symptoms or degrees of distests experienced by the patient are greatly diversified. That which first attracts his attention is a flush of the ankles, a remaining long in the erect posture. This increases daily till the feet, legs, and thighs become so large, that the skin seems in danger of bulunting. When the disease approaches towards this magni- tude, the water shifts its place with the posture of the body; so that after lying in the horizontal posture all night, the swelling of the legs will be much diminished, while that of the trunk, arms, and face will be increas'd. In this stage the patient often experiences dyspnoea and thirst, with loss of appetite; the secretion of urine is diminished; the feronium, or labia are so distended, that walking becomes im- practicable, when the swelling and flush of the feet alone would not have rendered it so. This is the usual progress of anaerases; but it sometimes supervenes so suddenly, that the whole body will partake of the swelling in twenty-four hours. There is no doubt that it may often exist alone, without any other species of droppy; we however very com-monly find it combined with Hydrothorax, or Ascites; and it is then of course more difficult of cure. The prognosis is generally unfavourable, in old people especially, or those who have injured their constitution by the abuse of spirituous liquors. Where the affection is slight, and brought on by sitting up for several days and nights, in a good constitution we may always expect a cure.

The treatment should be adapted to the state and degree of the disease. In slight affections of short standing, flannel rollers to the feet and ankles, with bark or flannel internally, will generally succeed. In severe cases we attempt the cure on the following plan, viz.

1. We obviate all causes of debility by diet, air, and excursive; and we endeavour to restrain all debilitating evacuations.

2. We should then employ the means which are found most successful in evacuating the collected fluid. The first of these is to promote its absorption; which is done,
   A. By the pressure of bandage and friction, with or without mercurial ointment.
   B. By Emetics; especially hydrag, virtilatous, cu- prum virtilatous, pulvis antitumoralis, and, above all, chloratum in powder.
   C. By Purgatives, such as columel, gamboge, elate- rium and jalap combined with crystallis of tartar, nitre, or kali acetum. The absorption, in this case, most probably, is a consequence of the in- creased evacuation from the intestines.

When the aqueous fluid is absorbed and carried into the blood, the secretion by the kidneys is commonly increased, by which it is carried out of the body. But if this should not take place, we have recourse to these medicines called

D. Diuretics. Whether these exert their action on the kidneys alone, or whether they produce their effect by promoting the activity of the absorbent system, is not ascertained. The most successful diuretics are mercury, whether introduced by friction or taken internally; and it appears to be a good prepara-
tion for the employment of all other remedies of this class. Squills, recent or dried, or an infusion of them in Lisbon wine; the tincture of digitalis, which being a medicine of great power, requires diligent watching; kali saturet with vinegar of squills; the juice of leeks; the extract of brain tops; the infusion of juniper berries with sweet spirit of nitre, infusion of tobacco, sic & sic. The

3. When by such means as these we have evacuated

4. Dr. Dyer's cure for an anaemia is an electuary composed of decum prepared with sulphur and crude antimony, each an ounce; digastricum, four ounces; make a fine powder of these; then add as much of any syrup as will make a soft electuary.

5. ANASCHOUADI, in Batavia. See ELEPHANTOPUS.

6. ANASSA. See BRONELIA.

7. ANASSAS, in Natural History, the name of a fruit very common in Guinea, and in some other parts of Africa. It is very beautiful to the eye, and not less agreeable both to the taste and smell, and is by some accounted the finest fruit in the world. The descriptions we meet with of it are very imperfect, but as there is nothing in them that contradicts its being the pine-apple, it may be that fruit, and if so, it deserves all the praise that is given to it. See BRONELIA.

8. ANASSUS, or ANAXES, in Ancient Geography, a river of Italy, in the territory of Venice, now the Poce. According to M. d'Anville, it runs from the north to the south, and falls into the bottom of the gulf, to the west of Aquileia, near Muranum.

9. ANASTAMIA, in Geography, a considerable sea-port town of Japan, the principal commerce of which is wood.

10. ANASTASIA, in Ancient Geography, a town of Melopotamia, nearly south of Nisibis. It was for a long time a small place known by the name of Dara. When the Persians and Romans concluded a treaty, the emperor Anallaus fortified Dara, enlarged and beautified it, and called it Anallaus.

11. ANASTASIOPOLIS, a name given to five cities; one in Syria, another in Phrygia, a third in Caria, a fourth in Galatia, and a fifth in Thrace.

12. ANASTASIS, a Greek word adopted into the English language, which denotes a resurrection.

Chief has given us a dissertation on Childerie's tomb, under the title of Anastasii Chalderiei. Trusler has published the figure of a man and woman in the ancient German habit, as found in an ancient urn, under the title of Anastasii vetera Germani Germanorum Eaiminit.

13. ANASTASIS, among Ancient Physicians, denotes a rising up to go to flot. It likewise signifies a migration of humours, when expelled from one place and obliged to remove to ano her.

14. ANASTASII I. in Biography and History, emperor of the East, born at Dura, in Lylyricum, A.D. 432; and, from being one of the officers of the great chamberlain, called Silentiarius, and before he had obtained the rank of senator, was advanced to the empire, A.D. 491. His promotion was owing to the interest and influence of Ariadne, the widow of Zeno, who prevailed upon the senate to acknowledge Anslafius, in opposition to the claim of Longinus, the brother of Zeno, as his successor. As soon as he had attained this dignity he married Ariadne, bring them in the 50th year of his age. Such was the estimation in which he was generally held, on account of his temperance and integrity, before his advancement, that, upon his receiving the purple and diadem in the circuit, the people, applauding his promotion, exclaimed with a voice, "Regn, Anslafius, as you have lived." The first act of his reign confirmed their expectations; for he immediately remitted whatever was due to the treasury, and entirely abolished the infamous tax, called the CHRYSEURUS. He also expelled all informers from Constantinople, and put an end to the enormous abuse, introduced by his predecessor Zeno, of expelling to exile public officials, and hewing, to the great oppression of the people, the chief governors on the highland borders. The tranquility of his reign, though that popular at its commencement, was soon interrupted by the rebellion of Longinus and the Haitians, who, seizing the arms and money lodged by Zeno in a fort of Hastia, were enabled to raise and equip an army of 150,000 men. Comon, bishop of Apamea, in Syria, abandoning his flock, joined his countrymen, and became one of the ringleaders of the revolt. The emperor, however, soon collected a force, which, under the conduct of two of the most renowned generals of that age, John, the Scythian, and John, the Parthian, encountered the rebels in the vicinity of Ctyca, in Phrygia, cut off a great number of them, and obliged the rest to seek refuge among the inaccessible mountains of Hastia, where they maintained themselves for five years, notwithstanding the utmost efforts of the whole generals of the empire. In the following year the emperor, whose temper was naturally avaricious, devoted from the liberal plan with which he commenced his reign, and laid a heavy tax on the inhabitants of Constantinople, called evravias chryfothela, which, being unexpected, incurred the rage and detestation of the emperor's ministers, and dragged them through the chief streets of the city, together with those of the empress Ariadne, uttering very injurious invectives against her and Anslafius. This tumult was no sooner suppressed than it was succeeded by others equally mischievous and dangerous; in one of which the emperor narrowly escaped being murdered in the circuit by the populace, because he refused to release some prisoners who had been concerned in a riot. In 499 the Bulgarians invaded Thrace, and defeated the Romans; and in 502 the Persians entered Armenia with a powerful army, took Amida, pillaged the town, and put most of the inhabitants to the sword. In the mean time Anslafius dispatched a strong force against the enemy, which was defeated. However, in the following year, Amida was again besieged, and upon the conclusion of a truce between the Persians and Romans, the city was restored to the former, on condition of their paying to the king of Persia fifty talents. This truce between the two empires was concluded A.D. 505. About this time Monedo, a Goth, having settled with many of his countrymen, in some uninhabited places beyond the Danube, seized on a fortress called Fleria; and from hence, by frequent incursions into the Roman territories, continued to harass the subjects of the empire, and assumed the title of king. Anslafius dispatched against him Sabinianus, at the head of 10,000 chosen men; and this circumstance obliged Monedo to seek the succour of Theodore, the Gothic king...
of Italy, who had the year before reconquered Pannonia, and
recovered Scirium out of the hands of the Gothicus. Monte,
by this alliance with Theodoric, was enabled to defeat Sa-
biminus in a pitched battle, near Marquis, in Lower Dacia,
and forced him to take refuge in the castle of Nato. The con-
sequence of these hostilities was a misunderstanding be-
 tween Anaflatus and Theodoric. Such were the dangers that
threatened Constantineople and the adjacent country, that
Anaflatus was obliged to betray the impotence of his arms by
building a halver, called the long wall, and the wall of
Amphilas, of which the Byzantine historians make frequent
mention. This wall was distant from Constantineople about
40 miles, and extended about 60 miles from the Propontis to
the Euxine, including not only the metropolis, but the city of
Selymbria, and the neighbouring country, which was a
cultivated garden, with an incredible number of thatly
villas and hounts of pleasure, richly furnished and adorned.
It was 20 feet broad, and defended by towers at small dis-
tances from each other, by which means the inhabitants, upon
the slightest warning, had an opportunity of putting them-
theselves in a posture of defence, and of easily repelling the
barbarians. He likewise placed the city of Daras, a frontier
town towards Persia, to be repaired and fortified, in order to
prevent the Persians from invading the empire on that side.
The other difficulties with which Anaflatus struggled were
considerable, compared with those in which he was involved
by a religious war, the first that disgraced the Christian
name. The emperor, who was a zealous patron of the
doctrine of Eutyches, abolished the orthodox addition,"who
was crucified for us," that had been made by the devo-
tion of Antiuch to the "Trifgigion," i.e., three holy,
"Holy, holy, holy, Lord God of hosts," which was a hymn
used in public worship. This alteration occasioned a violent
tumult, in which many perfons lost their lives; and the
emperor was compelled to take refuge in his gallery, till the
orthodox patriarch, Macedonius, had pardoned and interceded
for him. Macedonius was afterwards banished, and upon his
exile the sedition was again renewed; the statues of the
emperor were broken, and his person was concealed in a suburb,
till, at the end of three days, he ventured to implore the
mercy of his subjects. Accordingly Anaflatus, without his
diadem, and in the posture of a supplicant, appeared on the
throne of the circus, and was happy to reconcile himself
with his people by the sacrifice of two unpopular minifters
who were condemned to the lions. These furious but tran-
sient seditions were encouraged by theuccfes of Vitalian,
one of the emperor's generals, who, expounding the cause of
Macedonius, and the other orthodox bishops, perfeeted
by Anaflatus, approached Constantineople with a numerous
army of Huns and Bulgarians, and threatened to depose the
emperor, if the banished bishops were not restored, and
the Eutychians expelled. As the emperor hesitated in comply-
ing with this demand, Vitalian, the champion of the catholic
faith, depopulated Thrace, besieged Constantineople, and ex-
terminated 65,000 of his fellow Christians, till at length he
obtained the recall of the bishops, the satisfaction of the
popes, and the establishment of the council of Chaleco.
In consequence of this treaty, which Anaflatus was compelled
to sign, A.D. 514, Vitalian withdrew from Constantineople,
and disbanded his troops. Pope Symmachus, it is said,
engaged in this quarrel, and, by excommunicating Anaflatus,
let the first example of the employment of spiritual thunder
against adversaries. Anaflatus, delivered from his fears, re-
newed his persecution of the catholics; but he did not long
survive the humiliating act to which he was obliged to sub-
mit. In the year 518, the 88th year of his age, and the
28th of his reign, he suddenly closed his life, being as much
hated and persecuted by his subjects in his latter years, as he
had been beloved and exalted in his earlier days. By the
Catholic historians he is charged with avarice and cruelty,
and almost all the crimes that could disgrace a sovereign;
but his want of orthodoxy, which, in their judgments, was
one of his greatest crimes, might possibly induce them to ex-
aggerate his other bad qualities. The vast treasure which he
possessed at his death was accumulated by the sale of public
offices, and by sharing with his governors the spoils of an
Anaflatus II., whose proper name was Artemius, was
advanced by the free voice of the senate and people, to the
throne of Constantineople, A.D. 713, from the low condi-
tion of a secretary to his predecessor Philippius, who had
been deposed.
He was a man of learning and prudence, and had been
from his youth employed with singular success in the man-
agement of public affairs. In the beginning of his reign he
appointed Leo, the Itaurian, a person of great military
experience, commander in chief of all his forces, and sent
him with a powerful army to the frontier of Syria, in order
to protect Asia Minor against the inroads of the Saracens.
He also prepared for defending their design of laying siege
to Constantineople by a naval armament; by repairing the
walls, by filling the public granaries, and by ordering those
citizens, who had not laid up provisions for three years, to
quit the city. When news was brought that the enemy's
fleet had failed to Phcenicia, he ordered his to assemble at
Rhodes; but the admiral by his endeavours to maintain strict
discipline,occasioned a mutiny, and lost his life. The fea-
men, dreading the punishment which they deferred, and
knowing that they could not avoid it, openly revolted, de-
clared Anaflatus unworthy of the empire, and obliged
Theodorus, a person of mean extraction, and receiver of
the revenue at Atradum, to accept of the purple.
Anaflatus, when he heard of this revolt, fled to Nice; and
Theodorus hastened to besiege Constantineople, which he
reduced after a defence, on the part of the garrison, for six
months. Anaflatus, being promis his life by the con-
queror, renounced all claim to the empire; and, assuming
the habit of a monk, was banished to Thessalonica, after he
had enjoyed the title of emperor about two years. In 719,
whilst Leo was emperor, Anaflatus quitted his retirement,
and induced the Bulgarians to acknowledge and support his
claim to the crown. With a numerous army of these barba-
rions he laid siege to Constantineople; but his followers,
being disappointed in their expectation of easily becoming
masters of the city, feized the unfortunate Anaflatus, and
delivered him up to the emperor, who put him and his ac-
Anaflatus, pope, succeeded Syricius in the papal chair,
A.D. 355. During his pontificate a dispute arose between
Jerome and Ruffinus, occasioned by the following circum-
stance. Ruffinus, being an admirer of Origen, had pub-
lished a Latin translation of his "Periarchon," or treatise
of principles, which was much read at Rome, and served to
delineate the distinguishing sentiments of this celebrated fa-
ther. Having published this translation, without any anti-
maderverion on the part of Syricius, he left Rome, and re-
turned to Aquileia, where he was presbyter. Upon the ele-
vation of Anaflatus, Marcellus, a Roman matron, complained
to the new pope of the prevalence of new doctrines, re-
quested his interposition for preventing the evil, and accused
Ruffimus
Rufinus, the author of the translation to which it was owing. Anastasius, for some time declined either proceeding against Rufinus, or continuing his translation; but at length Arnaud, in a new version of the work, undertook to prove that several opinions at Origen were heretical, and as such ought to be condemned by the church. He also inveighed against Rufinus, suggesting, that he had translated the work of Origen merely for the purpose of propagating the errors which it contained. A council was convened, which condemned the errors of Origen, and Origen himself as a heretic, and forbade all persons, under the jurisdiction of several of the bishops, who were assembled, either to read or to retain in their possession, any of his works. Origen being thus condemned as a heretic, about 150 years after his death, Anastasius, at the mitigation of Marcellus, and some of Jerome's friends, summoned Rufinus to Rome, and demanded an account of his faith. Rufinus sent a confession of his faith to Anastasius, but it was not satisfactory; and the pope was at first prevailed upon to separate himself from communion with him. Anastasius has no other claim to notice than that of being a zealous defender of the Catholic faith. He died in 402; and his epistle to John, bishop of Jerusalem, who had written to him in behalf of Rufinus, is extant. Fabr. Bib. Grec. lib. c. 35. § 8. Dupin's Ecc. Hist. vol. iii. p. 58. Bower's Lives of the popes, vol. i. p. 277, &c.

Anastasius II. pope, was the son of a Roman citizen, and succeeded Gelarius, A. D. 496. He was more peaceably disposed than either of his two predecessors, and was dehors of effecting a reconciliation between the see of Rome and that of Constantinople, which had for some time been at variance. With this view he wrote a humble and respectful letter to the emperor Anastasius, and sent two bishops, accompanied by Felix the patrician, as legates, to execute his purpose. Although the bishops were well received by the emperor; he chose to confer with Felix rather than with them; and he contrived to pervert him to sue his interest with the pope for reconciling the eastern and western churches, upon such terms as he thought proper to propose. The pope himself was disposed to acquiesce; and to allow the name of Acacius to remain in the Dityches, as well as to receive and sign the Henoticon; but this conciliation on his part gave great offence to the Roman clergy. The church of Alexandria, availing themselves of the peaceable disposition of the pope, sent deputies to Constantinople in order to negotiate a reconciliation with Rome. But these pacific measures were defeated by the premature death of Anastasius. Whilst the legates were on their return to Italy, and before they reached Rome, the pope died, A. D. 496; and this unpromising event was a great disappointment and mortification to Felix, who, depending on his inclination to peace, and the confidence reposed in him by the pope, had entertained hopes of soon restoring the ancient harmony between the east and west, and of being himself instrumental in accomplishing so desirable an object. The disposition and conduct of Anastasius, who was ready to sacrifice even the pretensions of his see to the welfare of the church, however laudable in themselves, were no recommendation to the honours that were conferred in that age of ignorance and bigotry. He was not thought worthy of a place in the calendar; and his memory has been asperated, as if he were an enemy to the Catholic faith; and his death, before he had completed two years of his pontificate, has been represented by Platina and others as a judgment from heaven. His letter to the emperor, and another to Clavis, the first Christian king of the Franks, congratulating him on his conversion to the Christian religion, are still extant in the Books of councils. Cave's Hist. Let. vol. i. p. 495. Fabr. Bib. Grec. lib. c. 35. § 8. Bower's Hist. Popes, vol. iii. p. 258, &c. Dupin, Ecc. Hist. vol. iv. p. 181.

Anastasius III. pope, was by birth a Roman, and succeeded Sergius, A. D. 911. This pope, at the request of Berengarius, king of Italy, sent many rich ornaments to the church of Pavia, and granted to the bishop of that city the use of a canopy, the privilege of riding a white horse, with the croziers carried before him, and of sitting in all councils at the pope's seat. He died in 913, and was buried in the Vatican. He is commended in his epitaph for the mildness of his government, his integrity, and the purity of his manners. He died nothing blame-worthy,fails Platina, which, in the popes of those days, was a subject of commendation. Bower, vol. v. p. 85.

Anastasius IV. pope, was a native Roman, of the name of Conrad, and succeeded Eugenius III. A. D. 1157. His temper was mild and peaceable; of which he gave evidence in his method of compromising a difference that had arisen in the last pontificate between the emperor Frederic and the Court of Rome. For this purpose he sent cardinal Gerhard into Germany, whose impertinent behaviour incurred the displeasure of the emperor, so that he was ordered to quit the country. The cardinal, it is said, died of grief in his way to Rome. This pope took no notice of the allarm, but yielded to the emperor the point in dispute. This conciliatory conduct, which might possibly have been the means of preventing the horrors of war, has been condemned by the advocates of the dignity of the papal see, as an instance of irresolution and putridness. Anastasius restored William, archbishop of York, who had been deposed by Eugenius, to his see; and in the same year he also inflicted a bull, confirming and enlarging the privileges of the Knights of the Hospital at Jerusalem, since known by the name of the Knights of Malta. In a great scarcity of corn, which happened during his pontificate, he manifested his humanity by liberally contributing to the relief and supply of the poor. After a Pontificate that lasted little more than a year, Anastasius died, A. D. 1154; and was buried in the church of the Lateran, in a tomb of porphyry, exquisitely wrought, in which had lain the body of St. Helena, the mother of the emperor Constantine. Ten letters of this pope are preserved in the Collections of Councils by Labbe and Harduin, and in du Chése's History of France. Fab. Bib. Grec. lib. c. 35. § 8. Bower's Hist. vol. vi. p. 75, &c.

Anastasius, anti-pope, was elected in 855 by the envoys of the emperors Lotharius and Lewis in opposition to Benedict III. ; but the bishops of Othii and Albano, alleging that he had been deposed in a council, refused to consecrate him; upon which the envoys abandoned Anastasius, and he was obliged to relinquish his pretensions. Bower's Hist. vol. iv. p. 265, &c.

Anastasius Sinait, a monk of Mount Sinai, lived in the sixth century, in the year 561 was promoted to the dignity of patriarch of Antioch, and died in 599. Evagrius represents him as a person eminently skilful in sacred literature, exemplary in his conduct, and particularly attentive to the duties of piety. He was the author of several works in Greek, which are still extant; such as "Omnes, or "A Guide in the Way against the Acropolys," printed in 410. at Ingolfstadt in 1666. "Quellen et Responiones de varii Argument in S. Scripturnm," numero 154; printed in Greek and Latin at Ingolfstadt in 1617, 410. "Anagogiarum Contemplationum in Hexameron, libri iii." or, "Mysteries Contemplations on the six Days' Creation," published...

Anastasius, Theodotius, was bishop of Antioch, and flourished in the sixth century. He expounded the opinions of a sect denominated Aphthartodorces, and on this account Julianus designed to depose him; but being prevented by death from executing his purpose, Julianus the younger banished him in 570, and he remained in exile twenty-three years. Mauritius restored him to his see in 593. He died in the year 599, and was succeeded by another Anastasius, who was killed in a tumult by the Jews in 609. This bishop of Antioch has left some sermons, and treatises on the Trinity, and other points of faith, which were published in Latin at Ingolstadt in 1616, 4to.; and also the “Annunciation of the Virgin Mary, and Transfiguration of Christ,” published in Greek and Latin, in the first volume of “Commeni. Auctarum,” fol. Paris, 1648. Fabr. Bib. Græc. lib. 5. c. 35. § 1. tom. ix. p. 312. p. 332.

Anastasia, the Librarian, was a Roman abbot and prebendary, and flourished in the ninth century. He had the charge of the Vatican Library under several popes; in 869 he assembled at the general council of Constantinople, and translated into Latin the acts of that council, and also the acts of the council of Nice, held in 787, which are still extant. To this translation he prefixed “A History of the Schism of Photius and the Council.” He also wrote, or compiled, the lives of the popes down to Nicholas I. continued by others, and published with the ecclesiastical history of Nicephorus Syncellus, and Theophanes, at Paris, in 1629, fol. An enlarged edition of this work has been since published by Bianchini, in four volumes folio, at Rome, in 1718. Anastasia was a learned man, and a tolerable writer. Cave’s Hist. Lit. vol. ii. p. 56. Fabr. Bib. Græc. lib. v. c. 35. § 8. tom. ix. p. 332.

Anastasia, St. in Geography, a small island near the coast of Eil Florida, south of Mallacoota inlet, where the river Mallacoota forms two islands of the same name at its mouth. St. Anastasia island is bounded on the north by St. Augustine’s bar. It has a quary of fine stone for building.

Anastasia, formed from ovata, referring, from its quality of surviving in water, in Botany, a genus of the tetracyclina fusculosa clausa and order, of the natural order, filiformis, or crustiformes, and the crustacea of Jullien; its characters are, that the calyx is a four-leaved and deciduous perianthium; leaves ovate, elong. convexe, erect and deciduous; the corolla is tetrapetalous and cruciform, the petals roundish, flat and spreading, with claws nearly as long as the calyx, but more spreading; the stamens have six filaments, staminate, of the length of the calyx, from erect spreading; anthers roundish; the pistillum has a bifid, very small germ, staminate style of the length of the stamens, and permanent, the stigma capitate; the pericarpium is a very short siliqua; partition ending in a staminate point, oblique and longer than the stile itself, the valves parallel, making a cell of the lower half, but standing out from the upper, rounded, convexe, gaping, and oblique, and hence having the form of a sheep’s hoof; the seeds are solitary and roundish. There are two species.

1. A. hierociontis, thalphi rota de hierico of Mor. Hist. rota hierociontis of Bauhin and Ray, &c. common anaftasia, or rota of Jericho, with leaves obtuse, spikis axillary and very short, stiliaceous and thorny. This plant grows naturally on the coasts of the Red Sea, in Palestine, and near Cairo, suddenly places; and was cultivated in Kew Garden by Tradescant in 1633. It has the epithet of thero or Marie given to it by the monks, who have superstitiously imagined that the flowers open on the night in which our Saviour was born. But the truth is, that the dry woody plant being set for some time in water, will dilate and open, so as to disclose the feed needles and feed. This has been done when the plants have been many years gathered; so that some curious persons prefer them in their repositories of curiosities, for the singularity of this property. 2. A. friana, bonis friana of Gardiner, maygrum rotatorium of Super. Zan and Pallas, thalphi, &c. of Bosc. Muif. rota hierociontis, similar of Baulin, Syrian anaftasia, with leaves acute, spikes longer than the leaf, stiliaceous ovate, beaked, and not at all biled. This is a native of Austria, Stiria, Carniola, Syria, and Sumatra, and was introduced in 1788 by M. Thouin. It flowers in May and June.

Culture.—These plants, being annual, can only be propagated by seeds, which rarely ripen in England, unless they be sown on a hot-bed in the Spring, and the plants afterwards put into pots, which should be plunged into another hot bed, in order to bring them forward. They will not perfect seeds unless the Summer is very hot and dry; but if they are kept in a frame, with free air in warm weather, they will flower in June, and the seeds will ripen in September. Martin’s Miller.

Anastasia, in Natural History, a species of verticilla, in the fifth order of Vermes, Infusoria. It is compound, with bell shaped flowers; foot-stalks feally and rigid. Linn. and Mill.

This is the second species of clustering polype described by Trembley. These polypes form a group resembling a clouther, or more properly an open flower; this flower or clouther is supported by a stem, which is affixed by its lower extremity to some of the aquatic plants, or extraneous bodies, that are found in the water; the upper extremity forms itself into eight or nine lateral branches perfectly similar to each other; these have also subordinate branches, whose collective form much resembles that of a leaf. Every one of these affemblinges is composed of one principal branch or nerve, which makes with the main stem of the clouther an angle somewhat greater than a right one; from both sides of this nerve the smaller lateral branches proceed; these are flatter the nearer their origin is to the principal branch.

At the extremity of the principal branch, and also of all the lateral ones, there is a polype or verticilla. There are others on both sides of the lateral twigs, but at different distances from their extremity. These polypes are all exceedingly small, and of a bell-like figure; near their mouth a quick motion may be discerned, though not with a sufficient dilitufness to convey an adequate idea of its caule; upon the branches of these clouthers are round bodies.

Every clouther has eight or nine of these branches or leaves; they do not all proceed from the same point, but the points from whence they set out are not far alander; each of these branches is bent a little inwards, so that all of them taken together form a kind of shallow cup. If the eye is placed right over the base of this cup, the appearance of the whole eight or nine branches is like that of a fan, with so many rays proceeding from the center. If the clouther is slightly touched, all the branches instantly fold up, and form a small round mass. The stem which supports the clouther contracts also at the same time, folding up like a workman’s measuring rule, that consists of three or four joints. This extraordinary affembling constitutes one organized whole, formed of a multitude of similar and particular ones. A new species of society, in which all the individuals are members of each other in the strictest sense, and all participate of the same life.

A few days after one of these clouthers is formed, small round
round bodies or bulbs may be perceived to protrude in several places from the body of the branch; these grow very fast, and arrive at their greatest growth in two or three days. The bulbs detach themselves from the branches out of which they spring, and go away, swimming till they can settle upon some habitation which they meet with in the water, and to which they affix themselves by a short pedicle; the bulbs are then round, only a little flattened on the under side, the pedicle continues to lengthen gradually for about twenty-four hours, during which time the bulbs also change their figure, and become nearly oval; there are in a cluster but few of these bulbs compared with the number of vorticelles, neither do all the bulbs come out at the same time. The bulb then divides lengthways into two smaller ones, but which are still much larger than the vorticelle themselves. It is not long before these are separated from the first, and thus form four bulbs on the same stalk; these again divide themselves and form eight, which again subdivide, and consequently make sixteen. They are all connected with the stalk by a proper pedicle, but they are not all of an equal size; the largest continue to divide, and the smallest begin to open, and take the bell-formed shape. Mr. Trembley observed from one round bulb in about twenty-four hours, by repeated divisions, one hundred and ten vorticelle to be formed. Vide Phil. Trans. Adams Microsc. &c. &c.

ANASTOMASIS, or Anastomosis, formed of an, through, and vena, month, in Anatomy, is sometimes used to express such aperture of the mouths of the vessels as lets out their contents.

ANASTOMASIS is more frequently used to denote the opening of two vessels into one another; or the union and juncture of the mouths of two vessels, whereby they come to communicate with the other.

Anastomosis take place in considerable number in the absorbing and circulating vessels of animals. For an account of their number, situation, and uses, the reader is referred to the articles Absorbing Vessels, Artery, Circumstances observable in the Ramification of, and Vessel, Circumstances observable in the Distribution of.

ANASTOMOSIS, in Botany, a species of Phalus.

ANASTOMOSIS, in Entomology, a species of Phalena of the bombyx tribe. Thorax reddish-brown; anterior wings, grey, with three whitish, anastomosing streaks. Limous.
The larva is brown, with white spots on the back, lateral line yellow, with a red dot on each ring; a bifid protuberance on the shoulders and tail; pupa black, with two red, longitudinal streaks; feeds on the willow.

ANASTOMOTICS, formed from anasomos, but, or Anastomotic medicinae, are, in a general sense, the same as apertures; but in a more special sense, the term denotes such as are fitted to open the extreme orifices of blood-vessels, so that the blood may circulate the more freely.

ANASTROUS, fætæs, in Aestivation, an appellation given to the dodécatomia, or the twelve portions of the eclipse which the signe passed anciently, but have been deserted by the prelection of the equinox.

ANASTROPHE, from an and strophe, I turn, in the Ancient Military Art, denotes the turn of a battalion to its former latton, after a turn or evolution either to the right or left. The anathrope stands opposite to the epistrophe.

ANASTROPHE also denotes a grammatical figure, whereby a preposition, which regularly ought to precede, is placed after its case, e. gr. "Saxa per et escopolus," for "per Saxa et escopolus."

ANASTROPHE, in Retorica, denotes a quaint inversion of the order of the words in a sentence, e. gr. "ut sitque posset ad quo expedita loqui," for "quo ad expedita loqui."

ANASUS, or ANUS, in Ancient Geography, now the

ANATHEMA, from an and theo, I lay up, in Antiquity, denotes a present offered to some god, and hung up in his temple.

Making presents to the gods was a custom even from the earliest times, either to pacify them when angry, or to obtain some future benefit, or as a grateful acknowledgement of some past favour. They consisted of crowns and garlands, garments, cups of gold, and other valuable metals, and any other things which conduced to the ornament, or to the enriching of the temples.

There were commonly termed anabaptiste, and sometimes antikleistus; from their being deposited in the temple, where they were sometimes laid on the floor, sometimes hung upon the walls, doors, pillars, or the roof, or any other conspicuous place. Sometimes the occasion of the dedication was inferred either upon the thing itself, or when the matter of that could not bear inscription, upon a tablet hung up with it.

When any perfum left his employment, or way of life, it was customary to dedicate the instruments belonging to it, as a grateful commemoration of the divine favour and protection. Thus in an ancient Greek epigram we find a fisherman makes a present of his nets to the nymphs of the sea. Shepherds hung up their pipe to Pan, or some of the country deities, as we find done by one in Tibullus. So Lais, decayed with age, dedicates her mirror to Venus. Pafanizes has left us a particular description of the anathemata, in the Delphian temple, which was the richest of any in Greece.

The term anathema also occurs in a like sense, applied to Christian offerings.

The anathemata, or ornaments of the ancient churches, are otherwise called in ecclesiastical writers donaria.

Such in particular were those called anathemata, answering to the votive tablets of the heathens. Also pictures, medallions, inscriptions, and at length images, statues, crucifixes, &c.

Cebos's beautiful tabulation of Human Life, is laid in the introduction to it, to have been among the anathemata, in the temple of Saturn.

ANATHEMA, in an Ecclesiastical sense, denotes an excommunication, attended with execrations and curses. In this sense the word is usually written in Greek anathema, to distinguish it from an offering to the gods, called anabaptiste; though it is certain several of the Greek fathers do not observe this distinction; but use anathema indiscriminately for both.

There are two kinds of anathemata; the one judicial, the other abjuratory.

The former can only be denounced by a council, a pope, bishop, or other qualified person; and differs from a simple excommunication in this, that an excommunication only prohibits the criminal from entering within the church, or from holding communion with the faithful, whereas an anathema cuts him off from the body, the society, and even the converse of the faithful, and delivers him over to the Devil.

The latter kind of anathema usually makes a part of the ceremony of Absolution; the convert being obliged to anathematize the hereby abjured.

The critics and commentators are divided about the manner wherein St. Paul wishes to be anathema for his brethren. Romans ch. ix. 2. See Accursed.

In ancient censures we meet with an extraordinary for-
ANATHO, or ANNAH, in Ancient Geography, a city of Mesopotamia, the actual residence of an Arabian Emir, was composed of two long streets, which included, within a natural fortification, a small island in the midst, and two fruitful spots on either side, of the Euphrates. It was situated on the south-east of Cirethum. The warlike inhabitants of Anatho showed a disposition to fly the march of a Roman emperor; till they were diverted from such fatal premonition by the mild exhortations of prince Hormidas, and the approaching terror of the fleet and army. They implored, and experienced, the clemency of Julian, who transplanted the people to an advantageous settlement near Chalae, in Syria, and admitted Pseudo, the governor, to an honourable rank in his service and friendship. See ANAN.

ANATHOTH, a city of Palestine, north-east of Jerusalem, and not far from it. This city had been given to the Levites, and was one of the cities of refuge. It belonged to the tribe of Benjamin; and was the birth-place of the prophet Jeremiah, and the inheritance of many of the Jewish pontiffs.

ANATHREPSIS, in Medicine, amounts much to the same with analepsis.

ANATICULA, a diminutive of anas, and used by the old Roman Authors, as a term of fondness, to express the passion of love. There is another of the same kind from a different bird, palumbus.

My little duck, my little dove, were the most endearing terms the lovers of those times could use; nor was this the custom of the Romans only, but the Greeks, as far back as Arilophanes, have it.

ANATIFERA, in Zoology, a species of lepas, called bernacle, that adheres by means of its membranous pedicle to the bottoms of ships, timber, and other substances floating in the water. The shell is compressed, and consists of five valves, is smooth, and affixed to a pedicle. Linnaeus.

This curious marine production consists of many unequal membranous branches, or arms, at the ends of which the shells are disposed in an irregular manner; the larger clustering with the smaller in groups, and forming bunches of various sizes. The branches are of a fine red: the shells of a bluish violet. The animal within is a triton, and is furnished with many cirribi, or tentacula, with which it takes its food. These tentacula are pelticated like feathers, and hang out of the shells when open. In the 16th century they were in fact supposed to be feathers, and hence arose the whimsical belief that these shells produced geese, of the species called bernacles. (Anna Erythropolis of Linnaeus.) Nor was this a vulgar opinion only; it was sanctioned by the grave details of naturalists of that time, and particularly by Gerard, whose observations are worthy of notice.

"What our eyes have seen, and hands have touched, we shall declare. There is a small island in Lancashire, called the isle of Foulere, wherein are found the broken pieces of old and bruised ships, some whereof have been cast thither by shipwreck, and also the trunks and branches of old and rotten trees, call up there likewise; whereon is found a certaine pine, or froth, that, in time breedeth unto certaine shells, in shape like those of the muskell, but sharper pointed, and of a whitish colour, wherein is contained a thing in form like a lace of fife, finely woven as it were together, of a whitish colour; one end whereof is fastened into the inside of the shell, even as the fifth of oysters and mussels are; the other end is made fast unto the belly of a rude maffe, or lumpe, which in time commeth to the shape and form of a bird. When it is perfectly formed, the shell gapeth open, and the first thing that appeareth is the foresaid lace or fibling; next come the legs of the bird, hanging out, and as it groweth greater it openeth the shell by degrees, till at length it is all come forth, and hangeth only by the bill; in short space after it cometh to full maturitie, and fallith into the sea, where it gathereth feathers, and groweth to fowle bigger than a mallard, and leffer than a goose; having blacke legs and bill or beak; and feathers blace and white, spotted in such manner as is our magpie, called in some places..."
places a pie-annet, which the people of Lancashire call by no other name than a tree goose; which place aboved, and all those parts adjoining do so much abound therewith, that one of the best is bought for three-pence. For the truth hereof, if any doubts, may it please them to remove unto me, and I shall institute them by the tellamore of good vituailles," Gerard's Herbal.—Vide Donov. Brit. Shells, &c.

ANATII. in Ancient Geography, a people of Gallia Narbonensis, mentioned by Pliny. Their situation is disputed. Martin says, that they were situated to the left of the mouth of the Rhone, near the site of the lake called Sugmum Tauri, and he supposes that they were the same with the Atlantus of Avienus. Some authors have inferred from an inscrption of questionable authority, that their capital was Hercules. M. d'Anville places them at the mouth of the Rhone, more to the right than to the left.

ANATINA, in Conchology, a species of Mya. Shell globular, brownish white, and pellucid; primary tooth of the hinge prominent and rounded. Gmelin. This shell is found on the shores of Guinea, and other parts of Africa, and bears young affinity to Solen anatina. It is marked with streaked lines, that intersect each other.

ANATINA, is likewise a species of Ostrea, that inhabits the Nicobar islands. The shell is pellucid, lamel-lated and laterally incurred. Gmelin. It is thin and fragile, and variegated with white and violet, and about three inches in length, including the incurvature, which is nearly half of that length. From a fancied resemblance of this shell to a duck when fitting it has acquired the specific name anatina.

ANATINUS, in Conchology, a species of Solen. The shell is ovate, membraneous, and covered with pile or soft hairs; a hooked rib at the hinge. This species is found on the sandy shores of the Indian ocean, and is named by Rumphius rodrum anatias. It is pellucid, white, and very thin; one end rounded, the other gaping. Tooth in both valves of the figure of an ear-picker. Gmelin.

ANATINUS, is likewise a species of Mytilus, of an oval shape, somewhat compressed fragile, with a membraneous margin, and decorated beaks. Gmelin. This species has been frequently confounded with Mytilus cygnecus; from which it differs in several particulars. It is very common in the rivers of England, and is known by the name of duck or small horse mussels. Vide Donov. Brit. Shells, pl. 113.

ANATIS, in Ancient Geography, a river, which, according to Pliny, belonged to Mauritania Tingitana.

ANATIS, in Entomology, a species of Pediculus that infests the wild duck. It is whitish; first segment of the thorax orbicular, truncated on each side, the other and the abdomen long and narrow. Scharneck.

ANATIS, in Natural History, a species of Ascaris, of the order Intestina in the Vermes class, that is found in the intestines of the wild duck, (anas boschas). It is from four "six inches in length, and is viviparous. The specific character, according to Gmelin, is, white, posterior part flatfish.

ANATIS is also the specific name of another creature that is found in the intestines of the velvet duck. The body is scarlet, its form ovate, thorax and proboscis covered with hooked points, and it has a long smooth intermediate neck. Gmelin. This belongs to the genus echinorhynchus, in the order intestina and Vermes class.

ANATIS is likewise the specific name of a third creature of the order of the intestina in the class of Vermes. This is Fasciola ANATIS of Gmelin. The body is reddish, and of a roundish form, with a single pore. This kind is found in the intestines of the domestic duck. It is small, somewhat pellucid, and uniformly white, the forepart truncated and triangular, behind roundish, intestines long and blackish.

This is ceculus considericus of Bloch, and hirudo falcularia of Mull. Z. J. Dan.

ANATOCISM, ANATOCISMUS, an furious contract, wherein the interest arising from the principal sum are added to the principal itself, and interest exacted upon the whole. The word is originally Greek, but used by Cicero in Latin; whence it has descended into most other languages. It comes from the proposition ana, which in composition signifies repetition or duplication, and the suffix, injury.

Anatocism is what we properly call interest upon interest, or compound interest.

This is the word kind of injury, and has been severely condemned by the Roman law, as well as by the common laws of most other countries. See Interest.

ANATOLIA, in Geography, a province of Turkey, in Asia. See Anatolia.

ANATOLIUS, in Biography, patriarch of Constantinople, succeeded Eulian in the year 449. Before his entrance to this dignity, he favoured the Eutychians; but after the accession of Marcian, he attached himself to the party, which he patronized, and which held the orthodox faith of two natures in Christ, and thus ingratiated himself both with the emperor and with pope Leo. Whilst he was supported by the imperial power, he maintained a vigorous contest with Leo, for the equality of the two churches of Rome and Constantinople, but when Marcian seemed to be inclined to allow to the see of Rome the supremacy in the church, he acquiesced. In order farther to engage Leo's favour, he called a council at Constantinople, which denounced an anathema against Nestorius and Eutyches; and then sent deputies to the pope to affume him of the purity of his own faith. He afterwards concurred with the emperor Marcian and the pope in hostile measures against those who did not openly professed the doctrine of the church. Upon the whole, Anatolius seems to have been a time-serving ecclesiastic, whose character claims no commendation. Duspin's Eccl. Hist. vol. iii. p. 228.

ANATOLIUS, bishop of Laodicea, in Syria, was a native of Alexandria, flourished under the emperors Probus and Carus, and succeeded Eusebius about the year 270. He was the most eminent prelom of his time, for his acquaintance with philosophy and the Greek literature, and for his skill in arithmetic, geometry, astronomy, grammar, rhetoric, and logic. His distinguished qualifications recommended him to the citizens of Alexandria, and at their request he is said to have set up a school for the Aristotelian philosophy. The tenets of the Peripatetic sect were the basis of his system, and with them he incorporated other doctrines, both Pagan and Christian, thus forming a new school, in which Aristotel was the chief matter. Some have doubted whether he actually complied with the request of the Alexandrians, and set up such a school; however this be, none of his commentaries upon Aristotel are extant, and, therefore, the particular manner in which he philosophized is unknown. Whether he was a native Christian or a convert from paganism, is not certain; but he was undoubtedly a Christian long before he became bishop of Laodicea, for he was upon terms of intimate friendship with Eusebius, his predecessor in that see, about the year 265, when Bruchium, or Pylrichium, one of the quarters of the city of Alexandria, in which was the citadel, was besieged. A circumstance occurred on this occasion, which reflects peculiar honour on his character. See Alexandria, Eusebius.
Eusebius says of him, that with universal consent he had pre-eminence above all the magistrates or senators of Alexandria, that were in Alexandria. After this he left Alexandria, and went into Syria; and he was ordained bishop by Theoctistus, bishop of Caesarea, designated by him for his successor, and actually appointed his colleague; but in his way to a council at Antioch, held by the Christian brethren upon the concerns of Paul of Samo- nate, he was detained at Laodicea, and appointed bishop of that city. Anatolius appears to have been a distinguished ornament of the Christian church; and though he did not write many books, yet his eloquence and extensive knowledge and learning are sufficiently manifest in those that are extant. His work on "Ecclesiasticus," called "The Pseudo-Canon," is cited by Eusebius; and an ancient Latin version of it, said to be Räfumus's, was published by Augustinus Bucerus, in folio, at Antwerp, in 1634. Of his ten books of "Institutes of Arithmetic," extracts are preferred in a collection, entitled "Theologumena Arithmetica." Some fragments of his philosophical writings are collected by Fabrianus, from which it appears, that, after the publication of his treatises on physics and mathematics, he made mathematical learning subservient to philosophy. This learned Alex- andrian concurred with other Christians, in a high respect for the scriptures of the Old and New Testament. The time and manner of his death are not certainly known; but some have supposed that he died a martyr. Enseb. Hist. Eccl. lib. vii. c. 32. p. 284. ed. Vales. Cave's His. I., vol. i. p. 136. Fabr. Lib. Gr. lib. iii. c. 10. tom. ii. p. 275—278. Brucker's Hist. Phil. by Enfield, vol. ii. p. 306. Lardner's Works, vol. iii. p. 265—269.

Fabrianus (B. G. lib. Gr. lib. vii. tom. v. p. 277.) has mentioned several other works of the same name, which ought to be distinguished from Anatolius, of whom we have given an account. Cave also (ubi supra) shows, that this Anatolius is different from him, whom Eusebius mentions as master of Jamblichus; though they are confounded by Valesius, and his opinion has been approved by Balfage. Anatolius, of Berytus, in Phoenicia, was a man of great learning, good judgment, and much candour. He was a faithful subject and able officer, under the emperor Constantius, being prefect of Illyricum, from the year 358 to the time of his death in 360. Photius, speaking of his work concerning agriculture, says, that it is a collection out of several writers upon the same subject, such as Democritus, Aetius, and Athenaeus, Perseus, Apuleius, Florus, Valens, Leon, and Pamphilius, and also from the paradoxes of Diophanes. The work consists of 12 books or sections. It contains, says Photius, many useful directions for agriculture and husbandmen, and may be reckoned one of the best books written upon the subject. There are infested at the same time many strange and incredible things, favouring of the error of Gentilism: but he adds, a pious hus- bandman may let those things alone, and forget only what is useful. Anatolius is highly commended for his integrity and eloquence, for his knowledge of the laws, and for his patronage of learning. Lardner's Works, vol. ix. p. 8—11.

ANATOMY. The word signifies simply dissection, yet there are usually comprehended under this term all those artifices by which the structure of animal bodies is developed and exhibited. As a science, anatomy must be admitted to be of the highest and most important; and while other sciences lead us abroad in pursuit of knowledge, in this we are engaged at home, in the study of our own being, in the means by which we live, and move, and have our being. Anatomy also furnishes us with knowledge which teaches how to preserve health, to correct disease, and rectify the effects of those injurious to which we are inevitably exposed.

Anatomy is divided into human and comparative; in the former our references are restricted to our own bodies; but in the latter, we may range over the whole field of animated nature.

The anatomical description of the body is technically arranged under the following heads, to which we refer the reader for more particular information.

1st. Osteology, or the description of the skeleton, shape, and parts of the bones.

20d. Syneciology, or the description of their connection by ligaments, and the structure of the joints.

3d. Myology, or a description of the moving powers or muscles.

4th. Angiology, or a description of the vessels engaged in nourishing the body, in absorption, and in the removal of superfluous parts.

5th. Aenology, or a description of the glands, in which various liquids are separated or prepared from the blood.

6th. Splanchnology, or a description of the different bowels, which serve various and different purposes in the animal economy.

7th. Neurology, under which title the brain, the nerves, and organs of sense must be comprehended.

This arrangement, which is not very well adapted to the purposes of anatomical description, is, however, not at all suited to the views of physiology; for this subject, therefore, we must refer the reader to another series of articles. The functions carried on in animals, in the explanation of which physiology consists, may be thus arranged.

The terms, however, by which they are distinguished, do not exactly express the nature of each function, as will be shown more at large under their respective titles.

1st. Digestion, or the conversion of extraneous matter into the nature of their own bodies.

2d. Circulation, or the distribution of the converted matter to every part of the animal for its repair and augmentation. The proofs is named circulation, from the mode in which it is carried on in the generality of animals.

3d. Secretion, or the separation and deposition of the particles composing the structure of animals and vegetables, as well as various substances which they produce from the circulating fluids.

4th. Absorption, by which external matter is imbied, and that which is deposited by secretion more or less removed.

5th. Respiration, or the exposure of the nutritive fluid to the action of the atmosphere.

6th. Irritability, or the action which is exerted in carrying on the circulation, secretion, and absorption, and which is more strikingly manifested in the accidental actions of the muscular powers.

7th. Sensation, by which animals become conscious of the existence of external objects, and also of their own.

8th. Generation, by which new beings, similar to the parents, are formed and produced.

Most of these powers are observable in vegetables.

ANATOMY. History of: The writers on the history of medical science, and of anatomy, as forming a part of it, generally divide it into four portions. The first contains the state of these sciences previous to the life of Hippocrates, who was born about 460 years before the Christian era; the second contains an account of the additions and alterations that were made before, and by the labours of Galen, who lived about one hundred and fifty years
years after the birth of Christ. The third part comprehends the declension of these sciences, with learning in general, in the sixth and seventh centuries, and their revival in the fourteenth and fifteenth, to their more perfect establishment by Harvey’s discovery of the circulation of the blood. The fourth part contains an account of the more perfect state of these sciences from Harvey to the present time. The study of investigating the structure of the body seems so natural a kind of curiosity, and so intimately connected with self-preservation, that we cannot wonder if a considerable portion of such knowledge should be acquired, even where the opportunities of research may have been very limited and inadequate. Onai, who was brought by Capt. Cook from Owhyhee, when he surveyed Dr. Hunter’s Museum, manifested considerable acquaintance with the subjects before him, and a great desire of further information. The slaughter of animals for food, the preparation of them for sacrifice, and accidental opportunities of examining the human skeleton, &c. were the first sources of anatomical information.

Amongst the Egyptians, the most ancient nation, of whose manners we have authentic memoirs, the rites practiced in honour of the dead, by embalming their bodies, would familiarize the people to anatomical inquiries. The custom of carrying about, at their seasts, a skeleton, left their guests, in the midst of feasting and merriment, should forget the frail tenure of life and its enjoyments, seems a sufficient proof of this affection. It is also related, that one of their kings left writings on anatomy.

Our accounts of this science are, however, very slight and imperfect, till it was cultivated by the enlightened inhabitants of Greece. If the pursuit of anatomical knowledge is so natural and important as to interest even barbarous nations, it was likely to be professed with greater ardour and success as knowledge increased, and the powers of the mind in obtaining it began strengthened by exertion. At the time of Homer the Grecians seem to have possessed much general anatomical knowledge, as the writings of that poet evince. We read, that the stone, which Diomed threw at Ajax, not only crushed the bone of his thigh, but also tore the ligaments of the acetabulum. Merion was wounded in one of the large veins, which return the blood to the heart, known to anatomists by the name of vena cava; and Ulysses meditated to wound the Cyclops just where the liver adheres to the diaphragm. Anatomical facts were collected, and the physiology of animals investigated by the philosophers of Greece, who taught their subjects, as well as other branches of science, at the philosophical schools of Rhodes, Cos, Cnidus, Cyrene, and Crotona. The first dissection on record, is one in which Democritus, of Abdera, was engaged, in order to ascertain the sources and course of the bile. It is natural to suppose that anatomical and medical knowledge would be hereditary in families; the father would instruct the son how to explore the structure of animals by dissection, and the son would communicate his knowledge to his children. Thus would medical science be retained and augmented in such families. It was the case in the family of Hippocrates, who was said to be the fourteenth descendant from Eileanus. In the eightieth Olympiad, about 460 years before Christ, Hippocrates formed medicine into a distinct science, and collected, arranged, and published all the anatomical and medical information which mankind possessed. Anatomical knowledge was considerable for the age in which he lived, and it has been disputed whether he dissected human subjects; but if he did, the number must have been very small, his anatomy seeming to be of that kind and extent which the contemplation of the human skeleton, and the dissection of brutes, would naturally produce.

No important additional knowledge of anatomy was obtained, till the formation of a medical school at Alexandria, in Egypt, where the dissection of human bodies was patronized by the descendents of Alexander. Here Herophilus and Erasistratus flourished about 200 years before the birth of Christ. They seem to have been accurate dissectionists, and some minute parts of the body are still named after them as discoverers. Their writings have been lost, and it is chiefly Galen who has made us acquainted with their labours and their merits. The Alexandrian school long flourished, and medical men referred to it for a knowledge of anatomy, which they could obtain in no other place. Here even Galen received his education. It is quite unnecessary to notice the important anatomical remarks made in the writings of the Roman authors before or after the time of Galen.

Galen, however, greatly devalues our attention and praise; not merely because he collected and arranged all the then acquired information, but because he was also an indefatigable dissectionist, and considerably enlarged the limits of anatomical knowledge. He also investigated physiology by experiments, of which it may be right to mention one instance: he refuted the opinions of the Alexandrian anatomists, that the arteries were tubes, distributing air throughout the body. By laying bare one of these vessels in a living animal, tying it in two places, and opening it between the ligatures, he ascertained that it contained blood and nothing else. He therefore concluded, that both veins and arteries served the same purpose, that of distributing blood for the supply of the body, but that the arterial blood contained more air than the purple blood of the veins. In an inliry of this kind it seems right to mention the effects of anatomical studies on the mind of Galen: after contemplating the structure of the hand and foot, and their adaptation to their different functions, he breaks out into an apostrophe, which has been much admired, and in which he is said to have excelled any ancient in pointing out the nature, attributes, and proper worship of the Deity. In explaining these things, he says: “I cleave myself as composing a solemn hymn to the author of our bodily frame, and in this, I think, there is more true piety than in sacrificing to him heart-crews of oxen, or burnt-offerings of the most costly perfumes: for I first endeavoured to know him myself, and afterwards to shew him to others, to inform them how great is his wisdom, his virtue, his goodness.” There was no addition made to anatomy worth remarking by the writers who succeeded Galen: the science gradually diminished, and afterwards seemed almost lost amongst the Arabs.

The first Arabian physicians appear to have employed themselves in compiling syllums from the Grecian writers, and the later ones in copying from each other. Medicine certainly declined amongst them, and their religious notions made them almost entirely neglect anatomy. In the tenth century Constantine, a native of Bagdat, brought with him the Arabian doctrines on medicine to the Salernitan school in Sicily; and here anatomy began slowly to revive. In the fourteenth century Mundinus dissected human bodies in Italy, and by degrees other nations acquired that useful knowledge.

Anatomical knowledge, on its revival in Europe, was greatly promoted by the exertions of eminent painters, who were early and accurate dissectors, correctly delineating the mufcles, after they had removed the integuments which covered them. Raphael, Titian, and Leonardo da Vinci were famous for their anatomical skill, which is indeed sufficiently evident in their paintings. A number of sketches, designed
ANATOMY.

as studies by Leonardo da Vinci, are still extant in his Majesty's collection of drawings, and are spoken of by Dr. Hunter in the most encomiastic terms. Albert Durer, who also is ranked by Hailer among the reformers of anatomy, published many plates representing the proportions and gestures of the human form and countenance.

When the Turks had subdued Greece, the inhabitants fled for safety to the western nations of Europe, bringing with them the Grecian authors on medicine, and translating them; which works the invention of printing, that happened about the same time, greatly contributed to diffuse throughout Europe. People had now an opportunity of becoming acquainted with the writings of Galen and the ancients, and, by these means, of arriving at the source of that knowledge which they had hitherto obtained only through the channel of the Arabian physicians. The superiority of the former was soon discovered, and the opinions of the Grecian writers were confidered, even in anatomy, as unimpeachable.

In the middle of the sixteenth century several eminent anatomists flourished, particularly Sylvius and Vesalius, Fallopian and Eulachius. Sylvius taught anatomy in Paris in 1532. Vesalius first advised anatomists to inject coloured fluids into the vessels of the body, in order to facilitate the labour of minutely tracing them. Whilst he was a young man in college, he pursued anatomical inquiries with great ardour and assiduity, and published some of his discoveries before he was twenty-five years of age, and even books on the anatomy of the human body before he was twenty-nine, A. D. 1542. These books contain great discoveries, and, in many circumstances, correct the ancients. But although they have entitled their authors to the gratitude of posterity, they procured to him scarcely any thing but animosity from his contemporaries. At that time the authority of Galen was held in high veneration; but when Vesalius exposed his errors, the hatred of all seemed turned against him. People could not bear to be fat right by to young a man, and even Sylvius denounced perpetual enmity against him. But knowledge was increased by these contentions, all parties were obliged to refer for the materials and support of controversy, to the book of nature, which they could not consult without receiving instruction. Even Vesalius was detected, in some instances, in the error with which he charged Galen; that of describing the anatomical structure of the human body from the dissections of brutes. In 1561 Fallopian, in Italy, published his Observationes Anatomicae; he was an indefatigable anatomist, and made great discoveries. About the same time Eulachius made himself conspicuous eminently by promoting anatomical knowledge. He seemed calculated for public investigations; he drew many figures of the human body, and engraved his own plates, the accuracy of which cannot fail of exciting surprize in an anatomist of the present day. When the labours of these eminent men had, as it were, smoothed the path, anatomy was taught with a moderate degree of correctness and minuteness in the different schools of Europe.

Shortly after, as Hailer has observed, the different nations being engaged in war, the fame attention was not paid to public institutions and dissections. Anatomists had therefore recourse to the examination of the bodies of brutes, from which they derived many important discoveries.

In the year 1628 Harvey published his discovery of the circulation of the blood. The principal facts relating to this subject were known before his time; it remained for him to reject the specious conjectures then maintained concerning the blood's motion, and to examine the truth of those facts which were then known, and by experiments to discover those which remained to be detected. This he did, and thereby rendered his name immortal. His doctrines were at first opposed; but when they could no longer be contended against, the merit of the discovery was assigned to former anatomists.

It seems proper in this place, to review the several steps which were made in the investigation of this important subject. Hippocrates believed that all the blood is communicated with each other, and that the blood underwent a kind of flux and reflux from and to the heart, like the ebbing and flowing of the sea; and he mentions the throbbing of the temporal arteries, as an evidence of this fact. The anatomists at Alexandria adopted a wrong, but ingenious opinion; as they found the arteries empty, and the veins containing blood, in their dissections, they imagined that the former were tubes for the distribution of air, and gave them that name which they have borne ever since; and that the veins were the only channels for the blood. The heart of man, consisting of two sets of cavities not communicating with each other, and its connection with the lungs, were to them delusive circumstances, and seemed to favour their opinions. It is true they sometimes found blood in the arteries, and in the left cavities of the heart, but then they believed that the air or spirit had escaped, and that the blood had oozed through the tubes of these air vessels, and supplied its place. Galen, as has been said, refuted this opinion by experiment, and ascertained that blood flowed both by the arteries and the veins, though he knew not then its natural course.

On the revival of anatomy in Europe, the pulmonary circulation was known to many eminent men. The valves at the mouth of the pulmonary artery proved the course which the blood must take in that vessel, and it seemed natural to follow, that it must return to the pulmonary veins. This appeared to be the case to Realdus Columbus, Michael Servetus, and the celebrated Sarpi. But when Vesalius afterwards examined the subject of the blood vessels, we can only attribute his failure in discovering the truth of the circulation to his mind being more directed to expose the errors of Galen, than to a candid examination of the subject. Fabricius ab Aquapendente, the preceptor of our famous Harvey, particularly described the valves of the veins, the mechanism of which would absolutely prevent the blood from flowing in those vessels towards the extremities. When Harvey returned from his studies in Italy, his attention being excited to the subject, he began those experiments, by which he learned and demonstrated the fact of the circulation. Harvey's first proposition of the subject impresses conviction so strongly on the mind, that we are left in perfect astonishment, that a circumstance so luminously evident should so long remain unobserved. It must be granted, that the heart projects about two ounces of blood into the aorta at every pulse; what, then, it may be asked, becomes of this large quantity of blood, unless it circulates? It must be granted, that the heart receives that quantity prior to every pulse. From whence is it received, unless the blood circulates? Harvey tied an artery, and the corresponding vein received no blood: he tied a vein and all its branches, and those of the corresponding artery were choaked with blood, even to the entire obstruction of circulation and motion. But Harvey was not acquainted with the direct communication which exists between these sylphs of vessels. He imagined that the blood transpired from the arteries into the veins through a spongy, or parenchymatous substance. Much yet remained to be ascertained by microscopical observations, and subtle anatomical injections and dissections.

In 1624, a little before the publication of the circulation, the lattal absorbents of the intestines were discovered.
covered by Aselli; and shortly afterwards, the lymphatic or general aborbing ducts of the body were brought into notice by Rudbeck and Bartholin. In 1672, Peucot published his discovery of the trunk of this system of vessels, by which all the matter absorbed from every part of the body, as well as that which was given by the intestines, is poured into the left subclavian vein. See the Article Absorbing Vessels.) Swammerdam, about the year 1662, taught anatomists to site walled infections, which, hardening when cold, enable us to trace and examine the intertussure of minute vessels with certainty and exactness. Shortly after, in the art of injecting and making anatomical preparations, Ruyfch, who was professor at Amsterdam, particularly excelled; and by the anatomical instruments which he invented, he was enabled to develop the vascular structure of the body, with a degree of minuteness and exactness hardly credible.

Malmigh, a great anatomist and professor at Meffina and Bononia, in 1666, brought very ingenious and clear ideas respecting secretion. He believed that the minute arteries poured a liquor into little cells contained in glands, from which it passed off by other tubes, called excretory ducts. Ruyfch denied the existence of cells, and affirmed, that the secretory and excretory vessels were continuations of the same tube. These eminent men had each numerous partizans, but the opinion of Ruyfch, which is most simple, and drawn from accurate observations, is now considered as ascertained. Ruyfch also contributed to our knowledge of the absorbing system, by particularly describing the structure of its vessels, and Nick had no inconceivable share of merit on the same account. Leuwenhoek, who greatly promoted anatomy, not merely by his own microscopical observations, but by showing what important discoveries might be made by the microscope, saw the circulation in the transparent parts of fish and amphibia, and thus was the knowledge of the circulation perfected. By these discoveries much light is thrown on the animal economy; and we are enabled clearly to discern many circumstances which before either escaped observation, or were imperfectly seen. By the discovery of the circulation we see the truth of the scriptural expression, that in the blood is the life of an animal; for from this vital fluid every part is formed and maintained. By the discovery of the absorbers which we perceive how the blood itself is supplied, from the food, which is converted into a milky fluid, by the digestive organs; and how the old particles of our bodies, which are no longer fit to remain in it, are removed and conveyed into the blood, to be eliminated by the excretory organs.

When anatomy had thus become a clear and distinct science, it was inculcated and taught, in the different nations of Europe, by numerous professors, with a zeal and industry highly honourable to themselves and useful to mankind. It would occupy a volume to relate their labours and discoveries; we must restrict ourselves to mention only the names of the most eminent, and the principal subjects, which engaged their attention. The celebrated Harvey led the way in investigating one of the most curious processes in the animal economy, that is, the procreation of the species. Leuwenhoek and Buffon observing certain germs of microscopical animalculces in the seminal fluid, formed rather wild speculations respecting them, which, however, considerably excited the public attention. De Graaf, in 1672, was the proposer of the most rational opinion on this subject. In viviparous animals he shewed the existence of minute ovules formed in the ovaries, which, when fecundated, passed through the fallopian trumpet into the uterus, and there grow to maturity; the late experiments of Spallanzani, in Italy, and some in this country, seem to have confirmed his opinion, and proved that the female of almost every species prepares an ovum, which contains parts, which are, as it were, animated, and set in motion by the semen of the male. As a prosecution of the history of the same subject, we may mention, that Dr. Hunter in this country, has given a most complete history, with beautiful explanatory engravings, of the growth of the human ovum, and of the changes which the uterus undergoes after the ovum has been received into that cavity.

The more conspicuous parts of the body, the bones and the muscles, have been most accurately described and delineated; the former by Albinus, Chelfelden, and Sue; the latter by Albinius and Cowper. Albinus, in a minute anatomy, also describes the highest parts. In 1672, Diderot, professor at Utrecht, published a system of anatomy; and in 1711, Winslow published a very excellent and accurate work of the same kind in Paris, which long served as a kind of text book for students. But when Albinus and Haller had greatly simplified the description of the body, and improved the knowledge of its minute structure, some other systematic work became necessary, but none for a long time appeared.

In the mean while Haller published, at Gottingen, in 1743, his Icones Anatomicae, with a view to supply the deficiencies and correct the errors of Winslow. The description of the arteries particularly deserves our praise and gratitude. Professor Wathen, of Berlin, has, with equal, or even superior diligence, traced the distribution of the most important nerves, and published splendid representations of them; and lately Meffeni has given to the public a most elaborate and complete account, with elegant plates, of the absorbing vessels. Haller not only promoted anatomical knowledge by his accurate dissections, but discovered and established physiological truths by experiments made on living animals. In like manner Mr. John Hunter pursued his enquiries; he was an accurate and minute dissector, a patient experimentalist; and in his researches surveyed the whole field of animated nature. To him we owe in anatomy the definition of the teftis, and the natural history of the teeth; by him physiology has been greatly promoted, and the structure and economy of animals displayed and explained. In Germany the brain has been examined, and the nerves traced with the most judicious attention; and of late Mr. Da'Azry, in France, an anatomist equally comprehensive and minute, has published representations of the brain, which are allowed to exceed all others. Dr. Monro, in our country, has also published on these subjects. Some anatomists seem to have directed their attention chiefly to the investigation of some single organ. Zinn has examined and explained the structure of the eye with surprising minuteness and accuracy. Cotumin, Meckel, and Scarpa, the ear; and the latter has also paid attention to the organ of the smelling sense. Of late some excellent systems of anatomy have been published by Sabatier, in France, and Soemmering and Hildebrand, in Germany.

Morgagni, the pupil of Valdivia, professor of anatomy in Padua, who had very extensive opportunities of observation, and who much improved anatomy in his old age, in the year 1761 published the result of his observations De Sedibus & Causis Morborum per Anatomiam Indagatis, a work of the greatest utility. Doctor Baillie has of late, in this country, professed the same subject, though in a different manner. He has published on the morbid anatomy of the body, and illustrated his descriptions by many elegant, expressive, and accurate plates; the prosecution of this subject promises the greatest advantages.

We have thus cursorily mentioned the principal subjects, in which the most eminent anatomists have been engaged. The names and employments of numbers of men of high
A N A T O M Y.

defect have, however, been omitted; indeed, they could not be properly noticed unless this article were of itself to make a volume. Chronological order has been much treasured against, and we therefore return to mention the most remarkable anatomists, in a series, according to the time in which they lived. As it is difficult to adjust their precedence in this respect, we shall rely on the authority of Haller, whose knowledge and judgment will not perhaps be called in question. He considers Bene¡dictus, Berengarius Carpen¡us, Nicolaus Maffa, Sylvius, Velaffus, Servetus, and Columbus, as the chief reformers of anatomy, whose writings are dated from the beginning to the middle of the sixteenth century. After the reformation of anatomy, the schools in Italy particularly excelled, and most anatomists received their education in them. From amongst the most eminent of the Italian school we may select the names of Falle¡us, Eufalchius, Aurantius, Ccafartius, Varolius, PlanTER, Caesar Balbus, Aldrovandus, Casserius, Fabricius ab Aquapendente, Risbamus, Hoffman, and Spigelius, whose writings extend from the middle to the conclusion of the sixteenth century.

The beginning of the 17th century the dissection of human bodies began to decline in the Italian schools, and more attention was paid to comparative anatomy and physiology. Amongst the most eminent in this department we may recite the names of Afellus, Harvey, Marcus Aurelius Severinus, T. Bartholin, C. V. Snieder, Van Horne, Highmore, D. de Marchetettis, Rudbeck, Gliffon, Wepfer, Blaafus, Malpighi, Steno, De Graaf, Herborn, Ruyfch, Swammerdam, C. Bartholin, Brunner, Luenwenhoek, Duverney, Bidloo, and of those who confined themselves chiefly to human anatomy, R. Vieuxfleas, Cowper, Raw, &c. &c. all of whom flourished in the 17th century. In the beginning of the 18th century, Haller confines anatomists as having attained a greater degree of learning and knowledge in the science which they studied, and under the title of the more learned in anatomy he gives an account of the works of Morgagni, Winflow, Chelfeld, &c. which were dated in about the first 30 years of that century, except Morgafal's work, "de Sedibus et Caufis Morborum," which he published at an advanced age. Under the title of the perfect state of anatomy, Haller reviews the works of Albinus, Senac, Monnas, (the latter and fon), Haller, Nicholls, Lieutand, Ludwig, Leiberqyin, Dr. Hunter, and his brother Mr. Hunter, Dubenton, Camper, Walther, Meekel, Zinn, Fontana, Wirsberg, Spalanzani, Hewfon, Portal, Sabrtcar, Scarpa, Blumenbach, Troja, &c. whose writings extend to the present time. The History which is given must necessarily be brief, and cannot, in consequence, be otherwise than imperfect. We therefore refer the reader for more ample and correct information on this subject, to the writings of Le Clerc, Fried, Coelieke, Portal, and to the Bibliothee of Haller.

A N A T O M Y. Comparative,-by this term is popularly understood the anatomy of animals, compared with the structure of the human body as a standard. This definition, however, is not sufficiently comprehensive. The organization of every animal forms a part of our knowledge of nature, and as far as it exemplifies or explains any of the functions exercised by animal bodies, furnishes those data which constitute the basis of physiology. The anatomy of the human body is not more applicable to this purpose than that of other animals, and many of the most important functions can only be understood by comparing the organs by which they are performed in the different classes of animals.

The agreement which necessarily exists between the structure and the habits of animals, renders comparative anatomy an essential branch of zoology. No classific division of the subjects of natural history can be either permanent or useful, which is not founded upon internal structure as well as external characters, and in proportion as this is attended to, we come nearer to that natural arrangement, which should be the chief object of all classification. It is in comparative anatomy, then, that the physiologist principally discovers the laws which determine the phenomena of organized matter, and that the naturalist finds all his observations upon the appearances and manners of animals verified and explained.

The anatomy of animals must have formed one of the very first subjects of human investigation, because in the most simple and early stages of society, almost all the means of subsistence or of enjoyment which man's kind possesses, are drawn from other animals. The savage, therefore, in killing his prey, and preparing it for the different purposes to which it is to be applied, is necessarily led to distinguish the structure and appearance of the several parts, one serving for food, another for tawment, a third for a weapon or an ornament, and so on; it cannot be supposed that this examination should be frequently made, by the most ignorant, unaccompanied by some reflections upon the uses of these parts to the animal in which they are found, or without comparing the same degree the anatomy of one animal with that of another:—a very considerable portion, therefore, of knowledge on this subject must have been obtained in savage society, but which has been lost to after ages, from the want of any record of human knowledge.

Thefacric of animals which has always made a part of the religious worship of uncivilized nations, afforded also many opportunities of observing the internal structure of animals.

The first account that we possess of comparative anatomy is being studied as a branch of philosophy is amongst the Greeks. Demonis is reported to have directed himself to this subject with so much ardour, that he at first incurred the suspicion of insanity, but when his objects were explained, the utility of his pursuits was fully acknowledged.

Aristotle may be considered as the first professional anatomist; his zoological researches were carried so far that his works are read with pleasure and improvement, even at the present day: his opportunities of studying the subject were indeed unparalleled; for we are told that Alexander bestowed upon him 100 talents, (a sum equal to 50,000l.) to be expended in procuring animals for dissection.

Herophilus and Erichius, who succeeded Arifotle in the school of Alexandria, are said to have dissected human bodies, but it is more probable that the anatomy of Alexandria was still taught by the dissection of animals, as besides the natural feelings to be conquered, there prevailed at that time a notion, that the touch of a dead body communicated a moral pollution; notwithstanding which, this school became so celebrated, that it was not only visited by the learned men of Greece, but by those of all nations. During the dark ages, comparative anatomy suffered nearly an equal depression, with the other sciences, and it was not until the latter part of the 15th, and the beginning of the 16th centuries, that it began again to be much cultivated; about this time flourished Rodeletius, Bellonius, Eufalchius, Cauferius, Coffer, Fabricius ab Aquapendente, Cafferius, Severinus, and several others, whose works may be still consulted with profit. The discovery of the circulation of the blood, and of the abscorbet syphilis, which may be reckoned as the commencement of another era in anatomy, opened the door to physiological enquiry, from which con-
ANATOMY.

Comparative anatomy derived the greatest improvements, as many of these researches were most conveniently conducted upon animals about this time; also the application of the microscope to the observation of the more minute structure of parts, furnished a new field for investigation; amongst those who most illustrated the anatomy of animals during this period may be enumerated Alliolius, Harvey, Stenon, Portacius, De Graaf, Redi, Willis, Raylch, Malpighi, Swammerdam, Leuuenhock, Perault, Needham, Blaffis, Ogerus Jacobus, Lillar, Bucillus, and Tyton. Comparative anatomy continued to improve in a regular and steady manner, during the early part of the last century, which will appear in the works of Valilnere, Valentinii, Geoffrey, De Reanum, Bradly, Maitre Jean Petit, the elder Monro, Trembly, Baker, Bonnet, &c. but it was not until the middle, and towards the close of the last century, that the anatomy of animals became a connected science; the discourses of the preceding ages were then arranged, compared, and systematically applied to the purposes of physiology; many new and important facts were added, and several of the most curious and interesting circumstances in the animal economy were fully investigated and explained. Collections of preparations to exhibit the structure of animals were formed in Paris, Paris, Gottingen, London, and some other parts of Europe: in the three first places, public lectures were delivered, by which a knowledge of the subject was diffused over the continent; this might be considered as the Augustan age of comparative anatomy, in which we meet the names of Camer, Daubenton, Vic d’Azir, Blumenbach, Pallas, Scarpa, Comparetti, Hunter, Monro, Hewson, besides a great number of others of the first character.

Some of these eminent men are still living, to whom may be added, as the most distinguished anatomist of the present time, citizen Cuvier.

It would be impossible, within the limits of this article to give any detail of the several discoveries which have been made upon this subject; they have only in a very few instances been published in distinct essays, and are chiefly to be found scattered through works on natural history and human anatomy, or in the transactions of literary societies. The works of Collins, Valentine, and Blaffis, which were published under the name of Sylvans, are mere collections of facts, without any suitable arrangement, and although as a simple compilation no book can have more merit than the "Anatome Animahum" of Blaffis; it is, however, to citizen Cuvier we are indebted for the first systematic work on comparative anatomy; the want of such books, and of public lectures has hitherto made this science less an object of general attention than its utility and interesting nature would deserve; but it may be expected that these deficiencies will be supplied by the present age, in which the value of every kind of knowledge is duly appreciated.

All those who have lately written or lectured upon comparative anatomy, have very properly chosen to arrange the subject in a physiological manner, instead of describing the structure of each kind of animal separately. This mode, however, if strictly adopted, would prove highly inconvenient in a dictionary, in which the matter should be so distributed, that it could be immediately referred to, under similar heads or titles; on the other hand, to multiply divisions much is tedious and perplexing, and incompatible with the perfect understanding of this subject, which requires that a number of facts should be known before any comparison or conclusion can be drawn. The plan pursued in the present work, combines in some degree both methods of arrangement. Thus certain classes of animals are established upon the basis of an agreement in their general anatomical structure; each of these classes forms a distinct article; and the faculties and functions belonging to the animals it contains, are made to many subdivisions or letter heads, under which the structure of the organs, subservient to these functions, is discussed.—See Classification of Animals and Functions.

Anatomy, Vegetable.—All natural science confills in the discovery and application of facts; its usual progress, therefore, is gradual; history records no period in which nature has not been studied, and in which the foundation of most of the sciences has not been clearly laid. The internal structure of vegetables, however, during the early ages of mankind, was involved in almost perfect obscurity. It was not indeed until the latter part of the 18th century that the anatomy of plants was formed into a distinct science; before this period the same opinions were entertained upon the subject that were taught by the Greeks, and which were not established upon actual observation so much as the analogy that was very properly imagined to exist between animal and vegetable bodies. Thus they attributed four parts to all plants:

1. The sap or juice, which they considered similar in its uses to the blood.

2. Secondly, the fibre of plants, which they called nerves, from their resemblance to those parts in animals to which, however, they did not ascribe the property of sensation.

3. Thirdly, the veins or vessels that were supposed to contain the fluids.

4. Lastly, the pits, which they conceived to be analogous to the spleen of animals. A further account of the early state of this branch of science may be obtained in the writings of Anistote, Theophrastus, &c. and in the physiologia of Du Val.

It was only by investigations, conducted with the microscope, that the real structure of vegetables could ever have been developed; it is to the invention of this instrument, therefore, that we owe almost all the knowledge that is at present possessed upon the subject.

The microscope was first made use of to discover the organic structure of plants by Grew and Malpighi, for what was done before them by Mr. Hooke, and some others, scarcely deserves to be noticed, as their attention was chiefly directed to the examination of the external parts of vegetables. In no instance, perhaps, have the first labours on any branch of science gone so far as those of Malpighi and Grew. The books which they published under the title of the anatomy of plants, rank amongst the highest authorities upon the subject at the present time. It is remarkable also that on the 7th December, 1671, the same day on which Grew prefixed to the Royal Society the first part of his Anatomy of Plants, the society also received the manuscript of the first part of Malpighi's "Anatome Plantarum."

In consequence of the degree of perfection to which these eminent men carried vegetable anatomy, the writers who have followed them have been employed in the investigation of the functions, rather than the structure of plants. Some curious and highly important facts have, notwithstanding, been added with respect to the growth of timber, the anatomy of the bark, and the more minute organization of the vessels, leaves, flowers, seeds, &c.

These more modern discoveries in vegetable anatomy may be principally found in the writings of Leuuenhock, Bonnet, Duhamel, Relro, Gartner, Hill, Baron de Gleichen, Reichh, Mayer, Guttard, Hedwig, Walther, Duoflure, Desfontaines, and Mirbel.

There is scarcely any branch of science more interesting...
in the pursuit, or which holds out a more valuable end, than vegetable anatomy. The delicate, minute, and complicated arrangement of parts, which appears in the organization of vegetable bodies, presents a continual subject of admiration and amusement, in procuring which, the feelings are never wounded, nor the senses digusted. But this science is not a subject of mere curiosity or idle speculation; it affords the greatest illumination of the structure and functions of animals, and tends in an eminent degree to improve the arts of agriculture and gardening, from which civilized man derives all his means of subsistence, either by his own immediate consump- tion, or the support which is obtained for domesticated animals.

There are certain parts of vegetable bodies which may be termed common, on account of their being generally distributed throughout the system. There are the cortical substances usually included under the names of bark—the wood, the medullary part or pith, and the different orders of vessels for containing the sap, air, or secreted fluids.

There are other parts again which, from possessing different external figures, and performing separate uses in the vegetable economy, might be called peculiar parts; these are the roots, the trunk or stem, the branches, the buds, the leaves, the organs of reproduction contained in the flower, the seed or fruit. It is under these several heads that the anatomy of plants is discussed at large in this dictionary. Such an arrangement appears the most convenient, if not the most suitable, as by adopting it popular terms are obtained for most of the articles, a thing very desirable in conveying knowledge by means of a dictionary. This disposition of the subject also is nearly the same, that has been chosen by other systematic writers upon the anatomy of plants.

The functions of vegetable bodies are described, arranged, and their proper references pointed out, under the article PhysioloY vegetable, which see.

Anatomy, Perspective.—By this term is implied that degree and kind of anatomical knowledge, which is requisite for painters and sculptors, &c. comprehending chiefly the bones which support the figure, the muscles which move them, and the integuments with which they are covered.

Every confederate person will allow, that the painter, &c. who represents the human figure, cannot obtain any great celebrity in his art without some knowledge of anatomy; but it may not soon appear to every one, that there is a necessity for that considerable degree which it is requisite for him to know; and it may be concluded, that little or none of this kind of information will be absolutely necessary for those artists, who devote themselves to the repre- sentation of clothed figures. It may also be conceived, that however proper the knowledge of the external musculi may be to the painter of nude figures, the bones, being mostly covered by them, will be no considerable object of his attention; and that statues, with the living model, will communicate all the information required.

The skeleton being the frame-work supporting the human fabric, it would be diametrically opposite to our opinion to think lightly of osteology. As the bones describe the grand points of the figure, and are acted upon by the muscles and tendons, a principal part of the painter's attention should be given to the configuration of the bones, especially of the joints; and although the knowledge of the musculi which move them and fill up the cavities demand much of the artist's considera- tion, yet it is presumed, that with the use of statues and living models, a person well informed in osteology would make a more rapid progress in the representation of figures, were his knowledge of the musculi has not been obtained, than he who has well studied the mythology, but had not a competent acquaintance with the bones. This observation will also apply to the supposition of clothed figures being painted without a prior acquaintance with anatomy; it being pre- disposed, that however capable such a person may be of painting drapery, without a considerable degree of anatomical knowledge, his figures will resemble bundles of cloth or linen without that animation and grace, which are to be seen in the works of those artists who have been honoured with the approbation of the judicious.

It is certain that statues and living figures are of great use to the painter; the antique figures will form his taste, and living figures are so continually used by all painters who have to excel, that they form a very considerable branch of the education of artists in all their academies. It is, however, next to impossible to a painter should copy the object before him, if he do not understand it; for, let him be ever so diligent and attentive, he will fall into considerable mistakes. Although in attitudes without motion or exertion, the living figure may for a long time direct his pencil with facility; yet when violent motion and exertion are to be expressed, the living model can but affi- l the hand for a few moments; here the knowledge of anatomy lends its aid, without which the wearied figure before him will only perplex and render his representations inanimate.

"Nor is it, as some may be apt to imagine," says Algarotti, "merely to represent athletic and vigorous bodies, in which the parts are most bold and determined, that anatomy is requisite: it should be understood, to represent persons of the most delicate frame and constitution, even women and children, whose members are smoothest and roundest, though the parts may be known by it are not to be strongly expressed in such subjects; just as logic is equally requisite under the polished inflections of the orator, and rough arguments of the philosopher. But it is needless to spend much time in proving, that a painter should be acquainted with anatomy, or in showing how far his acquaintance with it should extend.

"He must be acquainted with the figure and connection of the bones, the origin, progression, and shape of the muscles, the different degrees with which they are covered with fat, which substance lies thicker upon some places than in others; but above all he should know in what manner the muscles act the various motions and gestures of the body." Count Algarotti wrote with judgment upon painting, and his remarks upon anatomy deserve respect. The following extract was written by a physician, who seems to have had a taste for painting; although some of his remarks may have been anticipated, it is thought proper to present them to our readers; they will be found, amongst other useful things, in Dr. Brisbane's Anatomy of Painting. After speaking, in the preface, to surgeons, the doctor observes, that "as the representation of the outside, or the surface of the human body, is the chief object of his art, he ought to study the structure of the body and its inward parts, chiefly for the sake of, or as they affect, or are referred to the external surface, and make their appearance there, or are adherent in the better drawing and representation of it. Hence the parts which they themselves upon, or affect the surface of the body, ought to be the sole or chief object of the study of a painter. The parts, therefore, that lie nearest to the surface, or outside of the body, and consequently that are most immediately concerned in forming its outline, are first to be considered by a painter, viz. the external layer of the muscles, especially the larger ones, and those that are most subject to appear in the movements and attitudes of the body. As to the skin and fat under it, these are spread over the
the whole body, and are to be considered merely as a drapery or covering to the more inward parts, which appear every where more or less through them, at some times and places in a stronger, and at other times in a obscure manner. But though the parts nearest to the surface are the first and most obvious that belong to the study of a painter, yet nature has so contrived the human body, that the external parts cannot be well understood, without a full idea of the internal ones; even of those which are, as it were, buried in the centre of the body: I mean the bones or skeleton, which are the foundation and frame on which the whole fabric is built, and to which, as a base, all the other parts are mediatly or immediately referred; particularly the muscles, so necessary to be known by painters, which are chiefly implanted into the bones, and make considerable marks and impressions upon them; and consequently without the knowledge of the bones, the muscles, and other soft parts cannot be understood; but there is another reason why the bones must be studied by the painter, viz. because parts of the bones, though covered by the integuments, appear not obscurely to the eye in many places of the body, and, like the large muscles, are the cause of the outline, and of the character, proportion, beauty, and appearance of many parts; and when properly considered and understood, the bones, by many fixed points, give the finest direction to a painter, not only how to find and place the muscles, but also how to draw the human body; nor can it be so judiciously or readily drawn by any painter, as by one who understands anatomy in a matterly manner, particularly the bones and external muscles, and can point them all out upon a living man, and, by means of that knowledge, determine all his points, and the forms and proportions of every part and member, adding one part to another as he knows they lie upon the body; this is the true and natural method of drawing the human figure. But though the bones and external muscles are the most necessary part of the anatomical study of a painter, yet it must be confessed, that at least a general knowledge of the whole fabric is of great use, in order to a more complete and matterly representation of the human body, and in order to be able to diversify, and give reason for every appearance; and not only the solids must be known by a painter, but he ought likewise to have some idea of the fluids, as on these chiefly depend the various tints and colours of the skin that appear in the different sexes and ages of life, in different characters and occasions, climates, and nations. And as the human frame is so contrived, that the movements and passions of the mind affect the body, and are evidently seen and distinguished upon the countenance, and are expressed there and in other parts of the body by strong and certain characters; and as this is the most delicate and highest part of the painter's art, by which he is capable to move, to delight, and to instruct mankind, and to recommend himself and his art to the study and admiration; therefore, the study of the mind, and its various characters, passions, and movements, so far as they are marked upon and expressed by the body, ought to be above all things the study of a painter; for as the members of the human body, in a good picture, beautifully appear through the drapery; and as the bones and muscles appear through the skin, so the mind itself, in all its characters and passions, appears upon the countenance, and in the expressive proportions, attitudes, and tints of the various parts. A lover of the arts of design, or indeed any anatomist of true taste, will look upon the human body, and all its parts, with the eye of a painter; otherwise, he will see and describe it in an ignorant and rustic manner. Observing the human body with the eye of a painter, enables us to see all its beauty and perfection, and raises in our minds a thousand ideas of the use and propriety of the several parts, whereas one ignorant of painting will be totally infensible; and, in describing the human body upon this plan, we naturally do it in the most clear, short, and agreeable manner. We wish to impress upon the mind of the young painter, that he may absolutely obtain a competent knowledge of anatomy, and therefore have strengthened by quotation what we before obferved. At the same time we have purposely omitted Dr. Prior'san's representation of the method adopted by all artists, viz. that of proportioning the figure by leads, &c. (see Adrian's measure of the antique figures) which, if he had well understood and understood, he could not have rejected.

In a well-formed figure, all its parts are in proportion to each other: if the head be the tenth part of the height of a perfect model, its imitation cannot be well, or with certainty, made without this being used as a scale for the other parts: if the face be divided into three parts, and one of these parts be allowed to be the length of the nose, which it is in all the fine specimens of beauty and proportion, either ancient or modern, then may the figure be said to measure eight heads in height, or thirty times the length of the nose; and this scale will give a right proportion to figures of all dimensions. It is well to caution the student against departing from the reversed ancient path by the hastily determination of any person, as the young artist may be induced by his adherence to individual instead of the general of nature. See Reynolds's Discourses to the Students of the Royal Academy. See also Fufci's Lectures. While he is beginning this pursuit, at the very time when he is the most liable to err, we present our caution. It is not intended to speak of picture-regale anatomy, merely to amuse persons who wish to have some conception of it, but to endeavour to treat the subject, as to assist those who desire to be directed into the right path of attaining necessary information in order to practice; to point out the method, by which the study is to be pursued; what books, tables, and calls are conceived to be most proper; and which, by experience, have been found the most useful. Some observations will also be made that we apprehend are very much required, and which are not to be found in any printed work upon this subject, that we know to be extant. Some of our readers may think too great fires are laid upon anatomy for artists, while others those instructions will seem superficial. To the former, we recommend a second consideration of what has been said; to the latter we submit, and refer our readers, for deeper knowledge, to the anatomical labours of the gentlemen, to whom these parts of the Cyclopædia are committed; while at the same time we advise the student in painting not to pay too much attention to these curious parts of anatomy, which do not concern his profession. In excise for any want of connexion which may appear, though it is meant to be as methodical as the nature of the requirements will admit, it should be noticed, that some of our observations are meant to be impressed upon the memory, and retained as distinct maxims.

