fer, that the prophecies of these twelve were already collect- ed and digested into one body. It is farther evident, that in 

the time of our Saviour the canon of the holy Scriptures was drawn up, since he cites the Law of Moses, the Pro- 

phets, and the Psalms, which are the three kinds of books of which that canon is composed, and which he often styles “the Scripture,” or “the Holy Scripture.” Matt. xxvi. 

42. xxii. 29. xxvi. 54. John, v. 39. This flew that they were distinguished from others, and formed a separate body. 

The person who compiled this canon is generally allowed to be Ezra. According to the invariable tradition of Jews and 

Christians, the honour is ascribed to him of having collected 
together and perfected a complete edition of the Holy Scrip- 
tures. The original of the Pentateuch had been carefully pre- 
erved in the side of the ark, and had been probably intro- 
duced with the ark into the temple at Jerusalem. After 

having been concealed in the dangerous days of the idolatrous 
kings of Judah, and particularly in the impious reigns of 

Manasseh and Amon, it was found in the days of Josiah, the 

suceeding prince, by Hilkiah the priest, in the temple. 
Prideaux lays, that during the preceding reigns, the book of 

the Law was so destroyed and lost, that, besides this copy of it, there was then no other to be obtained. To this pur- 
pose he adds, that the surplice expressed by Hilkiah, on the 
discovery of it, and the grief expressed by Josiah when he 
heard it read, plainly shew that neither of them had seen it 
before. Upon this, the pious king ordered copies to be 
written out from this original, and to be dispersed among the 
people. 2 Kings, xxiii. 8—13. 2 Chron. xxxiv. On the 
other hand, Dr. Kennicott supposes, that long before this 
time, there were several copies of the Law in Israel, during 
the separation of the ten tribes, and that there were some 
copies of it likewise among the tribes of Judah and Benjamin, 
particularly in the hands of the prophets, priests, and Le- 
vites, and that by the instruction and authority of these M.S., the various services in the temple were regulated, 
during the reigns of the good kings of Judah. He adds, 

that the surplice expressed by Josiah and the people, at his 
reading the copy found by Hilkiah, may be accounted for 
by admiring to the history of the preceding reigns, and by 
recollecting what a very idolatrous king Manasseh had been 
for 55 years, and that he wanted neither power nor inclina- 
tion to destroy the copies of the Law, if they had not been 
secreted by the servants of God. The Law, after being so 
long concealed, would be unknown almost to all the Jews; 
and thus the solemn reading of it by Josiah would awaken 
his own and the people's earnest attention; more especially, 
as the copy produced was probably the original written by 
Moses. From this time copies of the Law were exten- 
vively multiplied among the people; and though within a 
few years, the autograph, or original copy of the Law, was 
burnt with the city and temple by the Babylonians, yet 
many copies of the Law and the Prophets, and of all the 
other sacred writings, were circulated in the hands of private 
persons, who carried them with them into their captivity. 
It is certain that Daniel had a copy of the Holy Scriptures 
with him at Babylon; for he quotes the Law, and mentions 
the prophecies of Jeremiah, in the ninth chapter of 
Daniel, xxv. It appears also, from the fifth chapter of Ezra, and from the 

ninth chapter of Nehemiah, that copies of the Law were 
difpered among the people. It is unnecessary, therefore, to 
turnpoe, with some of the ancient fathers, such as Tertullian, 
Clemens Alexandrinus, Baill, &c. that Ezra restored the 
Scriptures by a divine revelation, after they had been lost 
and destroyed in the Babylonish captivity. For this opi- 

nion they had no other authority than the fabulous relation 
which occurs in the 14th chapter of the second apocry- 
phal book of Enoch; a book too absurd for the Roman-

ists themselves to admit into their canon. The whole 

which Ezra did may be comprised in the following particular. 
He collected as many copies of the sacred writings as he 
could find, and compared them together, and out of them 
all, formed one complete copy, adjusted the various readings, 
corrected the errors of transcribers, and as some say, annexed the “Keri cheitis,” which are found in the margins of the 
ancient MSS. He likewise made additions in several parts of 
the different books which appeared to be necessary for the 
illustration, correction, and completion of them. To 

to this class of additions, we may refer the last chapter of 
Deuteronomy, which, as it gives an account of the death 
and burial of Moses, and of the succession of Josiah after him, 
could not have been written by Moses himself. Under the 

same head have also been included many other interpreta-
tions in the Bible, which create difficulties that can never be 
solved without allowing them; as in Gen. xii. 6. xxii. 14. 
xxvi. 3. Exod. xvi. 35. Deut. ii. 12. iii. 11. 14. 
Prov. xxv. 1. The interpolations in these passages are ascribed by 
Prideaux to Ezra; and others which were afterwards added 
he attributes to Simon the Jull. Ezra also changed the old 
names of several places that were become obsolete, putting 
instead of them the new names by which they were at that 
time called; influences of which occur in Gen. xiv. 4, where 
Dan is substituted for Laish, and in several places in Genesis, 
and also in Numbers, where Hebron is put for Kirjath Arba, 
&c. He likewise wrote out the whole in the Chaldee charac-
ter, changing for it the old Hebrew character, which hath 
from that time been retained only by the Samaritans, and 
among whom it is preferred even to this day. In the church 
of Dominic, in Bononia, there is said to be a copy of the He-
brew Scriptures, preferred with great care, which they pre-
tend to be the original copy written by Ezra himself, and 
for which great pains have been occasionally borrowed by the 
Bonontians upon the pledge of it, and which have again 
been paid for its redemption. This copy is written in a
The Books of the Old Testament were compiled in the time of Ezra (Ezr. viii. 2). The Books of the New Testament were compiled in the time of St. John the Evangelist (Luke x. 42). The Books of the Apocrypha were compiled in the time of St. John Chrysostom (Chrys. hom. x. 1). The Books of the Pseudepigrapha were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Polyc. epigr. iv. 1). The Books of the Gospels were compiled in the time of St. Irenaeus (Iren. ad Her. iii. 6). The Books of the Acts of the Apostles were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Eph. epigr. iv. 1). The Books of the Epistles were compiled in the time of St. Irenaeus (Iren. ad Philid. epigr. i. 7). The Books of the Apocalypse were compiled in the time of St. John Chrysostom (Chrys. hom. x. 1). The Books of the Martyrdoms were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Polyc. epigr. iv. 1). The Books of the Fathers were compiled in the time of St. Irenaeus (Iren. ad Her. iii. 6). The Books of the Theology were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Eph. epigr. iv. 1). The Books of the History were compiled in the time of St. Irenaeus (Iren. ad Philid. epigr. i. 7). The Books of the Geography were compiled in the time of St. John Chrysostom (Chrys. hom. x. 1). The Books of the Topography were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Polyc. epigr. iv. 1). The Books of the Chronology were compiled in the time of St. Irenaeus (Iren. ad Philid. epigr. i. 7). The Books of the Pseudepigrapha were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Polyc. epigr. iv. 1). The Books of the Apocrypha were compiled in the time of St. John Chrysostom (Chrys. hom. x. 1). The Books of the Gospels were compiled in the time of St. Irenaeus (Iren. ad Her. iii. 6). The Books of the Acts of the Apostles were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Eph. epigr. iv. 1). The Books of the Epistles were compiled in the time of St. Irenaeus (Iren. ad Philid. epigr. i. 7). The Books of the Apocalypse were compiled in the time of St. John Chrysostom (Chrys. hom. x. 1). The Books of the Martyrdoms were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Polyc. epigr. iv. 1). The Books of the Fathers were compiled in the time of St. Irenaeus (Iren. ad Her. iii. 6). The Books of the History were compiled in the time of St. Irenaeus (Iren. ad Philid. epigr. i. 7). The Books of the Geography were compiled in the time of St. John Chrysostom (Chrys. hom. x. 1). The Books of the Topography were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Polyc. epigr. iv. 1). The Books of the Chronology were compiled in the time of St. Ignatius of Antioch (Ignat. mag. ad Polyc. epigr. iv. 1).
the Prophets, the reading of which they ever after continued. Thus, when the reading of the Law was restored by the Maccabees, the fection which was read every sabbath out of the Law served for their first lesson, and the fection out of the Prophets for their second lesson; and this practice was continued in the time of the apocryphes. Acts, xiii. 15. xiii. 27. These fections were divided into verses, called by the Jews "Pefukim," and they are marked out in the Hebrew Bible by two great points at the end of them, called from hence "Soph-Pafuk," i.e. the end of the verse. This di\inion, if not made by Ezra, is very ancient; for when the Chaldee came into use in the room of the Hebrew language, after the return of the Jews from their captivity in Babylon, the Law was read to the people first in the Hebrew language, and then rendered by an interpreter into the Chaldee language; and this was done period by period. To distinguish these periods was an object of importance; and hence arose the division into verses, which was first applied to the Law, and afterwards to the Prophets and Hagiographa. The manner by which these divisions, or verses, are now distinguished is by the "Soph-Pafuk?" but it is not certain that this was the ancient method. Puddeus apprehends, that the Pefukim, or verses of the Hebrew Bibles, were anciently di\ivided in the same manner as the "Stichii" afterwards were in the Greek Bibles. The manner of their writing thefe flich at first was to allow a line to every flichus, and there to end the writing, where they ended the flichus, leaving the ref of the line a void break. But this mode occasioning a waste of parchment, on which their books were written, and making their bulk too heavy; in order to avoid thefe inconveniences, they afterwards put a point at the end of every flichus, and continued the writing without leaving any blank. In the Hebrew Bibles they adopted the fame mode, and put the two points, called "Soph-Pafuk," at the place where one verse ended, and continued the writing of the next verse in the fame line, without leaving any void space. The division of the holy Scriptures into chapters is of a much later date. The Psalms, indeed, appear to have been always divided as they are at present. Acts, xiii. 33. But as to the reft of the Bible, the prefent division into chapters was unknown to the ancients. See Chapter and Concordance.