Having thus far offered general observations, we might now immediately proceed in the particular steps, by which the student is to pursue his practical knowledge, were it not for a consideration, that an attention to theory should in a flight manner, at least, precede practice, for which reason it is thought necessary to exhibit a general survey of the bones and muscles in this place. This has been done by excellent writers upon anatomy, but many of them have been too particular for our present purpose. As we think it may not be in the power of our readers to procure those works which are written in a flight manner, such as is at present required, when it will be necessary; for this reason the following
ANATOMY.

lowing general systems of occultism and mythology may be here introduced with great propriety.

The system of the bones of the skeleton, is, as it were, the solid frame that contains, defends, and gives stability to the softer parts, and to which they are ultimately attached, and consequently this bony fabric has of itself the general form, size, and appearance of the entire body. This solid frame is most artfully composed of different parts, jointed to one another, so as to be capable of every useful and graceful motion in the whole and in all its parts: and the various bones and pieces of which it is composed differ in size, form, and strength, in position, connexion, and motions, according to the uses and exigencies, and even the beauty of every part, to which they often add a certain grace and character, by obscurely appearing here and there through the softer parts, even in the living body.

The head is, as it were, the dome or cupola to the whole edifice. In this highest part the bones are placed, and the brain defended by solid bone. The head, like the rest of the body, derives its size, form, proportions, and principal characters first from the bones; but the softer parts that cover them add life to the motions and the finishing beauty, in which last the hair also concurs; and it is surprising how few simple organs, and so thin a covering to the soft parts, are capable of such infinite variety of forms and expressions as we see in the human countenance, affording an endless field of study. In the head the bony part is a more complete fabric, and comes nearer to the form of the living subject than any other part of the skeleton; being the seat of so many noble organs, and the chief part to be studied by the painter, it deserves the first place, according to the custom of some anatomists.

Here vestiges of the smooth polished bone flew themselves in the forehead, in the ridges all round the eye, in the hollow of the temples, on the nose and cheek bones, and margin of the jaw, giving great pleasure to the painter who understands anatomy.

Next comes the elegantly bent pillar of the spine, strong, yet flexible, by confilting of so many parts firmly tied together. This bony column, at the same time, gives size, strength, and motion to the body, attachment to many surrounding parts, and being hollow through its whole length, serves to conduct and secure the spinal marrow, and to transmit nerves to every part of the trunk and extremities. The spine consists of four and twenty vertebrae, generally increasing in size as they descend, and gradually varying in their figure; even of these vertebrae belong to the neck, which admit of peculiar and considerable motion, and allow of many graceful movements to the head and neck. The next twelve belong to the back; these are almost rigid, and admit of very little motion: to these, as to a solid body, the twelve ribs of each side are attached, which, together with the sternum and their own cartilages, form a kind of yielding cage or basket to contain the heart and lungs. This bony case admits of a small motion when we breathe; to the lower margin of it all around is fixed the diaphragm, a transverse muscular partition, dividing the thorax from the abdomen, a main organ of respiration, and of other functions. The five lower vertebrae belong to the loins, admit of considerable motion, and are of great use in the firm and graceful attitudes, and flexions of the trunk, and in many offices of common life. Between the ribs and pelvis there is a great void in the skeleton, especially before. In this space lie many of the abdominal viscera, with the parts that contain and cover them, making on the fore-part the beautiful swell of the abdomen, elegantly marked by the containing parts.

To the superior part of the thorax, by means of the transverse clavicles, and of large and strong muscles, are appended the upper extremities, which, at the shoulders, give breadth to the thorax above, and serve many noble purposes of strength, of art, of defence, of expression, and of beauty. They are divided into the shoulder, consisting of the clavicle before, and the thin broad scapula behind, which, moving free among the muscles, by their means govern the motions of the whole arm, and its triangular form has a most beautiful effect, seen floating among the soft parts in the naked figure; and indeed the whole shoulder is a noble noble part, and a fine excuse to a painter; for, besides large muscles, the bones themselves also mold beautifully and distinctly appear. Next comes the arm bone, capable of a large and free motion, whose round head at the shoulder, in lean persons, obscurely appears, and at the lower end its condyles are evidently seen, where it is joined to the fore arm; this consists of the radius and ulna, which move upon the arm bone with the more confined motion of flexion and extension; but for the sake of the hand, and its various and important uses, the radius and ulna likewise receive each other lengthways, in a very curious and singular manner, turning the hand alternately prone and supine, as upon an axis. Lastly comes the hand itself; it consists of the carpus, metacarpus, and five fingers, the thumb being, as it were, an antagonist to the other four; the whole together, by its general form, and different parts and motions, serving almost every possible use, and its various attitudes being capable of great beauty and variety.

We come now to the pelvis and lower extremities; the pelvis supports and defends the lower viscera. The back part, or os facrum of a triangular form is, as it were, the basis and continuation of the spine, whose vertebrae it obscurely resembles, and performs its offices by receiving the extremity of the spinal marrow, and transmitting nerves to the surrounding parts. The lateral and fore-parts of the pelvis, though fixed and immovable, answer in some respects to the seapulz and clavicles, as they afford sockets for the thigh-bones, and also a seat to many strong muscles that belong to the trunk and extremities. The upper margins of the os ilium appear gracefully in the living body on the fore-part, and form a kind of boundary between the belly and the thighs. The spine of the os ilium, as of the vertebrae, obscurely appear in bodies not loaded with fat, and also the great trochanter is deeply immersed among large and strong muscles; but at the knee the bones make a very fine appearance, viz. the condyles of the thigh-bone, the tops of the tibia and fibula, and the patella, a bone so beautiful and so useful in the government and defence of this joint. The bone of the tibia appears through the whole length of the leg, and at the lower part of the tibia and fibula, the two ankles elegantly appear, and fix the bounds between the leg and foot. The foot, a thick and solid part, serving as a basis and support to the whole body, consists of the tarsus, metatarsus, and toes; in the whole, and in every part, it in some part resembles the hand, and, although much inferior, comes next to it in beauty.

The skeleton is one simple system of solid parts, serving as a jointed frame on which to build the rest of the body. But the muscular or flabby parts that clothe and move the skeleton are soft, and form a more various and complicated system, consisting of different fibres or layers, one covering another, and divided into numerous portions of different size and figure, regularly disposed over the whole body, composing a great part of its bulk, and the chief cause of the size and form of the members; for when stripped of its uniform coverings, viz. the skin, and cellular or fatty membrane, the
ANATOMY.

The muscles differ greatly in their size, figure, and other particulars, according to the parts where they are situated, and the uss to which they are applied. But in general they are compos'd of fibres; the middle part or belly being large, soft, and red, and the extremities or tendons, which are generally iner'ted in bones, being smaller and harder, white and shining. The red part is properly the moving power, and acts by contraction, during which it swells, and becomes hard and flatter, sometimes to a great degree, and thereby pulls the parts to which its extremities are affixed. The muscles are governed by the power of the will, except the fibres of the heart and of the melle, &c. which are of all others the most irritable; the muscles of respiration act in both ways. The muscles can act in a most gentle and delicate manner, and also with great strength and velocity, though much of their power is lost by the places and manner in which they are often situated and iner'ted on the parts to be moved. The cau'ses of muscular motion are difficult to be accounted for.

The muscles are arranged in their places, and allowed to slide upon each other by means of the cellular or fatty membrane; and their fibres are lubricated every where by the oil it contains, and in the fabric of the body, and of the muscles themselves, many contrivances are used to affit their actions. The muscles are in sufficient number, and so disposed and contriv'd, as to be a warm covering and defense to the more inward parts, as well as to move the joints in all the directions they are capable of, to affit in many functions of the body, and to place and retain it in every possible attitude; in doing which the particular muscles seldom act alone, but in the most various manner co-operate with, or oppose each other; so that the whole muscular system may be consider'd as one muscle, every fibre being under the power of the will, at the pleasure of which the whole body, and all its parts, are at once or alternately moved and govern'd, as it were, by so many bridles. Besides this grand purpose of the muscles, they likewise serve the general uses of the animal machine, being the chief cau'se of respiration, and of the circulation of the blood and juice; also promoting diffusion, absorption, secretion, excretion, nutrition, and growth; hence they likewise prevent and cure obstructions, and other diffe'ses, and by their incessant action, are one great cause of the hardening and wasting of the body, and the decays of old age.

Although we think too great an attention to the minuties should be avoided by the student, especially at the first, yet it will be worth the attention of the young articl't to examine the nature of a muscle a little more carefully; and to know that the tender part of a muscle consists of a bundle of thin long threads, and is divided into a great number of fasciculi, or little muscles, each inclosed in its proper membrane. The fasciculi of muscular fibres have not always the same situation in regard to each other, nor run in the same direction, but sometimes run parallel to themselves and their tendons, and are sometimes disposed obliquely both to their tendons and to each other; but information respecting circumstances of this nature will be more completely obtained by inspecting the muscles themselves. A sight of the object will impress the knowledge conveyed by the anatomist in the most forcible manner upon the student's mind.

Some have thought that the most proper method for the painter to begin his studies is under the instruction of some able anatomist; but, unless the anatomist understand the arts of design, this we disapprove, and think it bel' that the affittance of directions should rather follow than precede the general practical knowledge. It is therefore recommended that the student provide himself with some of the tables which anatomists have published. The tables of Albinius are deservedly esteemed; and what are, perhaps, better, those cut in wood, and which illustrate the ancient folio volume of Vellanius, edited in 1543, said to be drawn by Titian; but whoever the artist was, they are delineated with great judgment, the figures are graceful, the muscles are represented in a robust figure, and properly swelling to the action of the figures: this be of no great consequence to surgeons it is to painters. These tables may be copied with great advantage. We suppose the student to be expert in drawing, which is the first step to be taken in the painter's art. Timney's compendious treatise of anatomy is also to be recommended: it is a selection made with judgment, although the plates are copied; the shapes and situation of the external muscles their names, attachments, and u'se are mentioned. This compendium was published by Sayer, in Fleet-street, in 1772. While such representations as these are copying, which should not be in a careless, but in a decided and determined manner, the student will attain a great deal of the general knowledge of anatomy, especially if he should write upon the margin of his different views of the skeleton the names of the principal muscles, which, in the complete figure, unite themselves by their tendinous attachment to the bones, with lines drawn to their origin and their insertion; and also if the drawings of the muscular figures in this work have in their margins the names of the muscles, to which may be added their characters as flexors or extensors, and the limb they bend, extend, or rotate, pronate, or supinate, &c. Timney's compendium, before mentioned, will readily affit in this particular, although the original figures in Vellanius are more recommended as objects to copy after, if that work can be procure'd.

The next step we recommend is to obtain the use of a good skeleton, furnished with a careful imitation of the natural cartilages and its articulations. With this should be compared the drawings which the student has directed to make, and the different views they represent, as in front, side, or behind, gratifying his curiosity, and imprinting the object upon his memory. To the complete bony fabric, the head, trunk, and limbs should be obtained separate, for convenience, and their more particular inspection; and some of the bones finely, that the joints, &c. may be more carefully observed. We advise the young artist to draw these in different views; first, the separate bones as large as nature, marking the tuberosities and ridges, which give attachment to the muscles, the condyles of the joints, &c. with written remarks on the margin. We conclude that the student has been initiated into the principles of grace, and knows, in some degree, how to produce a figure in easy progressive motion, or prepared for such motion, which is what painters mean by grace (see GRACE.) In the skeleton he will observe how the joints, &c. by their mechanism, admit the muscles to produce the effects in the living body; this will open a great field of contemplation respecting his art, and in the wonderfully contriv'd object before him, the profound wisdom of his Maker. When he has thus advanced to an examination of the skeleton itself, he may derive much assistance from an anatomist, who knows how to point out to the artist such parts as will be requisite in his art; adapting himself properly to the degree of attainment which the student has made. In the want of such a friend, however, the works of anatomists are recommended.

The following hints, we apprehend, will be of use; they are few and short, though they may be important, as we only mean to give directions respecting the manner in which the painter is to pursue his studies.
It is of no great consequence whether we commence with the head or the pelvis: but in conformity to the system already given, the head is first mentioned; in which it was observed, the bony parts come nearer to the form of the living head than any other part of the skeleton. This should, like the rest, be drawn carefully; the face being complicated in its parts demands great attention, which may be deferred for the present. Let the artist, however, examine the malarial process of the head, which will be important to him in future; let him observe how the head is placed upon the atlas of the spine, which moves freely upon the tooth-like process of the second vertebra. Let him observe the general form of the head, which is given by the trunk and upper extremities by the basin of the several vertebrae, the degree of motion which is allowed to each part, much in the neck and loins, little in the back, and none in the vertebrae of the facium; how near the centre of the body this is placed, although the spinous processes of the vertebrae in the back approach so near to the contour of the figure, forming that ridge which is usually called the backbone; yet the pillar of support which is composed by the basin of the vertebrae, articulated in a peculiar manner to each other, is, upon the whole, much nearer to the centre of the body than will be supposed upon the first inspection. Although the figure of each rib, which is attached to the spine, may be examined in figure with more attention, yet, at first, we recommend the consideration of the whole together, that is, the general figure of the ribs with the sternum and cartilages, as the student's proper object, for consideration; the sudden turns which the ribs take backwards from their connexion with the spine, after which their curvature is not so sensible; also that the capacity of the upper part of the trunk is very small when compared with that which is below, contrary perhaps to what might be expected from a sight only of the living figure; he may be inquisitive respecting the extent of motion of the ribs while breathing, in which his anatomical instructor can greatly assist him. Let him examine the junction and situation of the clavicle; the degree of elevation to which the other end of the clavicle being attached to the acromion of the scapula, is permitted to rise by the elevation of the shoulder. The scapula should be carefully drawn as well as inspected, the outside of the parts behind, and especially the spine of that important bone; how much it can be moved by the elevation of the arm above the head, and how much nearer the bases of the scapula can approach each other, when the shoulders are drawn backward; also how distant from each other the bases are, when the shoulders are drawn forwards. Several views of the end of the scapula should be delineated, both in connexion with, and without, the bone of the arm, marking the acromion and coracoid processes. The inside view of this bone should be fetched with the clavicle and humerus removed; that the mind may be clear in these parts, although they are very much hidden by muscles, &c. in the living figure. When the nature of the ball and socket-join of the humerus with the scapula has been well observed, nothing need, at present, to be noticed, but to draw and mark that bone of the arm, and notice the parts upon it which give attachment to the muscles, until the muscle come to the extremity united to the ulna; which, we think, should have considerable attention paid to it, both as united with the bones of the fore-arm, and separate, that the hinge-joint may be well understood, being careful to examine the condyles, and also the smaller tuberitis, &c. If he can have an opportunity of drawing from a natural skeleton (a natural skeleton is one prepared with its own proper cartilages) it will be greatly advantageous to him; and more so, if he can inspect and draw from these parts when newly dissected. We also advise that particular attention be given to the inner and outer protuberance of the humerus, giving attachment to some very important muscles with which artists ought to be acquainted.

The ulna should be drawn separate and in connection with the radius, its hinge-joint also with the humerus: this should not be paid over hastily. Its extremity at the elbow should be very much considered, and the permission it receives by the hollow of the humerus, &c. of folding, as it were, into that hollow, when the arm is extended. The same attention must be paid to the peculiar shape of the radius, the degree of the upper extremity of this bone with the ulna and humerus, the rotation motion which is admitted, in pronation and supination, the size of these bones at the elbow and at the wrist, the head of the ulna being larger above, smaller below, and the contrary in the radius; as well as the general shape and proportion when both are united together.

Lastly, with respect to the present consideration of the radius, we call particular attention to the tubercle, in which is inserted the tendon of the biceps muscle. The compact bones of the wrist or carpus being articulated to the radius, with the considerable motion it allows, will be an object to which, even at first, the attention is due, and its union with the hand, &c. The metacarpal bones, and those of the fingers may be well understood by making careful drawings.

We now descend to the pelvis, composed indeed of several bones, but perhaps better understood by artists, when they are together, than when separate, as they admit of no motion in themselves, except at the coccyx; but the motions of the pelvis itself, upon the thighs, demands, we think, even at the very first, as much attention, if not more, than any other bone of the human body.

The understanding of the turns which this compages of bones take in standing or moving figures, will particularly afford the informed artist to produce graceful effects in his imitations, or, at least, without knowledge of this particular, it is by accident only that he can produce his figures in graceful positions. When by drawing this balus for the abdominal viscera (without concerning himself with its contents), he is become acquainted with its form, he should fluty in the following manner: let him observe the upright posture of a graceful figure, standing upon one leg, right or left; let him next consider how the spine of the ilium will appear in that flat; then place the pelvis so before him, and draw it carefully, the inclination of that important part being according to the posture. This will do for a person who is eager in the pursuit of knowledge, in all other flats in which the action moves the pelvis; and will exhibit him the different nature of the fluid of anatomy, in a surgeon or a painter, or to what different ends the same figure may be applied.

The ball and socket-join should be well considered, where the femur is articulated with the ilium, the whole form of the thigh-bone should have due attention paid to it; particular notice should be taken of the great trocanter, and also some observation should be made upon the ridges in the femur. This should be studied by the artist; being let in the different postures that it sustains, under particular actions, as was before directed for the pelvis; but the condyles, and the nature of the joint, and its tuberitis, demand strict attention in connection with the large bone of the leg. It should be observed, that this joint is very ridged when the leg supports the figure, and admits of no rotatory motion; this joint should also be studied without, as well as in connection with the patella. When the leg is firmly extended, as in supporting the body, the patella is drawn up by strong muscles, and rises above the joint, being then flattened on the outside of the
the head of the femur; but when the leg is bent, the point of the patella again falls within the joint.

By carefully drawing the tibia and fibula they will be understood; but the protruberances forming the ankles must be observed, and the faithful delineation of them forced up in the mind; noticing that the inner ankle, formed by the tibia, is higher, and advances more forward than the outer ankle formed by the fibula. The heel and tarsal bones with the metatarsal should be studied as they are united, nothing the manner in which the bones of the leg are placed upon them, together with the whole of that finely constructed arch that bears up the whole body.

In addition to what has been said upon the study of the knee, the aid which the natural skeleton affords should lead the draftsman to correct knowledge of this important and beautifully formed and useful joint. If he has opportunity, it should be also studied after a fresh dissected subject, with the leg in extension, as well as in its state of flexion and, as before hinted, his observations written on the margin should accompany the drawings.

In contemplating the articulations in the natural skeleton, it will be observed, that the shortening of the body at one time more than another, is not by drawing out like a worm one part of the body from another, but by the muscles bringing the bones more perpendicularly over each other. This leads to the consideration of the muscles.

A muscle is composed of two tendinous and slender parts,” as Count Algarotti expresses himself; “one called the head, and the other the tail, both terminating at the bones, and of an intermediate part, called the belly: the action of a muscle consists in an extraordinary swelling of this intermediate part, while the head remains at rest, fo as to bring the tail nearer to the head, and consequently the part to which the head of the muscle is fixed, nearer to that part into which the head of it is inserted. There are many motions, to effect which several of the muscles (for this reason called co-operating muscles) must swell and operate together, while those calculated to effect a contrary motion (and therefore called antagonist muscles) appear soft and flaccid. Thus, for example, the biceps and the brachiius internus labour, and when the arm is to be bent, and become more prominent than usual, while the gemelli, the brachiius externus, and the anconaeus, whose office is to extend the arm, continue as it were flat and idle. The same happens respectively in all the other motions of the body. When the antagonist muscles of any part operate alone and at the same time, such part becomes rigid and motionless; this action of the muscles is called tonic.” It is to be wished that the student may be informed by a dissected subject of the nature of the different forts of muscles, as those whole fibres are direct, like the biceps, of others which are oblique, like the pectoral muscles, of those which are called penniform or featherly, as that which moves the thumb. Those which are round, being internal or little seen, do not belong to his studies. He should also be taught that the tendons admit of no contraction or extension; that they are long for convenience, and that they are in general confined near the centre of motion, by annular ligaments, to prevent deformity, and also to admit of a more quick motion, as in the wrists; but where the contrary arrangement renders them more useful, they are not thus confined as in the hamstrings, and the bend of the forearm.

He should know that the same muscles are used to draw the body to the arm, which draw that member to the body; also, that those muscles which bend the thigh on the body, when the feet are fixed, bend the body on the thigh; that some muscles have not all their motions engaged in every action in which such muscles are employed, but only part of them, as the deltoid, the portions of which have various motions; such portions, however, never act without the concurrence of some other adjoining muscle with them.

These things being premised, the student is to be directed how to proceed, and what are the ready means. We before directed him to the tables published by anatomists: this advice, we suppose, to have been complied with. It is, therefore, recommended him to draw with care from a good cast of a muscular figure, after the skin and other integuments have been taken away by a skilful anatomist. In the Royal Academy there is a valuable figure of this kind, which is strongly recommended to those who can have access to it; and where he will also find other subjects of this nature worthy his attention, as well as proper instruction from a very respectable professor of anatomy; but in the want of the instruction which that institution has provided for its students, &c and the use of the large anatomical casts, which it poiffeis, a cast should be procured from those shops which supply artists with anatomical and other figures in plaster of Paris. Mr. Banks made an excellent model after the original, which we mentioned to be in the Royal Academy, about three feet in height, which was cast in plaster; and we recommend it above any others that we know can be obtained. The figure (of which this is an admirable copy, though of reduced size) was prepared for the benefit of the late Dr. William Hunter, to which every attention was paid by him and the artists who assisted him in placing the figure in a graceful attitude.

The unfortunate subject of that cast was executed for murder, the body was taken from the place of execution as quickly as possible, and while warm, and the muscles capable of contraction, to which their nature disposes them (even without the influence of the will), the body was set in the posture it now stands, and in which it was dissected; then the cast, of which we speak, was produced. Many similar attempts have been made, but this appears to be by far the most successful of any figure we are acquainted with, which arises from several concurring circumstances; such as its being a well proportioned figure, its attitude graceful, the limbs so disposed as to shew each part distinctly, and its having been prepared by a great anatomist. Being a cast from nature itself, the mind has an unbounded confidence that he who studies from it cannot be misled by the mistakes of an artist; and that the figure being set while the muscles were warm, they have, in a great degree, the proper swell, comporting with the statue of the limbs. Mr. Spong made a small model of this figure, the bronze casts from which, for their size, are excellent. There are several other casts to be met with which may greatly assist the student: that after the anatomical figure which was modelled by Mr. Rubilius, is very natural and good; there are also some executed by the French Academy. We recommend the head and neck as large as life from the French, and also the trunk and upper extremities in a reduced size; one side having the external muscles taken off, and the other side retaining them for the sake of comparison. Another of the leg and thigh of a man with half the pelvis, exhibiting the psoas muscle; the latter which we particularize, and desiring as much notice as any, are two dissected arms, cast under Dr. Hunter, which are fine exhibitions of muscular strength. While the student is in practice, and as his judgment expands, or his fellow practitioners recommend, he will find afflicting objects of this nature presented to him in abundance. These hints concerning the casts, &c may be of use to some of our readers, especially those who are situated at a distance from the metropolis.

Whatever cast of the muscles the student’s judgment or con-
convenience has selected, he ought to examine and copy different views, writing upon the margin (as we directed concerning the study of osteology) the names of the muscles, their origin, insertion, and their use, as flexors, extendors, and rotators; observing, with the same attention, the situation of the bones behind the muscles, and where the projections on the surface are caused by them. While the young artist is making such drawings, he will do well continually to examine and compare the living figure with the anatomical cast; the figure being placed in the same attitude with the object of his imitation; tracing with the finger the bones and muscles of the living subject to ascertain the causes of the effects he observes, and which he cannot otherwise account for. This will greatly facilitate his knowledge.

A common-place book for anatomical sketches, as well as the complete drawings he has been advised to make, will be very useful, in which the separate parts may be delineated; beginning with the head, and descending to the lower extremities, in the following manner. First, suppose it to be the front view of the head and face of the skeleton; then he may draw from a plaster cast of the head, &c. with the skin taken off; such as the large dissected head, from nature, which we mentioned as being prepared by the French academy; or if this be not at hand, the head from any of the before-mentioned anatomical figures. Then a drawing should be made in the same view from a living person, in whom the muscles are to be distinguished, the subject not being covered too much with fat. Several views of the face should be treated in this manner.

What has been said of the head will apply to the neck, trunk, the arms, hand, thighs, legs, and feet; this practical method will be of considerable use to the artist, and if the separate parts in different views be also drawn from some of the antique figures, such as are placed in a similar posture, his taste and style will, at the same time, be greatly improved; it will naturally suggest itself, that such of the antiques as are robust and herculean, will be most proper for him at first to select, for such purposes; these objects will lead him not only into the knowledge of the parts, but he will naturally imbibe the right style of representing muscular motion from them. We are acquainted with no critic who has observed any anatomical error in the antique statues, or an instance in which the profound knowledge of anatomy does not appear; none who have detected a false swelling of the muscles, or any offensive display of anatomy; for those well-informed artists exhibited no more of their knowledge than was proper, as it respected the character of the subject, either delicate or robust, at rest, in motion, or in violent exertions.

This remark, we believe, is strictly due to the statues and fragments of the ancients, though it may not be so applicable to the valuable works, in other respects, of the great Michael Angelo himself; whose figures will, notwithstanding, be of a very improving nature, especially while the artist is in pursuit of anatomical knowledge; but he should be cautioned not to follow even this extraordinary man in representing these appearances too strongly, where it is not requisite; nor in giving the swelled motion of the muscles to the whole body and limbs, flexors, and extensors, at the same time,—which cannot be, but in rare instances, as in sudden starts of surprise or agony. A common-place book of the nature which has been recommended, besides the original exercise, will restore to his memory the impression which time may efface from it. This being the student's own work, a sight of it, and his other studies of the same nature, will more affix his recollection, concerning the subject he has formerly considered, than a much longer examination of prints or drawings by other persons can be supposed to do.

In order to prevent embarrassment amongst the great number of muscles, the following arrangement is made; by which the student's attention at first may be circumvented, and those demand his particular attention, &c.

</table>

These muscles selected, and thus arranged, are few in number, and will not perplex the student; considering how important they are to his art, he should not be discouraged when informed, that with most of these he ought to be intimately acquainted. With respect to the pnoe, and one or two more of the internal muscles, it is necessary only to know that they exist, and where they are situated; but most of the other muscles, thus particularised, should be very familiar to him, not only where they are placed, but how they appear when at rest, in common action, or in violent exertion; and if the method we have recommended be attended to, a tolerable capacity will attain a great degree of knowledge respecting the muscles, as well as the bone of the human figure.

In the Royal Academy will be seen, before that already mentioned, another muscular figure, prepared by Dr. Hunter, one side only of which has the skin, fat, &c. taken off, that a comparison may be made with the other side of the figure, in which it may be seen how much thicker some parts of the human body are covered than others. The student ought to have information respecting this circumstance by other means, if he has not access to this figure. It should also be known that although there is a considerable difference in the size of the muscles in different subjects, between those who are accustomed to labour and exercise, and those who are more sedentary; yet it is the cellular membrane, or fat, which principally constitutes the difference between corpulence and meagreness, and not the muscular fleshy substance of the body; and also that children's muscles are in proportion with adult, according to their size and age; the painter will see the propriety of this remark.

One more observation is necessary to be made respecting the covering of the muscles, which is concerning those tendinous expansions that wrap up and bind them together in

Vol. II.
in many parts; these are usually strong, although thin and transparent; on this account they cannot in general be so well expressed by carvings or drawings, but in the dissected subject, which the student should inspect if possible; the limb and fat being taken off, the expansions are discovered by their white and shining appearance. We advise all young artists to obtain instruction respecting these aponeurotic expansions, and particularly the facia, which arises from the tendons of the biceps muscles inserted into the radius, and also from the palmaris covering the palm of the hand, and the expansion from the gluteus, where it is united with the trochanter, covering the muscles of the thigh; he should consider this as no trivial object of his concern. In the fore-arm the structure from the aponeurosis is so strong as greatly to affect the form of that part of the limbs where it passes over the pronator teres, flexor, carpi radialis, palmaris, &c. and it is strong enough to shew itself, even in carvings from nature; in the calf from an arm prepared by Dr. Hunter, this is beautifully preferred, although a dissected arm will shew it better.

It will perplex the student to account for such appearances in general, although he may have the most perfect knowledge of the bones and muscles, unless he be informed respecting this circumstance also. — In various parts of the body some of the larger veins appear, such will be found upon the surface of the subjjects, from which the painter makes his studies, and therefore he need not to be particularly directed, nor concerning those which redden the parts upon exertion, as the fore-arm, when the hand is strongly grasping a sword, &c. or the redness and paleness occasioned by the different passions of the soul. See Passions.

We might describe the action of the muscles we have selected, and in the order they are arranged; but this would be defending to particulars more than we proposed, especially as they are best learned under the immediate instruction of an anatomist, pointing them out on the living figure, or which the student may observe upon his own perfon in a glass, (a method much recommended by the late Dr. Wm. Hunter,) or upon a living muscular subjject. We shall, however, particularize a few muscles as specimens, in order to lead him into the proper method, by which he is to proceed with the rest, and also prevent some observations for his consideration.

A figure standing gracefully cannot, with propriety, be said to be in motion or exertion, but many of the muscles are in exertion to produce even this effect, i.e. those which support the figure in the erect position, especially the muscles of the standing leg and of the loins.

When the body is prepared by the mind to receive and support a weight, the muscles are in exertion, prepared to support what it expects to be received; should a man offer to another any heavy weight, covered with a light subfubance, as cork, &c. bearing it with such an air as to imply it was not heavy; from the mind being thus deceived, there would not be a preparation or exertion of the muscles adequate to support it, and consequently it would fall and endanger his toes, although the person would be more than capable of supporting it under other circumstances. On the contrary, if a body of a light nature be thus preferred, covered so as to represent a very heavy subfubance, and the person conveying it seems to exert himself as bearing a considerable weight, so soon as the palms of the hand come in contact with the pretended heavy subfubance, the muscles would be so prepared to exert themselves, as immediately to upheave it into the air. This may be seen also in the muscular exertion of a person catching a ball projected with a strong degree of force. An artist may obtain information respecting the propriety of muscular exertion, from the ancients, by placing a living person in the action of any of the antique figures; as perhaps what they represent the figure doing: trenchly comparing with the figure the several muscles and limbs, as well as the general form, whether standing gracefully, as the Antinous, more exerted as the Apollo Belvedere, or in violent exertion, as the Laocoön.

This method is the best we can recommend for the improvement of the student's taste and judgment, other methods will conduces to his knowledge of the parts; but this will communicate the idea of graceful motion and the proper expression of the figure. Studies from the living figure should be continually made, and those who are wise and are not prevented by other avocations, should in England, as in France and Italy, never forsoke the life academy, in which school much of practical knowledge will be learned; but the student's taste must be formed from the antique figures, in all that relates to proportion, elegance of form, and anatomical propriety. A sound knowledge of anatomy, is the ground of the painter's art; it is, however, better to know and produce the effects like the ancients, after their deep researches, so as to hide the artifice by which those effects are produced. Art of edare artem.

Although it is not our intention to describe the motions of the muscles, included in the list, yet we shall notice a few of them and some other circumstances, as a specimen. Dr. Hunter has often been heard to say, that the principal method he used in order to attain the knowledge of muscular motion was by consulting his own body, because he could give the action to those muscles he wished to examine, and he strongly recommended this method to others. This trial, from a eminent character, will be adopted so far at least, as it respects the intricate muscles of the fore-arm, and by a glafs he may inspect the front of the whole figure; but such parts as cannot thus be examined, must be sought for in another person. When a living muscular subject is placed before the student, (with an affiant to oppose the effort which he is to make, in order to retain the muscles in action for a short space of time, while they are under immediate notice,) the commencement may be with the head. The maffeter and temporal muscles will be in exertion when the teeth are strongly pressed together; this exertion will be seen in a man when he is lifting a great weight; these muscles should be felt as well as seen, that the mind may be quite satisfied respecting them. The effect of the stylogmatiac muscles in drawing up the corners of the mouth will be perceived when the subject is smiling, &c. Although these muscles do not always shew themselves, they ought to be considered attentively, as they have a great influence in expressing the passions. Sternohyoides will be in action when there is an attempt to swallow any thing. We suppose all the muscles in our arrangement have been well considered; and that the student has become acquainted with their form, origin, and insertion, and also with the use of the separate muscles.

The sternomastoideus draws the head downwards, forwards, and sideway; in order to notice the action of this muscle, first let the man turn his head over the right shoulder, when it will be found that the portion of this muscle, which is on the left side, will belly out, consequently it will grow tenfe, and shorten itself, while that portion which is on the right side, will be longer and flaccid; this will be evidentiy seen, and may be felt and measured with a string, that the student may be perfectly informed respecting a muscle so important to all artificers. The face should be then placed in the centre, and the person must be then directed to endeavour to bring his face down upon the breast,
ANATOMY.

break, while an assistant places his hands upon the forehead of the living model, to oppose his bringing it down; while making this attempt the thoraco-mamillaries will be seen in strong action in both portions, and be very conspicuous; but when the head is in the centre, and in each way in the same direction with the body, and that perfectly upright, this muscle will not so visibly shew itself, excepting near the insertion in the scapula.

The pectoralis will be seen in very strong action, by the man endeavouring to bring the fore-arm to his breast, the hand being lifted up about the height of his shoulder; if the assistant, at the same time, make an effort to keep the arm outwards. If the man with his arm thus raised, move it inwards and outwards several times, an opportunity will be given to observe the motion of this muscle; so also if the hand be lifted higher than the head, then brought downwards and inwards, he will also perceive that the pectoralis should properly be considered as a muscle belonging to the arm, notwithstanding it is situated upon the breast.

Thus the flexors and extensors, pronators and supinators, should be examined in motion, after their place and use have been rendered familiar by the order and method of study we have been detailing. What has been advanced upon the study of muscular motion in a few instances, we hope, will be proper clue to all the other external muscles; many errors may be avoided, and much time will be saved, if the several parts be pointed out to the student, by a skilful anatomist, who will demonstrate to him, that although it may be proper to remark the action of the separate muscles by themselves, yet still no action of a limb is performed without the cooperation of several muscles. This should become as evident to the mind of the artist, as that the detoid elevates the humerus, or that the biceps is a flexor of the fore-arm.

He will, by such an instructor, be informed that some of the muscles, or parts of them, are so thin, as to shew the motion of those which lie underneath, as the latissimus dorsi; and although others are deeply seated, yet they have great expression in some actions, as the longissimus dorsi, which will become very conspicuous, when the body of the figure, being bent downwards, endeavours to regain an erect position.

The student should let the figure before him raise his head and depress it again; turn it over one shoulder, then over the other; this may be done quickly and repeatedly, while he makes his observations on the muscles in the neck.

He should direct the man to bow his body downwards, and bring it up again repeatedly, at one time more quickly than at another, while he observes the motion of the rectus abdominis, &c.

The model should also be directed to draw in his breath, to shew the boundary of the true and false ribs, which must be well observed. He should make him stand upon one leg, then upon the other, shifting them continually more or less quickly, while he notices, with great strictness, the change this will cause in the shape of the ilium, and the other parts of the pelvis; on this we lay particular stress, as in a preceding instance, when directing the study of the bones, without the muscles.

He may now examine the motion of the patella, and the muscles rectus and vastus of the thigh, with the same care.

He should cause the man to lift up one foot, and bring the heel to the other knee, in order to exhibit the motion of the vastor muscular.

By quickly moving the toes, the man will shew the muscles in action, which give them their motion.

He should be directed to elevate and depress the arms, as well as bend the fore-arm, to shew the performing muscles of those parts; to turn the palm of the hand upwards and downwards, which will exhibit the pronators and supinators. The wrist bent and extended, and the fingers quickly moved will shew their muscles.

When the back of the figure is seen, the same method should be pursued to express those muscles which are behind upon the trunk, and the extremities; carefully noticing the motion of the scapula, especially the different situations of that bone, when the arm is lifted upwards, and brought downwards; likewise examining the motion of the muscles in the side view of the figure in the same manner.

Particular attention should be given to those muscles which form the edges of the armpits, and of the hand and fingers of the thighs; and lastly, as study and drawing ought to be considered by the painter as synonymous words; we advise that such things as strike the mind, when they are newly discovered, should be noted by the student in a book kept for the purpose, with such sketches as may tend to recall to his mind in future, or defer to others, what cannot be so well conveyed by words alone. Advice of this sort has been repeated under each head of study, as we know the consequence it may be of to some of our readers.

Dr. Brisbane judiciously observes, respecting comparative anatomy, "that the painters should at least be acquainted with the anatomy of those animals which are most commonly introduced into their works, particularly of that noble and useful animal, the horse, and of that faithful companion of mankind, the dog: as for other animals, as they more rarely appear in pictures, and are less particularly known and attended to, a slighter representation of them may generally suffice." We, however, believe that birds should be examined in the interior, as opportunity offers, especially the skeleton. In respect to the horse, we recommend the painter to read, and examine the valuable labours of Mr. Stubbs and Mr. Blaine, which we conceive to be an honour to our country. He may also be furnished with an anatomical chart of an horse, which is fold at the shops; from whence information in this respect may be derived, especially after the human figure has been well understood; for, by knowing what are flexors, and what are extensors, in general, the student will be in a great measure informed how they will act in this animal. Assistance will be also gained by observing the animal itself, which he will have before him while he is painting it. Some animals, but especially leopards and tigers, are formed so much like a cat, that this common animal will be very useful to him; their muscles may be judiciously expressed, if a dead cat be put into the posture of the animal to be represented, before its muscles are cold, and then the skin being taken off, it will be an almost perfect direction to the painter, who is familiarly acquainted with the action of the muscles in general.

See the names of the muscles of the human body in the Cyclopaedia, their character, nature of their fibres, origin, insertion, and uses, to which our readers are referred for more particular directions concerning them.

ANATOMY, Veterinary.—Human anatomy, in point of interest and importance to mankind, evidently holds the first place; that of brutes, particularly such as are domesticated and employed for various important purposes in society, in respect to their anatomy, holds the second place. The anatomy of these, without being entered upon so circumstantially as the human anatomy, deserves a due share of regard equal to its importance. To describe each part of the horse individually and separately, would be often only repeating the more elaborate

B b 2
descriptions
descriptions of the human anatomy more frequently than those but little convenient with this subject would suffice; many of the fishes, and even the mythology of the trunk and extremities, often correspond in their principal circumstances: there are, however, great and various differences in the structure of the two animals, which it will be our duty more particularly to describe. For the same reason that the study of the human anatomy is useful, as it tends to preserve the health and lives of men, equally so is that of brutes, inasmuch as it tends to save the lives of these useful and often costly animals. Nor will it be necessary to defend far down the chain of quadrupeds; the few only which from their domestication are rendered servicable to mankind, deserve this particular notice; in conveying anatomical research farther among the brutes, and in descending into the more subordinate orders of animated beings, the study of their anatomy receives its share of importance, in proportion only as it serves to illustrate the uses and functions of particular organs and parts of the more complicated and noble animals, from the very various figure and structure these parts are found to assume in them, from which much information of their use may be obtained; and then, instead of veterinary anatomy, it becomes properly the subject of, and arranges under the head of comparative anatomy.

This science may be properly termed veterinary anatomy, which, in strict propriety, should include only those animals employed as beasts of burden, as the root of the word (volo corde) from whence it is derived implies; but it is necessarily extended to all domesticated animals employed in the service of man. The horse, the ass, the camel, the ox, the hog, the dog, the sheep, &c. rank principally under this class. The anatomy, however, of the horse has only been much cultivated, and that but of late years; various establishments of considerable munificence have appeared within the present century for the cultivation of this fudy, as that of Charenton near Paris; Lyons, Berlin, London, Copenhagen, Vienna, &c. These institutions, together with the exertions of individuals, have begun to advance this science into respect and estimation; the anatomy and surgery have already received a high state of cultivation, as being more easily attainable by direct mechanical means; the progress of medicine is more slow, and it will be more readily admitted by those most conversant with the subject, to be at present in a state of great obscurity; and from certain difficulties attending the culture of medical science in general, and particularly in these animals, a long period will be necessary for it to obtain much constancy or precision; small effects are with difficulty traced in mute animals, and no feeling or change in them can be described or known, unless powerful enough to be externally visible. On the other hand it is but just to remark, there is a more free and unlimited opportunity of experimental inquiry and research, as their diseases are fewer, and arise from less complicated causes, than those of men.

This science, though it has long lain in a neglected and degraded state in this country especially, and throughout all Europe, yet has not wanted men of refinement for its cultivators. Among the writers who have distinguished themselves in this line of science are to be enumerated among the ancient Romans, Vegetius; he is supposed to have lived about the time of the emperor Valentinian the Third, in the fourth century, and is generally considered the fame writer, whose book "De Re Militari," has been so much admired, as giving the best account of the military tactics and warlike weapons of the ancients; his treatise "De Arte Venenaria," is not less curious in the present age, as handing down to us the practice and opinions on the veterinary art at a very refined period of the Roman empire: his work is principally a compilation from the most esteemed authors of his own time; and especially the Greeks; the prefaces, or introductory chapters to his four books carry with them sufficient evidence of their author, and are remarkable for the firm and elegant language. Better reasons or apologies for the cultivation of this science have, we believe, never been penned; and though medical reasoning and physiology were at this period in a low state, till we view with surprize, that the practice was very often not materially different from that which would be suggested by the most refined reasoning of the present day. Columella has treated largely on this subject; he lived prior to Vegetius, in the second century, under the emperor Tiberius. Cornelius Celsus, about the same period, is also underflow to have written on this subject, but of his work there are unfortunately no remains. At a still more remote period than this we find Greek writers on this subject of considerable note; no less than seventeen are enumerated by Ruelli, who was physician to Francis I, king of France. The surviving fragments of these authors were edited by Ruellius, by the orders of his munificent patron, first in Latin, in folio, in the year 1550; afterwards the original Greek text, in Svo, in the year 1537; both splendidly printed, so as fearfully, in this respect, to be surpassed by any thing of the present day. To this collection of essays, Ab-yrus, Eumenelus, Hierocles, Peloaeus, Theonellus are among the chief contributors; their writings consist of dissertations on the various diseases of the horse, beginning moilily in the epistolary form, with the usual intimations in the among the Greeks. We learn from Suidas, that Abyrus was a Bithynian by birth, and served under Constantine in the Scythian war. Hierocles appeared in the courts of law in trials respecting those animals, and did not, like Theomnello and Abyrus, serve in the armies of the emperor. The period in which the others lived there are no means left of ascertaining; it appears, however, to be most probable that they lived at an early period after the formation of the empire. In these writers the symptoms of some disorders are pointed out with much acuteness, in which consists the greatest value of their writings. Their prescriptions are often ill-digested farragoes, composed of many incongruous ingredients, some but little known, and others altogether disguised at present in medicine. In the administration of remedies of a surgical nature they were more happy, especially that of topical bleeding, which they well understand, from every part of the body. Xenophon has also treated expressly on these subjects in twelve short essays or chapters respecting the training, management, and external figure of horses, and is the most ancient of all the writers extant on horses, being between three and four hundred years before Christ. At the decline of the Roman empire this science underwent the general fate of all the other sciences, and suffered an occultation longer than almost any of them. A period of more than a thousand years elapsed without adding as much to the human knowledge of this subject as has been done within the last twenty only in Europe: during this period, however, of the obfuscation of science, at an uncertain date, was propagated the art of shoeing horses' feet with iron, and which at length became general; an art that has been variously practiced, and never yet reduced to certain rules. It appears also, that, during this period of declining literature, the veterinary art ceased to exist as a distinct profession, or was practiced so feebly, that, on the discovery of the art of shoeing, what knowledge then remained of it was easily transferred to the working smiths, who alone could practice this art. Its fitter science, human surgery (it would hardly now be credited), underwent a similar fate; and, for the want
A N A T O M Y.

And in this place we cannot help noticing a singular barbarism, that appears to have been the offspring of the above writers, which has found its way into common use, in one of the terms belonging to the veterinary science, and which we conceive ought no longer to pass uncorrected, as terms misapplied in science are always confusing, and oftentimes lead to error. The word 

*ferrari* is at this present time universally in this country employed to signify the whole veterinary art, and is a barbarous mode of spelling the word *ferrius*, as it is immediately derived from *ferre*, French, to shew a horse, and that from the radical *ferrum*, Latin, iron; and should signify no more than what the word implies, the application of the iron shew to the horse's foot. The want of regular practitioners in the veterinary art rendered it necessary that the ferrer should adopt the art; and hence the whole art became included in the general term ferrariy. In reducing this word to its proper spelling, for there can be no authority to justify the present mode of spelling it, and in expunging it, we commit no violence on the usage, or introduce any innovation on the English language, for there exists sufficient testimony to prove that the old English writers did not spell it as we do at present; as in Blundeville, who wrote during the reign of Queen Elizabeth, which, according to Johnson (see preface to his Dictionary), was the purest era of the English language, we find it spelt, with great propriety, with an e; see book fourth, in his "Address to the Gentlemen of England;" he writes, "All horses, for the most part, do come into their decay sooner than they should do, by one of these four wanies: that is to say, either for lacke of being well bred, or through the rashnes of the rider, the negligence of the keeper, or else through the maliciousnes of the *ferrer.*" Again, in the same chapter, "Martin Ghelly, of Arton, called Martin Alman, chiefe *ferrer* to the Queen's majestie;" and so on throughout the work. The title of Earl of FERRERS and DERBY might also be adduced in proof of this being the ancient and proper mode of spelling this word, the arms of this nobleman being quartered with the horse-shoe, and formerly accompanied with some singular privileges to the family. This word, therefore, reduced to its original and proper signification, only relates to the art of making and applying the iron shew to the horse's foot; and in this sense we shall have occasion to employ it, as the veterinary art embraces and all the other branches of the science. Indeed, on pursuing an historical retrospect of the state of this science in England, it has seemed to us, for the last hundred years and upwards, to have been taking a retrograde course, which we feel rather disposed to attribute to the unbounded rage for horse-racing, which, while it was of great service to the British nation, by encouraging the bell breeds of strong and fleet horses, was of disadvantage, by promoting an artificial vaccinated taste with regard to these animals, which overawed all attempts at model inquiry respecting their diseases. The knowledge of horses was supposed to confound in a sort of intuition, which was not to be defined or taught to others. Jockeys, sharpeners, and gamblers, were supposed principally to possess this knowledge, which was all that was thought necessary respecting them, and all farther information could be of no use. Jockeys before this period were of small note, but from being entwrought with the secrets of the course, soon became engines of great importance in pursuing this species of traffic, and men at length were brought to reign their understandings to them, imagining it a subject too mysterious and difficult for them to comprehend; hence also appears to have arisen the great difficulty of founding a seminary for the study of veterinary medicine and surgery in this kingdom, which was almost the last country in Europe that adopted this salutary step for the improvement of the art.

A more
A more free and candid mode of considering this subject led me to suppose; and a style of writing and enquiry, which
must (however it may labour under difficulties for a time)
bring both light, and, with the great improvements in che-
mistry, and all the arts and sciences which can promote it,
will soon place it on a footing far beyond what was known
in ancient or modern times.

Having gone through what appears to us to be the out-
line of the history of the art, as far as we are at present
acquainted with it, we shall immediately pass to a descrip-
tion of the skeleton of this useful animal.

On taking a general survey of the bones of the horse,
(see Plate 1) we may divide them into those of the head,
spine, trunk, fore and hind extremities; and here it will be
proper, in pursuing this general view of the skeleton, to
remark a circumstance that is not universally known, viz.
that the horse, when in the habit of proceeding and leaping,
comes within the square, the head and upper part of the
neck only being excepted; and this applies alike to horses
of every description, as well as the race-horse as the dray-
horse: to explain this attention, the dotted line is given,
pointing out the limits of the figure. If this principle was
more generally known to the painters and statuary, we
should not have so many ugly and nefariously disproportioned
animals from their hands. This subject we propose to treat
of more extensively under the article Symmetry of Horses.

On a further examination into the general properties of
the skeleton, we propose to show, that the weight of the
horse is supported by a counterpoise of the angles of the
superior part of the fore and hind extremities, as the shoul-
derd-blade, or scapula, a, b, c, d, e, from the withers, leans
obliquely forward, forming an obtuse angle with the arm, or
humerus, f, g, h, i; in the hind extremity the reverse of
this structure is observable in the position of the bones, as
the hip-bone, or ilium, a, b, c, d, g, and the ischium, f, f1,
which pass in a sloping direction backwards, and form with
the thigh-bone, or femur, b, m, k, n, an obtuse angle for-
wards. Now it is evident, that the angular position of these
bones being opposed to that of the shoulder and arm, will
readily, by acting in opposition to it, support the weight of
the body which is placed between the two angles; the rest
of the two extremities are disposed nearly in the perpendi-
cular line to these angles, and support the weight as simple
columns, still, however, following, in a slight degree, at the
hocks and knees the above angle of support. From this
curiosity view of the entire skeleton, it will be necessary to
pass to a more detailed examination of the bones which
compose it, without being too minute for an elementary
work of this kind; and we shall begin with the head, which
is formed of the skull, face, and jaws, and which are di-
visible into about 32 distinct bones; the skull consists of 11
bones; the two frontal (see Plate 1.) bones, a, b, the two pa-
tietal, c, four temporal, b, i, k, l, one pteroid, one ethmoid,
and one occipital bone, d, e, f, g. The temporal bone in the
horce is made up of two distinct portions, the squamous and
petrosus, which in this animal always remain distinct. The
occipital bone differs much from the corresponding one in
the human skull, forming the top of the head, and is pof-
fed of very great strength and thickness, with a deep de-
pression on the centre, where the cervical ligament is at-
tached. The face is made up of 21 bones, as follows, two
nasal bone, (see Plate 1). r, two angular bones, m, two malar,
or cheek bones, l, two superior maxillary, n, o, p. The in-
ferior maxillary bone, q, is not found in the human skeleton,
and has been termed by Prof. Blumenbach, the inter-
maxillary bone; it was supposed by him for a considerable
time to be peculiar to the brute, and would serve for a dif-
tinctive mark by which every species of the mammals
might be distinguished from the human; but latter researches
have, however, discovered that no such bone existed in some
of the long-tailed monkeys, though, it is worthy of remark,
that the same bone is found in several of this tribe of animals
with short tails. There are two superior palatine bones, two
inferior palatine, two superior turbinate, two inferior, two
prepygoid bones, and the vomer. The turbinated bones
are particularly large in the horse, as are also the maxillary
cavities; and by the elongation of the face, the head of
the horse is extended in length beyond almost every other
quadrapod. Two thin plates of bone, almost distinct from
the palatine bones, and divided by a future, following the same
to the direction as the large palatine, are observable in the space
between the malar and molar teeth of the upper jaw:
these might be termed the lesser palatines; they are, how-
ever, merely processes of the intermaxillary bones, and not
divided from them by any future. The intermaxillary bones
in this animal contain the whole of the inferior teeth, but
not the canin, or tusks, the future pitting between them.
The inferior maxilla, or rather, in the horse, the pectoral,
or jaw bone, is formed of one bone, at least in the adult,
and is not, as in the human, made up of two bones, united
by sutures at the chin; it is necessarily longer and deeper
than the jaw of most other quadrupeds. The jaws are fur-
nished with alveoli, or excavations, which receive 40 teeth,
viz. 12 upper, or incisor teeth; 4 tusks, or canine teeth;
and 24 grinders. The tusks are never found in the horse,
though they are in the dog, and some other carnivorous
animals; the three first pair of molar teeth are also
found in the horse, and receive a second set; the three last
pair are permanent; the first set of incisors, or milk teeth,
are also found as in all other animals. For the growth,
structure, and other particulars of these bones, and some
remarks respecting the indications of the age, we refer the
reader to the article Teeth of Horses. The face is a canal
of bone, of a very elongated conical figure, and, in the
horse, is made up of about 32 pieces, independent of the
bones of the tail, which is formed of about 14 bones.
The cervical vertebrae are seven in number, which it has
been remarked by anatomists, prevail in all quadrupeds,
whether the neck be long or short. These bones in the
horse are altogether different from those of the human ske-
eton in their formation: the body of the bone is consider-
ably more elongated, and the processes of a different figure.
The first vertebra in the horse is termed, as in the human
skeleton, atlas, but evidently with not so much propriety,
as the head of the horse is rather suspended from this bone
than resting upon it; it differs essentially in figure from the other
vertebrae of the neck, being more extended laterally, and
in being without any dorsal apophysis; it is also much shorter
than any of this range of vertebrae; it receives anteriorly the
condyloid processes of the occipital bone, and likewise poste-
riorly the tubercle of the second vertebra within its articu-
lating cavities.

The second cervical vertebra is in figure almost the reverse
of the former, being long and narrow in its body, the dorso-
proces, or crita, very elevated and enlarged, rough on its
upper surface, for the strong insertion of ligament; and this
spine, or elevated plate of bone, at its posterior part, is
bifid, or cloven, with a middle depression, or foria, affording
a stronger and wider surface for muscular and ligamentous
attachment. This vertebra has no superior oblique pro-
cesses, and enters the former bone by a half tubercle, or ca-
pitulum, exposing the spinal marrow on its upper part, and
is kept in its situation by two broad lateral articulating sur-
faces.

The
ANATOMY.

The other five bones, which compose the neck, are of a more uniform figure than the two former, confiding of a body of bone, somewhat lengthened, having a large cylindric perforation for the passage of the spinal marrow, exter-}

nally of an irregular, almost triangular, figure, having various angular and spiny elevations of bone, which are termed according to their situation, as the spinal apophysis, the superior and inferior oblique processes, the transverse and anterior processes, which are intended for the strong insertion of muscles, tendons, and ligaments for the support and motions of the neck. The articulating processes of these bones confit of a round head of bone, the posterior articulating surface of a flat feelance to receive it. This knob of bone is observed by Stubb's to be wanting in the sixth vertebra of the neck; these bones possess also various perforations for the transmission of blood vessels and nerves.

The dorsal vertebrae are 18 in number, sometimes 19, and are remarkable in the horse for the length of the dorsal or spinous processes, extending from the first to the eighth, and which form what is called the withers of this animal, and against which the superior part of the shoulder is brought to recline.

The dorsal vertebra differ in structure from the cervical, being much shorter in the body or solid part of the bone, the spinal apophysis being longer, the anterior processes wanting for the underfide of these vertebra, and thofe of the joints present a smooth rounded semicircular surface to the vifera. The interposing cartilage, or cartilaginous, in the vertebral column, is not in the dorsal vertebra; it makes in the recent skeleton more than an eighth part of the whole length of this part of the spine.

A dorsal vertebra of the horse poifles almost a similar number of processes as are found in thofe of the neck, though very differently situated and proportioned; these processes are all placed superioriy to the two articulating surfaces of the ribs; and it is almost unnecessary to repeat that they poifles foramina for the passage of nerves and blood vessels, and the spinal marrow.

The lumbar vertebrae. Where the ribs terminate, begin the lumbar vertebrae, which are six in number, and poifles very much the fame poifles and character as thofe of the back. The spinous processes are stronger, the lateral processes broader and longer, and sometimes articulate with the body of the vertebra, and in some measure serve the purpose of spurious ribs. These bones are often united into one mafs in the horse, by osseous deposit, as are also thofe of the back.

The five next bones of the spine are united into one mafs in the adult, to give strength and energy to the various motions of the hind quarter, and in their consolidated state are called the os sacrum. The interlites occasioned by the union of these bones on their underfide, form what, at first sight, appear to be huge foramina, being rounded, as thofe generally are.

The superior part of this bone poifles longer spinous processes thofe of the loins, and admits a vallf feelance for the attachment and depofit of muscles; and here are placed the muscles of loco-motion, which, in all animals, are the lafit in the body.

On the superior surface of the transversf processes of this bone rei the flat inferior surface of the ilium, to which surface it is attached by strong ligaments, fo that the body of the horfe is, as it were, entirely fiupended by ligamentary and muscular tabfluence, for the scapula has no other than this species of attachment: hence the entire exclusion of a solid bony articulation of the extremities with the spine must often every motion of the animal to itself, and consequently to what it has to carry.

The remaining portions of the spine, confiding, in the horse, of 18 pieces, gradually lose the structure and properties of the foregoing parts of the spine, and become simple rounded cylinders of bone, solid and enlarged at the points of articulation, and towards the extremity of the tail are of a confitence nearly cartilagious.

Of the trunk. The coxal, or ribs, are bones of a curved figure and elafic, serving to defend the principal part of the thoracic and abdominal viscera; and in the horse are generally 18 in number, sometimes 19; these are articulated by one extremity to the dorsal vertebra by two surfaces, a lateral and terminating articulating surface. The eight flrfl of these ribs terminate on the sternal itself by an equine cartilagious tabfluence; the others do not reach the sternum, but are attached to each other by a long surface of adhesion of the same kind.

The sternum in the horse is composed of seven pieces of bone firmly united, and differs widely from the human in being curved, and, instead of being flattened, is anteriorly acute, like the prow or keel of a vessel. This anterior part is also of an oblong-cartilagious consistence, terminating above by an obtuse eminence above the articulation of the first rib, and inferiorly by the faceticular cartilagious of an oblong figure. This structure enlarges the chest, and gives room for a stronger attachment of the fore extremities to the shoulder for the support of the body.

Of the ilium, ischium, and pubis.—These we may consider as forming part of the trunk; they are, however, only attached to the spine by ligaments, having no actual articulation, and might be referred to the hind extremities. These bones form collectively the haunch, the thigh being included, and internally the pelvis.

The ilium, or hip-bone, in the horse, is not of a rounded figure, as in the man, but is extended in three directions, forming three powerful branches or processes, which may be denoted, by way of distinction, the superior, inferior, and posterior rami, the three extremity margins or edges of the bone included; between the above rami we propose to distinguish by the terms anterior, superior, and inferior crista. The ramus inferior is shorter than the others, and obtusely truncated, giving an anterior and posterior pointed angle. The extended branches and wide upper surface of the ilium give a place for the attachment of several strong muscles which are thus situated; to the greatest mechanical advantage, to the points on which they are to act, giving with the ischium a magnitude and power to the buttock not equalled perhaps by any other animal.

The ischium in the horse is remarkably extended, forming a strong process posteriorly for the reception and attachment of powerful muscles, and which process is entirely wanting in the human skeleton. This elongation of the ischium may be denominated the processus ischii from its figure: this singular process dips the muscles attached to it very advantageously for powerful action on the thigh and leg, by removing them to a distance from the centre of motion.

In the os pubis there is to be remarked the very extraordinary depth of the lymphatic, affording an extensive surface for muscular attachment.

The above three bones unite in forming the acetabulum, or cup, which receives the head of the thigh bone, in both the human and equine skeleton.

There appears to be a slight degree of motion of the ilium on
on the transverse process of the sacrum; arising from the ligamentous connection between these bones; in the dog this motion of the shin is more evident, and on dissecting this part we have observed a regularity which, we believe, has not been generally noticed, and which is worthy of remark in this place. The os human in this animal arises to considerable advantage over the transverse processes of the lumbar vertebra on its internal part, that the middle of it, instead of being occupied as in other animals with the iliacus internus muscle, is entirely filled up by the muscles of the back, and the above muscles entirely wanting. We may, perhaps, illustrate the cause of this peculiar structure by remarking, that the action of the dog, as in gallopping, is performed principally by the muscles of the back, in the horse it is more effected by the action of muscles of the extremities.

In taking a view of the figure of the pelvis in this animal we may observe its depth is greater, its area wider, and acts more in the line of the spine than in the human.

Of the extremities.—The great variety of accidents and abodes to which the extremities are liable, and the peculiarity of structure which attends these parts in the horse, render a knowledge of them more interesting and necessary to the veterinarian or amateur in these matters than any other part, and will engage us to consider them with more minuteness and detail than we have done in executing the preceding imperfect outline of the description of the other parts of this animal.

The extremities of the horse are constructed of much the same members as the human, though very differently distributed and proportioned; the human hand, the first of all executive instruments, is here converted into the foot, useful only for support and progression; the hand grows more complex towards its termination, while the horse's foot becomes more simplified, following the purpose for which it is designed. Notwithstanding, these parts in all quadrupeds have a relation to each other, and pose the rudiments which even appear superfluous, but serve to point out the connexion between the different families of them; as the hyloid bones of the horse are evident rudiments or relics of the two outside metataral bones of the digitated animals, and appear to serve no very important purpose, as the mammae or nipples of the male quadrupeds are rudiments void of use of the same parts, which are highly useful in the female.

Of the fore extremity. The scapula, blade bone, or shoulder of the horse is considerably lengthened, and is considerably narrower than the human, being of an oblong triangular figure, poliellizing neither acromion nor coracoid processes, though there is a prominent, obtuse point of bone in the situation of the latter, and a rounded eminence often on the spine of the scapula, which denotes the situation of the former. The horse, we may observe, pose the scapula in this part no proper back, for the withers can hardly be considered as such, therefore the scapula does not materially pass out of the plane of the os humeri, or arm, as in the human, but is simply reclining on the side, its upper part reaching near the extremities of the dorsal apophyses or withers, its lower part directed forwards, and approaching the stilt rib and upper extremity of the ilium. The under face of this bone is concave, and is found in old horses covered with sulci for muscular attachment; the upper surface is divided longitudinally into two unequal parts by a bony ridge, called its spine, affording surface for the attachment of various muscles and tendons; the base or broad extremity of the scapula is furnished with a cartilage, which embraces the muscles of the withers; its small end pose the articular cavity which receives the head of the humerus, and is termed the glenoid cavity. The motion of this bone is different from any other in the body, not moving upon either extremity, but librating round a point which is situated near the centre of the bone.

Of the humerus, or arm. This bone is particularly short when compared with the bone of the human arm, scarcely passing beyond the line of the chest, and is proportionally stronger, passing from the point of the scapula in an oblique direction backwards; and instead of partaking of the various motions of the above bone, pose but one motion, that of being brought from its inclined position forwards to the perpendicular line of the body. This bone pose the various strong elevations and depressions for the lodgment and insertion of muscles, of which there is hardly any trace in the bone of the human arm. It articulates inferiorly by two strong conveys with the radius. It is this bone, often being too long, that brings the horse's fore-legs too much under his body, a fault much disliked by the amateurs of riding horses; this may also arise from the shoulder being too upright. The fore-limb of the horse not requiring any rotary motion, as in the human arm, we find no distinct os ulna, but the point of the elbow, or olecranon, being very much enlarged and extended in length, is firmly fixed to the back of the radius, sending off a process of bone downwards, which is brought to a point about the middle of the radius, uniting firmly with it; from its position being fixed in respect to the radius, it can perform but one of the offices of the human ulna, and serves for the attachment of those muscles, which bring back the fore-arm, from its bent position forwards, to the straight line, under the pressure of the weight of the body. For the os radius, see Fig. 1. l. l. The radius or fore-arm of the horse is nearly straight towards its middle and inferior extremity, bending a little forwards; it is usually mistaken for the arm of the horse by casual observers, its posterior surface is flattened, it grows broader at its extremity, forming two conveys, poise the motion, upon the bones of the knee, admitting an extent from the perpendicular of the leg, considered together with the bones of the knee, to a very acute angle backwards.

Bones of the carpus, (see Plate 1. figs. 1, 2, 3, 4, 5, 6.) are the bones which compose the carpus, vulgarly called the knee of the horse, and correspond to the bones of the human wrist; these bones do not afford a similar extent of motion with the same bone in the human carpus, not admitting any motion forward beyond the perpendicular line, nor of any lateral motion whatever.

On a first view of the bones of the knee of the horse, their position seems reversed to the human wrist, the olecranon or elbow being placed at the back of the radius, and the flexion taking place in a direction towards it; and the bones which form the back of the wrist appear to form the front of the knee. This inversion, however, is only apparent, and not really so, as by a flight rotation of the radius, the human wrist may be placed in the same relative position to the ulna, as the bones of the knee of the horse are with respect to it.

The knee of the horse is made up of seven bones, sometimes eight, a very small, round bone being often superadded on the side, about the size of a pea, and is not preserved in the generality of the skeletons of the horse.

This joint is formed of two regular layers or phalanges of bone, the upper phalanx or row being placed upon and between the divisons of the other three in each phalanx, the 7th being thrown behind.

The first layer, viz. that placed on the cannon, has little
or no motion: the second layer has considerable motion on the first as those have also on the radius, making in their total flexion about 30 degrees of a circle.

To strengthen this joint, and to secure these bones more firmly in their situations, they are formed with alternate elevations and depressions both in their upper and lower surfaces; this joint is also rendered stronger from having an articulation, which admits of motion in one direction only, that of flexion, and that in the opposite direction to the flexion of the hock, tending by this means to support the animal, as we have before observed.

The weakness of this joint, called knuckling in horses, observable in those that have been overworked, or grown old, does not, we believe, proceed from any defect of the joint itself, but from the rigidity of those muscles which serve to bend it, and especially those which pass to the foot, the extensors, which are comparatively small, not having sufficient power to counteract it.

These bones have but little resemblance to those of the human wrist, though they occur in the same number; it will therefore answer no good purpose to force an analogy between them by calling them by the same names; for the use of the names deduced from the human anatomy makes a perpetual recurrence to those names necessary to see where they may, without impropriety, be introduced, and where they cannot be admitted; it is this circumstance which has rendered it absolutely necessary to compare both the skeletons in this present essay.

These bones might very naturally be denominated from their situations as follows; the or externum superior and inferior, or internum superior and inferior, or medium superior and inferior, or pollicem, or accessorium, and this would be a very desirable thing, for they would belong to a great number of quadrupeds without being misappalled. There is, however, a confiderable objection to their adoption, which is, that in describing the attachment or infections of ligaments or muscles, it would render a circumvention necessary if any other language was used, which would be attended with inconvenience, and for which reason we decline the use of them.

Mr. Stubbs, in his excellent work, in following too closely the names of the bones after the human skeleton, has been betrayed into the use of names, which cannot well be admitted in the equine anatomy. The or facifom is a very small rounded bone in the human, not larger than a pea; the or pollicem, though a perfectly distinct bone, and differently figured from any in the human anatomy, has been described by Mr. Stubbs under that name.

If it were desirable to make any analogy between these bones and the human carpels, we should on comparing them remark, that in the horse’s knee there is a confolidation of some of the human carpal bones, and a separation or division of others; there is, however, the small accessorium bone included, the same number in each, viz., eight bones.

The or trapezoides and magnum appear conjoint in the horse, forming one large flat bone, whilst the bone in the horse, which serves the purpose of the unicofem bone at the back of the knee, is made of two distinct bones; the human unicofem bone appears in front of the wrist as well as behind and is one single bone. This curved bone also differs in the horse in being removed to the upper row or phalæs, for the bone serving the same purpose in the human wrist, is seen in the lower row of the carpal bones.

In this way they may be compared and understood, as, after this explanation, the others fall in very naturally in their proper situations in both. Were it not on account of the names, it would not be necessary at all for the veterinarian to pursue any comparison with the human skeleton, and we think it would be advantageous to avoid it; for the alteration of their figure, on which the human names are founded, renders the same names in the horse totally inapplicable.

A nomenclature for the equiæology, which would include nearly, or quite all the quadrupeds known, might be constructed, and would be attended with great utility; such a nomenclature, however, would require, that neither figure nor situation should supply the names, as these would be perpetually varying.

It is no easy matter to give appropriate and unexceptionable names to all these bones, nor should we be disposed of undertaking it, if the above circumstances, and others that might be added, did not point out the absolute necessity of it; we are aware of the circumflexion necessary in such a measure; and after such consideration as we have time to devote to this subject at present, venture the following as the best adapted which at present occur to us.

The middle bone in the upper phalæux we propose to name as intermedium, being found near the middle of the upper range of bones in all the animals we have examined.

The large internal bone of the same phalanx we propose to denominate as parietum, which, not conveying any particular geometric figure, will apply, without glaring impropriety, to a great variety of shaped bones: the external bone of this range, as gibbium, having some gibbous elevations on its surface.

Of the lower series, the central one we should be led to express by the term as majorium.

The external one, as pollicare, carrying the thumb in all digitated animals, and sitting even in the horse on the internal thyloid bone, which appears evidently the corresponding rudiment of this member in the horse, and is actually elevated above the level of the third bone, and is placed higher than the thyloid bone on the opposite side, serving to confirm the resemblance. It is this bone which so frequently becomes dilated with office deposit, termed splints.

The external bone of this range we would denominate as facifom or falcifom, being provided with various elevated points, rudiments of the hook-like process, and corresponding to the human facifom bone.

The bone serving the office of the facifom bone in the horse, and holding nearly the situation of the pliiform, connecting and supporting the tendons, &c., which pass through it, being altogether a different bone from that of the human serving the same office, which has a curved process on the inside of the wrist, that no confusion might arise with this bone, we change the terms unicofem, or pollicem, in the horse, and call this additional bone, which is found in most quadrupeds, and even in the feline tribe, where digitated extremity is a much nearer approach to the human hand, the or pollicem, or the pol-carpal bone.

This bone gives great force and support to the tendons which pass through it, or are attached to it, allowing depth and solidity to the knee. It is this bone which occasions the prominent point at the back of the knee, affording a strong and handsome outline to this part; it also serves for the attachment of a very strong tendon at its extremity, which being then removed farther from the centre of motion in the joint, is empowered to act with very great force, and resembles, in this respect, the office of the os calcis on the hind extremity.

The or accessorium is a small round bone, about the size of a pea, which articulates with the posterior surface of the os pollicem.

The os pollicem has been termed by Vicet, a celebrated French writer on this subject, os hors de rang, a name perfectly
ANATOMY.

We shall only further observe on the bones of the present point, that the surfaces for motion between the second phalanx and the first are particularly disposed to the outside of the joint, tending by this means to separate the legs when in action from each other, and prevent cutting. This is particularly remarkable in the or fabulaciforme and mammiform. The flexion of the upper phalanx upon the radius is hereby backwards only, and forwards to the perpendicular of the extremity.

Of the metacarpal or Shank bones.—The great difference of proportion in the parts which compose this extremity to the human is not here more conspicuous than in the metacarpal bones. The range of bones which form the wide palm, or the paws, of animals, is here for the principal part conduced into one broad cylindrical bone, longer considerately than the humerus itself, the rudiments considerably abbreviated of the two exterior metacarpal bones remaining to point out the general connection among quadrupeds; the cow has the Shank bone double of splot bones, but at its inferior extremity is divided, forming two condyles for the reception of the two claws, and in this way forms near an approach to the firsted animals, though in a different way.

The Shank bone is flattered posteriory for the reception of the tuniporous ligament and tendons going to the foot, which we may observe is more considerable in the fore extremity than the hind one; the latter is longer, and of a more cylindrical figure, being generally describ'd as having no perceptible difference. The phaloid, or splot bones, adhering to the Shank bone strongly, and are mostly united to it by osseous depositions, otherwise wherever preserving a divided outline between the two bones. In the fore extremity these mostly dwindle to a point, about two-thirds down the length of the Shank bone, and are no longer large in the hind extremity. These splot bones, though so often productive of diseases, tend to strengthen the joint laterally; and perhaps by their elastic yielding to the perpendicular prefrere of the limb, being elevated above the general articulating surface of the Shank, may act as cushions in a slight degree in preventing concussion; they also serve to strengthen the limb, by affording a surface for ligamentary attachments. The inferior extremity articulates with the pattern bone by a condyle, having an elevated ridge of bone in the middle to support it, which enters a corresponding depression in the pattern bone. This joint, though strongly fortified with ligament and tendon, is more subject to suffer from violent ulage than any in the body. In the cloven footed animals the division begins in this part.

Osseous tendons. Sefamoid bones, fig. 1. p. q. r. s. v. are placed at the back of the pattern joint, and resemble, in their figure and properties, the same bones in the human foot; diminishing friction, powerfully softening the tendons going to the foot, and at the same time supporting the pattern joint by their prefrere.

Of the or safrinaeum, or pattern bone. This bone corresponds to the first phalanx of bones of the fingers, the five bones of which may be considered as consolidated into one single bone; its general figure resembles sufficiently a bone of this part.

The pattern bone, at either end, is indented for the reception of the prominent condyles of both the Shank and corone bone, fig. 2. q. p. t. u. t.

The or corone, or corone bone, fig. 1. r. r. s. t. w. w. is, like the former, a similiar condensation of the five bones of the second phalanx of the fingers, and is proportionably shorter than it; it articulates by a divided condyle with the collum bone.

This and the preceding are rough on their sides, with depressions for the strong insertion of ligament, especially laterally, in the point of the axis of the condyle, where a deep indentation is observable.

Of the or bufis, or collum bone. fig. 1. i. j. x. x. —This name, and that of the two former bones, have been taken from those Latin writers who have treated on this subject, and, we conceive, will not require any alteration.

A dilatation resembles may be traced between the enlarged rounded point of the extremity of the bone of the fingers and this bone. The particular structure, however, of this bone and the flot bone, and their various appendages and integuments, is sufficiently important to form a separate description. See Foot of the Horse.

Of the hind extremity.—The femur, or thigh bone, of the horse, compared with the human and, indeed, with most other quadrupeds, is unusually short, so as fearly to appear beyond the parietes of the abdomen externally on a curvory view, and is therefore overlooked by those unacquainted with this subject, and the bone below is usually mistaken by them for the thigh of the horse.

This bone is of vast strength, posseing several elevated and depressed points for the strong insertion of tendons and muscles, which serve to distinguish it from the thigh bone of every other animal. See Plate I. fig. 1. b. i. k. l. m. n.

The head of the thigh bone in the human is carried by an oblique process, or neck, to a distance from the bone, whereas, in the horse, the head is without any length of process of this kind, placed at right angles, nearly to the bone, not affording that variety of motion which the human structure of this part does; a motion directly backwards and forwards, being for the most part the only movement requisite in this animal.

In a state of rest the thigh bone is not nearly in the perpendicular line of the body as in the human thigh, but inclines forward, making an angle with the body of about 45 degrees, and forms posteriorly an obtuse angle with the rect of the extremity. This circumstance is necessary to be observed with attention previously to understanding the design of the muscles of this extremity, concerning the nes of which we propose to advance some ideas, which, as far as we know, have not before been entertained respecting them.

The muscles which are attached to the posterior part of this bone are called its extensors, serving to draw it from the oblique line it describes forwards, backwards to the perpendicular of the body, being attached near its head, and rather laterally.

These muscles also which render this angle more acute, by drawing it forwards under the belly, are called its flexors, and are attached to its anterior superior part. We mention these rules respecting the functions of the muscles of this part the more particularly, as the terms flexion and extention but ill express the operation of these two classes of muscles on this bone, for the inversion of the terms would apply almost equally well; adduction and abduction are also generally attributed to other muscles, as they are found to attach to the inside or outside of the limb. We propose to demonstrate that such are rarely or never necessary among quadrupeds; and that such a val bone of muscles as there are to be found in both extremities of this description, have a much more important purpose to perform.

The great trocanter of the horse, see fig. 1. Plate I. rises considerably above its articulation with the acetabulum. This removal of the surface of attachment of the gluteus muscle farther from the head of the bone, must befow uncommon power.
power on this muscle in the horse, in extending the thigh backward.

The lesser trocanter in the human thigh is placed almost behind it, in the horse laterally internally.

The most notable circumstance in the thigh bone of the horse is a flaring, curved process of bone on the outside opposite the lesser trocanter, see fig. 1 t. k, which receives in its curvature the vastus externus muscle, m. vastus lateralis, and m. vastus medialis, fusing itself with the external ligaments of the thigh muscle. Mr. Stubb’s terms it the protuberating part of the linea aspera; and Vitet’s apophysis recta, tom. i. p. 121.

On the posterior and inferior part of this bone, near its external condyle, there is a deep cavity, in which the perrotatus muscle takes its rise.

The condyles of this bone are remarkable for their magnitude and strength; the outer condyle is larger, and is placed posteriory to the inner condyle.

In the dog, and also in the cat, we have observed a small, round, movable bone attached to the external condyle by a ligament not observable in the horse.

*O f the patella.—* The knee-pan, or little bone, is particularly large, elevated, and thick in the horse, having the lubricous cartilage on its inside where it meets the femur possessing correspondent, impressed condyles for this purpose. This species of cartilage is common to all surfaces of bones which are contiguous; therefore the continual repetition of this circumstance, in describing the articulations of the bones of the skeleton, has been omitted.

This bone serves to increase the surface for tendinous insertion of the muscles of the thigh, &c. passing over an angle on which it can easily glide; it elevates the tendons high above the point they are destined to act upon, and in this way vastly increases their force on the principle of the pulley and block; and we may here observe a property of this bone not generally observed, that it serves to unite in one focus the action of the muscles lying on the opposite sides of the bone, as the vastus externus, internus, and anterior, bringing them to act for one purpose on a single point, in which is clearly seen an instance of a principle we are about to deduce respecting the adductor and abductor muscles.

*Of the tibia, or leg-bone of the horse.—* This bone corresponds in structure with the human much more than the femur; it is, however, shorter, cat. par. There is near its head a sharp apophysis, which might be called its anterior cripita; its external side is concave, in which lie the bodies of several muscles; its internal side convex, posteriorly it is flattened; its epiphysis may be divided into two condyles, external and internal, in the young foal; from the latter springs a small, finous process of bone, the rudiment of the human fibula, which is totally wanting in the ox; the hog, cat, and dog possess a perfect fibula.

*Of the tarvis, hough, or back of the horse.—* This important joint in the horse is made up of six bones, sometimes seven; the internal cuneiform being sometimes divided in two parts, as in the preparation at present before us. This joint in the ox, deer, and sheep appears to have no more than four bones, which seems to point out an extraordinary provision in the horse to increase the perfection of the joint, and prevent the ill consequences of violent concussion, as the additional bones in the joint of this animal are evidently well calculated for such a purpose.

The human tarvis makes a right angle with the tibia, and, in the act of standing or walking, meets the ground; in the horse it makes a very open angle with the tibia, and is very far elevated above the ground; and here we may remark, that all the bones from the hock downwards are used for walking on by different tribes of animals; where the metatarsal bones are elongated, it is raised above the ground. The kangaroo, however, appears to be a remarkable exception to this general rule.

The astragalus bone in the horse possesses two very strong, prominent condyles, which are not observable in the human astragalus.

The *os cuboideum* is found holding the same figure and situation in both animals reposing by its inferior surface upon the external flayloid and shank bone, its upper surface receiving the inferior extremity of the os calcis by an articulation not poising motion.

The two central cuneiform bones of the human calcis appear to be united in the horse to form one flat extended bone, which rests upon, and covers the greatest part of the articulating surface of the head of the shank bone.

The *os naviculare* also of the human tarvis is here converted into a flat extended bone, resting on the former; these two bones together equal in height the *os cuboideum*. By these two flat plates of bone, with their interposing cartilages, a species of cushion is formed, which renders the effect of the violent efforts and concussions this part is exposed to; that they have a purpose of this kind may be inferred from their taking no part in the flexion of the joint.

The internal cuneiform bone, or a bone that holds its situation in this animal, is found resting on the head of the internal styloid bone, which appears to correspond with the bone of the great toe in the human anatomy.

We are again subject to the same difficulty in giving appropriate names to the bones of this joint as we were respecting those of the knee. The bone, called in the human anatomy the *articula*, in no respect in the horse resembles a boat, nor the one beneath it a wedge, therefore to continue these names would be absurd; their situation also as little corresponds as does the purpose they serve in the two animals.

The cuboid bone, the *os cuneiform* and internal cuneiform bone may, without any impropriety, continue to receive those names in the horse, and particularly as it will be attended with convenience to hold as many names as can be admitted corresponding to the human anatomy, by which, at all times, a more ready communication can be held between the two sciences, but not so as to prefer this comparison too far by a servile copy of it, and a comparison between things which have little or no resemblance, or relation, by which the greatest confusion may be created, and the science at its commencement be clogged with improprieties.

The only changes it will be necessary to make in this joint from the human anatomy respects the two flat bones, which may be termed, with propriety, the *os planiforme superius and inferius*. These are the bones which often become diseased with the deposition of offirce matter, forming an enlargement which is termed *tarsus planus*, and also the *internal cuneiform* bone.

The metatarsal, or shank bones of the hind extremity do not differ in any respects, so as to deserve a separate description, from those of the fore extremity; the differences there adduced, we may perhaps add, that the styloid bones in general descend lower in the hind extremity, and are often elevated at the extremity instead of being pointed.

*Of the muscles of the horse, &c.* The following is a brief account and explanation of a large portion of the most interesting muscles of the horse; the short space of time al-
ANATOMY.

rowned for the preparation of this article, and the prejudice of other affairs have prevented us from considering more accurately this subject; the muscles of the extremities, as being the most interesting and important, are more particularly selected; they are accompanied with descriptions taken from actual dissection, during our studies, in the year 1793. The remainder is an explanation of two of the principal muscular figures, given by Mr. Stubbs.

This account is necessarily imperfect; it may nevertheless afford those who are curious only of an elementary knowledge of the subject sufficient information; those who wish to descend deeper into this study will do well to consult the following writers: Bougerel, Elements de l'Art Veterinaire; Laplace, Cours d'Hippatrique, and especially the useful work above mentioned of Mr. Stubbs: a good monograph on the muscles of the horse, giving a proper description of their figure, attachment, insertion, and use, till remains a desideratum in veterinary science, to which it should be subjoined the synonyma of the different writers on this subject.

Our description of the muscles of the hind extremity is with deference presented to the public, as a specimen of the manner we conceive such a work should be executed.

Of the panniculac cornutus. The fleshly panniculus is the most exterior and general of all the muscles of the body; it is found in molt or all quadrupeds, and often serves them in lieu of hands, lying immediately underneath the skin, to which it is attached, and over the cellular membrane covering the muscles; it is of a pale red colour, and envelops a large part of the body; as it passes towards the extremities it forms a thin expanded tendon or aponeurosis, which descends to the superior part of the extremities, enveloping the muscles, and lodging itself in the cellular membrane of those parts, and by attachment to the tendons and elevated points of bone.

When this muscle contracts it corrugates the skin, and affords perhaps by other muscles, it can shake the whole frame with considerable violence, thereby dislodging from the coat duff, dirt, flies, and other offending matters.

The butchers are careful in exposing this muscle on their meat, which serves to give it a more agreeable appearance; it is seen of a pale red colour, and here and there they cut through it a longitudinal nick or slit to expose the white cellular membrane and fat with which it is beneath.

The muscles of the fore extremity of the horse are about 34. They are disposed about the limbs when detached from the body so as to form a pyramidal figure, whose base is attached to the body, and whose apex is resting on the ground; on the bafe of this pyramidal, if we may be allowed the expression, or upper end of the extremity, the muscles are found to possess a four-fold position, viz. an exterior, interior, anterior, and posterior position; such is especially their arrangement about the scapula and humerus; as we descend they become more simple, and occupy at length only a two-fold position, serving for more flexion and extension, as is observable about the radius; at the apex of the cone no muscles are observable but merely the tendons of the last series of muscles, with the bones and ligaments to which they are attached.

Abduction and adduction have been the use imputed to such muscles as are attached to the inside or outside of the scapula, extension and flexion to such as are attached behind or before it; it will, however, we believe, be obvious on reflexion that the scapula can have no occasion for such movements as adduction or abduction, and so also respecting some of the humerus; therefore we are disposed to conclude that these muscles in whatever direction situated have their principal effect in producing a combined operation, promoting the grand object in view, the support and propagation of the animal; and we shall endeavour to shew hereafter, that an abductor and adductor contracting at the same instant of time with equal force, will not produce an effect in either of those directions, but will co-operate according to the position of the bone in an extensor or flexor motion.

The muscles of the scapula are six: trapezius, rhomboideus, levatorius, pectoralis anticus, triangularis, serratus mayor.

1. The trapezius, is a thin extended muscle of a triangular figure, whose point or termination is fixed on the spina scapulae, rather above its middle, its base extending from the cervical ligament along the ligament of the 1st, 2nd, 3d, 4th, 5th, 6th, 7th, spinae apophyses of the dorsal vertebras or withers. It forms an aponeurosis which envelops great part of the abdominal muscles, terminating at length on the linea alba; it also sends off a fleshly portion to the muscles of the neck. Le Trapeze, Vitef. tom. i. p. 155. Stubbs, Anat. Horfe, tab. i. p. q. g. r. f. l. u. x. x. x.

2. The rhomboideus is a short almost square, fleshly muscle beneath the former, takes its attachment to the cervical ligament and ligament connecting the spinae apophyses of the dorsal vertebras, and pusses underneath the cartilage at the base of the scapula, which it almost wholly occupies by its fleshly adherence.

This muscle possesses no tendon, and serves, independent of its effects on the motion of this part, strongly to attach the scapula to the body.

3. Levatorius, or extensor scapula. This muscle is of considerable length, and of a conical figure, its base being fixed to the superior and anterior angle of the scapula, its fibres mixing with those of the rhomboideus, from which in some subjects it can hardly be separated; it pusses tapering along the neck, adhering to the cervical ligament till it terminates in a point or tendon on the same ligament about the second vertebrae.

4. Triangularis. The triangular is a fleshly muscle arising from the occiput; where it embraces the neck it grows narrower as it approaches the scapula, where it terminates by a flat tendon, uniting itself to the rhomboideus, and to the tendinous insertion of the serratus major; its fibres are straight, and the muscle is divided into distinct fascicules by interposed cellular membrane.

5. Serratus major. This very large muscle forms collectively the figure of a fan inverted, the point thereof being towards its insertion beneath the scapula, its circumference on the ribs. It takes attachment by numerous digitations of muscle from the first to the 9th or 10th rib, the posterior digitations of this muscle interweave themselves with the digitations of the oblique muscles of the abdomen, and the anterior portions of or with the intercostal muscles. The triangularis above described may also be considered as a part of this very extensive muscle; the fibres converging from this vast circumference at length terminate by a transverse fleshly adherence to the superior interior part of the scapula between the rhomboideus and subscapularis muscles. There is a falcin arising from the upper surface of this muscle which runs to the linea alba over all the muscles of the abdomen.

These digitations of the serratus major may act in succession, as so many separate muscles, or in masses, the motion being transferred from one to the other, by which it can cooperate with any other series of muscles or alone, by producing a species of rotation of this bone about its axis.
ANATOMY.

It is also in quadrupeds a powerful suspender of the body, raising it on its contraction upon the extremities. Plate II. c, d, e, f. Vitet, Le grand Domet. Stubbs, Anat. H. Plate II. c, d, e, f.

6. Pectoralis major. This is a strong muscle of considerable length, of the figure of a very elongated cone; its base being attached by strong fibres to the sternum and first rib, anteriorly to the large pectoral, from whence it grows narrower till it terminates on the anterior crista, or edge of the scapula, it also contracts a strong adherence to the pectoralis minor, and its aponervosis covers all the muscles of the scapula. Plate II. c, d, e, f. Le pectoral antérieur. Stubbs Anat. Horfe. Plate II. c, d, e, f. Pectoralis major anticus, p. 12.