Besides those books which were received into the canons of the books of the Old Testament, and those that have been deemed apocryphal, there are feveral others which are cited in the Old, and also in the New Testament, which seem either to have been lo\ved, or excluded by Ezra from his canon. Of fuch books are the books "of the wars of the Lord," cited Numb. xxi. 4. but it does not appear that in this place any book is mentioned, "of the Covenant," of which it is faid mention is made Exod. xxiv. 7, but evidently referring to the laws received by Moses from the hand of God, related in the preceding chapters; the "book of the Lord," mentioned H. xxxiv. 16. which does not feem to be any particular book; the "book of Jasher, or the upright," cited in Jotha, x. 13. and 2 Sam. 1. 18. supposed by fome to be an historical book, but more probably containing of hymns and songs; and the "books of Nathan (1 Chron. xxix. 20. 2 Chron. ix. 29.) of Gad, (1 Chron. xxix. 29.) of Shemaiah, (2 Chron. xii. 15.) of Ithda, (2 Chron. xix. 15. xii. 22.) of Abijah, (2 Chron. ix. 29.) and of Jehu, (2 Chron. xx. 34.), which were memoirs compiled by thofe prophets, or rather prophecies, which contained a part of the history. The fame may be faid of the book of the "Journals or Chronicles" of the kings of Judah or of Israel; which are different from the Paralipomena, or Chronicles; the book of "Samuel the Seer," cited in the last chapter of the firft book of Chronicles; the diffcours of Hoftiah, cited 2 Chron. xxxiii. 18. 19. the "Acts of Uzziah," mentioned 2 Chron. xxvi. 22. the "three thousand and Proverbs, written by Solomon," (see 1 Kings, iv. 32.); a thousand and five Songs, &c. composed by the fame author, and mentioned in the fame place. Jeremiah speaks of a volume of prophecies which he had dictated to Baruch, suppo\sed by fome to be the Lamentations. (See Baruch.)

Besides these books that are lo\ved, there are others, not included in the canon of the Old Testament, which are till extant; fuch as the "Prayer of king Manafleth, when captive at Babylon," cited 2 Chron. ch. xxxiii. "the third and fourth books of Efras," "the third and fourth books of the Maccabees," "the genealogy of Job," and "a speech of Job's wife," annexed to the Greek edition of the book of Job; "a Psalm," added to the Greek edition of the Psalms; the book of "Ezechias," not entire, cited by feveral of the fathers, and regarded by them as apocryphal, and referred to by Jude, v. 14. the book of the "Assumption of Moses," and his "Testament," placed by St. Athanasius among apocryphal books; the "Assumption, Apocalypfe, or Secrets of Elijah," cited by Origen; and a number of others forged by the Jews, and fathered on the Patriarchs. See New Testament.

It may not be improper to refer, in one view, the books of the Old and New Testaments to their proper authors. We may suppose them, without ascribing to the region of conjecture, and tracing the origin of any books, or parts of books of the Bible to patriarchal times, that the Pentateuch conftits of the writings of Moses, put together, perhaps, by Samuel, with a few additions; that the books of Joshua and Judges were, in like manner, collected by him; and the book of Ruth, with the first part of the firft book of Samuel, written by him; that the latter part of the firft book of Samuel, and the second book, were written by the prophets who succeeded Samuel, viz. Nathan and Gad; that the books of Kings and Chronicles are extracts from the records of the succeeding prophets, concerning their own times, and from the public genealogical tables, made by Ezra; that the books of Ezra and Nehemiah are collections of like records, some written by Ezra and Nehemiah, and some by their predecessors; that the book of Ezechias was written by some eminent Jew, in or near the times of the transactions there recorded, perhaps Mordecai; the book of Job by Mofes, or a Jew of an uncertain period; the Psalms by David, and other pious owners; the books of Proverbs and Canticles by Solomon; the book of Ecclefeiastes by Solomon, or perhaps by a Jew of later times, speaking in his person, but not with an intention to make him pafs for the author; the Prophecies by the prophets, whose names they bear; and the books of the New Testament by the persons to whom they are ufually a\cribed. See New Testament. There are many internal evidences, and in the eafe of the New Testament, many external evidences also, by which these books may be known to belong to the authors here named. Or, if there be any doubts, they are merely of a critical nature, and do not at all affect the genuinenefs of the books, or not alter, at leaft materially, the arguments that may be adduced in favour of their authenticity and authority. It is readily allowed, that objections have been made to the alleged authors of several of these books. Abenazer, followed by Hobbes, Pereira, Spinosa, and some others, deny the firft five books to have been written by Mofes. F. Simou, in particular, afferts, that the books, as we now have them, are not the original\ls written by the inspired penmen, but abridgments of them, made in after\times by a kind of college, or order of public authours, or scriber,
B I B L E.

scriber, appointed for that purpose. See Pentateuch, and each of the books of the Bible, under its proper title. See also New Testament.

The original language of the Old Testament was, without doubt, the old Hebrew, at least the greatest part of it; for all the books do not appear to have been written in the same language. Some chapters of Ezra and Daniel, (see Ezra and Daniel,) are judged to have been composed in Chaldee; and it has been supposed, that other chapters of this latter writer, and also the apocryphal books of Maccabees, &c. were written in Greek. Tobit and Ecclesiasticus, either in Greek or Syriac. As for the New Testament, it was written in Greek, except the Gospel of St. Matthew, which is thought by some to have been composed in Hebrew. Some few have thought that the Gospel of St. Mark was written in Latin, and also the epistle to the Hebrews. See the Title of each Book, and Testament.