Note. The human subclavius muscle is only wanting, all the other muscles belonging to this part in the human anatomy are found in the horse.

The muscles of the humerus of the horse are 12: Elevator, antispina tus, communis, pectoralis major, depreflor, dorsalis major, latissimus dorsi, subcapularis, pectoralis brevis, additator, poliza spina tus additator, additator brevis.

1. Elevator proprius lies immediately before the antispina tus, uniting itself with its attachment. Its attachment is along the anterior crista of the scapula; passing with the antispina tus it terminates on the lateral internal part of the humerus. This muscle is so closely connected with the antispina tus, that one and the other contraction is common to them both. It terminates on the anterior processes of the head of the humerus by a tendon which surrounds it.

2. Antispina tus. This muscle fills the whole space of the scapula anterior to the spinous ridge, adhering to its whole surface by strong fibres; it terminates by strong tendon on the head of the scapula, covering entirely the protuberance representing the coracoid process.

3. Communis. This muscle is of considerable length and nearly uniform size throughout, and is common to the humerus and neck; the panniculus carneus forms strong fibrous adhesions to this muscle; its first attachment is by a small tendon to the side of the atlas; it there forms attachments to the muscles of the neck by strong fibres going to them, and lower down the neck it sends off similar portions, mixed with tendon, to be inserted in the oblique processes of the 4th, 5th, and 6th cervical vertebrae, passing over the articulation of the humerus with the scapula, it terminates on the anterior part of the humerus, about its middle, by a short tendon; it sends off a large aponervosis, which unites several muscles together, and forming at the joints the annular ligaments. It also contracts a very strong adhesion to the lesser pectoral muscle. Vitet. Med. Vet. i. p. 158. L'Humerus cervical.

The above three muscles come under the denomination of extensors.

4. Pectoralis major. On removing the skin and fibrous panniculus this muscle is seen taking its attachment along the sternum and ribs, from the middle of it, between the forelegs, to its posterior extremity, growing smaller as it approaches the humerus, terminating on the internal surface of the superior condyle of the humerus.

5. Latissimus dorsi. This vast muscle is situated above the serratus major, and under the panniculus carneus; its aponervosis is covered by that of the trapezius. It takes rise by a very strong aponervosis on the spinous processes of the last dorsal vertebrae, extending to the loins; on the back it becomes fleshy about its middle, covering part of the false ribs, and part of the surface of the serratus major; passing between this last muscle, and the scapula, it terminates by a thin tendon on the lateral internal part of the humerus: it has likewise a strong attachment by tendon to the middle of the deep pectoral muscle, passing with the tendon of that muscle to the small prominence on the inner side of the middle of the humerus, going between the extensors of the ulna. Plate II. r. t. s. t. v. 160. Vitet, Le grand Dorsal. i. p. 160.

6. Depreßlor, or teres major. This muscle is of some length, oval, and somewhat flattened, lying on the under side of the scapula, and closely embracing the subcapularis, having its attachment to the superior and posterior edge of the scapula; passing over the articulation, it terminates by a flat tendon with the preceding muscle, observing the same direction in its course as the long abductor does on the opposite side of this bone. Le grand rond. Vitet. i. 159.

The above three muscles are depressors or flexors of the humerus.

7. Abductor proprius seu coraco-humeralis. This is a small muscle, cylindrical, and tapering at each extremity, forming a tendon; the uppermost takes its attachment to the lateral internal part of the coracoid process of the scapula, the lower tendon to the inferior and anterior part of the humerus, passing over the articulation, and in contact with the inside of that bone. This muscle acting singly draws the lower part of the humerus to the body, as the subcapularis does the upper part of this bone. Vitet. Med. Vet. Le Coraco Humeral. i. p. 161.

8. Pectoralis brevis. This muscle will admit of being variously divided, and is strongly attached to the panniculus carneus. This muscle forms the breast like prominence between the fore-legs of the horse; it is of a figure nearly square, divible into distinct parallel fascicules, from the point of the sternum, where it joins the muscles on the opposite side, it passes, forming a flattish tendon to the humerus. We have seen this muscle deficient on the one side, and full on the other.

9. Subcapularis. It occupies the under side of the scapula, with which it accords in figure, and needs not any particular description, growing narrower with this bone it descends, forming a broad tendon in the large inner process of the head of the humerus, and will admit of being separated into several smaller muscles. Vitet. Med. Vet. Le sous scapulaire. i. 160.

There are also two other small muscles, which may be considered as adductors, or perhaps rather infl exors; the first of these is not so small as the other, and takes its rife at the interior projection of the scapula, or rather superior part of the glenoid cavity by a flattish tendon passing over the joint on the inner side, and taking an oblique direction over the humerus; it terminates in the cavity formed by the condyles of the humerus. We give it the name of M. articularis major. The other, which is much smaller (M. articularis minor) arises from the tendon of the preceding muscle, or the superior and inferior side of the glenoid cavity, and terminates on the head of the humerus by a fleshy attachment. This muscle is not found, we believe, in every subject. These small muscles, it is clear, cannot produce any motion of the limb; their bulk is too small, and they are situated too near the centre of motion to operate with any force in this way. Some have imagined these small muscles about the articulation were designed to move the capular ligament out of the way of being pinched, an idea we cannot subscribe to: those ligaments surrounding the cavity of the joint not being lax.
ANATOMY.

ix enough to be in any danger of this sort, and with their inner surfaces to well lubricated to be caught hold of by an oblique round head of bone. The above three muscles may be confined with the two small ones when acting chiefly as adductors.

13. *Abductor pollicis longus* occupies the oscillopart of the scapula, behind the hamulus ridge; it grows narrower with the bone till it reaches the joint, where it forms a haunchy carilage, which is kept in its situation by two round prominences in the head of the humerus, acting like the sides of a pulley-block: it then terminates on the external就想 of the head of the humerus. *Plate II*. fig. 1, 2, 3, 4, 5.

11. *Abductor brevis* takes its site at the inferior and posterior edge of the scapula, or rather from the fibres of the *polybrachii muscle*, lying between it and the *longus abductor*. This and the former pass over the exteriors of the cubitus, and terminate between the above muscles on the large crooked processes of the humerus. It only differs from the former in being considerably shorter. It sends a tendon to the februous edge of the cotyloid cavity. *Vitell Med. Vet.* t. p. 162. *Le petit rond*. The effect of the principle we wish to establish respecting the co-operation of muscles on opposite sides of the bone, is no where more obvious than in the two foregoing muscles, with their accoutrements, the adductors on the inside. This mode of operation of these muscles appears to have escaped entirely the writers hitherto on this subject. Vitel has remarked respecting them, "ils font executer a l'humus des mouvements, de flexion, et de demitrotation en dehors."

The muscles of the radius and ulna are fewer; two to bend, five to extend them.

1. *Extensor longus* seu posteriores. This muscle is the most exterior of those which fill up that triangular space formed by the humerus and scapula. It takes attachment at the superior and posterior edge of the scapula, and passing down closely, adhering to the large extensor, it terminates on the extreme point of the olecranon. This muscle is the most perfectly situated of any of this extremity. *Plate II*. P. Stubbs* Vitel. Med. Vet.* p. 167, Le long ancœur.

2. *Extensor magnus*. This is nearly the largest muscle of the extremity, of a triangular figure, and occupies great part of the angle between the humerus and scapula posteriorly; it rises by tendinous fibres from two-thirds of the posterior and lower edge of the scapula, growing narrower, it terminates on the inner side of the olecranon by strong and short ligamentous fibres. *Plate III*. fig. 1. N. Vitel. Med. Vet. Le Moyen ancœur, p. 164. Stubbs, *Plate II*. N.

3. *Extensor accessorius*. This muscle is of a figure nearly square; passing obliquely across the other muscles, it rises from the interior part of the crooked spinous proces of the humerus, and terminates on the point of the ulna, uniting often with the preceding. *Plate II*. O. Vitel, Med. Vet. Le Cour ancœur.

4. *Extensor pygmeus*, is situated beneath the others, of a cylindrical figure, tapering to either extremity, rising from the middle part of the humerus, and terminating by tendon on the inner side of the olecranon. Le petit ancœur. *Vitet, Med. Vet.* p. 165.

5. *Extensor minimus*. This is a small muscle of a pyramidal shape, whose base is fixed by fleky fibres to the *olcranon* on its anterior edge, growing narrower, it terminates by fleky fibres on the back part and inside of the humerus, rather below its middle; this muscle fills up the cavity formed by the two condyles of the humerus posteriorly. Stubbs, *Anat. Horfe*, tab. 5. *Vitet, Med. Vet.* L'Oli-canien, p. 167.

These muscles strengthen the limb after it has been carried forward by the flexors, raising the body upon the extremity as a fixed point.

6. *Carpus radius*. This beautiful muscle is externally covered with a ligamentous coating, which gives it a firly appearance, especially on its inside, a strong tendinous fascia enveloping it: it occupies the front of the humerus, extending from the coracoid eminence of the scapula to the anterior part of the head of the radius, to which it is fixed by strong, short, ligamentous fibres. Near its lower extremity it lends off a strong tendon, which, passing along the radius, inserts itself into the tendon of the anterior muscle of the hand. This muscle, in passing the joint, is lodged between the two circular, smooth prominences on the anterior part of the head of the humerus, and is provided with a lubricious cartilage beneath. This muscle is the biceps of the human anatomy, which name will not apply in the horse, having but a single origin. Its body is very deeply cleft. Stubbs, *Anat. Horfe*, *Plate VII*. i, L, d, n. *Vitet, Med. Vet.* Le Curo-Cubital, p. 165.

7. *Flexor convolutus*. This muscle lies in contact with the bone, filling the large cavity or neck of the humerus; formed by the curved process on its exterior part it rises under the posterior part of the head of the humerus, making a spiral turn, it lapses over the bone, filling the cavity above-mentioned, and terminates anteriorly in the hollow of the head of the radius. Stubbs, *Anat. Horfe*, tab. 9, t. r. *Branchials internus*. *Vitet, Med. Vet.* p. 165. La brachial.

The two last muscles are termed flexors; they carry the lower part of the extremity forwards, and the extensors serve the purpose apparently of removing the body to it as a fixed point on the ground.

The muscles of the knee and shank are fixed, two to extend, four to bend them.

1. *Extensor carpi*. It is the body of this muscle which forms the handsome roundity observable on the lateral and rather external part of the radius. It is attached superiorly to the anterior condyle, uniting to the extensor of the foot; it descends, suddenly, forming a flat, broad tendon, lying close to the bone, passing under the lateral extensor tendon, and over the bones of the knee, it terminates on the superior part of the Shank bone, on the anterior tubercofity, by strong ligamentous fibres. Stubbs, *Plate III*. a, b. *Plate II*. d, e. *Extensor carpi radialis*. *Vitet, Med. Vet.* Le Cubital externe anterior, p. 168.

2. *Extensor laterealis*. This muscle takes its attachment for a considerable length along the sharp edge on the external side of the radius; forming a flat tendon, it takes a direction across the leg, and passing over the tendon of the principal extensor, purfuing an oblique direction over the bones of the knee, it terminates on the inside this joint on the os pollicare. *Plate II*. g. Stubbs, *Plate II*. e. L*exten- teur de Genou, L'afolle.

3. *Flexor carpi pollicer*. This muscle has an attachment by strong tendons to the posterior and lateral external part of the humerus; increasing in size, and becoming very flat, it descends, keeping an uniform size, down the radius, forming a large flat tendon, dividing into two parts; one is strongly
ANATOMY.

A strongly inflected in the crooked bone, *pus proficeum* is the other pallest to the shank, and is inflected on its head. Stubbs, *Plate II. m, w, a, o, p, q, r, s*. Vitell. i. p. 169. Le Cubital externe polletane.

4. Flexor offis pollicis. This muscle takes its attachment on the opposite side of the humerus to the former, fending off a considerable branch to the inside of the olecranon, it terminates by a strong tendon on the external condyle of the post-carpal bone. Stubbs, *Plate XII. l*. Vitell. Le Cubital interne polletane.

5. Flexor internus. This muscle is smaller than the two former, and is placed more internally; it takes attachment at the lateral internal condyle of the humerus, and, passing along the radius, forming a thin tendon, which passes through the capsule ligament; it at length terminates on the posterior part of the cannon or shank bone, and infrapinor ligament of the perforans muscle. Vitell. Med. Vet. Le Cubital interne.

6. Flexor pollicis. This small muscle is the most posterior of those about the head of the radius, extending from the point of the ulna on its inside to the annular ligaments of the knee, uniting to the cartilage which surrounds the flexor of the foot, its aponeurosis covers the whole surface of the extensors of the cubitus. Le cubital grêle, Vitell. i. p. 175.

Besides the above muscles, there are two others belonging to the shank bone which are very minute; they are termed by Lafosse les canoines, and by Vitell lombicaux, p. 175. These very small muscles, which are not always described, are found between the suprapinor ligament and the distal bones, one on each side; they rise under the knee, are flexed about two or three inches, then form a tendon, which terminates on the cellular membrane of the fetlock joint. They appear of little use, and may rather be considered as the eflète rudiments of the interosseus muscles, or lumbricielles of digastit quadruples.

The muscles of the pattern, coronet, and foot are five; two to extend, and three to bend them. These three bones always forming one line and making an angle to the side of the limb, we consider as one bone in describing the muscles and their effect, as any division would tend to confuse rather than elucidate the general purpose of the muscles going to these parts. Lafosse has, we think, erred in being too minute in this respect by subdividing parts needfully connected.

1. Extensor fuffraginis is a small, thin muscle, rising by flexy fibres from the external condyle of the humerus; it passes flexy about half way down the radius; adhering to its external sharp edge, it passes in a groove through the annular ligaments and capsular ligaments of the knee, and continues its course along the outside of the shank to the fetlock, where it becomes wider, and terminates by a broad tendon on the anterior part of the pattern bone. It lends off a branch of tendon which passes round the knee to the flexor tendons under the pectoral bone. Vitell. i. 1752. L'extenieur antérieur du Pataron.

2. Extensor flulis. This is the largest of that assemblage of muscles which surrounds the head of the radius. It arises from the external condyle of the humerus uniting its flexy fibres with those of the exteror of the humerus or shank, it becomes tendinous above the knee, being lodged and confined by ligaments in a groove; it perforates the capsular ligaments of the joint, and, passing down the front of the shank at the fetlock joint, it forms an union with the extensor of the pattern, and growing broader, and enveloping almost the whole front of the coronet, it finally terminates on the anterior eminence of the coffin bone. Stubbs, Anat. Horfe, tab. viii. i. 2. 2. 5. 5. 6. 6. Extenfor Digitorum Communis. Vitell Med. Vet. i. p. 175.

The two former muscles serve to bring the three bones of the foot forward, and we may remark, when compared with the flexor, disproportionsamall, for the weight of the horse operates as a powerful extensor of this part, and renders great muscular power unnecessary.

3. Perforans. This muscle takes its attachment by flexy and tendinous fibres to the internal condyle of the humerus; uniting with the perforans near the knee, it forms a strong tendon, which, at the back of the knee, (within the concavity of the pectoral bone,) is received within a strong ligamentous groove, passing down the shank behind the tendon of the perforans; at the patella it forms a remarkable ligamentary annulus for the reception and passage of the perforans tendon, expanding into a broad flat tendon at the back of the patella, and, covering the perforans, it divides, forming two tendons which pass obliquely over the joint, and terminate on the upper part of the coronet. Stubbs, Anat. Horfe, tab. 15. m, n, s. Sublimis, p. 42. Vitell. Med. Vet. i. p. 173. Le Perforé.

4. Perforans, is a considerable muscle rising with the former, and lying more internally; it will admit of division into three parts, which Monf. Lafosse has described, with his usual bounty, as three distinct muscles. This muscle is flexy till it reaches the knee, when it forms a flat tendon united by the flexor pollicis cubitis, and radius tendons inserted into a flat, smooth cartilage under the *os pollicis*, forming here a large cylindrical tendon, when about half way down the shank it is joined by a ligament from the posterior part of that bone arriving at the fetlock, it passes through the annulus of the perforans, and continuing between its divided tendon, terminates by a broad, flat tendon on the inferior surface of the coffin bone being covered by the frog. Stubbs, Anat. Horfe, Profundus. Vitell. Med. i. p. 174. Le Perforant.

5. Adjutorius. This is a flat muscle lying close to the radius, and filling the hollow on the posterior part of that bone, it soon becomes tendinous, uniting with the tendon of the perforans.

Of the Ligaments of the Fore Extremity. 1. Ligamentum fupensiformis, supenformy ligament, takes its rise a little below the head of the shank by muscular and ligamentous fibres, lying between the heads of the styloid bones, it paves down the posterior surface of this bone, quitting its adherence to it about the middle, and, becoming detached, it divides at the fetlock into two branches, which closely and strongly embrace the islaemoid bones; it forms one ligament again at the back of the patella, filling its hollow cavity, and finally terminates on the head of the coronet bone. At the fetlock it also sends off two branches in an oblique direction downwards, which unite with the extensor tendon of the coffin bone, and preserves it firmly in its situation. Stubbs, Anat. Horfe. Interossœum. Lafosse has made a muscle of it. Plocchier du Pataron.

This ligament is the main support of the fetlock joint, and this joint, though so strongly fortified, is, for obvious reasons, with less risk subject to be injured of any part of the body.

There are many other ligaments belonging to this extremity, which the proposed limits of this article will not allow us to give a description of, as the lateral ligaments, the capsular ligaments, the burial ligaments, the returning ligaments, crucial ligaments, &c.

The muscles of the abdomen, allowing for the magnitude and depending position of this part in the horse, are much resembling those of the human. Obliquus externus, see Pl. II.—I. I. I. K. K. L. m, n.

The Muscles of the posterior extremity of the Horse and other domesticated Quadrupeds, with the Synonyma of human and veterinary Authors.

2) De variationibus hereditatis paffaru, qua7 laudati dioitariffider; VII Vegetius, T. 35.

The different muscules of the hind extremity of the horse are performed by the means of about thirty two muscules.

15 proper to the thigh, 3 to extend, 4 to bend it, 4 termed adductors, 5 called rotators.

2 common to the thigh and leg, 1 to bend and turn them inwards, 1 to extend and turn them outwards.

8 proper to the leg, 3 extensors, 2 flexors, 3 adductors.

2 proper to the hock and Shank, 1 to the os calcis, called an extensor, and the other to the anterior side of the head of the Shank, called its flexor.

1 to the coronet bending it backwards.

4 to the foot, 1 flexor, 1 extensor, and their lateral muscules, 1 to each.

On dissecting the muscules of a man’s thigh and leg, and those of the thigh and leg of the horse, and comparing them together, the dissimilarity has been found so great, that it would only create confusion and misconception to apply the same names to both; where they agree we gladly embrace the human names, where they are not at all alike, we do not attempt to make them appear so by imposing the same names, but have given names expressive of the situation, attachment, or shape of the muscle. Where the comparison between the human and the horse was doubtful, we have taken some intermediate animal so dilately removed from man in structure, by which we could more easily detect the coincident part, and transfer them to the horse.

The muscules of the thigh are 15, distributed as follows:

Gluteus esternus

G. magnus

G. parvus

P. bursa

Iliacus major

minor

Adductor teres

magnus

parus

Musculus extensor

intemus

Pyramidalis internus

M. parrus articulationis

Genelii.

Gluteus

Straighten the thigh by drawing it backwards, or rather move the body forwards to the thigh already advanced by the flexors.

Flexors, advancing the thigh forwards.

From their situation appear to act as drawing the thigh closer to the body, but probably in conjunction with the common muscules on the opposite side, which terminate about the little, co-operate in the general purpose of removing the body.

Termed rotators; a purpose they cannot serve in this animal, and therefore their use appears by human anatomists to have been wrongly assigned; they appear to co-operate according to their situation with the muscles above described.

From the manner in which these muscules are described, and their uses assigned in the publications on human anatomy, we conceive they convey but a feeble idea to the mind of the student of their real purposes. In the horse their uses are more striking and strongly marked, which suggested the explanations which are here given of their effects, though we are convinced much more remains to be done than has been hitherto done on this extensive and complicated subject.

Previously to entering on these muscules we must advert to the description given of the thigh bone in the osteology, to which we must refer the reader.
Gluteus externus. This muscle lies the most exteriorly of all the muscles of the buttock, and is of a small size: it extends from the second and third spinous process of the sacrum to the anterior angle of the inferior ramus of the ilium, where it joins the fascia lata; from thence it extends to the procerus recruratus externus of the thigh. This muscle is surrounded on all sides by aperoneuriis, that on its superior part, covering over the muscles of the rump, is affixed to the spinous processes of the loins; the aperoneuriis of its posterior part falls underneath the sacroitabalis externus, to which this muscle is contiguous in passing to the external curved process of the thigh.

The gluteus externus is so small in quadrupeds, that a doubt might arise whether this was not a part of the fascia lata, and the muscle beneath it the corresponding one to the gluteus maximus of the human anatomy. From a further investigation of this subject, we believe that not to be the case, and that it is the real representative of the gluteus maximus.

The singular diminution of this muscle in the quadruped may be, perhaps, explained on the following principles of the difference of structure necessary to the two animals. In the man, the legs have to perform a greater variety of motions, as abduction, adduction, rotation, &c. which the horse, whose motions are principally confined to going straight forwards in a line, does not require, so we see this great abductor of the human anatomy becoming a very small one in this animal, while the muscles of the rectilinear progression are vastly increased in bulk, as we may see by looking on the gluteus medius, which is the maximus of the horse in point of size, and from its attachments, is evidently a direct extensor of the thigh. Others might say it was diminished on account of the increase of the purchase obtained by its junction into the extended point of the curved processes of the thigh being taken farther from the centre of motion, which would compensate for its want of power; for it seems pretty nearly the same thing whether we make a muscle very large, or give it a powerful insertion; sometimes bulk, sometimes power only is necessary, but the composition of which power should be obtained by accumulated muscular fibres, or by favourable insertion, would lead us beyond our present purpose.

This point once admitted, viz. that it is the gluteus maximus of the human body, the others follow naturally, and admit of a nearer comparison. The anatomy of the thigh of the dog, which has no curved processes, seems to confirm this opinion.

Its ufe. The direction of this muscle seems to point it out as an abductor; the best way, however, of considering it is to regard it in this animal as a tensor aperoneuri of the buttock, abducting the muscles of this part, by its gentle compression and elastic springing and retraction, in their motions.

In the ox it exists with pretty much the same characters.

In the dog it is much larger than in the horse, and is a small muscle, having a strong attachment to the fascia underneath the muscles of the tail, and terminating in the back of the thigh by a long tendon.

In the cat the same as in the dog: but here it might well be denominated the gluteus poecilus.

2. Gluteus medius. This vast muscle lies immediately under the preceding, occupying great part of the upper surface of the ilium; it takes its rise by a point on the lumbal muscles, growing more flabby as it reaches the ilium; it takes a strong adherence, by flabby fibres, to the external angle of the inferior ramus; after passing the ilium it becomes smaller, and dividing itself into two bodies, one terminates on the superior posterior trochanter, the other by a strong tendon on the inferior external trochanter, which is covered by the tendon of the external gluteus. This muscle may be divided into two distinct parts, one of which might be considered by some as the maximus of the human; however, the nature of its attachments seems fully to prove its agreement with the medius.

Its ufe. To draw back the thigh, or (the leg being made a fixed point on the ground) to advance the body upon it.

In the ox. This muscle is more diffinately divided into two bodies, nor does it pass so far over the muscles of the loins. There is also a small almost linear muscle not found in the horse.

In the dog. It is not at all attached to the muscles of the loin, but fills up the ilium entirely, and terminates on the posterior trochanter, and in the cat the same.

3. Gluteus parvis. This is a short, strong, and (though small, compared with the former) not inconsiderable muscle, lying immediately over the joint; it takes attachment round the posterior ramus of the ilium; passing over the head of the femur it fills the anterior concavity formed by the superior trochanter of the thigh.

Its ufe. It operates in the combined effect of extending the thigh; its position is that of an abductor.

In the ox, nearly the same. Le petit feflier, Vitt. p. 185.

In the dog, it is of a different shape, being more pyramidal, and attached at the anterior superior part of the thigh.

4. Pfaus magnus. On removing the interlines from the abdomen and the pentoneum, this beautiful muscle presents itself; it is attached to the inner side of the two last ribs, and to the transverse apophyses of the lumbar vertebrae, passing to the edge of the pelvis it joins the iliacus, and is with it inserted into the little trochanter, running between the iliaca major and minor: this muscle can never be mistaken for any other in any animal; it is rather depressed at its origin, but becomes cylindrical and pointed going to its termination; this muscle, near its insertion, is confined by a ligament which binds it and the iliacus muscles in their situation.

The pfaus parvis we consider as a flexor of the loins, by bending the pelvis (to which it is always attached) on the lumbar vertebrae.
ANATOMY.

Veterinary writers have mostly described this muscle as belonging to the thigh; it, however, generally terminates where the femur begins, forming together a digastric muscle of great length.

Ox nearly the same. Le grand Pfaos. Vitet. p. 188.

Dog. It is attached to the four last lumbar vertebrae, is vaUy larger, and more fleshy in proportion to the animal; it terminates in the same place: but the iliacus parvus, we may observe, does not in this animal terminate where the femur begins, for this muscle rises from the anterior angle of the ilium.

In the cat there are three very distinct muscles of this description.

5. Iliacus major. This muscle takes attachment to the whole inferior ramus of the ilium growing cylindrical, and tapering it is joined to the pfaos magnus, passing with it through Poupart's ligament to the little trocanter of the thigh.

In the ox it is more intimately blended with the iliacus parvus.

In the dog it is remarkable this muscle is entirely wanting. The ilium is elevated so far above the lumbar vertebrae, that the muscles of the back occupy its place: it is flagellar, that this circumstance should have escaped the notice of Douglas, who has expressly treated of the anatomy of this animal.

In the felis the same as in the dog.

6. Iliacus minor. This muscle, which, in general, is quite separate from the iliacus major, takes its rise from the midle of the first acral apophyses all the length of the posterior ramus of the ilium, passing over the head of the femur it terminates with the pfaos and iliacus on the little trocanter; it permits the pfaos to pass between it and the iliacus major, and might be considered as a portion of the latter; it is connected by areatrofus with the muscles which line the pelvis.

If these last muscles have all the power of bending the femur; the two last on the pelvis, the pfaos on the loins, bending both femur and pelvis.

Ox. Not a distinct muscle.

Dog. Is altogether wanting, but appears to be compehented by having three pfaos muscles.

Cat. The same as in the dog.

7. Adductor teres is a cylindrical muscle, which makes its appearance on the hinder of the thigh; the integuments being removed, it takes its rise on the os pubis, near the lymphatics, attached to the same ligament with the rectus abdominis; it terminates along with the adductor magnus, about half way down the hinder of the thigh, or rather on the back part of this bone.

Comparison of this muscle with the human péctineus. We fee by its attachments that it is by no means the same muscle; it is much more nearly allied to the triceps adductor primus, which it also differs from; it rises too near the lymphatics instead of the brim of the pelvis; and terminates by inflection along with the large adductor low down the thigh; it is also a more external muscle than the péctineus; but as there is no real péctineus, nature seems to have united in this one muscle the properties of the péctineus and adductor longus, so that we have chosen to call it by a different name from either, viz. adductor teres.

The ox has a much fatter muscle, and it bends off a flip to the ligaments of the knee.

Dog. This muscle is rounded, and much resembles the human long head of the triceps.

The cat. There are four adductors, one of which resembles more nearly the human péctineus.

8. Adductor magnus. There are three distinct muscles of this description in the horse; this portion of it is very distinctly by removing the adductor planus of the leg, taking attachment to the lymphatics pubis, and extends down to the posterior and inner part of the thigh, and sending off another portion which is attached to the tibia, or rather to the joint of the femur and tibia by a flat tendon. This muscle may be divided into two portions; one has been called by veterinary writers, la portion moyenne, et la portion anterieure; but this we consider as unnecessary and unnatural; for after such division it does not correspond to the three portions of the triceps muscle in the human.

Comparison with the human. On actually comparing this muscle with those of the human thigh, it is difficult to decide whether it most resembles the short or great head of the triceps, but it certainly is not much like either of them; therefore, to prevent confusion, we have given it a different name, and left out the term triceps altogether; this muscle, and the vastofemoralis internus both agree in some points with the great head of the triceps, and differ in others. Stubbs considers it one, and the French writers the other; in this confusion I think it belt, for distinctly, to avoid the comparison, and give it a name that will not interfere with either.

Dog. This muscle lies underneath the long head of the triceps, and is the largest of the extremity.

Cat. In this animal the artery perforates the tendon of the adductor magnus, as it does in the human body, to pass to the gaitrochecium, which serves to identify the muscle in this animal.

Ox. No such portion appears.

9. Adductor brevis fr quadratus. This muscle lies immediately underneath the former, and is of a linear figure, being throughout of nearly equal size, resting on the os ischii near the edge of the foramen obtur., it takes an oblique direction, and terminates on the posterior flat part of the thigh, on the back of the posterior trocanter.

Ox. It exists of the same figure. Vitet. L'Ischio-crural, p. 185.

The dog possesses it, and also a muscle which exactly corresponds to the short head of the triceps in the human.

10. Tensorius, or M. ischiaticus. This is considered by some a muscle of the leg, others of the thigh; in this animal, however, it is common to both, and might be very well placed with the common muscles before mentioned. This muscle often varies in figure, but is generally of a triangular shape,
shape, formed of two or three flabby bodies, the superior point of the triangle is affixed to the os ilium on the external angle of its inferior ramus, its posterior point is affixed to the procissus recurrentus femoris with the gluteus externus, with which it forms an intimate union, its inferior part terminates by apsacuous which covers all the muscles of the inside the thigh, and its anterior part, extending also over the patella and tibia.

Os. This muscle not so completely divided into two portions.

Dog. Besides this muscle there is another strong muscle above it, and which has been noticed by Douglas.

Cat. The same as in the dog.

Stubbs, Anat. Horfe, tab. 3. Fadila lata.

Lafoffe, Cours d'Hippothrique, p. 120. Le falsa lata adductore de la jambe.

Bourgelat, Elem. d'Hipp. adducteur de la cuisse.

Ten's vagina femoris, limes et alis.

Douglas, Myolog, comp. 164.

Although the utmost brevity has been observed in the foregoing descriptions and remarks, and nothing introduced which was not of importance in establishing this science on a rational basis, yet have we already passed the limits we had proposed in treating of this article; and if the remaining muscles were considered as the subject at present demands, it would extend beyond the proper bounds for a communication of this fort, we shall, therefore, confine ourselves for the remainder of this extremity, to give only the names as we find them in our MSS. and conclude this article by a description of a few of the most interesting vicera of the horse.

11. Obturator externus.

12. Obturator internus.

13. Pyramidalis.

15. Gencilli.

16. Vagus externus.

17. Vagus internus, Plate III. 7, 8, 9.

18. Vagus anterior, Pl. III. 1, 1, 1, 2, 2, 3, 3, 4, 4, 5, 6.

19. Adductor planus tubo, Pl. II. e, g, f, Gracilis, Stubbs.

20. Adductor longus, Pl. II. 8, d. Sartorius, Stubbs.

21. Popliteus, Pl. III. b, h, i.

22. Sacroiliaci externus, Tab. 2, i, l, l, u, u, c, v, a, s, y, y.

23. Biceps Cruris.

24. Sacroiliaci posterior. Bourgelat and Vitet consider this as the biceps cruris, and Stubbs the feminocephaloi, Pl. II. 16, 17, 17, 18, 19.

25. Sacroiliaci internus. We infer the synonymy of this muscle, to shew the confusion that is likely to arise from purifying too cloe a parallel with the human anatomy.

Lafoffe, Cours D'Hippothrique, le gros adducteur de la jambe, p. 119.

Stubbs, Anat. Horfe, adductor magnus femoris. We have here an equal division of opinions, whether it should be confidered as part of the triceps, or the semimembranous. Stubbs has also given a muscle which he calls semimembranosus. The writer of this article is at a loss to understand what is there intended, but is disposed from the figure to believe that the short portion of the sacroiliaca has been divided and taken for that purpose.

These immense muscles evidently co-operate to one effort, and are better denoted and understood by confidering them in this way, and by the above names than by the human names, even supposing their corresponding muscles in the human body could be clearly ascertained, as those names would only serve to convey the confused and erroneous idea of a detached office to each of those muscles, and as though they were in no way connected; it was the confideration of the three muscles last mentioned that firft gave us the idea of the real effect of adductor and adductor muscles, in promoting animal locomotion. That such vast muscles of muscle as these should be carried about by the animal to perform such trivial offices as abduction or adduction it would be highly absurd to imagine; for it may be laid down as an axiom that the bulk of the muscle always bears some proportion to the importance of its office, and purifying this reasoning a step farther, we may conclude that even abstraction and adduction itself are often performed by the co-operation of muscles termed extensor and adductor muscles.

26. Tibialis anticus, Pl. II. tab. 1. Pl. III. 10, 11, 12, 13, 15, 16.

27. Tibialis internus. a muscle not always distinguishable.

28. Gastrocnemius, Pl. II. m, m, m.

29. Linearis, fea tibialis externus.

30. Extensor brevis pedis.

31. Extensor longus pedis, Pl. II. 36, 36.

32. Peroneus, Pl. II. 37, 37.

33. Peroneraus, Pl. III. 25, 24, 25, 26, &c.

34. Peroneraus minor.

Of the lungs of the horse. This viscum in the horse consists of three lobes, two large ones which occupy the sides of the chest, having at their anterior presentation two elongated auriform appendages which closely envelope the heart; the third or central lobe is much smaller, lying between the other two, and presents itself to the sternum. It is not unfrequent in the lungs of horses that small red patches are observable that will not inflate like the other parts of the lungs, and are therefore, not improbably, obliterated cells from colds, inflammation, &c. the settling of the blood will also give an appearance of this kind, but this does not prevent the lungs from inflating.

The trachea of the horse, where it paffes into the chest, and previous to its entering the lungs, has a singular duplication of the cartilaginous rings which is more extensive than the rest of this tube, so as to admit by very slight preflure, the fides of the tube to be brought in contact, and the total obliteration of its cavity: this structure may perhaps adapt the diameter of the trachea to any quantity of air that is passing through it to the lungs.

Of the liver. This viscus in the horse is large, deeply chit into lobes, and poffeffing no gall bladder. The ductus venosi of the human fotal circulation is also wanting in the equine fpecies.

Of the foimach. The foimach of the horse consists of a pouch or bag of the fmal oblongate or unifoim figure without, within, it is lined with membranes, which more refemble the coats of the different foimachs of ruminating animals than the indefinite of the generality of foimachs of this external figure.

There is distinguishable in the infece a white rugose coat, (fe Plate IV.) not vascular, which appears to be a continuation of the fthaline infensible white tiffue, which lines the oesophagus; this spreads over the upper part and broad end of the foimach, till it abruptly terminates about its middle; this part of the foimach corresponds very much to the pauch, or first foimach of ruminating animals.

The second division occupying the lower part or greater arch of the foimach, extending high up the fides, towards D d 2 the
ANATOMY.

the small arch, and reaching nearly to the cardiac orifice is lined with a smooth red membrane, and is highly vascular, resembling more the stomach of carnivorous quadrupeds; the rest of the stomach extending from the termination of the former to the entrance into the duodenum consists of a pale red membrane, extremely loose, and thrown into longitudinal folds or duplications, intermixing with the former by almost imperceptible gradations of colour; this coat is thickly covered with a flimy mucous, not observable on the other coats; this part of the stomach has a strong resemblance to the fourth, or last stomach of ruminating quadrupeds.

The exact purpose of these three constructions of membrane in the same stomach is not easily ascertained; whether they all unite in one common purpose, as though the stomach consisted of one common membrane for its lining, or whether the food is changed by the succedaneous operation of each of these membranes, we know not: we may observe on opening the stomach that the food makes pretty much the same appearance in whatever part of the stomach it may lie, that one should be hardly led to conclude they have in the horse distinct functions, but combining in one common effect, and are in reality the rudiments only of the structure of the stomach, peculiar to the generality of graminivorous quadrupeds, without producing any specific effect here; for it seems difficult to imagine how the different operations should take place in the same track without disturbing each other. Nature seems to obviate a connected sytem, not only in the entire animal, but also in each particular organ, forming an inflated sytem of structure and operations.

It is generally imagined there is some valvular apparatus to this vicus, which prevents the horse from vomiting, and much has been written on this subject: we never could discover any thing of the kind, and are disposed at present to believe, that as the form of the horse would render vomiting inconvenient, the power of receiving the impression which excites this operation is withdrawn from the animal, as it would be idle to suppose a power given to vomit with a structure of parts not admitting of it; it would be as inconsistent as placing the head of the lion on the shoulders of the horse, or giving the disposition of the horse to the lion's form, by which the very purposes of nature would be defeated. It was, however, an opinion entertained with some confidence, at the Veterinary College of Copenhagen, that the root of the white hellebore (veratum album) would occasion a horse to vomit, being placed under the skin.

In an ass's stomach I have seen a valvular apparatus at the cardiac orifice, and the infePlace the between the inside of the stomach, about one inch, forming a loose fold, which served to mark the divisions of the stomach more strongly, but could not in the smallest degree operate as a valve; this is, however, not very frequent. The stomach of the hog also partakes of this sort of structure, though not so distinctly marked as in the horse.

Of the chyle duct of the horse. This duct in the horse is not very difficult to find, both from its magnitude and situation, lying on the aorta, at the loins, very much exposed as it passes forward towards the thorax, it lies lower beneath the surface passing near both under the aorta, it is much smaller in the middle and enlarging to each end; about the 4, 5, 6 ribs, it is as large as a man's thumb, it becomes narrower again as it passes into the axilla, but enlarges again at its termination, where it enters the vena cava, or rather the vens formed by the union of the two jugular veins, and anterior to the subclavian, it there forms a large round head or cuff, and is provided with a valvular apparatus to prevent the return of the chyle or the blood from entering the duct. Toward the loins it has a strong adherence to the coats of the aorta, and lower down is strongly embraced by the tendon of the diaphragm; it then enlarges, and passing upon and by the side of the lumbar veins, discharges itself by several openings into them, which openings are also provided with valves.

The openings of this duct into the lumbar veins which have never before been remarked, seem to point out a double circulation in this vessel, viz. from the middle to each end as the smalls of it in the middle would also seem to indicate; we have, however, in some subjects found a valve opening anteriorly, or towards the jugular veins, within six inches of its posterior termination; this duct, however, is subject to very great variation.

In another subject we found this duct terminate about the second lumbar vertebra, where it divided one branch forming a sharp curvature, circumscribing a portion of the formation of the diaphragm, the other seeming to be lost about the fourth or fifth lumbar vertebra in smaller ramifications. In another subject which we injected, the duct was discovered on the left side, about the situation of the last dorsal vertebra, it crossed the aorta, and passed to the right side, immediately before and relating against the superior mesenteric artery; it then divides into several small canals, which appeared to be passing to their termination in the lumbar veins.

Parts of generation. No animal whatever is more richly provided with the various apparatus belonging to these parts than the horse, for nature here seems to have lavished with profusion whatever can tend to perfect the generative act; there is no part of the human construction of these parts but is found in the horse; the most essential difference appears to us to consist in the male, of the penis being suspended from the integuments of the abdomen, and not immediately from the pubis as in the human; hence the acuteness of the angle where it passes the pubis, is such as to render the passage of the catheter almost impracticable.

We have remarked that the penis of the horse possesses a voluntary power of erection, not known to the human, or perhaps to all other animals; this power is exerted on making water, and though the erection is not very considerable, it is yet sufficient to bring the penis from its sheath, which is effected apparently by its increased gravity from blood accumulating in the cavernous cells of this part. After placing this semi-erection of the penis subdues, and it again is retracted within the sheath; this operation, though occurring daily to the fight of every one, has not, it is apprehended, been noticed by any veterinary writer.

The urethra of the horse is mucular from one extremity to the other, being formed on the outside of strong transverse fibres and supported by a strong ligament.

Naturalists were long at a loss to discover the mamma, or teats of this animal; in the male they were at length detected by Buffon, on the sheath of the penis. Mr. John Hunter also made the same remark without knowing that Buffon had previously noticed it; these teats are larger in the fucus and young foal.

In the glands of the penis, immediately over the opening of the urethra externally, there is a large cell or cavity, smooth on the inside, and lined with a membrane, which secretes a brown mucous substance for the lubrication of the penis, and defending it from the corrosive effects of the urine; another cell of a similar description with the former is observable, on the side of the urethra, and nearly surrounding it, it is separated from the former by a membranous partition.

The apparently inanimate secretion above described is miscible with water; it burns, however, in the fire like an oil
The cavernous body of the penis has no longitudinal septum; its cells are divided by transverse fibres, which are probably muscular; it terminates in a point near the extremity of the gland, where it is surrounded on every side by the venous body, termed in the human corpus spongiosum.

Another irregularity in the genital parts of this animal is, that there is an immense congestion of veins, lying on the back of the penis, which are filled during copulation, forming an elevation nearly as large as the penis itself; these veins communicate with both the cavernous and spongy bodies.

The **uinctus femininis**, and the bladders attached to them, are very large in the horse, having integuments of considerable thickness.

There is a great peculiarity in the structure of the **vas deferens** of the horse, which, in passing over the bladder, enlarges to the size of the human thumb; this amplification extends from its entrance into the urethra to the distance of five or six inches from this point, where it again becomes of its ordinary diameter.

The inside of this enlargement is composed of cells, and somewhat resembles in construction the cells of the **corpus cavernosum penis**, passing in a transverse direction across the tube. In the centre of this enlargement pass the small canal of the **vas deferens**, each cell communicates by one, two, or more small pores with the canal of the vas deferens; these cells diminish as they approach the neck of the bladder till they are lost in a smooth passage entering the urethra.

What the purpose of this structure is does not appear; it must retard the passage of the **fenes**, and probably adds some fluid to it, secreted from the cells themselves.

On a first view of the pudenda of the mare the position of the clitoris appears to be inverted, compared with the position of the same part in the human, being found on the lower part of the vagina; this apparent difference is removed when both are considered in the same position.

That the present article may not be too far extended we refer the consideration of the other vices and parts of the horse to be introduced under their proper heads.

Anatomy is also used for an artificial representation of the structure and parts of the human body in metal, platter, wax, or the like. In this sense we say, the wax-work anatomy. R. Dickenf. flatuery, finifhed an human anatomy in platter of Paris, representing a man standing upright with his skin flayed off.

There is likewise a wax-work anatomy, said to have been invented by Gaetano Giulio Zuma, a Sicilian of Syracuse.

Yet M. des Noyes, who learnt it of him, and probably made some improvements in it, bringing it to Paris, arro-gated the chief honour of it to himself. Some prefer, above all the rest, for public lectures and courses, the use of real parts of dead bodies prepared by injection. Anatomical injections are either of mercury, or mixtures of equal parts of bilimun, lead, and tin. Neumann. The inconveniences that attend the dressing of dead carcases, have occasioned the invention of another cleaner and more durable kind of subjects. Reifelius contrived a human statue, wherein the circulation of the blood was represented to the sight, and some hint of the like kind was shown by M. Choret; and more lately still by Madame Bacheron, who has brought this art to great perfection. See her observations on the artificial anatomy, in the Memoirs of the Acad. des Sciences. an 1739. Hist. 94.

**Anatomy** is sometimes used to denote the subject to be anatomized. Thus (by 39 Hen. VIII. cap. 12.) the company of barbers and surgeons may have and take yearly four persons condemned, adjudged, and put to death for felony, for **anatomy**; and to make incision of the same dead bodies.

And by 25 Geo. II. cap. 37, the bodies of felons convicted of murder, in the county of Middlesex, or city of London, are, after execution, to be delivered to the hall of the surgeons company, to be filcified and anatomized; and in case such conviction and execution shall happen to be in any other country, or place, in Great Britain, then the body of such murderer shall be delivered by the sheriff, &c. to such surgeon as the judge shall direct.

Anatomy is also used, in an improper sense, for the analysis of mix bodies.

In this sense the chemists sometimes call their art **physics**, **anatomy**, **anatomy pyrotechnia**.

In which sense we sometimes say the anatomy of vitriol, the anatomy of sulphur, the anatomy of Rhennia wine, &c.

Anatomy is also used for an exact search or examination of the parts of a discourse, business, or the like: in which sense, we say the anatomy of a book, a doctrine, or the like.

**Anatolia**, in Geography, a small town of Greece, anciently Tanagra.

**Anatropolis**, from **α** νατριως, I wear, in the Ancient Medicine, denotes friction.

The word is sometimes also written simply **tripsis**.

**Anatron**, or **Natron**. See **Natron**.

Anatron is also used for **Glass Gall**.

Anatrope, **ανατροπης**, from **ανατροπης**, to subvert; a subversive literally, or relaxation of the stomach, attended with the loss of appetite, vomiting and nausea.

Anattom, in Geography, an island in the southern Pacific Ocean, and the most southern of those called New Hebrides. S. lat. 20° 4'. E. long. 170° 4'.

Anatzarthon, in Ancient Geography, an archi-pelagical fee of Asia, under the patriarchate of Antioch.

Ana, or **Anava**, a city placed by Herodotus in Phrygia, between the rivers Marfylas and Meander, but nearer their sources than their confidences. To the south-west of this city, and near it was a lake, from which they obtained salt.

**Anaudia**, among **Naturalists**, denotes dumbfounded, or a want of the use of speech.

Anaudia is, by some, made to differ from **aphonia**, as the former is owing to a defect of the nerves of the tongue, the latter to that of the nerves of the larynx.

Infants and mutes are **anaudia**, **αναουδιος**, not **aphoniis**, **αφονιος**.

**Anauodama**, or **Anadoma**, in Ancient Geography, a town of Ethiopia, near Egypt.

Anavinga, in Botany, a genus of plants, with in-complete flowers, comprizing some trees of the East Indies, which are not much known to botanists. The generic characters, according to La Mareck, are, that the flower has a calyx of five oval, concave leaves, opening in a rofe, and permanent; it has no corolla, but at the base of each foliule of the calyx are seen two pedicles shorter than the foliules of the calyx, and somewhat hairy; the stamina are ten, of the length
length of the calyx, and have their filaments inserted alternately, between the pedicels, upon the base of the follicles of the calyx; the authors are small, ovate, and divided into two by a vein or furrow; the ovary is superior, globular, or oval, invested in a whitish style, and terminated by a stigma, with a spherical head. The fruit is an oval or globular berry, marked by five slight channels, and containing ovate and reddish seeds in a pulp. There are two species: 1. A. lanceolata, with alternate leaves, lanceolated, slightly ferrated, subpulpeous beneath, with oval berries longer than the pedicule. 2. A. oxyacantha, with alternate leaves, ovate, acuminate, and ferrulate, and globular berries equal to the pedicule. This is also called baldor and a berries. The anarca is a tree of middle size, that grows in the sandy soil of Malabar, in the East Indies, especially about Cochín. It is evergreen, and its fruits or berries are ripe in August. Its leaves, bark, and fruit have a bitter taste.

The juice of the berries drank excites sweat, cures malignant distempers, and keeps the body salubr. A decoction of the leaves in water makes a fit bath for such as are afflicted with worms in the joints.

ANACHION, from α, ανα, and α, χαινω, I think, in Antiquity, the crime of refusing to serve in the drift. The punishment assigned for this offence was infamy.

ANAEUS, in Ancient Geography, a river of Greece, in Thessaly: also a river of Syria; and a river of the Tros, near mount Ida.

ANAX, in Ancient Writers, denotes a hero or god. The word seems formed of the Hebrew_enum, or _enaim, which dignifies the name. Some will have it originally to import giants, called also _pyrion, earth-born. Cicero affirms, that the three chief sons of Jupiter, called _oero, were also deorum._

ANAXAGORAS, in Biography, one of the most illustrious philosophers of antiquity, was born at Clazomene, in Ionia, in the first year of the 50th Olympiad, or the 500th year before Christ. In the ardent pursuit of knowledge he left his native country, in which he posseised a patrimony sufficient for securing him distinction and independence, and went to reside at Athens. Having surrendered his lands to his relations, he devoted himself wholly, as Cicero says, (Tufc., Quadr., lib. v.) to the divine pleasure of learning and inquiry. At Athens he diligently applied himself to the study of eloquence and poetry, and was particularly conversant with the works of Homer, whom he admired as the best preceptor, not only in writing but in morals. From Athens he removed to Miletus, that he might attend upon the public instruction of Anaximenes. At the age of 20 years he left Miletus, and entered upon the study and profession of philosophy at Athens, where, according to Diogenes Laertius, he remained 30 years. As a teacher of philosophy he acquired high reputation, and his pupils were some of the illustrious men of the age in which he lived; such were Euclidides the tragedian, Pericles the orator and statesman, to whom Socrates and Thucydides devoted themselves with treasurable performances. But the chief offence of Anaxagoras was, probably, the propagation of new opinions concerning the gods. There can be no doubt that he contradicted and opposed the vulgar opinions and superstitions; accordingly, it is related, that he ridiculed the Athenian priests for predicting an unfortunate event from the unusual appearance of a ram which had but one horn; and, in order to convince the people that there was nothing preternatural in the phenomenon, he opened the head of the animal, and showed them that it was so constructed, as necessarily to prevent the growth of the other horn. Anaxagoras, however, was thrown into prison, and condemned to death; and it was with difficulty that Pericles obtained from his judges the milder sentence of fine and banishment. Upon receiving his sentence of condemnation, he confided himself by saying, “Nature long ago pronounced the same sentence against me;” and to one of his friends, who expressed regret on account of his banishment, he said, with a mixture of fortitude and vanity, “It is not I who have lost the Athenians, but the Athenians who have lost me.” When news of the death of one of his sons was brought to him, as he was delivering a lecture of philosophy, he calmly said, “I know that I begat him mortal.”

After his banishment he passed the remainder of his days at Lampacus, where he employed himself in instructing youth, and obtained great respect and influence among the magistrates and citizens. At length the infirmities of age terminated his labours in the year before Christ 428. Through his whole life he appears to have supported the character of a true philosopher. Superior to motives of avarice and ambition, he devoted himself to the pursuits of science; and, in the midst of the vicissitudes of fortune, preserved an equal mind. Being asked, just before his death, whether he wished to be carried for interment to Clazomene, his native city, he said, “It is unnecessary; the way to the regions below is everywhere alike open.” In reply to a melange sent him, at that time, by the senate of Lampacus, requesting to be informed in what manner they might honour his memory after his decease, he said, “By ordering that the day of my death he annually kept as a holiday in all the schools of Lampacus.” His request was complied with, and the custom remained in Lampacus in the time of Diogenes Laertius. The festival Anaxagoros was instituted on this occasion. The inhabitants expressed their veneration for his memory, by erecting a tomb, and inscribing upon it the following epitaph:

“Εικοδ., πλαγω αληθειας; ει τε μερα περιοιαν. Οδηγησι κειμεν κλημεν Ἀναξαγορας.”

“This tomb great Anaxagoras confines,
Whole mind explored the paths of heav'nly truth.”

It is also said, that two altars were raised in honour of his memory, one dedicated to “Truth,” and the other to “Mind,” an appellation which was given him on account of the doctrine which he taught concerning the origin and formation of the world.

With the credible records of Anaxagoras many fabulous relations are intermixed; nevertheless, it is sufficiently attested, that this philosopher possessed a very extensive and accurate knowledge of nature, considering the age in which he lived, and allowing for the strange and erroneous conceptions which are blended with his more rational opinions. Of the heavens he seems to have had no other idea than that of a solid vault in which luminous bodies are fixed; and these bodies he conceived to be flanes, raised from the earth by the rapid motion of the ambient ather, set on fire by its heat, and kept in their places by the orbit of the circular motion of the heavens. On the other hand he is said to have taught, that wind was produced by the rarefaction of the air; that the rainbow is the effect of the reflection of the solar rays from a dense cloud placed opposite to it like a mirror; that the moon is an opaque body enlightened by the sun, and an habitable
habitable region, divided into hills, vales, and waters; that the comets are wundering flars; and that the fixed flars are in a region exterior to those of the sun and moon.

Of the opinion of Anaxagoras concerning the origin of the material world, the information transmitted to us is more correct. Having learned in the Ionic school that bodies are composed of minute parts, and having observed in different bodies different and often contrary forms and qualities, he concluded, that the primary particles of which bodies consist, are of different kinds; and that the peculiar form and properties of each body depend upon the nature of that class of particles, of which it is chiefly composed. A bone, for instance, he conceived to be composed of a great number of bony particles, a piece of gold of golden particles; and thus he supposed bodies of every kind to be generated from similar particles, and to assume the character of those particles. This system is thus exhibited by Lucretius, lib. i. v. 385, &c.

"— Principium rerum quam dicit homoeomieriam, Osa videlect & paullinis atque minutis Oslibus: sic et de paullinis atque minutis Vifceribus visus gigani; fangueque creerii Sanguiinis inter fe multis coeuntibus guttis; Ex aurique putat micos confinlere po/e Aurum; et de terris terram concerificare parvis; Ignibus ex ignem; humorem ex humoribus effe; Cætera confinlili fingit ratieni, putatque."

"With Anaxagoras, great Nature's law
Is similarity; and every compound form
Confists of parts minute, each like the whole;
And bone is made of bone, and flesh of flesh;
And blood, and fire, and earth, and mafly gold;
Are, in their smellt portions, fill the fame."

The absurdity of this notion is evident; it admits of no simple, uncompounded principles; it makes no provision for production or dilution, the formation of any new body being, according to this doctrine, nothing more than the collecting together of a number of small similar bodies; and it gives no explanation of the original formation of the small compound bodies of which the larger consist. The invention of the system, however, excited the ingenuity of the author, who had recourse to the notion of similar particles, with a view of obviating the objections which lay against the doctrine of atoms, as he had received it from Anaximenes. But the most important improvement which Anaxagoras made upon the doctrine of his predecessor, was that of separating, in his system, the active principle in nature from the material masses upon which it acts, and thus introducing a distinct intelligent cause of all things. The similar particles of matter which he supposed to be the basis of nature, being without life or motion, he concluded that there must have been, from eternity, an intelligent principle, or infinite mind, existing separately from matter, which, having a power of motion within itself, first communicated motion to the material masses, and, by uniting homogeneous particles, produced the various forms of nature. That Anaxagoras maintained an infinite mind to be the author of all motion and life, is attested by many ancient authorities. Plato (Phaid. Hippasus major) expressly affirms, "that this philosopher taught the existence of a dispassionate mind, the cause of all things."

Aristotle says, (Metaph. lib. i. c. 3.) that Anaxagoras taught, that mind was "the cause of the world, and of all order," and that "while all things else are compounded, this alone is pure and unmixed; and that "he ascribes to this principle two powers, to know and to move, saying, that mind put the universe into motion." Cicero (De Natura Deor. lib. i. c. 10, 11. tom. ii. p. 511. Tuelfel. Quaest. lib. iii. c. 24. tom. ii. p. 404. De Orator. lib. iii. c. 34. tom. i. p. 371. ed. Olivet.) also affirms, though not without some inconstancy, with what he had before said of Thales, that Anaxagoras was the 3rd who taught that the arrangement and order of all things was contrived and accomplished by the understanding and power of an infinite mind. Plutarch (in Pericul. Oper. tom. i. p. 174. ed. Xylander) confirms this account of the doctrine of Anaxagoras.

"The Ionic philosophers," says he, "who appeared before Anaxagoras, made fortune, or blind necessity, that is, the fortuitous or necessary motion of the particles of matter, the first principle in nature; but Anaxagoras, affirmed, that a pure mind, perfectly free from all material conceptions, governs the universe." To the same purpose Diogenes Laertius (lib. ii. n. 6. tom. i. p. 82.) represents Anaxagoras as teaching, that "the universe consists of small bodies composed of similar parts, and that mind is the beginning of motion." He was the first," says the same writer, "who superadded mind to matter, opening his work in this pleasing and sublime language," "All things were confounded, then came mind, and dispofed them in order." Dr. Davies in his note on the passage, in which Cicero seems to be charged with inconstancy, observes, that Thales supposed God to be the soul of the world, mixed and united with matter; whereas, Anaxagoras held him to be a pure mind, free from all material union and mixture. From these and other concurrent testimonies, it sufficiently appears that Anaxagoras was the first among the Greeks who conceived mind as detached from matter, and as acting upon it with intelligence and dexterity in the formation of the universe. The infinite mind or deity which his predecessors had confounded with matter, making them one universe, Anaxagoras supposed to have a separate and independent existence, and to be simple, pure intelligence, capable of forming the eternal mafs of matter according to his pleasure. Thus he asigned an adequate caufe for the existence of the visible world. Diogenes Laertius, lib. ii. in Anaxag. Plutarch in Pericle, ibi fippea. Suidas, Gen. Dic. Brucker's Hill. of Philos. by Enfield, vol. i. p. 148—153.

ANAXAGORIA, in Antiquity, a festival oberved in honour of ANAXAGORAS.

ANAXANDRIDES, in Biography, a comic poet, was a native either of Rhodes or Coalophon, and flourished during the reign of Philip of Macedon, B. C. 370—30. Suidas says he was the first who introduced on the stage love-adventures, turning upon the mishaps of young damsels. He was a perfomable man, and affected great magnificence in his drefs and equipage, and he is said to have once recited a piece at Athens on horseback. His temper was morose and sullen; and he was much chargned at the ill success of his performances, which were often incorrect, and which he would not take pains to amend and polish. Of 65 plays which he composed, ten only were crowned. The Athenians condemned him to die of a famine for a line in which their government was cenured. An "Odyfsey" of this poet is mentioned by Athenaeus. Caubon suggests, that Anaxandrides was the Alexanderides of other writers. Gen. Dic. ANAXARCHUS, a Grecian philosopher, was a native of Abdera, and belonged to the democratic faction. He flourished about the 110th Olympiad, or 340 years before Christ, and enjoyed the confidence of Alexander, whom he treated with the freedom of a friend in some instances, but with the servility of a sycophant in others. On one occasion, when Alexander aspired at the honours of divinity, this philosopher checked his vanity by pointing to his finger when it bled, saying,
ANAXILUS, a native of Lamia, lived in the time of Augustus, and professed himself a follower of Pythagoras. That his pretenions to an intimate acquaintance with the mysteries of nature, and to the exercise of magical powers might obtain credit, Pliny (Nat. Hist. lib. xix. c. 11. lib. xxviii. c. 15.) relates several curious arts by which he astonished and alarmed the ignorant multitude; and of these one was that of giving a livid and ghastly hue to the countenance by means of sulphureous flame. He was banished from Italy in the 28th year before Christ, by order of Augustus, for the crime of magic. Brucker's Hist. Phil. vol. ii. p. 10.

ANAXIMANDER, a famous Greek philosopher, was the disciple and friend of Thales, and was, probably, born at Miletus, in the 3rd year of the 4th Olympiad, or in the 610th year before Christ. An anecdote is related concerning him, from which it has been inferred, that he was employed in the instruction of youth. Being laughed at for finging or reciting his verses ill, he said, "We must endeavour to sing better for the sake of the boys." He was the first among the Greeks who taught philosophy in a public school; and is often spoken of as the founder of the Ionic school, though this honour really belongs to Thales. The mathematical and astronomical sciences are, without doubt, much indebted to Anaximander. He framed a connected series of geometrical truths, and wrote a summary of his doctrine. He is said to have been the first who delineated the surface of the earth, and marked the divisions of land and water upon an artificial globe. The invention of the fudial has been ascribed to him; but Herodotus (lib. ii. c. 72.) with greater probability, ascribes the origin of this instrument to the Babylonians. He might possibly have used a gnomon, in order to ascertain more correctly than Thales had done, the meridian line, and the points of the solstices. Pliny (lib. ii. c. 17.) refers to this philosopher the discovery of the obliquity of the ecliptic; but if Thales was acquainted with the method of predicting eclipses, he could not be ignorant of this obliquity. It is related of him that he predicted an earthquake; but we need not say, that, as this is impossible, the relation must be fabulous. Among the physical notions imputed to Anaximander are these: That the flares are globular collections of air and fire, borne about in the spheres in which they are placed; that they are gods, that is, inhabited and animated by portions of the divinity; that the sun has the highest place in the heavens, the moon the next, and the planets and fixed stars the lowest; that the earth is a globe, placed in the middle of the universe, and remains in its place; and that the sun is 28 times larger than the earth.

The doctrine of this philosopher concerning the first principles of things, and the origin of nature, is so obscure and variously related, that it cannot be well ascertained. His general system seems to have been, that infinity, τὸ ἁμαρτζόμενον, is the first principle of all things; that the universe, though variable in its parts, is immutable as a whole; and that all things are produced from infinity, and terminate in it. What Anaximander meant by infinity, and whether he understood by it the material subject, or the efficient cause of nature, are subjects of controversy. Plutarch affirms, (Philo. Philib. lib. i. c. 7. Oper. vol. ii. p. 875.) that the infinity of Anaximander was matter; and Aristotle (Nat. Audio. lib. i. c. 5. lib. iii. c. 4. Oper. tom. i. p. 310—323.) explains it in the same manner; and several modern writers adopt the same idea. Others suppose that he used the term infinity to denote the humid mass of Thales, together with the divine principle by which he supposed it to be animated. This opinion is supported by the authority of Herimans, who affirms (Iris. Gen. § 10. apud Tation.) that Anaximander supposed an eternal mover or first cause of motion, prior to the humid mass, or 18 ὑγιόν of Thales. And Aristotle himself speaks of the infinity of Anaximander, as comprehending and directing all things. Anaximander is said to have been the first who laid aside the defective method of oral tradition, and committed the principles of natural science to writing. Anaximander lived 64 years. Diog. Laert. lib. ii. Strabo, lib. iii. Pliny, lib. vii. c. 76. Suidas. Ensef. Prap. Er. lib. x. c. ult. Brucker, by Ensef. vol. i. p. 145—147.

ANAXIMANDRIANS, a name given by some writers to the followers of Anaximander. These are otherwise denominated hypotithites; and stand opposed to the atomists. The Anaximandrians make the most ancient sect of philosophical atheists; they allow of nothing in nature but bodies. These bodies, they assert, admit of qualities which produce and destroy each other, in a circle without beginning or end. See ANAXIMANDER.

ANAXIMENES, a philosopher of Miletus, was born about the 57th Olympiad, or 535 years before Christ, and was a disciple and companion of Anaximander. On his inquiring into the nature and origin of things, he traced the footsteps of his master, and endeavoured to throw new light upon his system. According to him the first principle of all things is fire, which is infinite or infinite, and perpetually active. The other is a productive body, animated with a divine principle, whence it becomes the origin of all things, and is God. His doctrine, therefore, was a continuance of that of Thales and Anaximander, with this difference, that he supposed the divine energy to reside in air or ether. He also taught, that all minds are air; that fire, water, and earth proceed from it by rarefaction or condensation; that the sun and moon are fiery bodies of a circular form; that the stars, which are fiery sublunations, are fixed in the heavens, like fluids in a crystal plate; and that the earth is a plane tablet rising upon the air. Plato. Plac. Philib. lib. i. c. 36. lib. ii. c. 11. lib. iii. c. 10. Oper. tom. ii. p. 876—888—894. Cicero. de Nat. Deor. lib. c. 10. Oper. tom. ii. p. 511. Academ. lib. ii. c. 57. tom. ii. p. 64. Suidas. Diog. Laert. lib. ii. Brucker, by Ensef. vol. i. p. 147.

ANAXIMENES, a Greek rhetorician and historian, was the son of Aristocles, of Lampascus, and the disciple of Diogenes the Cynic, and of Zosimus of Amphipolis, who railed against Homer. He was born about 530 years before Christ; and employed by Philip of Macedon to instruct his son Alexander in the art of rhetoric. Some have ascribed the treatise on rhetoric, which bears Aristocles's name, to Anaximenes. This learned man, with many others, accompanied Alexander in his expedition against the Persians; and he contrived by a smart and reasonable retort, mentioned under Alexander, to preserve the city of Lampascus. On another occasion having conceived a grudge against the historian Theopompus, he revenged himself by writing a severe satire against the Spartans and Thebans, exactly in the style of Theopompus, and adding to it, under his name, to the Athenians. By this deception, though not of the most honourable kind, he gratified his resentment, and exposed his adversary to reproach and ill-will throughout all Greece.
Greece. Anaximenes wrote a history of the life and actions of Philip, and another of those of Alexander; and he also wrote 12 books on the early history of Greece, beginning with the theogony, or fabulous history, and ending with the battle of Mantinea, which was fatal to Epaminondas. But none of these works are extant. Suidas, Pausian. Eliae lib. ii. c. 19. p. 495. ed. Kuhnii. Gen. Dict.

ANAZARBUM, in Ancient Geography, a city of A sia, in Cilicia Pepper, or Cilicia Campellis. It was situated on the river Pyramus, at some distance from the sea. Suidas informs us that it was first called Cyinda, and afterwards Anazarb, from its founder Anazarbus, who was sent by the emperor Nerva to rebuild it, after it had been quite ruined by an earthquake; but he is certainly mistaken, since Piny, who died long before the reign of Nerva, calls the inhabitants of this city Anazarb. The etymology of Stephanus Byz. is therefore more probable, who derives its name from mount Anazarbus, at a small distance from the place where this city stood. The territory adjacent to Anazarb was very fertile, and produced abundance of grain and fruit. The symbols of this fertility were expressed on the coins of the city; such as the cornu-coqus, ears of corn, branches loaded with fruit, &c. This city is distinguished by an era, marked on its medals, called the era of Anazarbus. The Abbé Belley, (Mem. de Lit. tom. xxx. p. 714.) proves that this era ought to commence with the year of Rome 735, 10 years before the Christian era. By a decree of the senate it had permission to assume the name of Caphares, in acknowledgment of the privileges conferred upon it by Augustus. It also took the name of Julianopolis and Julianinaopolis, in honour of the emperors Julian and Justinian. When this city was nearly demolished by an earthquake, it was repaired by Nerva; and after a similar catastrophe, it was raised from its ruins under the reign of Julian or Justinian. The citizens of Anazarb were divided into three classes or orders, comprehending the people, the council, and the senate. At the commencement of the fifth century Cilicia was divided into two provinces; and Anazarb was the metropolis of the second province. This division contained nine cities, and Anazarb excluded the jurisdiction of a metropolis, and its bishops had the rank and jurisdiction of metropolitans. It possessed the distinguishing privilege of autonomia, i.e. of having its own magistrates, and of being governed by its own laws. When the provinces of Asia were divided under the emperors of Constantanople, after the reign of Herachius, into themes, or military departments, Anazarb was comprised with Cilicia in the theme of Seleucia. When this city embraced the Christian religion, it became dependent on the patriarchate of Antioch; and it is said to be the first church in the world. The Turks call it An-Zeber. This city was the birthplace of Dioscorides, and of the poet Oppian.

ANAZIA, in Geography, a town of Asia, in Greater Armenia, near Mount Taurus. It is in the government of Van, not far from a lake which bears this name.

ANAZZO. See Gnata.

ANBAR, in Geography, a town of the province of Chaldia, or Irac-arabi, on the Euphrates, called also Aschemin.

ANBERTKEND, in the Eastern Languages, a celebrated book of the Brachmans, containing the Indian philosophy and religion. The word in its literal sense denotes the cipher, wherein is the water of life. The ambertkend is divided into fifty beths, or discourses, each of which consists of ten chapters. It has been translated from the original Indian into Arabic, under the title of Mursat al Mawii, q.b. "the marrow of intelligence."

ANBORD, in Geography, a town of Peris in the province of Khwafan, 50 leagues north-east of Meshid.

ANBURY, in Agriculture, is a dilsafe in the roots of Vol. II.

turnips, which is described by Mr. Marshall, in his Rural Economy of Norfolk, in the following manner: "It is a large excrecence, which forms itself below the apple. It grows to the size of both the hands, and, as soon as the hard weather sets in, or it is by its own nature brought to maturity, becomes putrid, and smells very offensively. At present (says he) the state of these specimens which have been taken up and examined attentively, is this: the apples of the turnips are just forming (about the size of walnuts in the hulke), while the asparagus are already as big as the egg of a goose. They are irregular and uncouth in their form, with inferior excrecences (refembling the races of ginger) hanging to them. On cutting them, their general appearance is that of a hard turnip; but on examining them through a magnifier, there are veins, or firing-like vessels, dispersed among the pulp. The smell and taste somewhat resemble these of turnips, but without their mildness, having an aulfer and somewhat disagreeable flavour, refembling that of an old firngy turnip. The tops of these which are much affected turn yellow, and flag with the heat of the sun: so that in the day time they are obviously distinguished from those which are healthy. It seems to be an idea among farmers, that the caufe of the anbury is the soil's being tired of turnips; owing to their having been too often sown on the same land. This, however (he contends), is positively erroneous; for the piece from which these specimens were drawn was an old orchard, and never before bore turnips in the memory of man."

The nature and caufe of this vegetable disease do not appear to be yet fully explained; but it is probable that drought has much effect in producing it, as it is found to be the most prevalent in such places. The author just mentioned, however, seems to suspect that it may be induced by some form of grub or other, wounding the vessels of the tap-root, and thus diverting the course of the sap-juice, by which means excrecences of this kind are formed, instead of the apple of the turnip. Whatever may be the cause of the disease, experience has shown, that the most effectual remedy is that of frequent hoeing, or stirring the ground about the plants, in order to admit air and moisture more freely.

ANCA, in Middle Age Writers, denotes the thigh, or hind-leg.

In which sense the word is also written Ancus.

ANCEUS, in Entomology, a species of Papilio found in India. The wings are entire, black, with a blue bar on the anterior pair, and a ferruginous one on the posterior pair. Under side green. Gmelin. This is the Papilio Obrinus of Fabricius.' Spec. Inf.

ANCALE, or Acalp., in Ancient Geography, a town of Arabia Felix, according to Ptolemy.

ANCALITAE, inhabitants of Britain, were feated near the Attribates, and were probably a clan of that nation. Mr. Baxter (Gloss. p. 14.) thinks they were the cangi, or herdmen and shepherds of the Attribates, and policed those parts of Oxfordshire and Buckinghamshire which were most proper for pasture. After they were subdued by the Romans, the government of them, with that of some of their neighbouring states, was followed upon Cogidunus, the British king of the Dobuni, as a reward for his early submission, and great fidelity to the Romans.

ANCAMARA, or Antamara, in Geography, a people of South America, who live near the banks of the river Madera, which discharges itself into the river of the Amazons.

ANCANICUM, in Ancient Geography, a district of Spain in Bética.

ANCAON, Serra de, in Geography, a chain of mountains in Beira, a province of Portugal, which joins to another called Serra d'Estrella.
ANCARA, in Ancient Geography, a town of Italy, mentioned by Stephanus Byz.

ANCARANO, Peter Dr, in Biography, a celebrated citizen of Bologna, flourished in the 15th century. He rivalled Baldus, his master, in the knowledge of the civil and canon law. In 1469 he defended the council of Pisa against the ambassadors of Robert duke of Bavaria, and evinced its right to proceed against Gregory XII. and Benedict XIII., in order to terminate the schism. He died at Bologna in 1471, and left behind him in Latin, "Commentaries on the Decretals and Clementines," printed at Lyons, Venice, Bologna, &c. On his tomb was inscribed an epitaph, in which he called "the mirror of the canon law, and the anchor of the civil."

ANCARANO, in Geography, a town of Italy, in the marquisate of Ancona, situated on the Tronto, six miles call of Acoli. N. lat. 42° 48'. E. long. 14° 54'.

ANCASTER, a village of England, in the county of Lincoln, was formerly a Roman station, of which many vestiges are now visible: 116 miles from London.

ANCEIS, a town of France, and principal place of a district, in the department of the Lower Loire. It is situated on the Loire, in a very agreeable and fertile country. It is the ancient Ancisium, the capital of the An- mites, a people who lived about the mouth of the Loire. The place contains 2,623, and the canton 11,169 inhabitants. The territory includes 200 kilometres and 7 communes. N. lat. 42° 23'. W. long. 1° 15'.

ANCEPS, in Botany, denotes two-edged.

ANCEPS, in Conchology, a species of Patella. It is solid, glossy, and rather pointed, outside pale chequers, within white tinged with flesh-colour. Gmelin.

ANCÉRVILLE, in Geography, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Bar-le-due; one league call of St. Diézir, and three leagues south-south-west of Bar-le-due. The place contains 2,200, and the canton 9,669 inhabitants. The territory comprehends 220 kilometres and 18 communes.

ANCÉRVILLE is also a town of France, in the department of the Moselle, and chief place of a canton, in the district of Morhange, three leagues and a half well-north-west of Morhange, and three east-south-call of Metz.

ANCESTORS, progenitors, are those from whom a person is descended, exclusively of his immediate parents.

The word is derived from the Latin ances, written, by contraction, for anced, q. d. gers before.

Most nations have paid honour to their ancestors. It was properly the departed souls of their fore-fathers that the Romans worshipped under the denomination of morts, lemures, and houseold gods. Hence the ancient tombs were a kind of temples, or rather altars, wherein obligations were made by the kindred of the deceased. The Russians have still their anniversaries feasts in memory of their ancestors, which they call rotitflis bod, q. d. ines fobath, wherein they make formal visits to the dead in their graves, and carry them provisions, canestales, and presents of divers other kinds. They interregate them with loud lamentable cries. What are they doing? how they spend their time? what it is they want? and the like.

The Quis, a people of Africa, offer sacrifices of rice and wine to their ancestors, before they ever undertake any considerable action. The anniversaries of their deaths are always kept by their families with great solemnity. The king invokes the soul of his father and mother to make trade flourish, and the chace succeed.

The Chinefe seem to have distinguished themselves above all other nations in the veneration they bear their ancestors. By the laws of Confucius, part of the duty which children owe their parents consists in worshipping them when dead. The service, which makes a considerable part of the national religion of the Chinefe, is said to have been instituted by the emperor Kun, the fifth in order from the foundation of that ancient empire.

The Chinefe have both a solemn and ordinary worship which they pay their ancestors. The former is held regularly twice a year, viz. in Spring and Autumn, with much pomp. A person who was present at it gives the following account of the ceremonies on that occasion.

The sacrifices were made in a chapel well adorned, where there were fly altars furnished with censers, tapers, and flowers. There were three ministers, and behind them two young acolytes; he that officiated was an aged man, and a new Christian. The three former went with a profound silence, and frequent genuflexions towards the five altars, pouring out wine; afterwards they drew near to the fiinth, and when they came to the foot of the altar, half-bowed down, they said their prayers with a low voice. That being finished, the three ministers went to the altar, the priest took up a vessel full of wine, and drank; then he lifted up the head of a deer or goat; after which taking fire from the altar, they lighted a bit of paper; and the minister of the ceremonies turning towards the people, said, with a high voice, that he gave them thanks in the name of their ancestors for having well honoured them, and in remunence he promised them, on their part, a plentiful harvest, a fruitful line, good health and long life, and all these advantages that are most pleasing to men.

All the Chinefe, Pagans as well as Christians, give their ancestors another simpler and more private worship. To this end they have in their houses a niche or hollow place, where they put the names of their deceased fathers, and make prayers and offerings of perfumes and spices to them at certain times, with bowing, &c. They do the like at their tombs.

It has been a question warmly agitated of late years, whether the worship which the Chinefe pay their ancestors be religious, or only of a civil nature. The Jefuits, who not only allow their neophytes, or new converts, to join in it, but even allow it to themselves, are necessitated to maintain the latter, to screen themselves from the charge of idolatry; the Dominicans and other missionaries maintain the former, and prohibit the service as absolutely unlawful.

The Jefuits argue, that with relation to the first institution, these honours might be given to our ancestors, since at first they appear to have been only civil; even though they should since, through the superfluous disposition of the people, have degenerated into idolatry. But it is answered, that, by this argument, the most grotious worship of idols might be authorized, because all idolatry appears at first only to have been civil worship, as is maintained in the book of Wildom. chap. xiv. ver. 15.

The Jews settled in China are said to worship their ancestors like the heathens, and with the same ceremonies, except that they offer not wine's flesh. Near their synagogue they have a hall, or court of ancestors, wherein are niches for Abraham, Isaaq, &c. The Jefuits also conformed, and were permitted by their general to conform to this, and many other superfluous customs of the Chinefe. See the proof of this in Pathchall's Provincial Letters, paffim.

There is one peculiarity of another kind, wherein the Chinefe shew their regard for their ancestors; in proportion as any of their descendants are preferred to a higher degree of dignity, their dead ancestors are at the same time preferred and ennobled with them. The kings Ven, Van, Veu, Van, Cheu, and Cum, who were descended from vassal kings, when they mounted the imperial throne, raised their ancestors from the vassal...
ANC

valid or depending late wherein these had lived, to the dignity of emperors; so that the same honours were for the future rendered them as if they had been emperors of China. The same example was followed by the subjacent kings, and now obtains among the grandees and literati; all now worship their ancestors, according to the rank which they themselves hold in the world. If the son be a mandarin, and the father only a doctor, the latter is buried as a doctor, but sacrificed to as a mandarin. The like holds in degradation, where the condition of the fathers is that of their sons. The law distinguishes between ancestor and predecessor; the former being applied to a natural person, as such an one, and his ancestor; and the latter to a body politic or corporate, as a bishop, and his predecessors.

Ancestor, disability by the act of. See Disability.

Ancestrel, in Law, something relating to a man's ancestors.—Thus.

Ancestrel, homage, signifies homage that has been done or performed by one's ancestors.

Ancestrel, alien, See Action.

Anca, in Geography, a town of Asia, in Mingrelia, 120 miles north-east of Trebizond.

Anca is also a town of Asia, in the country of Georgia, and province of Satabago, 65 miles south west of Akhaliza.

Anchedia, an island near the western coast of India.

Anchesmus, in Ancient Geography, Agisios Gegezor, or Mount St. George, a mountain of Attica, upon which was placed a statue of Jupiter Anchesmus. Paulanias, in Attic. lib. i. c. 52. p. 78.

Anchial, a town of Asia, in Cilicia Campetris, situated near the sea, to the south-west of Tarsus. Some authors say, that it was built by Sardanapalus. Athenodorus pretends, that it was founded by Anchiale, the daughter of Japhet.

Anchiale was also a town of Illyria, built by the Parians.

Anchialus, a river of Cilicia, which watered the town of Anchiale.

Anchialos, or Anchialus, called by Pline Anclialus, a town of Europe, in Thrace, situated upon the Euxine sea, south-west of Mælembia. It was an episcopal see, dependent upon the patriarchate of Constantinople.

Anchialos was also in Greece, towards the Pelage gulf, according to the Argonauts of Orpheus.

Anchialos was also a town of Epirus, the inhabitants of which pretended that Anchiles died in their town. Others refer it to Illyria.

Anchiops, or Anchilops, in Surgery, from any near, and ςυς, the eye; a tumor in the lacrymal sac, near the inner angle of the eye, forming an inflamed fistula lacrymalis. See that article, and Egiilops. These swellings are of different kinds. The most common kind is a tumor, situated in the cellular texture immediately surrounding the lacrymal sac, and combined with redness, heat, and pain, which afflicts the external skin, and bears a considerable resemblance to an inflamed fistula lacrymalis. This resemblance frequently becomes more marked by the cutaneous inflammation acting upon the lacrymal duct in such a manner, as to obstruct the passage of the tears through it; the consequence of which is a flow of tears from the eye, and a swelling of the lacrymal sac.

The inflammatory tumor soon goes on to suppuration; an event which, provided we can do it early enough, we should endeavour to prevent by the external application of a fumunine wash, and other remedies that promote resolution of the inflammation, as well as by cooling evacuants. When suppuration has already taken place, and produced an abscess at the inner canthus of the eye, we are still more liable to be led into error, as we may easily mistake the fluctuation of the pus for the motion of some fluid contained in the lacrymal sac. This error, which might possibly induce us to make an incision into the found lacrymal sac, may, however, be easily avoided, by recollecting that the lacrymal passage was not previously diseased, that the tumor was at first hard, and that the lacrymal sac, only suppurated after wards. Moreover, in this disea, the matter cannot be squeezed with the finger out of the tumor, through the pointa lacrymalis, or the nose, (as it may when the lacrymal sac is filled with matter) unless the matter has already corroded the lacrymal duct, so as to produce a communication between it and the abscess. We may also distinctly observe, that both the inflamed and the subfequent suppuring tumor lies flat under the skin, and that at first the collection of matter is surrounded with inflammatory hardnes; whilst, on the contrary, the lacrymal sac, when filled with matter, is soft, and affords the sense of fluctuation throughout its whole extent, from the very commencement of the disorder. This complaint, however, may at times produce a real inflammation of the lacrymal ducts, and consequently also a true fistula lacrymalis.

When, in an inflammatory tumor of the angle of the eye, symptoms of incipient suppuration make their appearance, the surgeon may apply, during the night, the Emp. Litharg. vel diacetyl. comp. and, in the day time, emollient and somewhat stimulant poultices, in order to invite the matter towards the surface. These must be applied warm and frequently; in doing which, care should be taken that they do not come into contact with the eye, which, on that account, should previously be covered with compresses dipped in rofe-water. As soon as there is the least reason to suppose that pus has been formed, the tumor must be cut open; for, in these cases, it is of great consequence that the pus should be discharged as soon as possible, as otherwise it easily makes its way downwards, by which not only the lacrymal sac may be laid bare and corroded, but also the neighbouring bones, &c.

The incision is made with a lancet, but as remote as possible from the inner canthus of the eye, and proportionate to the magnitude of the tumor. The lancet must not be introduced in a perpendicular direction, but obliquely, for fear of injuring the lacrymal sac. When the matter and blood have been discharged, we should introduce some loose lint into the orifice, and cover it with a simple plaster. Over this we may lay a compresse, dipped in rofe-water. The ulcer is afterwards to be cleansed with mild digestive ointment, and suffered to heal up.

When the surgeon is not called in till the abscess has already been completely formed, he should immediately lay it open, and examine the state of the bone. When the bone is bare, some tumour of myrrh, or aloes may be used, and dry dressings applied, in order that we may not increase the ulceration, which is generally already considerable. When the exfoliation of the bone, and the cleaning of the ulcer have been completed, the healing of the sore should be promoted by the proper applications.

The anchilops may at times consist in a hard tubercle or knot, from which a cancer may be produced. This disease is to be treated like other scirrhous tumors. See Scirrhus.

Sometimes the tumor is of the encysted kind, most generally of the species of Atheroma. In this disease no pain is felt, the tumor is of an uniform colour, circumscribed, smooth, and moveable. Such a tumor also, like every other...
archilops, may by its mere prelative impede the function of the lacrymal ducts, and occasion an lvetinus, or watery eye. It may generally be softened by means of Empl. thach. comp., and brought to suppuration; otherwise it is to be diffected out with the knife.

This tumor may also arise from an accumulation of fluid between the lacrymal sac and the external skin. Such a sonous, uninflected tumor seldom opens itself spontaneously outwards; it more commonly happens, that it is connected with one of the two puncta lacrimalis, or lacrymal ducts, generally lower in which case the fluid may indeed be diffected out through one of the puncta lacrimalis; but it may, nevertheless, be easily distinguished from a swelling of the lacrymal sac, by the circumstance that the latter generally yields to the slightest pressure, whilst the former cannot be made to collapse, unless by pressing it from below upwards, and its tension can be diminished except in a gradual manner.

When the sonous archilops is not yet in communication with the lacrymal ducts, (as generally is the case,) it may readily be distinguished from the dilation of the lacrymal sac, by the single circumstance of its not being by any means praecificable to squeeze out the fluid.

There are certain circumstances under which the lacrymal tumor does not yield to prelative; namely, when the lacrymal ducts are contracted or inflamed, foas to prevent the reception of the fluid contained in the lacrymal sac. But when these passages are in a sound condition, and when the tumor of the larger canthus does not yield to prelative, there can be no doubt that the disease is situated without the lacrymal sac.

When the resolution of such a sonous tumor, which we may at first attempt to bring about, does not soon take place, the safest and most expedients method is to open it, and discharge the matter by means of a lancet, which must here also be introduced in an oblique direction. The wound should be filled up with dry lint, which, in the subsequent dressings, ought to be dipped in some detersive and drying solution, such, for example, as a very weak solution of lapis infernalis, and secured by means of a plaster.

Finally, in the venereal disease there is sometimes produced, in the region of the larger canthus of the eye, an exfoliis from the menings coronaee, or maxillare; by which a tumor is formed in this part that may easily be distinguished from other kinds of archilops. By its being hard, improveable, and generally of an uneven surface. It occasionas a comprenion of the lacrymal passages, which gives rise to a constant epiphora. We may, in such cases, employ internally mercurial remedies, and a decoction of Coft. Mzererei, and, at the same time, rub mercurial ointment upon the tumor, apply mercurial plasters, &c. by which a speedy cure is frequently produced: but, for the treatment of venereal disorders, see Syphilis and Lues Venereae.

ANCHROMACUS, in Middle Age Writers, denotes a kind of vefel, which, on account of its nimble failing, was used for the conveyance of anchors, and other necessary utensils of ships.

In this fenfe, the word is also written ancremoragus, anchirromacbus, ancremagonus, anchirhomagonus, ancremoragonus, and anchirromagonus.

ANCHISES Portus, a name given by the ancient Romans to the port of Onchiums, in Epirus, to the ealt of Corcyra.

ANCHISES, in Entomology, a species of Papilio (Eq. Tr.) that inhabits America; it is black both above and beneath, with seven oval scarlet spots on each of the posterior wings. Lieznus. The larva from which this butterfly is produced, is said to be gregarious, spinous, brown with white rings, and yellow borders; the pupa brown, with four teeth at the anterior part. Vide. Fab. Gmel. Me- tian, &c.

ANCHISES, in Fabulous History, a Trojan prince, descended from Daradus, and the son of Capys. Venus appeared to him in the form of a beautiful nymph, and made love to him. Their offspring produced Aneas, the hero of Virgil's Aeneid. It is said that he lived to the age of 80, and was buried on Mount Ida, where the Shepherds paid honours to his monument. According to Virgil, Aneas took his father on his shoulders, and made his choice with him the night on which Troy was taken. See Aneas. Some say, that Anchises lived till his son's arrival in Italy, that kind of promienie, which the deities had ordered him to go in search of, through a thousand dangers. Cat. Damiarius Faliscus, and Strabo, adopt this opinion. Gen. Dict.

ANCHISIUS, in Ancient Geography, a mountain of Peloponnesus, in Arcadia, to the north of Mantinea.

ANCHITHE, a people placed by Tolemy in Arabia Felix, near mount Chiraz.

ANCHOA, a town of Greece, in Braxis, placed by Pline at the mouth of the Cephiphus. Strabo mentions also a lake of the same name.

ANCHOR, Anchora, from the Latin ancor, or anchor, of the Greek ακών, which comes from ακόι, incurvus, curved, a large, strong, and heavy piece of iron, composed of a long shaft, having at the end a ring to which the cable is fastened, and at the other two arms or flukes, with bars or edges on each side, and used for fixing and retaining a vessel in a harbour, road, or river.