With regard to the style of the several writers of the Old and New Testament, there is a very considerable diversity. The style of Paul may be easily distinguished by its peculiarity from that of any other writer. A discriminating reader will not easily confound the style of Luke with that of either of the evangelists, who preceded him, Matthew, or Mark, nor would he be in any danger of mistaking the apostle John's diction for that of any other penman of the New Testament. The same difference of style will be discovered by one who is but moderately conversant with the Hebrew, in the writers of the Old Testament. In this we have a greater variety than in the New. Some of the books are written in prose, and some in verse; and in each the differences between one book and another are considerable. In the book of Job, for instance, the character of the style is remarkably peculiar. What can be more dissimilar in this respect, than both are excellent in their kind, than the towering flights of the sublime, and the plaintive strains of the pathetic Jeremiah? In several books of Scripture we can specify the concise style and the copious, the elevated and the simple, the apophasise and the diffusus. This diversity in the diction of the several penmen is perfectly reconcileable with the idea of their inspiration; and in speaking on this subject, we should duly attend to the difference between the expression and the sentiment, and avoid confounding the two, as if they were the same, whereas they are widely different. The truths implied in the sentiments are essential, immutable, and have intrinsic value; the words which compose the expression are in their nature circumstantial, changeable, and have no other value than what they derive from the arbitrary conventions of men. That the Holy Spirit would guide the minds of the sacred penmen in such a manner as to prevent their adopting terms inimicable to his design, or which might obstruct his purposes; and that in other respects he would accommodate himself to their manner and diction, is both reasonable in itself, and required for the manner of expressing themselves, which have the like characteristic differences of style, which we find in other compositions. Can it be accounted more strange that the Holy Spirit should, by the prophet Amos, address us in the style of a shepherd, and by David, in that of a warrior, that by the one he should speak to us in Hebrew, and by the other in Chaldee? It is as reasonable to think that the Spirit of God would accommodate himself to the peculiarity and diction, to the tenor of voice and pronunciation of those whom he was pleased to enlighten; for it cannot be denied, that the pronunciation of one person in uttering a passage, might be more articulate, more audible, and more affecting than that of another; and in like manner, as one style has more harmony, elocution, and perspicuity than another. Caius thinks justly, (Def. cont. Beza.)

"Res dictat Spiritus, verba quidem et lingiam loquenti aut scribere liberam permittit; i.e. the Spirit dictates the things, leaving the words or language free to the speaker or writer. Jerom also observed a thousand years before, (Comment. in Epist. ad Gal. cap. 1.) "Nee putamus in verbis Scripturarum evangelium esse, fed in fendo;" i.e. let us not imagine that the Gospel conflicts in the words of Scripture, but in the sense. To the same purpose is the observation of the ingenious and learned bishop Lowth, De Saera Poeh, H. B. Pref. xvi.) "Hoc ita facens variabilis studia, ut nihil derogetum Divini Spiritus usitatum, et hisue interea sum pro-prise ejusque Scriptus,itatione naturae atque ingenio concedamus: nec ex eo nonnulla divina in concitator variis animis, ut praecario obvius humiles indoles; attestantur et exigui, non exiguuntur aut occultantur naturae praecario faciuntis; et quamquam Mosis, Davidis, et Iaiae, scripta eorum praecario quidam tam exsauum tamque elocuto, ut plane videantur divinissima edita, nihil tamen minus in us Molon, Dauidem, Hianam, spectaculo aemulatissimam; i.e. we shall dart nothing from the dignity of that inspiration, which proceeds from higher causes, while we allow to the genius of each writer his own peculiar excellence and accompaniments. The Divine Spirit by no means takes such an entire possession of the mind of the prophet as to subdue or extinguish the character and genius of the man; the natural powers of the mind are in general elevated and refined; they are neither eradicated, nor totally obscured; and though the writings of Moses, of David, and of Isaiah, always bear the marks of a divine and celestial impulse, we may neverthelesse plainly discover in them the particular characters of their respective authors. See Inspiration.

It must be allowed, that many circumstances do not render the style both of the New Testament and of the Old; of the historical books, as well as of the prophetical and argumentative, generally obscure, and often ambiguous; although we ought not to admit the exaggerated representation of father Simon, (Hist. Crit. des V. T. liv. iii. c. 2.) with regard to the greater part of the Hebrew words, which, he says, are equivocal, and of course their signification altogether uncertain. The origin of this kind of statement must be sought in the author's attachment to tradition, rather than to that kind of scepticism with which he is charmed by Bezaet, bishop of Meaux, and which tended to undermine Christianity itself. To any person who duly reflects, this father's representation must appear to be unfounded, or beyond all bounds hyperbolical. It is not just in its reference to the prophetical writings; and as to the historical books, they are, in general, remarkable for perspicuity. The fault quality by which the facred history is distinguished is simplicity, which arises from this property of the Hebrew language, the verbs of which have not, like Greek and Latin, a variety of moods and tenses, nor do they abound, like the modern languages, in auxiliaries and conjunctions. This quality very much conduces to the perspicuity of its style. In this simplicity we have an example of the first paragraph of Genesis, consisting of five, not long, verses, and containing not fewer than eleven sentences, which are figurally simple; the substantives not being attended by adjectives, nor the verbs by adverbs, without synonyms, or superlatives, or any effort towards expressing things in a bold, emphatical, or uncommon manner. In the Pentateuch, there is also a simplicity of sentiment, arising from the very nature of the early and uncultivated state of society, about which its books are conversant, and this renders the narrative, in general, extremely clear and engaging. Besides the simplicity of structure, and the simplicity of sentiment, there is another species of simplicity, for which Scripture history is more remarkable than any other.
other compositions of any language. This may be denominated simplicity of design. The subject of the narrative often engrosses the attention of the writer, that he disappears, as it were, from the view of the reader. He introduces nothing as from himself; no opinions of his own, no remarks, conjectures, doubts, or inferences; no reasoning about the cause or the effects of what is related. He never interrupts his reader with the display, either of his talents or his passions: he makes no digressions; he draws no characters: he supplies us merely with naked facts, from which we are left to collect the character. We observe no attempt to shine by means of the expression, composition, or sentiments. Plainness of language is always preferred, because it is the most natural, the most obvious, and the best adapted to all capacities. In this last fort of singularity, for which Xenophon among the Greeks, and Cæsar among the Latins, have been recommended, our Lord's biographers particularly excelled. With respect to the first species of simplicity, or that of nature, the difference of the genius of the Greek language from that of the Hebrew must, without doubt, occasion some difference in the manner of Matthew, Mark, Luke, and John, from that of Moses: but the identity of idiom still occasions a strong resemblance between them. If genius, therefore, may be justly said to poise the first rank for simplicity of composition in the sentiments, the Gospels are certainly entitled to the second: and John and Matthew have it in a higher degree than Mark and Luke. As to the second species, or simplicity of sentiment, the change of times, which is very great, as well as the difference of subjects, would necessarily confer the first degree of it upon the former. But in simplicity of object or design, the evangelists, of all writers, sacred and profane, appear the foremost. Their manner is indeed, in some respects, peculiar and unrivalled. We direct our attention from the historical, or narrative parts of the Bible, to the writings of the poets and prophets, we shall discover the animated, elegant, and sublime intermixed, as the subjects afford, and the occasions require, with the simple and perspicuous. But for other particulars, in reference to this subject, see Style and Testament. See also the titles of the several books of the Bible, for the distinguishing character of their writers.

Having considered the appellations by which the Bible is distinguished, the books of which it consists, the time, and manner in which they were collected, their respective authors, and the language and style in which they were written, it may not be improper to subjoin a few observations on the genuineness of the authenticitv of the Scriptures, on their high original and divine authority, and on their great importance and utility.

It should here be considered, that the genuineness of the Scriptures proves the truth of the principal facts contained in them; to which purpose we may observe, that it is very rare to meet with any genuine writings of the historical kind, in which the principal facts are not true, unless it be in instances where both the motives which engaged the author to falsify, and the circumstances which gave some plausibility to the fiction, are apparent; neither of which can be alleged in the present case with any colour of reason. As this is rare in general, it is more rare, when the writer treats of things that happened in his own time, and under his own cognizance and direction, and communicates his history to persons under the same circumstances; all which may be said of the writers of the Scripture history. Besides, the great importance of the facts mentioned in the Scriptures makes it more improbable, that the several authors should either have attempted to falsify, or have succeeded in such an attempt. This is an argument for the truth of the facts, which proves the genuineness of the books at the same time. However, the truth of the facts is inferred more directly from their importance, if the genuineness of the Scriptures be previously allowed. The same observation may be applied to the great number of particular circumstances of time, place, persons, &c. mentioned in the Scriptures, and to the harmony of the books with themselves, and with each other. These are arguments both for the genuineness of the books, and truth of the facts distinctly considered, and also arguments for deducing the truth from the genuineness. Moreover, if the books of the Old and New Testaments were written by the persons to whom they have been ascribed, i. e. if they be genuine, the moral characters of these writers afford the strongest assurance, that the facts ascribed by them are true. The sufferings which several of the writers underwent both in life and in death, in attestation of the facts delivered by them, furnish a particular argument in favour of these facts. Again, the arguments here alleged for proving the truth of the Scripture history from the genuineness of the books, are as conclusive in respect of the miraculous facts, as of the common ones. It may also be observed, that if we allow the genuineness of the books to be a sufficient evidence of the common facts which they record, the miraculous facts must also be allowed, from their close connection with the others. It is necessary to admit both or neither. We cannot conceive, that Moses should have delivered the Thracites from their slavery in Egypt, or conducted them through the wilderness for forty years, at all, in such manner as the common history represents, unless we suppose the miraculous facts intermixed with it to be true also. In like manner, the fame of Chrift's miracles, the multitudes which followed him, the adherence of his disciples, the jealousy and hatred of the chief priests, scribes and pharisees, with many other facts of a common nature, are impossible to be accounted for, unless we allow, that he did really work miracles. And the same observations hold, in general, of the other parts of the Scripture history. We might urge a particular argument in favour of the miraculous part of the Scripture history, that may be deduced from the reluctance of mankind to receive miraculous facts; which would put the writers and readers very much upon their guard, and would operate as a strong check upon the publication of a miraculous history at or near the time when the miracles were said to be performed; and thus would serve as a strong confirmation of such an history, if its genuineness be previously granted. The converse of the proposition, now stated and explained, is also true: i. e. if the principal facts mentioned in the Scriptures be true, they must be genuine writings. In connection with the preceding proposition we may observe, that the genuineness of the Scriptures proves their divine authority. Porphry in effect acknowledges the truth of this proposition, in its reference to the book of Daniel, by being unable to devise a method of invalidating its divine authority implied in the accomplishment of the prophecies which it contains, without affecting, that they were written after the event, or that they were forgeries. Many of the other books of the O. and N. Testaments have unquestionable evidences of the divine foreknowledge, if they be allowed genuine: such are thofe supplied by Moses to the fHOW we delivered; Joshua's concerning Cyrus; Jeremiah's concerning the duration of the Babylonish captivity; Chrift's concerning the destruction of Jerusalem, and the captivity, which was to follow; St. John's concerning the great corruption of the Chriftian church; and Daniel's concerning the fourth empire in its declension; which left was extant in the time of Porphyry, at least, that is, before the events which
it represents. The truth of the proposition might also be argued from the possibility and excellence of the doctrines contained in the Scriptures; in no respect fusing the supposed authors, or the ages in which they lived, their education or occupation; so that, if they were the real authors, we are under the necessity of admitting the divine authority. The converse of this proposition is, that the divine authority of the Scriptures inheres in their genuineness, will be readily and universally accepted, and. And there are several evidences for the Divine authority of the Scriptures, which are direct and immediate, and prior to the consideration both of their genuineness, and of the truth of the facts contained in them. Moreover, the truth of the principal facts contained in the Scriptures prove their divine authority. Such is the frame of the human mind, that the Scripture history, allowed to be true, must convince us that Christ, the prophets, and the apostles, were endowed with a power greater than human, and acted by the authority of a Being of the highest wisdom and goodness, but if natural religion be previously established, the truth of the principal facts of the Scriptures prove their divine authority, in a more easy and more convincing manner; for the knowledge and power manifested by Christ, the prophet, and apostles, and also their moral characters, shew them to be in an eminent manner the children, servants, and messengers of him, who is previously acknowledged to be infinite in power, wisdom, and goodness; and they actually lay claim to a divine mission, which claim cannot be thought a lie, if it were their credentials: or, in other words, the truth of the principal facts mentioned in the Scriptures proves the divine mission of Christ, the prophets, and apostles, that is, the divine authority of the Scriptures.

By such mode of arguing it is found, that the genuine facts of the Scripture, the truth of the principal facts contained in them, and their divine authority, appear to be so connected with each other, that any one being established upon independent premises, the other two may be inferred from it. On the subject of the inspiration of the Scriptures, see Inspiration.

Another argument of proof of the genuineness of the books of the Old and New Testaments, and of the truth of the principal facts contained in them, may be deduced from the manner in which they have been transmitted down from age to age to another; especially that, in which all other genuine books have been preserved, without any mixture of spurious

As a sequel of the Greek and Roman writers were accustomed to take this statement to be true, transmitted it to them by their authors in a continued succession, from the times when the inspiration of authors lived, to have the books of the Old Testament, by the Jewish nation, and title of the New by the Christians; and it a authentic evidence in the full sense, that the genuine Christians were not a distinct nation, but a very mixture of people, throughout the whole nation, and the Roman empire, and even extending itself beyond the bounds of that empire. As the Greeks and Romans always believed the principal facts of the historical books, so the Jews and Christians, and hence we have the evidence of all ages of the permanence of the text of any part of the scripture from, what can be considered as the modified state of many parts of the Old Testament, without being bound for the Jewish and Christian. Now, a well-learned performer at the titles of the Hebrew books, as the Jews, and Christians, and hence we have the evidence of all ages of the permanence of the text of any part of the scripture from the Greek and Roman ages, as we recognize those to the modified state of many parts of the Old Testament, without being bound for the Jewish and Christian.

New, with it a liberal performer at the books of the Hebrew, and the Greek and Roman books, philosophers, etc., to be given, and the principal fact preserved or abdead to them to take time, and that one chief evidence of the great truth, the history of the times, not to be read, they neglect, therefore, to pay the same regard to the books of the Old and New Testaments, since there are the same or greater reasons for it. Besides, these traditional evidences are sufficient, and we thus obtain a real argument, as well as one "ad hominem," for receiving books this handed down to us. For it is not conceivable, that whole nations should either be imposed upon themselves, or concur to deceive others, by forgeries of books or of facts. These books and facts must, therefore, in general, be genuine and true; and it is a strong additional evidence of this, that all nations must be jealous of forgeries for the same reasons that we are. On the conclusiveness of this argument, as it relates to miracles; see MIRACLES.