The anchor is an instrument of very ancient use. Pline (lib. viii. c. ute.) describes the invention of it to the Thracians; and Paulainias (Attic. lib. i. c. 2. p. 12.) refers it to Mithis, the son of Gordius, who built the city Ancyra. The most ancient anchors were of iron, and sometimes of wood, to which a quantity of lead was attached; in some places they used balest full of flones, and bakes filled with sand. These were fastened by cords, and their weight regulated the movement of the ship. After this anchors were constructed of iron, and furnished with teeth or flukes, which falling to the bottom of the sea, kept the ship immovable; hence κομόν, teeth, are used for anchors. The first anchors had only a tooth or fluke, on one side; and on this account they were denominated κομόμοι; the contrivance was completed, according to Pline, (ubi supra.) by Eupalamus, who made them flaked both ways, or according to Strabo (lib. vii. ex Ephor. tom. p. 46.) the second tooth or fluke was added by Anacharis, the Scythian. The anchors with two teeth were called κομόμοι, or κομομομοι. Every ship had several anchors, the largest of which was called μεγαλος, sacred, and was never used but in extreme danger; whence the phrase “σαμαρανθαρομαντε" is proverbially applied to such as are reduced to their last refuge.

All anchors have now two arms; but not they might fill be used with only one arm, which structure would have this advantage, that they would be lighter, and yet in fine weather would hold equally firm with the double kind. The reason of having two arms is, that the anchor may always take, in order to which it is necessary that it be very heavy; besides, that anchors with a single arm would require more preparation for service.

Travellers tell us of people who make use of wooden anchors in their navigation. The inhabitants of the island of Ceylon, in lieu of anchors, use large round stones, and...
in other places, their anchors are a kind of wooden machines, loaded with stones. Sometimes bags of sand have been made use of, but these chiefly obtained in rocky places, where anchors would not take hold. In England, France, and Holland, anchors are made of forged iron; but in Spain, they are sometimes made of copper, and likewise in several parts of the South sea.

The anchors now made are so contrived as to sink into the ground as soon as they reach it, and to hold a great strain before they can be loosened or diffused from their position. The parts of which an anchor is composed are the ring, into which the cable is fastened, the beam, or flank, which is the longest part of the anchor, the two arms, at the end of which are the two flukes or flukes, by some called the palms, which with their bars fallen into the ground, and the fluke, which is a long piece of wood, fastened across the beam, near the ring, and serving to guide the flukes in a direction perpendicular to the surface of the ground; so that one of them sinks into it by its own weight, as soon as it falls, and is held preferred readily in that position by the fluke, which, together with the flank, lies flat on the bottom. In this situation it must necessarily sustain a great effort before it can be dragged through the earth horizontally. This, indeed, can only be effected by the wind or tide, or by both of them; the effect of which is sometimes increased by the turbulence of the sea, and acts upon the ship so as to stretch the cable to its utmost tension, and may thus dislocate the anchor from its bed, especially if the ground be soft, and oozy, or rocky. When the anchor is thus displaced, it is said, in the sea-phrase, "to come home".

The several parts of the anchor, above enumerated, bear the following proportions. The length of the arm, from the inside of the throat to the bill, is the distance marked on the flank for the trend, taken from the inside of the throat; and three times that is the length of the flank from the tip of the crown; and the flank, from the tip of the crown to the centre of the ring, is the length of the iron stock; when made, the two arms, from the inside of the throat to the extremity of the bill, should form an arc of a circle, containing 120 degrees. See Plate XI. Ships.

Of anchors there are the fleet, becket bower, small bower, and spare anchor. These do not vary in form or weight in other, in the navy. Stream and kedge anchors are smaller, and grapnel are only for boats. Ships of 120, 100, 98, and 50 guns, have seven anchors; from 80 to 20 guns inclusive, fix anchors; ships of 300 tons, and sloops have five; and brigs and cutters three anchors.

Anchors, method of making. The goodness of the anchor is a point of great importance; the safety and conserva-
tion of the vessel depending principally upon it. The flank, arms, and flukes, are first forged separately; then the hole is made at one end of the flank for the ring, which being also previously forged, is put into the hole of the flank, and the two ends flut together. After which the arms are flut to the flank, one after the other, and the anchor is finished.

The flank is made of many long bars of the best touch iron, well wrought together; and great care should be taken, that the iron be neither too soft nor too brittle; the latter rendering it liable to break, and the former to fracture. The number of bars sufficient to make the flank of the intended size must be regulated by experience. Several parts of the anchor are governed by the size of the trend, which is marked on the flank at the same distance from the inside of the throat as the arm measures from the inside of the throat to the extremity of the bill. The flank is rounded to the square of the upper part, and is there called the small round, being the smallest part. The two sides in the direction of the arms are flat surfaces, about an inch less than the trend, in large anchors, and something less in smaller ones. The squared part is of the same size as at the trend each way, and hanches into the small round, one-sixth of the length of the flank. The hole, or eye, for the ring, is punched through the square part, or the flatted side, once and a half the thickness of the ring, from the upper extremity of the flank, which has its corners flatted or diamonded, on the same sides nearly, in the middle. Between the hole for the ring and lower part of the square are two small prominences, raised across from the fold, called nuts, for securing the stock in its place. At the lower part of the flank is left a leaf, or flatted surface, with a shouder on each side, for flutting on the arms.

In making every part of an anchor the nicest attention should be observed, as to its being smooth, fair, and even; and that the edges and angles are preferred straight in their direction, as well-made anchors should profess beauty as well as strength. The ring, being previously forged, is put through the fore-mentioned hole in the flank, and the two ends are well flut together. The arms are made of shorter piece than the flank, but as good in quality, and as well put together; these are round and flatted on the different sides, to resemble the flanks, and are of the same size as the flank, at the throat and small round. The rounding part is continued to the palm, which is nearly in the middle of the arm; from thence it is made with a square tapering to the bill on the flatted side; and, on the inner rounded side, is made a square foot for flutting on the palm, that the palm, when flut on, should project its thickness at the bafe or inner part, the outer part making a straight surface with the neck or bill. The bck or outer side of the arm is made straight from the rounded part, or hanch, to the snape, and there kept to half the subsidence of the inner part. The snape resembles the bill of a duck, and is one-third the breadth of the palm in length. The thickness of the ring is to be half the diameter of the small round. The diameter of the ring, including the thickness, reaches from the hole in the upper part of the flank to the hanch of the small round. The inner part of the arm is molten made straight, from the bill to the throat; and it is thought stronger for having a small angle in its length, inclining to the flank. Shanks taper in their length, one and one-half inch in small anchors to three inches in large, keeping their proper size at the trend; and three-fourths of an inch to two inches in the flatted way. The arm in its length inclines to the flank, and forms a small angle, the touch or point thereof being in the middle. The throat-end of the arm is curved, or flatted, to answer the scarf in the flank, to which the two arms are united (after the palms are flut on) in the firmest manner possible; and it is elevated above the horizontal plane, or inclined to the flank, that each arm may spread at the neck or bill. The length of the arm, from the inside of the throat to the extremity of its bill, is then taken, and that length from the inside of the throat is set upon the flank, and called the trend; from the trend to the bill is formed an angle of about 60 degrees. The palms, or flukes, are two thick plates of iron, made of various thickness, well wrought together, in the form of an isosceles triangle; one and one-half inch to one and one-fourth inch longer than the breadth of the bafe, and curve about as much in their sides. The bafe or lower part, is to be straight; the inner flat surface curves a little in the breadth, but is straight lengthways.
The anchor is computed, that the lower side half of the upper end of the shank, transverse to the flukes or palms; and the nuts are let into the middle of the stock. The length of the stock is the length of the shank and half the diameter of the ring; the depth and thickness in the middle are as many inches as the stock is feet in length. The ends are to be kept square, half the depth or thickness in the middle. The upper side next the ring is always kept straight, as is the lower side half the depth on each side the middle; and thence it tapers to each end in the above proportion. It is necessary to leave an opening in the middle of one and one-half inch, between the two pieces, that the hoops may be driven nearer the middle, in case the stock should shrink. The making of anchors is a very laborious business, and has been much facilitated by the invention of two machines, called the Hercules and the Monkey.

Proof is made of anchors, by raising them to a great height, and then letting them fall again on a kind of iron block placed across for the purpose. To try whether the flukes will turn to the bottom, and take hold of the ground, they place the anchor on an even surface, with the end of one of the flukes, and one of the ends of the stock reposing on the surface; in case the anchor turns, and the point of the fluke rises upwards, the anchor is good.

For the proportions of anchors according to Manwaring, the shank is to be thrice the length of one of the flukes, and half the length of the beam. According to Aubin, the length of the anchor is to be four-tenths of the greatest breadth of the ship; so that the shank, e. gr. of an anchor in a vessel thirty feet wide, is to be twelve feet long. When the shank is, for instance, eight feet long, the two arms are to be seven feet long, measuring them according to their curvature. A to the degree of curvature given the arms, there is no rule for it; the workmen are here left to their own discretion.

Aubin, in his Marine Dictionary, gives a table from a Flemish writer, wherein the lengths of the shanks of anchors for vessels of all widths, is computed, as well as the weights of the anchors. from a vessel eight feet wide within, which requires an anchor three and one-half feet long, weighing thirty-three pounds, to a vessel forty-five feet wide, which demands an anchor eighteen feet long, and weighing 5832 pounds. He likewise observes, that the anchor of a large heavy vessel is smaller, in proportion, than that of a lighter one. The reason he gives is, that though the sea employs an equal force against a small vessel as against a great one, supposing the extent of wood upon which the water acts to be equal in both, yet the little vessel, by reason of its superior lightness, does not make so much resistance as the greater; the defect whereof must be supplied by the weight of the anchor.

From these and other hydrometeric principles, the following table has been formed; wherein is shewn, by means of the ship's breadth within, how many feet the beam or shank ought to be long, giving it $\frac{1}{2}$ or $\frac{3}{4}$ of the ship's breadth within; by which proportion may be regulated the length of the other parts of the anchor. In this table is represented likewise the weight an anchor ought to be for a ship from eight feet broad to 45, increasing by one foot's breadth; supposing that all anchors are similar, or that their weights are as the cubes of the lengths of the shanks.

M. Bouguer directs to take the length of the shank in inches, and to divide the cube of it by 1150 for the weight. The reason is obvious; because the quotient of the cube of 201 inches, which is the length of an anchor weighing 7000 lb., divided by the weight is 1150, and therefore by the rule of three, this will be a common divisor for the cube of any length, and a single operation will suffice. The same author, in his Traité de Navire, gives the following dimensions of the several parts of an anchor. The two arms generally form the arch of a circle, whose centre is three eighths of the shank from the vertex, or point where it is fixed, to the shank; and each arm is equal to the same length or the radius; so that the two arms together make an arch of 130 degrees; the flukes are half the length of the arms, and their breadth two-fifths of the said length. With respect to the thickness, the circumference at the throat, or vertex of the shank, is generally made about the fifth part of its length, and the small end two-thirds of the throat, the small end of the arms of the flukes, three fourths of the circumference of the shank at the throat. These dimensions should be bigger, when the iron is of a bad quality, especially if cast iron is used instead of forged iron.

The table above provides the approved dimensions and weight of anchors for various weights. Each row represents a different weight category, with columns detailing the length of the shank, arms, breadth of the palm, thickness of the palm, size of the trend, outer diameter of the small round, and thickness of the ring, along with the corresponding weight values.
The Number of Anchors allowed each Ship in the Royal Navy, with their Weight and Value.

S. stands for Sloop, K. for Cutter.

See Murray's Treatise on Ship-building, &c. Elements and Practice of Rigging and Seamanship, \(\text{4to. 1794}\), p. 77—82.

The distinctions of anchors are taken from their use, and the proportions they bear in the ship, where they are employed; for that which in one ship would be called a kedge, or kedge-anchor, in a leafer would be a flat-anchor.

Anchors, kedge, is the smallest, which, by reason of its lightness, is first to flop the ship in kedging a river.

This is what the Dutch sailors call kedge-anchor, the French ancre à tourel. It ought to weigh 500 pounds.

The grapnel is an anchor for a small ship or boat. See Kedge and Grapnel.

Anchor, kedge, is a small anchor fastened to a shackle, wherewith to ride in rivers, and gentle streams, and to flop a tide withal in fair weather.

Anchor, beat, or filthy, is the biggest and strongest, being that which the seamen call their last hope; never to be used but in great extremity.

This is what the Romans call anchora fueri; the Dutch peeg-anker, and jop-anker; the French mainteure-anker, or grande ancre.

The other anchors are called by the name of the first, second, and third anchor; by any of which the ship may ride in any reasonable weather, sea-gate, or tide. These are something bigger than another, and usually when they fail in any forecast, or are near a port, they carry two of these at their bow; in which respect they are also called by the name of first and second bowers.

Anchor, fistnent, called by the Dutch borger-anker, or dangelys-anker, is that ordinarly made use of.

Anchor, croft, called by the Dutch my-anker, or vorty-anker, and by the French ancre d'afforeche, is a middling anchor thrown across or opposite to another. This ought to weigh 1500 pounds, or nearly as much as the second anchor.

Anchor, floating, is a simple machine, which is made to dive beneath the dwell of the sea, and retain the vessel where there may be no other anchorage. It consists of two flat bars of iron, each in length half the breadth of the midship beam of the vessel for which it is used, and riveted together in the middle by an iron faucer-headed bolt, clenched at its point, that they may be swung parallel to each other for easy rowing. At each end of the bars is a hole for a rope, or twister to pass through, which must be hove tight to extend the bars at right angles. To this twister is marked a double or four-fold canvas cloth, so as to be on that side of the iron bars nearest the vessel when used. In each bar are two holes, at equal distances from the centre, and to which holes the ends of two pieces of rope are fastened; the ropes are seized together in the middle to form a crow-foot, having an eye in the centre, which is well fixed with spun-yarn, and to this is bent, when the anchor is used, a cable or hawser, by which it is made to sink and incline in the water. See Plate XI. Ships. In the end of one of the bars is fitted an iron ring to which a buoy is made fast, by a rope about 12 fathoms long, to prevent the anchor from sinking to the bottom. When it is thrown over-board, the cable and a rope made fast to the head of a buoy, are carried away sufficiently to ride the vessel. To get it on board, haul upon the buoy-top, which will bring it to the vessel's surface so as to be easily drawn to the vessel. Have the mizen stay-fall ready to hoist, so as to keep the vessel to the wind, till the anchor is hauled on board.

A floating or swimming anchor will serve to prevent a ship, in a storm, from driving to leeward in deep water. Dr. Franklin suggests that an anchor, effectual for this purpose, ought to have the following properties. It should have a surface so large as being at the end of a hawser in the water, and placed perpendicularly, should hold so much of it, as to bring the ship's head to the wind, in which situation the wind has least power to drive her. It should be capable of being situated below the heave of the sea, but not below the undertow. It should not take up too much room in the ship. It should be easily thrown out, and put into its proper situation. And lastly, it should be easy to take in again, and flow away. Many contrivances have been suggested...
ANCHOR.

suggested for this purpose. One for a large ship might have a stem of wood 25 feet long and four inches square, six four boards, 18, 16, 14, and 12 feet in length, and one foot wide, with a hole in the middle of each, about four inches square, so that it might be occasionally flipped upon the stem at right angles with it; and when these boards are fixed at the distance of four feet from each other, the anchor would have the appearance of the old mathematical instrument called the foreafl. This thrown into the sea, and held by a hawser veered out to some length, would bring a vessel up and prevent her driving, and when taken in it might be flowed away by separating the boards from the stem. Such a swimming anchor would have some good effect, but as it lies on the surface of the sea, it is liable to be hoisted forward by every wave, and then only give so much leave for the ship to drive. Dr. Franklin has proposed two machines for this purpose, which he conceives, would be more effectual and more manageable. The first of these is to be formed, and used in the water on almost the same principle, with those of a paper kite in the air; only that the paper kite rises in the air, this is to defend in the water; and its dimensions must be different for ships of different sizes. The other machine is to be made more in the form of an umbrella. See a particular description of both these machines, with figures, in the Transactions of the American Philosophical Society, vol. ii. p. 311–314.

ANCHOR, to back an, in Sea-language, is to let go a small anchor a-head of a large one, to which it is fattened, that it may partake of the strain, and serve as a check upon it, should it come home. The backing anchor is carried out in a long boat, to the buoy of that which is already down, whole buoy-rope is cast off and bent to the cable or hawser of the backing anchor; when that is done, the boat is rowed further a-head, till the buoy-rope and cable of the backing anchor become tight, when it is let go, the buoy that was taken from the large one being previously bent to it. In this situation, should the large anchor come home, the scope of cable from it to the anchor a-head, participating of the strain communicated to the innermost one, checks its progress, and secures to the vessel a greater security. Where there is more room to drive without danger, and it blows so hard, that the sea runs too high for boats to work, an anchor is backed by cleaving round that part of the cable next the hawse-hole, the end of a cable bent to another anchor on board; this being done, the second anchor is let go under foot; the ship is then suffered to drive, and the cable thus becomes tight from the ring of the anchor last down to its own anchor, which also, by the driving, is now become a cable's length a-head of the former anchor.

ANCHOR, riding at, the state of a vessel moored and fixed by her anchors at some proper station. Where a great number of vessels are moored in the fame port, care is to be taken by the pilots, or those who have the command, that each ship be at a due distance from the rest, to prevent their running foul of each other; also, that they be neither too near, nor too far from land. The proper space between vessels is, from two to three cables' length. See Mooring.

ANCHOR, dropping, or let fall the; otherwise called calling anchor, imports the letting it down into the sea. In some cases it is necessary to drop two anchors opposite to each other, one of them to keep the ship firm against the tide, or flow, the other against the ebb. On approaching an anchorage, the anchor and buoy are got clear, and a range of cable, stretched along the deck, suitable to the depth of water. Care should be taken that nothing is in the way to check the cable, or flop its running out; then, at a proper distance, a turn is taken round the bits with the cable, thus: føril pass the cable from the anchor underneath the cross-piece, then take up a bight of the cable abaft the bits, and throw it over the bit-head. The end of the cable is clenched round the orlop beams in the royal navy, and round the main-mast in the merchant service. It is necessary to have water near the bits to prevent its firing by the friction. STOPPERS and RING-ROPES of all kinds should be ready for use. The flock-lashing being cast off, and nothing but the anchor-hooper and shank-pointer retaining the anchor, men are stationed to stand by them, and let go at the moment when the order is given.

A ship should generally be brought to anchor under an easy fall, such as the three top-fails, jib, or fore topmast day-fall, and sometimes the mizen, according as the vessel has more or less inclination to fall off or come to the wind. An anchor should never be dropped to leeward of the place you mean to bring up in; because that which would often render it necessary to call two anchors at once, for fear of dropping still more to leeward. When the wind is so violent as to bring the anchor home, and make the vessel drive, the cable is veered away; and in veering away, the turns of the flopper laniards are flackened, and a portion of the cable suffered to go out of the hawse, to let the vessel further a-head of her anchor; in which situation the bears left strain on the flukes, and is left liable to drag the anchor; for, the more cable is out, the flukes become deeper buried, and the ship rides in greater safety. In letting go an anchor, care should be taken that the water be not too shallow as to endanger the ship burning herself upon it, and that the anchor be not fouled by the cables getting about the fluke or flack. Nor should the water be too deep, because the cable, when out, should approach as nearly as possible to an horizontal direction. This principle is so true, that three cables laid together on end of each other, are kept bent to the bower anchor, to be used in cases of necessity; and it is found, that one good anchor, with a long range of cable, is a safer anchorage than two anchors with short cables. However, when the ship has not room to drive, and in a dark night, let fall a second anchor under foot, with a range of cable above the deck. At all events, the deep-sea lead should be thrown over the gun-wale, and the line frequently handled, to be certain that the ship does not drive. In hard and rocky bottoms, where anchors cannot have much hold, cables are chafed and cut to pieces. When necessity requires anchoring in such places, a chain should be run up the cable from the ring of the anchor to a certain distance, in order to secure it from danger. When a chain is not to be had, empty casks, well bunged, are good substamines, flung and fastened to the cable at equal distances, to support and keep it from the bottom. When ground is soft and oozy, and anchors will not hold securely, but come home with little wind, it is common to cover the flukes with a broad triangular piece of plank, much larger than the fluke. Sometimes the anchor is backed, or retained, by carrying out the stream, or kedge, a-head of the anchor by which the ship usually rides. In this situation, the bower anchor is combined by the stream, or kedge, in the same manner as the ship is restrained by the bower anchor. In preparing to come to anchor, when the wind is not violent, the top-falls ought always to be clued up at the mast-heads; that is, let go the sheets, and haul the clews and bunt-line close up; take away the top-fails, and take in the slack of the braces as the yard comes down. In this manner you run less risk of splitting and tearing the falls than by any other method. For the various methods of anchoring in different circumstances, see Elements of Rigging, &c. vol. ii. p. 252–256.
Anchor, weighing, imports the act of withdrawing, or recovering the anchor into the vessel, in order to haling. The anchor is ordinarily weighed, or recovered by means of a capstan or windlass.

In large ships which have a main and jeer capstan, and the main is thought too great for the men-ager alone, the jeer is used thus: three or four turns are taken round the jeer capstan with one end, for as to leave that hole clear on which the cable is coming in; and past the other end through the vlog-block, which is lashed round the main-mast on the lower deck. It is then carried forward, and pulled round the rollers in the manner near the hawse-holes; then brought aft, and spliced to the other end with a short splice; and the ends marked down tight. That side of the vlog on which the cable is coming in is fastened to the cable by nippers; and thus the continued efforts of the capstan are conveyed to the cable, until it is hoist. The nippers are clapt on the capstan, from one to two fathoms aboiver; and the vlog is applied to the midship, or inside of the cable. Nippers are clapt on by taking three or four turns round the vlog, four turns round the cable and vlog, and then three or four turns round the cable. This method is very suitable to quick hewing; but when the cable is great, and the cable muddy, the nippers clapt on after this method will not nip sufficiently; in which case recourse is had to the following method: throw hand or afties upon the cable, and take a long dry nipper, which middle, and pass one half aft, racking it in and out round the cable and vlog; then worm its end round the vlog only. After this pass the other half in the same manner forward; but worm its end round the cable only, and let each end of the nipper be held on. The advantages of this method are, that, as the cable of the main or the cable lies forward, and that of the vlog aft, the nipper will be drawn so tight as to effectively hold the cable till something give way. Besides, they can never jamb, for both ends are clear for taking off.

Ships without a jeer capstan heave on their cables by the meffenger, which has an eye spliced in each end; one of which ends is passed with three or four turns round the capstan on the upper deck, and the other end is passed forward round the rollers, at the forepart of the capstan; then brought aft to the other end, and laid thus: several turns are passed through the eyes, crossing each other in the middle, then a half hitch is taken round the parts, and the ends stopped with snub-yarn. What remains of the operation is performed as by the vlog, excepting that the meffenger is applied to the outside of the cable, and when the nippers are insufficient, the meffenger may be hitched by fastening its bight round the cable at the capstan with a rolling hitch, and in the bight round the cable before the hitch.

When the carpenter has been gotten up, and the cable of the second anchor enters the larboard hawse-hole, the operation of getting up this anchor is the same, observing only, that the meffenger must be shifted, and the turns on the capstan reversed; and the men, who before held on the larboard side in the first operation, will hold on the larboard side now; the motion of the capstan is performed the contrary way, and the cable on the larboard side is fixed and hove in.

Most merchant ships and small vessels heave up their anchors by a windlass, round which are taken three turns of the cable, and held on by hand, or by a jigger, thus: the end of the rope which has the take-up pailed round the cable, with a round turn, close to the windlass, the leading part of the rope coming over the sheave, and the rest of the rope being of the same length as the cable, and therefore the cable is pulled up, the windlass being turned, and the anchor, after a certain length of rope is taken up, is received on the capstan, and hauled up.

An anchor is weighed with the long hawse, by taking the anchor out of the hawse, and putting the buoy rope round the davit of the long hawse, and a hawse rope; by which, the anchor is weighed out of the ground. When this is done, the cable is hoisted on-board; the buoy rope, and hawse being secured in the boat, they approach the ship as the cable is hove in, and the anchor cast off and lowered. Small anchors and grapnels are got up by the davit, hauling on the cable or grapple rope by hand.

An anchor is weighed by under-running, when the cable is placed over the davit-head, and it is under-run, till it is nearly a peck, when it is tripped by means of tackles, as in the former case by the buoy rope. This method is troublesome, and is only adopted when the buoy is gone, and a ship cannot get near its anchor for want of water. See Elements of Rigging, &c. vol. ii. p. 326, &c.

Anchor, dragging, is when the anchor gives way, or loses its hold in the ground by the force of the wind, or sea, and the vessel drives from the place.

Anchor, to cast the, is to hook the cat-block to the ring of the anchor, and haul it up close to the cat head. See Stowing of Anchors.

Anchor, clearing the, signifies the getting of the cable off the fluke.

Generally also, when they let fall the anchor, they use this term, to see that neither the buoy rope, nor any other ropes, hang about it.

Anchor, fetching, or bringing home the, denotes the weighing it in the boat, and bringing it aboard the ship.

The anchor is said to come home, when the ship drives away with the tide or sea.—This may happen, either because the anchor is too small for the burden of the ship, or because the ground is soft, and oozy; in such places shoewing is used.

When a ship is compelled to anchor on a lee-shore, or in a narrow road where there is deep water, with an apprehension that the ground is either too hard or too light for good holding ground, drop the common riding bowser, first keeping 25 or 50 fathoms of cable on board, and throw over the lead. If by this means, or by the land, it appears that the anchor drags, let fall the bell bowser, and at the same time give out the rest of the common bowser cable, till the bell bowser gives her a check; after which bend on a sufficient rope or hawser to the common bowser, without the hawse-hole, and pass it through the windlass, making it fall. Then call off the common bowser, and pass the cable end through the hawse-hole, and take a running clinch with it round the bell bowser cable, and let it go. As soon as you think the vessel has dragged her bell bowser cable far enough to strain the common cable on the ground, veer out as much of the bell bowser as may be agreeable; when, however violent the weather, the vessel will never drag them home. A small vessel, which rides hard in a head sea, will be powerfully affted by falling an empty but to the cable, about 10 fathoms from the vessel; for that will first receive the motion of the sea; and check it before it comes to the vessel, so as to cause its rising up to the swell, and effectually aid in refting the violence.
ANCHOR.

Anchors to fish for, is to draw up the flukes of it towards the top of the bow, in order to flow it, after having been casted.

Anchors, gamboling the. See Gambuling.

Anchors, flowing of. In fitting out ships, the anchors are brought in craft near the bows, being most convenient to the hawse-holes, through which the cables pass to be elench'd. The bowser anchors are fir'd catted, which is performed by hooking the hook of the cat-block into the ring of the anchor, and bowling upon the fall that leads into a fluke-block on the fore cable; the cat-falls being previously revetted through the sheaves of the cat-head and cat-block, keeping the hook of the cat-block downwards, and its point inwards. They are then filled, by means of the half-davit, pendant, and tackle, thus: the davit is fir'd stopped in the channel on the side wanted, and supported by guys; the mast-head guy goes over the end of the davit, with an eye; the other end falls round the foremast head, with a round turn and two half hitches. The fore-mast guy goes over the end of the davit, the other end falls round the cat-head, with two half hitches, and securely stopped. The after guy goes over the end of the davit, and makes fast with two half-hitches through an eye bolt in the after part of the fore channel. At the outer end of the davit is hung, by its trap; a large single block, through which is revetted the pendan't, with a large iron hook filched in the lower end, to hook the anchor within the flukes; then to the inner end of the pendan't is made fast a tackle, by thrusting a toggle through an eye in the block-fall; after that has passed through an eye in the pendan't, the other block of the tackle is hooked in an eye-bolt in the fore part of the quarter-deck; the effect of the tackle is communicated to the hook, by means of the pendan't, by men's bowling on the tackle fall. Thus, the flukes of the anchor are raised and placed on the gun-wale, where it is made fast by the shank-painter chain. That the flukes may lie level, the block is bowled upon by the anchor-flock tackle, the double block of which is hooked to a felting, fastened round the block of the anchor under the first hoop, and connected by its fall to a single block, hooked to a felting fastened round the laniard of the main fall: the fall leads in upon the forecastle. The belt bowser is then placed forward near the bows on the forecastle side; the small bowser near the bows on the forecastle side, a little abaft their respective cat-heads; and are secured by their stoppers, from the cat-heads and shank-painters. The stopper has one end clenched round the cat-head; the other end paffes through the ring of the anchor, returns upwards, and leads over a large thumb cleat bolted to the cat-head, and is made fast with several turns, and the end hitched round the headrail and timber-head, on the forecastle side of the cat-head. The shank-painter hangs the shank and fluke of the anchor to the ship's hide out-board; and when lowered, the shank-painter is passed under the inner fluke round the shank of the anchor, and made fast with two or three turns, and the end fotp round timber-heads on the forecastle. With these two bowser anchors ships are generally moored, when lying in a tide's way, or in a fleet.

The fleet and spare anchors are hoisted by runners and tackles, main-fall, and yard tackles, and are lowered securely with block and bill lashings at the after part of the forefrouds, before the chefs-trees on each side of the ship, with one of the arms resting on a chock, bolted to the gunwale; the block being bowled to by the anchor-flock tackle. The fleet-anchor is lowered on the forecastle side, and is the first resource in a gale of wind, after parting with either of the bowser; for which reason, when in port, the fleet cable is kept bent, and the anchor is over the side, supported by the floper and shank-painter, ready for cutting away in case of necessity. The spare anchor is lowered on the forecastle side, and is seldom used, but when one of the others is lost.

The stern anchor is lowered on the spare anchor; and, when used, it is sent in the long boat, or launch, with its cable bent, and let go at any particular spot, either for weathering the ship, when riding by only one bowser, or to affit a ship when in-shore, or to warp her. &c.

The kedge is lowered on the spare anchors, and is frequently used to flop a ship for a tide, in little winds; but, if the wind be too powerful for the kedge, the stern anchor is substituted. The kedge is sometimes used in moderate weather to warp the ship, so as to shift her birth. Elem. of Rigging, &c. p. 287, &c.

Anchors, in Architecture and Sculpture, denotes an ornament in form of an anchor, or arrow's head; frequently carved on the ovolo of the capital, in the Tuscan and Ionic orders, as well as in the bed-moulding of Ionic and Corinthian cornices.

The anchors are usually intermixed with representations of eggs; whence the aleinar or ovolo itself is popularly called egg and anchors.

Anchor, anchor in Literary Matters, the figure of an anchor,
ANCHOR, representing in ancient books; which is of two kinds, superior and inferior. The superior, &c. is where the crooked part is uppermost, used to denote a thing or thrall strongly expressed. The inferior is where the crooked part is at the bottom, to denote a thing poorly or meanly fet forth.

Anchor is also used, in a left proper sense, for any thing that holds another thing fast, to prevent its driving.

In this use, sea-muscles are said to ride at anchor, by a fort of threads the thickness of a large hair, which they emit out of their body, to the number sometimes of a hundred and fifty, which fastening to the flutes and other adjacent bodies, keep them firm in their place. The same is done by the PINNA MARINA.

Anchor, in Heraldry, is the emblem of Hope; and is taken for such in a spiritual, as well as in a temporal sense.

Anchor, a misuse. See Anchor.

Anchor Island, in Geography, an island in Dusky Bay, in New Zealand, visited by Captain Cook in 1773, and by Captain Vancouver in 1791. The harbour was particularly surveyed by the latter navigator, who observes, that it appeared to be perfectly secure, and may be found convenient, when accidents prevent vessels from getting into Facile harbour. It has two entrances; that to the north of the Petrel Islands is a fair, clear, and very deep channel; its general foundings were from 33 to 38 fathoms: in the narrowest part it is about a cable's length wide, and free from danger; as the shores are steep, without any funken rocks or shoals, excepting within the passage close to the south side of large Petrel island, where they are discoverable by the weeds growing upon them, and are quite out of the way of its navigation. The other passage is to the southward of the Petrel Islands; and if a strong northern wind compels any person to make choice of this in preference to Facele harbour, the south-west point of large Petrel Island should be kept close on board, in order to weather the rock that appears above water in the middle of the harbour, and to avoid a funken one, which does not appear, and over which there is no greater depth than 12 feet at low water. Anchor Island harbour, though a very secure port, is not very convenient to get to sea from, on account of its narrow limits, great depth of water, and the above mentioned funken rock in its western entrance. The mountains of Anchor Island, and others round the bay, which, on Vancouver's arrival in November, were perfectly free from snow, were, after a storm which they experienced, covered with it. In a few days the greater part of it disappeared; and it is probable that fresh falls of snow are not frequent, as they do not check the luxuriance of vegetation.

ANCHORAGA, in Entomology, a species of the Fabrici genus BRENTUS, found in India. It is linear, wing-cafellated with yellow, and thorax elongated. Fabricius. This insect is described by Linnaeus as a species of Curculio, under the same specific name as Fabricius has adopted; its description is, head long, wings decd, wing ca elles fatted with yellow, and thorax elongated. Gmelin has removed this species from the Curculio to the Brentus genus in the last edition of the Systhema Nature.

ANCHORAGO is like as a species of CINX which inhabits North America; the general colour is blue, apex and base of the scutellum yellowish, margin of the abdomen yelow with black spots. Fabricius and Gmelin.

ANCHORED, Anchored, in Heraldry. See Anchor.

ANCHOVY, in Ichthyology, a little sea-fish much used by way of sauce or feezoning; it is the Chupa maxilla superiore longiorie of Artedi; and CLUPEA ENCRASICOLUS of Linnaeus. See Encrasicus.

The word anchovy is derived from the Spanish anchovia, or rather from the Italian anchio, which signifies the same.

The anchovy is caught in the months of May, June, and July, on the coasts of Catalonia, Provence, &c. at which season it constantly repairs up the Straits of Gibraltar into the Mediterranean, where they are taken in large quantities. The great fishery is at Gorgona, a small isle west of Leghorn. Collins says, they are also found in plenty on the western coasts of England and Wales. Near a century ago the anchovy was found at the mouth of the river Dee, by Mr. Ray; but since that time it has been found very rarely and only by Mr. Pennant, in 1769, on our coasts.

The filleting for them is chiefly in the night-time; when a light being put on the stern of their little fishing-vessels, the anchovies flock round, and are caught in the nets. But then it is affected to have been found by experience, that anchovies taken thus by fire, are neither so good, so firm, nor so proper for keeping, as those which are taken without fire.

When the fishery is over, they cut off the heads, take out their gall and guts, and then lay them in barrels, and salt them. The common way of eating anchovies is with oil, vinegar, &c. in order to which they are first boned, and the tails, fins, &c. flipped off. Being put on the fire, they dissolve almost in any liquor; or they are made into sauce by mixing them with pepper, &c.

Some also pickle anchovies in small delf, or earthen pots, made on purpose, of two or three pounds weight, more or less, which they cover with platter, to keep them the better. Anchovies should be chosen small, fresh pickled, white on the outside, and red within. They must have a round back, for those which are flat or large are often nothing but Turning.

Besides these qualities, the pickle, on opening the pots or barrels, must be of a good taste, and not have lost its savour.

ANCHOVY pear, in Botany. See Grains.

ANCHUSA, *ων* *ωο* *σο* *σο* *σο* *σο* *σο*, from its supposed conjurating quality, or, as others say, because it stings serpents, in Botany, buglossium of Tournefort and Gartnner, a genus of the pedantia monogynia clafs and order; of the natural order of offerolife, and borragines of Julius; its characters are, that the calyx is a perianthium five-parted, oblong, round, acute, and permanent; the corolla is monopetalous and funnel shaped; tube cylindrical, of the length of the calyx, limb semiquinquefoil, from erect expanding and obsolete; throat clothed with five small scales; convex, prominent, oblong, and converging; the stamina have very short filaments, in the throat of the corolla, anthers oblong, incumbent,
Incumbent; and covered; the *pilibium* has four germs, style filiform, of the length of the stamina, stigmas obtuse and emarginate; no pericarpium, but the calyx, enlarged and erect, contains the seeds in its bofon; the seeds are four, oblongish, obtuse, and gibbous. Martyn enumerates ten, and Gmelin sixteen species. 1. A. officinalis, buglofa, buglofa italic, b. longifolia, b. vulgaris, echium italicum spinosum, officinal, or common alkanet or buglofa, with leaves lanceolate, second spikes imbricate, and ovate bracts. This species is a perennial, and flowers in June and July. The stem is about two feet in height, erect angular, foliose, somewhat branched and paniced, the root is filiform, and externally black; the herb is hairy and rough; the leaves are lanceolate, acute, and slightly decurrent; the upper ones, subovate at the base; the racemes are mostly double, and revolute; the bracts ovate, and not as in the A. angulifolia, linear-lanceolate; the flowers purple and funnel-shaped. It grows wild in Italy, Spain, France, Germany, Sweden, Denmark and Siberia, by road fides and in corn fields. It is found also with us amid rubbiish or in marshes; as on the links near Hartley Pans, in Northumberland. Miller cultivated it in 1749. When it is tender in the Spring, it is boiled and eaten in Upland. The tube of the corolla is melleferous, and the bees are very fond of it. This is not the anchusa, but the bugloss of official writers; but it does not appear that our buglofas possesses the same properties with that of the ancetas; for it has no claim to the title of euphorionnum given to theirs (see Pliny. Hist. Med. lib. 25. c. 8.), as it has no exhilarating quality, although its flowers have been long referred to the class of the four corollas. This plant, says Dr. Lewis (Mat. Med. p. 167.) appears to be nearly similar to borage, in its medicinal qualities as well as in its external form. The principal difference seems to consist in the leaves being somewhat less juicy, and the roots more mucilaginous. The roots, leaves, and flowers are ranked among the articles of the materia medica, but they are very seldom used. In China this plant is said to be much esteemed for gently promoting the eruption in the small pox. 2. A. angulifolia, borage of Zanz. hirt. buglofa angulifolium of Allion. and Mor. buglofa folis lin- genformibus apseris, &c. of Haller, echii facies buglofa of Lob.; narrow-leaved alkanet, with racemes almost naked in pairs. Haller thinks that this is not a distinct species from the first. In gardens it grows to the height of two feet, but in its wild state does not attain more than a foot. The leaves are narrow, and not so hairy as the first; the spikes of flowers are double, and have no leaves; the flowers are small, and of a red colour; the roots will continue three or four years in poor land. It is found wild in Italy, Ger- many, and Switzerland: flowers in July and August by way fides, and in the borders of ploughed lands; cultivated here by Miller in 1755. Boerhaave recommended the juice of the plant as a remedy for the flux and melancholy. 3. A. Halenia buglofa of Haller, Ray, and Bouthin, Italian alkanet, with leaves lucid and frigidae, racemes two-parted, two-leaved, flowers somewhat unequal, bearded at the throat. This differs from the first species in size, in that the flowers are equal and funnel-shaped; whereas in this they are smaller-shaped; they are much more imbricate in that, the segments of the calyx being broader and shorter; those of the corolla ovate; with the scales of the throat only slightly tomentose. 4. A. undulata, waved A. frigide, leaves linear toothed, pedicels less than the bracts, fruit-bearing calyces inflated. This plant is three feet high, with many strong lateral branches, produced from the main stem near the ground; the leaves are hirsut, rough, fix or seven inches long, and about half an inch round at the top, closely embracing the branches at the base, and two inches broad, indented and waved on their edges, the upper surface beft with hairs, and rough to the touch: spikes of flowers axillary, a foot or more in length, reflex: corollas fine blue; the root decays after the seeds are perfected, though sometimes, in gravel, or the joints of stone walls, it will live three or four years; but such plants are seldom more than a foot high, and have small narrow leaves, so that they appear like a different species. It is a native of Spain and Portugal, and Gmelin found it in Siberia; cultivated in 1739 by Mr. Miller. 5. A. tinctoria, buglofa tinctorum of Allion. Dyer's A. downy, leaves lanceolate, obtuse, and stamens shorter than the corollas. This species is perennial, and resembles the first in its leaves and branches, only that they are more woolly; the root is red. It much resembles the seventh species, and is entirely covered with a white down. It grows about Montpellier in France, in Silefia, Spain, and Italy; and was cultivated here in 1683 by Mr. James Sutherland. The roots of this plant, when in perfection, are externally of a deep purplish red colour. The red cortical part, separated from the whitish woody pith, imparts a fine deep red to oils, wax, and all unctuous substantias and also to rectified spirit of wine; but to water it gives only a dull brownish hue. The spirituous tincture, when infusitated to the consistence of an extract, changes its fine red to a dark brown. The root has little or no smell, and scarcely any taste; extracts made from it, by water and by spirit, are bitterish and roughish, but in too low a degree to be regarded as medicines, though they were formerly in repute as aperient, for dissolving congealed blood, refraining diarrhreas, and drying invertebrates ulcers. Its chief use at present is for colouring oils, plasters, lip-salves, &c. which receive a fine deep red from one-fortieth of their weight of the root. For this purpose the coniferous unctuous materials are to be liquefied in the heat of a water-bath, the powdered anchusa added, the mixture stirred now and then till sufficiently coloured, and then strained through a linen cloth. The roots of buglofas boiled in a decoction of Brasil wood are sometimes substituted for those of alkanet; but these will not dye oils red. Lewis and Murray, 6. A. virginica, lithospermum virginianum of Morfon and Ray, virginian A. with flowers scattered, and item smooth. This is perennial, and a native of North America, where it grows in the woods, covering the earth with bright yellow flowers, and known by the name of *psecon*. 7. C. lanata, woolly A. with villose leaves, hairy calyces, and stamens longer than the corollas. This species was found by Brender near Al- giers, and is very like the fifth. 8. A. latifolium, buglofa latifolium sempervirens of Dillon in Ray's Synop. borago sempervirens of Gerard, evergreen A. with ovate leaves, and two-leaved and capitated peduncles. The root is thick, and externally black; the herb stem evergreen and hispid; the items angular round, and foliose; the leaves alternate and ovate; the peduncles axillary, foliary, capitated, and two-leaved at the apex; the limb of the corolla blue, rather flarer-shaped than funnel-shaped, segments rounded, tube at the base four-cornered; the germ imbedded in a hollow glandular receptacle; seeds one or two, generally abortive, rough, and very hard. In habit and character this plant approaches to myosotis. It is found wild in Spain and Italy. With us it has been found by road-sides, among rubbiish, and in the joints of old walls, in several places about Norwich, at Haddicote in Suffolk, near Birmingham, Worcester, and Sidmouth, near Rochester and London, and in the ruins of Maes Glas monastery in Flintshire. It is perennial, and flowers in May and June. Withering's Bot. Arr. vol. ii. p. 227. Smith's Flor. Brit. vol. i. p. 215. 9. A. barreria, buglofa barrellum of Allion.
ANCHYLOBLEPHARON. See Anchylolophus. Anchylolepharon. See Anchylolophus.

ANCHYLOPSIS, in Surgery. (From αγκύλος, curvo) Anchyl, Anchyl, Anchylia, Anchylia. Immobility of the joints. This term is used when any joint of the body becomes, whether from external or internal causes, stiff and inflexible. It is divided into the true and the spurious anchylitis. By the true anchylitis is understood that disease, in which the bones of the joints form such a synostosis with each other, that they appear to consist of a single piece. In the spurious anchylitis, the motion between two bones at the joint is in some degree, though not entirely, lost.

The mobility of a joint may be more or less interrupted by various causes, amongst which are different diaphyses of the bones, particularly a tumefaction of their extremities, caries, fracture, near to or within the joint, dislocation, twining, and crumhing of the bone; as also several kinds of tumors, such as fleshly excrescences, aneurisms, hydropalamic accumulations, &c. The muscles may also give rise to the stiffness of a joint, when the flexors contract so strongly that the extensors lose their force, in which case a contraction, as it is termed, is produced. This generally arises from internal causes; sometimes, however, from external, or diaphyses that have attacked the joints, in which case the ligaments and other surrounding parts of the joint are likewise affected. To the internal causes belong the swelling of the bones, the rickets, a metallic deposition of corrupted fluids in the joints, a deficiency of the synovia or mucus which lubricates the joints, a continued pain, under which the patient finds relief from a certain position of the limb, in which he consequently keeps it for a long time, the colica fatumia, gout, chronic rheumatism, and paralysis. Some indeed have alleged, as causes of impeded motion in joints, the inflammation and accumulation of the mucus which lubricates their cavities; but even though we should admit that this synovial mucus might become preternaturally thick by the limb being left too long without motion, it cannot, however, be proved that its inflammation may increase to such a degree, as entirely to prevent the motion of the joint, as even the thickest mucus is still able to lubricate smooth surfaces, and facilitate the motion of one upon the other. On the contrary, a too long continued and violent exertion and motion of the body, as well as long continued repose, may deprive the fibres of their natural flexibility, as in both cases more earthly particles are deposited, and the fibres themselves rendered more dense, in consequence of which the ligaments also refit the extension and flexion of the joint.

The true anchylophus may easily be known by the impossibility of moving the bones in their joints, by the insurmountable difficulty which opposes their flexion or extension; but we may also with equal ease discover the false anchylophus by both seeing and feeling that the part still retains some power of motion at the joint. The prognosis depends upon the knowledge of the true cause of the disease, according to which the cure is either perfect or imperfect. By the imperfect cure we can only alleviate the inconveniences of the true anchylitis. Namely, the incurable synostosis of the bones; so that the perfect cure can only be successfully accomplished in the spurious anchylitis.

In general the method of cure is to be determined according to the different causes which have given rise to the incurvation and impeded motion of the joint. When the proximate cause consists in a contraction, we must endeavour to discover and remove the cause by which the contraction has been produced, and afterwards afflit the cure by means of external applications; for frequently, even though the internal causes may have been removed, the contraction of the muscles still remains. The contraction may be discovered by the tendons of the muscles, which keep the limb bent or extended, being very much stretched. Moreover, all that has been said concerning the internal causes and diseases, with a view to the cure of the immobility of the joints, applies also to the external causes and diseases; such as white swellings, suppuration of the joints, preternatural excrescences in the joints, cauries, dryness of the joints, burns, cicatrization, &c.

When now the internal or external causes have been removed, the surgeon must apply the proper remedies for restoring the motion of the joint itself. These remedies consist in endeavouring to soften the muscles, tendons, adipo membranes and ligaments, afterwards slowly and gradually to extend them, and progressive efforts to move them by degrees to their former condition; for which, however, a long space of time is generally required. In an anchylitis arising from a fracture of the bones of the joint, besides prescribing a light diet, we should rub the disfigured parts about the joint with flannel, in order to attenuate the fluids, and increase the effect of the remedies peculiarly adapted for the cure of the disease. For, in order to restore the mobility, it is particularly necessary that the muscles, ligaments, skin, and cellular texture should be softened and relaxed by emollient remedies, which should be employed very liberally, and persisted in for a great length of time. Contracted muscles should be rubbed, throughout their whole extent, with emollient applications, for the space of half an hour or more at a time, and three times every day.

The
The limb itself should constantly be kept moistened with the same applications, by wrapping it, every time after it has been rubbed, in flannel dipped in the emollient fluid.

While we are applying the frictions, we should endeavour to extend the limb as much as the patient can bear, slowly, but with perseverance.

When the contraction is situated in the knee-joint, we may make use of a machine, with the view of preventing the shortening of the muscles. The extension should by no means be performed too quickly, as pain and inflammation might easily be the consequence. Mr. B. Bell, in his System of Surgery, has recommended a useful machine for this purpose; Mr. Koehler (Anleitung zum Verband, &c. Leipzig, 1795, S. p. 168.) recommends a bench, and Mr. Trampel (Archivums dien Werke die Wundartzweiflichtswissenschaft. Bd. i. St. 1. p. 23. Fig. 1.) a machine similar to that of Mr. Koehler.

Amongst the emollient remedies adapted for the cure of this disease are particularly to be enumerated all sorts of animal oil, such as the fat of ducks, geese, and hogs; the leam of warm water; warm baths; fresh expressed oils, the Unkt. althea. Some recommend also an ointment made of the dripping of hares, turpentine, and okum oil; also baths and embrocations mixed with brandy; and finally, the vapour bath. When the substance of the fibres has become too dense, repeated embrocations, with a warm solution of sal ammoniac in water, are particularly useful. When these remedies are not found adequate to the removal of the affections, we may employ more powerful ones, such as embrocations with the brine of herrings with vinegar, vitriol, and alum; also with a solution of the balsam von exter. the empl. de gabanbo & de ammonico; especially the gumm. ammonico. boiled in wine vinegar to the confidence of a plaiter, spread thick upon leather, and applied to the diseased part.

Previously to every use of the vapour-bath, we may rub the part with a solution of Venice soap, or alo with ol. major, ol. tartari, etc., or some other similar oil. In proportion to the effects which it produces on the patient, the vapour bath may be applied for the space of half an hour or an hour, twice or thrice a day, or only every other day. The fluid employed for forming the vapour bath may consist, of warm oil, diffused in it, sal ammoniac, balsamum vitse externum, &c. In the intervals, the embrocations are to be applied. Fumigations, with volatile substances, have also been employed with great advantage.

Where the affections of the joint owes its origin to a dilation that has been reduced, and where the soft parts have been bruised, repeated blood-letting, with emollient and diffusent poultices should be used, till the tumor and swelling have disappeared, after which the parts may gradually be moved. But when the dilation has not been reduced we must attend to the tumor, hardnefs, and inflammation, which are to be treated with general remedies. Where these obstructions do not stand in our way, we may let blood, and attempt the reduction, provided the disorder is not of too long standing.

When symptoms of a deficiency of the synovia are observed, or the blood is inadequate to its secretion in the glands of the joints; we must not only put our patient upon a proper regimen, but also employ general remedies adapted to the complaint; such as gentle evacuations, moderate frictions to the diseased parts, baths with decoctions of emollient herbs, or alo emollient poultices, to which we may add a quantity of black soap. When, on the contrary, there is too great an abundance of synovia, particularly when the diseased parts are affected with pain and swelling, we must let blood, and before using diffusent poultices or baths, rub the diseased parts with warm flannel, and, at the same time, gently move the joint. But should this not be sufficient, we may mix stimulating herbs with the poultices, and add to the baths a quantity of lime-water, kitchen-felt, or sal ammoniac.

Distortion of the limbs is sometimes a congenital disease, which most frequently occurs in the foot. See VARI & VALEI.

ANC, in Greek Αντωνιόνες, anclet-elbowed, from αντς, a cowl, and οιιος, an elbow, a name given by Hippocrates to those who, from lifting the head of the ας lumern into the ατη, have an arm shorter and smaller than it ought to be, and the calf or tibia of a weak.; whereas they are called by some without, which fully expresses the Greek word, or barely anc. The disorder that gives occasion for the name, happens either in the womb, where the ας lumern suffers a luxation, from too much moisture; or in tender years by means of an object deeply seated about the head of the ας lumern. See DISLOCATION and LUXATION.

ANCIAIO in Geography, a small town of Portugal, in Betra, containing one parish, and about 1200 inhabitants.

ANCIAIUS, in Ancient Geography, a town of Greece in Ephesus, which was an episcopal see. It is thought to have been the same with the Oncheirvia of Plutarch.

ANCIENT, or ANTIENT, in its usual sense, denotes a thing which existed in times long ago; and thus it is opposed to modern.

We say ancient nations, ancient architecture, sculpture, philosophy, &c. ancient manners, ceremonies, poets, physicians, and the like.

ANCIENT, in Church Discipline. See ELDERS.

ANCIENT, in Ins of Court, imports a distinction of a certain degree. Thus, the society of Gray's Inn consists of benchers, ancients, barristers, and students under the bar: here the ancients are the elder barristers.

In the ins of chancery there are only ancients, and students, or clerks; and among the ancients one is yearly the principal, or treasurer. In the Middle Temple ancients are such as have gone through, or are past their reading.

ANCIENT is sometimes also used, in a military sense, for the colours, or ensign.

ANCIENT, or ANSEMT, in the Naval armament, a small flag or dreamer set upon the stern of a ship, or on a tent, similar to the guidon used at funerals, which was called an ensign.

ANCIENT demeque or domain, in Law, is a tenure, whereby all manors belonging to the crown in William the Conqueror's and St. Edward's time were held.

The number of names of all manors, after a survey made of them, were entered in a book called "Domedday Book," yet remaining in the Exchequer; so that such lands as by that book appeared to have belonged to the crown at that time, and are contained under the title "terra regis," are called ancient demeine. The tenants in ancient demeine are of two sorts: one who hold their lands freely by charter; the other by copy of court-roll, or by the verge, at the will of the lord, according to the custom of the manor. The advantages of this tenure are, 1. That tenants holding by charter cannot be rightfully impleaded out of their manor; and when they are, they may abate the writ by pleading the tenure. 2. They are free from toll for all things relating to their livelihood and husbandry; nor can be impammed on any inquest. These tenants held originally by ploughing the king's lands, plashing his hedges, and the like service, for the maintenance of his household; and it was on this account that such liberties were given them, for which they may
ANCILLA, in Entomology, a species of *Phalena*, of the Bombyx tribe. The wings are brown, with three transparent white spots on the anterior pair; abdomen yellow, with a black streak. Gmel. This is the same insect as Fabricius describes under the specific name *obscera*, *spec. inf.* and is likewise the Nocta *Ancilla* of Wien. Schmetterl. It inhabits Germany, according to Gmelin, and feeds on the lichen paricinum; Fabricius notes it in the cabinet of Dr. Allioni as a native of Italy. In some specimens the posterior wings are without spots; in others, yellow, with a brown margin and curved mark.

This species must not be confounded with the *Phalena Ancilla* of Cranmer, Pap. t. 149, which is an Indian insect, and the variety (v) of the Nocta *Fulonica* of Gmelin, and *Nocta Dioscorea* of Fabricius.

**ANCILLON, DAVID**, in Biography, a French Protestant divine, was born at Metz in 1617. In early life he applied to his studies with such diligence, that it was necessary, on some occasions, to restrain, what his biographer calls, the excess and intemperance of his studious disposition. From the age of 10 years he pursued his course of learning at the college of the Jesuits at Metz; and at this time many attempts were made by the directors of the institution to gain him over to their religion and party; but all their efforts were ineffectual. Having determined to devote his life to the profession of divinity, he removed in 1632 to Geneva; and, during a residence of seven or eight years in that place, he acquired an extensive and accurate knowledge of philology and theology. In 1641 he underwent an examination before the Synod of Charenton; and so far approved himself by the specimens which he exhibited of his talents, learning, and modesty, that he was appointed to the church of Meaux, which was one of the most considerable benefices then vacant among the reformed. Here he exercised his ministry with very great satisfaction both to himself and to those with whom he was connected for 12 years; and such was his reputation, that he was admired and esteemed by persons of all persuasions, both Catholic and Protestant. His popularity as a preacher recommended him to the attention of a wealthy person, who had one daughter, to whom he was affectionately attached, and he was induced by the respect which he entertained for him to declare to some of his friends, that if Ancillon would come and demand her of him in marriage, he would be happy in admitting him to an alliance in his family. In process of time a negociation commenced, and it terminated in 1649 in an union, which was the source of much domestic felicity. Four years after his marriage, Ancillon availed himself of a vacant benefice in his native city to remove thither. Here he uniformly maintained the same character, and purified his studies with unabating ardour. The fortune he had acquired by marriage enabled him to indulge his favourite propensity, which was that of the purchase of books; so that his library became both large and curious; and as it was one of the few private collections in France, it was visited as an object of curiosity by travellers who passed through Metz. Ancillon purchased the best editions of books, for which he gave these good reasons: that the left the eye was fatigued in reading a book, the more is the mind at liberty to judge of it; and that as the beauties and faults of a work are more clearly seen in print than in manuscript, so the fame beauties and faults are more clearly seen when it is printed on good paper and in a fair character, than when the paper and type are bad. Ancillon was no less indulgent in the use of the books which he read for amusement or for general information; and such others as were useful to him in his profession. The former he read but once, curiously, according to the Latin proverb, "suete canis ad Nilum bibere et fugiere," like the dog that drinks at the stream as it runs; the latter he read over several times with attention and care, and omitted no means of impressing their contents correctly upon his memory. He marked his books with a pen as he read them, and placed in the margin references to other authors. Ancillon, though he was uncommonly industrious in his pursuit of knowledge, did not allow his fondness for study to occasion a neglect of the duties of his profession; but in order to reconcile the one with the other, he addicted himself in too great a degree to a recluse and sedentary life; and he could never be prevailed upon more than three or four times to visit a country-house which he had near the city. He scarcely ever left his own habitation, unless to go to church, or to perform the functions of his office; but he never neglected the services of religion, nor disregarded the calls of humanity. He discharged all the important and useful duties of a Christian minister without ostentation, without ambition, and without avarice.

After having enjoyed the sweets of literary retirement for upwards of 40 years, and occupying the station of minister to the Protestant church at Metz, with great reputation and usefulness, for 22 years, Ancillon's repose was disturbed by the demon of persecution. Upon the revocation of the édit of Nantes, in 1685, this excellent person was reduced to the necessity of abandoning his library, his church, his friends, and his country, and of seeking refuge, through the phrenzy of religious bigotry, among strangers. He fled into Germany; and his library, a few books which he had concealed excepted, fell in small parcels, and for very inadequate payments, into the hands of the monks and clergy of Metz, and the adjacent towns. Thus deprived of the fruits of an attention bestowed on his collection of books for 44 years, and of the pleasure and benefit which he derived from them, he might well exclaim:

"Impius haec tam culta novalia miles habebat, Barbaras habebat."

VIRG. Eclog. 1. v. 71.

"Did we for these barbarians plant or sow?"

On these, on these our happy fields below?"

In the city of Hanau, Ancillon found an asylum; and here he had an opportunity of exercising his ministry, at the request of the French church, with great acceptance, till the jealousy of the other two ministers of the church, excited by his popularity, rendered his situation extremely uneasy, and induced him to withdraw from Hanau, and to retire to Frankfurt. With a view to the settlement of his family, he soon afterwards removed to Berlin, where he was favourably received by the elector of Brandenburg, and obtained the charge
charge of a French church. In this situation he remained, enjoying the comfort of seeing his children and other relations well established, and supporting the character, which he had maintained through life, of a learned scholar, an excellent minister, and in all respects a truly worthy man, till death finished his course in the year 1672. His literary works are few. In 1657 he published, at Sedan, in 4to. A Relation of the Controversy concerning Traditions, held between the Author and M. Bedacres, a Doctor of the Sorbonne." At Hanau he printed in 1666, "An Apology for Luther, Zuinglius, Calvin, and Beza." He also wrote, "The Life of William Farel, or the Idea of a faithful Minister of Christ," of which only a spurious copy was printed in Holland. Some of his learned conversations were published by his son in a miscellany, mentioned in the next article. Gen. Diet.

Ancillon, Charles, an advocate, the son of the subject of the last article, was born at Metz in 1629, and was a learned and zealous defender of the Protestant cause. After the revocation of the edict of Nantes, he was commissioned by the reformed at Metz to solicit at court an exemption in their favour; but he only succeeded in obtaining a mitigation of the treat of his persecuted brethren. At Berlin, whither he removed, he was appointed inspector of the tribunal of justice, instituted for the French in Prussia, historiographer to the king, and superintendent of the French school in this city he died in 1715, at the age of 56 years. He wrote, in French, "An History of the Establishment of the French Refugees in the States of Brandenburg," printed in 8vo. at Berlin, in 1690; "A critical Miscellany of Literature, collected from the Conversations of his father, Minister of Metz," 3 vols. 8vo. 1698; "The Life of Soliman II.," 4to. 1760; "A Treatise on Eu nuchs," 4to. 1767; "Memoirs of many literary Characters," 12mo. 1709. Gen. Diet.

Anci, in Geography, a town of France, in the department of the Higher Pyrenees, and chief place of a canton in the district of La Barthe de Neste, five leagues south-west of Bagneres.

Ancnabris, in the Religion of the ancients Romans, denoted a table in temples, wherein the priests cut their portion of the sacrifices and oblations.

Anclace, in Ancient Geography, a people placed by Ptolemy in Asia Minor.

Anci, in Geography, a town of Germany, in the Circle of Upper Saxony and duchy of Pomerania, situated on the river Peene, in a fertile country. On one side of it are swamps and meadows, with a fine dyke, a quarter of a German mile in length, and on the other deep moats and walls. It has two parishes, churches, and a good trade both by land and water, and has driven under the Prussian government. It is the capital of the circle to which it gives name, and the territory belonging to the town is near three German miles long, and contains 17 villages and two farms. It is eight leagues south of Gripswald, and 14 north west of Stettin. N. lat. 52°. E. long. 14° 9'.

Ancle, See Ancile.

Anclothe Point, in Geography, on the peninsula of California, coast of the North Pacific Ocean, lies in N. lat. 30°; and W. long. 116°, southward from the town of Vel i ceta, and north-east from the small island of Guadaloupe.

Ancobaritis, in Ancient Geography, a country of Melopotamia, known to Ptolemy, and placed by Strabo in Arabia Deserta.

Ancober, Ancobar, Cobere, or Gold River, in Geography, a river of Africa, which runs into the Atlantic, between the Gold Coast and the country of Axim. At its mouth is a good harbour. N. lat. 4° 48'. W. long. 40'.

Ancober, of Ancobar, a town and district of the Gold Coast, extending from north to south about 18 or 20 leagues along the river of this name. In this small kingdom there are women who never marry, but devote themselves, by certain ceremonies of an infamous kind, to public prostitution.

Ancocus Creek, in Geography, lies in New Jersey, being a water of the Delaware, six miles south-west from Burlington. It is navigable 56 miles, and considerable quantities of lumber are exported from it.

Ancoe, a small town of South America, three leagues from the city of Guanama.

Anc on, in Anatomy, denotes the curvature or flexure of the arm, wherein we rest in leaning.

This is otherwise called ulnacanum.

Anc on, in Architecture, is used to denote the corners or quoins of walls, crofs beams, or rafters.

Anc on is also used in the Ancient Architecture, to denote the two parts or branches of a square, which meet in an angle resembling the letter L.

Anc on is also used by Vitruvius, to denote a kind of mensa, or tables before doors, bent somewhat after the manner of vultures, so as to reemblce the letter S.

It flowers in May and June. 3. A. latifolium, (agrimonia decumbens of Linn. Suppl.) hairy A. "with fermen demerged, ducules pace-forum, spikes elongate, leaflets oblong, covered, and villo.so, and fruits armed on every side." The calyx closes as the seed ripens, and thickens into an orate globose, sub-stellated, white-tomentose bark, armed every way with short bristles, thickened outwardly, and having four recurved barbed little prickles. The seed single, ovate-globose, produced at top into a boss, smooth and pale; covered with a thin membranaceous skin, and on the outside of that with a coriaceous, hard, thick, integument, resembling a shell. Martyn's Miller.

Ancizan, in Geography, a town of France, in the department of the Higher Pyrenees, and chief place of a canton in the district of La Barthe de Neste, five leagues south-west of Bagneres.

Ancolnabris, in the Religion of the ancients Romans, denoted a table in temples, wherein the priests cut their portion of the sacrifices and oblations.

Anclace, in Ancient Geography, a people placed by Ptolemy in Asia Minor.

Anci, in Geography, a town of Germany, in the Circle of Upper Saxony and duchy of Pomerania, situated on the river Peene, in a fertile country. On one side of it are swamps and meadows, with a fine dyke, a quarter of a German mile in length, and on the other deep moats and walls. It has two parishes, churches, and a good trade both by land and water, and has driven under the Prussian government. It is the capital of the circle to which it gives name, and the territory belonging to the town is near three German miles long, and contains 17 villages and two farms. It is eight leagues south of Gripswald, and 14 north west of Stettin. N. lat. 52°. E. long. 14° 9'.

Ancle, See Ancile.

Anclothe Point, in Geography, on the peninsula of California, coast of the North Pacific Ocean, lies in N. lat. 30°; and W. long. 116°, southward from the town of Vel i ceta, and north-east from the small island of Guadaloupe.

Ancobaritis, in Ancient Geography, a country of Melopotamia, known to Ptolemy, and placed by Strabo in Arabia Deserta.

ANCRA

In this sense answer amount to the same with what the Greeks call wopbolw, protopside.

Ancor is particularly applied in the Ancient Architecture to the brackets, or shouldering-pieces, called consoles and corbels by the moderns.

Ancor was also used by the Carthaginians, to denote a dark pillar or dungeon. Strabo mentions one of this kind, in which Gelmer used to put all who displeased him; from which Bellerophon delivered many merchants of the call, whom the tyrant intended to put death.

Ancor is also applied to the angles or flexures of rivers: sometimes also to the tops of mountains.

Ancor, in Ancient Geography, a town of the Lucus-Syrians, in Cappadocia. M. d'Anville places it upon the Euxine Sea, between Amusius to the west, and the Promontorium Heracleum to the north-east.

Ancona, a town of Italy, in Picenium to the north, situate on a small island, which joins the promontory of Camerium to the continent. As Gray notes it is a small island, its name is probably deduced from its situation. Some lay that it was built by the Cynurians, from which they fled from the tyranny of Dionysius, towards the year 429 B.C., before Christ. It was famous for the beauty of its dyeing, and the purple of Ancona was only inferior in elegance to that of Aegina. It became a Roman colony probably about the war of Tarquin, about the year of Rome 455, when the consul P. Sempronius conquered the Picentines, and extended the boundaries of the Roman possessions as far as Aegina. The emperor Trajan constructed a good port, in commemoration of which a triumphant arch of fine veined marbel was erected on it. The mole, which fills makes a beautiful appearance. Ancona was insufficiently beseiged by the Goths under Totila, A.D. 551; but it was taken by Ariulf, king of the Lombards, and duke of Spoleto, in 592. In 839 it was taken and pillaged by the Saracens. It is now the capital of the country of the same name; a free port, with a convenient harbour, securer by a strong mole, which are generally mounted 8 or 10 guns; and its chief exports are grain, wool, and silk. It is the seat of a bishop, immediately under the pope. The Jews are very numerous in Ancona; however they live in a particular quarter of the town, and are obliged, by way of distinction, to wear a bit of red cloth in their hats. The exchange in Ancona has a beautiful front, and over the entrance an equellinarian statue; and within it is a lofty spacious apartment, in which, among other statues, are those of Faith, Hope, Charity, and Religion. The inhabitants of Ancona, says Keynes, (vol. iii. p. 289,) especially the female sex, so far excel those of the other parts of Italy, in shape and complexion, that they seem to be a different race of mankind. In the shallows near Monte Comoro, or Conaro, about 10 Italian miles from Ancona, there is a singular species of tesselous fish, calledballani, or ballari, which are found alive in large foms. The skin of this fish is thin, rough, and of an oblong figure, resembling a date; and hence they are called Dattili del Mare, or date-fishes. These ballari are laid within the mole, and come to perfection. In feeding for them, such fishes are selected as have the surface full of little holes, which indicate that these fishes have minguated themselves into them. When the fish in which the spawn has penetrated are taken, several of these fishes are found in them. Both the fish and its juice are so luminous in the dark, that one may see to feed by the light they afford; and even the water in which this fish has been squeezed, when put in a glass, emits an effulgence which lasts from eight to twelve hours. Great quantities of the ballari are brought to Rome, where they are reckoned "beccome di cardinale," or, dainties fit for a cardinal. Oysters are preferred here alive in sea-water for several years; but the oysters of Ancona, though large, are flabby and unpalatable. Here is also a kind of sea fowl fish, called nocchia, resembling our looher, but of a more delicate flavour. In the harbour of Ancona there is also a fish called the sepi, which has a long white shell on its head: these shells are often found along the shore, and, when pulverized, are used for cleaning plate. Ancona is 107 miles north-west of Rome. N. lat. 43° 37'. E. long. 13° 30'.

Ancona, Magnifico, a province of Italy, in the pope's territories. It is bounded on the north and east by the Adriatic, on the south by Umbria and Abruzzo Ultra, and on the west by the duchy of Urbino. The air is indifferent, but the soil is fertile, particularly in hemp and flax, and there is plenty of wax and honey. The province is about 22 leagues in length, and 16 in breadth; and along the coasts towers are erected, and furnished with cannon, in order to keep off the corsairs. The chief rivers are the Ruftele, Afpido, Tasto, Tono, Ragusia, and Tronto. The principal towns are Ancona, Acri, Camerino, Perno, Jef., Loreto, Macerata, Montello, Oliva, &c.

Anconus, or Anconius Marcellus, in Anatomy, arises tenuous from the back part of the external cowl of the ribs; it becomes fleshy, and terminates by a slight flexure attached to the outer and back part of the ulna. Its use is to afford in extending the forearm. Formerly all the extensor muscles of the elbow were called anconer, and that which now exclusively bears the title was the anconer quadratus, or minor.

Ancony, See Iron, Manufacture of.

Anchorarius, a town of Africa, in the Hither Mauritania. According to Pliny the wood which grew upon it had the smell of citron, and was called citrus.

Ancourt, Florent Carton D', in Biography, an eminent actor and comic writer, was born at Fontainebleau, in 1661, and educated at the Jesuits' college in Paris. Defined for the law, he became an advocate at the age of 17 years; but falling in love with an actress, whom he married in 1699, he then devoted himself to the stage as an actor; he excelled in the graver comic parts; and, as a dramatic writer, his particular line was humorous farce. He was distinguished by his exhibition of rustic characters; his dialogue, though filled with the jargon of the peafantry, was gay and lively, and abounded with smart fables; and his plots generally consisted of little incidents, contrived to ridicule the follies of the day. His pieces were popular, and attracted numerous auditors. His prose was much better than his verse. His company was much fought by the gay and great, and Louis XIV. was fond of him. In 1718 he quitted the theatre, and retired to an estate in Berry, where he employed himself in those religious duties, pertaining to his spiritual safety and welfare, with which, according to the maxims of the Roman Catholic religion, the profession of a player is incompatible. He died in 1726, and left two married dochughters. His works were printed in 1739, in nine volumes. A selection of the best of them has been published in three volumes. Gen. Dict.

Ancres, in Geography, a small town in France, in the province of Picardy, upon a small river of the same name, five leagues north-east of Amiens. N. lat. 46° 59'. E. long. 2° 45'.

Ancree, Ancrade, or Anchored, in Heraldry, is said of a cross whose extremities turn back like the flukes of an anchor, or terminate like the cross patonce, but in a sharper turn. Care must be taken not to mistake the cross ancre for the cross moline, which is of the same form, and by some of the old heralds called a cross ancre, or anchored.

Ancrina,
ANC

ANCRINA, in Ancient Geography, a town of Sicily, according to Ptolemy, at some distance from the sea coast.

ANCTERES, in the Ancient History, seem to have been the same, at least to have suffered the same fates as our Sutures.

Some also speak of a strong kind of fleshy platter under this denomination.

ANCETERIUMUS, in Medicine, the operation of applying a filula to close the two patent lips of wounds. This is also called by Latin writers, infilulatin.

ANCETERIUMUS is more particularly used to denote the passing a filula through the prepuse of the ancient flagellators and buccinators.

ANCUAH, in Geography, a town of the province of Alavahat, to the north of Egypt and of the Thebaid.

ANCUBITUS, among Ancient Physicians, denotes a disease of the eyes, wherein there is an appearance of sand, or little stones sprinkled on them.

This is otherwise called Petrification.

ANCUD, in Geography, an archipelago or cluster of islands in a part of the Pacific Ocean, between the coast of Ancud, that of Chili, and the island of Chiboe.

ANCUD is a name given to a coast of South America in the province of Chiboe, between the archipelago of Ancud to the west, the Andes to the east, the country of Olorn to the north, and the Terra Tagelliana to the south.

ANCUPOPOLIS, or the city of Anchors, in Ancient Geography, was one of the cities of the Hi-ranomus in Egypt, mentioned by Ptolemy, and so called from a neighbouring quarry, out of which those anchors were cut.

ANCUS, a name for such as have an arm bent crooked, so that they cannot extend it. See Ancer.

ANCUS MARTIUS, in Biography, the fourth king of Rome, was grandson of Numa Pomphilius by his daughter Pomphila and Marcus his relation, the son of that Marcus who perfused Numa to accept of the kingdom, and who afterwards killed himsel, because he was not chosen in his room.

His name Ancus was derived from the Greek word ανκος because he had a crooked arm, which he could not stretch out to its full length. He succeeded Tullus Hollius, according to the common computation, in the year before Christ 534. He began his reign by endeavouring to retain the religious ceremonies, which had been neglected in the time of his predecessor, to their former use, to revive husbandry, and to promote the arts of peace. Nevertheless his natural disposition was martial, and he gained various advantages for his country by his arms. The Latins gave him an early opportunity of exercising his military talents. Having violated the treaty which had been made with Tullus, by invading the Roman territories, Ancus declared war against them with all the religious solemnity enjoined by Numa, and took the field with an army consisting entirely of new-raised troops. After having taken several cities, he defeated them in a pitched battle, obliged them to sue for peace, and obtained a triumph at Rome for the advantages which he had gained. He also recovered Fidenae, which had revolted; defeated the Sabines, and obtained victories over the Veientes, for which a second triumph was decreed him by the senate.

During his reign Rome was greatly enlarged, by carrying the walls round the Aventine Hill, and including the hill Janiculum, which was on the other side of the Tiber, and which was now made a fort of citadel for Rome. A communication was also opened between this citadel and the city, by means of the bridge Sublicius, which Ancus erected over the Tiber, and that part of the river which washes the foot of the Aventine Hill. He also built a large prison in the Roman forum. Ancus likewise extended the territories of Rome as far as the sea, and established the port and city of Ostia, in order to secure to his subjects the advantage of trade. About this time he caused many salt-pits to be dug, and distributed salt among the more indigent classes of his subjects. He rebuilt the temple of Jupiter Feretrius in a very magnificent manner; and having spent the latter years of his reign in improving the city, and enriching its inhabitants, he died, after a prosperous reign of 24 years. Livy, lib. i. c. 35. 38.; t. i. p. 134—144. Dion, Hal. lib. iii. t. i. p. 170; &c. ed. Oxon.

ANCY, in Geography, a small town of South America, three leagues from the city of Guaramanga.

ANCY LE DUC, a town of France, in the department of the Saone and Loire, one league north of Marcigny les Nonains.

ANCY LE FRANC, or Encre, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Tonnerre, eight leagues east of Auxerre, and three south-east of Tonnerre.

ANCY LE, in Antiquity, denotes a small kind of brazen shield, supposed to be the shield of Mars, and said to have fallen from heaven into the hands of Numa Pomphilius, at the same time that a voice was heard, that Rome should be mistress of the world while the preferred that shield. Though there was but one ancle that fell from heaven, yet there were twelve preferred; Numa, by the advice, as it is said, of the nymph Egeria, having ordered eleven others, perfectly like the first, to be made by Victorius Mamurris, so that if any should attempt to deal it, as Ulysses did the Palladium, they might not be able to distinguish the true ancle from the false ones. These ancylia were preferred in the temple of Mars; and were committed to the care of 12 priests or fali, instituted for that purpose. They were carried every year, in the month of March, in procession all round Rome; and the 30th day of that month they were again deposited in their place.

ANCY LE, le Anchylosisin.

ANCYLOBLEPHARON, or Anchylolophus, (from ἀνκυλό-, ὄξος, and ἵππος, palpebra) in Surgery, an adhesion of the eye- lids. This may either be a natural or a congenital defect, or it may be produced by accidents, such as burns, violent inflammations, and ulcers. The eye-lids may either adhere to each other only, or they may adhere to the eye-ball itself; and sometimes both kinds of adhesions are present together.

There are properly three degrees of this disease. The first is, when the eye-lids are only glued together by means of pus or thick mucus, as happens in many inflammations of the eye, particularly in the suppurating inflammation, whilst the patient is asleep; also in the small-pox, when the eye-lids have been kept close for several days in consequence of the general swelling of the face; in such cases, therefore, it is also termed the purulent species of the disease. The second degree is when the edges of the eye-lids not only adhere together, but are even connected by means of a cicatrix. The third degree is where the eye-lids have also formed an adhesion with the conjunctival coat, or the ball of the eye. This third degree is also particularly termed symblepharon. These two last degrees are accounted the genuine species of the disease.

In the first degree, when the eye-lids are glued together by a purulent or tough mucous matter, we must employ emollient applications. The eye-lids should be moistened with a lukewarm mixture of milk and water, or with an infusion of rad. aloes, or with an emollient decoction, applied upon a piece of linen, till they spontaneously separate from each other. We may also rub them gently with an ointment consisting of fyr, papav. ol. amygd, and camphor, and after-wards
wards apply an emollient poultice of lb. glbr. f. m. linu and milk. Should these remedies not produce the desired effect, we may cautiously introduce a probe with a knife between the eye-lids, and thereby prevent the adhesion.

In the second degree the edges of the eye-lids either adhere together at all points from some cause to the other, so as to form a perfect concretion, or they are only more or less connected together at one or the other angle of the eye. In the first case, the patient is entirely deprived of sight; in the second he can see by turning the ball of his eyelids sideways, so that if the disease be not speedily removed, squinting may easily be the consequence. The method of cure in this disease is to separate the eye-lids from each other by means of an incision.

In this operation the surgeon must use great caution in directing his instrument, so as to avoid the ball of the eye, and prevent its injuring the eye-lid in such a manner as to lay bare the tarsus, the consequence of which might be a very troublesome ulceration. This may be accomplished without difficulty, when the eye-lids do not entirely adhere together, but are still separate at some point; for example, when there still remains an opening at the internal canthus. Some use for this purpose a small grooved probe, which they introduce between the eye-lids, and then carry along the groove a thin and somewhat crooked-bladed knife, or a small pair of scissors, or a lancet. But in preference to the probe we may use, as a more convenient and safe instrument, a small knife, with a straight back, but somewhat curved at the edge, and terminating at the point in a very small probe with a knob, about two lines in length.

For performing the operation the patient is placed upon a chair, in a convenient posture; an anesthetic fees the head, and, at the same time, draws the superior eye-lid upwards, whilst the surgeon draws the inferior downwards with two fingers, or else draws it with a small forceps downwards, and, at the same time, off from the eye. Sometimes the surgeon himself may stretch both eye-lids from each other with the fingers of one of his hands.

With the other hand he introduces the scalpel above-mentioned under the eye-lids, in such a manner, that the back is directed towards the ball of the eye, and the edge to the place where the preternatural adhesion is situated; that is, to the interval between the two edges of the eye-lids, or between both rows of eye-lashes, which frequently remain uninjured by the disease, pushes it forwards, and thus divides the preternatural adhesion. In case of necessity he may also use a small pair of eye-scissors, though this instrument is not so safe and convenient as the blunt-pointed scalpel.

When the eye-lids are entirely closed they must first be opened at some external point, by drawing out the skin into a crook fold, and introducing a lancet into it, so as to form an aperture through which a scalpel or probe may be introduced; which being done, the rest of the operation is performed after the manner already described. But left the ball of the eye might be injured, the first aperture should be made with caution, and always either at the inner or outer canthus of the eye, for fear of wounding the transparent cornea, which might thereby be rendered opaque. The safest method of proceeding will therefore be to draw at the same time the eye-lids from each other. This incision, however, but seldom becomes necessary; for even in a complete adhesion an opening may always be perceived at the inner canthus of the eye, through which a scalpel or probe may be introduced. When the puncta lacrymalis are likewise obstructed, a species of fistula lacrymalis remains after the operation, unless the puncta can be opened. See Fistula Lacrymalis.

When the divison of the preternatural adhesion has been performed, we should apply to the eye a piece of very fine soft linen spread with Gumul's tincture, or some other cooling ointment; and after the first dressing we should daily rub between the eye-lids a quantity of ointment made with fresh butter and flor. vini. or fulva, either with or without half a Peruv. or else some buttermilk ointment. The patient should likewise repeatedly open and move his eye-lids during the day; and in the first night after the operation he should let himself be frequently awakened, in order to prevent the formation of a new adhesion. In this, as in all other operations on the eye, we should do all that is in our power to prevent inflammation, and to relieve any that may have taken place.

But, before we operate upon a complete adhesion, we should carefully examine whether the ball of the eye be perfectly found, and whether the eye-lids have not formed adhesions with the ball of the eye also; which may happen in cases of burns, or when quicklime has fallen into the eye, in which cases not only the edges of the eye-lids, but the ball of the eye itself is generally injured, and the cornea rendered entirely opaque. For when the cornea is entirely opaque, and the eye-lids adhere not only with each other, but also with the ball of the eye; when the patient perceives no sensation of light, while a candle is held close to his eye in a dark room, and in general cannot distinguish light from darkness; when the eye-ball is felt under the eye-lids small and collapsed; and when from the cornea, by which the disease has been occasioned, there is reason to suspect that the cornea has been rendered opaque—the patient's sight cannot be restored by an operation, which consequently will be superfluous. We may conclude that the eye-lid adheres to the ball, and that an operation will consequently be difficult, if not impracticable, when the eye-lid cannot be moved backwards and forwards upon the ball, or when we feel that the patient cannot move the ball of his eye, or when, in moving it, the eye-lid contracts itself into wrinkles. However, when the eye-lid does not adhere throughout, but only at particular points, and not on the cornea, to the ball, it is worth our while to attempt the operation, for which purpose we must first draw the eye-lid under, and then separate the adhering lid from the ball.

In the third degree, which consists in a preternatural adhesion of the eye-lids with the ball of the eye, there sometimes also exists an adhesion of the edges of the eye-lids with each other; in many cases, however, the adhesion subsists only between the eye-lids and the ball, forming what is termed Symblepharon. Of such adhesions several varieties are observed; they are sometimes firm, or bloody; at others, loose or membranous. Either the whole surface, or a single part of one or the other eye-lid adheres to the ball. In the first case, which is very rare, the patient is altogether unable to open his eye; in the second he can only open his eye-lids partially, and fee when he turns the ball of the eye to the aperture; in which case he may easily become subject to Strabismus by habit. The adhesion of the upper eye-lid occurs far more frequently than that of the lower.

The separation of the preternaturally united parts can here be performed only by the knife. A small crooked knife, formed like a probe, at the point, has been proposed for this purpose. In performing this operation, we must take care that we may not injure either the eye-lid or the ball of the eye, which it is the more difficult to avoid, as we frequently cannot see how we carry the knife, on account of the hemorrhage. By pricking the ball of the eye with the blade of our instrument backwards from the eye-lid, and at the same time drawing, or letting an anesthetic knife draw the eye-lid forwards from the ball, we may in many cases not only perform a part of the separation without cutting; but also, if in action
tion should be necessary, we may use our instrument with greater safety, and without injuring any of the parts. With this view Mr. Kaltschmidt has recommended to use a small lancet in such a manner, that its surface lies firm upon the surface of the eye, the edge being steadily directed against the fibres which form the adhesion, so as to divide them more by pressure than by moving the lancet to and fro. Moreover, we ought, in performing this operation, to be particularly cautious not to injure the inner surface of the eye-lid, it being better to cut away a part of the conjunctiva of the eye, than to injure the eye-lid itself. But when the eye-lid adheres to the cornea we must spare the latter, and press the knife more upon the eye-lid. For performing this operation a steady and experienced hand is particularly necessary.

This operation, however, is always very difficult, and will it be attended with no benefit when the cicatrisation is firm and fibrous, and when the eye-lid adheres closely to the ball. Neither will it be productive of any benefit when the eye-lid, though adhering only at one point, is connected with the cornea, and the adhesion is of a mucular nature; so that it is highly probable the cornea will be rendered opaque, unless we can hope afterwards to restore its transparency. In this case, however, as in every case where the adhesion is mucular and cicatrisated, it is very difficult to prevent the parts from forming new adhesions with each other. It is, therefore, only in those cases where the adhesion is loose and membraneous, and only a small part of the ball connected with the eye-lid, and that at the side, that the operation can be performed with facility, and with a fair hope of a fortunate event; though even here it is often very difficult to prevent a new adhesion from taking place. When the adhesion is very loose, we may frequently dispense with cutting instruments, and effect the separation by means of a small blunt knife, shaped like a spatula.

In order to prevent the formation of a new adhesion, after the operation, some introduce into the eye, others a piece of linen or fine leather, in the form of a crescent, others a thin, smooth plate of ivory, lead, or horn, shaped so as to correspond with the form of the eye, or only a thin, flat piece of wax. All these foreign substances, however, when introduced between the ball and lid of the eye, irritate, press, and inflame the eye; neither do they keep their situation. It is therefore better to direct the patient frequently to roll the ball of his eye, and not to sleep too long at a time; and when the haemorrhage has ceased, frequently to introduce upon the inner surface of the eye, with a hair pencil, a little cream, oil of almonds, fatumine or tawty-ointment; or to drop, into the space, between the lid and the ball, some gently astringent and drying collyrium. We may also (as Heister advises) introduce repeatedately towards the termination of the cure a blunt probe between the lid and ball of the eye, and move it gently backwards and forwards; but this must be done with the utmost caution. Any remaining opacity of the cornea must be treated with the proper remedies.

The method of treatment, practised by Fabricius Hildanus (Obsev. Centur. v. Obf. 7.) might also in some cafes be attempted. His method was gently to introduce a crooked probe at the inner angle of the eye, under the upper eye-lid, between the lid and ball of the eye, till its point projected out of the outer canthus. He then fastened a fine silk thread to the point of the probe, and introduced the probe again in the same manner as before; the ends of the thread he tied together under the eye, and fastened a small lump of lead to them. During the day time the lead was suffered to hang to the thread, but it was taken off when the patient went to bed. By means of this thread, and the weight suspended to it, the adhesion was separated in the space of nine days, the eyelid and ball of the eye completely recovered their motion, and nothing of the dis ease remained behind except a small speck upon the cornea.

ANC夷LOGOSSUM, or ANCYLOGLOSSUM, in Surgery, (from Gr. an, to scrape, and klyxos, a tongue) An cyclyon, and adhesion of the tongue, or the being tongue-tid. This term is applied to that mol formation of the parts, in which the frenulum of the tongue confines its apex too much, and impedes its motion, either by its being continued too far forwards towards the extremity of the tongue, or by its being too short, confounded in its perpendicular direction. Both these defects are generally natural ones, and are therefore most commonly observed in new-born infants. However, in adults, the frenulum may sometimes be shortened, and the motion of the tongue impeded in consequence of a wound, ulcer, &c. We discover the existence of this defect, when we find that we cannot introduce the finger under the tongue, and raise it up; when the infant neither sucks the finger, when it is introduced into its mouth, nor the nipple of the mother; when the child, after it has begun to speak, cannot properly pronounce the letters which are principally articulated with the apex of the tongue, namely, ï, ï, r, (a very complete adhesion of the tongue, whether by means of the frenulum, or any other preternatural connecting subnance, may even occasion complete dumbness); and when the apex of the tongue cannot be drawn forwards, beyond the teeth, to the gums or lips.