We may proceed to observe further, that the great importance of the histories, precepts, promises, threatenings, and prophecies contained in the Scriptures, are evidences both of their genuineness, and of the truth of the principal facts mentioned in them. The history of the creation, fall, deluge, longevity of the patriarchs, dispersion of mankind, calling of Abraham, descent of Jacob with his family into Egypt, and the precepts of abstinence from blood, and of circumcision, were of such concern, either to mankind in general, or to the Israelites in particular, and some of them of so extraordinary a nature, as that it could not be a matter of indifference to the people amongst whom the account given of them in Genesis was first published, whether they received them or not. On the supposition that this account was first published amongst the Israelites by Moses, and then continued by clear, universal, uninterrupted tradition, it will be easy to conceive, how it should be handed down from age to age among the Jews, and received by them as indisputable. But supposing the account to be false, or that there were no such vestiges and evidences of these histories and precepts, it will be difficult to conceive, how this could have happened, let the time of publication be what it may. If early, the people would reject at once the account for want of a clear tradition; if late, it would be natural to enquire how the author was informed of things never known before to others. If the account was delivered, as having been communicated to Moses by divine revelation, which is not very consistent with the numerous references that occur in Genesis to the existing vestiges of the things related, his fictitious credulity would thus be embarrassed, and his contemporaries would be induced very particularly to examine them. As a number of commentaries and theopomies current among Pagans, which are occasionally quoted for arguments against the Mosaic history; because they were generally regarded merely as amusing fictions; and yet they concealed in figures, or expressed in plain words some truths, which agree with the book of Genesis, and afford a strong presumptive evidence in favour of this book. With respect to the law of Moses, this was extremely burdensome, expensive, and a very particular instance in its reference to the crime of idolatry, to which mankind were then extravagantly prone; and it was abhorred, according to human judgment, in the instance of prohibiting their furnishing themselves with harpies for war, and of condemning all the males of the whole nation to appear at Jerusalem three times a year. Nevertheless, it claims divine authority, and appeals to facts of the most notorious kind, and to emblems and ceremonies of the most peculiar nature, as the memorials of these facts. Can we then conceive, that any nation, with such motifs to rejoin, and such opportunities of detecting the forgeries of the book of Laws, Levities, Numbers, and Deuteronomy, could yet believe them, and fall upon the heavy yoke? That the Jews did not believe to the law of Moses, in these circumstances, is evident from the books of the Old and New Testaments, if we allow them the least truth and genuineness, even from profane writers, and from the present de-
fervance of it by the Jews scattered throughout all the kingdom of the world. Should it be said, that other nations have ascribed divine authority to their lawyers, and submitted to very severe laws, it may be alleged in reply, that the pretences of lawyers amongst the Pagans to inspiration, and the submission of the people, may be accounted for from their peculiar circumstances at the time, without recurring to real inspiration; and more especially, if we admit the patriarchal revelations related by Moses, and his own divine legislation, as heathen lawyers copied after these, and hence we derive a strong argument in their favour. Besides, no instance occurs among the Pagans, of a body of laws framed at once, and remaining unvariable; whereas the body politic of the Israelites assumed a complete form at once, and has preferred it with little variation, to the present time, and under many external disadvantages; thus supplying us with an instance altogether without parallel, and shewing the high opinion which they entertained of the great importance of their law. In short, of all the fictitious or forgeries, that can happen amongst any people, the most improbable is that of the Jewish body of civil laws, and it seems to be utterly impossible in the case of the law of Moses.

If we further examine the history contained in the books of Joshua, Judges, Ruth, Samuel, Kings, Chronicles, Ezra, and Nehemiah, and extending from the death of Moses to the re-establishment of the Jews after the Babylonian captivity by Ezra and Nehemiah, we shall find a variety of important facts, most of which must be supposed to have unhallowed themselves, either external and visible, or internal in the minds and memories of the people, as would verily them if true, or cause them to be rejected, if false. The conquest of the land of Canaan, the division of it, and the appointment of cities for the priests and Levites, Joshua; the fragmentary annals of the Israelites to the neighbouring kings, and their deliverance by the judges; the creation of a kingdom by Samuel; the translation of this kingdom from Saul's family to David, with his conquests; the glory of Solomon's kingdom; the building of the temple; the division of the kingdom; the idolatrous worship set up at Dan and Bethel; the captivity of the Israelites by the kings of Assyria; the captivity of the Jews by Nebuchadnezzar; the destruction of their temple; their return under Cyrus, rebuilding the temple under Darius Hystaspis, and re-establishment under Artaxerxes Longimanus, by Ezra and Nehemiah;—these events are some of them the most glorious, and some of them the most reproachful, that can happen to any people. How can we reconcile forgeries of such opposite kinds, and especially as they are interwoven together by various complicated and necessary connections, which do not admit of separation? The facts, indeed, are of such importance, notoriety, and permanency in their effects, that no particular persons among the Israelites could first project the design of deceiving them, that their own people would not concur with such a design, and that neighbouring nations would not permit the fiction to pass. Nothing but the invisible evidence of the facts, here alleged, could induce a jealous multitude amongst the Israelites or neighbouring nations to acquiesce. This must be acknowledged upon the supposition that the several books were published, or in the times when the facts that are recorded in them happened. But suppose all these historical books forged by Ezra—the hypothesis is evidently impossible. Things so important and notorious, so honourable and so reproachful to the people, for whose sake they were forged, would have been rejected with the utmost indignation, unless there were the strongest and most genuine traces of these things already amongst the people. They must therefore, in part at least, be true. If it be said that additions were made by Ezra; these additions must have been either of important or trivial matters. On the first supposition, the difficulty already stated recurs; and if the important facts are true, what possible motive could have induced Ezra to make additions of no importance? Besides, if any ancient writings were extant, Ezra must either copy from them, which destroys the present supposition; or differ from and oppose them, which would betray him. If there were no such ancient writings, the people would be led to enquire with regard to matters of importance, for what reason Ezra was so particular in things of which there was neither any memory, nor account in writing. Should it be said, that the people did not regard what Ezra had thus forged, this reduces the subject to question to matters of small, or of no importance. Besides, why should Ezra write, if no one would read, or regard? Further, Ezra must have had, like other men, friends, enemies, and rivals; and fame, or all of these, would have been a check upon him, and a security against him in matters of importance. If we suppose these books, instead of having been forged at once, to have been forged increasively, at the interval of one, two, or three centuries after the facts related, we shall involve ourselves in the same or similar difficulties. Upon the whole, then, we may conclude, that the forgery of the annals of the Israelites appears to be impossible, as well as that of the body of their civil laws. It is needless to examine the books of Esther, Job, the Psalms, Proverbs, Ecclesiastes, and Canticles; and we might proceed to the Prophecies. But this subject will be resumed under the article Prophecy. For the importance of the subjects comprehended in the books of the New Testament, see TESTAMENT, and Christianity.

We shall here subjoin some general evidences in attestation to the importance of the books of Scripture. That Jews and Christians have thought their sacred books very highly important, most genuine, and true, appears from the perfections and sufferings which they have undergone on account of their attachment to them, and because they would not be prevailed upon to surrender them. The preservation of the law of Moses, probably the first book written in any language, whilst many others of a later date have been lost, shews the great regard that has been paid to it; and from this circumstance we may infer, that this and the other books of the Old Testament have been preserved on account of their importance, or from some other cause, equally evincing their genuineness and truth. The great importance of these books appears also from the many early translations and paraphrases of them; and these translations and paraphrases seem to correct errors that are unavoidable in the lapse of time, and to secure their integrity and purity. The hesitation and difficulty with which some few books of the New Testament were received into the canon, shew the great care and concern of the primitive Christians about the canon, and the high importance of the books admitted into it; and afford a strong evidence of their genuineness and truth. The same observation is in a degree applicable to the Jewish canon. Moreover, the religious hatred and animosity which fulfilled between the Jews and Samaritans, and between several of the ancient sects among the Christians, convince us of what importance they all thought their sacred books, and disposed them to watch over one another with a jealous eye.

Further, the genuineness of the books of the Old and New Testaments may be evinced from the language, style, and manner of writing used in them. The Hebrew language, in which the Old Testament was written, being the language of an ancient people, who had little intercourse with their neighbours, would not change so fast as modern languages have
The agreement of the Scriptures with history, national, and civil, is a further proof of their genuineness and truth. The history of the fall agrees in an eminent manner both with the obvious facts of labour, sorrow, pain, and death, with what we feel and feel every day, and with all our philosophical enquiries into the frame of the human mind, the nature of social life, and the origin of evil. National history bears a strong testimony to Moses' account of the deluge. Civil history affords many evi- dences, which corroborate the same account. (See Deluge.) The Mosaic account of the confusion of languages, of the dispersion of Noah's sons, and of the state of religion in the ancient post-deluvian world, is not only rendered probable, but in a very high degree established, by many collateral arguments. See Contusion of Languages, Dispersion of Mankind, Inology, Sacrifice, &c.

The agreement of the books of the Old and New Testaments, with themselves and with each other, affords an argument both of their genuineness and truth. The laws of the Hebrews are contained in the Pentateuch, and referred to, in a great variety of ways, direct and indirect, in the historical books, in the Psalms, and in the Prophecies. The historical facts also in the preceding books are often referred to in those that succeed, and in the Psalms and Prophecies. In like manner, the gospels have the greatest harmony with each other, and the epistles of St. Paul with the Acts of the Apostles, and, indeed, there is scarcely any book of either the Old or New Testament, which may not be shown to refer to many of the red, the blue, or the other. For the illustration of this argument, let us suppose that no more recorded of the Roman writers than Livy, Tully, and Horace, would they not by their references to the same facts and customs, by the names of style in the same writer, and difference in the different ones, and numberless other such like circumstances of critical consideration, prove themselves, and one another to be genuine, and the principal facts related, or alluded to, to be true? Whoever will apply this reasoning to the present case will perceive, that the numberless minute, direct, and indirect agreements and coincidences, that present themselves to all diligent readers of the Scriptures, prove their truth and genuineness beyond all contradiction. See Acts, Epistles, and Testament.

The harmony and agreement of the several writers of the Old and New Testament appear the more remarkable, when it is considered that their various parts were penned by several hands in very different conditions of life, from the throne and sceptre down to the lowest degree, and in very distant ages, through a long interval of time; which would naturally have led a spirit of imposture to have varied its schemes, and to have adapted them to different stations in the world, and to the different vicissitudes of every age. David wrote about 400 years after Moses, and Isaiah about 250 after David, and Matthew more than 700 years after Isaiah. And yet these authors, with all the other prophets and apostles, write in perfect harmony, confirming the authority of their predecessors, labours to reduce the people to the observance of their instructions, and loudly exclaiming against the neglect and contempt of them, and denouncing the severest judgments against such as continued disobedient. Conclusively, as the writers of the Holy Scriptures, though they all claim a divine authority, yet write in perfect concordance and harmony, mutually confirming the doctrine and testimony of each other, and congeniality to establish the very same religious truths and principles, it is a strong proof that they all derived their inspirations from the same fountain, the wisdom of God, and were indeed under the direction and illumination of the same spirit. This leads us to add, that the unity of design, which appears in the dispositions recorded in the Scriptures, is an argument not only of their truth and genuineness, but also of their divine authority.

In order to perceive the force of this argument, it is only necessary to inquire what this design is, and how it is pursued by the series of events and divine interpositions, recorded in the Scriptures. (See Dispersion.) We may further add, that divine communications, miracles, and prophecies, recorded in Scripture, are agreeable to natural religion, and even seem to be necessary in the infancy of the world. (See Miracles, Prophecy, and Revelation.) It should also be considered, that the historical evidences in favour of the genuineness, truth, and divine authority of the Scriptures, do not become less from age to age; but, on the contrary, it may rather be presumed, that they increase. Since the three great concursing events of printing, the reformation of religion in the western parts, and the restoration of letters, so many more evidences and coincidences have been discovered in favour of the Jewish and Christian histories, as may serve, in some measure, to supply the want of th
B I B L E.

...those that have been lost in the preceding times; and as this improvement of the historical evidences is likely to continue, there is great reason to hope, that they will grow every day more and more irresistible to all candid, serious inquirers.

The moral characters of Christ, the prophets, and the apostles, prove the truth and divine authority of the Scriptures. The characters of the persons who are said in the Scriptures to have had divine communications, and a divine mission, are so much superior to the characters that occur in common life, that we can scarcely account for the more eminent figure of one, and much less for so large a succession of them, continued through so many ages, without allowing the divine communications and assistance, which they allege. Notwithstanding confidable imperfections that pertained to many of these eminent persons, and the heinous occasional offences chargeable upon some of them, yet the impartial reader should consider, whether the prophets, apostles, &c. were not so much superior, not only to mankind in an average, but even to the best men among the Greeks and Romans, as is not fairly to be accounted for by the mere powers of human nature.

If this statement should be disputed, their characters, however, are too good to allow the imputation of an impious fraud and imposture, which must have been the case if they had not divine authority. Besides, it should be recollected, that the undoubted and impartial manner in which the imperfections and faults of the eminent persons mentioned in Scripture are related, furnishes a remarkable additional evidence for the truth of such parts of the Scripture history in which such relations occur, besides such evidences as extend to the whole.

The excellence of the doctrine contained in the Scriptures is an additional evidence of their authority. This argument has great force independently of all other considerations. Suppose, for instance, that the author of the gospel, which goes under the name of St. Matthew, was not known, and that it was unsupported by the writers of the primitive times; yet such are the unaffected simplicity of the narratives, the purity of the doctrine, and the sincere piety and goodness of the sentiments, that it carries its own authority with it. The same observation is applicable in general to all the books of the Old and New Testaments; so that if there was no other book in the world besides the Bible, a man could not reasonably doubt of the truth of revealed religion. If all other arguments were set aside, we may conclude from this simple consideration, that the authors of the books of the Old and New Testaments, whoever they were, cannot have made a false claim to divine authority. The Scriptures contain doctrines concerning God, Providence, a future state, the duty of man, &c. far more pure and sublime than can in any way be accounted for from the natural powers of men, so circumstanced as the sacred writers were. Let the reader consider whether it can be reasonably supposed, that Jewish shepherds, fishermen, &c. should, both before and after the rise of the heathen philosophy, so far exceed men of the greatest abilities and accomplishments in other nations, by any other means than divine communications. Indeed, no writers, from the invention of letters to the present times, are equal to the penmen of the books of the Old and New Testaments in true excellence, utility, and dignity; and this is fairly such an internal criterion of their divine authority, as ought not to be refuted.

The many and great advantages which have accrued to the world from the Patriarchal, Judahical, and Christian revelations, prove the divine authority of the Scriptures. These advantages relate partly to the knowledge, and partly to the practice of religion. The internal worth and excellence of the Scriptures, as containing the best principles of knowledge, holiness, conversion and hope, and their consequent utility and importance in a moral and practical view, fully and directly demonstrate their divine original. The wonderful nature, and superior excellence, of the attempt made by Christ and his apostles, for reforming mankind, and making them happy in a future state, are evidences of their divine authority; which is further illustrated and confirmed by the manner in which the love of God and of our neighbour is taught and inculcated in the Scriptures. This may also be inferred from the doctrine of the necessary subordainment of pain to pleasure, and from the mutual instrumentality of beings to the happiness and misery of each other, unfolded in the Scriptures. The divine authority of the Scriptures may be further deduced from the superior wisdom of the Jewish laws, considered in a political light, and from the exquisite workmanship manifested in the tabernacle and the temple. The time and manner in which the Scriptures were written and delivered to the world, furnish arguments for their divine authority; nor is the want of universality in the publication of revealed religion any just objection to it. The exclusion of all great degrees of enthusiasm and imposture from the characters of Christ, the prophets, and apostles, prove their divine authority; and it may be also inferred, from the reception which Christ, his followers, and their descendents, have met with in all ages. See these arguments stated, illustrated, and applied at large in Hartley's Observations on Man, p. 350—411. See also on the subject of this article, Prideaux's Conn. vol. ii. 475, 497, 840. Dupin'sHist. of the Canons, ch. i. and ii. Kennicott's slate of the printed Hebrew text of the Old Testament, diff. ii. p. 295, &c. and Dacier's General Index, annexed to the second volume of his Hebrew Bible. Taylor's Scheme of Scripture Divinity, ch. 39. ch. 42.