The cure of this defect consists in the operation of dividing the frenulum, which, however, is very frequently performed without necessity, and to the very great detriment of the infant. (Fabricius ab Aquapendente) Chirurg. Operat. cap. xxxvi.) advised, that among a 100,000 children that were born, scarce one actually required this operation. See also Jourdan on the dices of the Mouth, vol. ii. p. 594. and 622.) For only in that very rare case, in which the infant is unable to suck, in consequence of the immobility of the tongue, are we authorized and obliged to perform the operation. Should even the frenulum be something too short, and the apex of the tongue not sufficiently moveable, so that there is cause to apprehend that the child, when he learn to speak, will not be able properly to articulate the lingual letters, we ought, provided he be not prevented from sucking by that defect, to defer the operation to a future period, for it is unnecessary to perform it at present; and should it afterwards become necessary, for the purpose of enabling the child to articulate his words properly, it may then be performed with greater facility, safety, and accuracy; besides, that the frenulum often becomes spontaneously elongated, and sufficiently extended in consequence of the mere inotion of the tongue. As there are various other causes, which may be impediments to the infant in sucking, we must not always look for the fault in the state of the frenulum. Nay, though we should even find the tongue actually moveable in an infant that either cannot or will not suck, we are not authorized immediately to suppose that the defect of the frenulum is the cause of it, and so undertake the operation without further examination. For we sometimes find that preternatural membranes and ligaments, which proceed from the lateral edges of the tongue, and connect it with the gums, were the cause of the impeded motion of the tongue; and that, after these have been divided, the infant is able to suck. In new-born infants the tongue sometimes adheres so strongly to the gums, by means of a viscid mucus, that...
that the patient cannot suck, may, if early, draw breath; this
may also be easily removed by means of a spatula.

In performing the operation, we have principally to take
care to make the incision into the frenulum of the proper
length; for if it make it too long, that is too far on to-
wards the root of the tongue, the tongue becomes too
movable, and another defect, of which we shall treat here-
after, is produced; whilst, if we do not make it long
enough, the tongue does not acquire sufficient mobility, and
the intention of the operation is not completely answered.
However, it is always better rather to make the incision too
short than too long, as in the former case the operation may
be repeated, and the division made longer, whilst, in the lat-
ter, the fault cannot be remedied. Moreover, we ought al-
ways to make the incision as much as possible in the middle,
between the tongue and the subjacent soft parts, and avoid
the blood-vessels, nerves, and salivary ducts.

When it is determined to perform the operation, we pro-
ceed in the following manner: The patient being properly
secured, and his mouth opened, we introduce the common
mouth-spatula under the apex of the tongue, in such a man-
er that the frenulum lies in the flat of the spatula. Instead
of this spatula we may also use a grooved probe, with a flat
and flat handle. Some recommend, instead of the spatula,
to use a small two-pronged fork, with knobs at the points.
With one or other of these instruments, which we hold in
the left hand, we raise the apex as much as possible, and
stretch the frenulum. This manoeuvre, as well as the reef
of the operation, may be facilitated by applying external
pressure under and behind the chin, by which means the
soft parts under the tongue are elevated. We then divide
the frenulum with a round-pointed pair of scissors, which we
hold in our right hand. The crying of the child greatly fac-
itates the operation; in performing which we may also
compel his nostrils, which will compel him to keep his
mouth open.

Various other complicated instruments have been propos-
ed for performing this operation, but they may all be dispensed
with, as none of them have any advantage over the more simple
ones, the spatula, and scissors; indeed we have often performed
the operation with no other instrument than the scissors.
When the frenulum has been properly divided, there is seldom
any necessity for employing any peculiar treatment; it may,
however, be useful, during the first period after the opera-
tion, to draw a linen rag, neatly spread with fine-powdered
fogar or honey, several times a day under the tongue, in or-
der to prevent the formation of a new adhesion. Sometimes
also it happens, especially when the frenulum is uncommonly
fibrous, or has been divided too far back, that a haemorrhage
follows, which, though not usually a matter of grave conse-
quency, may frequently be rendered dangerous, nay, even fatal in consequence of the
flocking ensuing in new-born infants, upon awakening, when
the breast is not soon given them. This accident may be
prevented by attending to the infant for the first twenty-
four hours after the operation, and as soon as it awakes,
taking it up, and laying it to the breast till it falls again
asleep. But there is still greater cause to apprehend a dan-
gerous haemorrhage, when, through want of the proper cau-
tion, any considerable blood-reflux under the tongue has
been injudiciously drowned with strong astrigent remedies, as vinegar, wine, vinegar, spirit, vin-
reli, Theden’s aq. vinos. etc., which may all be employed
in this case, being and laid under the tongue; or with blue
vitriol, or agate, pressure being at the same time applied.
In order to prevent the fatal haemorrhage, which might af-
terwards supervene, it is necessary that the child should be
attended to during the first days after the operation, that we
may see whether it moves its lips or appears to suck or
swallow anything; and when it does so, we must im-
mediately examine whether any blood is discharges, in order
that we may be able immediately to stop the haemorrhage.
We have known a very troublesome excrescence arise under
the tongue of an infant, after it had been cut too deeply by
an officious nurse.

The frenulum may also, in some cases, possess too great
a facility of motion; namely, when, by a fault of the or-
iginal conformation it is too long in its perpendicular di-
rection, or when it does not extend far enough from the root
of the apex of the tongue. This fault is not to be dis-
covered till the child begins to speak. Little or nothing
can be done to remedy it, though it sometimes spontaneously
sublimes as the child grows older. A similar defect is pro-
duced when the frenulum has been divided without necessity,
or when, in performing the operation from proper indica-
tions, the incision has been made too long. When either this
or the preceding defect is present in a high degree, it some-
times happens that the infant, or which is in the habit of suck-
ing as soon as it awakes, sucks down the apex of its tongue,
and is suffocated. If we discover the accident in time, and
extract the tongue with one finger, the infant immediately
recovers; it will, however, be necessary that we should pre-
vent the recurrence of a similar accident. Thus we may do
by two different means. As soon as the infant awakes, and
begins to suck, we must either let it have the breast imme-
diately, or we must put a finger or some other substance into
its mouth till the breath can be given it. When it has been
weaned it gradually looses the habit of sucking its tongue,
and then there is no more danger to be apprehended. When
circumstances do not admit of such attention being paid to
the infant, or when the child, after it has been weaned,
still retains the habit of sucking its tongue, we may prevent
the tongue from being drawn down into the throat, by applying
an ivory stick between the jaws of the child, which is to be bal-
ced behind the neck and under the chin with strings. With
adults whose frenulum is either too loose, or does not extend
far enough towards the tip of the tongue, we may employ
the tongue-handage of M. Petit or Pibrae, of which we shall
take notice under the article Wounds of the Tongue.

Finally, by frequent and forcible suction of the retro-
verted tip of the tongue, adults may sometimes stretch, elon-
gate, and relax their frenulum, which before was quite per-
fected, in such a manner as to produce all the defects above-
mentioned.

Instead of a frenulum we sometimes find, in infants, a
flacile excrescence under the apex of the tongue, which fre-
cently is so large as to prevent both suction and deglutition,
and can only be removed by excision. In this operation we
have chiefly to apprehend the haemorrhage, which sometimes
is so profuse as to occasion the death of the patient. As the
remedies abovementioned are not applicable in such cases, we
ought to employ the actual cautery, or sometimes we may
succeed with compression. It might, perhaps, be advisable
to cut out, at first, only a part of the excrescence, so as to
enable the patient to suck and swallow; after which, as he
gets older, the rest of it may be extirpated with greater
care and safety, if it produce any inconvenience. Both in
children and adults, fiction, deglutition, speech, and mal-
ition are sometimes attended by painful excrescences on the
frenulum, which ought to be removed by cutting, tying, or
cauting. Ulcers, ulcers, and encysted tumours, which are
frequently found on the frenulum, must be treated in the
same manner as when situated in other parts of the body.

Vide Chr. Car. Lang. Diff. de frenulo linguae, epit. in-
Schweigbauer
ANCYRA, now called by the Turks Ancoreti, in Ancient Geography, a city of Asia Minor, and formerly the capital of Galatia, situated near the small lake Czamas, and not far from the river Halys, and belonging to the Techofagi. Panemnias (Attic, c. iv. p. 12.) intimates that it was founded by Midas, and that it derived its name from an anchor which was found there, and which was preferred in the temple of Jupiter. It was afterwards greatly enlarged and adorned by Agustus, who, on this account, might be deemed the founder of it. In the time of Nero this noble city received the title of the metropolis of Galatia, and it is still populous. Its inhabitants, according to Suidas, were denominated Hellenogalates, or Græco-Galli. See Ancora.

ANCYRA, Ancyra Abydilis of Strabo, a town of Phrygia, mentioned by Pliny (l. v. c. ult.) and confounded by Steph. Byz. with the Ancyra of Gallo-Greece of the preceding article.

ANCYRE, a town of Sicily, mentioned by Diodorus Siculus, lib. xiv. c. 49.

ANCYREUM, a promontory of Asia Minor, noticed by Dionysius Periegetas, as situated where the Euxine Sea terminates, and where the Bosphorus commenced.

ANCYROIDES, ἀνκυροῖδης, is used by some writers in Anatomy for the procfs or shooting forth of the shoulderbone, in form of a hook; otherwise called coracoides.

ANCZAKRISH, in Geography, a river of Podolia, which discharges itself into the Black Sea, near Oczakow.

ANDA, in Botany, is a tree of Brazil, found, according to Pison (Hist. Nat. Raccen.), in the forests, at a small distance from the sea-coast; the wood of which is finegrained and light; the leaf long, fibrous, and pointed; the flower large and yellow; and the fruit a grey nut, which mingles under a double rind, two kernels of the taste of chestnuts. The fruit is said to be purgative, and a little emetic; two or three of the kernels are a dose. The Indians extract oil by expression from these kernels, with which the natives anoint their limbs. The rings of the fruit are esteemed proper to stop a looseness; thrown into ponds they kill the fish.

ANDA, in Ancient Geography, a town of Africa, according to Appian.

ANARBAT, in Antiquity, a kind of gladiators, who fought hand-winded; having a sort of helmet that covered the eyes and even the face. They were called anabataras, quivi anabataras, oftenas, because they fought mounted on horseback, or out of chariots. Others derive the word from an, against, and bas, I go.

Some say, the anabataras fought in the dark, or late at night, after the cirensia were over. There were two men in the chariot, viz. the driver, or auriga, and the anabataras, who was also called anabataras, q. d. adfensuros, or mounted; whence by corruption the Latins formed the anabatara.

It has been disputed among critics whether the anabataras were a people who actually fought blindfold in their wars, or a set of combatants who only practised this method of fighting for the sake of appearance.

ANDABATIS, in Ancient Geography, a town of Cappadocia, according to Antonine.

ANDACA, a town of India, which surrendered to Alexander, but its situation is unknown.

ANDAGUAYLAS, in Geography, a jurisdiction of the empire of Peru, in South America, subject to the archbishop of Lima; situated east by south of the city of Chimuques, extending between two branches of the Cordillera above 20 miles, and watered by several small rivers. It abounds in sugar plantations, grain of most sorts, and fruits. This province is one of the most populous in these parts; and its climate is partly hot, and partly temperate.

ANDAGYRA, or Andegi, a district of the island of Samtara, with a populous town of the same name, situated on a river commodious for trade; the chief article with which this district abounds is pepper.

ANDAJA, a river of Spain, in Old Castile, which joins the Duero.

ANDALUSIA, a province of Spain, which formerly comprehended the kingdom of Granada, then called Upper Andalusia; but the name is now appropriated to Lower Andalusia, which is the most weftly province of the southern part of Spain. It is separated, on the north, from Elframadura and New Castile by the Sierra Morena Mountains; on the east, from Portugal by the river Chagan, and on the west, from Algarve by the Guadiana; on the south, it has the ocean, the Straits of Gibraltar, and part of the Mediterranean; and along the south-east it has the kingdom of Granada. Its utmost length from Ubeda to Ayamonte, is ninety leagues, and its breadth about fifty. Its chief cities and towns are Seville, the capital, Baeza, Carthage, Corduba, Cadiz, Medina Sidonia, Jerez; Port St. Mary, &c. Its principal rivers are, the Guadalquivir, Xerila, Odor, or Odilo, Guadalate, and Tinto, or Azeeche. Andalusia is reckoned the richest and most fertile province of Spain; abounding in exquisite fruits of all kinds, honey, excellent wine, grain, silk, sugar, fine oil, numerous herds of cattle, particularly horses, metals, timmer, and a species of quicksilver. The air, though warm, is refreshed by cool breezes, and the great extent of sea coast is favourable to commerce. The wool of Andalusia, says Keyler, (Travels, vol. iii. p. 22.) is known to surpass all others; though the flocks on which it grows were originally natives of England. The name of Andalusia is applied by the Arabs not only to the modern province, but to the whole peninsula of Spain. Some have derived the name from Vandali, the country of the Vandals; but the Vandali of Carthage, which signifies in Arabic the region of the evening, or of the west, or the Hesperia of the Greeks, is perfectly apposite. Gibbon's Hist. vol. ix. p. 467.

ANDALUSIA NEW, a district of South America, in the eastern part of the province of Terra Firme, situated on the coast of the Atlantic, opposite to the Leeward Islands. The boundaries of this territory are indefinite, as the Spaniards pretend a right to countries in which they have never established any settlements. If the districts of Camana and Paria are included, it extends, according to the most reasonable limits, 500 miles from north to south, and about 270 from east to west. The interior country is woody and mountainous, variegated with fine valleys that yield corn and pasture. The produce of the country consists chiefly in dyeing drugs, gums, medicinal roots, Brazil wood, sugar, tobacco, and some valuable timber; to which may be added pearls, for which the Spaniards used to fish along this coast to Carthagena. The capital of Andalusia is Camana, Cu.
ANDANIS, a river of Carmania, so called by Ptolemy and Pliny, but denominated by Arrian, Anamis.

ANDANTE, in Muffe, from andante, lat. to walk, &c., neither to run nor to creep, but the medium between both those motions. Andante, the diminutive of andante, is applied to movements somewhat quicker, and bounding on allegretto, or rather grazioso.

ANDARAE, a people of India, on the other side of the Ganges, who turned, according to Pliny, a very powerful nation. Hardouin is of opinion, that the country which Pliny meant to describe was the kingdom of Pegu.

ANDARAX, in Geography, a town of Spain, in the country of Granada, six miles north-west of Ayna.

ANDARIA, in Ancient Geography, a town placed by Antonine in Dalmatia.

ANDARGE, in Geography, a river of France, which rages in the valleys of Oudon, and joins the Arvon near Venecul.

ANDARIACA, a town of Asia Minor, which was situated, according to Ptolemy, in Lyca.

ANDARIINI, a pulse of indiscriminately reduced into the grains, like amaranth.

ANDARISTUS, in Ancient Geography, a town of Europe, in Macedonia. Ptolemy refers it to the Naxaccas.

ANDAROS, in Geography, lies on the western coast of the peninsula of India. N. lat. 10°. and E. long. 73° 35' 35.

ANDASTES, an Indian nation, in Canada.

ANDATE, in Mythology, the goddess of Victory, was one of the principal deities of the ancient Britons; she had a famous temple at Cambodunum.

ANDATIS, in Ancient Geography, a town of Ethiopia, on the banks of the Nile, according to Pliny.

ANDAUTONIAM, a town of Higher Pannonia, upon the river Savus, north-call of Sicilia.

ANDAYE, in Geography, a sea-port town of France, in the department of the Lower Pyrenees, near the mouth of the Bidassos, on the borders of Spain, with strong fortifications, and a good trade; five miles south-west of St. Jean de Luz. N. lat. 43° 25', W. long. 1° 45'.

ANDEAH, a town of Hindostan, in the precinct of Bilhar, 30 miles east-north-east of Dilloh, and 120 south of Agra.

ANDECRUIUM, or ANDERUM, in Ancient Geography, a town of Dalmatia.

ANDEB, or ANTEAR, in Geography, a town of Turkey in Asia, in the government of Aleppo, situated on the road that leads from Aleppo to Erzerum, near the river Seckhard, in a valley that abounds with vines, various kinds of fruits and apples of a large size. This was anciently Antiocha ad Taurus.

ANDEGAN, the capital of Fergana, one of the provinces of great Bucharia.

ANDEGAVI. See ANDES.

ANDEIRA, in Ancient Geography, a town of Asia Minor, in the Thracian Cilicia, at some distance to the north of the small river Scillus. Near this town there was a chapel consecrated to the mother of the gods, and a subterraneous groto, which extended as far as Psicca.

ANDEL, in Geography, a town of France, in the department of the northern coast, and chief place of a canton, in the district of Lamballe, seven miles east of St. Brieuc.

ANDELANGA, in Middle Age Writers, occurs as part of the formula of divers donations.

In this case we meet with donare per andelangam et felicem, vendere & tradere per andelangam, &c. Some will have the term properly to denote what we call an andiron;
AND

iron, &c.; others a long staff, or rod, which it is known was much used in the act of putting into possession.

The word is sometimes also written andelangus, andelage, andelhage, or andelague, &c.

**ANDELINGEN** or ANDELINGEN, in Geography, a town of Switzerland, in the canton of Zurich; seated on an eminence in a vantage of the same name, and near the river Thur; 17 miles north-north-east of Zurich.

**ANDERLECH**; a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Chaumont, on the river Rougon; 16 miles north-north-east of Chaumont.

**ANDELSCH**; a river of Germany, which runs into the Danube, near Schier.

**ANDELUS**, in Ancient Geography, a town of Spain, placed by Ptolemy among the Pyrenees.

**ANDELY**, in Geography, a town of France, and principal place of a district, in the department of Eure. It is divided into two by a paved causeway; one of the parts is called Le Grand Andely, and the other Le Petit Andely; the one is upon the Seine, the other upon the river Gambon. It is 20 miles south-east of Rouen. N. lat. 49° 15'. E. long. 1° 14'.

**ANDEA**, in Ancient Writers, denotes a swath in mowing. The word is likewise used to signify as much ground as a man can plough over at once.

**ANDEAS**, in Geography, a small island of Norway, in the North Sea, with a town of the same name. N. lat. 69° 30'. E. long. 14° 54'.

**ANDEOL**; or **ANDOL**, a small town of France, in the Vivarais, at the junction of the Ardeche with the Rhone. It is four leagues from Viviers. N. lat. 44° 24'. E. long. 29° 50'.

**ANDERA**, a beautiful village of Egypt, on the Nile, in which are found several monuments that indicate its former grandeur.

**ANDERAB**, the chief city of the province of Tokara, in Great B Hawaii, situated near a pass through the mountains of Hindoosh Koh, which separate India and Persia from Bucharia, andpossessed by the Ubeck Tartars. As there is no other way of crossing the mountains towards India with beasts of carriage, except through this city, all travellers and goods from Bucharia are obliged to pay four per cent. On this account the khan of Balk maintains a considerable number of soldiers in this place, which is otherwise of no great strength. Andarab, though small, is very rich and populous. The neighbouring mountains yield quarries of lapis lazuli, which furnish a considerable trade between the Buchari and Persia and India.

**ANDER-ESCH**; a town of the duchy of Luxemburg, two leagues and a half south of Luxemburg.

**ANDERITUM**, or **ANDERIUM**, in Ancient Geography, afterwards called Gabala, the capital of the Gabala, in Aquitania Prima. It was an episcopal see; but the city was ruined by an incursion of the Alamanis, and the see was transferred to Mende.

**ANDERLECH**, in Geography, a town of Brabant, three miles south-west from Brussels.

**ANDERNACH**, a town of Germany, in the circle of the Lower Rhine; in the archbishopric of Cologne, and in a prefecture of the same name. It was anciently called Antoniacum, Antonacum, and Antonacensium, and was a free imperial city. In the year 1496 it was by force of arms rendered municipal by the elector of Cologne, to whom it now belongs. It is seated on the Rhine, and a toll is levied on travellers for the support of its walls. Its trade, for which it is advantageously situated, consists principally of stone ware, tiles, timber, and the forlorn, a stone used in constructing dykes, which are conveyed to Holland by the Rhine. It is also remarkable on account of the large rafts which are here built upon the borders of the Rhine, the smaller ones being brought down the rivers Mayn and Rhine from Franchen and the country about Mentz, which are here united with those of Andernach. One of these rafts, when it arrives in Holland, whither they pass from the month of May to the end of August, is calculated to be worth about 80,000 guilders. They frequently require from 2 to 500 men to guide them. An irrecusable animosity subsists between the inhabitants of Andernach and those of Liitz, and it is kept up by an annual sermon preached against the latter in the open market-place of Andernach. There are three medieval springs in its vicinity. It is situated on the confines of the electorates of Treves, three leagues north-west from Coblenz, and eight and a half south-east from Cologne. N. lat. 50° 20'. E. long. 17° 56'. R. Render's Tour, vol. i. p. 316.

**ANDERNO** Port lies on the east side of Scarpante, near the Archipelago Islands, nearly in the course of the east end of Candia Island to Rhodes, to the north-east.

**ANDERO**, St. A sea-port town in the Bay of Bacca, in Old Caffia, seated on a small peninsula. It is a trading town, and contains about 700 houses, 2 parish churches, and 4 monasteries. Here the Spaniards build and lay up some of their men of war. N. lat. 43° 20'. W. long. 4° 50'.

**ANDERSON** Island, St. See **ANDRES**.

**ANDERSKOW**, a town of Denmark, in the island of Zealand, one mile south-east of Flagele.

**ANDERSON, Alexander**, in Biography, an eminent mathematician, was born at Aberdeen, in Scotland, and flourished at the latter end of the 17th, and beginning of the 18th centuries. He was professor of mathematics at Paris, where he published several ingenious works in geometry and algebra both of his own and of other persons. In 1612 he published in 4to. a supplement to Apollonius, written by Ghetaldus, under the title of "Supplementum Apollonii Redivivi." His "Antilagiæ," treating of the analytical method of reasoning, and containing farther observations on the former work, was published at Paris in 4to. in 1614. About the same time he published two treatises of Vietæ, "On Equations," with a dedication, preface, and appendix, and Vietæ's tract of "Angular Sections," with demonstrations. A cousin of this gentleman, whose name was David Anderson, was also distinguished for his acquaintance with mathematical and mechanical science. His daughter was the mother of the celebrated James Gregory, and as soon as she discovered his propensity to these sciences, she took pains in giving him necessary instructions in the elements of mathematics. Hutton's Math. Dict.

**ANDERSON, Sir Edmund**, an English lawyer, was descended from a Scots family, settled in Lincolnshire, and prosecuted his studies, first at Oxford, and afterwards in the Inner Temple, where in due time he became a barrister. In the 19th year of Queen Elizabeth, he was appointed the queen's serjeant at law, and soon after one of the justices of assize. In 1581 he went the Norfolk circuit, and distinguished himself by his zeal against Browne, who was the founder of the sect denominated Brownists. His continued zeal in support of the established church recommended him to the queen; and in 1582 he was advanced to the
the dignity of lord chief justice of the common pleas. In the following year he received the honour of knighthood. In 1580 he was appointed one of the commissioners for trying Mary, queen of Scots, and he sat in the bar-chamber when sentence was pronounced against her. He afterwards, in 1587, sat in the same court, when Davidson, the queen's secretary, was charged with illusing the warrant for the execution of Mary, contrary to queen Elizabeth's command, and without her knowledge; and it was his opinion that the secretary had done "iulium non jutit," what was right but not in a due manner; upon which Mr. Grazier very properly observes, that this distinction was "excellent logic for finding an innocent man guilty," and drawn from the same mode and figure with the queen's order and no order for Davidson's signing the warrant." The distinction, however, was admitted; and the secretary was sentenced to pay a fine of 15,000 pounds, and to be imprisoned during the queen's pleasure. Judge Anderson seems to have imbibed, in connection with this subversion to the will of the court, an intolerant and persecuting spirit; and he has been reproached on this account, and unjustly, by the Puritan writers. Mr. Pierce, in his "Vindication of the Differences," p. 126, (ed. Lond., 1617,) charges him with very unjustifyable conduct, with regard to Udal, a Puritan minister, who was confined in 1586, and tried and condemned the following year, and with endeavouring to trick him out of his life. Upon an examination of Udal, at the house of Lord Cobham, in January, 1589-90, the lord chief justice endeavoured to draw from him a confession that he was the author of certain books, which furnished the charges against him; though a law, 42 Edw. III. c. 3. to which Udal referred, says generally, that no man shall be put to answer without pretence before judges, or matter of record, or by due process, and writ original, &c. Udal, indeed, was not tried till July following; nevertheless the judge must know that, considering the disposition of government towards paranatics, such a confession might endanger his life. He manifested a similar spirit in 1596; when he declared in his charges, in the northern circuit, that those who opposed the established church, opposed her majesty's authority, who was suprime in all cases ecclesiastical as well as civil, and on this account they were enemies to the state, and disturbers of the public peace; and he directed the grand juries to inquire concerning persons of this description, that they might be punished. At Lincoln, in his first and second charge, as we are informed by the letter of a clergyman, preferved in Strype's Annals, vol. iv. p. 267, he intimated with wonderful vehemency, that the country is troubled with Brownists, with disciplinarians as he called them, and creators of Presbyterians. He also called the preachers knaves; saying, that they would start up in the pulpit, and speak against every body; he urged the grand jury to suppress, by the statute against Conventicles, a meeting held even with the bishop's allowance, at Lowth; and declared that he would complain to her majesty of any, though never so great, who should show themselves discontented with the jury for any such matter; in short, he conducted himself with so much wrath, so many oaths, and such reproachful revilings, upon the bench, that offence was taken at it by persons of principal credit and note, throughout all the circuits.

He was nevertheless an able lawyer, and adhered with rigorous exactness to the statutes; nor does it appear, that his obedience to the will of the sovereign proceeded, like that of others, from view of personal interest, or from a fear of losing his office, but from respect for what he deemed the constitutional right of the crown. In a case, when the queen would have hitherto her prerogative beyond the limit of the law, the lord chief justice and his brethren resisted, and by their headmen obliged the queen to relinquish her claim. He also, together with the other judges, signed a remonstrance against the arbitrary proceedings of the court, by which at the command of a councilor, or nobleman, subjests were frequently committed to prision, and detained without good cause, and contrary to the laws of the realm; a spirited measure which produced considerable effect; for we are told in Sir William Anderson's reports (Reports, part ii. p. 267,) that "after this there did follow more quietness than before." Upon the accession of James I., the lord chief justice was continued in his office; and he retained it till his death in 1607. "With a harsh and severe temper, and intolerant principles, which rendered him hostile to lecaries, and with notions of arbitrary power, which made him, in some cases, an instrument of tyranny, he appears to have possessed great firmness of temper, and independence of character. If his principles would not suffer him to be always an equitable judge, he was a great lawyer, and, on the whole, a honest man." His works are "Reports of Cases," adjudged in the time of queen Elizabeth, in folio, London, 1644; "Reformations and Judgments in the Courts of Welfmiller, in the latter end of the reign of queen Elizabeth," published by John Goldseborough, Eqt. 1653. The title is now extinct. Bog. Brit.

Anderson, John, the son of a rich merchant, was born at Hamburgh, in 1674. Having made great proficiency in canon law, natural history, and the languages, he was made synodic of the city of Hamburgh, and he was employed in various negotiations in the principal courts of Europe. In the prosecution of his studys and research, he directed a particular attention to the northern nations, and both by reading and conversation obtained a very considerable degree of information concerning them. By means of the Danish colonies established in Davis's Straits, he gained an accurate knowledge of those sequestered parts, and he was enabled to correct many erroneous and fabulous accounts, concerning the state of Iceland. The result of his inquiries was communicated to the public in a German work, entitled, "The natural history of Iceland, Greenland, Davis's Straits, and other northern regions;" since translated into other languages. Mr. Anderson died in 1743; and left behind him MS. pieces, that have not been published. Moreri.

Anderson, Adam, a native of Scotland, was brother to Rev. James Anderson, D. D. editor of the "Diplomata Scotiae," and "Royal Genealogies," miniifer of the Scots church, in Swallow-street, Piccadilly, and known in London, among his connections, by the name of bishop Anderson; a learned but imprudent man, who lost a great part of his property in the year 1720. Adam Anderson was for 40 years a clerk in the South Sea House; one of the trustees for establishing the colony of Georgia, in America; and one of the count of affidants of the Scots corporation, in London. His well known work, entitled, "An Historical and Chronological Deduction of the Origin of Commerce," was first printed in two volumes, fol., in 1764; and a new edition of it, with considerable additions, was published in four volumes, 4to., in 1789. Mr. Anderson died in Red Lion-street, Clerkenwell, Jan. 10, 1755.

Anderson's Island, in Geography, a small island in the North Pacific ocean, discovered soon after Mr. Anderson, the surgeon of the Resolution, had breathed his last, and so called after his name. It was seen at some distance from a rocky point called Cape Newham, situated in N. lat. 58° 42', E. long. 107° 36'.

Andes, in Ancient Geography, a small place of Italy, near Mantua, celebrated as the birth-place of Virgil; hence he
he is called Andes, according to some copies of Silius Italicus, lib. viii. v. 596; whilst others read Aemius. It is now the village of Bandas, situate where the Veron-fue hils imperceptibly slope down into the plain of Manuta.

Andes, Andegavi, or Andevar, a people of Gaul, to the east of the Namnetes or Namnetes, and to the north of the river Liger. Phryn (lib. iv. c. 18.) calls them Andegavi, and they are denominated by Tacitus (Annal. iii. c. 41.) Andevar, which Polymy has corrupted into Ondevacs. Their chief city was called Juohomagus or Civitas Andicavorum. It is now Angers, and the territory of the Andes was the previous Anjou. The Andes, or Andevairi, were valiant, and fought bravely in defence of their liberty; they entered into the conspiracy of Vereingotexos, under the conduct of Dumnacus; and under the empire of Tiberius, when they were greeenly oppressed with taxes, they raised the standard of rebellion.

Andes, a chain of mountains in South America, called by the Spaniards Cordillera de los Andes, or great chain of Andes, which commences near the capes of Ispido and Pi-lares, in the southern extremity of the continent, and stretches along the Pacific ocean, at the mean distance of about 100 miles, traversing the kingdom of Chili, and the provinces of Buenos Ayres, Peru, and Quito, to the west side of the gulf of Darien, through an interval of not less than 4600 miles. From thence they continue their course through the extensive kingdom of New Spain, till they lose themselves in the unexplored countries of the north. The chief summits of this range of mountains are near the Equator, not far from the city of Quito. The highest of them is Chimborazo, about 100 miles south of Quito, and about 10 miles north of Riobamba; and its height was computed by the French mathematicians, who were employed from 1735 to 1742, in measuring the degree of the equator, to be about 3217 French toises, or 20,280 feet, above the level of the sea; that is about 5000 feet higher than Mont Blanc. But as these mountains are elevated on the high plain of Quito, which is elevated farther above the sea than the top of the Pyrenees, and constitutes more than one-third of the computed height, they are inferior in actual elevation to Mont Blanc. That part of Chimborazo, which is covered with perpetual snow, is about 2400 feet from the summit. The mountain next in height is supposed to be the volcano of Cotapashi, which is estimated at about 18,000 feet, and is situated about 25 miles south-east of Quito. Other elevated summits are Pachuchina, a few miles north of Quito; and the Altar and Santos, four miles south of Chimborazo. In the province of Quito, the Andes form a double chain, including the plain of Quito. The western ridge comprehends Pachuchina, Illinai, Chimborazo, &c.; and the eastern is composed of Cotapashi, the Altar, Santos, &c.; and this double ridge is extended for about 500 miles from the south of Cuenca to the north of Popayan. The highest of these ridges is barren, and covered with snow, although it lies in the torrid zone; the other, which is lower, is fruitful in woods, groves, &c. and abounds with wild hogs and sheep, called guanacos, which resemble a camel in shape, but of a smaller size, and bearing hair for tatfoos, tunics, and colours, preferred for silk.

There are several arms, or ramifications, which proceed from the Andes, and which serve to confound the union of the southern with the northern parts of America. The most northern of these, or that of the coast of Venezuela, lying between nine and ten degrees of N. latitude, is the most lofty and narrow. This great chain of the Andes extends from the high plain of Quito, by Popayan and Choco, on the west of the river Atauro, towards the Andes, where, on the banks of the Chagre, it forms mountainous land only about 1200 feet high. From the same Andes proceed several branches, one called the Sierra de Abbe, towards the province of St. Marta, covered with snow, and visible from the sea. This chain is restricted, as it approaches the gulf of Mexico, and cape of Ver, and afterwards runs due east towards the mountains of Panama, or even to the Isle of Trinidad. The greatest height is in the two Sierras Ne-vadas of St. Marta, and of Merida; the first being near 5000 toises, and the second 5400 toises, about 3550 toises, or 44,000 English feet above the sea. Several mountains of this chain are perhaps equal in height to Mont Blanc; they are perpetually covered with snow, and frequently pour from their sides streams of boiling sulphurous water; and the highest peaks are elevated amid mountains of a little height, that of Merida being near the plain of Caracas, which is only 260 feet above the sea. The general height of the chain of the coast is from 3 to 800 toises; the Ne-vada of Merida is 23,500, and the Silla de Caracas 13,160, lowering towards the east, so that cape Codera is only 756 toises. This depression, however, is only of the primitive rock; for there are secondary calcareous mountains from cape Unara, which are higher than the granite, or foliated granite, and the micaeous schistus. These calcareous mountains, covered with calcareous stone, follow this chain on its southern side, and increase in height towards the eastern point of the continent. The chain of the coast is more steep towards the north than the south; and there is a dreadful perpendicular precipice of 1300 toises in the Silla de Caracas, above Caravello: the northern part of this chain being perhaps broken by the gulf of Mexico.

The second chain, which is that of Parima, or of the cataracts of Oinoco, was fearfully deemed passable till within 50 years, since the expedition of Ituriga and Solano. It leaves the Andes near Popayan, and stretching from west to east, from the sources of the Guaviaro, appears to extend to the north-east of that river, forming the cataracts of May-pura and Atures, in the Orinoco, lat. 5°, which are truly dreadful, and nevertheless afford the only passage yet opened towards the vale of the Amazonas. Thence this chain continues its course, with a breadth sometimes of 120 leagues, north-east to the river Caronas, but further to the east its continuation is little known. It has, however, been displayed by Don Antonio Santos, who, under the disguise of an Indian, passed from the mouth of the river Caronas, to the little lake of Parima, and observed this range between 5° and 5° 10' lat., when it is about 60 leagues broad, and divides the waters which fall into the Orinoco and Esquibo, from those that fall into the river of Amazonas. Further to the east, this range becomes still wider, descending south along the Mato, where the Dutch call a part of it Dorado, or the mountain of gold; as it is composed of bright micaeous schistus, which gives a similar character to a small hill in the lake of Parima. To the east of the Esquibo this range takes a south-east direction, and joins the granite mountains of Guana, in which is the source of the river of Surinam, and also of other rivers. This last group of mountains is very extensive, the same gneis is found at 3° 20' and 2° 14' N. This wide range is inhabited by a number of savage tribes, which are not much known in Europe. It no where seems to rise to an equal height with the northern range of the coast; the mountain of Duida, whose volcano is in lat. 3° 13' N., not far from Esmeraldas, being deemed the highest, and, by the measure of Humboldt, found 12,239 toises above the sea. This is a picturesque and majestic mountain, ejecting flames towards the close of the rainy season, and sitting near a beautiful plain, covered with palm-
trees and ananás. Towards the east it seems to terminate in broken rocks; but without any appearance of any secondary flata, the rocks being granite, gneiss, micaceous schistus, and hornblende flate.

The third chain of primitive mountains, that of Chiquitos, unites the Andes of Peru and Chile with the mountains of Brazil and Paraguay, and stretches from La Paz, Poto, and Tucuman, through the provinces of Moxos, Chiquitos, and Chaco, towards the government of the Moxo, and of St. Paul, in Brazil. The highest summits appear to be between 17° and 20°; the rivers there flowing to that of Amazon, or that of La Plata.

Between these three great ridges are three immense valleys; that of Orinoco, that of the river of Amazon, and that of the Pampas of Buenos Ayres, from 19° to 52° south lat. all opening to the east, but shut on the west by the Andes. The middle valley, or that of the Amazon, is covered with forelcs so thick, that the rivers along form roads; while those of Orinoco and Pampas are savannahs or grassy plains, with a few scattered palms; and so level, that sometimes for 800 square leagues there is no elevation exceeding eight or ten inches. In the northern plain the primitive rock is covered with limestone, gypsum, and freestone, while in that of the Amazon the granite every where appears. The general inclination is to the north-west, which, according to Humboldt, is the usual arrangement of primitive rocks. In the Andes petrifactions are uncommon, but there are sometimes patches of gypsum, and secondary limetone; while the range of Parima confines entirely of granite and other primitive rocks. But in the calcareous freestone of the northern ridges of the coal, Humboldt found many shells, seemingly of recent petrification, as they are close of the sea, now at the distance of nine leagues. In the plain of Orinoco are found petrified trees, in a coarse breccia. Granite forms the chain of Parima; but in that of the coal it is covered, or mingled with gneiss and micaceous schistus. It is sometimes stratified in beds from two to three feet thick, and sometimes contains large crystals of felspar. The micaceous schistus sometimes presents red gneiss, and fappa; and in the gneiss of the mountain of Avila green garnets appear. In the range of Parima there occur large masses of most brilliant tale, formerly imparting such reputation to the Dorado, situated between the rivers Esquicho and Mao, and other mountains, which like burnish gold, reflect the light of the sun, and have hence been denominated the shining mountains. Smeléit, or soft jad, is formed in islands; and Condamine discovered that hard jad, called Amazon fone. Schistose chlorite also occurs; and beautiful hornblende fible rises through the streets of Guiana, or S. Thome. Other substanccs are decomposed felspar or kaolin, primitive limetone and plumbago; and there are veins of quartz, which contain auriferous pyrites, and antimony, native gold, grey copper, and malachite. The copper mines of Aroa are alone wrought, and produce about 1,500 quintals yearly. Slate is rare, but sometimes covers the micaceous schistus; and in the northern chain there are rocks of serpentine, veined with bluish fesitate. The grunstein of Werner sometimes occurs in that ridge. Among the rocks called transitive by Werner, as connecting the primitive with the secondary, are trap, green flate, amygdaidel, and the schiitofe porphyry of that author, green with crystals of felspar. The secondary rocks are limetone, gypsum, argillaceous schistus, and freestone, or calcareous flate, with coarse breccia.

The eastern spurs of the Andes, according to Helms, a pracitical German mineralogist, who was employed for some years in the mines of Peru, sometimes present red and green granite, and gneiss, as towards Cordova, and Tucuman, but the grand chain consists chiefly of argillaceous schistus, or various kinds of thin flate, bluish, dark red, fesh colour, grey and yellow; on which, in many places, are incumbent flata of limetone, and large masses of ferruginous flate. No mountains, says this author, have been observed by him in Hungary, Saxony, or the Pyrenees, which are so irregular as the Andes, or broken into such alternate flubences, manifesting such prodigious revolution of nature. Amid the argillaceous schistus the metals sometimes occur in veins of quartz, sometimes in alluvial layers of sandstone, and iron sand. Near Poto are irregular beds of large bullets of granite; and the celebrated mountain, so rich in silver ore, is chiefly composed of a firm yellow argillaceous flate, full of veins of ferruginous quartz, in which are found some of the best ores. In passing the highest ridge of the Andes, between Poto and Lima, Helms still found argillaceous schistus, the predominant substance; sometimes with fleta of sandstone, sometimes with long extents of granite. Near the lake of Titicaca the Andes are of prodigious height, this being the centre of the chain, and also the summit parts. The French mathematicians, who visited the Andes, for measuring a degree of the meridian, have given a particular account of the occurrences that befell them on this occasion. Having divided themselves into two bodies, Don George Juan and M. Godin, at the head of one party, went to the mountain of Pambarama; and M. Bouguer de la Condaminne, and Don Ulloa, with their allies, ascended the highest summit of Pachinchica. Both parties suffered from the extremity of the cold, and the impietuosity of the winds, which on these heights blow with incessant violence. They had commonly, in other uncomfortable situations, pitched a field-tent for each company; but on the top of Pachinchica this was impracticable, and they were under the necessity of contenting themselves with a very small hut, which, like all the other adjacent parts, was soon covered with ice and snow. The air on this summit was also so fubtile, as to render respiration very difficult. They generally kept within their hut; which they were obliged to do, on account of the intemperance of the cold, the violence of the wind, and the darkness occasioned by a thick fog. When the fog cleared up, the clouds defended towards the earth; and surrounded the mountain in such a manner.
manner as to represent the sea, with the rock on which they were situated like an island in the centre of it. When this happened, they heard the horrid noises of the tempests, which then discharged themselves in Quito, and the neighbouring country. They saw the lightnings issuing from the clouds, and heard the thunder rolling far beneath them; and whilst the lower parts were involved in tempests of thunder and rain, they enjoyed a delightfule serenity; the wind abated, the sky was clear, and the enlivening rays of the sun moderated the severity of the cold. But when the clouds rose, respiration became difficult, and snow and hail fell continually, and the wind refumed its former violence; so that by this operation, left their shoe should be overturned, and blown down the precipice, on the edge of which it was built, or that they should be buried under it by the accumulation of ice and snow. Their fears were increased by the dreadful concussions occasioned by the fall of enormous fragments of rocks, and the velocity with which the wind moved dazzled their sight. For their greater security they fastened the door of their hut with thongs of leather, and stopped every crevice on the inside; and they also completely covered it with straw; but all this precaution was not sufficient to prevent the wind from penetrating. They had no other light in this confined state, but that of a lamp or two, which they kept burning; but notwithstanding the smallness of their habitation, and the heat of the lamps, the cold was so intense, that each of them was obliged to have a chaffing-dish of coals. Such were the effects of the severity of the climate, that their feet were swollen and fo tender, that they could not even bear the heat, and walking was attended with great pain. Their hands were covered with chillblains; their lips were swelled and chopped; so that every motion, in speaking or the like, drew blood. Their common food in this inhospitable region was a little rice boiled with some flesh or fowl, which was procured from Quito; and instead of water, their pot was filled with ice; and whilst they were eating, every one of them was obliged to keep his plate over a chaffing-dish of coals, to prevent his provisions from freezing. When they attempted to augment their inward heat by drinking strong liquors, they felt no strength in them, nor were they any greater preventive against the cold than common water. The Indians, who attended them, could not by any encouragement, or threat of punishment, be prevailed upon to continue with them. Upon their first feeling the rigour of the climate, they immediately prepared for departure; and such was the inconvenience resulting from this circumstance, that they were in danger of being confined in their hut, by the masses of snow, which it was the business of these Indians every morning to remove. Such, and similar to these, were the difficulties and inconveniences with which they encountered during the whole progress of their occupation in forming triangles for measuring the degrees of the meridian. D. Juan Don Ulla's Voyage to South America, by Adams, vol. i. p. 214, &c. Journal de Physique, Melior An. ix. July, 1851. Helms's Tagebuch, &c. ; or Journal of a Journey through Peru, from Buenos Ayres to the great river La Plata, by Potofio to Lima, &c. 8vo. Dreden, 1798. Pinkerton's Modern Geography, vol. ii. p. 673, &c. ANDESAGE, a town of France in the department of the Lot and Garonne, and chief place of a canton, in the district of Villeneuve d'Agen, 10 miles north-east of Agen. ANDETHANA, in Ancient Geography, Epiphaniach, a town of Gaul, belonging to the Treveri, in Belgia prima, between Augufa Treverorum to the east, and Orobannum to the west. ANDETRIUM, (Phlay), ANDRETRIUM, (Strabo), AN-DETRIUM, (Dion Cassius), and ANDRETRIUM, (Ptolemy), a town of Dalmatia, situated on an almost inaccessible rock, surrounded with deep valleys and rapid torrents; where it appears to be the capital now called Dijia. N. lat. 43° 20'. E. long. 17° 40'. ANDEVALLO, in Geography, a small country of Spain, in Andalusia, on the frontiers of Portugal and Spanish Extremadura. ANDEZIEU, of DIDERZIEU, a town of Poland, in the palatinate of Cracow; 52 miles south-west of Cracow. ANDIANITES, a people, according to Ptolemy, of Lower Pannonia. ANDIATORQUE, a lake of Canada, in North America, near New England. ANDILLA, a town of Spain, in the province of Valencia, six leagues from Alicarn. ANDIRA, or ANGELIN, in Botany, G. Pison; a tree in Brazil, the wood of which is hard and proper for building. Its bark is of an ash colour; its fruit is of the shape and size of an egg, green at first, but growing blacker by degrees. It is covered with a hard rind, including a grain, or yellowish kernel, of a bitterish, astringent taste. They pulverize this nut, and give it for worms; but not more than one scruple; for more than this is said to be poisonous. In the Linnaean syslem by Gmelin, andira is a genus of the diadelphus decandria class and order; the characters of which, are, that the calyx is uncolducted almost entire, or quinverted; the corolla has two petals; and the fruit is a dry pod, ovate, furrowed, and containing a single seed. ANDIRA, in Zoology, is an animal called also andira-guaco, a kind of bat in Brazil; the largest of which are as big as our pigeons: they call them horned bats, from a fort of excrecence, or plant body, above their beak. Some of these are very dangerous; for they get into chambers in the night, and so subtilly open the veins in the feet of those who are in bed, that they are not perceived but by the flowing of the blood, which is difficult to be stopped. The inhabitants reckon the tongue and heart of that animal among poisons. The andira is the vesperstumbio spectrum of Linneus. See SPECTRE. ANDIRIAR, in Botany, the name by which Raphae, and some others, express the FABACO. ANDLAU, in Geography, a town of France, in the department of the Lower Rhine, situate on a mountain, and defended by a castle. It was formerly an imperial free city, and has a nunnery, instituted for ladies of noble extraction. It is 18 miles south-south-west of Strauburg. N. lat. 48° 24'. E. long. 7° 24'. ANDLAU is also a river of France, which rises near the town of the same name, and discharges itself into the Ill, near Fegerheim, in the department of the Lower Rhine. ANDOCIDES, in Biography, an Athenian orator, was born at Athens, the first year of the 78th Olympiad, or 468 years before Christ. He was attached to oligarchy, and not to popular government. When Alebiades was tried for demolishing the statues of Mercury, Andocides was suspected, and he escaped by acknowledging the crime, and accusing his accomplices. The style of his orations is plain and simple, and almost entirely delittute of ornament. Four are extant, of which the two first are vindications of himself; the third is on the subject of peace with the Lacedemonians; and the fourth against Alebiades, who had sent him into exile. They were first published with those of Antiphon, &c. by Aldus Manutius, in folio, at Rome, in 1513; and afterwards in a more splendid manner, in 1575, by Henry Stephens. The orations of Antiphon, Andocides, ...
ANDOLOGENSES, in *Ancient Geography*, a people of Spain, according to Ptolemy.

ANDOMADUNUM, ANDOMATUNUM (Ptolemy), ANTIVAVUM, (Antonne), CIUTATS UNIUSUM, (Tacticus), now LUGUES, a city of Gallia Belgica, was a Roman colony, and appears, by many remains of antiquity, to have been considerable. It was situated on an eminence as the termination of Eruns imports. N. lat. 47°. E. long. 5°.22'.

ANDONY RIVER, in Geography, lies on the coast of Benin, in Africa, called from Cape Formosa, between the new and old Calabar rivers, in about N. lat. 4° 30', and E. long. 9° 55'.

ANDORA, a town of Italy, in Genoa, whose neighbourly produce good wine; two miles north-east of Ongella.

ANDORINA, in *Ornithology*, a name by which the Portuguese in the Brasilian savannah, more usually known by its Brasilian name tupaera.

ANDORINEPOPO, in *Ancient Geography*, a town placed by Ptolemy in Britain. Hartwell calls it Andurfe.

ANDORNO, in Geography, a town of Italy, in the principality of Piemonte, and lordship of Vercelli, 25 miles north-west of Vercelli.

ANDORRA, a town of Spain, in Catalonia, situate in a valley of the same name, which is surrounded by the Pyrenees, and formerly made a part of the county of Foix, with which it joins; the valley is fertile, and watered by a small river, called Belin, that runs into the Segura, three leagues north of Urgel.

ANDOSIIA, a town of Spain, in Navarre; two leagues from Cauter. Perre.

ANDOSINI, in *Ancient Geography*, a people placed by Polybius, in Spain, towards the Pyrenees.

ANDOVER, in Geography, a borough town of England, in the county of Hampshire, pleasantly situate near the river And. It has a manufacture of shalloons, and a considerable trade in malting. Its market is on Saturday. It is governed by a bailiff, steward, recorder, ten other persons of approved reputation, and 24 burgesses. It sends two members to parliament. A navigable canal is making from this town to Southampton; it is 67½ miles from London, and 12½ from Salisbury. N. lat. 51° 30'. W. long. 1° 50'.

ANDOVER is also a large and thriving town of North America, in Essex county, Massachusetts, containing two parishes, and 2803 inhabitants. It has a paper mill and powder mill and an excellent academy, called "Philips Academy," from the name of its founders. This town lies about 20 miles west of Newbury port, and about 22 north of Bolton.

ANDOVER is also a town of Hillborough, in New Hampshire, incorporated in 1779, and containing 645 inhabitants.

ANDOVER is also the south-western most township in Windham county, Vermont, situate 52 miles north east of Bennington, and containing 1275 inhabitants.

ANDOVER is also a place in Suffield county, New Jersey, near the source of Pequell river, five miles south-west of New-Town, and 16 in the same direction from Wallack.

ANDOVILLE, a town of France, in the department of the Mayenne, a chief place of a canton, in the district of Laval, near the river Eude, six miles north of Laval.

ANDRAE, in *Ancient Geography*, a town of Aisia Minor, placed by Ptolemy in Cappadocia, in the prefecture of Chamaene.

ANDRACHINE, in Botany, *Telephoides* of Tournefort, a genus of the *arum conica* (pentandria trigyna, Ginchi's Linnaeus) class and order; of the natural order of *trigidae* and *trigidae superior* of Junius; the characters of which are, that it has male and female flowers; in the former the calyx is a five-leaved, equal, marooned petalium; the corolla has five petals, emarginate, longer, and shorter than the calyx, the nectary has five leaves, umbilic, herbaceous, one within each petal, and less than it; the stamina have five filaments, small, inserted into the tube of each style, and simple anthers; in the latter the calyx is a five-leaved, equal, permanent petalium; the corolla has no petals, the nectary as in the male; the pistillum is a germ superior and globose, fleshy three, filiform, and 2-pointed, the stigma globose; the *pericarpium* is a capsule globulo-trilocular, three-celled, cells inturned, of the size of the calyx, (tricoccous calicis, G.) the seeds are in pairs, rounded on one side, triangular and obtuse on the other. Obf. It is related to elata.

Art. 2. the *symb. telephoides* of Dill and Buxchglanz of Bocey, proconsul, and herbaceous. This is a low plant, with branches trailing on the ground; the leaves are round, ovate, and of a sea-green colour; found wild in some parts of Italy, and in the Archipelago, whose seeds were sent by Tournefort to the royal garden at Paris; and cultivated in Kew garden by Dr. Sherard, in 1732. As it has no great beauty, it is only preferred in botanic gardens for the sake of variety.

Art. 3. the *fruticosa* and *latifolia* of Linn. Martiss. erect and shrubby. It rives 12 or 14 feet high, with branches bearing spear-shaped, pointed, smooth leaves; the flowers are small, and of an herbaceous white colour; some flowers are male, with one-leaved round flat obtuse calyx, a little quinquifid, others on the same plant female, five-parted; a native of the East Indies, in China, and also of La Vera Cruz, in New Spain. 

Art. 4. the *arborea* of Miller, with arborect form, and leaves ovate, obtuse, hoary underneath. This has a strong woody stem, which rives more than 20 feet high, with branches from which proceed oval blunt leaves hoary on the under side, and furrowed on the upper, and placed alternately on the branches. This species grows naturally at Campbanchy, and the seeds were sent from thence to England by Dr. Houtain. There is another fort, raised from seeds, sent from Jamaica; the leaves of which resemble those of the laurel, except that they are much larger; this has not yet flowered in Europe.

Culture. The seeds of the first species may be sown on a moderate hot bed in March; and the plants, which spring up in about a month, may be removed, each into a small pot, and plunged into another moderate hot bed; in mild weather they should have plenty of air and be often watered; in June they will produce flowers, and the seeds will ripen in August and September, after which the plants decay. The second and third species are very tender plants; their seeds should be sown in pots, which must be plunged in a hot bed of tanner's bark and watered; when the plants come up, each of them should be planted in a small pot, plunged into a warm bed, and they should be shaded till they have taken fresh root, and afterwards in warm weather exposed to the air, but constantly kept in the back stove.

ANDRACHNE. See A r h y s .

ANDRADA, Diego de Payva d' or Andradius, in *Biography*, a learned Portuguese divine of the 16th century, was born at Coimbra, distinguished in that University, and sent by Sebastian, king of Portugal, to the council of Trent, where he was celebrated for the understanding of a
AND

deep theologian, and for the tongue of an eloquent orator. During the session of the council he wrote a "treatise," entitled, "Orthodoxarum Explicationum Libri Decem," in answer to an attack upon the Jesuits by Chemnitz. This was answered by Chemnitz. Andreada prepared an elaborate rejoinder under the title of "Defenso Tridentine fidelis," or a defence of the Catholic faith, &c. first published in 1602. at Lisbon, in 1578, and afterwards at Ingolstadt, in 1582. Andreada published also seven volumes of sermons, although a champion for orthodoxy, he had the candour to allow that the heathen philosophers might be saved. Gen. Dict.

ANDRA, Francis, historiographer to Philip III. King of Spain, was the brother of the preceding Andreada. He wrote "The History of John III. King of Portugal," in the Portuguese language; which was published, in 1602., at Lisbon, in 1535.

ANDRARIA, in Ancient Geography, a town of Italy, in the vicinity of Podotinum.

ANDRAGIRI, or GUDAVIRI, in Geography, a province and town in the island of Sumatra. The town is in the middle of the island, and belongs to the Dutch, who have built a fort for its security.

ANDROMET, ANDRAMIT, or ANDRAMITI, a town of Natolia, in Turkey, in Asia. The Turks call it Palament. See ANDRAMITIUM.

ANDRAPANAM, in Ancient Geography, a town of Asia, in India, arrived by Ptolemus to the Indolethians.

ANDRAPODISMUS, in Ancient Writers, the selling of persons for slaves.

Hence also andrapodisthes, aw-handres, a dealer in slaves, more particularly a kidnapper, who steals men or children, to sell them, a crime for which the Thessallians were noted.

ANDRAPODICAPELLI, Mancipiorum Vindictores, in Antiquity, dealers in slaves. They cleansed the skins of the slaves with balsam prepared with barley and other kinds of meal, to which nitre, according to Galen, was occasionally added. They whipped them lightly with cords, and then smeared them with oil, and used various other arts to make them sleek and plump, and to give them an appearance of health. They were also called Mangones, and the art Mangonciam. Calcelli Lexicon.

At Athens, several places in the forum were appointed for the sale of slaves. Upon the first day of every month, the merchants brought them into the market, and exposed them to sale, whilst the crier, standing upon a stone erected for that purpose, called the people together.

ANDRARUM, or Anderum, in Geography, a town of Sweden, in the province of Schonen; it is celebrated by Chrestianstad.

ANDRASTE, in Antiquity, one of the ancient bearers of the ancient Britons, supposed to have been the same with Venus or Dian.

ANDRE, Sr., in Geography, a town in the kingdom of Leon, in North America, near the mouth of Nafius river, which falls into the Gulf of Mexico.

ANDRE, a small river of France, in Britain, which runs into the Loire, at Nantes.

ANDRE, a town of Phrygia in Asia Minor.

Andre, Sr., in Biography, born at Dijon, the 15th of February, 1701, received his education at Montpelher, and in 1729 was admitted member of the company of surgeons, at Verailles, and appointed one of the surgeons to the king. He applied himself particularly to the study of the diseases of the urethra, and was expert in the application of bougies, on which he placed his principal dependence in thefe complaints, varying the ingredients of which they were composed, to make them more or less stimulating and corroding, as the circumstances of the cases required. In 1754, he published his "Differtations pour les maladies de l'uretre, qui ont besoin de bougies," 12mo. Paris, and in 1758; "Maniere de faire usage des bougies antiveneriques." Svo. also at Paris. For an account of other publications by this writer, see Eloy. Dict. Hist.

ANDREA, in Geography, a town of Africa, in Upper Guinea, about a quarter of a mile from the river Mefurado, and eight miles from its mouth; it contains about 40 or 50 houses; its chief riches are palm, wine, and rice; a trade is also carried on in ivory and slaves.

ANDREA ANDREANI, in Biography, an eminent engraver, was born at Mantua, and died A. D. 1625, at a very advanced age. Besides his own engravings, he executed many performed by other persons, and sold the impressions under his own name. He engraved only on wood, in a peculiar style, distinguished by the name of "Chiaroscuro," which is performed with two, three, or more blocks of wood, according to the number of tints required, which are dampened upon paper, one after another, so as to produce the effect of a washed drawing. The invention of this species of engraving was much prior to the art of this artist. His great merit as an artist, is acknowledged by all who are conversant with his prints. His drawing is excellent, executed with great spirit, and in a very matterly style. In the heads of his figures are characteristic and expressive, and he has displayed great judgment in the management of his various tints. His works are considered as admirable transcripts from the sketches of many of the greatest painters. Among his most finished prints may be reckoned, "Christ departing from Pilate," who is washing his hands; a large print lengthways, on two blocks, engraved from a bas-relief of Giovani Bologna; "An emblematical Print," representing the Christian, after his spiritual warfare in the present life, received as victorious into heaven, and crowned by Christ; "The triumph of Julius Caesar," from Andrea Mantega, the original of which is at Hampton Court; it is cut on 10 blocks of wood, dated 1568; "The entombing of Christ," from Raphael de Reggio; "The rape of the Sabines," from a group by Giovani Bologna. The fearcst of all his works is said to be "The pavement of Sicilia," after a drawing of Francesco Vanni. Strutt.

ANDREA DA PISA, a sculptor and architect, was born at Pisa in 1470. He built several castles, and the church of St. John, at Pisa; but his skill in architecture was greatly improved at Florence, where he enlarged and fortified the palace of the duke, by erecting many mansions in it, and surrounding it with magnificent towers and gates. On this account he obtained the right of citizenship. At the request of the duke of Athens, he made a model of a cruiser, which he intended to erect for retaining the Florentines; upon which they took the alarm, and expelled the duke; but Andrea passed the remainder of his days at Florence, cultivating the fine arts, such as painting, poetry and music, besides those which were professedly his own, and died in 1545, aged 75.

ANDREA DEL SARTO. See SARTO.

ANDREA MANTEGA. See MANTEGA.

ANDREA, in Biography, an apothecary at Hanover, was born 17th December, 1724. By the attention of his mother he was well educated in the languages and sciences; and in 1744 he visited Berlin, where
where he attended lectures on chemistry, anatomy, botany, and natural history. In the following year he inspected the various mines in Saxony, and proceeded through Liepzig, Halle, the Hartz, and Caffel to Frankfort, where he resided till the Spring of the year 1746. From hence he removed to the university of Leyden, and studied chemistry under Gauthiot, botany under Royen, and natural philosophy under Mulchenbrok. In the year 1747, he visited England, and returned to Hanover where he succeeded to his father's business, in 1751, and distinguished himself by his skill and diligence. He wrote many useful papers in the Hanoverian Magazine, and other periodical works, by which he gained considerable reputation and esteem; in 1761 he made a tour to Switzerland, the original of which was published in 1776, in a 4to. volume, with engravings; and in 1765 he was charged by government to examine the principal kinds of earth and marl in the electorate, and to publish a work on their nature and use, for the benefit of farmers, which appeared in 1789, under the title of "A Treatise on various kinds of earth in his Britannic Majesty's dominions, &c. and their uses in agriculture." In December 1791, he was attacked by an inflammation of the urethra, which at length terminated in his death, on the 1st of May, 1793. His writings and collections of natural history procured for him an extensive acquaintance with men of literature and science, and an admission into many learned societies. Gen. Biog.

Anaximenes, in Entomology, a species of Carabus. The thorax obicular, black, and glossy; wing-cases pale, with a black band in the middle. Fabricius. Inhabits Italy.

Anaximander, is likewise a species of Cimex, that inhabits the West Indies. It is red, except the antennae, tincted of the legs, beak and wings, which are black. Linnaeus. The cimex rubicollis of Muf. Lud. Ulr., and cimex thoracis nigro of Thumberg are supposed to be varieties of this species.

Andeanoffski-Ostrove, or Andenovian isles, in Geography, a cluster of islands, between Asia and America, which in a general view may be regarded as the same with the Fox islands, being the western part of the same range; or the Andrenovian isles, in a more limited sense, may be considered as forming a group of six or more isles, about 500 miles to the south-east of Bear Island. These, in both respects, are a kind of cluster of the American promontory of Alaska, and in the most recent maps of Russia they are comprehended under one general name of Aleutian isles.

Andreas, John Valentine, in Biography, a Lutheran clergyman, was born in the year 1686; became dean of Vayingen, chaplain to Everhard Ill. duke of Wurttemberg, abbot of Bebenhausen, and halfly of Adelberg; and died June 27th, 1654. His principal works are "Mythologia Chirithiana;" "De curiositati pernicie;" "De religioni reipublicae Chrithi, in Germania;" "Suidia rei chritianae et literaria;" "Theoplius, five de religioni christiana colenda;" "Menippeus prior et posterior;" "Peregrinus in Patria;" "Fama Andreae relores;" which contains the life of his grandfather, and various poems in honour of Augustus, duke of Wolfenbuttle, inserted in a book, entitled "Selenia Augustalina." Some have represented John Valentine Andreas, as the founder of the Rothercruins. Gen. Biog.

Andreas, Valerius, learned Brabantian, was born at the village of Debachel, November 25th, 1688. He studied the Greek language at Antwerp, under Andreas Schottus, and the Hebrew under John Hay, a Scots Jefuit; and his proficiency in the latter language was such that he was invited to be professor of it at Louvain. He afterwards applied to the study of the law, and in 1641 obtained the degree of doctor. In 1665 he was appointed professor of the "Institute," and in 1668 librarian to the academy. His works are "Orthographia Latino, ab Aldo Manutio collecta, bene multis aucta: cum libello de ratione inter- punendo ac seconfundo notis;" "De Initis Collegium Bulli- dianum, duce vita et scriptis professo renjimo collemgi;" "De Lingua Hebrewica Lachma, antiquitate, dignitate, neceditate;" "Difertation de Toro et Sago;" "Topogra- phia Belgica." His principal work was "Bibliotheca Belgica, de Belgia vita scriptoribus claris," first printed in 1675; and afterwards with considerable additions in 1679. Gen. Biog.

Andreas, John, a famous canonist of the 14th century, was the natural son of a priest, and born at Magello, near Florence. He prosecuted his studies at Bologna, and particularly that of the canon law, under the professor Guy de Baff, who procured for him the degree of doctor, gratis. He was a professor at Padua, about the year 1350, and also at Pisa; but he acquired the greatest reputation at Bologna. He is said to have led a very aulterine life, maccinating his body with prayer and fasting, and lying upon the bare ground for 25 years successively, under a covering of bear-skin. He married a woman named Milantia, by whom he had a beautiful daughter, whom he called Novella, after the name of his mother, and who is said to have read lectures for him when he wanted leisure. Respect for his mother and affection for his daughter induced him to entitle his "Commentary upon the Decretals of Gregory Ixth," the "Novelle." Having lost his natural son Bonaccinotto, who published several books, he adopted a learned canonist, whose name was John Calderinus, and gave him his daughter in marriage. Andreas died of the plague at Bologna in 1348, after having been professor 45 years, and was buried in the church of the Dominicans. He was the author of several books, such as "A glossa upon the sixth book of Decretals;" "Glosses upon the Clementines;" "A Commentary in Regulae Sexi," entitled "Mercuriales," either because it was written on Wednesdays, (diei Mercuri), or because it contained his Wednesday's disputations. He also enlarged the "Speculum of Durant," in 1347. However he has been accused of great plagiarism. Gen. Diét.

Andreas, John, was born a Mahometan at Xativa, in the kingdom of Valencia, and succeeded his father as Alfauqui in that city. He was converted to Christianity by a sermon preached in the great church of Valencia, in 1451, and professing his faith was baptized, in memory of the calling of St. John and St. Andrew, by the name of John Andreas. Soon after his conversion, he became a priest and a public teacher, and was employed by king Ferdinand and queen Isabella, on a mission to the Moors of Granada, many of whom he induced to abjure Mahomet, and to assume the profession of Christianity. He was afterwards made a canon, and appointed to undertake the conversion of the Moors of Arragon; but the queen's death prevented the execution of this undertaking. However, he translated from the Arabic into the language of Arragon, the whole law of the Moors, that is, the alcoran, and its glosses, and the seven books of the Suni. He also wrote a work, entitled "The Confusion of the sect of Mahamed," for the purpose of exposing the follies of Mahometanism, which was published first in Spanish, has been translated into many languages, and is often cited by those who have occasion to write against the Mahometans, as Hoornbeek, Hottinger, and Schultetus. Gen. Diét.
AND

Andreas, Tobias, professor of History and Greek at Groningen, was born at Brunsfels in the county of Solms, in 1604. He studied at Herborn under Alcideus and his uncle Pictator, and afterwards resided seven years at Bremen. After his return to his own country, in 1628, he removed to Groningen, where he read lectures on all parts of philosophy, and obtained the appointment of tutor to the sons of Henry Alting, his patron, and afterwards in the family of the Prince Palatine. In 1631 he succeeded James Gebhardus, professor of History and Greek at Groningen, which office he retained till his death in 1676. He was distinguished by his attachment to Des Cartes, whom he ridiculated by his writings, both during the life and after the death of that eminent philosopher. He instituted a profession against Martin Schookius, professor of philosophy at Groningen, for accusing Des Cartes of atheism. The result was, that the accuser acknowledged Des Cartes's innocence, but was himself acquitted. His “Methodi Car- tellianae Asfertio,” was published in the year 1651. Gen. Diê.

Andreas, James, a famous Lutheran divine, was born at Waibling, in the dutchy of Wirtemberg, in 1528, and though of mean parentage, was encouraged in the profession of his studies first at Stuttgard and afterwards at Tubingen, where he connected theology and Hebrew with philosophy, and took the degrees of bachelor and master of arts; and in 1546 he was appointed minister of the church of Stuttgard; but upon the publication of the “Interim” he was obliged to retire to Tubingen, where he officiated as minister. In 1553 he took the degree of doctor of divinity, and was appointed pastor of the church of Gopping, and superintendent of the neighbouring churches. After performing several trusts that were devolved upon him, in order to promote the reformation from popery, he attended the diet of Worms in 1557, and was appointed one of the secretaries at the conference at Worms between the papists and the divines of the Augultan confederation. In 1560 he attended the diet of the empire at Augsburg; and after his return from Paris, in 1561, he was made chancellor and rector of the university of Tubingen. In 1565 he established a church at Hangenau, an imperial city, where he preached many sermons on the principal points of the Christian religion, which were afterwards printed. He took several journeys, in order to effect an union of the churches of the Augultan confederation, and engaged in ineffectual conferences with Beza and others, with a view of terminating theological disputes. His last public act was a conference at Baden, in 1559, with John Filiborus, who then inclined to Calvinism, but afterwards revolted to popery. He had a prelament of his death for some time before it happened; and upon its approach he expressed his constancy in the faith which he had affected, and in the exercise of a lively devotion he expired in 1569, in the 42d year of his age. Hischaracter and learning were held in high estimation; and the books which he wrote were so numerous, that it was said that he left 150 works upon various subjects. Gen. Diê.

Andreas, St., in Geography, a town of Germany, in the circle of Austria and dutchy of Carnithia, upon the river Lavant, with a bishopric suffragan of Salzburg; 15 leagues east of Clagenfurt.

Andreasberg, a town of Germany, in the circle of Lower Saxony, and principality of Grabenhagen, having in its environs some considerable iron-mines, 12 miles from Goslar, and 12 from Northaum.

Andree, Yves-Mary, in Biography, a French Jesuit, was born in 1675, at Chateaulin, in the county of Cornouailles. Having occupied the chair of professor of royal of mathematics at Caen, from 1726 to 1729, when he was 84 years of age, and enjoyed a repose of four years, he finished his laborious life in 1733. He was not only a good mathematician, but well acquainted with other branches of learning; and he also wrote elegant verses. Of his "Elly on the Beautiful," written in French, a new edition was given in a collection of his works, published in three volumes, 12mo in 1766. The subject is treated with perspicuity of method, strength of argument, and dignity of style. Gen. Biog.
and he was also praised by Queen Anne, of Bretagne, whence he styled himself, "Poeta reginis ac reginae." Andreinius was celebrated by many of his contemporaries as the first poet of the age, and as having contributed in an eminent degree, to promote literature in France. Eufebius, however, though he praised him when alive, gives an unfavourable account of his talents and morals after his death. He changed him with licentiousness of manners, and with a tumultuous and quarrelsome disposition. Nevertheless he obtained a high degree of reputation as a professor and writer till the time of his death, which happened at Paris, in February, 1488; and his memory was honoured with elegies, inscriptions, &c. Vossius compares the poetry of Andreinius, which consisted of sonorous verses and pompous expressions, without much meaning, to a river of words with a drop of sense, and Eufebius contends the grant of this drop. Most of his poems have been infected in the first volume of the "Deliciae Posthumae Ital." They chiefly consist of elegies, eclogues, and panegyrical pieces on various occasions. He also wrote moral and proverbial epistles in prose. Gen. Dict.

ANDRENA, in Entomology, one of the new genera in the Fabrician arrangement, containing, for the most part, of such insects as belong to the Apiis genus in the family of Linnæus. The tongue is trident, or three-cleft, lip cylindrical, and on each side two membranaceous bristles; antenna filiform. Fabricius. In the Entomologia Systematica of Fab. are thirty-one species of this genus. viz. ceruleolens, rubipes, spiralis, coriacea, labica, florca, metallica, zoea, cyanacea, marginata, helvola, bicolour, tricolor, curvipes, cineta, frigata, nigrita, fasicata, zonata, circulata, pilipes, carbonaria, hirfuta, hirtipes, histerholaidis, gulo, bidentata, nigricornis, viricets, cigalata, and fuscicenitis, which see respectively.

ANDRENEH, in Geography. See ANDRENA.

ANDRENOVIAN ISLES. See ANDRENOVIAN.

OSTROVA.

ANDRES, or ANDERO ISLAND, is situated south-east by east from Cape Gracias a Dios, the farthest point easterly of the province of Honduras, not far from St. Catherine's, or Providence Island, to the west-south-west, in N. lat. 22° 39', and W. long. 61° 40'.

ANDRES, a town of Asiatic Turkey, 60 miles east from Angura.

ANDRETTA, a town of Italy, in the kingdom of Naples, and Principato Ultra, six miles north of Conza.

ANDREW, in Biography, an apostle of Christ, was born of Jewish parents at Bethsaida, in Galilee. The name of his father, who was a fisherman of that town, was Jonas; and both he and his brother Peter followed that occupation. John Bapt, who was the herald of Christ, and who introduced him to the notice of the Jewish people as the promised Messiah, pointed him out to Andrew and Simon Peter, under the emblematic appellation of the Lamb of God; upon which they accompanied him to the place of his residence. Andrew seems to have been the first disciple of Christ; for he underwrote the sacrificial allusion of John, and said to his brother, "We have found the Messiah." John i. 35-41. He was afterwards chosen by Christ as one of his twelve apostles. To the brief account given by the evangelical writers of this apostle (Matt. iv. 18-20. Mark i. 16-18. i. 29. xii. 20. John vi. 7. xii. 20-22.) tradition has added several particulars of his certain authenticity. Eusebius relates, (Eccle Hist. lib. iii. c. i. p. 72.) that, when the apostles arranged the objects of their mission for the propagation of Christianity, Andrew made choice of Scythia. Other accounts are less worthy of credit than this.

"The Acts of the passion of St. Andrew," which mention his martyrdom at Patre, in Achaia, and said to be written by the priests of Achaia, are preferred in Surius's History of the Saints, and approved by Baronius, Bellarmine, and others of the Romish communion; but they are rejected by the best critics as spurious. The ancients, says Dupin (History of the Canon, &c. vol. ii. p. 140.), knew no other acts of St. Andrew besides those which had been corrupted by the Manichæans, mentioned by Eusebius, (Eccle Hist. lib. ii. c. 25.) Philostratus (Heres. 87.) Epiphanius (Heres. 47. n. 1. Id. 61. n. 1. Id. 63. n. 2.) and Angullus (2d conf. Manicheos.) and which pope Gelasius has placed among the apocryphal writings. This work was not cited till the seventh century; and neither its doctrine nor language agrees with those of the early ages. Besides, these Acts of St. Andrew are not found in any of the ancient catalogues of the sacred books, nor are they appealed to by any Christian writers, nor read in any of their assemblies, but on the contrary expressly condemned as an impious forgery by every one who has mentioned them. As they contained some doctrines which were favourable to the Manichæans, Encratites, Apotætists, or Apollinarians, and Origenists, it is no wonder that they should have esteemed this apocryphal piece above other scriptures. The "Gospel of Andrew," and other books that have been factioned by his name, belong to the same class of apocryphal writings. The relation of those who say that he was crucified on a cross in the form of the letter X, hence vulgarly called St. Andrew's cross, or on an olive tree, which others have ascribed, is entitled to no credit; nor indeed is it certain that he was crucified. According to Jerome (Adv. Vigil. p. 22.) his body was removed from St. Luke's to Constantinople in 357. The accounts of this apostle that are given by Gregory of Tours in the fifth century, by Nicephorus of Constantinople in the 9th, and by Nicephorus Callinicus in the fourteenth, contain many fabulous particulars. The legend of Gregory, therefore, will claim no regard; which informs us, that dreams of oil flowed from the tomb of this saint on the anniversary of his martyrdom, and sometimes swelled to the middle of the church. Dupin, ubi supra. Jones's Canon, vol. i. p. 145—187. Fabr. Cod. Apost. Nov. Tell. p. iii. p. 526.

ANDREW, Bishop of Cæsarea, in Cappadocia, lived, according to Cave, about the year 500. He wrote a commentary upon the book of Revelation, prefacing it with an exhortation of the book, for which he was accused by the authorities. He was of Cyril of Alexandria, Bishop of Ephesus, Methodius, and Hippocrates; and reducing it into 24 larger, and 72 smaller sections. He appears to have received as authentic all the books of the New Testament which we receive; he mentions the symbols of the four evangelists, viz. the lion for John, the calf for Luke, the eagle for Mark, and the man for Matthew. After citing some opinions with regard to the period of about a thousand years, mentioned in this book, he considers it as denoting the time of the preaching of the gospel, or the time of the gospel dispensation. Cave. Hist. Lit. tom. i. p. 467. Fabr. Bib. Græc. tom. vii. p. 791. Lardner's Works, vol. v. p. 240—252.

ANDREW, bishop of Samoëtana, was an intimate friend of Theodoret, and flourished in the fifth century. About the year 429 he was appointed by John, bishop of Antioch, to refute, on behalf of the eastern bishops, the "Anathemas" of Cyril. Under the pretence of illness he declined attending at the council of Ephesius; however, he vigorously opposed the Nestorians, and for many years renewed his hostilities against Cyril. Some curious extracts from his first book against Cyril are found in Cyril's "Apologias for
AND

Andrew, bishop of Crete, was a native of Damascius, and flourished at the close of the seventh and beginning of the eighth century. Cave places him about the year 635. The early part of his life was spent by him as a monk of Jerusalem. Theodoret, patriarch of Jerusalem, invited him to attend the sixth general council of Constantinople; and he afterwards copied the acts of that assembly against the Monothelites. He was appointed bishop of Crete, and probably remained in that see till his death, about the year 720. He wrote several homilies, which are extant; and which, according to Mosheim, (Ecc. Hist. vol. ii. p. 174.) are delectable of true piety and eloquence. They were collected, and published in folio by Francis Combelsius, at Paris, in 1644. Cave, Hill. Lit. vol. i. p. 582. Fabr. Bib. Grec. lib. v. c. xii. § 2. tom. x. p. 121.

Andrew, John, secretary of the Vatican library, was employed under the popes Paul and Sextus IV. When printing was first introduced into Rome, in reviving MSS., writing prefaces and dedications, and correcting the press. Cardinal de Cusa, who had been his school-fellow, gave him the bishopric of Accia in Corsica; and pope Paul II. afterwards appointed him to that of Aleria in the same island, where he died. He published an edition of Livy, and of Aulus Gelius, printed at Rome, in folio, in 1469; of Herodotus, in 1473; and of Strabo, printed at Venice, in folio, in 1472. He was also the editor of the Epistles of Cyprian, and of the works of St. Leo. Nouv. Dict. Hist.

Andrew, prebendar of Ratihon, was an historian of the 14th century, and flourished under the emperor Sigismund. He wrote in Latin "A Chronicle of the Dukes of Bavaria," published at Ansborg; and "A History of Bohemia," in seven books. His countrymen called him a second Livy. Volf. de Hist. Lat. lib. iii. c. 5.

Andrew I. king of Hungary, was a prince of the bloodroyal, and eldest son of Ladislaus the Bald. When king Peter was restored in the year 1044, he was obliged to take refuge in Russia; but the idolatrous Hungarians promised to kill Peter, and to expel all foreigners, provided Andrew would abolish the Christian churches. The compact was fet; and, after a great slaughter and plunder, Andrew was placed on the throne in 1047; instead of Peter, who was imprisoned, loft his eyes, and soon died. Andrew, however, in violation of his promise, obliged all his subjects to profess Christianity. After having settled his disputes with Albert of Austria, he invited his brother Bela, with his family, to settle in Hungary, and assigned him a third part of his dominions. When the emperor Henry III. invaded Hungary, he was reduced to such straits by Andrew and Bela, that, in order to avoid total destruction, he entered into a treaty, of which it was one condition, that the daughter of Henry should be married to Solomon, the son of Andrew. This son was five years old, and he was then crowned; but, fearing that his brother Bela would disturb the succession, Andrewsent for him, and instructed two of his confidential servants to act. "I shall oblige him," said the king, "a crown, the symbol of the royal authority, and a sword, that of the church. If he choses the former, militantly put him to death; if the latter, let him live." An officer, who overheard this order, whispered to Bela, "chafe the sword." Accordingly he took the sword, and his brother Andrew was satisfied; but Bela soon after retreated to Poland, and came from thence at the head of an army to dethrone him. Andrew was protected by the emperor; but, meeting his brother on the banks of the Tefts, he was defeated, abandoned by his own men, and killed in the pursuit, A. D. 1059. Mod. Un. Hist. vol. xxxii. p. 107.

Andrew II. king of Hungary, was the second son of Bela III. Having occasioned a rebellion against his elder brother, he was defeated by his army, and, in endeavouring to make his escape, taken prisoner, and brought to Emeric, by whom he was freely pardoned. From this time his sentiments were changed, that he became a steady supporter of the throne. After the death of his nephew Ladislaus, Andrew succeeded, and was crowned by the universal consent of the fathers. During the first twelve years of his reign he enjoyed unmitigated peace; but when pope Honorius III. ordered a new crusade to be preached, Andrew resolved to make an expedition into the Holy Land. He proceeded to Constantinople; but there he heard that during his absence a tragical event had occurred in his kingdom. The government had been entrusted to Banchanus, one of the nobles, and it was administered to universal satisfaction. But the wife of the governor, who was very beautiful, was debauched by Queen Gertrude's brother, who visited her during the king's absence, and the queen was accessory to the defilement. The injured lady informed her husband of this atrocious act; upon which he revenged himself by slaying the queen; and, rushing out into the street with his bloody sword, he published his wrongs, and the revenge he had taken; declaring, at the same time, that he would not decline a trial, but go immediately to Constantinople to receive the sentence of the king. Andrew acquitted him, and ordered him back to his government. At the trial the accusation against the queen was found to be just. Banchanus was acquitted, but his family was ruined by the resentment of the king's sons. Andrew transported his troops into Syria, and displayed his courage in some conflicts with the Saracens; but, being weary of the expedition, he determined to return home, though he was threatened with excommunication by the patriarch of Jerusalem. He proposed, however, to leave one-half of his troops in Palestine, under the command of the duke of Austria, and with the other half he was allowed to return into Hungary. Accordingly he set sail on board the Venetian fleet, with a variety of precious relics, and with the title of the " Hierofolymitan;" and, in his visit to the prince of Elia, by whom he was honourably entertained, he fell in love with his daughter, married her, and took her with him into Hungary. The remaining period of his reign was devoted to the business of healing the discontents of his subjects, and forming a system of legislation. Besides other measures which he adopted, he was the author of a famous decree, which confirmed and augmented the privileges of the nobility, and allowed them to take up arms in their defence, if he or his successors attempted to abridge them: a stipulation nugatory against a powerful monarch, and which has answered no other purpose than that of rendering the arisocracy less a nation, and the body of the people slaves. Towards the end of his reign the Tartars made some successful inroads into Hungary. Andrew, having reigned 31 years, died in 1255, and left the kingdom to his eldest son Bela, to whom he had ceded the sovereignty before his death. Mod. Un. Hist. vol. xxxii. p. 120-123.

Andrew III. king of Hungary, was the grandson of Andrew II. and being born and brought up in Venice, obtained the surname of "Venetian." On the death of Ladislaus in 1290, he succeeded to the throne, in opposition to a number of competitors, by the unanimous consent of the Hungarians. In his way from Italy through Austria he was detailed.
detained by Duke Albert; and obtained a release by promising to espouse Agnes, the duke’s daughter. But in the year after his ascension he declared war against Albert, and laid waste the country, till at length a peace was obtained by the intercession of the prelates. Upon his return to Hungary, Andrew found his kingdom in a dismembered state; the pope and many of the ecclesiastics and nobles having acknowledged the right of Charles Martel, who, in consequence of their invitation, had set out for Hungary with his wife and fan. Charles Robert, on christening, was an infant. The majority of the Hungarians were attached to Andrew; but as the party of Charles was very numerous, and Andrew having no children, Charles continued in possession of part of Hungary for several years without opposition. The two rival kings are said to have both died in the same year, 1291. Charles, having gone to the jubilee at Rome, died at Naples. Andrew died at Buda, and, leaving no male issue, the line of St. Stephen terminated in him. Mod. Un. Hist. vol. xxxi. p. 120.

Andrew, Knights of St. Andrew, or the Thistle, commonly called the Order of St. Andrew, in Scotland; according to John Lesley, bishop of Ross and others, was instituted by Achaicus, king of Scots, in memory of an appearance in the heavens of a bright croft in fashion of that whereon St. Andrew suffered martyrdom, and seen by that king the night before the battle which he fought with Athelstan, king of England, over whom prevailing, he went in solemn procession to the kirk of St. Andrew, to thank God and his apostle for the victory; promising that they and their posterity should ever have the figure of that croft in their ensigns and banners. Favin, in his Theatre of Honour, relates it to be instituted upon the famous league, offensive and defensive, made between Achaicus and Charlemagne, king of France; to preserve the memory of which alliance, Achaicus added the treasured of fleurs de lys to the lion, the then royal arms of Scotland, and took for device the thistle and rue, which he composed into a collar of his order; and for his motto, Pour nos defence. Menenius makes these the symbols of two different orders; one of the Thistle, whence the Knights were so styled, and the motto, Nemo me impune lacessit; the other called Scottum Ratus, or Garland of Rue: nevertheless, to both collars hung one and the same jewel, that is, the figure of St. Andrew bearing his crofts. Their solemn meeting was annually on St. Andrew’s Day, in the church of the town dedicated to his name; at which the knights, thirteen in number, in allusion to our blessed Saviour and the twelve apostles, were richly habited, and wore their parliamentary robes, having thereon embroidered on their left shoulder an array round charged with a fuller argent, St. Andrew’s crofts enflled in centre, with a crown composed of fleur de luce or. The sudden death of James V. of Scotland, the rebellion against Queen Mary, and the troubles which ensued in that kingdom nearly extinguished the order, which continued to be neglected until it was revived by King James II. of England, who, on the 29th of May, 1687, allowed his warrant for letters patent to be made out and passed per fallum, under the great seal of Scotland. In consequence of this revival several new knights were made, and the order continued to flourish during the remainder of that king’s reign; but on his abdication, and the advancement of King William to the throne, the order was again diffused.

Queen Anne, by her letters patent, bearing date at St. James’s, 31st Dec. 1703, revived, continued, and re-established the order; and ordained by the statutes, “that the number of knights should consist of twelve besides the sovereign, making in the whole thirteen, as heretofore; that the sovereign’s habit should be such as the sovereigns them-
AND

**Patronus Ruffin;** and in the middle an A. the initial of the empress Anne, who framed the statues, and asigned the habit of the order. The feast is held on the 30th of November. In 1793 it had 63 knights. The badge is fastened to a blue ribbon, and suspended from the right shoulder; but at fesitals is pendent to a collar of gold composed of square chains and roses.

**Andrew's Crofs,** is a badge worn in the hat by the people of Scotland, on the day of the feast of that Saint.

It consists of blue and white ribbands, disposed into a crofs, or faiter; and is intended as a commemoration of the crucifixion of St. Andrew, the tutelary Saint of Scotland.

**Andrew's St. in Geography,** an ancient town of Scotland, in the shire of Fife; and formerly the metropolis of the kingdom of the Picts. It is leated on an eminance, and commands an extensive prospect. N. lat. 56° 18'. W. long. 2° 37'. The legendary account of the origin of this city is as follows: St. Regulus, a Greek of Achaea, being warned by a vision to leave his native country, and to visit Albion, an illfated in the remotest part of the world, was instructed to take with him the arm-bone, three fingers, and three toes of St. Andrew. After a tempestuous passage he was shipwrecked on the coasts of Othelonia, in the territory of Hergulis, king of the Picts, in the year 370. The king, as soon as he heard of the disfalter, ordered the strangers to be refpeetfully received, and granted to the fain his own palce, near which he built a church, called St. Regulus. The place was then fyled Mucrofs, or the Land of Boars. St. Regulus changed the name to Kirkymont, and established the first Christian priefh of the country, called Culdees. This church was fupreme in the kingdom of the Picts, and un- gus the king ordained that the crofs of St. Andrew should come the badge of the country. In 518, after the con- quett of the Picts, the epifcopal fce was established at St. Andrew's, and the bishop was fyled, **"Maximus Scotorum Epifcopus."** It is faid to have been erected into an arch- biffhopric at the intercettion of James III. This fce contained the greteft part of the shire of Fife, with a part of Perth, Forfar, and Kincardine shires, and a very large number of parifhes and churches in other dioces.