The Jews, at first, were very reverent in communicating their Scriptures to strangers; despising and hating the Gentiles, they would not confide to them any of the treasuries concealed in the Bible. We may add, that the people bordering on the Jews, as the Egyptians, Phcenicians, Arabs, &c. were not very curious to know the laws or history of a people, whom in their turn they hated and despised. Their first acquaintance with these books was not till after the several captivities of the Jews, when the singularity of the Hebrew laws and ceremonies induced several to define a more particular knowledge of them. Jophesus (Contr. Apion, p. 1033.) seems surpris'd to find such flight footsteps of the Scripture history interposed in the Egyptian, Chaldean, Phcenician, and Grecian histories; and accounts for it from this circumstance, that the sacred books were not as yet translated into Greek, or other languages, and consequently not known to the writers of those nations. The first version of the Bible was that of the LXX. into Greek, in the time of Ptolemy Philadelphus, about 280 years before Christ; though some maintain that the whole was not then translated, but only the Pentateuch; between which and the other books in the version of the LXX. critics find a great diversity in point of style and expression, as well as of accuracy. See Septuagint.

Various kinds of books have been composed on the Bible, either to explain the sense, or make its doctrine more obvious, to facilitate the remembrance of it, or to emblesh particular opinions from it; such as Introductions, Appendices, Summaries, Manuals, Histories, Expositions, Commentaries, Harmonies, &c. Bibles are distinguished, according to their language, into Hebrew, Greek, Latin, Chaldean, Syriac, Arabic, Coptic, &c.; some account of each, and their several editions, &c. we shall here subjoin.

**Bibles**,
The Hebrew, or Talmudic, is either manuscript or printed. The print is less exact, but more common. The two kinds are easily distinguished from each other; the former being in beautiful characters, like the Hebrew Bibles of Bomberg, Stephens, and Plantin; the latter in characters, like those of Munder, and Grafton. F. Simon observes, that the oldest manuscript Hebrew Bibles are not above six or seven hundred years old; nor does rabbi Menahem, who quotes a vast number of them, pretend that any of them exceed six hundred years.

Dr. Kennicott, in his Dissertatio Generalis, annexed to his Hebrew Bible, p. 21, observes, that the most ancient MSS. were written between the years 900 and 1100; but though those that are the most ancient are not more than 800 or 900 years old, they were transferred from others of a much more ancient date. The MSS. preferred in the Bodleian library is no less than 800 years old. Another MS. not less ancient, is preserved in the Casaree library at Vienna. The same learned writer informs us, that almost all the Hebrew MSS. of the Old Testament, which are known at present, were written between the years 1000 and 1457; and hence infers, that all the MSS. written before the year 700 or 800, were destroyed by some decree of the Jewish senate, on account of their many differences from the copies then declared genuine. This circumstance is also alleged by Walton (Pr. Legomena, 4, 8.), as the reason why we have so few copies of the age of 500 years, and why even the copies of 700 or 800 years are very rare.

The Hebrew distinctions and denominations of the various parts of the Hebrew Bible, as they occur in the titles of the ancient MSS. will be easily understood by the following table of distribution.

Dr. Kennicott, by the industry of his research, has formed a catalogue of the titles and places of above 440 different MSS. of the whole, or of parts of the Hebrew Bible: a number about three times as great as that of the Greek MSS. of the New Testament, which have been collected at a vast expense, and collated with a truly laudable zeal. (See Testament.) Of these MSS. 54 are preferred in the Bodleian library at Oxford, and 15 in different colleges of the university; 4 are reprinted in the public library at Cambridge; and 3 in different colleges; 27 are found in the British Museum; one in the Lambeth library; and one in the library of the Royal Society. The preceding MSS., with 7 copies of the Samaritan Pentateuch, amount to 112 copies, making 125 volume. Other MSS. copies are preferred at Nicaea, or Complutum in Spain, Alton in Swabia, Amsterdam, Arnholt-Defaum, Augsburg, Baden, Berlin, Berne, Bohemian, Bologna, Britz in Silesia, Cairo in Egypt, Cefena in Italy, Copenhagen, Dresden, Erford, Florence, Furt in Prussia, Glasgow, Halfe, Hamburg, Hanover, Heidelberg, Hiltal, Heile-Carl, Holba near Danemarck, Iena, Koninkgberg, Leipzig, Leydon, Lyons, Mechlin in Flander, Milan, Morzen, Nuremberg, Padua, Paris, Pekin, Rome, Schaffhausen in Swifterland, Stralsburgh, Toledo, Treviso near Venice, Turin, Vicence, Vienna, Ulm in Swabia, Upsal, Utrecht, Walhalla, Zerbli in Saxony, and Zurich. Besides these, there are others at Fex in Austria, Thebaldonica in Greece, and Confultipompe, Ethiopia, Malabar, and Conchin, at a small distance south of Grangone, where are about 4000 Jews, who have a synagogue, in which they are carefully kept, their records, engraved on copper plates, and where, it is said, they can hew their history from Nebuchadnezzar to the present time. See the sequel of this article.

The most ancient printed Hebrew Bibles are those published by the Jews of Italy, especially of Pefaro and Breffe. Those of Portugal, also, printed some parts of the Bible at Lisbon before their expulsion. This may be observed in the general, that the best Hebrew Bibles are those printed under the inspection of the Jews; there being to many mistakes to be observed, that it is feared possible for any other to succeed in it.

The first printed edition of the Hebrew Bible, or at least of that part of it, comprehending the prior prophets, was printed at Soncinam in 1486, according to Le Long (Bibl. Sacra); it contained also the posterior prophets, according to Wolius (Bib. Hebr. i. 397.); and it seems to have made a first or a second part to the next we shall mention, or Dr. Pellet's, which is generally the third. The edition presented by Dr. Pellet, in 1575, to the library of Exan college, being that of a third part of the Hebrew Bible, comprehending the Cethubim or Hagiographa, was printed at Naples in 1487. This whole edition was burst by the Jews, excepting this copy, which had the singular good fortune of escaping the flames. It is printed on vellum, in two folio volumes, and has many readings different from all the other printed copies, and contrary to the Mafora, which probably was one of the reasons for which the whole edition was destroyed. This edition is mentioned by Wolius in his "Bibliothea Hebrarum," as formerly belonging to Schreider of Gluckstadt. The antiquity of this edition is argued from its being printed on vellum, as was the case with the first printed books, and from its having variations in the text, which are not found in any later edition. The first edition of the whole Hebrew Bible was printed at Soncinam in 1488, and is mentioned by Le Long, who says that it was printed by Abraham, the son of Rabbi Ithain, or Chaim. Le Long and Wolius affirm, that they saw an Hebrew Bible in 8vo, printed at Brescia in 1494.

In the beginning of the 16th century, Dan. Bomberg printed several Hebrew Bibles in folio and quart., at Venice, most of which are esteemed both by the Jews and Christians: the first in 1518, (the dedication being dated in 1517,) which is the least exact, and generally goes by the name of Felix Pratensis, the person who revised it, and who, as Hoder says, (p. 461.) was "ext Ludo Monachus." This edition contains the Hebrew text, the targum, and the commentaries of several rabbins. It is not known from what particular MSS. the Hebrew text of this edition was taken; but it agrees most with very late MSS. and such as were corrected according to the Mafora. The editor, in his dedication to pope Leo, complains of the very corrupt state of the Hebrew MSS., and speaks of his having collated and corrected (probably by means of the Mafora) many MSS. which were used...
B I B L E.