The town of St. Andrew's was erected into a royal bo- rough by David I. in 1140, and its privileges were afterwards confirmed. The charter of Malcolm II. on a small piece of parchment, is preferved in the toboleh; and here are also deposited the silver keys of the city, which are delivered to the king if he fhoald visit the place, or to a victorious enemy. The axe, which in 1646 took off the heads of Sir Rt. Spot- woud, and other diftinguifhed loyalfaits, is fhewn in this place. St. Andrew's is now much reduced as to the number both of houses and inhabitants, the latter being estimated at about 2000. It is ftil decorated with magnificent relics of its ancient splendour. The principal of thofe is the cathedral, which was founded by bishop Arnold in 1161, but it was not completed till the year 1318. Its demotion, however, was efeected by John Knox and his followers, in 1559, in one day. The eafther end, with its two high pinacles, is complete; and one turret of the weft point yet remains, adorned with fome curious carved work in a peculiar fyle; but the pillars and fome of the arches of the fide aile, exhib- it a fpecimen of the pure Gothic, when it admited of very little ornament: the precinct of this church forms a common burial-place to the town. In the centre of the inclofure is a plain, square tower, of a very extraordinary height, different in its structure from the cathedral, and not unlike fome of the relics of Norman architecture in England. This is the tower of the chapel of St. Regulus, the body of which re- mains, but the inside chapels are demolished. The arches of the windows and doors are round, and fome exceed fo circles; whence we may infer the antiquity of the building. Some trace it to a very early period; but it is com- monly thought to have been founded in the eighth century, and efteemed the earlieft Christian church in Scotland. The priory was founded by Alexander I. in 1122; and the monks, who were canons regular of St. Augustine, were brought from Scone in 1140, by Robert, bishop of this fee. By an act of parliament in the reign of James I. the prior had precedence of all abbeys and priors; and on the feftival days wore a mitre and all epifcopal ornaments. The revenues of this priory were very considerable, being in mo- ney 2237L. 28s. 10d. besides large quantities of different forts of grain, and 480 acres of land. The ruins adjoin to thofe of the cathedral; and nothing now remains but the inclofure wall, which encroaches a large area, and one fingle arch, very much defaced. The inclofure extends from the cathedral to the shore. Above the harbour stood the collegiate church of Kirk-heugh, originally founded by Conflan- tine III. who is faid to have retired either from the world, and to have become a Culdee. The remains of the castle oc- cupy the fummit of a high eminance, which overlooks the coast. Separated from the town, by a deep chaffin, over which was a draw-bridge, and from the country by an impetu- ous sea, foaming over a rocky bed, this castle was juftly efpe- cted one of the strongest fortifications in the island. It was founded in 1451 by bishop Trail; and it was the refi- dence of cardinal Beaton in the zenith of his power and prosperity; but with all his attention to render it, as he con- ceived, impregnable, it was not of fufficient strength to de- fend an ambitious ruler against the rage of an exasperated people. In this fortrefs the cardinal was fparing by Nor- man Leflie, with 15 attendants, in 1546, and affaffinated in the midst of his numerous retainers. In 1547 the castle, po- fefled and guarded only by 150 men for five months, was at last reduced and demolished. The death of Beaton led to the downfall of the Catholic religion in Scotland; and with that religion the finest edifices of St. Andrew's moulder- into ruins, its castle was neglected, and the city deferted. The entrance into the castle is till visible; and ftrangers are fhewn the window out of which, it is faid, the cardinal leaned to enjoy the crucifixion are the place of George Wishart, who was burnt on an adjoining fpot. Of the four great parallel streets of this city, only one now remains entire, one being totally lofd, and other two in a very decayed condition. The university of this city was founded in 1411 by bishop Wardlaw. It conflited once of three colleges. St. Salvator's was founded in 1558 by bishop Kennedy. This is an irregular pile of building, of confiderable extent, united with a large church, which contains a fine old monument of the founder, who died in 1466. The interior of the college, though spacious, is gloomy, and consists of two large old halls, and a range of apartments in rather a more modern style, of which, however, only one side is finifhed. The college of St. Leonard was founded by Prior Hepburn in 1523, but it is now converted into private houses, and the collegiate part is united with the laft. The third college is the New, or St. Mary's, which was established by Archbishop Hamilton, in 1553; but the house was begun by James and David Bea- ton, who did not live to complete it. This has a far more cheerful appearance than the old college, though it is much smaller. The library belonging to the whole university is connected with this college. In this library are kept two curious maces, exquisitely carved in brass work, and a fourth is preferred in the audit-room of the old college. These maces were dug for under the great altar of the cathedral by the direction of an old man, who was told to have in his possession
paffion many papers relating to the church and its environs; six were found, one of which was presented to each of the three universities of Edinburgh, Glasgow, and Aberdeen; and the other three are kept at St. Andrew’s. On the site of this college formerly stood, as it is said, a “Schola bulbuli” long before its establishment into an university. It is called the “New College,” because of its late erection into a divinity college by the archbishop.

This university is governed by a chancellor, who is elected by the two principal, and the professors of both the colleges. The rector is the officer to whose superintendence are committed the privileges, discipline, and duties of the university. Each college has a principal; that of St. Salvator has nine professors, and the New College has five professors. The students in the former are generally about 100, and in the latter about 30. This university has many advantages to recommend it in point of situation, instruction, and discipline.

The commerce of St. Andrew’s is inconsiderable; and its manufactures, whatever they might formerly be, are reduced to that of golf-balls, which maintains a great number of people.

Andrew’s, St. Bay, is situated between the Forth and the Tay. The haven is defended from the violence of the easterly sea by a stone pier; the entry is very narrow, and it has only seven or eight feet at neap tides, and ten or eleven at spring tides. The city is at the bottom of the bay close upon the shore.

Andrew’s, St. A small town of America, in the contested country between New Brunswick and the United States, situated behind an island of the same name, on the east side of the arm of the inner bay of Passamaquoddy, called Scoodick. The town is laid out in the form of an oblong square, and the inhabitants are chiefly employed in the lumber trade.

Andrew’s, St. is a township in Caledonia county in Vermont, 100 miles north-east from Bennington.

Andrew’s, St. is also a parish in Charlestown district, South Carolina, containing 2947 inhabitants, of whom 370 are whites, and 2540 slaves.

Andrew’s, or Andrea, St. Bay, a secure harbour in the gulf of Mexico, on the south coast of West Florida in North America. It is situated between Santa Rosa bay on the north-west, and St. Joseph’s bay on the south; and being almost surrounded by land, is well sheltered from all winds. N. lat. 30° 15’. W. long. 85° 45’.

Andrew Bay, lies on the south shore of the Straits of Magellan, between Port Holland on the west, and Cordes bay on the east, at the entrance of which there is a good anchorage in 12 fathoms water.

Andrew’s, St. of Andrea, Cape, lies on the west coast of Madagascar island, in the Indian or eastern ocean, and nearly call from Mozambique, on the coast of Africa. S. lat. 15° 46’. E. long. 45° 22’.

Andrew’s, St. Cape, lies also on the eastern coast of South America, between Rio de la Plata, on the north-north-east, and Anegada bay on the south-south-west. S. lat. 37° 55’. W. long. 66° 45’.

Andrew’s, St. Cape, is also on the north shore of Magellan Straits, in the reach which trends from Cape Forward to the West.

Andrew’s Cape, or Andrea, lies on the east point of Cyprus. N. lat. 35° 31’. E. long. 34° 56’.

Andrew’s, St. Island, or Andrea, is a small island in the gulf of Venice, on the west side of Lissa island.

Andrew’s, St. River and Point, lie on the coast of Africa, north-east by east from Cape Palmas, at the distance of 20 or 30 leagues. They are situated in that track of coast, extending seven leagues, which is called the Red Cliffs, or Red Land. Although no ships go up this river, a considerable traffic is carried on by means of the canoes of the Negroes, who bring down teeth for sale. Wood and water may be procured here, but no provisions.

Andrew’s, St. Sound, lies south of Jekyll’s island, and is formed by this and a small island at the mouth of the Great Sagilla River. The small river opposite to this found separates Camden from Glynn county, in Georgia.

Andrew’s, Lancelot, in Biography, an English divine, was born at London in 1565, and was bishop of Winchester, in the reign of James I. and Charles I. From Merchant Taylor’s school he was sent to Pembroke Hall in Cambridge; and by his affluence application he became acquainted with the sciences and modern languages, and he excelled more especially as a mathematician, and was often consulted in cases of confluence. The following anecdote will illustrate this part of his character: a corpulent alderman of Cambridge, who had been often reproved for speaking at church, and whose confluence troubled him on this account, applied to him for advice. Andrew told him it was an ill habit of body and not of mind, and advised him to eat little at dinner. The alderman tried this expedient, but found it ineffectual. He applied again with great concern to Andrews, who advised him to make a hearty meal as usual, but to take his full sleep before he went to church. The advice was followed, and the alderman came to St. Mary’s church, where the preacher was prepared with a sermon against speaking at church, which was thrown away, for the old alderman looked at the preacher during the whole sermon time, and spoiled his design. Andrews’s lectures, as a caufet, were attended by a numerous auditory. His learning, popular talents as a preacher, and zeal for the Protestant cause, procured him the patronage of Henry Earl of Huntingdon, and Sir Francis Walsingham, secretary of State to Queen Elizabeth; and he passed through several stages of preferment to the deanery of Westminster. Whilst he resided in London as prebendary and residuary of St. Paul’s, he read divinity lectures in that cathedral three times a week during term time; and he also maintained a connection with his college, of which he was chosen a master, and to which he was a liberal benefactor. Andrews’s style of preaching, which was pedantic and quaint, suited the taste of King James I. so that he was a great favourite with this prince. The king selected him in order to vindicate his sovereignty against the vehement attack of Balfarine, who, in reply to ‘‘James’s Defence of the Rights of Kings,” had written a tract under the fictitious name of Matthew Tortus. The dean’s answer was intitled “Tortura Torri,” or Tortus Tortured, and printed in 1609. This service was so acceptable, that in this year he was advanced from the see of Chichester, to which he had been promoted in 1605, to the bishoprick of Ely; and he was also nominated a privy counsellor, first for England, and afterwards for Scotland, where he attended the King in his journey to that kingdom. In 1613 he was raised to the bishoprick of Winchester, and the deanery of the king’s chapel, which preferments he held till his death, which happened at Winchester-house, in Southwark, in 1628, in the 71st year of his age. He was buried in the parish church of St. Saviour’s, Southwark, and a monument of marble and alabaster was erected over his grave, on which is an epitaph written by one of his chaplains in the highest style of panegyric. Bishop Andrews appears to have been a man of eminent talents, acquisitions, and virtues. He is said to have understood 15 languages: he employed a large portion of each day in devotion and study; and his learning and affability commanded the respect not only of his own countrymen,
men, but of foreigners, by whom he was visited; such as Vossius, Grotius, Caubon, Cluerius, Erpinius, and Dumoulin. His first biographer, Isaacson, informs us, that in the distribution of preferment he was disinterested, impartial, and judicious; that he provided liberally for the dependents of his early instructors and benefactors; that, after he became bishop, he never visited either of the universities without leaving 50 or 100l. to be distributed among poor scholars; that his charity kept pace with his advancement, his private alms amounted in the last six years of his life to upwards of 1300l. and that, as he died a bachelor, he left large legacies to charitable uses; and among the rest, a great part of his estate to be distributed among his servants. Bishop Andrews was a faithful son and zealous defender of the church; at the same time he was moderate in his political principles, independent in his spirit, and superior to the mean adulation that disgraced the court of James, as the following anecdote, related in the life of Waller the poet, will shew. Mr. Waller, going to the king at dinner, overheard a conversation between his majesty and two prelates, the bishop of Wincheste and Dr. Nalke, bishop of Durham, who was flourishing behind the king's chair. His majesty asked the bishops, "My lords, cannot I take my subject's money when I want it without all this formality in parliament?" The bishop of Durham readily answered; "God forbid, Sir, but you should; you are the breath of our pulps." Whereupon the king turned and said to the bishop of Wincheste, "Well, my lord, what say you?" "Sir," replied the bishop, 1 have no skill to judge of parliamentary cases." The king answered, "No put off, my Lord, answer me presently." "Then Sir," said he, "I think it lawful for you to take my brother Nalke's money, for he offers it." Milton thought bishop Andrews worthy to be celebrated by his pen; and, at the age of 17, wrote an elegy on his death, abounding with that rich fancy which has rendered his works immortal. The works of bishop Andrews, besides that already mentioned, are, "A Manual of Private Devotions," "A Manual of Directions for the Visitation of the Sick," a volume of tracts chiefly in Latin, containing sermons, theological dissertations on the ecclesiastical rights of princes, tythes, usury, &c.; published in 1629; a posthumous volume of "Sermons," published in folio by direction of the king, and under the inspection of the bishops of London and Ely; "The Moral Law explained, or Lectures on the Ten Commandments," with other sermons, printed in folio in 1642; and "A Collection of Poetical and Orphan Lectures," delivered at St. Paul's and St. Giles's, Cripplegate, printed in folio in 1657. The sermons of bishop Andrews, though learned and pious, afford many specimens of that pedantry and fable which marked the period in which he lived, and cannot be read with pleasure in an age of more correct taste. Biog. Brit.

ANDRIA, in Antiquity, a name given by the Cretans to the public entertainments, at which whole cities, tribes, or other bodies of men, were present. They were first instituted by Minos of Crete, and, after his example, appointed by Lycurgus at Sparta. They were conducted with the greatest frugality and decorum, and persons of all ages were admitted to them. The hall, or place of eating, where these entertainments were held, was designated androtrion, in the uppermost part of which was a contract table, set apart for strangers.

ANDRIA, also used by some naturalists, to denote a species of hemaphrodite, wherein the female sex has the preponderance.

ANDRIA, in Ancient Geography, now the Indre, a river of the interior of Gaul, which, uniting with the Care, discharges itself into the Liger.

ANDRIA, a town of Greece, in the district of Elia.

ANDRIA is also a town of Macedonia.

ANDRIA, or ANDRIACA, in Geography, a town of Italy, in the kingdom of Naples, and province of Bari, the see of a bishop suffragan of the archbishop of Trani. It is situated in a valley with hilly environs, about four miles from the coast of the Adriatic, five miles west-south-west of Trani. This town is said to have been built by Peter the Norman, and to have derived its name from the antra or caverns in which the first settlers took up their abode. N. lat. 41° 15'. E. long. 16° 47'.

ANDRIACA, in Ancient Geography, a town of Thrace, on the coast of the Euxine sea, near Salmydeus, according to Strabo.

ANDRIA is also a town of Asia Minor, in Lydia. According to Appian this was the port of Mira; but M. d'Anville places it to the south-west of Mira.

ANDRIA is a town placed by Tolemeus in Media.

ANDRICUS, or ANDRIPOLUS, a high mountain in Cilicia Trachis, placed between the promontory of Ancamium, and the river Selius.

ANDRICUS, a river of Cilicia, according to Polybius.

ANDRIMACHIDES, a people of Africa whose country is not known; but Alexander ab Alexandro reports, that their king obtained the first favour of the young women before they were introduced to their husbands.

ANDRINOPE, in Geography. See ADRIANOPE.

ANDRIPOURA, or Indrapor, a country of the island of Sumatra, including a town of the same name, and several others; the chief article of commerce is pepper. The town is situated on a rapid river, 60 miles north-west of Bengkoolen. S. lat. 2° 15'. E. long. 101°.

ANDRISCU, called by the Romans Pseudo-philippus, in Geography, is said to have been a native of Aderamytum, and descended from mean parents. He assumed, however, the character of a natural son of Peres, 16 years after the death of the king of Macedon, pretending, that his father had sent him to Aderamytum in disguise, and that he was not to disclose the secret of his birth till he arrived at the age of 14 years. Refusing Peres in his person, the story was more credible; and accordingly he went to the court of Demetrius Soter, who had married a daughter of that king. Demetrius, either suspecting the imposture, or dreading the Romans, delivered him up to the republic. From Rome he made his escape, and sought refuge in Thrace. Here he assembled a number of perfons, who became attached to his interest, and, marching to Macedon, he asserted his rightful title to the crown. Having made himself master of the country, he extended his conquests to the adjacent parts of Greece. Scipio, the Roman general, was sent to restrain him; but, by the aid of a body of auxiliaries, he drove him back to Macedon. When the emperor Metellus had commissione to terminate the war, he advanced to Macedon, and was attacked, defeated, and slain by Andricus. In consequence of this advantage Andricus was established on the throne, and the Carthaginians sent ambassadors to congratulate him, and to propose an alliance. Andricus, however, could not endure prosperity; but became cruel and oppressive, and lost the affection of his subjects. At this time the Romans sent Q. Caecilius Metellus to Macedon, and Andricus was under a necessity of valiantly contending for his crown and life. After some trilling advantage which he gained at first, he was entirely defeated, and compelled to retire into Thrace. The Thracians enabled him to return with a numerous army, but he was again defeated by Metellus;
tellus; and seeking refuge with Lyzas, a petty prince of Thrace, he was delivered by him to the Romans. Metabol led him in triumph, in the year before Christ 147; and he was afterwards put to death by the Senate. The Roman general, who succeeded in the war against Andronicus, obtained the appellation of Macedonius; and it has been doubted whether Andronicus was an impositor, or the son of a king. Mod. Uni. Hist. vol. vii. p. 98—137.

Andrias, in Ancient Geography, a river of Asia, which, according to Strabo, ran into the Scamander.

Andro, P. K. in Geography, in the island of Belle tite, on the coast of France, is round the extremest point of the island, called Print de Locmaria on the south half.

Androcalis, in Ancient Geography, a town of Ethiopia, near Egypt, according to Plan.

Androdias, in Ancient Writers, denotes the fortythird year of a man's life, otherwise called annus Egyptianus, and dimoral wignus.

Androgeus, in Etymology, a species of Papilio (Eq. Tr.) that inhabits Sumna. The wings are black and bronzed; on the under side painted spots of blue, red, and yellow. Fabricius and Gmelin. This species is very similar to papilio polydamas; and the Papilio acanthus of Cran mer is considered as a variety (5) of it.

Androgyne, in Botany, plants bearing male and female flowers on the same root, or bearing fonic flowers with stamens only and fome with pistils only on the same root, without any mixture of such are hermaphrodite. Of this we have examples in the melon and cucumber.

Androgynum, in Ecclesiastical Writers, is used to denote matrimony, or even one of the parties married.

Androgynum, balneum, denotes a bath common to both sexes.

Androgyne, or Androgyne, adrōgyν, a compound of adrō, man, and γυν, woman, q. d. man-woman, an appellation distinguishing those living creatures, which, by a monstrons formation of their generative parts, seem to unite in themselves the two sexes, that of the male and female, and synonymous with hermaphrodite. See Hermaphro dite. The term is also applied in ancient mythology to fabu lous creatures, each individual of which possessed the faculties and distinguishing characters of both sexes, having two heads, four arms and feet. Some fanciful writers have reported, that the first man was created with two bodies, a male and a female, and that of these God made two persons, by separating one body from the other. See Adam. It is generally said, that this was a fiction of the Rabbits; but there is reason to believe that it was of more early original. Plato's fable of the Androgyne indicates the tradition to which he had recourse; and it confirms the supposition, that a fragment of this kind might have had its first rise in the early times, when the Egyptians and Phenicians disgruntled the plain narratives which they found of the origin of things with their fables and mythology. See Enech. Prep. Evangel. lib. i. c. 10. According to Plato's account (in Conviv. Oper. vol. iii. p. 157. ed. Serrani) the Gods formed man with two bodies and two sexes. This fantastic being, possessing in itself the whole human fyltem, was endowed with a gigantic force, and became insolent, fo as to make war against the gods. Jupiter, exasperated at this insouler, determined to destroy it; but relenting, and averse from utterly annihilating the human race, he contented himself with debilitating this compound being by separating the male from the female, and leaving each half to subsist with its own powers alone. The office of reforming the separate bodies, and extending their skins so as to cover the whole surface, was asigned to Apollo, who imitated it to the unbiies. If this half rebelled, it was to be divided by another fiction, so that only one of the parts, which they composéd, should be left; and even the fouth part of a man was to be annihilated; it should perish in its obminity and frivolous attempts. The idea of these Androgynes might possibly be borrowed from a passage in Mose's account of the creation, in which he represents Adam as calling Eve "bone of his bone, and flesh of his flesh." A French poet has made an ingenious application of this fable of Plato. He attributes, as the philosopher does, the propinquity by which the sexes incline to one another to the mutual adornment which each half of the androgyne seek for reunion, and their inconsistency to the difficulty which each of the disjoined parts encounters in its efforts to recover its proper and original half. If a woman appears to us amiable, we instantly imagine her to be that modesty with whom we should only have constituted one whole, had it not been prevented by the influence of our original double-sexed progenitor.

"The heart, with fond credulity impris'nd,
Tell us the half is found, and hope for red;
But 'tis our cure, that sad experience shews,
We neither find our half, nor gain repose."

The alchemists also give the appellation androgyne to one of the planets as are sometimes hot, and sometimes cold, as Mercury, which is reputed hot and dry when near the sun, and cold and moist when near the moon.

Androide, in Mechanics, compounded of andros, ma θ, man, and izes, form, an automaton, in the figure of a man; which, by virtue of certain springs, &c. duly contrived, walks and performs other external functions of a man. Albertus Magnus is recorded as having made a famous Androide, which is said not only to have moved, but to have spoken. The construction of this machine must have been very ingenious and complex, if it be true that he was employed upon it 50 years. Thomas Aquinas is said to have been so frightened when he saw this head, that he broke it to pieces; upon which Albert exclaimed "Perit operis triginta annorum." Artificial puppets, which, by internal springs, run upon a table, and, as they advance, move their heads, eyes, or hands, were common among the Greeks, and from thence they were brought to the Romans. They were known by the name of "Neuropsilfa," and were much used at their shows. Ariosto (De Mundo, c. vi.) speaks of some which moved their heads, eyes, hands, and limbs in a very natural manner. They are also particularly mentioned by Galen, (De Utro partium, lib. iii.) Xenophon, (Sympos.) Antoninus, (De Seipla, ii. iii. iv. vi. vii. 3. xii. 97.) Horace, (Sat. ii. 7. 52.) Celsius, (lib. xiv. 1.) and others. That Daedalus made statues which could not only walk, but which it was necessary to tie, that they might not move, is related by Plato, (Meno, Oper. tom. ii. p. 97. and Enthypphon, Oper. tom. i. p. 11.) Ariosto, and others. The latter speaks of a wooden Venus, and informs us, that the secret of its motion consisted in pouring quick-filer into it. The Chiefe have used quick-filer for giving motion to puppets, and their method of doing it is described by Mufelerbrock, (Intro. ad Philol. Nat. vol. i. c. iii. iv. livii. p. 143, &c.) Figures or puppets, which appear to move of themselves, were formerly employed to work miracles; but this use is now superfeved, and they serve only to display ingenuity, and to answer the purposes of amusement. One of the most celebrated figures of this kind was constructed by Vaucanon, and exhibited by him at Paris, for the first time,
in 1738; and a particular account of it was published in the Memoirs of the Academy for that year. This figure represents a flute-player, which was capable of performing various pieces of music by wind issuing from its mouth into a German flute, the holes of which it opened and shut with its fingers. The figure was about 2½ feet high, placed upon a square pedestal 4½ feet high, and 2½ broad. The air entered the body by three separate pipes, into which it was conveyed by nine pairs of bellows, which expanded and contracted, in regular succession, by means of an axis of fleel turned by clock-work. These bellows performed their functions without any noise, which might have discovered the manner by which the air was conveyed to the machine. The three tubes, which received the air from the bellows, passed into three small reed-tubes in the trunk of the figure. Here they united, and ascending towards the throat, formed the cavity of the mouth, which terminated in two small lips, adapted in some measure to perform their proper functions. Within this cavity was a small moveable tongue, which, by its motion at proper intervals, admitted the air, or intercepted it in its passage to the flute. The fingers, lips, and tongue derived their proper movements from a fleel cylinder turned by clock-work. This was divided into 15 equal parts, which, by means of pegs pressing upon the ends of 15 different levers, caused the other extremities to ascend. Seven of these levers directed the fingers, having wires and chains fixed to their ascending extremities, which, being attached to the fingers, made them to ascend in proportion as the other extremity was pressed down by the motion of the cylinder, and, vice versa; then the act of one of a lever produced a similar act of or defect in the corresponding fingers, by which one of the holes of the flute was occasionally opened or floopped, as it might have been by a living performer. Three of the levers served to regulate the in-breaths of the air, being so contrived as to open and shut, by means of valves, the three reed-tubes above mentioned, so that more or less strength might be given, and a higher or lower note produced as occasion required. The lips were, by a similar mechanism, directed by four levers, one of which opened them to move the air a fleel passage before the other contrived them, the third drew them backward, and the fourth pushed them forward. The lips were projected upon that part of the flute which receives the air, and, by the different motions already mentioned, modified the tune in a proper manner. The remaining lever was employed in the direction of the tongue, which it easily moved so as to shut or open the mouth of the flute. The just succession of the several motions, performed by the various parts of this machine, was regulated by the following simple contrivance. The extremity of the axis of the cylinder terminated on the right side by an endless screw, consisting of twelve threads, each placed at the distance of a line and a half from the other. Above this screw was fixed a piece of copper, and in it a fleel pivot, which, falling in between the threads of the screw, obliged the cylinder to follow the threads, and, instead of turning directly round, it was continually pushed to one side. Hence, if a lever was moved, by a peg placed on the cylinder, in any one revolution, it could not be moved by the same peg in the succeeding revolution, because the peg would be moved a line and a half beyond it by the lateral motion of the cylinder. Thus, by an artificial disposition of these pegs in different parts of the cylinder, the figure was made by the successive elevation of the proper levers to exhibit all the different motions of a flute-player, to the admiration of every one who saw it. Another figure, constructed by Vaucanson, played on the Provençal shepherd's pipe, held in its left hand, and with the right beat upon a drum, or tambour de Basque. Another automaton, of the ingenious contrivance of Vaucanson, was a duck of the natural size, which moved its wings, exhibited all the gestures of that animal, quacked like a duck, drank water, ate corn, and voided something like excrement. We may here observe, that the flute-player of Vaucanson was not the first of its kind. In the beginning of the 16th century, the anonymous author of the poem, entitled, "Zodiacus Vitae," gave at Rome a figure made in like manner by a potter, but no account is given of its construction. The performances of Vaucanson were imitated, and even exceeded, by M. de Kempelen of Preßburg, in Hungary. The automaton constructed by this gentleman in 1769 was capable of playing chess. It was brought over to England in 1783 by its inventor, and remained here for more than a year. The figure is as large as life, in a Turkish dress, seated behind a table, with doors 3½ feet long, 2 deep, and 2½ high. The chair on which it sits is fixed to the table, which is made to run on four wheels. It leans its right arm on the table, and in its left hand holds a pipe; with this hand it plays after the pipe is removed. A chess-board of 18 inches is fixed before it. The table, or rather chest, contains wheels, levers, cylinders, and other pieces of mechanism, all of which are publicly displayed. The vellums of the figure are then lifted over its head, and the body is seen full of familiar wheels and levers. There is a little door in its thigh, which is likewise opened; and with this, and the table also open, and the figure uncovered, the whole is wheeled about the room. The doors are then shut, and the automaton is ready to play; and it always takes the first move. At every motion the wheels are heard; the image moves its head, and looks over every part of the chess-board. When it checks the queen it makes its head twice, and thrice in giving check to the king. It likewise shakes its head when a false move is made, replaces the piece, and makes its own move, by which means the adversary holes one. M. de Kempelen has exhibited his automaton at Petersburg, Vienna, Paris, and London, before thousands, many of whom were mathematicians and chess-players, and yet the secret by which he governed the motion of its arm was never discovered. He valued himself upon the construction of a mechanism, by which the arm could perform ten or twelve moves. It then needed to be wound up like a watch, after which it was capable of continuing the same number of motions. This automaton could not play unless M. de Kempelen, or his assistant, was near it, to direct its movements. A small square box was frequently consulted by the exhibitor during the game, and in this consulted the secret, which the inventor declared he could communicate in a moment. Any person who could beat M. de Kempelen at chess, was sure of conquering the automaton.

There have been many speaking machines, which seem to answer various questions propounded, sometimes in different languages, and even blow a huntsman's horn. The figure, or perhaps only a head, is often placed upon a box, the form of which, for the better deception, is filled with a pair of bellows, a founding board, a cylinder and pipes, suppos'd to represent the organs of speech. At other times the machine is only like a peruke-maker's block, hung round with a Turkish dress, furnished with a pair of arms, and placed before a table; and sometimes the puppet stands upon the table, or against a wall. The sounds are heard through a speaking trumpet, which the figure holds in its mouth. Some have pretended, that the voice of machines of this kind does not proceed from a man, but that it is produced by mechanism, like the music of an organ. Some affirm, that the voice issues from the machine itself; others, that the juggler answers, by speaking in the manner of ven-
trigleipsis, from the lower part of his belly, or by having the power to alter his voice; and hence believe that the answers are given by a man somewhere concealed. It is, however, well known, that a child or a woman is concealed in the juggler's box; or that some panion, in a neighbouring apartment, speaks through the wall to the puppet, and which conveys the answers to the spectators. The invention of such statues to speak, by this method, seems to indicate, that one can freely forbear conjecturing, that it was anciently employed to impose impositions; and many have imagined that the greater part of the statues were delivered in this manner. See Van Dale de Oraculis, 3.10. Anni. 1697, p. 291. Whether the head of Orpheus spoke in the island of Lesbos, or, as is more probable, the answers were conveyed to it by the priests, was a cause with the tripod at Delphi, cannot be now ascertained. That the impostor Alexander, however, caused his Alcubalus to speak in this manner is expressly related by Lucan. He took, says this author, instead of a pipe, the gulk of a crane, and transmitted the voice through it to the mouth of the statue. In the fourth century, when Bishop Theophilus broke to pieces the statues at Alexandria, he found some which were hollow, and placed in such a manner against a wall, that a priest could flap unperceived behind them, and speak to the ignorant people through their mouths. Theodor. Eccl. Hil. lib. v. c. 22. p. 218. Ed. Valphi. Beckman's Hist. of Inventions, vol. iii. p. 317. &c.

See Automaton.

ANDROPSY. formed of arv, man, and 
kapn. I take, in Antiquity, an action against those who protected murderers, by which if an Athenian were killed by a citizen of some other place, and such city refused to deliver up the criminal to punishment, it was held lawful to take three inhabitants of that city, and to detain them, till the murderer had either surrendered himself, or satisfied the law. This the Greeks called andropsia, and the Romans claritatio. Some authors also use andropsy for repri

SALS.

ANDROMACHA, in Entomology, a species of papilio (Parnassius) that inhabits New Holland. Wing above and beneath alike, dotted with black; anterior pair naked, posterior pair yellowish. Fabricius and Gmelin.

ANDROMACHA, a species of sphinx, (zygaena of Fabr

icius) that inhabits America. It is black, wings transparent, margin and band black, tail red. Gmelin. The sphinx canaus of Cramer is supposed to be a variety of this species.

ANDROMACHE, in Biography, the wife of Hector, was the daughter of Aetion, king of Thebes, in Cilicia. She lived in the happiest conjugal union with her husband till his death. At the siege of Troy she had the affliction of witnessing the precipitation of her son Aityanax from a high tower, and of being herself a captive slave to Pyrrhus, the son of Achilles, who was the deadly foe of Hector. She afterwards became the concubine of Pyrrhus, and had children by him. After the death of Pyrrhus, or, as some say, during his life, she married her fellow-captive Helenus, a son of Presm, and brother of Hector; and she reigned with him over part of Epirus, and perpetuated a race from whom Pyrrhus, king of Epirus, the antagonist of the Romans, is said to have sprung. Several tragedies, ancient and modern, have been composed on the subject of Andromache; but the interest of the most pathetic poem probably arises from sentiments foreign to her period and character. Gen. Duf.

ANDROMACHUS of Crete, was physician to the emperor Nero. He invented the composition, called after him, Theriac Andromachi, which he dedicated to the service of Nero, in a copy of Greek verses that have been preferred to the present time. Galen wrote two books in commendation of the medicine. It was given as an antidote against the poison of the viper, and was soon supposed to have equal power against all other poisons, and to prevent or cure malignant and infectious fevers. The emperor Antoninus is said to have made daily use of the composition, and it was kept constantly prepared in the palace by several succeeding emperors. The formula, or process for making it, is described by Aristaedus and by Galen, as well as by the inventor in his verses to Nero. The Venetians became so famous for making this medicine, which they sold for sale to all parts of Europe, that it is now more commonly known by the name of Theria Veneta. Venetian, than by that of the inventor. Andromachus is said to have been the first physician who was dignified with the title of Archiater. Haller, Bib. Med. Prat.

ANDROMEDA, in Astronomy, a constellation of the northern hemisphere, representing the figure of a woman almost naked, with her feet at a distance from each other, and her arms extended and shaded. It is supposed to have been formed in memory of Andromeda, daughter of Cepheus and Cassiopeia, and wife of Perseus, by whom she had been delivered from a sea-monster, to which her father had exposed her to be devoured, in order to preserve his kingdom from the plague. Minerva translated her into the heavens.

Dr. Hook thinks he has discovered the hidden meaning of the story of Andromeda. Vide Pott. Works. p. 487. Andromeda is sometimes called in Latin, "Perseus," "Mulier catarata," and "Virgo devota!" and the Arabs have changed the figure of this constellation from that of a woman to that of a sea-monster. Schickard has changed the name for that of "Abigail!" and Schiller calls it the "holy sulpuche," and exhibits it under that figure. The stars in the constellation Andromeda, in Tulemey's catalogue, are 23, in Tycho's 23, in Hevelius's 47, in Mr. Flamsteed's no less than 68. About 27 of these stars are visible to the naked eye, of which the principal are, α Andromedae, the head, β in the girdle, called mirach, or mizar, and γ on the south foot, named almak, and sometimes allamea.

Some of the stars of Andromeda have been reckoned among the changeable stars, whose brightness varies. Mr. Pigott and Dr. Hertel have made observations on their relative brightness, for which see Phil. Trans. vol. lxxvi. p. 203, 212. vol. lxxxvii. p. 357, 321.

ANDROMEDA, in Botany, licum of Mich. chamadeaphne and polifolia of Buxb. and erica of Tournefort, a genus of the decandria monogyne class and order, of the natural order of biornes and erica of Jussif. Its characters are, that the calyx is a perianthium, five-parted, acute, very small, coloured, and permanent, the corolla is monopetalous, campanulate, and quinquefoil, clefts reflex; the lilium have subulate filaments, shorter than the corolla, and scarcely fixed to it, another two-horned and nodding; the pistillum is a roundish germ, style cylindrical, longer than the flower, and permanent, stigma obtuse; the pericarpium is a capitate, roundish, five-corned, five-celled, five-valved, opening at the corners, partitions contrary, and the seeds are very numerous, roundish, and shining. Off. It differs from erica in number. In some species the corolla is ovate, in others perfectly campanulate. The anthers in some are awned, in others awnless.

Martyn enumerates 55, and Gmelin 24 species. 1. A. tetra-
gena, with peduncles solitary and lateral, corollas bell-shaped, and leaves opposite, imbricate, obtuse, and revolute. This resembles the passifera fliiformis, but the flower are very different, and
and familiar to those of the hills of the valley; the leaves are generally four-fold, whence its square appearance, and the name tetragona. Linnæus first observed it growing very sparingly in Lapland, in 1723; and Gmelin found it on the mountains of Siberia. 2. A. hypoleuca, with peduncles solitary and terminal, corolla bell-shaped, and leaves crowded and awl-shaped. It has the appearance of a weedy species, spreads over large tracts of ground in the Lapland Alps, and adorns them with its beautiful red flowers, the anthers are awned; it is also found in Denmark and Siberia. 3. A. cerina, with peduncles axillary, two-leaved, and one-flowered, and leaves alternate, ovate, and ferrate; the leaves are on short petioles, the corolla is bell-shaped, and the anthers oblong, yellow, two-lobed at the back. It is brought from the island of Otahite. 4. A. caralis, erica folio abietis, flore arbuti of Buxb. with peduncles aggregate, corollas ovate, and leaves scattered, linear obtuse, and flat; the anthers are without awns. It grows wild on the mountains of Lapland, more plentifully on the shores of Dalcarrick and Islay, and is also found in Denmark and Siberia. 5. A. Maritima, Maryland A. with peduncles aggregate and branched, corollas ovate-cylindrical, and leaves oblong-ovate, quite entire, and deciduous; the anthers are without awns; a native of North America; introduced here in 1756 by Peter Collinson, Esq. There are two varieties, a with oval leaves, and b with oblong leaves; the corollas are shaped like those of arbutus, are of an herbaceous colour, appear in June and July, and are sometimes surrounded by fruit, which seldom ripens in England. 6. A. farruginea, a native of Cape Finmark and Jutland, and is also found in Denmark and Siberia. 7. A. polifolia, polifolia of Buxb. erica humilis, &c. of Pluken, rhododendron polifolium of Scop. ledum palustre nostras arbuti flore of Ray, with peduncles aggregate and terminal, and leaves alternate, lanceolate, revolute, beneath glaucous. Martyn enumerates three varieties, viz. a. A. pol. latifolia, broad-leaved marth A. with leaves oblong, corollas ovate and flesh coloured, segments of the calyx spreading, ovate, and white, sometimes red at the tip. b. A. pol. media, common marth A. or wild rosemary; with leaves lanceolate, corollas oblong-ovate red, and segments of the calyx more erect. c. A. pol. angustifolia, narrow-leaved marth A. with leaves lanceolate linear, and segments of the calyx oblong and red. This is an elegant little shrub, which rises from six to eight inches in height, is erect and branched; the flowers are fleshly and nodding the calyx is red, the corolla of a pink colour, the anthers awned, the capsule erect and five-turrowed, the style white, with a purple stigma, and the seeds very many and small. It is a native of America and the northern countries of Europe on turf bogs; in Kullan, Sweden, Denmark, Germany, Swinemar, and in Britain, on the mouses of Cheare, Lancahir, Willmorlaine, Cumberland, Yorkhire, and Scotland, as on Brigsten mouses, near Kendal, Middleton mouses, by Lancelfet, on Blackstone-edge, between Halifax and Rochdale, upon Sowley mouses in great quantities, and not unfrequent in peat-bogs in the lowlands of Scotland. Its flowers in June, and is called marsh chilalis, wild rosemary, Poley mountain, moor-wort, and marsh holy rofe. There is some difference in the varieties as found in North America (a), in Europe (b), and in New-England and Labrador (y), as above specified. 8. A. bryanta, bryanthus of Gmelin, with flowers Corymbed, leaves elliptic, and profusely fruited. This comes up in thick clumps, like wild thyme, on the rocks of Kamptchata. 9. A. dacebacea, erica dacebacea, erica Hibemica, &c. of Ray, Irish whorts, Cantabrian heath, or trailing Andromeda, with racemes pointing one way; flowers quadrifid, ovate, and leaves alternate, lanceolate, and revolute. This was formerly an erica, and wants one-fifth in the parts of fructification, and ought, perhaps, with herkoidea and cervisia, to be removed to that genus. This species has the habit or air of an andromeda, but the character of an erica. The seed-veil is a four-celled, four-valved capsule; it has been observed to grow only in the Irish bogs, and flowers in June and July. 10. A. desponsa, erica glittonea of Berg, cernellus rosil foliis of Pet. clamy A. with racemes pointing one way, and leaves linear, hairy and villose. The number of parts of fructification varies from 4 to 8 or 5 or 10; it is fitted to N9&9, and has all the habits of Andromeda; a native of the Cape of Good Hope. 11. A. paniculata, paniculata A. with racemes terminal, panicled, corollas rounded, and leaves ovate, rather entire; the stem is about four feet high; the flowers grow in loose spikes from the ends of the branches, being shaped like those of arbutus, only a little longer, and appearing in July, but not producing seeds in this country; the anthers are awned: a native of Virginia, and cultivated here in 1748 by Archbold, duke of Argyle. 12. A. japonica, with racemes panicled, cylindric and bracted, and leaves elliptic, reflex, and ferrate at the tip. This is a tree, a native of Japan, near Nagasaki, and flowers in December. 13. A. arbores, tree-Andromeda, or forest-tree, with panicles terminal, corollas rather downy, and leaves elliptic, pointed, and tooth-letted. This is in Virginia a shrub, growing 10 to 12 feet high, but in Carolina it rises 20 feet; the branches are flancier, and bend downwards; the flowers grow in long, naked spikes from the sides of the branches, they are of an herbaceous colour, and ranged on one side of the stalk. This is in Virginia planted here in 1752 by Mr. Miller. 14. A. racemosa, branch- or Pennsylvania-Andromeda, with racemes terminal, simple, and bracted, corollas cylindric, and leaves oblong-lanceolate, and ferrate. This was found in Pennsylvania by Kalm, introduced here in 1756 by P. Collinson; flowers in July. 15. A. axillaris, notched-leaved A. with racemes axillary and simple, corollas oblong, leaves ovate, acute, and ferrate. A native of Carolina, introduced in 1765, and flowering from May to August. 16. A. corisaca, thick-leaved A. with racemes axillary and simple, leaves ovate, very entire, very shining, and branches three-cornered; found in North America, introduced in 1765, and flowering in July and August. 17. A. acuminata, A. lucida of Jacq, acute-leaved A. with racemes axillary and simple, leaves ovate-lanceolate, acuminate and ferrate. This is a shrub about four feet high, upright and smooth, with round branches, leafy to a considerable extent; the flowers smell like honey, the perianth is green, the corolla snow-white. It is a native of North America, was introduced in 1765, and flowers in July and August. 18. A. calypalata, calypalata A. with peduncles solitary, axillary, and pointing one way, two bracts, and leaves oval, fey-dotted, and obfoleter ferrate. There are three varieties: 8. A. cal. trinervi, trinervi of Buxb., globos-flowered calypalata A. with globos corollas, and oblong-lanceolate leaves; e. A. cal. latifolia, broad leaved calypalata A. with corollas oblong-cylindric, and leaves oblong-ovate, and obtuse; y. A. cal. angustifolia, narrow-leaved calypalata A. with corollas oblong-ovate, and leaves oblong-lanceolate. This is a low shrub, with leaves of similar shape and consistence to those of the box tree, with small punctures on them; the flowers grow in short spikes at the extremities of the branches, fuggle, between two leaves, and white; the leaves are oblong on the racemes, and from the axil of each produces a solitary, pedicelled flower; the calyx is covered at the base, with two oval leaves; the anthers are oblong, bifid, and awned; growing in Sweden, Ingria, Siberia, and North America, on mossy land.
land; cultivated in 1748 by Archibald, duke of Argyle. There is some difference in the varieties from Cilicia, Newfoundland (1), and North America and Siberia (2).

10. A. angulosus, with racemes crowded and leafy; leaves ovate, lightly serrate, amomnilobed underneath, and dotted. This is a shrub with hairy branches, ovate corollas, two-awned anthers, and oblong caps, gaping at the angles; found by Mistis in New Granada. 20. A. rufipilis, with leaves oblong, alternate and ferrate. A native of New Zealand. 21. A. jahiophila, willow-leaved A. with racemes pointing one way, and naked, corollas sub-cylindrical, and leaves lanceolate, acute, and quite entire; found by Commerson in the island of Mauritius. 22. A. busuifolia, box-leaved A. with racemes pointing one way, and naked, corollas sub-cylindrical, and leaves cordate-ovate, quite entire, with a little dagger point. This and the former species differ scarcely at all in their stamination, or in the structure of their leaves, and are distinguishable only by their form; this, however, has none of those lines parallel to the midrib that are so conspicuous in the other species. It is a native of the Isle of Bourbon where it was found by Commerson.

23. A. ficifolius, with peduncles aggregate, leaves alternate, ovate-lanceolate, obtuse, slightly crenulate and coriaceous. 24. A. jamaicensis, with peduncles aggregate, corollas ovate transparent, leaves alternate, broad-lanceolate, obtuse, entire, beneath all-coloured and membranaceous. 25. A. otandera, with peduncles aggregate, corollas cylindrical quadrifid, and leaves alternate, ovate-lanceolate, entire, and membranaceous. The three last species are natives of Jamaica. Gmelin enumerates the following species besides several of those above described, viz. A. ferequinifera, with flowers aggregate, axillary, and terminal, leaves rounded at the margin, revolute, and beneath ferequiniform; fraggellat not to be distinct from the A. ferequina; A. nitida, with peduncles aggregate and axillary, leaves alternate, lanceolate-ovate, entire and permanent; A. natesulis, with racemes ovate and axillary, leaves alternate, petiolate, ovate-lanceolate, ferrate and permanent; A. reticulata, with racemes ovate and axillary, leaves ovate, acuminate, crenulate, alternate, petiolate, beneath reticulate and permanent.

Culture. Most of the species are hardy, deciduous shrubs, which thrive in moister ground; they may be increased by their creeping roots, which put up suckers at a distance, that may be taken off with roots, and transplanted where they are to remain. Those that are imported from America may be propagated by seed sown in the spring in a bed of moister earth; they may be increased by layers in autumn. The 13th fort must be sheltered from frost in winter, and in summer frequently watered. It grows naturally in boggy places, and requires greater heat than that of this climate.

Martyn’s Miller.

Andromeda, in Entomology, a species of Papilio (Parnassius) found in India. The wings are roundish, transparent, white; posterior pair red at the tip, with a single eye-shaped spot on each side. Fabricius and Gmelin.

Andromeda, in Natural History, is likewise a species of Medusa amongst the Vermes mollusca. It is hemispherical, without marginal arms; right round, ramose, foliaceous arms on the under part. Forik. Fy. Arab. Gmelin. This kind is extremely abundant on the coasts of the Red Sea. The body is transparent, and of a pale brownish colour with white rays; the margin is entire; in the middle is a black croze; the arms are white, and rather thicker than a goose quill at their base. Gmelin, &c.

Andromeda, in Middle Age Writers, denotes a kind of garment made of rain-ykins.

Andron, or Andrum, in Antiquity, an apartment in houses assigned for the use of the men. This was otherwise denominated androna, and andronitis. The andron stood opposed to the gymnacum, or apartment of the women. The Greeks also gave their dining-rooms the title andron because the women had no admittance to feasts with the men.

Androna, in Ancient Writers, denotes a street, or public place, where people met and conversed together. In some writers androna is more expressly used for the space between two houses. In which sense the Greeks also used the term euon, as for the way or passage between two apartments. The word is sometimes also written andro, andria, and andronium.

Androna is also used in Ecclesiastical Writers, for that part in churches destined for the men. Anciently it was the custom for the men and women to have separate apartments in places of worship, where they performed their devotions amidst; which method is still religiously observed in the Greek church. The euon or androna was on the southern side of the church, and the women’s apartment on the northern.

Andronicus I. Comnenus, in Biography and History, was the son of Isaac and grandson of Alexius Comnenus, and one of the most conspicuous characters of the age, so that his genuine adventures might form the subject of a very singular romance. He was strong and beautiful; the want of the softer graces was supplied by a manly countenance, a lofty stature, athletic muscles, and the air and deportment of a soldier; and the preservation of his health and vigour in old age, was the reward of temperance and exercise. Dextrous in arms, he was ignorant of fear; his persuasive eloquence could accommodate itself to every situation and character of life; and in every deed of military service, he had a heart to resolve, a head to conceive, and a hand to execute. In his youth he followed the retreat of the Roman army, and in the march through Asia Minor he wandered into the mountains, was taken by Turkish hunters, and became a captive to the sultan. Both his virtues and his vices recommended him to the favour of his cousin, the emperor Manuel; and whilst he lived in public incest with his niece Theodore, Andronicus openly maintained a licentious intercourse with her sister Eudocia, who gloried in the name of his concubine. She accompanied him in his military command in Cilicia, where he professed, with active ardour, the siege of Mopueitia; but he was surprized and thrown into disorder by a Sally of the enemy. On his return to the Imperial camp in Macedon, Eudocia attended his motions; and their tent was suddenly attacked at midnight by her brothers, who were impatient to expiate her infamy in his blood. Refusing to assume a female habit, in compliance with her advice, he started from his couch, and cut his way through the afflatus with his sword. At this time he engaged in a treasonable correspondence with the king of Hungary and the German emperor; in consequence of which he was arrested, and strictly confined in a tower of the palace of Constantiopole. In this prison he remained for more than 12 years; and after repeated and ineffectual attempts to escape, in which he manifest singular resolution and dexterity, he at last succeeded, and retired to the court of the great duke of Ruflia. Having gained this asylum, he solicited the Rulfian prince to join his arms to those of Manuel in the invasion of Hungary, and thus obtained forgiveness from the emperor; and, after a campaign on the Danube, he returned with Manuel to Constantiopole. By refusing the oath of allegiance, which he was required to take to the prince of Hungary, who became the presumptive heir by marrying the emperor’s daughter, he again incurred
And the artful hypocrite was elevated, by acclamation, apparently against his own content, and merely to protect the young emperor and to support his authority, to a partnership in the empire. This partnership, which was merely a preparatory step to the sole sovereignty, he soon terminated by the death of Alexius, whom he caused to be strangled with a bow-string; and the tyrant, inflexible to pity or remorse, after viewing the body of the innocent youth, struck it rudely with his foot: "Thy father," he cried, "was a knave, thy mother a whore, and thyself a fool!" Having thus attained to the dignity of sole emperor, A.D. 1183, he fowed the sceptre about three years and a half, as the guardian or sovereign of the empire. His government exhibited a singular contrast of vice and virtue: when he likened to his pabions he was the scourge, and when he consulted his reason he was the father of his people. In the exercise of private justice he was equitable and rigorous; the provinces, which had been neglected and oppressed, received in prosperity and plenty; and millions applauded the distant blessings of his reign, while he was curbed by the withehdes of his daily cruelties. The nobler families, especially those who claimed any alliance to the Comneni, were either massacred or exiled. At length his throne was subverted by a rival without merit, and a people without arms. Isaac Angelus, a descendant, in the female line, from the great Alexius, being marked as a victim, defended his life and liberty from the executioner, and fled for refuge to the church of St. Sophia. The populace were roused, and Isaac was instantly raised from the sanctuary to the throne. Andronicus, who was indulging himself in the delicious islands of the Propontis, in the society of a young wife and a favourite concubine, returned with all speed to Constantinople; but he found, upon his arrival, that he was universally deserted, and that no condition which he proposed, however self-denying and humiliating, would be accepted. Accordingly he attempted to make his escape; but he was pursued and taken in his flight, and brought back, loaded with fetters, and with a long chain round his neck, to the presence of Isaac Angelus. "His eloquence, and the tears of his female companions, pleaded in vain for his life; but instead of the decencies of a legal execution, this new monarch abandoned the criminal to the numerous sufferers, whom he had deprived of a father, an husband, or a friend. His teeth and hair, an eye and a hand were torn from him; and a short reprieve was allowed, that he might feel the bitterness of death. Afraid on a camel, without any danger of a refuge, he was carried through the city, and the base of the populace rejoiced to trample on the fallen majesty of their prince. After a thousand blows and outrages, Andronicus was hung by the feet, between two pillars that supported the statue of a wolf and a lion; and every hand that could reach the public enemy, inflicted on his body some mark of ingenious or bloody cruelty, till two friendly or furious Italians, plunging their swords into his body, released him from all human punishment. In this long and painful agony, Lord, have mercy upon me!" and "Why will you bruise a broken reed?" were the only words that escaped from his mouth. His death, in the 73d year of his age, closed a reign of two years, and with him terminated the dynasty of the Comneni. Anc. Un. Hist. vol. xii. p. 138, &c. Gibbon's Hist. vol. ix. p. 39.-108.

Andronicus, Cyrestes, or of Cyrillus, was an Athenian astronomer, and celebrated as the inventor of weathercocks. He erected an octagon tower of marble, on each side of which he engraved figures representing the eight winds mentioned by Vitruvius, under the names of Solanus,
AnHAND

Androcnus, Livius, the oldest of the Latin poets, is said to have been a Greek slave, and to have been emancipated by Livius Salinator, whose children he instructed, and whose name he assumed. His performances were chiefly dramatic and comic, and he acted in his own pieces; and, it is said, that when he became home, he caused the world to be revivified by a servant, while he himsifen expatiated the gellulation. He also wrote hymns to the gods, one of which, in honour of Jove, is said, by Livy and Valerius Maximus, to have been sung through the city by girls. An eddyfly is also attributed to him. Some lines, which are quoted by grammarians and critics, are the only relics of him, and they have been printed in the fragments of the other ancient Latin poets, in the "Comica Latina," and the "Corpus Poetarum." Andronicus represented his full piece on the stage, A. U. C. 514, B. C. 246, a year before the birth of Ennius. VoUius.

Andronicus of Rhede, a peripatetic philosopher, came to Rome in the time of Cicero, and served to revive and establish the philosophy of Aristotle. Andronicus collected the writings of Aristotle, by means of the library of Apellicon, sent to Rome by Sylla, and Tyrannio's use of it, arranged, corrected, transcribed, and published them; and, according to Plutarch, he annexed indexes to them; so that he may be considered as a refector of these writings. Andronicus wrote a paraphrase of Aristotle's Categories and Physics, and probably of some other pieces, but none are extant, unless the paraphrase of Aristotle's Ethics, published under his name by Heinlius, 8vo. at Leyden, in 1617, and at Cambridge in 1679, be his, which Salmasius, VoUius, &c. dispute. It is doubted whether a small treatise "On the Pallions," published by David HocheHius, in 1593, was written by this Andronicus. Plut. Vit. Sylla apud Oper. tom. I. p. 468. Gen. Dict.

Andronicus of Thebaisonia, flourishing in the 15th century, and among other learned men, who left Conflagintopile when it was taken by the Turks, contributed to the revival of letters. He taught Greek at Rome, and was entertained in the house of Bellarion; but his salary was so inconsiderable that he was obliged to leave Rome and repair to Florence, whence he removed to Paris, where he died at an advanced age. His knowledge of the Greek language and of Greek authors exceeded that of any of his contemporaries; but he was disqualified for public speaking by a bad pronunciation. Gen. Dict.

ANDRONION, in Physic, the name of a pafil, invented by an ancient physician named Andro, said to have been of great efficacy against the carbuncle and herpes. Its ingredients, according to Aegina's prescripition, are the fumane of copper, et fyllum, fil ammoniaci, alumen robustum, shavings of verdigris, and frankincense, all wrought up with wine. Celiius gives another recipe, and Aetius a third.

ANDROPHAGI, from ang. man, and ca. I eat, among Ancient Geographers, denoted man-eaters. These were more usually called anthropophagi. Herodotus and Pompp. Mea spoke of a nation of androphagi, in Scythia, who observed neither laws nor justice, and had nothing in common with the other inhabitants but their dreads and occupation of feeding cattle.

ANDROPOGON, q. d. man's beard, in Botany, a genus of the polygama monstrosa class and order, and of the natural order of gramina, or grasses. Its characters are, that the hermaphrodite flowers are solid, that then calyx is a glume, one-flowered, two-valved, oblong, obtuse, carinate, and awnless, the outer valve concave, flatish at the back, embracing the inner, which is narrower, with its edges; the corolla is a two-valved glume, and more slender than the calyx; outer valve smaller, often very small, within the inner valve of the calyx, sharp or broad at the end, in mould of the pods is awned; awn terminating, or from the base of the glume, long, with a bent joint, and twisted at the bottom; the inner valve lanceolate, double at the edges; vestigial two-leaved; leaflets thickish and diaphanous; the lamina has three segments, capillary, very tender; authors oblong, forked at both ends, and incumbent; the pistillum is an oblong germ, three-awned, and capillary, fimbriate oblong, and feathers; no pericarpium; glumes of the corolla and calyx invariant, and inclining the seed: the seed, thin, oblong, and covered, armed with the jaw of the corolla, which easily falls off. The male flowers are peduncled, single, or in pairs to each hermaphrodite: the calyx, corolla, and flaves as in the others, except that the corolla has no awn. Martyn enumerates 35, and Gardin 38 species. on androcnus, gramn. capricainum of Rhamp, with spikes solitary and imbricate, seeds fragrant, awns naked and contorted. A. native of Ambouina and Japan. 2. A. contortum, Aegilops Madras-parata, &c. of Schenck. gramn. caleculum indicum, &c. of Pluk. and Mor. with spike solitary, male flowers awnless on the back of the spike, female flowers on the belly of it as long as the spike, with twisted approximating awns, longer than the whole spike. A native of the East Indies; introduced into Kew Garden in 1779 by Anthony Chamier, Eq. 3. A. ornatum, with spikes solitary and thyagge; awns naked, jointed, and very long. A native of Japan; found by Thunberg. 4. A. divaricatum, lagurus humilior, &c. of Gron. Virg. &c. with spike oblong, flowers woolly, remote and divaricate; awn flaxen and naked. A native of Virginia. 5. A. glabrula, Aegilops bromides epica purpurascens of Schenck, gram. sparteum flectuecum, &c. of Barr. gram. avenaceum, &c. of Monti, with peduncles of the panicle entirely simple and three-flowered: the hermaphrodite flosculous, awned, ciliate, and bearded at the base. A native of Piedmont, Verona, Montpelier, Cavacole, the Grifons, and Switzerland. 6. A. faebraturata, with branches of the panicle simple, florets in pairs, hermaphrodite, awnless, the other awnless, pedicellate, withering, pedicel and rachis woolly. A native of Jamaica. 7. A. nutans, with panicle nodding, awns twisted and poliished, glumes of the calyx thyagge. A native of Virginia and Jamaica. 8. A. ciliatum, with panicle nodding, outer calyx many flowered and ciliate, awns contorted and hairy. Found by Thunberg on the mountains of Nagasafii in Japan; flowering in September. 9. A. ferrutum, with panicle loose, one flosculous, villose at the base; the other pedicellate, with the pedicel villose, and shorter than the calyx. A native of Japan. 10. A. cotyledon, with panicle spreading, villose, awn-twilled, naked, pedicels clubbed or swelling at top, and hollowed like a faucer or dish. A native of Japan. 11. A. cymbarum, with panicle scattered, bractes boat-form, flowers transverse, awned, and threefold. A native of the East Indies. 12. A. squarroseum, A. maritimum of Retz, with panicle crowded, glumes oblong, and rugged. Koenig observed it in Ceylon, swimming on deep pools; it is used by the natives for its pleasant smell; they also make fans of it. 13. A. falfusum, with peduncles in five-flowered umbels, without calyces, the hermaphrodite flosculous awned. A native of the East Indies. 14. A. faldigatum, with spikes of the panicle solitary, peduncles several.
druels elongate subfusiligate, racis woolly, dloceles awned, and male fertile. A native of Jamaica. 13. A. alepecuroides, gram. dactylon, &c. of Sloane, with panicle loose, racis woolly, and a twisted awn to each spike, a native of Jamaica and Virginia. 16. A. glaucum, with spikes two, terminal, and culm undivided. Linné says that it grows wild in Swedeland. Schenchen had it from Smyrna. 17. A. sphanoeus, lagurus of Fl. Zeyl, gram. ad junceum accedens aromaticum majus fytianum of Mor. gram. dactylou aromaticum, &c. of Plukue. sphanoeus of Bauhin and Ray, sweet rush, or camel's hay, with spike of the panicule conjugate, ovate-oblong, racis phaeolet, floccules fusillo, with a twisted awn. It is brought over from Turkey and Arabia, in bundles about a foot long, consisting of smooth stalks, in shape and colour resembling barley straws, tall of a funereal pitch like that of rushes. It has an agreeable smell, and a warm, bitterish, but unpleasing taste. Delitilled with water it yields a small quantity of a yellowish, fragrant, and pungent essential oil, and the remaining decoction is bittherish, and somewhat acrid. The spirituous extract is pleasantly aromatic and bitterish. This plant was formerly employed as a warm dromache, and deobiurunt; but in our country its use is superseded by more common aromatic vegetables. It is kept in the shops merely as an ingredient in the mithridate and thercna; but these compositions being excluded from the pharmacopoeia, the sphanoeus, or juncus odoratus is left out of our materia medica. Lewis and Murray. 18. A. Virginicum, gram. dactylou biconce tomentosum minus of Sloane, with spikes of the panicule conjugate, peduncules simple, racis woolly, floceles awnlefs, the male one wanting. A native of America. 19. A. bicora, lagurus of Linn. horiz. chuf. and Gron. Virg. gram. dactylou biconce tomentosum maximum, sicisia numeros of Sloane, with spikes of the panicule conjugate, peduncules branching very much, racis woolly, awn caducous, male floccule wanting. A native of the East Indies, on dry hills, and there called by the English fox-tail grass. 20. A. fritum, gram. dactylou epica gemina of Scheuch. gram. dactylou lucum, &c. of Plukue, with spikes of the panicule conjugate, and calyces shaggy. A native of Portugal, Italy, Sicily, and Smyrna. 21. A. infun- lure, gram. aveneatum, &c. of Sloane, with panicle loose and smooth, floceles double and awnlefs, one pedicel shorter, calyces woolly. A native of Jamaica. See Panicum lanata. 22. A. barbatum, with spikes digitate, calyces permanant, and corolla dilate. A native of the East Indies; introduced into Kew gardens, in 1777, by Dr. Solander. 23. A. pubescens, chloris ciliata of Swartz, with spikes digitate, calyces subtiflorous, outer petals awned, keel and edge of the hermaphrodit flower ciliate. A native of Jamaica; introduced at Kew in 1779, perennial, and flowering from July to September. 24. A. nardus, lagurus of Fl. Zeyl, with branches of the panicule superdecemprolaphy and prolificlate. See Spicenard. 25. A. muticum, with spikes digitate, mostly three, and floceles alternate, sfille, and awnlefs. A native of the Cape of Good Hope. 26. A. fiche- num, gram. dactylou, &c. of Scheuchzer, with many digitate spikes, selile floceles, awnlefs and awnlefs, and woolly pedicels. A native of the Southern parts of Europe, growing on mountains, hills, and other dry situations; introduced to Kew, in 1778, by Mr. Thomas Blackie. 27. A. sdeniculatum, chloris radiata of Swartz, gram. dactylou, &c. of Mor. many-spiked andropogon, with spikes fiscate, very many and smooth, calyces two-flowered, valius acute, smooth and even, the outer like petals, and awned, the inner floccule barren. A native of Jamaica; introduced in 1779, and flowering from July to September. 28. A. polyglosson, chlohis polyglossa of Swartz, gram. dactylou elatum of Sloane, with spikes fiscate, outer petals awned, those of the lower floccule ciliare-bearded. A native of Jamaica. 29. A. quatuor, with panicle leafy, involucres and calyces two-flowered, calyces of the fiscule flowers three-valved, of the peduncled ones two-valved. A native of the East Indies, whence it was sent by Koenig. 30. A. ferratum, with spike simple, imbricate, with two rows of awned fiscule flowers, and two of awnlefs pedicelled ones, calyces one-valved. A native of Bengal, where it was found by Koenig. 31. A. nicoletum, with spikes fiscate, subfiscate, flowers twin, the female pedicelled and awned, the male sfille and awnlefs, the calyces one-valved. Found by Koenig in Tranquebar near rivers. 32. A. lanatum, with spikes twin, woolly, one valve of the calyces acuminate, the other truncate, three toothed, the larger petal-awned. Observed in the East Indies by Koenig. 33. A. aciculatum, with panicle contracted upright, peduncules three-flowered, male-flowers two, pedicelled, and acuminate, female fiscule and awned. A native of the East Indies in barren places. 34. A. Bladhii, with spikes about eight, hermaphrodite floccule, sfille, awned, neater pedicelled, ciliate, and awnlefs. A native of China, sent from thence by Bladh. 35. A. provinciale, with spikes fiscate, smooth, floceles alternate subfiscile, directed one way, and awned. A native of the south of France, where the seeds were sent by Dahl. Gmelin has omitted the 23d, 27th, and 28th species above enumerated, and introduced the following, viz. A. brevifolium, with spikes lateral and solitary, floccules alternate and remote, and flalk glicinulat and compressed. A. ranum, with spikes terminal conjugate, with double spicule, the male awned and pedicelled, withramous flalk. A. annulatum, with spikes at the top of the flalk crowded and alternate, flowers adpressed and germinate, the male awned and pedicelled, and an erect, ramous flalk. A. nnaclatum, with an erect, ramous panicle, spikes alternate, floceles by threes, thales inelegant and inferior. A. ater, with spikes three and terminal, and floceles all awned. Gmelin suggests that this is the Gir Gir, or Gelfe el Aube of Abyfthin, described by Bruce in his Travels, vol. v. Appendix, p. 47. Gmelin makes a distinct species of the A. murinatum of Koenig, which is above referred to the A. figurr- rnum, and describes it as having a constrained panicle, verticillate spikes, and calyces awnlefs and smooth. Culture. Few of these grasses have been cultivated in European gardens, as they are for the most part natives of the East or West Indies, they would require the protection of a flace. Martyn’s Miller.

Andropogon. See Saccharum and Stipa.

ANDROS, in Ancient Geography, now ANDROS, one of the most fertile and delightful islands in the Archipelago Sea, lies near the south end of Negropont. According to Pliny it was 93 miles in circumference, and had various names, viz. Ceres, Lafia, Nonagria, Eparis, Andantos, and Hydryfla. It is said to have borrowed the name of Andros from one Andrius, who, according to Diodorus Siculus (lib. v.), was one of the generals whom Rhadamantus appointed to govern the Cyclades, after their voluntary submission to him. Conon will have this Andrius to be the son of Anius, and grandson of Apollo and Creusa, and to have been the first who settled in this island. It received the name of Antandros, signifying “for one man,” from its having been given as his ransom by Alcinous, the son of Æneas, when taken prisoner by the Pelagians. The territory of Andros is still one of the most fertile and pleasant countries in the Archipelago, producing all kinds of delicious fruit, and watered with numerous springs, whence it had:
Androsace, Alp.; exsicc., the shield of a man, so called from the form of the calyx, which, in the common species, is large, in Botany, a genus of the penstemon monopetalous class and order, of blue-flowers, and is called by the botanists, Hyaloides. Nulliflora, its characters are, that the calyx is an involucre many-leaved, many-flowered, and very small, the perianth is one-leaved, five-corned, sepulchred, acute, cleft, and permanent; the corolla is many-petalled, and silvery-shaped; the tube ovate and involuted in the calyx; the perianth is more than the calyx; the anthers oblong, obtuse, entire: throat becat with glands; the stamens have very short filaments within the tube; the anthers oblong, acute, and included; the pistil is a globular gynoecium, style filiform, and very short; stigma, glandular and included: the pericarpium is a globular capsule, sitting on a flat calyx, one-celled, opening into five parts at the top; the seeds are very many, roundish, gibbous on one side, and flat on the other; the receptacle is erect and spine. Martyn enumerates 7, Willdenow 10, and Gneiscin 11 species: 1. A. maxima, oval-leaved A. with the perianth of the fruit very large. The flowers of this species appear in April or the beginning of May; the seeds ripen in June, and the plants soon after perish. It grows naturally among corn, in Austria, Bohemia, and other parts of Germany, in the Valais, Piedmont, Carniola and Hungary; and was cultivated here, in 1598, by Gérard. 2. A. elongata, clasper flowered A. with leaves lanceolate, toothed, fruiting umbel elongate, and corollas shorter than the angular calyx, a native of Austria, near Vienna, even in the suburbs; flowers in April, and perfect its seed in June; introduced, in 1776, by M. Thouin. 3. A. septentrionalis, arctic of Hall, toothed A. with leaves lanceolate, toothed, and smooth, and perianth angular, and shorter than the corollas: a native of Lapland, Sweden, Denmark, Switzerland, Germany, Russia, in mountainous situations; cultivated, by Mr. Miller, in 1755. 4. A. villoso, arctic of Hall, fedum of Clf. Chamomile alpina of Bauhin, hairy A. with leaves hairy and perianths flaggy; common in the Swiss Alps, Jura, &c. in the mountains of Austria and Carniola, in the Pyrenees, &c. introduced, in 1768, by professor de Saussure. 5. A. laebe, A. obtusifolia of Allion, arctic of Hall, fedum alpinum, &c. of Bauhin and Ray, gray, with leaves A. with leaves lanceolate and smooth, and umbel many times larger than the involucres, a native of the mountains of Switzerland, Austria, and Carniola, flowering, like the foregoing, in July and August. 6. A. carnea, arctic of Hall, fedum alpinum of Col. awl-leaved A. with leaves awl-shaped and smooth, and umbel equaling the involucres: a native of the Alps and Pyrenees, and introduced in 1768, by professor de Saussure. 7. A. filiformis, with leaves ovate-toothed, petioled, rays of the umbel capillary, and corollas exceeding the bell-shaped calyx; a native of Siberia. 8. A. brevifolia of Gmelin, with leaves lanceolate, petioled, and hispid, and peduncles four times longer than the involucres. This Willdenow ranks as a variety of the next species. 9. A. obtusifolia, with leaves smooth and lanceolate, calyces angular, pubescent, and less than the corolla, and the foliages of the involucres very short (G.) or with leaves lanceolate, narrow at the base and smooth, and the perianths angular and pubescent. It is found on the high mountains of Switzerland, Italy, and Styria. 10. A. odoratissima, with leaves trigonous and ciliate, and perianths flaggy (G.) or with leaves trigonous, lanceolate, and ciliate, the rays of the umbel short, and the perianths angular, and shorter than the corolla; found in the high mountains of Cappadocia. 11. A. pannifera, with leaves leathery-linear, and smooth, two peduncles of the length of the calyx, and segments of the corolla emarginate. Gmel.
AND

Gmel. 12. A. charnigeafume, A. villosa of Jacq., chamejass ite of Bauhin, femen alpinum, &c. of Clair. with leaves lanceolate and narrow at the base, ciliate at the margin, and with flabby perianths. It is found in the high mountains of Austria. Wild.

Culture. These plants being low, and having small flowers, without any great appearance, are precluded only in botanic gardens. All, except the first, require a shady situation. The seeds should be sown soon after they are ripe; if permitted to scatter they will grow of themselves; the annual peris off as soon as the seeds are ripe, but the others, by being merely kept clear from weeds, will live in an open border for several years. Martyn's Miller.

ANDROSACE. See Aretois.

ANDROSACE, in Natural History, a name given by some naturalists to the tubularia aceta bu lum of Linnaeus; this species is variously described by authors; it is corallina (androface) tubulifera simplex petla terminalis radiata of Pallas, androfaces cotyledon folium marum of Lobel, androfaces petrae inascentes of C. Bauhin, pin. herba marina androfaces of Bell. mus. acetabulum marum of Tournefort, plantula lapidea fusculata, and callophilophorum Matthioli of Domat. adn. Besides this Brown describes a variety, in which the target is not radiated. Vide Jamaica, p. 74. The Linnaean specific characteristic is, the fleshes biform and terminating in a calcareous target or cup, which is frutified and radiated. Gmelin. This kind inhabits the Mediterranean and American seas, growing upon shales, slates, &c. it is white, soft, and fragile when dry: the tubes are simple, about the thickness of a straw, and two inches in length. Gmelin. This substance, reduced into powder, has been used in France for destroying worms, and for dropse. Dr. Lewis observes, that it does not promise to be of use in either of these intentions, or to differ from the coralline, which has been used as a vermifuge with little success. The dried androface, when held in the flame of a candle, yields repeatedly for several times a dazzling brightness, which is a phenomenon exhibited also by the coralline.

ANDROSÆMUM, in Botany. See Hypericum.

ANDROSCOGGIN, or Amabiscoogin River, in Geography, a river of America, in the district of Maine, may be called the chief western branch of the Kennebec. Its sources are near Lake Umbagog, and it pursues a southerly course till it approaches near the White Mountains, from which it receives Moose and Peabody rivers; after turning to the east and south-east it passes within two miles of the sea coast, and again turning north, and running over Pejapskag falls into Merry-Meeting Bay, where it joins the Kennebeck, 20 miles from the sea. The lands near this river are good.

ANDROSIA, in Ancient Geography, a town of Aisia Minor, assigned by Ptolemy to the Trocni.

ANDROMOTY, or Andromathy, from andros, man, and 171,1, cut; the anatomy or dissection of human bodies. It is thus called in opposition to zoophyty, which is used to denote that of brutes.

Anatomy is the genus, and comprehends all dissections in general, whether of men, beasts, or plants; and andromogy and zoophyty are the species.

ANDROUET Du Cerceau, James, in Biography, a celebrated French architect, was born at Orleans, or, as some say, at Paris. He was sent for acquiring perfection in his art to Italy, where he was chiefly struck by the triumphal arch at Pola in Istria, to which there is a visible reference in the fylle of his works. Upon his return, though he was a Ready Calvisat, he was made architect to Henry III. who employed him, in 1573, in the construction of the pont neuf at Paris. Henry IV. employed him in enlarging the Tuileries, and continuing the great gallery that connects it with the Louvre. But perfecution obliged him to quit his country in 1583; and the place of his retreat, and the time of his death are not known. He left two sons, one of whom was eminent in his father's profession. He was one of the principal improvers of Architecture in France, and he published several books on the art; as his "Architecture," in 1560, comprehending designs of all the parts and ornaments of buildings; "Lessons in Perspective," in 1576; "The most excellent Idimatics in France," in 1575 and 1607, 2 vols. folio, being a description of 30 royal palaces and other buildings, with figures; "Architecture of Country-houses and Mansions," 1582; and "Roman Edifices, or a Collection of Remains of Antiquity, drawn on the spot."

ANDRUM, in Physiology, a local discharge, epidemic among the people of Malabar, being a peculiar species of hydrocele, or watery tumour of the feromum. The andrum, in the language of the country, is also called perica; sometimes para-physically andu zosaka, q. d. a popular water rupture. Its origin is derived from the vicious quality of the country waters, impregnated with corrosive muriatic salts, the force of which other discharges affect the Malabarians. Its signs, or symptoms, are an erysipelas of the feromum, returning every few months, by which the lymphatics are eroded, and a feverish state of the feromum. The means of prevention is by a heap of sand fetched from a river of the province Mangatti, and thrown in the wells. This is practised by the rich. As to the cure, they have only a palliative one, which is by incision, or tapping and drawing off the water from the feromum, once in a month or two.

ANDRUSA, in Geography, a town of European Turkey in the Morea, 20 miles north-east of Navarin.

ANDRY, Nicholas, in Biography, born at Lyons in 1658, was made doctor in medicine at Rhetom in 1683, having quitted the study of theology, in which he had been engaged several years. In 1697 he was admitted into the faculty of physic at Paris. In 1701 he was made professor of medicine there, and the following year censor or examiner of intended publications in that science. He died in 1742, aged 84 years. He was a considerable contributor to many of the medical and philosophical journals of the time, and in 1702, one of the editors of the "Journal des Savans." He wrote also a variety of other works, of which the principal are, "Cleons and Endoxe," 2 vols. 12mo. Paris; in which he strenuously infilts on the subdivision of the Surgeon to the Physician. "Acrom et ingenium scriptum," Haller says. "De la generation des vers dans le Corps Humain," 12mo. Paris. This was afterwards augmented to two volumes. At the end is an engraving of a tape-worm, of an enormous length, that had been voided entire by one of his patients. "Orthopedie, ou l'Art de prevenir et de corriger, dans les enfants, les disformites du Corps," two vols. 12mo. Paris, 1741; that is, the art of preventing or redressing any defects or deformities in the bodies of children. This is directed to be effected by regimen, exercise, and by various mechanical contrivances, and contains the germ, at the least, of every thing known on the subject at this time. The author composed this work, he says, as a supplement to the Callipedia, the art of getting handsome children, by Quillet; and the Pedotrophia, the art of rearing and nursing children, by
Scavola da St. Martha, two beautiful and well known
poems, of which he gives an analysis in the preface to this
work. The Ortopedia was soon translated into our lan-
guage, as well as into those of most of the countries in Eu-
rope, and still retains its popularity. For the titles of nu-
merous other productions by this writer, see Eloy’s Dict. Hiftor.
de la Medicine.

ANDRA ALA, eriophorius of Vaillant, in Botany, a ge-

nus of the fengesia polygonia angustifolia clas and order, of
the natural order of composite, brief officulote, and class of羽
dicifia. Its characters are, that the common calyx is many-
parted, short, rounded, and villose; the flowers are very many, sub-
equal, and fubulate (in a double row, G.); the compound
corolla is imbricate and uniform; the corollines are henna-
phrodite, numerous, and equal, each ligulate, linear, tran-
curate, and five-toothed; the flamina have five filaments, ca-
pillary, and very short, anther cylindrical, and tubifole; the
kijullum is an ovate germ, style stylem, of the length of
the filamina, ligiinma two, and reflex; no pericarpum, calyx
converging and globose; the seeds are solitary and ovate, the
down capillary, of the length of the calyx, (fesili. G.);
the receptacle is villose and flatihed, (acclavated and hairy, G.)
Martyn enumerates fix, and Gmelin eight species. 1. A.
integrifolia, fonchus lanatus of Dalech. and Bauh. S. villosus
luteus major of Bauh. and Parkinson. hicracium villosum of
Ray, hoary A. with lower leaves runcinate or notched, and
upper ovate-oblong and tomentofe. It is about a foot and
a half in height; the flowers are in small clusters at the top
of theflanks. yellow, and resembling those of bow-thistle;
flowers in July, and its seeds ripen in September. There is a
variety 8. A. finnata, which has the lower leaves indented
and woolly, but those on the stem are entire; it seldom rises
more than a foot high, and supports a few yellow flowers at
top. These are annual plants, growing naturally in the
South of France, Spain, Italy, and Sicily; and cultivated in
the Chelsea garden in 1711. 2. A. cheiranthifolia, A.
glandolosa of La Mare, A. tomentos of Seop. various-
leaved A. with leaves runcinate, upper ones lanceolate and
entire, down glanduliferous. It is perennial, three feet high,
and full of milk. A native of the island of Madeira, and in-
troduced by Mr. F. Maffon, who observed it there in 1777.
3. A. pinnatifolia, with leaves tomentose and pinnatifid,
and calyces tomentose and hairy, hairs rather stiff. There are
two varieties: o. tooth-leaved A. with leaves pinnatifid, and
pinnas dilatant and toothed; a native of Madeira: and 3.
wing-leaved A. with leaves deeply pinnatifid, and pinnas
short and entire. A native of the Canary islands; found by
Mr. F. Maffon; flowering in July and August, and intro-
duced in 1778. 4. A. crithmifolia, famphire-leaved A.
with leaves pinnate, linear, and tomentofe. A native of Madeira,
found by Mr. F. Maffon; flowering from June to August,
and introduced in 1778. This and the last species are bi-
ennials. 5. A. raphanifera, downy A. with leaves lanceolate, un-
divided, dentilatate, acute, and tomentose, and solitary
flowers. As it is very hoary it makes a pretty appearance
interspersed with others, whose leaves are green; but it will
not live abroad except in a dry soil and warm situation. It
has been received from Spain, from the Cape, and from Al-
giers. Linnaeus says, that it is a native of the islands of the
Archipelago. This species has leaves stiffer, more acute,
and more acutely toothed than the other species. 6. A.
lanata, hiracium montanum tomentofum of Dill. Hall.
and Mill. woolly A. with leaves oblong-ovate, slightly
toothed and woolly; and peduncles branching; biennial ac-
cording to Miller, but according to others perennial; flow-
ering in June, and ripening its seeds in August; the whole
plant is white. A native of the south of Europe; culti-
vated in 1732 by Dr. Sherard. 7. A. nigricans, with lower
leaves lyc-rhaped pinnated, peduncles ramose, and down
blackish above. Poir. voy. en Barb. 8. A. uniflora, with
leaves smooth, entire, dentatate, oblong-acute, with a single-
flowered flake. Schrank flor. hav.

Culture. All these plants may be propagated from seeds,
owing those of the hardy fort in spring, where they are to
remain. They require no other attention but to be thinned
and kept free from weeds; the 2d, 3d, 4th, and 5th require
the protection of a greenhouse, in which they will flower all
the Summer, often perfecting their seeds, by which they may
be propagated. The perennial forms may be propagated by
their creeping roots.

ANDRA ALA. See LEONTODON.

ANDUC Island. in Geography, one of the group called
the Maldives, on the call tide, in N. lat. 6° 25'. E. long.
73° 40'.

ANDUJAR, or ANDUXAR, a town of Spain, with a
castle, situate on the Guadalquivir, in the confines of Jaen
and Cordova, and built near the spot on which stood Illurgis,
or Illiturgis, called by the Romans Forum Julian, and now
Andujar el Viejo. Its principal commodity is silk. The
adjacent country abounds with wine, oil, honey, and various
forts of fruit and also game. It is 10 leagues east of Cor-
dova, and 90 miles from Jaen.

ANDUJINA, in Entomology, a species of PAPILLIO
(Nymph. Phal.) found in Ruffia. The wings are dentated,
fulvous, with black spots; under side of the posteri or wings
white, with two brown bands, and dotted behind with
black. Fabricius and Gmelin.

ANDUZE, in Geography, a town of France, in the de-
partment of the Gard, and chief place of a canton, in the
district of Alais, carries on a considerable trade in ferges
and other woollen stuffs; eight leagues north-west of Nimes,
and two south-west of Alais.

ANECDOTES, ANECDOTAE, a term used by some
authors for the title of Secret Historiae; but it more properly
 denotes a relation of detached and interesting particulars.
It is now often used for a biographical incident or minute pa-
assage of private life.

The word is Greek, anedota, q. d. things not yet known,
or hiberto kept secret.

Procopius gives this title to a book which he published
against Julianus and his wife Theodore; and he seems to be
the only per son among the ancients, who has repre fented
princes such as they are in their domestic relation. Varillas
has published anecdotes of the house of Medicis. We have
had repeated attempts for arranging anecdotes under diffe-
rent heads; a “Dictionnaire d’Anecdotes,” in two volumes,
was published at Paris in 1757; and a similar work was
published by Mr. D’Israel in 1753, entitled, “Differtation
Anecdotes.”

Anecdotes is also an appellation given to such works of
the ancients as have not yet been published.

In which fede M. Muratoris gives the name Anecdota
Grecia to several writings of the Greek fathers, found in the
libraries, and first published by him. F. Martene has given
a Thesaurus Anecdatarum Notae, in folio. five vol.

ANE, or ANEDE, otherwise called affées, in Commerce, denotes a
corn-measure, used in some provinces of France, particularly
in Languedoc and Maccouin.

The aene is not so properly a measure as the denomina-
tion or affimblage of a certain number of other measures.
The aene at Lyons confids of six bicics, equal to one fajhter
and three bushels Paris measure. At Macon the aene is
somewhat more.

Aneé is also used for a quantity of wine supposed to be
ANEGADA, in Geography, one of the Virgin Isles, in the West Indies, and dependent upon Virgin Gorda. It is about six leagues long, and so low as to be almost covered with water at high tides. On the south side is Trenure Point. N. lat. 18° 35', W. long. 63°.

ANEGADA Bay lies on the eastern coast of South America, and is formed by the mouth of the river Suaces, which falls into the South Atlantic ocean on the east, in S. lat. 39° 45', and W. long. 62° 50'.

ANEO, a town of Italy, in the kingdom of Naples and province of Otranto, eight miles south-west of Brindisi.

ANEL, Dominic, in Biographia, physician to the court of Savoy, published in 1707, in vol. "L'Art de faire les plaies sans fe servir de la bouche du Homme, &c." Among the instruments by which this was performed was a kind of syphon, "metuendae magnitudinis," of a fearful size, Haller says. But his principal work, and which is still respected, is his "Nouvelle Methode de guerir les fistules la- chrymales," published at Turin, in 1713. He here describes a small and a fine flexible tube, by which he was enabled to open the lachrymal duct, and by means of a syringe to wash away the fowes, and finally heal the passage. This work gave rise to numerous controversial pieces, in some of which his method is eulogized, or the honour of the invention of it denied him. But the academy of surgery, at Paris, declared his method to be equally new and ingenious; and it has certainly led the way to all the improvements that have since made in the method of treating this very troublesome complaint. Haller Bibl. Chirurg. Eloy. Dict. Hist.

ANELLE, or ANIL, in Commerce, the same with indigo. 23 Eliz. c. 9.

ANELLA, in Entomology, a species of Phalaen, of the tinea tribe. The anterior wings are grey, with an oblong brown stripe, and two central, sub-ocellated spots. Fabricius. This species inhabits Austria, is large, and has a fenumaginous abdomen.

ANEMIUS furnus, among Chemists, a wind-furnace, used to make fierce fires for melting, &c. The word is formed of anemos, wind.

ANEMO-CHORD, a name given to the Aeolian harp. An instrument of this kind was constructed by John Jamesz, who was born at Weingen, in the duchy of Wittemberg, in 1739, and having passed through several stages of mechanical employment, became at length musical instrument-maker to the Counts of Artois at Paris. The founding of a harp, hung by accident in a passage admitting a breeze, suggested to him the idea of that instrument, which, in 1790, he first exposed to sale by the name of anemochord.

ANEMOMACHIA, from anemos, wind, and μαχη, fight, in some Ancient Writers, denotes a whirlwind, or hurricane. In which sense, we sometimes also meet with anemone, anemotaraxix, &c.

ANEMOMETER, compounded of anemos, wind, and μετρει, measure, in Mechanics, a machine wherewith to measure the force and velocity of the wind. The anemometer is variously contrived. The first of the kind seems to have been invented by Wolfius in 1708, and first published in his "Aerometria" in 1709, and also in the "Acta Eruditorum" of the same year; afterwards in his "Mathematical Dictionary," and also in his Elementa Matheseos," vol. ii p. 319. In the Philosophical Transactions we have one described, in which the wind being fanned to blow directly against a flat side or board, which moves along the graduated limb of a quadrant, the number of degrees it advances shows the comparative force of the wind.

This machine is moved by means of falls, A, B, C, K (Plate IX. Pneumatick, fig. 60,) like those of a windmill, which raise a weight L, that, till the higher it goes, receding farther from the centre of motion, by felling along a hollow arm M, fitted on to the axis of the falls, becomes heavier and heavier, and presses more and more on the arm, till being a counterpoise to the force of the wind on the falls, it stops the motion thereof. An index then, M N, fitted upon the same axis at right angles with the arm, by its rising or falling, points out the strength of the wind, on a plane divided like a dial-plate into degrees.

It is objected to this machine, however, that it requires a considerably wind to make it work. Leutmannus has contrived another, the falls of which are horizontal, and are more easily driven than the former, and will turn what way forever the wind blows.

In the Philosophical Transactions for the year 1766, Mr. A. Brice describes a machine which has been successfully practiced by himself, of measuring the velocity of the wind by means of that of the shadow of clouds passing over the surface of the earth.

Mr. d'Ons en Bray invented a new anemometer, which of itself expresses on paper not only the several winds that have blown during the space of twenty-four hours, and at what hour each began and ended, but also the different strength and velocities of each. Vide Mem. Acad. Scienc. an. 1734, p. 169. For other instruments of this kind, and their use, see Wind-Gage.

ANEMONE, formed from anemos, the wind, because the flower is not fupposed to open, except the wind blows, or because it grows in situations much exposed to the wind, anemone and pulsatilla of Tourn. anemone, anemone-ranunculus, hepatica of Dill. anemone of Vaill. wind-flower, in Botany, a genus of the polyandria polygynia class and order, of the natural order of multiflora, and ranunculace of Jussieu; its characters are, that it has no calyx; that the corolla has petals in two or three rows, three in a row somewhat oblong; the flamine have numerous filaments, capillary, half the length of the corolla ; anthers twin and erect; the pistillum has numerous germs in a head, fylies acuminate, and fyligmas obtuse; no pericarpium; receptacle globular or oblong, hollowed, and dotted; the seeds very many, acuminate, retaining the stye. Obf. Hepatica of Dill. has a three-leaved perianth, remote from the flower; an involucre. Pulsatilla of Tourn. has a leafy, multifid involucre, with the seeds tailed and hairy. Anemoneoids and hepatica of Dill. have naked seeds, without a feathered tail. Martyn enumerates 28, Gmelin and Willdenow 29 species.

* Hepatica, with a subcalycal flower. 1. A. hepatica, hepatica, with leaves three-lobed, quite entire. The flower lies a year complete in all its parts within the bud; the seeds are oblong-ovate, involved in a fally substance, and many of them abortive; the plant is a mild allringent and corroboration; and formerly used with these intentions, in an infusion like tea, or in powder given to the quantity of half a spoonful at a time; but it is now expunged from the dispensatories, and its use does not extend beyond that of gargarins; it is found wild in Sweden abundantly, in Denmark, Swif droit, France, Spain, Italy, and other parts of Europe, in woods and among bushes, with blue, red, and white flowers, fingle; cultivated here, in 1566, by Gerard. There are many varieties of hepatica, which are common in gardens, as fingle and double blue, fingle and double red or peach-coloured, fingle and double white, fingle and double variegated red and white, fingle and double violet-coloured, and with striped leaves. Parkinson mentions a white, with red flaments. These are some of the chief ornaments of the Spring; the flowers...
flowers are plentifully produced in February and March; before the green leaves appear, and make a very beautiful figure in the borders of the pleasure-garden, especially the double sorts, which commonly continue a fortnight longer in flower than the single ones, and the flowers are much fairer.

**Pulsatilla**, with the peduncle involucrated, and the seeds told. 2. *A. pratensis*, pulsatilla pratensis of Mill, pulsatilla polyanthes violacea, namesakes of Brev., and Helv. woolly-leaved A. with peduncles involucrated, and leaves digitate and multifid. The corolla is white, villose underneath, and the flaments yellow; a native of Siberia, about Tobu, &c., and also of lower Lapland; cultivated here in 1759 by Mr. Miller. 3. *A. foliosa*, with peduncle involucrated, leaves triplicate-pinnate, hairy, flat, acutely glanded, and feeds tall d. 4. *A. labradorica*, with bitterate fragrant leaves, or with bitterate leaves, triplicate foliaceous, thid lancea, foliaceous involucrated, and woolly feeds, with a very short permanent style, Willd. It is distinguished from the A. alpina, which it resembles, by its leaves and feeds; and grows wild about Aigle, &c., in Switzerland, Mont Balbo, M. Cenis, &c. 5. *A. campestris*, pulsatilla vulgaris of Miller, with peduncle involucrated, leaves pinnate, foliaceous, bipartite, obtuse and sinuate, and erect flowers, Willd. The flower is red without and white within, and blooms earlier than our paque-flowers. It grows in the woods, bordering on the mountains, in barren lands, in Sweden, Germany, and the high Alps of Switzerland. 6. *A. cervina*, with peduncle involucrated, leaves pinnate, and flowers nodding. It differs from the last species in the nodding of the flowers, and in the leaves having more pinnae finely cut. Thunberg found it near Jeko, in Japan, flowering early in Spring. 7. *A. pulsatilla*, pulsatilla folio erinaceo et majore flore of Buxton Park, Mor. Ger. Helv. Camer. and Ray. pulsatilla vulgaris of Miller, A. pratensis of Sib. and Wither. paque-flower, with peduncle involucrated, petals straight, and leaves bipinnate. It grows wild on open hills in dry soils, in Sweden, Denmark, Switzerland, France, Italy, Germany, Carniola, Siberia, &c. and in England on chalky downs, as Gogmagog hills, near Cambridge; Barnack heath, near Stanford, in the neighbourhood of Pontefract, near Chelbury, in Oxfordshire, Lesham, Bury, Newmarket, &c. It is perennial, and flowers in April and May. It has the Italian name pulsatilla, from the downy feed being beaten about by the wind. The plant is acrid, and will ruffle blisters; the distilled water will vomit; and it cannot be given with safety in disorders of the lungs. The juice of the petals stains paper green. Goats and sheep eat it; but horese, cows, and swine refuse it. There is a variety with double, and another with white flowers. 8. *A. pratensis*, pupatilla pratensis of Miller, flore minore migrante of Buxh. and Helv. p. vulgaris, satiratiore flore of Clauss. p. flore minore of Ger. p. flore ciano obfolecto, petals reflexis of Helv. p. folis decompositis pinnatis, flore pendulo, limbo reflexo of Hort. Cliff. &c. Meadow A. with peduncle involucrated, petals reflex at the tip, and leaves bipinnate. It is very common in the barren flinty fields of Oxford and Scania, also in Denmark, Fredmont, and in Germany, where it grows in the open fields and flowers in May. It was first cultivated in England by Mr. Miller in 1734, and in our gardens it very much resembles the A. pulsatilla, which would prove a good sublitate to it; the principal distinctions between these species, as they grow naturally, are taken from the flower, which in this species is more pendulous, of a darker colour, and has the apices of the petals reflexed; the item is also said to be less hairy and shorter than that of the pulsatilla; to which may be added, that the leaves of the pratensis are somewhat tom.utofe, while those of the pulsatilla are of a bright green. All the anemones have a considerable degree of acrimony; but this (says Dr. Lewin) seems to puff in the greatest share. In its recent state the plant has scarcely any smell; but its taste is extremely acrid, and when chewed, corrodes the tongue and fauces; and the dried plant like vate retains a considerable shade of acrimony. The root is milder than the other parts. The liquor, obtained by distilling the plant with water, is strongly impregnated with its virtues; and the remaining extract is considerably active. It also appears from some experiments to contain a camphoraceous matter, which was obtained in the form of crystals, of an unctuous taste, and very inflammable. This plant, as well as others of great activity, has been received into the Matern Medica of the Edinburgh pharmacopeia, upon the authority of Baron Stoerck, who recommends it as an effectual remedy for most of the chronic diseases affecting the eye, particularly amaurosis, cataract, and opacity of the cornea, proceeding from various causes. He likewise found it of great use in vesicular nodes, nocturnal pains, ulcers, caries, indurated glands, suppurated meninges, leprous eruptions, melancholy and phlegy. Six cases of amaurosis, three of cataract, and seven of affections of the cornea, we received, were either entirely cured, or greatly relieved by this remedy. The feblebe operation of the medicine was nausea and vomiting, particularly when the distilled water was used; and increased flow of urine, and sometimes gripes and looseness with increased pain at first in the affected part. The dose of the distilled water to adults is about half an ounce, twice or thrice a day; of the extract, reduced to powder with the addition of sugar, five or six grains. Many German physicians have tried the effects of this medicine in diseases of the eyes, with successes; but several others, among whom is Bergius, bear testimony to its inefficacy in these diseases, though they increased the dose beyond that directed by Stoerck. Notwithstanding this, says Dr. Cullen, (Med. vol. ii. p. 216.) "I would fully recommend it to the attention of my countrymen, and particularly to a repetition of trials in that disease, so frequently otherwise incurable, the amaurosis. The negative exception of Bergius, and others, is not sufficient to discourage all trials, considering that the disease may depend upon different causes; some of which may yield to remedies, though others do not." Every part of the plant, except its root, is ordered for medicinal use, and was prepared by Baron Stoerck for that purpose into an extract, or distilled water, and an infusion; but the first form seems to have been preferred, and was given from seven grains to three or four times that quantity, twice or thrice a day. The fluid preparations of the plant are likewise recommended for external use in ulcers and disorders of the skin. The manner of preparing the extract is given in the Edinburgh pharmacopeia. Murray's Mat. Med. vol. iii. p. 93.--101. Lewis's Mat. Med. p. 525. Woodville's Med. Bot. vol. iii. p. 400--11. 9. *A. alpina*, pulsatilla flore albo of Buxh. and Lob. alpina A. with item-leaves ternate, connate, supredecompound, multifid, and feedsraggy tailed. Willdenow mentions as a variety, A. alpina alba major of Buxh. and Burt. This species grows wild on the Alps, Jura, and in Austria, and was cultivated here by Mr. Miller in 1734. 10. *A. stipitata*, pulsatilla lutea of Camer. and Celn. p. tertia alpina of Dalech. A. stipitata of Clus. with item-leaves ternate, connate, supredecompound, multifid, very slender, extremely hairy underneath. It has no smell, and is a native of the Leonz Alps. It is doubted whether it be a distinct species from the last.

**Anemone** with a leafy item, and tailed feeds. 11. *A. coronaria*, pulsatilla folis decompositis ternatis of Hort. Cliff.
Anemone.

Cliff. *A. tenuifolia*, simplici florio de Bauh. narrow-leaved garden *A*. with radical leaves ternate-decompound and involucral leafy, or with radical leaves ternate-decompound, mucronated teeth, leafy involucral and woolly feeds; according to Willdenow, who reckons as varieties *A. tenuifolia* multiplex rubra of Bauh. and *A. angustifolia* multiplex, mutata florea facie quotannis nova of Miller. This species grows naturally in the Levant, particularly in the islands of the Archipelago, where the borders of the fields are covered with it of all colours; but the flowers are fingle and have been rendered double by culture. It was cultivated in France long before it was known in Holland or England: in our gardens, however, it was found in 1596. Parkinson, in 1629, says, that some reckoned 30 sorts with single flowers; and of those with double flowers he gives 12 varieties. Ray enumerates near 300 varieties of this and the broad-leaved sort. The catalogues of our modern florists have usually about 150 or 200. The principal colours in anemones, according to Mr. Miller, are white, red, blue, and purple; and in some these are curiously intermixed; but the most prevailing colours amongst our English raised anemones are white and red; though we have received from France a great variety of blues and purples, which are very fine flowers. The plain colours in the modern catalogues are red, crimson, rose-coloured, purple, blue, clear and pale blue, ash-coloured and white. The principal variegated ones are red and white striped, rode and blue, and white, red, white, and purple; but there are innumerable shades of these and the other colours. A double anemone, in order to be fine, should have a strong upright stem, about nine inches high; the flower from two to near three inches in diameter, the outer petals firm, horizontal, except turning up a little at the end, and the smaller petals within these should lie over each other gracefully, so as to form an elegant whole. The plain colours should be brilliant and striking; the variegated ones should be clear and distinct. 12. *A. hortensis*, pulsatilla folii digitatis Hort. Clif. broad-leaved garden *A*. or hard-leaved *A.* or *A.* with leaves digitate and feeds woollly; or, according to Willd. with radical leaves digitate, lacinia trifid, stem leaves ternate, lanceolate, connate, and subdivide, and woolly feeds. It is found wild, with fingle flowers, in Italy, Provence, and Germany. There are several varieties of this with single and double flowers; it was cultivated here by Gerard in 1597. 13. *A. palmata*, pulsatilla folis palmatis Hort. Clif. *A*. latifolia flava of Bauh. or *A. hortensis* latifolia of Clif. with leaves heart-shaped and subulate, and calyx fixed, and coloured. This species connects the hepaticas with the anemones by its fixed-parted calyx. It was found by Clusius in Portugal, near the Tagus.

**Anemone**, with a naked flower, and tailless feeds. 14. *A. fabri*, with stem one-flowered, involute leafy, and obtuse; found by Gmelin in Siberia. 15. *A. fylvetris*, large white-flowered wood *A*. with naked peduncle and feeds roundish, fhanggy and awnless; or with a stem two-flowered and leafy, leaves triplicate, lacinia trifid and dentated, feeds roundish and woolly, and permanent ligula, according to Willdenow, who mentions as a variety, *A. fylvetris* alba minor of Bauh. &c.; a native of many parts of Germany, found also in Sweden, Alsace, and Siberia; flowering in May, and ripening its seeds in June. 16. *A. fragifera*, with peduncle naked, feeds roundish, woolly, awnless, glades of the leaves acute, and lanceolate; a native of Carinthia. 17. *A. virginiav*, virginian *A*. with peduncles alternate, very long, fruit cylindric, and feeds fhanggy and awnless; or according to Willd. with many flowered leafy stem, triplicate leaves, lacinia trifid acuminate and dentated, acute petals, fhanggy feeds, and very short per-
It is a very ornamental plant, suitable to the flower-garden or plantation, and loves a light loamy soil. 27. A. ranunculoides, A. nemorum hirta of Ger. ranunculus nemorosus hirtus of Bauhin, yellow wood A. with loose involucre multiflorous, involucre three-leaved tubular and foliolous, tallifera seeds, and petals elliptic and by fixus, Smith; or with acute seeds, leaflets gilded, petals rounded, and item mostly one-flowered. It differs from the A. nemorum or wood A. in having a yellow corolla, two petals alternately outer, and two inner, and one having one side within and the other side without the next petal, whereas that has three outer and three inner petals; it differs also in the peduncles being accompanied with two leaflets, the latter of which is furnished with three at the base. This is perennial and flowers in April; grows wild in Sweden, Denmark, Switserland, France, Germany, Autria, Carniola, Italy, and Siberia; and with us in shady places and hedges, near King’s Langley, Herts, and near Worthing, in Kent. 26. A. nasiciflora, ranunculus montanus, &c. of Bauh. nasiciflorus-flowered A. with flowers umbelled (involuced Wild.), and seeds oval-depressed and naked (radical leaves palmated and grafted dentata, Wild.). This grows wild on the mountains of France, Switserland, Autria, Silicia, Siberia, and Cappadocia: introduced here in 1773; by John, earl of Bute. 27. A. faziculata, ranunculus nemorosus, aquilegia foliis, &c. of Pluck. meadow rue-leaved A. with flowers umbelled, item-leaves simple, and verticillate; and radical leaves binate. It grows wild in Virginia and Canada, and was cultivated here in 1768 by Mr. Miller. 28. A. Halleri, with leaves flabby and pinnate, the pinnae acutely lobated, and the involucres multifid, Gmelin from Allion. flor. pedem., or with involucres peduncle, pinnated leaves, leaflets tripartite, acuminate, and villose, and flower somewhat erect, Wild.; a native of the Alps of Piedmont, &c. Willdenow has omitted the fragiater, faziculata and fulprenera, and inserted the following species, viz. A. trifrons, with leaves ternated, leaflets cuneated and slightly cut, and multifid involucres; a native of Brazil, and described by Vahl. A. reflexa, with item tubular, item-leaves by three and ternated, leaflets subtribed, at the tip dentated, and petals lanceolate, oblines, and reflex; a native of Siberia, and very much refembling A. ranunculoides. A. umbellata, ranunculus orientalis anelli folio lanuginoso flore albo of Tourn. with flowers umbellate and involucres, radical leaves tripartite, and lacinius trifid and entire; a native of Cappadocia.

Culture. The plants of this genus are mostly hardy perennials, and may be increased both by seeds and by the roots. The Hepaticae are some of the chief beauties of the Spring; they produce flowers in February and March, before the green leaves appear; and the double sorts especially make a very handsome figure, continue a fortnight longer in flower than the single ones, and afford much fairer flowers. The single sorts are easily propagated by seeds, which they produce every year. The best season for sowing them is the beginning of August, and they should be sown in boxes or pots of light earth, exposed only to the morning sun till October, and then removed to the full sun during the whole Winter. In March, when the plants begin to appear, they should be removed to a shady situation, and frequently watered in dry weather. In August they will be fit to be transplanted; for this purpose a border should be prepared facing the wall, of good fresh loamy earth, in which the plants should be set at about six inches distance every way, and the earth should be closed firmly to the roots, to prevent their being injured by the worms; in the following Spring they will flower their flowers, but it will be an interval of three years before the flowers are strong, and you are able to judge of their goodnes. If at this time any double flowers, or any of a different colour from the red should appear, they should be transplanted into the borders of the flower-garden, where they should continue at least two years before they are taken up or parted. The double flowers, which never produce seeds, are propagated by parting their roots in March when they are in flower. The soil in which they delight is strong and loamy, in an easterly situation exposed to the morning sun.

The palustris (2—10.) may be propagated by seeds, in boxes or pots filled with light sandy earth, and exposed to the morning sun till ten, and secured from it in the heat of the day, and in dry weather often refreshed with water. The seeds are sown in July and August soon after they are ripe. The pots should remain in a shady situation till October, and then exposed to the full sun during the Winter. About the beginning of March, when the plants appear, they should only have the forenoon sun, be refreshed with water in dry weather, and kept free from weeds. When the leaves are decayed, which occurs usually in July, all the roots should be carefully taken up, and immediately planted in beds of light, frehly, sandy earth, about three or four inches auster, and covered to the depth of about three inches with the same light earth. In the following Spring most of these plants will produce flowers, but they will be larger and fairer in the succeeding years, when the roots are larger.

The garden anemones (11, 12.) are natives of the east, from whence their roots were originally brought; but culture has so improved them, that they are become the chief ornaments to our gardens in the Spring. To prepare the soil for these plants, take a quantity of fresh, light, sandy loam, or hazel-earth, from a common or dry pasture, not dog above ten inches deep; mix this with a third part its quantity of rotten cow-dung, and lay it up in a heap; turn this over at least once a month, for eight or ten months, and every time pick out the flones and break the clods. After this mixture has been twelve months made, it will be fit for use, and fully prepared for the garden

In
In the beginning of April the early planted roots will begin to flower, and they will keep in flower near a month, if the weather prove favourable, and they are properly shaded with mats, laid over hoops in the greatest heat of the day: the second, and last planted ones, will follow these; and, in the whole, there will be at least two months fine flowering.

Toward the beginning of June the first planted roots will lose all their leaves, and they must be then taken up and washed clean, and laid dry on mats in the shade; after which they are to be put up in paper bags, and hung up till the time of planting them comes on again. The later planted ones are to be taken up afo as soon as their leaves decay, and not suffered to remain to make new shoots, for then it is too late to remove them.

They are propagated two ways, either by dividing the roots or by sowing. The roots are to be divided as soon as they are taken up out of the ground: they will succeed if broken into as many parts as there are eyes or buds in them; but they flower most strongly, if not parted too small.

The way, by sowing, is this: choose first some good kinds of single anemones, called by the gardeners poppy anemones; plant these early, and they will produce ripe seeds three weeks after the flower first blows. This must be carefully gathered, and in August it should be sowed in pots or tubs, or a very well prepared bed of light earth, rubbing it between the hands with a little dry sand, to prevent several of the seeds from clinging together, and spreading them as even as possible all over the bed; after this a light hair-brush should be drawn many times over the surface of the bed, to pull off any lumps of feed that may yet have fallen together; observing not to bruise off the feed, and as much as possible not to bruise it into heaps. When this is done, some light earth, about a quarter of an inch deep, should be sifted over the bed. If the weather be hot, the bed must be at times covered with mats laid hollow, and gently watered.

In about ten weeks after sowing, the plants will appear, if the season has been favourable, and they are to be carefully defended from the hard frosts by proper covering, and from the heat of the sun afterwards by a movable reed fence. As the Spring advances, if the weather be dry; they must be gently watered, and when their green leaves decay, there must be a quarter of an inch more earth sifted over them, and the like again at Michaelmas; and the bed must be kept clear from weeds, and the following Spring they will flower.

The single or poppy anemones will flower most part of the Winter and Spring, when the season is favourable, and in a warm situation; and they require little culture, for it will be sufficient to take up the roots every other year, and when they are taken up, they should be planted again very early in the Autumn, or else they will not flower till the Spring. There are some fine blue colours among these single anemones, which, with the scarlets and reds, form a beautiful mixture of colours; and as these begin to flower in January or February, when the weather is cold, they will continue for a long time in beauty, provided that the frost is not too severe. The seeds of these are ripe by the middle or end of May, and must be gathered daily as they ripen; otherwise it will often be blown away by the winds.

The roots of wood anemones (23, 24, &c.) may be taken up when the leaves decay, and transplanted into wild meadows, where they will thrive, and in the Spring have a good effect in covering the ground with their leaves and flowers. The blue anemone (24.) flowers at the same time with the foregoing, and intermixed with it, makes a fine variety. Double flowers of both these sorts have been obtained from seeds.

This, and most of the other wild anemones, may be propagated from offsets from the root, which they put out plentifully, and they will grow in most soils and situations Virginia anemone (17.) and some others, produce plenty of seeds, and may be readily increased also that way. Martyn's Miller.

Anemone puffilla. See DRYAS.

Anemone, in Natural History, a species of hydra in Gmelin's arrangement; but which should with more propriety be referred to the actiniae of Linnaeus. As Ellis had placed it with other analogous species before. The body is flexible and flat, the disk sub-hexagonal, and surrounded with numerous tentacula. It is found in the West Indian seas.

Anemone is likewise the trivial name given by fome to the actiniae of Linnaeus in general; hence the French author Dicqueymar calls the anemone puffilla of Linn. Anemone de la premiere epee, anemone stratiotes, anemone de la seconde epee, &c. &c.

The singular reproductive properties of this kind of venus is now sufficiently ascertained, yet it appears that we were in a considerable degree indebted to the accurate observations and experiments of M. Dicqueymarre, in the first instance, for the interesting discovery. This author conjectures that it is owing to the gelatinous texture of those creatures, that they possess the wonderful faculty of reproduction. He observs, that their limbs budded out successively after several amputations; nay, some of them were dissected through the body; and the bals, together with that part of the stump which was left, survived, projected new limbs, and the animal moved and eat bits of muscles, which are its usual nourishment. They appeared to bear a considerable degree of heat, and to live in a vacuum, at least in a very rare air; and they require for a very considerable time no other food than what they find disseminated in sea water.

Dicqueymarre endeavours to prove that sea anemones may be made use of for indicating the different changes of temperature in the atmosphere; but certainly without success, as the observations of later naturalists fully demonstrate. His account of this new kind of barometers is thus related. The sea-water, in which the anemones are placed, must be renewed every day, and this must be their only nourishment; and the observations should be made at intervals equally distant from the renewals of the water. If the anemones be cut and contracted, there is reason to apprehend an approaching storm; that is, high winds, and a rough agitated sea. When they are all shut, but not remarkably contracted, they forebode a weather somewhat less bisterous, but still attended with gales and a rough sea. If they appear in the leaf open, or alternately and frequently opening and closing, they indicate a mean state both of winds and waves. When they are quite open, tolerably fine weather and a smooth sea may be expected. And, lastly, when their bodies are considerably extended, and their limbs divergent, they surely prognosticate fixed, fair weather, and a very calm sea. The gales in which they are deposited may be strong at sea, in the same manner as the compacts, so that the rolling of the ship, may agitate the water as little as possible. These animals are viviparous; for several of them brought forth eight, ten, or twelve young ones in the hand.

The account of the species foetida, as related by Mr. Ellis, in the Philosophical Transactions, affords still more accurate information concerning this tribe of creatures, their internal organization, economy, &c., than the reports of Dicqueymarre. "This compound animal, which is of a tender fibrous sub stance, consists of many tubular bodies, swelling gently towards the upper part, and ending like a bulb.
bolb or very small onion; on the top of each is its mouth, surrounded by one or two rows of tentacles, or fleshes, which when contracted look like circles of heads.

The lower part of all these bodies has a communication with a firm fleshy wrinkled tube, which sticks fast to the rocks, and forms with other fleshy tubes, which creep along them in various directions. These are full of different fizes of these remarkable animals which rise up irregularly in groups near one another.

This fleshy tube, that secures them fast to the rock in flily bottom, is worthy of notice. The tubes that we observe are formed into several parts of it by its infusing itself into the interstices of the coral rock, or by grasping other pieces of shifs, part of which still remain in it, with the fleshy substance grown over them.

This shows us the instinct of nature, that directs these animals to preserve themselves from the violence of the waves, not unlike the anchoring of mufcles, by their thin fleshy filaments that end in feet, or rather like the fleshy hats of the fernulae, or worm-shells, the tree oyler, and the fupper barnacle, &c. whose bases formal to the shape of whatever substance they fix themselves to, grasping it fast with their tentacular claws to withstand the fury of a storm.

When we view the inside of this animal difsected lengthwise, we find a little tube leading from the mouth to the locham, from whence there rise fhrinked small gutes in a circular order, with a yellowish foflubiance in them; these bend over in the form of arches towards the lower part of the bolb, from whence they may be traced downwards to the narrow part of the upright tube, till they come to the fleshy adhering tube, where fome of them may be perceived entering into the papilla, or the beginning of an animal of the like kind, molt probably to convey it nourifhment till it is provided with claws; the remaining part of these flender gutes are continued on in the fleshy tube, without doubt for the fame purpofe of producing and supporting more young ones from the fame common parent.

The many longitudinal fberes that we discover lying parallel to each other, on the inside of the femi-transparent skin, are all inferted in the ferial claws round the animal's mouth, and are plainly the tendons of the mufcles for moving and directing the claws at the will of the animal: these may likewise be traced down to the adhering tube.

Another remarkable creature of this kind is defcribed in Hughes's Natural History of Barbadoes, and which, it is faid, was only found in a bayon in one particular cave.

"In the middle of the bafon," fays that author, "there is a fixed bone, or rock, which is always under water. Round its fides, at different depths, feldom exceding 18 inches, are foon, at all times in the year, infifting out of little holes, certain fubflances that have the appearance of fine vacated flowers, of a pale yellow, or a bright ftraw colour, lightly tinged with green, having a circular border of thick-feft petals, about the size of, and much refeemb ling those of a fingle garden-marigold, except that the whole of this foming flower is narrower at the diftures, or fettling on of the leaves, than any flower of that kind.

"I have attempted to pluck one of these from the rock, to which they are always fixed, but never could effeft it; for as foon as my fingers came within two or three inches of it, it would immediately contract close together its yellow border, and shrivel back into the hole of the rock; but if left undisturbed for about four minutes, it would come gradually in fight, expanding, though at firft very cautionfly, its foming leaves, till at al it appeared in its former bloom. However, it would again recoil with a fputrifying quicknels when my hand came within a fmall diftance of it. Having tried the fame experiment by attempting to touch it with my cane, and a fmal tender rod, the effeft was the fame.

"Though I could not by any means contrive to take or pluck from the rock one of these animals entire, yet I once cut off (with a knife which I had held for a long time out of fight, near the mouth of an hole out of which one of thefe animals appeared) two of thefe foming leaves. These, when out of water, retaining their shape and colour, but being compofed of a num brane-like fubflance, furprizingly thin, it soon thrilved up and decayed."

The fame author further adds, that many people coming to fee these creatures, and ocourning some inconvenience to a person through whole grounds they were obliged to pass, he resolved to defroy the objects of their curiiosity, and that he might do it effectually, caufed all the holes out of which they appeared to be carefully bored and drilled with an iron instrument, fo as to cauf their bodies to a pulp, and yet they again appeared, in a few weeks from the very fame places. It has been fuppofed that this Barbadoes amone may be a species of tubularia rather than actinia.

ANEMONOIDES, See Antemone.
ANEMONOSPERMOS. See Artocoris and Gorteria.

ANEMOSECOPE, derived from anemos, wind, and oscope, I confider, is some times used for a machine invented to foretell the changes of the wind. For this purpofe it fhould confift of an index moving about a circular plate, like the dial of a clock, on which the 32 points of the compass are drawn instead of the hours. The index, pointing to the divisions in the dial, is turned by an horizontal axis, having a handle-head at its outward extremity. This handle-head is moved by a cog-wheel on a perpendicular axis; on the top of which is fixed a vane, that moves with the course of the wind, and gives motion to the whole machine. The whole contrivance is very simple, and nothing is required in the conftuction, but that the number of cogs in the wheel and rounds in the trundle-head be equal; because it is neceffary, that when the vane moves entirely round, the index of the dial fhould also make a complete revolution. An anemoscope of this kind is placed in one of the turrets of the Queen's palace. An account of an anemoscope contrived by Mr. Pickering, may be seen in the Phil. Tranf. vol. xiii. pl. ii. p. 9; and another defcribed by Mr. Martin, in his Philof. Briton, vol. ii. p. 211. See ANEMOMETER and Wind Gage.

It has been observed, that hygroscopes made of cat's-gut, &c. prove very good anemoscopes; seldom failing, by the turning of the index about, to foretell the shifting of the wind.

The anemoscope used by the ancients seems, by Vitruvius's defcription of it, to have been intended rather to shew which way the wind actually blew, than to foretell into which quarter it would change.

Otto de Guericc also gave the title anemoscope to a machine invented by him, to foretell the change of the weather, as to fair and rain. It conftited of a wooden little man, who rofe and fell in a glafs tube, as the atmosphere was more or lefs heavy. Accordingly, M. Comiers has fhewn, that this anemoscope was only an application of the common barometer. See Wind.

The anemoscope of Varec is famous. It is made of the bird's nest, whose feathers are picked, the skin stripped off, visera taken out, and the skin in this state drawn a-new over the bones; this being hung up in the chimney, is said always to direct its bill to the point from whence the wind

AN-END, in Sea-language, denotes the position of any mast, &c. when erected perpendicularly on the deck. The top-masts are said to be an-end, when they are hulled up to their usual elevation.

ANET, in Geography, a town of France, in the department of the Eure and Loir, and chief place of a canton, in the district of Dreux, near the Eure; eight miles north-north-west of Dreux.

ANETHIFOLIUS, in Botany. See Proteus.

ANETHUM, derived from aedus basi, because it runs up quick or straight, a genus of the petunindra elginia clasfs and order, and of the natural order of umbelliferae or umbellifers; its characters are, that the calyx has an umbel universal and partial manifold, the involucre neither universal nor partial, the perianth proper obsolete; the corolla universal, uniform, filaments all fertile; proper; five petals, involute, entire and very short; the flowers have capillary filaments and roundish anthers; the pistillum is a germ inferior, styles approximating, obsolete; ligules obtuse; no pericarpium, fruit subulate, compressed, frayed and bipartite; the seeds are two, subulate, margined, convex, and frayed on one side, flat on the other. There are three species, i. A. graveolens, A. Hortensiae. Common dill, "with fruit compressed." Dill differs from fennel, which it most resembles, in having an annual root, a smaller and lower leaf, the leaves more glaucous, and of a less pleasant smell, the seeds broader and flatter, surrounded with a membranaceous rim, and of a less pleasant flavour than fennel seeds. This plant grows wild among the corn in Spain and Portugal, and also in Italy on the coast, and near Constantinople. It is annual, and was cultivated here in 1597; the seeds of dill are directed for use by the London and Edinburgh pharmacopoeias; they have a moderately warm pungent taste, and an aromatic smell, but not of the most agreeable kind. Water extracts very little of their virtues, either by infusion or digestion for many hours. In boiling, their whole flavour exaltes with the watery vapour, and may be collected by distillation. The distilled water, drawn off to the quantity of a gallon from a pound, is occasionally made the basis of carminative draughts or juleps. The simple water makes better than any in the lopes. Along with the water arks a considerable portion of essential oil, in taste moderately pungent, and tending strongly of the dill. Rectified spirit, digested in dill seeds, readily extracts both their smell and taste; but, by distillation, it brings over very little of the flavour, the active part of the seeds remaining in the extract. The seeds and the plant itself were formerly much used in medicine, and, from the time of Dioscorides, have been esteemed for their carminative and hypotonic powers; and they have, therefore, been recommended in flatulent colics, and certain dyspeptic symptoms proceeding from a laxity of the stomach. Foretus speaks highly of their use in allaying vomiting and hiccups. They are also said to be more effectual than the other seeds of this clafs in promoting the secretion of milk. At this time, however, the seeds of dill are seldom employed, though a simple distilled water from them is directed both by the London and Edinburgh pharmacopoeias. Allaine says, that the essential oil, rubbed on the abdomen, is useful in allaying flatulence and colic; and in a clyster, as a carminative. Lewis. Murray. Woodville.

2. A. fegatum, A. sylvæbre minus of Bauhin, fennulum luftianicum minus annuum ornechi odor of Tourin. "with three stem leaves, and oval fruits." It is annual, and a native of Portugal. 3. A. fumicincum, common fennel, or sinkle, "with gibbous fruits, and stem leaves numerous and deflexed."

It is a native of Germany, Spain, Italy, Madeira, China, &c.; it is binomial, and flowers in July and August, and the seeds ripen in Autumn. Linnaeus distinguishes four varieties of fennel, viz. sweet fennel; common fennel, F. vulgare germanicum of Bauhin. Italian fennel, F. vulgare italicum of Bauhin; and wild fennel, F. Sylviaria of Bauhin. Miller enumerates three varieties, viz. F. vulgare, or common fennel, F. Dolce, or sweet fennel, and F. azoricum, or azorian fennel, or smochio. The common fennel runs from three to five feet high, blue green, with yellow flowers. It has a strong puffy root, which penetrates deep into the ground, and will continue for several years; it has town itself in many places, and appears like a native in England; accordingly it is enumerated among our native plants by Hudson, Wilthorng, Smith, &c. and is now common on chalk cliffs, as about Marazion in Cornwall, in Sussex, about Gravefend and in other parts of Kent, Nottingham Castle, near Spetchly in Worcestershire, Lyttel, and other places in Cambridgeshire, and commonly on the western coasts. The sweet fennel has been supposed to be a variety of the common fennel, but it has been cultivated in the same ground with the other and retained its differences; though botanists affirm, that it will return to its pristine form and qualities. The seeds, which are longer, narrower, and of a lighter colour, are generally imported from Germany and Italy, and are reckoned superior to those of our own growth.

Dietetic and medical qualities of fennel. The tender buds of fennel are eaten in salads; the leaves boiled are used as fonce for fish, particularly mackerel, and they are eaten raw with pickled fish. In Spain they put them up with olives and pickled pork. The seeds of sweet fennel are admitted into the materia medica of the London and Edinburgh pharmacopoeias, and the root of the common fennel in that of Edinburgh. Sweet fennel seeds are useful remedial and carminative, and are sometimes given in powder, from a few to a dram; and sometimes candied. Water extracts the virtue of those seeds very imperfectly by infusion, but carries it off totally in evaporation. By distillation, they impregnate water with their flavour; a gallon of water receiving a strong impregnation from a pound of the seeds. A large proportion of essential oil separates in the distillation, and floats on the surface of the aqueous fluid; in colour yellowish, in smell moderately strong and diffusive, and exactly resembling the fennel, in taste mild and sweetish, like the oil of aniseeds, and like it also congealing, by a slight cold, into a white butyricaceous mass. These seeds contain likewise a considerable quantity in gross oil of the expressed kind, which, when freed from the essential oil, manifests no particular smell or taste. This oil is extracted, with the aromatic matter of the fennel, by digestion in rectified spirit, but separates and rises to the surface upon infusing the filtered tincture. The spirit, gently distilled off, has very little of the flavour of the seeds; the oily matter retains a part both of their taste and smell; but much the greatest part remains concentrated in the extract. The seeds of the common fennel are warmer and more pungent, but less sweet, and of a less grateful flavour than that of the preceding; and there is the same difference in the preparations from them; the spirituous tincture of the sweet fennel is yellowish, but that of the common greenish. The leaves impregnate water by distillation with a grateful flavour, and yield a considerable portion of essential oil. An extract made from them by rectified spirit is no incoherent aromatic. The roots, taking up early in the spring, have a pleasant sweetish taint, with a slight aromatic warmth. They are ranked among the aperient roots, and supposed by some to be equivalent in virtue to the celebrated ginseng of the Chinese, from which, however, they
ANEURISM.

differ in their useful qualities. They are said to be pectoral and diuretic, but now wholly disregarded. The fermentation of the Latins is supposed to be the μεθαιων of the Greeks, by whom it was highly esteemed for promoting the secretion of milk; and this opinion has been confirmed by the experience of some modern authors. The flavonoids, carminative, and other effects ascribed to fenelon, depending upon their stimulating and aromatic qualities, must be less considerable than those of dill, anise, and caraway, though termed one of the same greater hot feeds. Lewis, Murray, Woodville. The fenichel, supposed to have been originally brought from the Azores, has been long cultivated in Italy as a salad herb; and it is also cultivated in some few gardens in England.

Culture. Dill is propagated by sowing the seeds in autumn soon after they are ripe, in a light soil, where they are to remain, at the distance of eight or ten inches asunder. When the plants are come up, they should be hoed, and left at the above distance, and kept clear from weeds. When the seeds begin to be formed, those that are intended to be put into the pickle for cucumbers should be cut up, and those intended for seeds left till they are ripe; and then they should be cut, spread upon a cloth to dry, and beat out for use. The best time to sow the seeds of fenelon is soon after they are ripe; the plants will come up in the autumn or following spring, and require no other care besides being thinned and cleared from weeds: they will grow in any soil or situation. For the fenichel, good seeds must be procured; and a good spot of light rich earth, neither dry nor very wet, selected, the first crop may be sown about a fortnight in March, which, if it succeeds, will be fit for use in July; and, by sowing it several times, a supply may be had for the table till the frosts put a stop to it. When the ground has been well dug and levelled, a hollow drill must be formed by a line and the seeds thinly scattered in it, about two inches apart; the drills should be 18 inches asunder, that there may be room to clean the ground and earth the plants. The plants will usually come up about three weeks or a month after sowing; and then with a small hoe the weeds should be cut between them, and the plants thinned; and thus successively till they are at the distance of seven or eight inches.

The stems of the plants, which rise above the surface of the ground, should be earthed for blanching, about a fortnight or three weeks before they are used, and they will thus be rendered very tender and crisp. The second crop should be sown about three weeks after the first; and the crops should be continued in succession at such intervals till the end of July. In April, May, and June, the soil should be moistier than the first; and in July it should be drier and in a warm situation, and the beds at this season should be watered and shaded. In autumn, if sharp frosts should occur, the plants should be covered with peat-baum, or some light covering; and thus they may be preserved for use till the middle of winter.

Martyn's Miller.

ANEURIN, in Biography, one of the most eminent of the ancient bards of Britain, who was a chiefman of the Otodini, and bore a conspicuous part in the battle of Catraeth, about A. D. 530, the subject of a noble heroic poem composed by him; and which is printed in the Archæology of Wales, with another composition by the same person, entitled Odes to the Months. About the year 540, Aneurin is supposed to have left his territories in the north, in consequence of the growing power of the Saxons; and eventually, some old documents and traditions lay, that he took refuge in the famous monastery of Llantwit, in the country of the Silures, where he died, about A. D. 570.

ANEURISM, or ANEURYSM (from aneurys, dilato), in Surgery, a preternatural dilatation of an artery, or a collection of blood in the cellular membrane, occasioned by the rupture or puncture of an artery. The fistula has been called the true, or genuine aneurism; the second, the false, or fictitious aneurism. The true aneurism is again distinguished into the true circumscribed aneurism, in which the artery is only dilated in one small part, and the tumour is circumscribed; and the true diffused aneurism, when the tumour produced by the dilatation of the artery is of considerable extent, and, as it gradually loses itself in the surrounding parts, its boundaries cannot be accurately defined.

The fictitious aneurism is again divided into the circumscribed fictious aneurism, in which the blood is collected in a sac in some part of the cellular membrane, forming a distinctly circumscribed tumour; and the diffused fictitious aneurism, where the blood is effused into the adjacent cavities of the cellular membrane, forming an unequally elongated tumour. Besides these two principal species of aneurism, a third, the mixed aneurism is reckoned; which consists in a combination of the true and false aneurisms with each other. The fistula subdivision of this species occurs when the external membrane of an artery has been injured by puncture, cutting, laceration with the splinter of a bone, or any other accidental cause, whilst the internal membrane remains untouched. The internal membrane, which is unable of itself to refit the impetus of the blood, is protruded through the orifice in the external membrane, so as to form a tumour, partly by laceration, partly by dilatation of the artery, and consequently by a combination of both causes. The second subdivision occurs, when the face of the true aneurism bursts, and the blood, penetrating into the adjacent cellular membrane, surrounds the face. As the true circumscribed aneurism may be produced wherever arteries exist, and consequently as well in the internal as the external parts of the body; it is divided into the internal and external true circumscribed aneurism. Of the internal, that of the aorta, and of the external, that in the arm or hollow of the knee, is the most frequent.

The true circumscribed external aneurism may be known when the patient remarks an unusual pulsation in any part of his body; when, upon close examination, he discovers a small pulsating tumour on the part, which disappears on being pressed with the finger, and, as soon as the preffure is removed, returns. It also will often disappear when the artery is strongly compressed at some part above it, and returns again as soon as the preffure is removed.

This tumour is not painful, neither is the external skin discoloured. When it has once been produced, it generally goes on increasing with an uninterrupted progress. The larger it grows, the less the pulsation is perceived, which may at length entirely cease when the tumour has become very large. When the face of it is of considerable size, and the pulse under the tumour weak and small, the limb frequently becomes cold, collapsed, pale, weak, or oedematous. The danger is the greatest when the sac bursts, which it does either in such a manner as to leave the external skin, that covers it, entire, in which case the true aneurism is changed into the mixed; or, the sac bursts, together with the external skin, in which case a violent haemorrhage ensues, that proves fatal, unless speedy assistance can be procured. The rupture of the sac is sometimes produced by concussion, or any other external cause, and sometimes spontaneously; in which case it may generally be foreseen for some time before it happens, by the place, which before was particularly dilated and elevated, becoming thin, soft, or bluish.

The internal true aneurism is only to be discovered by an unusual, confluent, and violent pulsation in one part, which cannot be distinctly perceived till the tumour has attained a considerable
ANEURISM.

considerable magnitude; for whilst it is still small, this pulsation is very indistinct. When these tumours have attained to a considerable size, they sometimes at length appear externally, in which case they may easily be ascertained.

It now and then happens, however, that pulsation combined with dilatation does not certainly characterize this disease. (See Delfaut's Obst. Chir. and Medical Communication.) We have known the most careful observers deceived both in tumours of the extremities as well as internally, by forming their diagnoses from the pulsation alone. It is therefore necessary in these cases to take all the circumstances into consideration, from the earliest period of the disorder to its complete formation. When a soft tumour lies immediately upon an artery, the pulsation of the vessel may be felt through the tumour; and when the conglomeration of a real aneurism becomes firm, the pulsation may be obscure or imperceptible.

The proximate cause of the true aneurism is indubitably a preternatural dilatation of the artery in some part, whereby it is rendered unable to reflect the impetus of the blood, in consequence of which it yields, and is dilated into a sac. This may happen from a local injury; for example, a bruise, which may particularly be the cause in those parts of the body where the artery has but few muscular parts to cover it, and is situated near a bone. Probably a sudden and violent elongation or stretching of the artery may occasion this typical weakness; at least we sometimes see true aneurisms arise after violent stretching of a limb, in fractures, dislocations, violent bodily exertions, convulsions, &c. Sometimes, probably, the cause may consist in a violent and inordinate motion of the blood: the artery may also be deprived of its support, by an abscess in any part of the body, and weakened in such a manner as to be unable to reflect the impetus of the blood. In all these, and other similar cases, the aneurism defies the name of a typical disease. Frequently, however, and perhaps in the majority of cases, the aneurism is the consequence of a general dilatation of the whole arterial sytem. According to the experience of Morgagni and others, aneurisms are said to be sometimes produced by the venereal, rheumatic, scorbutic, and other constitutional taints in the sytem. Sometimes these tumours arise spontaneously, without any occasional cause; frequently several of them are produced at the same time in different external and internal parts: we also find in distempering the bodies of persons who have been afflicted with aneurism, that the arterial system is in many parts, nay, even universally, extremely feeble, and easily lacerated. This species of the disease, DIATHESIS ANEURYSMATICA, is, in the present state of our knowledge, to be considered as altogether incurable, as we cannot determine its cause with certainty.

The false or purulent aneurism consists in a rupture of the artery, the blood being effused through the orifice into the surrounding cellular membrane. As this species, like the true aneurism, may be produced both in internal and external parts, it is likewise subdivided into the internal and external. The causes by which a preternatural orifice may be made in an artery, are numerous: e.g. sudden violent exertion of a limb or of the whole body, the lifting of heavy burdens, violent spasms, vomiting, &c. The most frequent cause, however, is a laceration of the artery by some foreign substance, as by the splinter of a bone; and particularly by the lancet, when blood-letting is performed in an unskillful manner, at the bend of the fore-arm, of which we therefore shall treat more minutely than of the other kinds.

In cutting blood at the arm, the artery may be discovered to have been wounded, by the blood being thrown out with unusual force, in an uninterrupted but unequal stream, as it were by jerks; also by its florid red colour; and, which is the most certain sign, by the blood flowing out in an even stream, with less force, when pressure is applied to the artery above the wound. In these cases the dilatation of the blood forming a purulent aneurism is generally owing to the fault of the surgeon, in attempting to stop the hemorrhage too suddenly, either by pressing his fingers upon the wound, or by applying a bandage. The aneurism is produced either in consequence of the orifice in the external skin being displaced in such a manner that the blood can no longer be discharged through it, and must consequently diffuse itself in the cellular membrane; or by the pressure, which is hardly applied, being too weak, so as merely to close the orifice in the skin and vein, but not that in the artery, which consequently discharges the blood into the surrounding cellular membrane. The tumour produced in this manner is commonly of a red, bluish, and, finally, of a black colour.

The false dilated aneurism, arising from this cause, increases in size as long as the internal hemorrhage continues; and if this be not speedily stopped, it produces violent pain and immobility in the limb, nay, at length, inflammation, suppuration, and gangrene. The most recent case of this kind, with which we are acquainted, is related in the fifth volume of the Medical and Physical Journal, by Dr. Adams, of Madeira; and in this case a perfect cure was effected, by long continued pressure on the artery, at the superior part of the arm.

The circumscripted purulent aneurism is produced, when the hemorrhage has at first been stopped by the application of a proper prelitre, but the bandages have been removed too early, and before the orifice of the artery has been closed, so that the blood is effused through the wound, till left, or newly torn open, into the surrounding cellular texture; but, on account of the adhesion of the cellular membrane, produced by the prelitre previously applied, cannot penetrate into its cavities, and consequently collects itself into a mass, near to the orifice in the artery, dilating the cellular membrane into a sac. Sometimes, however, though rarely, this kind of aneurism is produced immediately after the artery has been wounded; namely, when on account of the smallness of the puncture in the artery, the hemorrhage takes place so slowly, that the blood first discharged becomes coagulated, so as to stop the aperture through which the proceeding discharge might pass into the cavities of the cellular membrane, and prevent its discharging itself. Sometimes also the artery is covered with a membrane, aponeurosis, &c., which prevents the diffusion of the blood, and compels it to collect into a mass.

The circumscribed false aneurism consists therefore of a sac, formed out of the cellular texture, and filled with blood, which is situated close to the artery, and communicates with the artery itself by means of the wound in it. In the false aneurism a pulsation can almost always be perceived, and that the more distinctly, the smaller the tumour is. The larger this sac becomes, the more it loses its elasticity, the greater becomes the accumulation of coagulated blood within it, and the weaker consequently becomes the perceptible pulsation, which in very large aneurisms of this kind entirely disappears. At first the tumour is small, and vanishes entirely under the prelitre of the finger; but as soon as the prelitre is removed it appears again. It vanishes in the same manner, when prelitre is applied to the artery above the tumour, and re-appears when that prelitre is removed. As soon as coagulated blood has accumulated in the sac, the tumour can no longer be made entirely to disappear by prelitre, but it becomes hard. It is without pain, and the integuments that cover it, present the natural appearance. When
Aneurism.

Once produced, it increases with a constant and regular progress, and at last becomes enormously large. The flow of the blood into the limb below the tumour is always impacted, the pulsation of the arteries in it becomes feeble and small, and the limb itself is cold, collapsed, torpid, pale, or cyanosed. A series of the neighbouring bones frequently takes place. This aneurism may also at length burst, and produce a fatal hemorrhage, unless promptly ligature can be procured. The part where it bursts previously grows thin, soft, and bluish, or of a purplish aspect.

Notwithstanding the great resemblance which exists between the phenomena of the true and those of the false aneurism, they may however in general be easily distinguished from each other, especially after the full period of their existence. The true aneurism yields to the pressure of the finger very quickly, and reappears as quickly, when the pressure is removed; the false aneurism, on the contrary, yields only in a gradual manner, and appears again in the same manner, as the blood contained in the sac cannot be wholly pressed through the orifice of the artery, nor again effused by flow degrees. Sometimes a whistling sound of noise may be distinctly heard, when the blood is pressed into the orifice, and again pours through it. The pulsation in the false aneurism is always weaker; and, as the tumour increases in size, diminishes much more rapidly than in the true aneurism, in which, even though it has attained a very considerable size, a strong pulsation can always be felt.

The false aneurism becomes sooner hard than the true one, and cannot then be made entirely to disappear by pressure, as coagulated blood is very readily accumulated within it. Moreover, any mistake that may be occasioned by the difficulty of the diagnosis between the two species, cannot often be attended by any bad consequences, as they both require pretty much the same method of treatment. The internal false aneurisms are, on account of the pulsation being much weaker and imperceptible, and vanishing much sooner, than in the true aneurisms, as difficult, may more difficult to be distinguished than these, though in other respects they excite similar symptoms.

When, in letting blood at the arm, the surgeon discovers, by the signs which we have already mentioned, that an artery has been wounded, he must immediately apply a tourniquet to the upper part of the arm, in order first to stop the hemorrhage, and obtain time for applying his bandages with the requisite care and accuracy. The hemorrhage from the vein is to be stopped with the common bandage. But, in order permanently to arrest the hemorrhage and close the wound of the artery, he must apply a compres with great exactness, which must be sufficiently tight entirely to prevent the hemorrhage, and not easily to be removed from its situation; it ought also to close merely the artery itself, without affecting the lateral branches and the veins, left a swelling and mortification might ensue from want of circulation. A pledget, or thin compres, is to be applied, the inner surface of which must be somewhat broader than the opening in the vein, immediately upon the external wound, otherwise the pledget might easily mis the orifice of the artery. All now depends upon this compres being sufficient to stop the wound, its being applied with an uniform pressure, and in such a manner as not to prevent the motion of the blood through the lateral branches and veins. The common bandage used in blood-letting does not answer these purposes so conveniently as by means of Plenks apparatus, which, however, must be applied with great exactness. (J. Jac. Plenks Sammlung von Beobachtungen über die Heilige Genesung der Wundarzneiwissenschaft. Vienna, 1775. 8. p. 195. Allo: Richters Anfangsgründe der Wundarz-

nyk. B. i. § 531. tab. iv. f. 7.) Should a small tumour arise close to the point of the pledge, the apparatus should still be screwed somewhat tighter, as the pressure was possibly not sufficiently strong. If nevertheless the tumour should grow still larger, we may be certain that the compres does not lie upon the wound of the artery; the tourniquet must therefore be immediately applied, and the dressings removed; after which they must be again applied with as great exactness as possible; but first the extravasated blood must be pressed back into the artery, by gently rubbing and squeezing the tumour. If at any subsequent time it should become necessary to remove the apparatus from the limb, the tourniquet must be employed in the same manner.

The apparatus being properly applied, the arm should be suspended, moderately bent, in a sling, and kept as much as possible at rest during the whole course of the cure. Should any swelling appear in the fore-arm, we ought to endeavour to diminish it by diligent friction with spirits and aromatic remedies. Moreover, the surgeon should daily examine whether the bandages remain firm and unmoved in their situations, and as soon as he discovers any tumour, he should proceed as above recommended. The length of time during which the compres ought to remain in its situation, in order to preclude the possibility of a future hemorrhage, cannot be accurately determined; if, therefore, we wish to examine whether it may be safely removed, we ought first to apply the tourniquet, and then take off the apparatus: this being done, we should gradually loosen the tourniquet, and carefully observe whether any tumour is produced at the place of the wound. Should no such tumour appear, we need not use these bandages any longer; it will, however, be proper, for security's sake, (as in some instances the wound of the artery has been known to burst open after) to apply gentle pressure, by means of a compres, to the artery, immediately after the bandages have been entirely removed, in order to diminish the flow of blood through it, and prevent its bursting. Every other motion of the limb should be avoided for some time after.

When a circumscribed false aneurism has already been produced, we may also in that case employ compresion, provided the tumour be still soft, and can be made entirely to disappear by pressure. For, as experience has proved, that the efforts of nature alone may, in such circumstances, sometimes effect a perfect cure of the aneurism, (Repertorium Medicin. u. Chirurg. Abh. &c. B. i. Leipzig. 1792. Svo. p. 807.) we have the greater reason to expect a favorable event from the employment of compresion. The surgeon ought, therefore, after having applied a tourniquet to the arm, as in the former case, to return the blood into the artery, by means of repeated pressing and stroking of the part, and then apply the compres. But when there is already coagulated blood in the sac, and the tumour can no longer be made to disappear under pressure, compresion can be of no use. Should there, however, be but a small quantity of coagulated blood, we may still attempt compresion; for it may sometimes succeed, and when it does not, it produces the advantage of compelling the blood to flow with greater force into the lateral branches, by the dint of which a favourable issue of the operation is secured.

Mr. Theden (in Neve Bemerkungen u. Erfahrungen zur Beriinerung der Wundartzwick. u. Arzneyzebrifl. th. i. Berlin. 1792. p. 30. & th. ii. p. 52.) has added an other method for curing aneurisms, which is applicable even where there is already a very considerable quantity of extravasated and coagulated blood. When, in performing the
the operation of blood-letting, we have wounded an artery, we are to suffer more than the proper quantity of blood, may even so much as to induce syncope, to be discharged, and in the mean time prepare whatever is requisite for bandaging the limb. Three or four compresses, into the lowermost of which we may introduce a small piece of money, are then to be applied in such a manner as to fill up the cavities in the angle of the elbow, which, till the rest of the bandages are ready, is to be prefixed by an attendant so tight upon the orifice of the artery, that no blood can be discharged from it. The bandaging must then be performed spirally, a longuette of the thickness of a finger's breadth must be laid upon the trunk of the artery, and inclosed in the bandage. When the hemorrhage has been stopped in this manner, a quantity of Thedecn's *aqua traumatica* is to be poured upon the whole of the bandages, so as to wet them through and through. The bandages should not be applied too tight at first, if we intend to soak them with the liquid, as it is well known that moisture causes them to contract and compress the limb with greater force, by which means obstruction, tumour, and pain might be produced. Should we, however, have applied them tight, on account of the hemorrhage, we must not wet them till after they have become somewhat loose. As our success depends upon the bandage lying equally close in every part, each turn of the bandage ought to cover half of the former, so that no part of the limb remain uncovered, or not inclosed within the bandage; neither ought any one turn of the bandage to be drawn tighter than the rest.

The first bandages may be suffered to remain on the limb for the space of three or four days, unless they should grow loose at an earlier period, as generally happens when there is a large quantity of extravasated blood, and this soon begins to be separated and re-absorbed. In applying the bandages the second time, we proceed in the following manner. The roller is taken off from the fingers, hand, and fore-arm, and these parts are bandaged anew before the bandages and compresses are removed from the joint and humerus. The roller is then applied over the elbow, and upwards to the axilla. The end of the filet is carried round the neck, in order to prevent the bandages from sliding downwards; and, as an additional security against this accident, the turns of the roller are fewed to each other from the elbow to the arm-pit; the whole is soaked with Thedecn's vulnerary, and kept continually wet. These dressings may remain in this condition for three or more days, provided the bandage becomes neither too tight nor too loose, and applies to the limb in an uniform manner. If, says Mr. Thedecn, all these measures are adopted immediately after the accident, the cure may certainly be effected in the space of eight days, only we must examine very attentively whether, at the place where the artery has been wounded, a new tumour or effusion takes place. Should this happen, we must still continue to apply the bandages for some time; but if the blood has been effused from the beginning into the cellular substance, as sometimes happens, the bandage must be wound till the whole has been re-absorbed, and the wound properly cicatrized. The utility of this method of Thedecn's has been confirmed by several practitioners, especially by the successful cure of a remarkable case, related by Mr. Schimalz. (Seltene Chirurg. u. Medicinische Vorfälle. Leipzig. 1794. 8vo. p. 59.)

But when there is a great deal of extravasated blood in the face, when the tumour is very large, so as not to admit of compression or bandaging, and there is reason to apprehend that the tumour may burst open, an operation must be performed without delay. The tourniquet being applied to the humerus, the skin which covers the tumour is laid open by an incision, made according to the direction of the artery, and carried across the middle of the tumour, so as to extend from one of its extremities to the other. The face, which is generally situated immediately under the skin, is opened in the same manner. The whole of the extravasated blood contained in the face is then taken out, upon which the wounded artery becomes distinctly visible at the bottom, and should be tied. But in order completely to stop the hemorrhage and prevent its recurrence, the artery must be tied not only above, but also below the orifice. Sometimes the surgeon is obliged to apply even three or more ligatures; for when, in the vicinity of the wound of the artery, between the two principal ligatures, any lateral branch is pressed from the trunk of the artery, these must be tied close to the trunk.

Since, after the operation has been performed, every thing depends upon the restoration of the circulation in the limb, by means of the dilation of the lateral branches in consequence of the increased impetus of the blood in them; the surgeon must be particularly attentive in performing the operation, not to injure these branches. For this purpose the two ligatures must be applied as near the wound of the artery as can be done with safety, lest any lateral branch should happen to be included between them, whereby it would necessarily be rendered useless. On this account also we must not use a very broad two-edged needle for applying the ligatures. Mr. Default used an animal needle of his own invention. It is needles, after having tied the vessels, to apply another tourniquet or other bandage to the humerus, with a view to prevent the recurrence of the hemorrhage; for if the ligatures have been skillfully applied, this precaution will be superfluous. In cases where the ligatures become loose, and preceding hemorrhages are produced, the method of Mr. Default has been recommended. At the third hemorrhage, which took place on the eleventh day after the operation had been performed on the femoral artery, he first applied new ligatures above and below, secured them properly, and renewed the bandages. But in order to prevent a recurrence of the hemorrhages, which might have subsisted in consequence of the collapse of the artery and the ligatures growing loose, he applied, four days afterwards, over the ligatures, and at the sides of the artery, small flat pieces of felt wood, fifteen lines long and three broad, which were secured by winding them round with several turns of waxed thread, and were made to compress the artery at the sides with more or less force, by introducing under their upper extremity small wedges of the same wood. By this means the impetus of the blood was restrained, and a new effusion prevented. Suppuration took place in the wound, and on the 35th day after the operation, the small pieces of wood fell off: the ligatures having come away some days earlier.

If it can be avoided the surgeon must take care not to include the nerve in the ligature. Sometimes the extravasated blood, which frequently penetrates behind the artery, separates the nerve from the artery; and in this case we may, in order to avoid including it in the ligature, bend the patient's arm, before applying it, and by means of a somewhat crooked probe, introduced into the open space, raise up the artery, and remove it from the bone, and then introduce the needle, to which the thread is attached, close under the artery. We must, however, not raise up the artery with too much force, lest we should tear some of the lateral branches. Moreover, it is always advisable not to draw the ligature tighter than is necessary for stopping the hemorrhage; lest we should cut through the coats of the vessel,
or conveys the nerve too forcibly, in case it should happen to be removed. Frequently the artery is so much detached from all the neighbouring parts, that the thread may easily be drawn through below it, by means of a common needle with the eye foreclosed. But when the artery is not detached from the subjacent parts, we must make use of a pointed needle having an eye near its point, taking care always not to puncture the nerve, or any tendinous parts, or to injure them in the ligature. The ligature should be secured with a double knot, and the ends of the threads suffered to hang out about two inches long. The tumour may then be immediately loosened, in order that we may see whether the ligature be sufficiently tight; after which the wound is to be dried lightly with lint, and the proper bandages applied; and the patient should be directed to carry his arm in a sling.

The wound is treated after the usual manner till the ligatures have come away. In order to reduce the natural heat in the forearm, and to diffuse the tumour in it, it may frequently be rubbed with spirituous, stimulating, and aromatic applications. M. Pontee affixes us, that no remedy has succeeded so well with him, in restoring the natural warmth and sensibility of the forearm, as dry heat applied by means of hot ashes or sand. The remaining debility may, in general, be speedily removed by using the diuretic, and external tonic applications.

When in consequence of an aneurism in a limb, the surrounding parts are destroyed, when suppuration or caries have taken place in a high degree, or when the limb remains lifeless after the operation, so as to threaten the production of gangrene, amputation becomes necessary. We ought, however, not to be too hasty in proceeding to this operation, since even in cases where gangrene has formed to be unavoidable, the limb has still sometimes been preserved; frequently after the lapse of several weeks the pulp has again become perceptible. We shall here subjoin an account of the method employed with success by Dr. Adams. (Med. and Phys. Jour. vol. vi. p. 535.)

On the 4th of February, 1797, a young baronet was blooded in the vena mediana basilica, and from having worn a tight flannel sleeve, it was not immediately observed that the blood came also from an artery. The orifice having been closed in the usual manner, bled again in the evening, but was stopped before Dr. Adams could see the patient. On the following morning a considerable extravasation of blood took place. In a few days, however, the gentleman was not thought in need of further attendance, although the arm did not recover its ordinary size. Six weeks afterwards a small circumscribed tumour had arisen in the arm, below the original cicatrix; and, on prelure, a very obscure pullation might be felt; it was firmly bound by the fascia, and not at all discoloured or painful. The tumour increased suddenly towards the end of March, with the same circumscribed appearance and an evident surrounding extravasation. Strong prelure was now applied by means of a roller to the upper part of the forearm, exactly upon the trunk of the artery, so as to lessen its pulsation; but the bandage was kept hollow, except over the artery, by several pieces of cane applied along different parts of the limb. Although this degree of prelure was had recourse to with the view of obliterating the large trunk of the artery, an increase of the swelling took place in about ten days, accompanied with flight pain.

The mechanical prelure on the vessel itself was then augmented, until but little pulsation could be felt in the radial artery. Painful sensations near the wrist, along the lower arm, and under the aneurism, were now complained of as intolerable. The fingers were without sensibility, the whole arm was enlarged, the veins became turgid, and the pulse remained very feeble. This process being perverted in, Dr. Adams had at length the satisfaction to obliterate the main trunk of the brachial artery, and to effect a complete cure. The mass of congealed blood, however, was discharged by a gaseous, hot, and abundant set of the arm, about two inches in diameter, which was cicatrizized before the end of July, 1797; and in January, 1798, every unpleasant symptom had disappeared. This plan of treatment, by compression, was adopted by the author without his having known that it had been several times practised with success, in different parts of the continent, for other cases of aneurism.

The treatment of the true external aneurism is in most respects the same as that of the false. If it be small in size, and not of long standing, external allargent applications, as also ice, have been used with very good effect. In trying such an experiment we may, at the same time, apply a tourniquet to the artery, above the swelling, in order to diminish the quantity and momentum of blood flowing into the sac. Compression has likewise been recommended in this species of aneurism, but only at the commencement. Mr. Bruckner, however, (D. Jull. Chr. Frederic Journal f. inner Medicin und Chirurgie, &c. i. ii. 2. Hef. 1797, p. 248.) has used it in a case of a very large and old aneurism in the hallow of the knee, in combination with the remedies before mentioned, together with Thedson's bandage applied from the toes upwards, and the concurrence of other favourable circumstances, with complete success. When compression is applied, it ought to be to every part of the surface of the tumour, as well as in the concide of the artery; and it will act with greater safety and efficacy, if we combine it with Thedson's manner of bandaging, as was done by Mr. Bruckner.

When none of these remedies are applicable, we must proceed to the operation, which (if we follow the old mode) is in no essential circumstance different from that performed in cases of false aneurism. It is, however, to be observed, that it is not advisable to cut through the posterior part of the sac, as in that case the ends of the artery easily contract themselves under the flesh; and if the first ligature should grow loose, they cannot easily be tied again. It appears from experience, that the operation has been far more rarely attended with a successful event in the true than in the false aneurism; it being frequently followed by violent pain, fever, swelling, gangrene, and death. Only in those true aneurisms which are small, and originate from external causes, the surgeon is able to operate with expectations of a successful event. Sometimes, however, these aneurisms require amputation to be performed, and that, under the same circumstances by which the operation is indicated in the false aneurism. But as this operation, as well as the application of the ligatures, very frequently mischieves, all the precautions with respect to the application of the ligatures, that have just been mentioned, are here also to be recommended.

Internal aneurisms, both true and false, are incurable: all that we can do is to retard the progress of the disease, by frequent blood-letting, spare diet, and the careful avoiding of every thing by which the blood may be heated, or its motion accelerated. Moreover, it is very advisable to cover the tumour well, as soon as it appears externally, and to defend it against all external violence, by friction, blows, &c. whereby its bursting might be hastened.

To the cure of the diffused false aneurism two things are requisite; namely, to close the wound of the artery, in order to stop the hemorrhage, and to diffuse the extravasated blood. The first is performed by compression, and the second by applying bandages to the whole limb, according to Thedson's method, and keeping them constantly.
A NEURIS.

Antily wet, either with Theden's vulnerary, or a solution of sal ammoniac in vinegar and water. But if the extravasation spreads farther, and the hemorrhage continues, the operation must be performed without delay.

The mixed aneurism, produced by a laceration of the outer and a dilatation of the inner coat of the artery, is rare, and exhibits no external symptoms by which it can be distinguished from the true aneurism. This, however, makes no difference; for we endeavour to remove it, like a true aneurism, by compression; and when this either does not succeed, or cannot be applied, the operation is performed in the same manner as in the true aneurism. The second species of the mixed aneurism is more frequent. This consists at first of a true aneurism, in which the sac, by occasion of violent motion, concursion, a bruise, or even spontaneously, in consequence merely of too great dilatation, has burst, and produced an effusion of blood, which surrounds the true aneurism. The change of a true into a mixed aneurism may in general be easily discovered. The swelling, which before was circumferential, suddenly spreads; the strong pulsation, which before was dimly perceptible in the tumour, suddenly grows weak and indistinct, or even becomes altogether imperceptible; and the tumour, which formerly was soft, suddenly becomes hard to the touch. The mixed aneurism, on account of the continual effusion of blood, and the increase of the false aneurism, generally requires that the operation should be speedily performed. The most common mode of doing this (perhaps not the most eligible) we have already described; but it is a fact worthy of notice, that the Greeks were acquainted with the practice lately recommended, of tying and dividing the trunk of the artery high above the tumour, as will appear from the following extract. (Etz. Tetr. iv. Serm. iv. cap. 10.) "At vero quod in cautelavitacit fit aneurismus, hoc modo per chirurgam aggredimur: Primum arteriam superiorem ab ala ad cubitem per internum brachi parte simplicem sectionem, tribus aut quatuor digitis infra alam, per longitudinem faciem, ubi maxime ad tautum arteria occurrit; atque ea paulatim demudata, dinceps incumbantia corpora etiam exsanguis, septum et parietes inter maxima eestinationem, et sectionem pollicis tririus explicat, ac adimiantis inbatis congrus delegationes adhibebit." Afterwards we are directed to open the aneurisima tumour at the bend of the elbow, and when the blood has been evacuated, to tie the artery twice, and divide it again. If the ancients had only omitted the latter part of their operation, they would absolutely have left nothing to be discovered by the moderns. What a linking example of the bold manner in which our forefathers have acted without being guided by the lights of anatomy and physiology! But there are two or three passages in Galen, Celsius, and Hippocrates, from which we may infer that even Etius himself was not the inventor of this operation of tying the trunk of an artery, &c. See also Paul. Agnin. lib. vi. cap. 57.

The operation of tying the large trunk of an artery, above the aneurism, seems to have been regarded by Dr. Wm. Hunter as "a proposal which a modern surgeon would think of with horror" (Med. Obs. & Inq. vol. i. p. 325); and Mr. Bromfield calls it a "most extravagant proposition." (Chir. Obser. vol. i. p. 306.) But we are now fully convinced by the evidence of incontrovertible facts, that this operation "may be done with a fair prospect of preserving the limb." Mr. Bromfield relates, that he "once saw an attempt of this kind in a true aneurism, situated in the ham," on which, however, he makes "no further remark, than that the patient died," and that he believes "the embarrassments which occurred, as well as accidents in the operation, will deter the operator from making a second attempt." We have reason to suppose that most of the cases of aneurism on record, in which patients recovered, after long enduring compression upon the artery, have in reality been cases where the vessel was totally obliterated by the pressure; although the opinion of surgeons has usually been, that the orifice of the artery had previously ceased, and healed like a common wound, still allowing the blood to circulate as before. Cases are likewise recorded in which a spontaneous cure of aneurism has been effected; and in these we may also conclude, that the vessels were obliterated as completely as they would have been by a ligature in the modern operation.

In the former part of this article we said, that a popliteal aneurism was one of those which occurred the most frequently. And its situation being such as to afford a full command of the vessel affected, this species of the disease has obtained a considerable degree of attention among surgeons; in hopes of their saving the limb as well as the life of the patient. After having made various trials, it is ascertained that the collateral branches of the femoral artery, of those of the profunda femoris, inculcating with the arteries of the leg, are generally sufficient to keep up the circulation in the lower extremity; and that the incoagulating blood vessels of the arm, in like manner, will dilate and nourish the limb when the humeral artery has been tied; so that in most aneurisms of the extremities, we have a very considerable chance of preserving both the member and the life of the patient.

Paulus Agineta, and after him the Arabian physicians, used to make two ligatures, one above and the other below the aneurism; after which they let out the coagulated blood found within the tumour, and healed up the wound according to the common principles of surgery. But Guillemeau, one of the disciples of Ambrose Paré, pointed out a more simple operation in the case of an aneurism at the bend of the arm; he laid bare the tumour, passed one ligature under the artery above the diseased part, then emptied the sac, and closed the wound. He directs the same plan to be adopted in other cases of aneurism: "Si en quelque autre partie extérieure, il le prefent au chirurgien pareil aneurisme, il peut feurement deover le corps de l'artère vers la racine et partie supérieure, et la lif de même façon, fans autre cernicin." (Les Oper. de Chir. liv. x. c. vi.)

In the year 1714, M. Ansel, of Paris, published an improvement on Guillemeau's method; which consisted in making a longitudinal incision over the aneurism, without wounding it, then making a single ligature upon the vessel, close above the tumour, and leaving the rest to nature. It is almost needless to mention, that in all these operations the surgeon applied a teuniquet upon the affected limb, so as to obtain an entire command of the artery. By this means little Ansel found the tumour disappear, until the whole was absorbed. This practice did not meet the approbation of surgeons in general, although it was often followed by Heilier and some few later operators. Indeed that author thinks it doubtful "whether or no this method will succeed so as to save the limb in wounds of the large crural artery?" Syltem of Surgery, part ii. sect. i. chap. xiii. § 22.) and it has therefore been referred for our contemporaries, to determine the point by actual experiment. We do not wonder, however, at the doubt expressed by Heilier, as he frankly confesses, that "he cannot conceive in what manner the blood is circulated through the lower parts of a limb, after this operation." How would he then have been surprised to learn, that it is even possible for a patient to recover of his limb,
ANURISM.

hub, when the humeral, or the subclavian artery, has been
surrounded by a ligature!

During the month of June, 1785, M. Duffaut, of Paris, 
performed the following operation for a popliteal aneurism
(Socio. de Melchrord, tome x. p. 37—47). Encycl. 
Methodique, Partie Anatom., p. 138; and Sabater de la 
Med. Operationes, tom. ii. p. 72); he made an incision 
about two inches above the arterioscleral tumour in the patient's 
hand; and, when he had expelled the artery, he separated 
the skin from the adjacent nerve, and passed a ligature around it, leaving the arterioscleral tumour. This wound was dressed in 
a simple manner, with a horse's ligature cast around the former 
one, as an additional security against future bleeding. The 
symptoms for the first six days were mild, and presented a 
favourable event; but M. Duffaut thought it prudent to tie 
the second ligature, the 7th, on the fifth day after the operation. 
The swelling diminished rapidly; the ligatures fell off on the 
eighteenth day. and there was a plentiful discharge of bloody 
matter on the day following, which caused nearly the entire 
disappearance of the tumour. In short, the external 
swelling was soon healed, and the cure seemed complete; when, 
unfortunately, the patient died of another complaint.

During the month of December, in the same year, an 
operation, somewhat similar to that of Duffaut, was 
performed by Mr. John Hunter (Sec Lond. Med. Journal, 
of Med. and Chir. Know. voi. i. p. 138). Mr. Hunter's pa-
ient was a coachman, 45 years of age; he was admitted 
into St. George's hospital with a popliteal aneurism, which 
he had first perceived three years previously to his admission, 
and had observed it gradually increase during the whole 
of that period. It was so large as to extend the two 
hampfins laterally, and make a very considerable rising 
between them; it was pulled into the vein; the pulsation was very distinct, and to be 
felt on every side of the tumour. The leg and foot of that 
side were so swelled as to be much thicker than the other, 
and were of a dark brown colour; the swelling was not 
of the ordetaneous kind, but felt firm and brawny, probably 
from the extravasation of coagulable lymph; the tumour 
retained its natural shape, and that it was larger. Pre-
viously to performing the operation, a tourniquet was applied 
upon the upper part of the thigh, but not tightened, that the 
parts might be left as much in their natural situation as 
possible.

The operation was begun by making an incision on the 
anterior and inner part of the thigh, rather below its middle, 
which incision was continued obliquely across the inner edge 
of the factorius medialis, and made large, to give room for 
the better performing of whatever might be thought neces-
sary in the course of the operation. The incision which 
covers the artery was then laid bare about three inches in length, 
after which the artery itself was plainly felt. A flight in-
cision, about an inch long, was then made through this incision, 
side of the vessel, and the incision dissected off; 
by this means the artery was exposed. Having disengaged 
the artery from its lateral connections by the knife, and 
from the other adhering parts by the help of a thin fípula, 
a double ligature was passed behind it, by means of an eyed 
probe. The doubling of the ligature brought through by 
the probe, was cut to as to form two separate ligatures. 
The artery was now tied by both these ligatures, but so 
lightly, as only to compress the sides together. A similar 
application of ligature was made a little lower. The reason 
for having four ligatures, was to compress such a length of 
artery as might, make up for the want of tightness, it be-
ing wished to avoid great pressure on the vessel at any one 
part. The ends of the ligature were carried directly out
at the wound, the sides of which were now brought to-
gether, and supported by a delicate platter and a linen roller, 
that they might unite by the first intention.

The hub was found, some hours after the operation, not 
only to retain its natural heat, but even to be warmer than 
the other leg. The second day after the operation, the 
brawny tumour of the leg was considerably diminished, it 
was became felt, brawny, and a good deal smaller; and the 
anurnsal tumour had lost more than one-third of its size.

Nothing could cause more plainly the action of the absor-
bents, than the change the leg had undergone in to a short a time; the diminution of the tumour probably arising from 
the flood blood it contained having poured into the lat-
teral branches, or into the tributary artery.

The fourth day, on the removal of the dressings, the edges 
of the wound were found united through its whole length, 
excepting where prevented by the ligatures; there was nei-
er pain nor tumefaction in part; but the anurnsal tumour was the same as on the second day.

On the ninth day after the operation there was a consider-
able discharge of blood from the part where the ligatures 
passed off; a tourniquet was therefore applied on the artery 
above, which stopped the bleeding; and, although the tour-
niquet was taken off a few hours after, no blood followed. 
On the tenth day was then placed upon the wound, in the 
direction of the artery, and over that the tourniquet, which 
was not, however, tightened more than was thought suffi-
cient to take off the impetus of the blood in that portion 
of the artery.

On the twelfth day appearances were much the same, only 
that between the compreses and the knee there appeared a 
little fulness, like beginning inflammation. On the eleventh 
day this was gone off, and on the fourteenth some of the lig-
aturess were taken from the smaller discharge, the tumour in the ham being lessened. On the fourteenth day the parts surrounding the anurnsal tumour were more reduced and pliable, so that it was distinctly to be felt.

About the latter end of January, 1786, six weeks after the 
operation, the patient went out of the hospital, the tumour 
at that time being somewhat lessened, and rather tumer to 
the feel. He was ordered to come to the hospital once 
every week, and, in the mean time, to make some degree of 
pressure, by application of a compres and bandage, with a 
view to excite the absorbents to action, which in most cafes 
has a good effect.

About the middle of February the tumour had decreased, 
and was become full firmer. March the 8th, the wound, 
which had cicatrizied, broke out again, and the patient was 
taken into the hospital. About the 8th of April, some of 
the remaining thread of the ligature came away, and an 
flammation appeared upon the upper part of the thigh. In 
the middle of May, a small abscess broke at some distance 
from the old cicatrix, at which opening some matter was 
discharged, but no pieces of ligature were observed. Several 
small threads were, at different times, discharged from the old 
fore, and the swelling subsided; but the thigh soon 
swelled again to a greater size than before, attended with 
considerable pain. In the beginning of July, a piece of 
ligature, about one inch in length, came away, after which 
the swelling went off entirely, and he left the hospital the 8th 
of July, at which time there remained no appearance of 
tumour in the ham, he being in every respect well.

After leaving the hospital, the man returned to his usual 
occupation of driving a hackney-coach, and being, from 
the nature of his employment, much exposed to cold, in 
March, 1787, he was seized with a fever of the remittent 
kind, which carried him off. He had not made any com-
plaint.
ANEURISM.

plait of the limb on which the operation had been performed, from the time of his leaving the hospital.

He died on the 18 of April, 1787, fifteen months after the operation; and leave was procured, with some trouble and considerable expense, to examine the limb, seven days after death, at which time it was entirely free from putrefaction.

The cicatrix on the anterior part of the thigh was scarcely discernible, but the parts under it felt hard. The ham had no appearance of tumour, and was to the eye exactly like that of the other limb; there was, however, a solid tumour perceptible to the touch, filling up the hollow between the two angles of the thigh bone.

The femoral artery and vein were taken out above the giving off the branch called profunda, and a little below the division into the arteries tibiales and tibiales. The arteries and veins that were previous being injected, the whole was carefully dissected.

The femoral artery was impervious from its giving off the artery profunda as low as the part included in the ligature, and at that part there was an obfuscation for about an inch and a half along the course of the artery, of an oval form, the rim of which was solid, becoming thinner towards the centre, and not bony, but ligamentous. Below this part the femoral artery was pervious down to the aneurismatic, and contained blood, but did not communicate with the fac itself, having become impervious just at the entrance.

What remained of the aneurismatic was somewhat larger than an hen's egg, but more oblong, and a little flattened, extending along the artery below for some way; the blood prefilling with greater force in that direction, and dilating that part so as, in some measure, to give the appearance of a separate bag. The fac was perfectly circumscribed, without having the smallest remains of the lower orifice into the popliteal artery; whether this arose from the artery being prefillied upon by the inferior portion of the fac, as appears to be the case in common, or was in consequence of the fac contracting after the operation, I will not pretend to determine; but it contained a solid conglutin of blood, which adhered to its internal surface. A section made of this conglutin, appeared to be composed of concentric lamelle, uniform in colour and consistence.

The popliteal artery, a little way below the aneurismatic fac, was joined by a small branch, very much contracted, which must have arisen either from the profunda, or the trunk of the femoral artery. About two inches below the fac, the popliteal gave off, or divided into, the tibiales.

The profunda was of the usual size, but a good deal oblied, for some length after leaving the femoral artery; the two tibiales, where they go off from the popliteal, were in the same latde.

The trunk of the femoral vein, where it passed along the side of the tumour, must have been obliterated; for at this part it appeared to send off three equal-sized branches, passing over different parts of the aneurismatic; these must have been dilated branches, none of them having the course which the trunk of the vein should have pursued.

These appearances throw some light upon the changes which took place in the limb after the operation. The ligature upon the femoral artery impeded the passage of the blood into the fac so much, as to allow its contents to coagulate, and render the opening into it from the artery impervious. By this a fac was only put to the increase of the tumour, its reduction to the size met with in the dead body, must have been the effect of absorption.

The conclusion to be drawn from the above account, appears a very important one, viz. that simply taking off the force of the circulation from the aneurismatic artery, is sufficient to effect a cure of the disease, or at least to put a stop to its progress, and leave the parts in a situation from which the actions of the animal economy are capable of restoring them to a natural state.

We have given the history of this case at full length, because the method adopted by Mr. Hunter has been since followed, with some slight variations, in almost every part of Europe. There is no reason, we believe, for supposing that Mr. Hunter took the hint of this operation from any of his predecessors: but, as Mr. Home has stated, this practice was the result of an opinion entertained by Mr. Hunter that the artery in aneurismatic cases is generally diseased some way above the fac, and therefore that the common cause of failure arose from tying an unfound artery, not disposed to congeal before the separation of the ligature.

The femoral and popliteal arteries are portions of the same trunk, presenting themselves on different sides of the thigh, and are readily come at in either situation; but where the artery is passing from the one side to the other, it is more buried in the surrounding parts, and cannot be exposed without some difficulty. In performing the operation for the popliteal aneurisma, especially where the tumour is large, the ligature was commonly applied on the artery at that part where it emerges from the muscles. This mode of performing the operation will be found inadequate, if the diseased of the artery extends above the fac; for if the artery should afterwards give way, there will not be a sufficient length of vessel remaining, to allow of its being again secured in the ham. To follow the artery up through the insertion of the triceps mulele, to get at a portion of it where it is found, becomes a very disagreeable part of the operation: and to make an incision upon the fore-part of the thigh, to get at, and secure the femoral artery would be breaking new ground; a thing to be avoided, if possible, in all operations.

Mr. Hunter, from having made these observations, was led to propose, that in this operation the artery should be taken up in the anterior part of the thigh, at some distance from the diseased part, so as to diminish the risk of haemorrhage, and to admit of the artery being more readily secured, should any such accident happen. The force of the circulation being thus taken off from the aneurismatic fac, the progress of the disease would be stopped; and he thought it probable, that if the parts were left to themselves, the fac, with its contents, might be absorbed, and the whole of the tumour removed, which would render any opening into the fac unnecessary.

Numerous trials have lately been made in the different public hospitals which confirm the truth of Mr. Hunter's reasoning. He had several opportunities of performing this operation before he died, and generally with perfect success; but reiterated experience has shown that it is best to secure the artery with only one strong ligature, without separating the vessel from its attachments. Some attempts have been made, both in London and Paris, to improve on this method, by giving a greater latitude for preffure on the artery, (either by the interposition of extraneous substances between the ligature and the vessel, or by employing a broad piece of tape:) but such attempts have been always attended with manifest disadvantages. The only considerable deviation from Mr. Hunter's mode, which we think deserves particular attention, is that of making two firm ligatures, about an inch distant from each other, and then dividing the artery between them; after the manner recommended by Aeusius, thirteen centuries ago, for brachial aneurismas.

In comparing this procedure with that which has formerly been had recourse to in popliteal aneurismas, every
A NEURURISM.

person must be struck with its decided superiority. The operation is in itself simple; it requires but a short time in the performance, and produces little, if any, affection of the constitution; but its advantages are more clearly seen by comparing it with the common mode of operating for the popliteal aneurism. This is, by exposing the tibia in the ham through its whole extent, laying it open, feepining the blood, searching for the two orifice leading into it, and taking up the artery with a ligature both above and below the face. When this operation is over, there remains a large deep seated hole, composed of parts not perfectly in a natural state, and in a mild disadvantageous situation; which face is to supplicate, granulate, and heal; a process that is not soon performed, and which must leave a stiff knee for some time afterwards. Yet this is considering the operation in the most favourable view; for there is always a risk, from the artery being dissected to close to the face, of the patient dying from a secondary bleeding; and when that does not happen, there is still some danger of not being able to support the constitution during the healing of a large face, under circumstances so very unfavourable.

It must not be obliedged, however, that there are some times very embarrassing circumstances attending the new operation, and that patients are not always free from the danger of hemorrhage, even to late as the third or fourth week after the ligature of the artery. Indeed, we can never be certain, in cases of spontaneous aneurism, that the vessel is not dissected along its course, above the point on which the ligature was made. For we have no positive security against the occurrence of an ulceration just under the ligature, from which a fatal bleeding may at any time ensue. But we cannot always effect an adherence of the sides of the artery, so as to produce a perfect obliteration of its cavity, by any means within our power. Besides which, the first surgeons, who most likely fall in their endeavours to include the naked vessel within a ligature; and at length may be compelled to make a fresh incision, or to amputate the patient’s limb, in order to save his life. But, with all these disadvantages, some of which indeed must apply to any kind of operation for aneurism, we are fully persuaded that Mr. Hunter’s plan is, on the whole, the most eligible and successful. It, therefore, cannot but strike us with surprise to find Mr. Benjamin Bell, in the last edition of his surgical works (vol. iii. 1801), declaring it to be doubtful whether this operation, or that of amputating the limb at the upper part of the thigh will fail to be preferred. It only remains for us now to point out some of the principal rules to be observed, in cases where this operation is indicated.

No skill or precaution can avoid the ill consequences which may ensue from a dissection in the trunk of an artery to form aneurisms: the objection, therefore, against tying the artery in this case, is not greater than it would be against amputating the limb at its upper part. If an aneurism have formed spontaneously, the chance of recovery is not equal to that in which the disease arose from an accidental cause; but still, we conceive, the spontaneity of the complaint is not alone a sufficient objection against the method we are recommending. Suppose, then, we have determined on performing the operation; it is first necessary to reduce the quantity of blood in the vascular system, if the patient be plethoric and young. He should also be prepared, by giving him a few doses of laxative medicine, and by a previous course of astringent infiltrates, especially if there be any tendency to an inflammatory diathesis. All things being in readiness for the operation, let a tourniquet be placed on the limb; or let an assistant compress the artery in the belt possible manner, where a tourniquet cannot be applied with advantage. Make your first incision through the skin and adipse substance; deflect readily and cautiously down to the trunk of the vessel you are seeking for; clear away with the scalpel, or with your finger, all the cellular membrane which lies loosely in your way; open the fascial covering peculiar to the artery; then separate the vein and nerve accompanying it, without unnecessarily tearing the vessels from their surrounding attachements; and pass a moderate sized common ligature around the artery, with a sufficient degree of tightness to stop the circulation entirely.

There are the ordinary steps of this operation. But it is probably the safest way to make a second ligature, about an inch below the former, and then to cut between them, as was practised by the ancients, so that the divided extremities of the artery may retire into the adjacent muscular substance. This method has been approved by some of our best surgeons, and seemed to lessen the danger of a secondary hemorrhage. In addition, however, to this security, a new mode of fastening the ligatures has been proposed and practised at Guy’s hospital (see Med. & Phys. Journal for July, 1802.) “An eyed probe, armed with a double ligature, having a curved needle at each end, was conveyed under the femoral artery, and the probe cut away. The ligature near the groin was first tied; the other was separated an inch from the first, and tied also; then the needles were passed through the coats of the artery close to each ligature, and between them; the thread they carried was tied into the knot of the ligature which had been already secured around the vessel; and thus a barrier was formed in the artery, beyond which the ligature could not pass. The wound was united by the first intention, except where the ligature projected: one of the threads separated on the 14th, the other on the 17th day.” This mode of forming the ligatures was found to be so effectual, that Dr. Ailley Cooper was unable, in an experiment made on a dead subject, to remove the thread from its situation, even by injecting water into the artery with all his force. The fuggelion was originally given to him by Mr. Cline, jun., and was put in practice in consequence of two cases having occurred, one to Mr. Cline (the father), and one to Mr. Cooper, in which the ligature slipped off the divided extremity of the blood vessel, after an operation for aneurism.

We have directed the artery to be tied alone; and not to be wantonly detached from the circumjacent cellular membrane, which gives support to the vasta sartorium nourishing the artery. For the same reason, we highly disapprove of all compresses, pads or instruments proposed to be laid in contact with the vessel; as these, we are of opinion, contribute to produce inflammation and ulceration of the artery, with all their dreadful consequences. The wound should be closed with adhesive plasters as accurately as possible, the ligatures hanging out, and a soft supper then passed over the limb for its further support. By this simple method, we have found the operation extremely successful; and there is but little comparative hazard of a secondary bleeding. Nay, it is even certain that ligatures may be made with complete success upon the great artery of the thigh, above Poupard’s ligament; and of the arm above the axilla. (See the cases published by Mr. Keate, Mr. John Bell, and Mr. Abernethy.)

Other methods have been recommended by ingenious men in cases of aneurism; such as that of Mr. Lambert (Med. Obs. and Inq. vol. ii. p. 360.), who proposes to stitch the artery by means of the hare-lip future, a plan which has been once imitated, without success, by Mr. John Bell; and likewise a contrivance of Mr. Defchamps (La Medicine celebre, tome iii. p. 67.), for compressing the arterial tube,
The town the upper which is apprehend, but will furgtons it xvi.), In dilferent the can will have able is by opinion, feem very surgery. This aneurifmal wound does happen?, in the latter case, the artery. The trunk of the vein may keep close to the trunk of the artery, and the very thin frustum of cellular membrane between them, may, by means of a little inflammation, and coagulation of the blood among its fragments, as it were, fold the two orifces of these veins together, fo that there shall be nothing like a canal going from one to the other; and then the whole tumefaction will be more regular and more evident a dilatation of the veins only. In other inffances the blood that rushes from the wounded artery, meeting with some difficulty of admission and passage through the vein, may dilate the cellular membrane between the artery and vein, into a bag, as in a common spurious aneurifm, and so make a fort of canal between these two vessels. The trunk of the vein will then be removed to some distance from the trunk of the artery, and the bag will be situated chiefly upon the underfide of the vein. The bag may put on an irregular form, from the cellular membrane being more loofe and yielding at one place than at another, and from being unequally bound down by the fefsia of the biceps muscle. And if the bag be very large, efpecially if it be of an irregular figure, no doubt ecafualtations of blood may be formed, as in the common spurious aneurifm.

As no surgical operation is required in this cafe, or but very rarely indeed, we need not dwell further on the fubjeft of aneurifmal varix. The difafe has, in different inffances, continued during the space of twenty or thirty years without getting worse, or demanding efpecial attention. See Varix and Varicocele.

ANEWOLONDAKE, in Geography, a small ifland of the Indian Ica, near the coaft of Ceylon.

ANFANTE, a town of Peña, 30 miles north-west of Zarango.

ANFELDTHYDE, or ANFAULTHE, in Lzev., a simple accufation; for the Saxons had two forts of accufation, viz. fimplex and triplices. That was called fimple, when the oath of the criminal, and of two more, were sufficient to difcharge him: but his own oath, and the oaths of five more, were required to free him a triplice accufation.

ANFOSSLI, Pafsquale, of Naples, in Biography. See Pasquale Anfossi. N n 2 ANGADD,
ANGADD, a barren desert of Africa, in the kingdom of Algiers. 25 leagues long, and 18 wide, formerly the seat of a tribe of the same name, and inhabited by Arabs, the chief of which were Guagida, Tenzugga, and Zerul. See Catarina Lottania.

ANGALAI-DIAN, in Natural History, a name given by Buffon to a species of cetacea, called lotenia by Gmelin. See Terra Lottania.

ANGAMALI, a town of the Eady Indies, in Malabar, on the river Aalor.

ANGARA, a river of Russia, which rises in the lake Biakal, and runs into the Emfly, not far from Uffelt.

ANGARAO, a province of South America, in the empire of Peru, subject to the archbishop of Lima, 20 leagues north-west by west of the city of Guaman. It abounds in all kinds of grain and fruits, besides vast droves of cattle both for labour and sustenance.

ANGARI, or ANGARI, in Antiquity, denote public couriers, appointed for the carrying of messages.

Angaros is derived from a word, which, in the Persian language, signifies a service rendered by compulsion. Hence the Greeks borrowed their verb ἄγγαρον, compelles, or cogere, and the Latinis angarari.

The ancient Persians, Budaus observes, had their ἄγγαρον δημοσίαν, which was a sort of couriers on horseback, posted at certain stations or distances, always in readiness to receive the dispatches from one, and forward them to another with wonderful celerity, answering to what the moderns call posts, q. d. postes, as being posted at certain places or stations. This invention of couriers is ascribed to Cyrus. As the Persian empire, after its last conquests, was of a vast extent, and Cyrus required that all his governors of provinces, and the chief commanders of his troops should write to him, and give an exact account of every thing that passed in their several districts or armies: in order to render that correspondence the more sure and expeditious, and to put himself in a condition of receiving speedy intelligence of all occurrences and affairs, and of sending his orders with expedition, he caused post-houses to be built, and messengers to be appointed in every province. Having computed how far a good horse, with an active rider, could go in a day, without injury, he stables built at equal distances from each other, and furnished them with horses, and groomes to take care of them. At each of these places he appointed likewise a post-mate to receive the packets from the couriers as they arrived, and to give them to others, and to take the horses that performed their respective stages, and to send fresh ones. Thus the courier went continually night and day with extraordinary speed; nor did either rain or snow, heat or cold, or any inquietude of the season interrupt his progress. Herodotus (lib. viii. c. 18.) speaks of the fame sort of couriers in the reign of Xerxes. The superintendency of the posts became a considerable employment; Darius, the last king of the ancient Persians, enjoyed it before he came to the crown. Xenophon takes notice, that this establishment continued in his time; and this perfectly agrees with what is related in the book of Esther concerning the edict published by Ahasuerus in favour of the Jews; which edict was carried through that vast empire with a rapidity that would have been impossible without these posts ereoted by Cyrus. See Post.

The angari were also called by the Persians ἄγγαρον; by the Greeks ἀγαρίον, on account of the long journeys they made in one day, which, according to Suidas, amounted not to less than 1,500 stadia.

Angari is also applied figuratively to porters, and others employed in laborious offices, as bearing burdens.
ANGEL, De St. Joseph, his true name was La Brosse, in Biography, a Carmelite monk, born at Toulouse, was sent to Ipiapan as a missionary. After residing several years in Peria, he returned to Europe, and was made provincial of his order in Languedoc. Having acquired a knowledge of the Persian language, he published, in 1681, Pharmacopoeia Persica, et idiomata Persica in Latinum translati, Svo, and, in 1684, Gazophylacium Linguæ Persarum, a Treasury of the Persian Language, fol. at Amsterdam. This work is in great elegance, containing, besides an explanation of Persian words and terms, many entertaining historical anecdotes and observations.

ANGEIOGRAPHIA, composed of αγιος, νας, υδραζυ, and ψυχικι, I describe; the knowledge or description of all kinds of ancient instruments, vesicles, and utensils, both domestic, military, and nautical. Angeography also includes the consideration of the weights, measures, &c. used by the several nations.

ANGEOLOGY, in Anatomy, derived from αγιος, a vesel, and λαγος, a diffuse, the history or description of the vesicles of the body, which are those concerned in the circulation of the blood, and in absorption. See Arteries, Veins, and Absorbing Vesicles. The essential structure of vesicles is the same in all. They are composed of thin skins or membranes, the inner part of which has a highly polished and secreting surface, allowing the contained fluids to glide along it without impediment, whilst the outer surface is rough and cellular, by which the vesel is connected to the surrounding parts. This essential part of the vesel is strong and unyielding, preventing it from rupture, and preferring it of an unvarying circular figure.

ANGIOTOMY. formed of αγιος, κεφαλι, and λαγος, a cut, in Surgery, is used by some to denote an artificial section of the vesicles, as in bleeding.

In this sense angiotomy may be divided into phlebotomy and arteriotomy.

ANGEL, a spiritual intelligent subsistence, the first in rank and dignity among created beings.

The word angel, αγιος, is not properly a denomination of nature but of office; denoting as much as νας, μαστορ, a person employed to carry one's orders, or declare his will. Thus it is St. Paul represents angels, Heb. i. 14, where he calls them ministring spirits; and yet custom has prevailed so much, that angel is now commonly taken for the denomination of a particular order of spiritual beings, of great understanding and power; superior to the souls or spirits of men. Some of these are spoken of in Scripture in such a manner, as plainly to signify that they are real beings, of a spiritual nature, of high power, perfection, divinity, and happiness. Others of them are distinguished as not having kept their first station (Judg vi.). These are represented as evil spirits, enemies of God, and intent on mischief. The devil as the head of them, and those as his angels, are represented as the rulers of the darkness of this world, or spiritual wickednesses or wicked spirits, το πυγμα της τουργειας των άνωγνωκτων (Ephes. vi. 12. Locke's Paraphrase) which may not be unholy rendered, the spiritual managers of opposition to the kingdom of God.

The existence of angels is supposed in all religions, though it is incapable of being proved a priori. Indeed, the ancient Sadducees are represented as denying all spirits; and yet the Samaritans and Caraltes, who are reputed Sadducees, openly allow them: witness Abufaid, the author of an Arabic version of the Pentateuch; and Aaron, a Caralite Jew, in his comment on the Pentateuch; both extant in manuscript in the king of France's library.

In the Alcoran we find frequent mention of angels. The Mussulmen believe them of different orders or degrees, and to be divided for different employments both in heaven and on earth. They attribute exceedingly great power to the angel Gabriel, as to be able to defend in the space of an hour from heaven to earth; to overturn a mountain with a single feather of his wing, &c. The angel Asrael, they suppose, is appointed to take the souls of such as die; and another angel, named Eraphiel, they say, stands with a trumpet ready in his mouth to proclaim the day of judgment.

The heathen philosophers and poets were all agreed as to the existence of intelligent beings, superior to man; as is shown by St. Cyprian in his treatise of the vanity of idols, from the testimonies of Plato, Socrates, Tnafmegillus, &c. They were acknowledged under different appellations; the Greeks calling them deities, and the Romans genii, or lares; and Episcopus seems to have been the only one among the old philosophers who absolutely rejected them.

Authors are not so unanimous about the nature as about the existence of angels. Clemens Alexandrinus believed they had bodies; which was also the opinion of Origen, Cefarius, Tertullian, and several others. Athanasius, St. BaII, St. Gregory Nicer, St. Cyril, St. Chrysolom, &c. hold them to be mere spirits. It has been the more current opinion, especially in later times, that they are substances entirely spiritual, that can, at any time, assume bodies, and appear in human or other shapes.

Ecclesiastical writers make an hierarchy of nine orders of angels. Others have distributed angels into nine orders, according to the names by which they are called in Scripture, and reduced these orders into three hierarchies; to the first of which belong seraphim, cherubim, and thrones; to the second, dominions, powers, and virtues; and to the third, principalities, archangels, and angels. The Jews reckon four orders or companies of angels, each headed by an archangel; the first order being that of Michael, the second of Gabriel, the third of Uriel, and the fourth of Raphael. But though the Jews believe them to be but four, yet it seems, from some intimation in Scripture, that there were seven. Rev. iv. v. viii. 2.

By the ancient councils men are forbidden to frame or give particular names to angels; the only names owned by the church are Michael, Gabriel, and Raphael, to which is sometimes added Uriel. Du-Cange.

Before the Babylonish captivity, the Jews did not know the name of any angel; at least we find none mentioned in the books written before this event. Clemens. Dict. Bib. Authors are divided as to the time of the creation of angels; some will have it to have been before the creation of the world, or even before all ages, that is from eternity; this is Origen's opinion, who, according to Leontius, held that all spirits, angels, devils, and even human souls, were from eternity.

Others hold angels to have been created before the world, yet not from eternity; of which opinion are Nazianzen, and others. Others again maintain that they were created at the same time with our world, but on what day is disputed. Theodore and Epiphanius fix their date from the first day.

Good angels are called angels of light, and guardian angels; and the contrary, who are the devil's ministers, angels of darkness, and fallen angels.

That angels are divine messengers employed on particular occasions for executing the divine will, has been a very prevalent opinion; but what is their sphere of action, and how far it extends, it is not easy to determine. Among the Jews it seems to have been a firm belief and tradition, that every man had a tutelary, or guardian angel from his birth;
AS

ANG

birth; and our Saviour seems to refer to this opinion in Mat. xvi. 19. The heathens were also of the same persuasion, and thought it a crime to neglect the adorations of fire; hence a guide. - Secroot publicly confided himself to be under the direction of Saxon, angel or daemon, as did also Phineas and others; on the other hand, they believed his happiness and good fortune depended. The ancient Persians so firmly believed the ministry of angels, and their superintendence over human affairs, that they gave their names to their months, and the days of their months, and affiliated them distinct offices and provinces; and it is from them the Jews acknowledge that they have received the names of the months and angels, which they brought with them when they returned from the Babylonian captivity: after which we find they also affiliated changes to the angels, and, in particular, the patronage of empires and nations: Michael being the prince of the Jews, as Raphael is supposed to have been of the Persians. Hyke. 

As to the fallen angels, it is not known at what time and for what offence they incurred the displeasure of the Almighty, and plunged themselves into an abyss of wickedness and misery. The time in which this event took place is generally imagined to have preceded the creation of the world; and some have accounted for it by the supposition, that the angels, being informed of God's purpose to create man after his own image, and to dignify his nature by Christ assuming it, and thinking their glory to be thus eclipsed, envied the happiness of man, and so revolted; and with this opinion that of the Mahometans has some affinity, who are taught that the devil, who was once one of those angels who are nearest to God's presence, and named Azael, forfeited Paradise for refusing to worship or pay homage to Adam at the command of God. But whatever was the occasion, or the mode by which it was manifested, pride seems to have been the leading sin of the angels, and it ultimately terminated in rebellion and apostacy. Of these fallen angels there is supposed to have been a great number; and it is apprehended that there was some kind of gradation or subdivision among them; one being considered as their prince, and called by several names, Belselemb, Satan, or Samael, by the Jews; Ahmarian by the Persians; and Ediz by the Mahometans.

The Scripture uses the term angel to denote other beings, or agents, besides those spirits that occupy a rank and dignity superior to man. According to the Hebrew and Samaritan schools, that the word angel does not only mean a spirit, but sometimes also all sorts of powers or instruments which God is pleased to use, and by means of which He acts. So that the elements of the world, fire, air, winds, and storms, in particular visions, and, in the language of Scripture, are called "angels of the Lord, which do his will." In this sense is to be understood the expression of Psalm (I, vi. 4.), that made his angels spirits, his ministers a flame of fire." etc. which maketh winds his angels, and lightnings his messengers. Moreover the Scriptures call a dream, a vision, a voice from heaven, a plague, a burning wind, "Angels of God!" and whatsoever God is pleased to do by them is said to be done by an "Angel of the Lord." For whatever declares God's will, or performs his pleasure, is "his angel." In the New Testament we find mention of an angel, by which God punished the blasphemous pride of Herod. Acts, xxi. 23. We find another mention of an angel moving at certain seasons the pool of Bethesda. John, vi. 4. In the Old Testament, we have also mention of an angel destroying the numerous army of Sennacherib. 2 Kings, xix. 35. The punishment inflicted on David for his sin in numbering the people, is described (1 Chron. xxi. 15.) by God's sending an angel to Jerusalem to destroy it. Acts, xi. 26. By the angel, in Acts, vii. 25, interpreters have understood the extraordinary delitement which proved fatal to him. In the case of David the parricide inflicted upon Israel was the angel of God, as 2 Sam. xiv. 15, 16. Thus the descent of the angel at the pool of Bethel (John, v. 44.) may signify the extraordinary motion of the waters, which was the sign of the miraculous virtue that attended them; although some interpreters conceive that the angel, in this case, was an officer or messenger deputed from the temple to fill the pool, and that the warm current, call in it communicated the healing virtue to the waters. The angel of the Lord which went out and smote the camp of the Assyrians, seems to be explained by the promise of the prophet Isaiah. 1 Kings, ii. 6, 7; in the account of Daniel's preservation, "God sent his angel," seems immediately explained in this sense; and hath shut the iron mouth, that they have not hurt me." Dan. vi. 21. The effect was taking the mouths of the lions; and in what way forever this was produced, under God's special direction and influence it may be said to be done by his angel, though a separate spirit had no concern at all in it. Thus also the Schechah, or material symbol of glory, and the oracle from heaven, may in this sense be called the angel of the Lord, and it is so called in Scripture; and though the true God himself was the only spirit, or intelligent agent, who acted and manifested himself on the occasion.

According to the opinion of those who maintain the fall of angels, they are represented as being cast out of heaven, abandoned to iniquity, and making it their business to seduce mankind, and taking pleasure in doing them all kinds of injury. Others, however, among whom we may reckon Dr. Priestley, consider the fall of angels as very problematical; and though it cannot be said that the thing is absolutely impossible, yet they conceive that it forms, upon the face of it, to be very improbable. Besides, if such exalted beings as these are supposed to have sinned, and to have thereby become obnoxious to the divine displeasure, what end, they ask, could it answer to them to be so afflicting in seducing mankind? Indeed, upon the supposition that their existence and torments were to be everlasting, it may be conceived to give them a kind of gloomy satisfaction to have "brethren in iniquity," for their companions in their sufferings. Priestley's Institutes, vol. ii. p. 453. Bekker, of Amsterdam, maintains, that the word translated "angels" in Jude, v. 6. and also 2 Pet. ii. 4. should be "messengers," adding, that here is no reference to fallen angels, but to the history of the persons left out by Moses to spy out, and make report of the land of Canaan; and to their false and wicked account, so as to discourage their countrymen from obeying the divine command.

Angel is more particularly applied to a person who sustained any particular character or commission. Accordingly there was an officer of the Synagogue, among the Jews, says Prideaux (Conn. vol. ii. 513.), who officiated in offering up the public prayers to God for the whole congregation, and who, as the mouth of the congregation, delegated as its representative, messenger, or angel, speaks to God in prayer for them, was therefore in the Hebrew language called "Sheleiah Zibbor," that is, "the angel of the church." He was also, according to Dr. Lightfoot, called "episcopus," because he overlooked the reader of the law.

In the Apocalypse, the denomination angel is also given to
to the pastors of several churches: who are called the angel of the church of Ephesus, the angel of the church of Smyrna, &c. This name, according to Prideaux (ubi supra), was borrowed from the synagogue. For as the Sheshach Zibbor, in the Jewish synagogue, was the prime minister to offer up the prayers of the people to God, he was also the bishop who governed over the church, the prime minister to offer up the prayers of the people to God in the church of Christ. Du Cange adds, that the fame name was annually given to certain popes and bishops, by reason of their singular sanctity, &c.

Angel is also used, in Commerce, for an ancient gold coin struck in England; so called, from the figure of an angel impressed upon it. It weighed 4 pennyweights, and was 23½ carats fine.

Its value in 1 Hen. VI. was 6s. 6d., in 1 Hen VIII. 7s. 6d., in 34 Hen. VIII. 8s. in 6 Edw. VI. it was 10s., in 2 Eliz, it was 10s. and in 3 Eliz. the same. And the half angel, or, as it was sometimes called, the anglel, was the moiety of this; and the quarter angelot proportionable.

The angel now subsists no otherwise than as a money of account, denoting 10s.

The French have also had their angels, demi-angels, and angelots; but they are now disused.

Angelic, in Ichthyology, the English name of the squamae squatina of Linnaeus; the French call it ange. See Squatina.

Angel, or Angles Road, in Geography, lies on the starboard side of Milford Haven, within the rocks, in the mid-channel of the haven to the call.

Angela, or Osigua, a town of Africa, in the kingdom of Barca, situation towards Egypt. Its territory, though mostly defert, hath good water, and produces dates.

Angelical, or Angelical, something belonging to, or that partakes of the nature of angels.

We say an angelical life, &c. St. Thomas is styled the Angelical Doctor. The angelical salutation is called by the Romanists Ave Maria; sometimes simply angelus.

Angelic garment, Angelica officinalis, among our Apothecaries, was a monkish garment which laymen put on a little before their death, that they might have the benefit of the prayers of the monks.

It was from them called angelical, because they were called angels, who by these prayers anima sanitatis suaviterur. Hence, where we read the phrase monachus ad suavitationem in our old books, it must be understood of one who had put on the habit when he was at the point of death.

Angelica, in Botany, a genus of the plants of the digyna class and order, and of the natural order of umbellata, or umbelliferae. Its characters are, that the calyx has an universal umbel, manifold, and roundish, and partial, when flowering, exactly globular; the universal involucre three or five-leaved, small; partial, eight-leaved, and small; proper, perianth five-toothed, fiercely observable; the corolla universal, consists of all fertile; partial, petals five-angled, lanceolate, flatish, incurved, and endospermous; the flower has simple filaments, larger than the corolla, and simple anthers; the pistil has a germ, inferior style reflex, and stigma obtuse, no pericarpium; fruit roundish, angular, solid, and bipartite; seeds two, ovate, flat on one side, and margins; convex on the other, scored with three lines. Martyn enumerates six, and Gmelin seven species. 1. A. apiacea, ang. officinalis of Miller, garden angelica, with the odd leaflet of the leaves lobed. The root is thick, fleshy, and savoury; the stalk is erect, about the height of five feet, ramous, hollow, round, smooth, and furrowed; the leaves are ternate and pinnate, leaflets are ovate-lanceolate, acute, gilled, and acutely serrated, smooth, fleshy, puberulent, with the old ocrea bipartite; the petiole at the base is membranous, and very much dilated and ventricose; the umbels globose and multitrate; the umbel's rufciceps denser and hemispherical; the involucres consisting of a few linear deciduous leaflets; the involucella suborbicular, linear-lanceolate and short; the calyx small, the petals ovate, reflex, and white-green; the fruit elliptic- roundish, compressed, and acutely ribbed. It is a native of the northern parts of Europe, and was cultivated here in 1568. With us it is found at Brewood, about seven miles north-west from Birmingham, is biennial, and flowers in September. In a cultivated state, says Withering, it is supposed to be a garden angelica, which is used in some distilled waters, and candied by the confectioners.

Mr. Miller makes a distinct species of the angelica, which grows naturally in Hungary, and some parts of Germany; about twice the size of the common sort, with much larger leaves, more deeply sawed on the edges, with the umbels much larger, and the flowers yellow. 2. A. flavescens, water A. or wild A. with leaflets equal, ovate-lanceolate and ferrate; the stem erect, about four feet high, round, smooth, and fleshy; the leaves bipinnate, and subglabrous, with leaflets ovate, distinct, acutely serrated, and ferrures mucronate; the umbels hemispherical and multitrate; the umbel's rufciceps denser; the involucella suborbicular, and very narrow, and sometimes none; the involucros polyphyllous and flavous; the calyx very visible; the petals ovate, reflex, and fleshy, and the fruit small; it is perennial, found in moat woods and hedges, and by the sides of rivers, and flowers in July. 3. A. verticillaris, with leaves very much divided, leaflets ovate and ferrate, and stem villous, with peduncles; a native of Italy and Silezia, introduced in 1774 by M. Richard. 4. A. atropurpurea, purple A. with the outermost pair of leaves coasied, and the terminal leaf petiolate; a native of North America, and cultivated by Mr. Miller in 1759. 5. A. heidges, thinning A. with leaflets equal, ovate, and galea ferrate; a native of Canada, flowers in June, and the seeds ripen in Auguill. 6. A. Rozalina, panax alpina, &c. of the Boecke, with leaves bipinnate, leaflets lanceolate, ferrate, and decurrent; a native of the Apennines and Piedmontese mountains, found on the former by M. Raoul, an apothecary at Perpignan, whose trivial name. 7. A. lobata, with the inferior leaves biserrate; the leaflets petiolate, ovate, and ferrate; the superior ferrate. 8. A. incisifolia, with the leaflets entire and petiolate. Martyn's Miller, Gmelin, Willdenow, Smith, Flor Brit.

Culture. All the sorts may be increased by seeds. The common angelica delights in a moister soil, in which the seeds should be sown soon after they are ripe; and when the plants are about six inches high, they should be transplanted at a large distance, about three feet asunder, on the sides of ditches or pools of water. In the second year they will flower, and their stems may be cut down in May, and heads will be put out from the sides of the roots, and thus they may be continued for three or four years; but if they had been permitted to feed, their roots would perish from after. If they are permitted to feed, they last but two years.

Dietetic and medical uses. The stalks of garden angelica were formerly blanched, and eaten as celery. The young shoots are in great esteem among the Laplanders. In Norway bread is sometimes made of the roots. The gardeners near London, who have ditches of water in their gardens, propagate great quantities of this plant, which they sell to the confectioners, who make a sweet-meat with the tender stalks.
flasks cut in May. Bohemia and Spain are supposed to produce the best; the college of London formerly directed the roots brought from Spain only to be kept in the shops. Linnæus, however, affirms us, that the plant proves most vigorous on its native northern mountains, and gives a decided preference to the root dug here either early in the Spring, or late in the Autumn. The roots of angelica are one of the principal aromatics of European growth, though not much regarded in the present practice. They have a fragrant agreeable smell, and a bitterish pungent taste; on being chewed they are first sweetish, afterwards acid, and leave a glowing heat in the mouth and fauces, which continues for some time. The leaf, leaves, and feeds appear to possess the same qualities, though in an inferior degree. Dr. Lewis says, that on wounding the fresh root early in the Spring, it yields, from the inner part of the bark, an mucuous, yellowish, odorous juice, which, gently exsiccated, retains its fragrance, and proves an elegant, aromatic, gummy resin. Rectified spirit extracts the whole of the virtues of the root; water but very little; and, in distillation with the latter, a small portion of very pungent essential oil may be obtained. The Laplanders extol the utility of angelica, not only as food but as medicine. For coughs, hoarseness, and other disorders of the blood, they eat the flaks roasted in hot ashes; they also boil the tender flowers in dairy milk till it attains the consistence of an extract; and they use this to promote perspiration in catarrhal fevers, and to strengthen the stomach in diarrhœa, &c. According to the explanations of Sir John Pringle, the herb is antiseptic, but the efficacy of the leaves is soon lost by drying them. The feeds also, which come nearest to the roots, can scarce be kept till the Spring after they are gathered, without the loss of their vegetative power, as well as a diminution of their medicinal virtue. These are the only part of the plant which is ordered by the London College, and that only in compound spirit of aniseed. The aromatic quality of the root is more considerable than that of any other part; but as many other simples surpass angelica in aromatic and carminative powers, it is seldom employed in the present practice. All the parts of the wild angelica are similar in quality to those of the former species, but rather weaker, and the former may be more easily procured. Cows, goats, and swine eat it, but horses refuse it. Lewis Murray, Woodville.

Angelica. See *Eupodium, Chelophyllum, Cicuta, Laserpitium, Selinum, and Smyrnium.*

*Angelica rue.* See *Arabia.*

*Angelica water* is one of the compound waters of the shops; thus called from the *angelica* root, which is the chief ingredient in the composition, and the most active part of that plant. Neumann.

*Angelica gravis,* a technical name given to Anderson's Scots pills.

*Angelica* was also a celebrated dance among the ancient Greeks, performed at their feasts.

It was thus called, from *aglbidon, nuncius, messengers,* because, as Polybus affirms us, the dancers were drest in the habit of messengers. *Angeli,* an ancient order of knights, instituted in 1154, by Ifaacus Anglicus Flavius Comnæus, emperor of Constantinople.

They were divided into three classes, but all under the direction of one grand master. The first were called *torquati,* from a collar which they wore and these were fifty in number. The second were called the *kings of justice,* and were ecclesiastics. And the third were called *kings of lords.*

Julliniani will have this order to have been instituted in the year 313, by Constance; and supposes the occasion thereof to have been the appearance of an angel to that emperor, with the sign of a cross, and these words, *In hoc signo vinces;* but that there was such a thing as any military order in those days, is a mere fable.

*Angelici,* in *Ecclesiastic History,* were also a sect of ancient Christians. St. Anguillus supposes them thus called from their yielding an extravagant worship to angels, and such as tended to idolatry; though Epphasinus derives the name from their holding, that the world was created by angels.

*Angelina zanoni acris,* in *Botany.* This is a tree of walt lize, sometimes above sixteen feet thick, growing on rocky and sandy places in Malabar, in the East Indies. It bears ripe fruit in December, and continues bearing for a whole century.

The dried ripe leaves, are laid to alleviate pains and fluxes in the joints, and diffuse an intumescence of the teats occasioned by a contusion, or any external violence; as also an *hydrole,* or *pneumatocele.* It is efficacious likewise in some veneral complaints, and hemorrhoidal fluxes.

*Angelio, Peter,* in *Biography,* a modern Latin poet, was born in 1572, at Barga, a castle of Tuscany, and hence usually called Bargasus. Having made a great proficiency in Latin and Greek at the early age of ten years, he was prevented from pursuing his studies by the loss of his parent, and obliged to enter into the army. Afterwards, however, he renewed his application to literature, and studied law under Alciatus, at Bologna. But he was obliged to leave this place on account of some seditious verses which he wrote, and to go to Venice, where he was employed by William Pellicier, the French ambassador, in correcting the Greek MSS. which were copied for his sovereign Francis I. In 1542 he removed to Constantinople, where his life was brought into danger by his zeal for the honour of his own nation, which urged him to kill a Frenchman who spoke disrespectful of it. From hence he escaped first to Genoa, and then to Milan; and from Milan he removed to Reggio, in Lombardy, and accepted an invitation to become public preceptor of Greek in that place. After a residence here of three years, he was invited by Cofmo I. duke of Florence, to a professorship, first of belles lettres, and afterwards of the ethics and politics of Aristotle, in the university of Pisa, where he continued 17 years. During his abode in this place, he defended it, with the aid of the scholars of the university, against an attack of Peter Strozzi, in the war of Sienna. In 1575 he was invited to Rome by the Cardinal Ferdinand de Medicis, who entertained him liberally at his court, and recompensed him for the dedication of his poems, with a donation of 2000 gold florins. His latter days he spent at Pisa, living at ease on the munificence of his sovereign; and he died there in 1596. His works in Italian and Latin, both prose and verse, are numerous; but to his Latin performances he chiefly owes his reputation. In five books of miscellaneous Latin poems, he has happily imitated the style of Catullus. His "*Cynegetic," or *Chace,* in six books, first printed in 1568, and laid to be the labour of 20 years, is reckoned one of the best specimens of modern Latinity, and highly commended by Lombin, De Thou, and Poffevin. His "*Syrias,*" an epic poem in 12 books, on the expedition of Godfrey de Bouillon to the Holy Land, was composed in his old age, and though it pleases elegance, it wants the majesty required for such a theme.

*Angelimus,* *Angelici,* in *Ecclesiastic History,* certain Christians, thus denominated from *Angelum,* the name of a place in Alexandria, where their first assemblies were held.
The Angelics appear to have been the same with what are otherwise called Senervi, sometimes Thedofanes and Damiani, from the names of their readers: sometimes also Tabellionijes.

They made their first appearance in the time of the emperor Anastasius, and pope Symmachus, about the year of Christ 494.

The distinguishing tenets of the angelics were, that the several persons of the Trinity had no distinct essence, substance, or deity, but only a subsistence or deity in common, or indivisible among them.

ANGELI, in Geography, a river of North Wales, which runs into the Dee.

ANGELI. See Angelin.

ANGELIN, Port of, is a harbour on the South Sea coast, in the middle between St. Pedro and Capoht; a broad open bay with good anchorage, but bad landing; and the Spaniards reckon it as good a harbour as Gualtan.

ANGELO, St. a small but strong town of Italy, in the Capitanata. There are several other towns and cities of the same name in Italy, particularly the city of St. Angelo at Rome. N. lat. 41° 45′. E. long. 15° 56′.

ANGelo Monte, St. a small part in N. lat. 41° 43′, and E. long. 11° 47′, within Cape Velletri, on the west side of the gulf of Venice, is so called from a high mountain within the cape, and the first land made after entering the gulf.

ANGelo Re, St. lies on the coast of Brazil, to the north-west from Cape St. Auguinile, and is a large opening, without depth of water, blocked up with muds, and rendered useless for navigation.

ANGelo Buonarotti, Michel, a celebrated painter, was born in the territory of Arezzo, in Tuscany, in 1474, and educated at Florence, where, purifying the best of his natural genius for sculpture and painting, in opposition to the remonstrance of his parents, he became, at the age of 14, the disciple of Domenico Ghirlandajo, who has gained great reputation by the artists which his school produced. Michael Angelo soon became superior to his instructor; and such was his uncommon merit, that Leonardo da Medici took him into his service, and employed him in founding an academy at Florence for painting and sculpture; and also in executing several noble works, particularly in that year, which gained him universal applause. By the death of his patron, and the disturbances which happened at Florence, he was obliged to quit the city; but he soon returned, and imbibed that incomparable figure of David with his flag, out of a large block of marble, which is deemed his master-piece, and worthy of the hand of an antique artist. The delightful excellence of this great master was sculpture; and he was the first painter who communicated to the artists of Italy a taste for what is grand and elevated, and enabled them to abandon the dry, stiff manner of Bergino and others. Although he cannot be commended for his colouring, yet the grandeur, elevation, and sublimity of his ideas, the exquisite taste of his design, and the jutine of some of his compositions, established his fame, notwithstanding many imperfections which have been imputed to him as a painter. He wanted elegance in the contours of his figures, and purity of outline; his attitudes are not always beautiful or pleasing; and he was, as Fresnoy observes, held even to raffles, in which he often succeeded.

His acquaintance with anatomy qualified him for devising every limb and joint of the human body, and the invention, as well as the power of every muscle, with great precision; but in consequence of his anatomical skill, he was apt to give too great a strength and swell to the muscular parts. However, it is said, that Raphael himself derived improvement from observing the grand ideas of Buonaroti, though he far excelled him in elegant simplicity, grace, and nature.

The most capital performances of this extraordinary genius are “The Crucifixion,” and “The Last Judgment,” which is the ornamental of the chapel of Sixtus V. in the Vatican. This picture employed him eight years; and as every muscle and limb are distinctly and curiously marked, the figures are entirely naked. This circumstance induced Biagio of Cefenna, the pope’s master of ceremonies, to observe, that such an exhibition of naked figures was more suitable to a brothel than a chapel. But Michael Angelo revenged himself for this sarcasm, by painting the portrait of Biagio exceedingly like, representing him as a daemon, with his eyes, encircled with a large serpent, and placing him in hell. The pope frequently instructed Buonaroti to deliver his matter of ceremonies from this place of torment: but he made this excuse, that he might have been revealed if he had only been in purgatory, but as he was in hell there was no redemption for him.

A late judicious traveller, having viewed that famous composition with a most critical attention, and proportionable admiration, says, that while he stood before it his blood was chilled, and he felt as if all he saw was real; and the very sound of the painted trumpet seemed to pierce his ears.

The composition, however, though grand, is not without perceptible faults. The faces express passions of the strongest kind, and communicate them to the beholders; but the bodies are of too gross an appearance. Indeed the face of our Saviour discloses a dignity, which language cannot describe; it has an astonishing mixture of divine sweetness and severity, which could only be happily expressed by the pencil of Angelo. M. Angelo discontinued painting in the 7th year of his age; and as he died at Rome in the 90th year of his age, A. D. 1564, he was splendidly interred in that city at the expense of Cafino, duke of Tuscany; but by order of this prince, his remains were secretly conveyed to Florence, and deposited, with great funeral pomp, in a magnificent monument, enriched with three marble statues, representing Painting, Sculpture, and Architecture.

Pilkington’s Diet. Keyler’s Travels, vol. i. p 139.

Sir Joshua Reynolds, in his spirited and masterly sketch which he has given of the character of M. Angelo in his “Discourse delivered to the Students of the Royal Academy,” Dec. 10, 1779, describes him as the most excellent founder and father of modern art, of which he was not only the inventor, but which he, by the divine energy of his own mind, carried at once to its highest point of possible perfection.” “M. Angelo (says this excellent artist and judge of merit,) polished the poetical part of the art to a most eminent degree; and his mechanical excellence invigorated and embellished his mind to carry painting into the regions of poetry, and to eminate that art in its most adventurous flights. M. Angelo equally polished both the mechanical and poetical qualifications; yet of the former there were certainly great examples to be found in ancient sculpture, and particularly in the fragment known by the name of the Torso of Michael Angelo; but of that grandeur of character, air, and attitude, which he threw into all his figures, and which so well corresponds with the grandeur of his outline, there was no example; they could therefore proceed only from the most poetical and sublime imagination.”

Were I now to begin the world again,” says the ingenious president of the Royal Academy, “however unequal I feel myself to that attempt, I would trend in the steps of that great master: to kiss the hem of his garment, to catch the flight of his perfections, would be glory and distinction
enough for an ambitious man. I feel a self-congratulation in knowing myself capable of such sentiments as he intended to express. I reflect, not without vanity, that these discourses bear testimony of my admiration of that truly divine man; and I should desire that the last words which I should pronounce in this academy, and from this place, might be the name of Michael Angelo.

*ANGELONI, Francis,* in Biography, an historian and antiquary of the 17th century, illustrated the Roman history by medals, in a work published at Rome, in 1625, and entitled "Historia Anglica par les Medaillles de" John Caesar qualifie Constanin le Grand. He also wrote a "History of Term," his native country, printed in 1610, at Rome, in 1645, where he died in 1652. Now. Dict. Hill.

*ANGELOS, Los,* in Geography. See Tlascal.

*ANGELOS, Puebla de los,* or the city of angels, a town of Mexico, and new capital of the province of Los Angeles or Tlascal, supplies the place of the ancient city of Tlascal, which is now dwindled to a poor inconsiderable village, and situated not far from it. It lies in N. lat. 10° 39', and W. long. 99° 10', on the river Zicata, in a fine valley, about 25 leagues to the eastward of Mexico. In the middle is a beautiful spacious square, from whence run the principal streets in a direct line, which are crossed by others at right angles. One side is almost entirely occupied by the magnificent front of the cathedral, and the other three consist of arcades, under which are the shops of tradesmen. The city is the see of a bishop, suffragan to the archbishop of Mexico. The number of inhabitants is computed at 60,000. In the town there is a mint, and glass-house, and a manufacture of excellent salt; and the adjacent valley produces vines and all sorts of European fruits. In the neighbourhood are several kinds of mineral waters.

*ANGELOT,* an ancient English gold coin, struck at Poitiers while under submission to the English. It was thus called from the figure of an angel supporting the sceptre of the arms of England and France. There was another coin of the same denomination struck under Philip de Valois.

*Angelo* is also used, in Commerce, to denote a small, fat, rich fort of cheese, brought from Normandy.

Skinner supposes it to have been thus called, from the name of the person who first made it up in that form, and perhaps flamped it with his own name. Menage takes it to have been denominated from the resemblance it bears to the English coin called *anglet.* It is made chiefly in the Pays de Bray, whence it is also denominated *anglet de Bray.* It is commonly made in vats, either square or shaped like a heart.

*ANGELUS,* in the Church History of France, denotes a prayer to the Holy Virgin, beginning with this word, instituted by John XXII. in the year 1336, and to be recited every day, morning, noon, and night. Lewis XI. established in France the practice of repeating it at noon; and he obtained from the pope an indulgence of 300 days for all the faithful who, at three o'clock, should rehearse three times on their knees an Ave Maria for the preservation of the king and kingdom. They began, toward the close of the year 1350, to use the angelus in an evening before they put out their fires; this prayer they entitled the pardon, on account of the indulgences attached to it.

*ANGELY (L'),* in Geography, a town of Germany, in the circle of Weilphalia and bishopric of Liège, four miles south-west of Charleroy.

*ANGEN,* a small town of Lower Austria, belonging to the count of Peltzburg.

*ANGER,* Hutchedon defines anger, a propensity to occasion evil to another, arising upon an apprehension of an injury done by him; or, as archdeacon Paley defines it, anger is the pain we suffer upon the receipt of an injury or affront, with the usual effects of that pain upon ourselves.

Anger is either deliberative or instinctive; and the latter kind is rash and ungovernable, because it operates blindly without affording time for deliberation or fore thought. Bishop Butler (Sermon viii.) very justly observes, that anger is far from
from being a selfish passion, since it is naturally excited by injuries offered to others, as well as to ourselves: and was designed by the Author of Nature not only to excite us to act vigorously in defending ourselves from evil, but to interest us in the defence or rescue of the injured and helpless, and to raise us above the fear of the proud and mighty oppressor. Be we angry, and fear not," is a scripture caution; and this supposes that all anger is not sinful, because some degree of it, and, upon some occasions, is inevitable. It becomes sinful, however, when it is conceived upon flightless and inadequate provocations, and when it continues long. The cautions and precepts relating to anger evidently supposeth, that this passion is within our power; and this power consists in mollifying our minds by habits of just reflection, as to be less irritated by impositions of injury, and to be sooner pacified. Such reflections as the following, as they conduce to this purpose, may be considered as the antitheses of anger, viz., the possibility of mislaking the motives from which the conduct that offends us proceeded; how often our offences have been the effect of inadvertency, when they are conceived into indications of malice; the inducement which prompted our adversary to act as he did, and how powerless the same inducement has, at one time or other, operated upon ourselves; that he is suffering perhaps under a contrition, which he is ashamed, or wants opportunity, to confess; and how ungenerous it is to triumph by coldness or inattention to a spirit already humbled in secret; that the returns of kindness are sweet, and that there is neither honour, nor virtue, nor ufe, in refraining them—for some persons think themselves bound to cherish and keep alive their indignation, when they find it dying away of itself. We may remember that others have their passions, their prejudices, their favourite aims, their fears, their cautions, their intertexts, their sudden impulses, their varieties of apprehension, as well as we: we may recollect what hath sometimes paffed in our own minds, when we have got on the wrong side of a quarrel, and imagine the fame to be_paffing in our adversary's mind now; when we became fensitive of our mifbehaviour, what palliations we perceived in it, and expected others to perceive; how we were affected by the kindness, and felt the fuperiority of a generous reception and ready forgiveness; how perseverance revived our spirits with our vanity, and seemed to justify the conduct in ourselves, which we before blame. Add to this, the insensitivity of extravagant anger; how it renders us, whilst it lasts, the fcor and fmitl of all about us, of which it leaves us, when it ceases, fensitive and afhamed; the inconveniences and irretrievable fpoudue, in which our infahibility has sometimes betrayed us; the friendships it has loft us; the diftrajces and embarrassments in which we have been involved by it; and the fore-repetance which on one account or other it always culls us.

But the reflelion calculated above all others to allay that haughtiness of temper which is ever finding out provocations, and which renders anger fo impetuous, is that which the Gospel proposes, namely, that we ourselves are, or shortly shall be, suppliants for mercy and pardon at the judgment-seat of God. Imagine our secret sins disclosed and brought to light; imagine us thus humbled and exposed; trembling under the hand of God; calling ourselves on his compassion; crying out for mercy—imagine such a creature to talk of satisfaction and revenge; refusing to be intreated, declining to forgive; extreme to mark and to resent what is done amiss; imagine this, and you can hardly bring to yourself an inflance of more impious and unnatural arrogance. Paley's Philof. vol. ii. chap. vii. p. 261, &c.

Physicians and naturalists relate some very extraordinary effects of this passion. Burritus cured a woman of an irrecoverable tertian ague, by putting the patient into a violent fit of anger. The same passion has been excited with salutary influence in paralytic, gouty, and even dumb persons; and these last have, in some cases, recovered the use of speech. Etmorel, among other inflances of singular cures wrought by anger, mentions a person, who, being afflicted with the gout, was provoked by his physician to a great degree, and thus cured. In some cases of this passion, mildly excited, has proved mortal. Valentinian the First, Wenceslaus, Matthius Corvinus king of Hungary, and others, have fallen sacrifices to it. Inflances might also be mentioned in which it has produced the epilepsy, jaundice, cholera morbus, diarrhoea, &c.

Anger, indeed, is of such a nature, that it quickly throws the whole nervous system into preternatural convulsions by a violent stiure of the nervous and muscular parts; and surprizingly augments not only the fyllole of the heart, and of its contiguous vessels, but also the tone of the fibrous parts in the whole body. It is also certain, that this passion, by the pspmodic stiure it produces in the parts, exerts its power principally on the stomach and intestines, which are highly nervous and membranous parts; whence the symptoms are more dangerous, in proportion to the greater content of the stomach and intestines with the other nervous parts, and almost with the whole body.

The unhappy influence of anger likewise, on the biliary and hepatic ducts, is very surprizing; since by an intense contrition of thefe, the liver is not only rendered feirrhous, but stones also are often generated in the gall-bladder, and biliary ducts; thofe accidents have fearely any other origin than an obstruction of the free motion and efflux of the bile, by means of this violent stiure. From fuch a stiure of thofe ducts likewise proceeds the jaundice, which in procfs of time lays a foundation for calculous concretions in the gall-bladder. Lastly, by increasing the motion of the fluid, or the impafs of the fibrous parts by means of anger, a larger quantity of blood is propelled with an impetus, to certain parts; whence it happens, that they are too much dilated, and the orifices of the veins distributed there, opened. It is evident from experience that anger has a great tendency to excite enormous hemorrhages, either from the nofe, the aperture of the pulmonary artery, the veins of the arms; or in women from the uterus; especially in those previously accustomed and disposed to fuch evacuations.

For the influence of this passion on the perspiration and urine of human bodies, see Perspiration, &c.

Anger, in Geography, a town of Germany, in the duky of Sibria, 12 miles north-north-call of Graz.

Anger is also a town of Germany, in the archduchy of Aulma, eight miles south of St. Polen.

ANGERAP, a river of Prufia, which runs into the Pregel, near Georgenburg.

ANGERBACH, a modern, well-built, and flourishing town of Prufia, in a government of the fame name. It is defended by a strong castle built in 1355 upon the bank of a lake, which is the source of the river Angerap. This lake, seven German miles long, and one and a half broad, is of great service to the town, and abounds with eels. In 1725 an arch-prefbytery was founded here, which has 12 churches under its jurisdiction. The belt Prussian manna is produced in the environs of Angerburg.

ANGERMANLAND, or ANGERMANNIA, a province of Sweden, bounded on the north by Bothnia and Lapland,
on the eall by the gulf of Bothnia, on the south by Medelpad, and in the west by Jamtland and Hagerdal. Its extent is about 10,000 miles in length, and 16 in breadth. It abounds with forests and mountains; amongst the latter of which the highest mountain called Skellefte is the most remarkable. The soil, however, is fruitful, and in these parts produces excellent corn. The dadon on the south side of Angermanland river yields rice, pate, flax, and good hay; and the numerous lakes afford good pastures for cattle. There are also several inland waters and Lakes abounding with fish. This province maintains fishing for the royal navy, and contains a kind of inland navigation, and two railways. It is one of the divisions of the episcopal diocese of the archbishop, which the 1st of July, and divided into two pro-

divisions. The same extends influence over the provinces of Angermanland, Medelpad, Jamtland, Hagerdal, and the whole government of the town Bothnia, Krambepark excepted, which belongs to the diocese of Abo.

Angermund, a town of the duchy of Courland, in the district of Pfits, 10 miles north-east of Pfits.

Angermund, also a town and prefecture of Berg, in the district of Pfits, 10 miles north-east of Pfits.

Angermund, a town of Germany, in the circle of Angermund, in the neighborhood of the town of Berg, 10 miles north-east of Berlin. It is a picturesque and interesting place, and belongs to the diocese of Abo.

Angermund, a town, with a church and iron-works, in the prefecture of Tuckum, and duchy of Courland.

Angelo, a town of Italy, in the kingdom of Naples, and Principe della; 10 miles west-north-west from S.

Angeron, in Mythology, a pagan deity of the Romans, similar to the Harpocrates of the Egyptians, and the Elegy of the Greeks, represented by them for relief under the name of an aqua or aqua. This deity is denominated by the Greeks as "the Goddess of Science, and Calemce of Mind," because she has divided all mankind and melancholy. She is represented with her mouth closed, and a finger applied to it, to denote silence, and the suppression of complaints. Her image was set up in the temple of the goddess Volupia, and was not placed at a metal altar, consisting of that patience under affliction and incognito with secret and sweet pleasures.

Angeronia, in Mythology, a colossus held by the Romans, the last of December, in honour of Angeronia, or Angeronia, the goddes of patience and silence.

Tuctus and Samboduc, quoted by Macrobius, Saturn, i. 1, c. 10, to derive the name from aqua, signifying and supposed the goddess to have been thus denominated, because she extinguished over that element. Others suppose it formed from acqua, grey, pain, to intimate that the gaw, relief to those afflicted thence. Others derive it from aqua, in pro, in the sense of being reputed the goddess of silence, &c.

Angers, in Geography, a small town of Welf phalia, in the duchy of Berg, situated near the fall of the Angers into the Rhine, nine miles north from Dusseldorf. The Angers, ancienlly Julia Angers and Angaram, a city of France, and capital of the department of the Mayne and Loire, situate on the Mayne, and divided by it into two parts, communicating with each other by two bridges. Before the revolution it was the capital of Anjou and the seat of a bishop, suffragan to the archbishop of Tours: its university was founded by St. Lewis in 1245, by whom the cathedral was built; and its academy of the letters in 1685. The first walls of this city were built by John, king of England, who was count of Anjou in 1214, but destroyed by Louis VIII., and rebuilt by his son, in their present form, in 1257; the city has its 16 parishes, and several religious houses; the cathedral is venerable for its age, and beautiful with regard to its structure; the roofs are covered with the black slate procured from the quarries of Anjou, and hence Angers is called "The Black City." The manufacture of Angers before the revolution conducted of candles, legs, and mixed stuff, and it carried on a considerable trade in other commodities. Its population is estimated at 300,000 inhabitants. It is divided into 16 leagues from Tours, 18 north-east from Nantes, and 67 south from Paris. It is a large island of 15 leagues, and 47 leagues in circumference. It is not inhabited, and is separated from it by the lake called Lago Maggiore. N. lat. 45° 36' 50". E. long. 5° 16'.

Angiglossi, from vivax, vivacious, and vivi, living, denote those who speak with difficulty, hesitancy, or even stammering.

Angilism, in our Old Writers, denotes a simple word, that is, the simple value of the man, or other thing. The word is compounded of the Saxon, on, one, and god, payment, price, or compensation.

In this sense, angilism stands contradistinguished from	inflammation, a double confinement: triligium, a triple confinement.

Angina, in Medicine, an inflammation about the muscles of the lungs or pharynx, attended with an acute fever, difficulty of swallowing, and danger of suffocation. The word is derived immediately from the Latin angina, I, form of a, to be, suffico, frangito. See Cynanche.

Angina lay, in Botany, a name used by some of the later Greek writers, to express what the more ancient writers of this nation called angina, and the Latin angina; this was the cafea or dodder growing on the flax, as that on the thyme was called epithymum. It was called angina lay, quinque of flavis, from its blooming that plant.

Angina petzaria, in Medicine, a name given to a disease, dangerous and not extremely rare, first described by Dr. W. Heberden, and so called from the seat of the disorder, and the sense of strangling and anxiety with which it is attended. The doctor's account of it is in the second volume of the London Medec. Trans. p. 56, &c. See also Medec. and Phil. Comment. vol. ii. p. 95. The patient, while walking, especially if soon after eating, is affected with a painful sensation in his breast; at first, it is removed by his standing still, but afterwards it does not go off so suddenly: it comes on.
on in bed, obliges the patient to get up, and continues for an hour and more; sometimes, though rarely, it attacks the patient standing or sitting still. It is brought on by trivial accidents, coughing, &c. or any flight disturbance. In some it is worse in Winter, in others in Summer. The knife, sometimes at least, is not disturbed. People affected with it often die suddenly, but some continue subjeft to it for upwards of 20 years. The patient commonly refers the fact of his complaint to the ilium, or to a line running across the middle of the ilium; and a pain in the middle of the left arm sometimes accompanies it.

The caufe of this distressing malady was not understood till lately, it being often supposed a spasmodic affection, or a cares of the ilium; but it is now believed to be an affection of the coronary arteries which supply the muscular substance of the heart with blood. This change of structure renders the heart unequal to the task of circulating the usual quantity of blood thrown upon it by violent exertions or palfions of the mind, and hence it is that there are the exciting cauæ of the diffice, in the early stages of the disease.

The prognosis must generally be unfavourable; but several means may be employed to diminish the sufferings of the patient, or to postpone the fatal issue of the disease. These are temperance in eating and drinking, and abstinence from violent exercise and paffions. As angina pectoris commonly attacks persons disposed to obesity and phthisis, these states should be avoided by a suitabe regimen, and occasional bleeding and purging. The circulation should also be kept as equal as possible in every part of the system, by warm clothing, and avoiding the cauæ of local congestion. Wine, or other cordials, taken at bed-time, prevent or weaken night-fits, but opium is the most effectual relief; ten, fifteen, or twenty drops of the Thoebac tincture, taken at bed-time, may be safely continued as long as requisite.

This disease has been accurately described, and suitable precautions or remedies proposed, by Dr. Fothergill, Med. Off. and Inq. vol. v. p. 253, 252; and Dr. C. H. Parry, of Bath, has published an Inquiry into the Symptoms and Cauæs of the Syncope Angina, commonly called Angina pectoris. (1807). This work contains every thing known on the subject.

ANGIOLELLO, JOHANN MARIA, in Biography, an historian, of the 16th century, was a native of Venice, and followed the young Junt Mahomet, to whom he was a slave, in 1533, into Persia, in the dreadful war carried on by Mahomet II. at the head of nearly 200,000 men. As an eye-witness of the events of this war, he wrote "A History of Mahomet II. in the Italian and Turkish languages, dedicated to the sultan, freely written, and yet well received and liberally rewarded. A work, "Of the Life and Actions of the King of Persia," was printed at Venice, under the name of this writer in 1553; and he also wrote, in Italian, "A Relation of the Life and Actions of Ullan Caffan." Gen. Dict.

ANGIOPERIS, in Botany. See Onoclea.

ANGIOSPERMIA, a term used by Linnaeus, to express the second order of the dyedynia plants, which have their seeds not lodged naked within the cup as in the gymnoferma, but included in a capsule, and adhering to a receptacle in the middle of a pericarp. The class of dyedynia contains the labiatad and perforated plants. The angiospermae are the perforated, the others the labiata kind. In this order many of the corollas are perforate, or labiata, with the lips closed; some, however, have bell-shaped, wheel-shaped, or triangular corollas.

To have seeds included in a pericarp is common to all, and hence the name of the order angiosperma. In most of the genera the calyxes are quinqufoli at; in some, however, they are bilab; one trifid, in many quadrifid, and in two multifid. This order, in Gmelin's edition of Linnaeus, contains 87 genera. See Didynamia.

ANGITAS, in Ancient Geography, a river of Thrace, which runs from the north-east, and discharges itself into the Strymon above Amphipolis.

ANGITILUS, or Nemus, a forest of Italy, situated near the Lucus Fucinus. Pliny calls the inhabitants Lucenci. Angitilla was the father of Medea and Crec, and was regarded as a goddes, because she preferred antidotes against poison and the bites of serpents. The name was probably derived from anguis, a serpent, a species of animals which abounded in this place. This forest is mentioned by Virgil (J. a. viii. 659), and by Silius Italiens (lib. viii. v. 468), and was situated in the country of the Marthi.

ANGITULA, a small river of Italy in Bruttium, which discharges itself into the Thermaic gulf, near Nepiata.

ANGLE, Angulus, in Geometry, the aperture or mutual inclination of two lines, meeting in a point.

Such is the angle BAC (Plate I. Geometry, fig. 15.) formed by the lines AB and AC, meeting in the point A. — The lines AB, and AC, are called the legs or the sides of the angle; and the point of intersection, the vertex or angular point.

Angles are sometimes denoted by a single letter affixed to the vertex, or angular point, as A; and sometimes, when several angles have the same vertex, by three letters, that of the vertex being in the middle, as BAC.

The measure of an angle, by which its quantity or magnitude is expressed, is an arc, DE, described from its vertex A, with any radius at pleasure between its legs, AC and AB; and the measure of the angle depends merely on the inclination of the lines by which it is formed, and not on the length of the radius, or the extent of the arc that bounds it.

Hence angles are distinguished by the ratio of the arcs which they thus subtend to the circumference of the whole circle. — And thus an angle is said to be of so many degrees, as are the degrees of the arc DE, by which it is measured.

Hence, also, since the arcs AB and AC, &c. (fig. 16.) have the same ratio to their respective circumferences; and the circumferences contain each the same number of degrees; the arcs AB and AC, &c. are equal; and therefore the angles themselves must be likewise equal. Hence, again, as the quantity of an angle is estimated by the ratio of the arc subtended by it to the periphery, it is of no importance what radius that arc is described with; but the measures of equal angles are always either equal arcs, or similar ones; and contrariwise.

It follows, therefore, that the quantity of the angles remains fill the same, though the legs be either produced or diminished. — And thus in similar triangles, and in similar figures, the homologous or corresponding angles are also equal.

The taking or measuring of angles is an operation of great use and extent in surveying, navigation, geography, astronomy, &c. The instruments chiefly used for this purpose are quadrants, sextants, octants, theodolites, circumferencetors, &c.

Mr. Hadley has invented a new and excellent instrument for taking angles, useful where the motion of the object, or any circumstance causing unsteadiness in the common instruments, renders the observations difficult or uncertain. Phil. Trans. N° 420, and N° 425. Mr. Dollond has likewise contrived
ANGLE.

To measure the quantity of an angle. - 1. On paper. Apply the centre of a protractor to the vertex of the angle C (Plate I. Surveying, fig. 1.), so that the radius CG may coincide with one of the legs; the degree shown in the arc, by the other leg of the angle, will give the angle required. To do the same with a line of chords, see Sector. See Geometry.

2. On the ground. — Place a surveying instrument, e. g., a quadrant, a semi-circle (fig. 2.), in such a manner that a radius thereof CG may be over one leg of the angle, and the centre over the vertex. The first is obtained by looking through the sights fixed at G, towards a mark fixed at the end of the leg; and the latter, by letting fall a plummet from the centre of the instrument. Then, the moveable index HI being turned this way and that, till through its sights you discover a mark placed at the extreme of the other leg of the angle; the degree it cuts in the limb of the instrument gives the quantity of the angle.

To take the angle with a quadrant, theodolite, plain table, sector, compass, &c. See several articles. To plot or lay down any given angle, i.e. the quantity of the angle being given, to describe it on paper. See Fluting and Protractor.

To bisect a given angle, as HIK (Plate I. Geometry, fig. 17.), from the centre I, with any radius at pleasure, describe an arc LM. From L and M, with an aperture greater than half LM, strike two arcs mutually intersecting each other in N. Then drawing the right line IN, we have HIN = HIK.

To trisect an angle, see Trisection.

Pappus, in his Mathematical Collections, lib. iv. treatises of angular sections, and more particularly of trisections.

Angles are of various kinds and denominations.

With regard to the form of their legs, they are divided into rectilinear, curvilinear, and mixed.

An angle, rectilinear, or right lined, is that whose legs are both right lines: as BAC (Plate I. Geometry, fig. 15.).

An angle, curvilinear, is that whose legs are both of them curves.

An angle, mixt, or mixtilinear, is that, one of whose sides is a right line, and the other a curve.

With regard to their magnitude, angles are again divided into right, acute, obtuse, and oblique.

An angle, right, is that formed by a line falling perpendicularly on another; or that which subtends an arc of 90 degrees. Such is the angle KLM (fig. 18.).

The measure of a right angle, therefore, is a quadrant of a circle; and consequently all right angles are equal to each other.

An angle, acute, is that which is less than a right angle, or than 90° — as AEC (fig. 19.).

An angle, obtuse, is that greater than a right angle, or whose measure exceeds 90° — as AED.

An angle, oblique, is a common name both for acute and obtuse angles.

With regard to their situation in respect of each other, angles are divided into contiguous, adjacent, vertical, alternate and opposite.

Angles, contiguous, are such as have the same vertex, and one leg common to both. — Such are FGH and HGI (fig. 20.).

Angles, adjacent, is that made by producing one of the legs of another angle. Such is the angle AEC (fig. 19.), made by producing a leg, ED, of the angle AED, to C. Two adjacent angles, x and y, or any other number of angles made at the same point E, over the same right line CD, are together equal to two right ones; and consequently to 180°. And hence one of two adjacent angles being given, the other is likewise given; as being the supplement of the former to 180°.

Hence also, to measure an inaccessible angle in a field, take an adjacent accessible angle, and subtract from 180°, the remainder is the angle required.

Again, all the angles x, y, z, E, &c. made round a given point E, are equal to four right ones; and therefore all make 360°.

Angles, vertical, or opposite, are those whose legs are continuations of each other. Such are the angles a and x, (fig. 16.).

If a right line AB, cut another, CD, in E, the vertical angles, x and y, as also y and E, are equal. And hence, if it be required to measure, in a field, or any other place, an inaccessible angle, x; and the other vertical angle, y, be accessible; this latter may be taken in lieu of the former.

Angles, alternate. See & Alternate.

Angles, external, are the angles of any right-lined figure made without it, by producing all the sides.

All the external angles of any figure, taken together, are equal to four right angles; and the external angle of a triangle is equal to both the internal and opposite ones.

Angles, internal, are the angles made by the sides of any right-lined figure within the said figure.

The sum of all the internal angles of any right-lined figure is equal to twice as many right angles as the figure hath sides, excepting four. This is easily demonstrated from Euclid, prop. 32. lib. 1.

The external angle of a trapezium inscribed in a circle is equal to the internal opposite one; and the two internal opposite angles are equal to two right ones.

Angles, homologous, or like, are such angles in two figures, as retain the same order from the first, in both figures.

Angle at the periphery, is an angle whose vertex and legs do all terminate in the periphery of a circle. Such is the angle EFD (Plate I. Geometry, fig. 21.)

Angle in the segment, is the same with that at the periphery.

It is demonstrated by Euclid, that all the angles in the same segment are equal to one another; that is, any angle EHD, is equal to any angle EFD in the same segment EFD.

The angle at the periphery, or in the segment, is comprehended between two chords EF and FD, and stands on the arc ED, and is measured by half that arc.

The measure of an angle without the periphery X (fig. 22.) is the difference between half the concave arc LM whereon it stands, and half the convex arc NO intercepted between its legs.

Angle in a semicircle, is an angle in a segment of a circle, whose base is the diameter of the circle.

It is demonstrated by Euclid, that the angle in a semicircle is a right one; in a segment greater than a semicircle, it is less than a right one; and in a segment less than a semicircle, it is greater than a right one.

Since an angle in a semicircle stands on a semicircle, its measure is a quadrant of a circle; and therefore is a right angle.

Angle of a semicircle, is the angle which the diameter
of a circle makes with the circumference. The chief property of this angle is, that it is less than a right angle, and greater than any acute right-lined angle.

**Angle at the centre**, is an angle whose vertex is in the centre of a circle, and its legs terminated in the periphery thereof. Such is the angle C.A.B (fig. 21).

The angle at the centre is comprehended between two radii, and its measure is the arc BC.

Euclid demonstrates, that the angle at the centre BAC is double of the angle BDC, standing on the same arc BC. And hence, half of the arc BC is the measure of the angle at the periphery.

Hence, also, two or more angles III.1, and HMI (fig. 23.) standing on the same, or equal arcs, are always equal. All angles at the centre are proportional to the arcs upon which they stand, and so are likewise all angles at the circumference.

**Angle without the centre**, HKI, is that whose vertex K is not in the centre, but its legs HK and IK are terminated in the periphery.

The measure of an angle without the centre is half the sum of the arcs HI and LM, whereon it and its vertical K stand when it is within the circle, or half the difference when it is without.

**Angle of contact**, is that made by the arc of a circle, or of any curve, and a tangent in the point of contact. Such is the angle IHK, (fig. 24).

The angle of contact, in a circle, is proved by Euclid to be less than any right-lined angle; but from hence it does not follow, that the angle of contact is of no quantity, as Poletarius, Wallis, and some others, have imagined. V. Wall. Algeb. p. 71, &c. Clavius, on the other hand, rightly maintained, that it is not absolutely nothing, but that it is of no magnitude compared with a right-lined angle, being a quantity of a very different nature: such as a line with respect to a surface, or a surface with respect to a solid, &c. And since this time it has been proved by Sir Isaac Newton, and others, that angles of contact may be compared with each other, though not with right-lined angles, and that the proportions which they bear to each other may be asigned. Thus, the circular angles of contact IHK, IHL, are to each other in the reciprocal subduplicate ratio of the diameters HM, HN; and the circular angle of contact may be divided by describing intermediate circles into any number of parts, and in any proportion. And if, instead of circles, the curves be parabolas, and the point of contact H the common vertex of their axes, the angles of contact would in this case be reciprocally in the subduplicate ratio of their parameters. But elliptical and hyperbolic angles of contact would be reciprocally in the subduplicate of the ratio, compounded of the ratios of the parameters and the transverse axes. Moreover, if TOQ (fig. 25.) be a common parabola to the axis OP and tangent VOW, whose equation is \(x^2 = ay\), \(x\) being the absciss OP, and \(y\) the ordinate PQ, and the parameter being \(1\); and if OR, OS, &c. be other parabolas to the same axis, tangent and parameter, their ordinates \(y\) being PR, or PS, &c. and their equations \(x^2 = ay\), \(x^2 = y\), \(x = y\), &c.; then the series of the angles of contact would be in succession infinitely greater than each other; that is, the angle of contact WOQ would be infinitely greater than WOR, and this again infinitely greater than WOS, and so on infinitely. Besides, between the angles of contact of any two of this kind, other angles of contact may be found ad infinitum, which shall infinitely exceed each other, and yet the greatest of them be infinitely less than the smallest right-lined angle. Thus also \(x = y\), \(x^2 = y\), \(x^2 = y^2\), &c. denote a series of curves, of which every suc-

ceeding one makes an angle with its tangent infinitely greater than the preceding one; and the half of these, \(\text{viz.}\) that whole equation is \(x^2 = ay\), or the semicircular parabola, is infinitely greater than any circular angle of contact.

**Angle of a segment** is that made by a chord with a tangent, in the point of contact. Such are HIK, (fig. 26.) the angle of the lesser segment IH, and HIL, the angle of the greater segment IH. And the measure of each of these angles is half the alternate or suplemental segment, or it is equal to the angle in it; that is, the angle HIK = IH, and HIL = IH.

**Angles, for the effects, properties, relations, &c. of**, when combined into triangles, quadrangles and polygonal figures, see Triangle, Quadrangle, Square, Parallelogram, Polygon, Figure, &c.

Angles are again divided into planes, spherical, and solid. Angles, plane, are those above-mentioned; which are defined by the inclination of two lines in a plane, meeting in a point.

**Angle, spherical**, is an angle formed on the surface of a sphere by the intersection of two great circles, or the inclination of the planes of two great circles of the sphere.

For the properties of spherical angles, see Spherical Angle.

**Angle, solid**, is the mutual inclination of more than two planes, or plane angles, meeting in a point, and not contained in the same plane. For the measure, properties, &c. of solid angles, see Solid Angle.

We also meet with other kinds usual sorts of angles among some geometers; as

**Angle, borned, angular cornutus, that made by a right line, whether a tangent or secant, with the periphery of a circle.**

**Angle, lunular, angular lunularis, is that formed by the intersection of two curve lines; the one concave, and the other convex.**

**Angle, ellipsoid, angular ellipsoides, is the inner angle made by two spherical convex lines intersecting each other.** See Cissoid.

**Angle, spheroid, angular spheroides, is that which has the form of a sistrum.**

**Angle, peleoid, angular peleoides, is that in figure of a hatchet.** See Peleoides.

**Angle, in Trigonometry.** See Triangle, and Trigonometry.

For the sizes, tangents, and secants of angles, see Sine, Tangent, and Secant.

**Angle, in Geography, a town of France, in the department of Vendee, and chief place of a canton, in the district of Sables d'Olonne, ten miles west-south-west from Laon.**

**Angle is also a town of France, in the department of Vienne, and chief place of a canton, in the district of Mont Morillon, on the Creuse, 25 miles east from Poitiers.**

**Angle, in Mechanics.** Angle of direction, is that comprehended between the lines of direction of two confining forces. See Direction.

**Angle of elevation, is that comprehended between the line of direction of a projectile, and any plane upon which the projection is made, whether horizontal or oblique. Such is the angle RAB (Plate 1. Mechanics, fig. 3.) which is comprehended between the line of direction of the projectile AR, and the horizontal line AB.**

**Angle of incidence, is that made by the line of direction of an impinging body, in the point of contact. Such is the angle DFA (fig. 4.)**

**Angle of reflection, is that made by the line of direction of
of the reflected body, at the point of contact from which it returns. See the Angle.

Angle of Incidence. In Catoptrics, is the angle included between two rays drawn from the two extreme parts of an object to the center of the pupil. — Such is the angle ABC (Plate 1, Optics, fig.) comprehended between the rays AB, and AC. This apparent magnitude of objects is greater or less, according to the angle, which appears to them. See Apparent Magnification.

Objects seen under the same, or an equal angle, always appear equal.

The least visible angle, or the least angle under which a body can be seen, according to Dr. Hooke; is one minute; though Dr. Jurin found, that at the time of his debate with Huyghens, on the subject, the latter could probably discover a single star made to subtend an angle as 20". But bodies are visible under smaller angles, as the sun's rays height of hillous. Dr. Jurin fixes the grounds of this controversy, and discusses the quantities at large in his Essay upon distinct and indistinct Vision, published in Smith's Optics, p. 118, &c.

Angle of the interval of two places, is the angle subtended by two lines drawn from the eye to those places.

Angle of incidence, in Catoptrics, is the lesser angle, made by an incident ray of light, with the plane of a speculum; or, if the speculum be concave or convex, with a tangent in the point of incidence. Such is the angle ABC (fig. 5.) Or, as some define it, it is the angle which a ray of light makes with a perpendicular to that point of the surface of any medium on which it falls.

Every incident ray, AB, makes two angles, the one acute, ABD, the other obtuse, ABE; though sometimes both right. The lesser of such angles is the angle of incidence. See Incidence.

Angle of incidence, in Dioptrics, is the angle AHI (fig. 4), made by an incident ray, AB, with a lens, or other refracting surface, HI.

Angle of inclination, is the angle ABD, contained between an incident ray, AB, and the axis of incidence, DB. See Angle, &c.

Angle of reflection, in Catoptrics. See Reflection.

Angle, reflected. 

Angle of refraction, in Dioptrics. See Refraction.

Angle, refracted. 

Angle of elongation, or Angle at the earth. See Elongation.

Angle, parallactic. See Parallactic angle and Parallax.

Angle at the sun, is the angle under which the diameter of a planet from the ecliptic is seen from the sun.

Angle of the Earth. See Nonagesimal.

Angle of obliquity, of the ecliptic, or the angle of inclination of the axis of the earth, to the axis of the ecliptic, is now nearly 23° 28'. By means of this inclination, such inhabitants of the earth as live beyond 45° of latitude, have more of the sun's heat, taking all the year round; and those who live within 45° have less of his heat, than if the earth always moved in the equinoctial. See Obliquity, and Ecliptic.

Angle of longitude, is the angle which the circle of a star's right ascension makes with the meridian, at the pole of the ecliptic.

Angle of right ascension, is the angle which the circle of

The apparent magnitude of objects is greater or less, according to the angle, which appears to them. See Apparent Magnification.

A N G L E.

The apparent magnitude of objects is greater or less, according to the angle, which appears to them. See Apparent Magnification.

A N G L E.

The apparent magnitude of objects is greater or less, according to the angle, which appears to them. See Apparent Magnification.
Angles, re-entering, or re-entrant, is that whose vertex is
turned inwards, towards the place.

Angles, oblong, or oblongi, is that which advances its
point toward the field.

Angles of the tenaille, or the outward flanking angle, called
also the angle of the mast, or the dead angle, is made by the
two lines oblong in the faces of the two billows, extended
till they meet in an angle towards the curtin. This always
turns its point in towards the work.

Angles, dead, is a re-entering angle, which is not flanked
or defended.

Angles of a wall, in Architecture, is the point or corner
where the two sides or faces of a wall meet.

Angle Bar, in Carpentry, is that which is perpendicular
to the horizon, in the angle formed by any two faces of a
bow-window, whose plan is a polygon.

Angle Bracket of a cove or cornice, is that which stands
in a perpendicular plane, passing through the diagonal of
the plan, ranging in every right line horizontally; directed
along the edges of the common ribs that are fixed on either
side of it.

Angle Rib of a groin, is that which stands in the
diagonal perpendicular plane, passing through the diagonal of
the plan, and ranging in right lines in every horizontal direction
with the common ribs that are fixed on either side of it. These
two lines are the same in principle, their difference being only
in the application; for their description, see a Groin.

Angles, or Angles, in Geography, a small district
of the duchy of Slefwick, in Denmark, from 16 to 20
miles in length, and about as much in breadth, situated
between Flensburg and Slefwick. See Angles.

Angles, a fisherman, or other person who practices
angling.

Angles are to be distinguished from poachers. Some
make the same difference between them, that is between
the fair trader and smuggler. Accordingly the legislature
has made the latter penal, but had no restraints on the former.
Angles can do no prejudice to the fish of a river. Anglers
fish for their recreation, not for lucre; whereas poachers
make it their livelihood.

Angles, in Ichthyology, the English name of the bata-
choes of Aristole and Oppian, and the genus plecostomus
of Pliny and Ovid: a species of Lophius.

Angles, Padre Camillo di Cremona, in Biology,
author of a musical tract entitled, "Regole di
Contrapunto," published at Mant in 1622.

Angles of a battalion, in the Military Art, are those
soldiers that are placed where the ranks and files terminate.
See Battalion.

The angles of a battalion are said to be blunted, when the
soldiers at the four corners are removed, so that the square
battalion becomes octagonal; this was an evolution very
common among the ancients, though now disused.

Angles, in Anatomy, are understood of the canthi, or
or the corners of the eye, where the upper eye-lid meets with
the under.

That next the nose is called the great or internal, and
that towards the temples, the lift or external angle, or
canthus.

Angles, in Astrology, denote certain houses of a figure,
or scheme of the heavens. Thus the horizon of the flat
horizon is termed the angle of the sky.

Angles, Instruments for measuring horizontal, in Astronomy.
See Horizontal.

Angles, in Geography, a town of France, in the department
of the Havain, and chief place of a canton, in the
district of St. Pois, three leagues well-north-west from
St. Pois.

Vol. II.

Angles, in Geography, are said to have been a tribe of the
Suvi, who, in the time of Caesar (Bell. Gall. li. v.), were
the greatest and bravest of all the German nations. This
tribe, after various adventures and migrations, settled in that
part of the Cimbic Chersonese, which now forms the
duchy of Slefwick, where some vestiges of their name still
remain in the district of Angles. The most probable ety-
moblogy of the name deduces it from the Saxons "Angle
or Angil," signifying "a fish-hook;" and indicating that the
Angles were much addicted to piracy, and were so called by the
neighbouring nations, because, like fish-hooks, they
captured all that was in the sea. From these people the
English are said to have originated; for when they were
invaded by the British ambassador to succour their
countrymen against the Scots and Picts, they embarked,
with greater spirit and in greater numbers than any of the
other German nations; and having expelled the Picts,
and made themselves masters of the country, they had
the honour of giving their name to England and its
inhabitants. The reason, it is said, why the name of Angles
was preferred to that of Saxons seems to have been, because
it was more distinctive and more honourable: that being
at that time a large nation of Saxons on the continent, who
were in disrepute on account of their manners, and the defen-
s which they had suffered from Charlemagne. It may
be added, that the Angles constituted the greatest part of
Egbert's subjects: all the northern, eastern, and midland
counties, being inhabited by them. Egbert published an
epitaph, dated at Winchfeather in the year 827, abolishing
the distinctions of Saxons, Jutes, and English, commanding all
his subjects for the future to be called by the latter name
only. Rupin's Hist. vol. i. p. 89.

Angles, or Anglesey, the Mona of Tacitus, in
Geography, the English name for Môn, an island on the nor-
thern extremity of Wales, from which it is separated only
by a narrow channel, called the Menai. It is about 20 miles
in length, by 17 miles in breadth; or as others say, 25 long,
and 18 broad; and is one of the six counties of North
Wales; which is divided into three hundreds: that is to say,
Aber Fraw, with its townships of Llviron and Malltrth;
Rhosyr, with its townships of Tindaethwy and Menai;
and Cemae, with its townships of Twrcelyn and Talybont.
According to a late estimate Anglesea contains about 200,000
acres of land, and 20,000 inhabitants; and is divided into seven
hundreds, 74 parishes, and four market towns; situated
in the diocese of Bangor. The chief town is Beaumaris.
The air is in general good, except when the thick fogs arise
from the Irish seas; but in autumn it is cold and arid.

The soil, which, on the first aspect, appears rocky
and mountainous, is nevertheless fertile, and produces a
number of cattle, and great quantities of corn, sent annually
to England. However much of the land lies plowed and
full of turf bogs, or pointed rocks; and yet there are some
rich farms in the interior and along the coast, particularly
that which is opposite to Caernarvonshire. The general
face of the country is low, flat, and unpleasing.

This island, which is known to the Welsh only by the
name of Môn, obtained the appellation of Anglesey, among
the English, from the following circumstance: in the year
829, Egbert invaded North Wales; and after ravaging sev-
eral districts, he passed over into Mona; defeated the
Welsh, in a bloody battle near Beaumaris; and, in conse-
quence of his victory, he gave possession of the whole island.
He was able to maintain himself there only for a short time;
being driven out by Mervyn, king of North Wales; never-
thelass, the English ever after continued to call the place
Anglesea, or the island of the Angles.

According to a curious historical document, contained in
the
the Britih Triads, this isle once formed a part of the main land. The passage is to the following purport: "The three original islands adjoining to Britain were Orkney, Man, and Wight; and afterwards the sea broke the land, so that Man became an island; and in like manner Orkney was broken; so that there were formed a multitude of islands; and other places on the coasts of Scotland and Wales were broken by the sea, and became islands."

The book entitled *Mona Antiqua* was written by Rowlands, to prove that Anglesea was the metropolis of Druidism. An hypothesis formed from the recital of the delusion of the Druids there by St. Bonosius Paulinus, or probably suggested by a partiality for his native place, and certainly without duly weighing its title to that preeminence, for if he had done so, he must have discovered such a position to be defective of any solid foundation.

Nothing more ought to be inferred from the account of the Druids having been found by the Romans in Anglesea, than that they were taken in their retreat; for they always avoided the fast of war, agreeable to their principles; but here they did not expect the appearance of the enemy so suddenly, and very likely they had not the means time enough of retreat farther.

In the next place, that island does not abound with any monuments or remains, in sufficient numbers to induce a belief of its having been the permanent centre of Druidism; and in truth there is not perhaps a country in all Wales, but which abounds more with such vylesges than Anglesea.

It is also to be naturally supposed that the principal place of meetings would have been fixed upon in the most convenient situation for the different flats of Britain and of Gaul to attend; and free from the obstructions of large rivers, and other obstacles; whereas the isle of Anglesea was peculiarly the reverse of all this; and we must, therefore, seek elsewhere for the alma mater of the Bards, Druids, and Ortes.

The open grounds of Wiltshire then necessarily draw our attention; there we find Avebury, the grand national circle of the Britons; and there too it is said to be by the bardic Triads; and compared with this, no similar work in the country bears any comparison in grandeur and extent of design.

The glory of Mona must, therefore, be confided to its proper sphere; for it never had a more extended orbit than it has now; in druidical times it had its small provincial circles, as in the present day it has its parish churches.

The great curiosity which Anglesea can boast, and the chief source of its wealth, is the Paris mountain, the name of which is most probably derived from the old Welsh word "Ffuras," signifying "brass," which might easily be corrupted into Paris. The copper-mines in this part of the island are supposed to have been known and worked by the Romans; a pool on the top of the mountain having been distinguished, long before the present works were formed, by the name of the Mine-pool. The mine of this mountain is considerably more than a mile in circumference, and on an average 1500 men are constantly employed in it. It has the singular advantage of being worked in the open air; a circumstance which expedites the labour, and secures the health of those that are employed.

Abundance of vitriolic water is found in these works, which is so strong as infamintaneously to turn whatever steel or iron is dipped into it, to the colour and appearance of copper. This water is exposed to the fun in large open troughs, and the copper quality is extracted from it by a curious process. Great quantities of sulphur are also produced, and its sublimation is carried on in various spots upon the mountain, till at last the whole is collected into some large boiling-houses, and formed into rolls of brimstone.

The copper ore is then carried down to some smelting-houses, constructed in the valley below near the sea-side, where every remaining operation is performed with wonderful art and affinity. Lead, silver, in silver, is also found in the same mountain; and in the north-eastern part of the island there is a quarry of green marble intermixed with abelites.

Anglesea sends two members to the imperial parliament: one for the county, and one for Beaumaris.

ANGLESQUEVILLE, a town of France, in the department of the Lower Seine, and chief place of a canton, in the dioc. of Dieppe, 15 miles north from Rouen.

ANGILIA, East, in Higlors, one of the kingdoms of the Heptarchy, bounded by the Angles that landed on the easterly coasts of Britain, under 13 chiefs, the survivor of whom, Offa, in 571, assumed the title of king of the East-Angils. This kingdom was bounded on the north by the Humber and the German Ocean, on the south by the sea ocean, on the south by the kingdom of Eastfris, and on the west by Mercia. Its greatest length was 80, and its greatest breadth 75 miles. It contained the two counties of Norfolk and Suffolk, with part of Cambridgeshire. The chief towns were Norwich, Thetford, Ely, and Cambridge. Earpold, the fourth monarch of this kingdom, was converted to Christianity by the influence of Edwin, king of Northumberland; but his wife, who was an idolater, soon brought him back to her religion. After his death, and the interregnum that followed, Sigebert, who had been educated in France, restored Christianity, and introduced learning among the East-Angils. Some pretend that he founded the University of Cambridge, or rather some schools in that place. Ethelbert, who was the last sovereign of this kingdom, and who received his crown from Ethelred in 790, was treacherously murdered by Offa, king of Mercia, in 792, who seized his kingdom; and from that time East-Anglia was united with Mercia.

ANGILICA, in Entomology, a species of *Pimplia*, found in England very rarely. It is black, anterior part of the thorax roundish, wing-cases fringed with dots, antennae reddish at the apex. Gmelin. This is the description of Fabricius, which Gmelin adopts. It was described by Fabricius in the species infectorum, under the name *Pimplia*; but in the latter arrangement of insects by that author, it is placed in the genus *Helops*, under the specific name *Pimpla*. Gmelin makes a subdivision of the genus *pimpla*, under the name *Helops*, in which this species is included.—Also, a species of *Chrysomela*, found in England. It is blue-black, wing-cases black, brassy and fringed with dots; wings red. *Ford.* Nov. Inf.—Fabricius.

ANGILCANA, a species of *Altica*, in the Fabrician arrangement, and found in England. It is in general black, except the wing-cases and tips of the legs, which are pale. Fabricius.

ANGILCANUS guta. See *Guttus*.

ANGILCANUS foder. See *Sudos*.

ANGILICUS, a word, or phrase, in the English *idio*; or a manner of speech peculiar to the English tongue.

ANGILICUS, in Entomology, a species of *Cerambyx*, found in England and France. It has a yellow body, and two oblique yellow stripes on the wing-cases. Gmelin. This is the Fabrician description, and in that arrangement it belongs to the *Rhagius* genus. It is also the lepta morax of De Geer, and Stemoceous of Geoffroy.

ANGLING is a branch of fishing; or the art of catching fish by means of a rod, to which is attached a line, a hook, and a bait. It is more generally practiced for amusement than for profit, and is a sport of considerable antiquity, and followed with the greatest avidity by some persons in every rank in life. It has some eminent advan-
tages over many other rural sports; it is but little dangerous, incurs but little expense, and is productive of some profit. It is peculiarly fitted for the placid and thoughtful; nor need the gay and volatile despair of finding their attention engaged, while the more active mode of fly-fishing remains in life. Perhaps there are few pursuits that display more elegant attitudes than that of throwing the fly; nor are there but few in which the expectation is so much kept alive, with so little bodily or mental exertion, as in this delightful branch of the art. On the other hand, simple float angling has its advantages likewise; for in this the inference and aged may partake, and the solitary or recluse may pursue the amusement, without fear of the interruptions of the busy or impertinent; here, likewise, the contemplative may combine relaxation with improvement, as few persons have a greater opportunity of studying nature in her varied garb than the angler.

The laws have ever been favourable to this pursuit, protecting the authorized fisher, and punishing the depredations of the poacher. As early as Edward I., we find, that imprisonment and triple damages, were awarded against any tarpellers, if a tainted at the suit of the party. 3 Ed. I. c. 29.

By Elizabeth it was enacted, that if any persons wrongfully take or kill fish, from any ponds, &c. kept for the purpose of angling, he or they shall be imprisoned, pay triple damages, and find securty for his or their good behaviour for seven years. 5 Eliz. c. 21. The 22d and 23d Car. II. c. 29, recites, that the use of an angle, net, hair, noose, troll, or spcar, or the taking of fish in any way, or the being aiding therein, without the consent of the owner, or lord of the manor, is forbidden; and that persons so offending shall, on discovery and conviction thereof, have triple damages awarded against them, to be levied by distress.

And in the same statute it appears, that any nuisance of the peace is authorized to take and destroy every instrument used for these purposes. By the 4th and 5th W. III. c. 23. § 5, 6. no person was even to have or keep in his possession any angle, net, or other engine for the taking or destroying of fish, other than the makers and sellers thereof; and than the owners and occupiers of a river or fishery. And again, 5 Geo. III. c. 14. § 1, 2, not only persons who entered any park or other ground fenced in, wherein there was any water containing fish, and rode thereout; but those who receive and buy such fish, shall be subjected, equally with the offenders, to seven years transportation. And again, § 6. the taking fish unlawfully from any water, not situated in enclosed ground, is punishable by the forfeiture of 5l.; but by the black act, the breaking down of the head and mound of any fish pond, was made felony without benefit of clergy.

There is no art, the practice of which appears more simple, at first view, than that of angling; yet there are few that require more nicety and precision, nor is there any for which it is more difficult to give precise rules. There is a species of acquired knowledge, amounting to a knack, that constitutes a successful angler, but which he can with difficulty impart to others.

The fish usually caught by angling are the salmon, salmon fry, salmon trout, bull trout or sea trout, eel, or whiting, bass, or bream, mullet, frit, bloodfish, balander, etc.; all which visit the salt water. Those which are likewise taken by this mode, and do not visit the salt water, are the trout, grayling, pike or jack, perch, tench, carp, chub, eel, eel, rudd, roach, dace or dace, gudgeon, bleak or whiting, minnow, loach, &c., which several fish feed under their proper heads.

These several fish require different tackle, baits of various kinds, and some are taken in one season, while others are secured in another; of all which it is essentially necessary that the angler should be aware, as well as of the particular weather, favourable to the sport.