In 1657, was published the London Polyglott, under the direction of the eminently learned Brian Walton, in which, however, the Hebrew text is printed Maforetically; almost an absolute agreement with the many former editions, and with the latest and worst MSS. Although the editor has shown clearly, that the Jewish transcribers have made many mistakes, and that the MSS. have many true readings, where the printed text is erroneous; and though he speaks (Proleg. 4. 12.) of having supplied some things which were not in the Venice or Basel editions, yet the only supplement which he has made is reëloring the two verbs in Joshua, which had been arbitrarily expunged by Maforetic authority. See Polyglott.

As to Hebrew Bibles in 4to that of R. Stephens, in 4 vols. Paris, 1539—1544, is esteemed for the beauty of the characters; but it is very incorrect. Plantin also printed several beautiful Hebrew Bibles at Antwerp; one in eight columns, with a preface by Ariamontanus, in 1571, which far exceeds the Complutensian in paper and print, and contents; this is called the Royal Bible, Biblia Regia, because it was printed at the expense of Philip II. of Spain; another at Geneva, in 1619; besides many more of different sizes, with and without points. Manasseh Ben Israel, a learned Portuguese Jew, published two editions of the Hebrew Bible at Amsterdam; the one in 4to. in 1635, who tells us in the preface, that he had altered a few letters; and where the most corrected copies differed, he took refuge in grammar rules and the Mafora; the other in 8vo. in 1632: the first has two columns, and for that reason is commodious for the reader. It is printed with points, in an elegant type, and has the Keri and Chetib in the margin. The 8vo. edition has vowel points and accents, and the marginal notes. In 1639, R. Jac. Lombroso published a new edition in 4to. at Venice, with small literal notes at the bottom of each page, where he explains the Hebrew words by Spanish words. This Bible is much esteemed by the Jews at Constantino-ple; in the text they have distinguished between words where the point kamets is to be read with a kames-lavaph, that is, by a, and not an a.

Of all the editions of the Hebrew Bible in 8vo. the most beautiful and correct are the two of Jo. Athias, a Jew of Amsterdam. The first, of 1661, is the Bible paper, which, notwithstanding its being corrected according to ancient MSS. is certainly so far as letters and words are concerned (agreeable only to the later, as the other printed copies were before it; but that of 1667 is the most exact. This was published by Leufden, who tells the reader, "Tibi damus Bibliam, impresa per Athianum, quibus correctiones numquam solam psekt." And yet, though the fun never saw of much implicit obedience paid to the Mafora before, the Rabbinists assure us, in their prefatory recommendation, that some whole words were here corrected "ex Mafora & a Maforeticis, qui fepem leges fecerunt." This supremely Maforetical edition appeared to their high mightinesses the States-general, so particular were the meritorious, that Athias, the typographer, was presented with a chain of gold, and a gold medal pendant. But it is somewhat extraordinary, that a Jew should thus be rewarded for an edition, in which Leufden (though a Christian) confesses, that he permitted the Latin contents, here added in the margin, to explain away some of the propheticies relating to the Messiah. Le Long, in loc.

Leufden's last edition of Athias was followed, in 1705, by Vander Hooght's very elegant edition. No corrections can be expected from this editor, who considered every letter in his book, howsoever it was introduced, as absolutely genuine, and maintained the Mafora to be infallible.
After Athias, three Hebrew proponents engaged in reading and publishing the Hebrew Bible; viz. Cladus, Jablonski, and Optilius. Cladus's edition was published at Frankfort in 1674, in 4to. At the bottom of the page it is the various readings of the former editions; but the reader does not appear to have been assisted by the poetical books; besides, as it was not published under his eye, many faults have crept in. That of David, edited by Jablonski in 1699, in 4to, at Berlin, is very learned as to letter and print; but, though the editor appears to have made use of the editions of Athias and Cladus, it seems, if it feared any thing different in the vars. of Domburg. For this man of eminent learning it was to lay the foundation for a reformation of the printed Hebrew text. This he has done in the preface, by making several excellent observations on the nature of the printed Hebrew MSS.; with the proper marks of their authenticity, and the great advantages to be derived from them. He has further shown, that the Jewish transcribers have committed many mistakes; that the Keri is various readings arising from the mistakes of transcribers; that the older MSS. have them in the text, but the later in the margin; and consequently, that the Masorah, which comprises the Keri in the margin, must be founded on the later copy; that one of the Hebrew MSS. at Berlin contains the words of various readings, and that the other old Hebrew MSS. have numerous differences from the printed text; and that these old MSS. have suffered many alterations from the late corrections of Masorah. He also states the publications of occurring, by due zeal and exertion, very ancient MSS. from such of the Jews as have been preserved in China, Ethiopia, Constantinople, Thessalonica, and other distant parts of the world. Jablonski is the first author, who, after announcing the actual existence of many various readings in the Hebrew MSS., has recommended both an accurate examination of those MSS. by known, and a diligent search after others, at present unknown, through the several quarters of the world. To him, therefore, belongs the honour of having planned the above scheme for correcting the various corruptions in the printed Hebrew text of the Old Testament; and yet not daring to praise what he recommends, he published the Hebrew text of the same, as it was adopted in his critically in Leiden's edition of 1697. His corrections have been collected almost entirely from the novel-points and success. The edition of Optilius was published in 4to, at Kiel, in 1709; the character is large and good, but the paper bad; it is done with a great deal of care; but the editor made use of no manuscript but those of the German libraries; neglecting the French edit., which is much more correct in all cases. Optilius copied from Leiden's Athias, though, he, like Jablonski, heeded the Massorah in his other places; but he did not add the Masorah, and he left only what was essential in his notes. He clearly states in his preface that he has copied from the Massorah as much as he could, and that he has simplified it. He printed the Psalms, last edited by him, in 1711: he has edited the Prophets, the Testament; and the Apocrypha, 4to, with the Massorah, with much industry. The book is notable for being the first Hebrew Bible, in 4to, that has been published, in 1776, the full value of the Hebrew Bible, in folio, entitled 

B I B L E.
entitled "Vetus Testamentum Hebraicum, cum variis Lectio-
nibus." The second volume, with the general disserta-
tion, was published in 1780. The text is that of Everard
Van der Hooght, in 1705, already mentioned, which is very
correctly printed, with the familiar Hebrew letters, remark-
ably sharp and well defined; differing from it only in the
dissipation of the poetical parts, which Dr. Kennicott has
printed in humilities, into which they naturally divide them-
selves; however, the words follow one another in the fame
order as they do in the edition of Van der Hooght; so that
any person may read those passages as prose, if he is so in-
clined; or may divide the humilities differently, according
to his own judgment. This edition is printed on an excel-
 lent size of paper. This edition is printed on an exquisitely
good paper, and emits the name, Dr. Kennicott, is exhibited in a column parallel with the Hebrew text; those parts of it only being intro-
duced, in which it differs from the Hebrew: and the rest of the Samaritan column being left blank, so that the eye
perceives at once, with the utmost ease, the variations of the
Hebrew and Samaritan texts. The numerous variations, both
of the Samaritan manuscripts from the printed copy of the Samaritan text, and of the Hebrew manuscripts from the
printed text of Vander Hooght, are placed separately at the bottom of the page, and marked with numbers referring
to the copies from which they are taken.

We shall subjoin to this article a breviate account of the life and
progress of that highly interesting and meritorious undertaking,
for the completion of which we are indebted to the indefatiga-
ble industry and perseverance of the late Dr. Kennicott. A very
general opinion seemed to have prevailed among learned men,
till about the middle of the last century, in favour of the
integrity of the Hebrew text; and Dr. Kennicott ingeniously
conceived, that he was misled by the common error. The Rabbins boldly asserted, and the Christians implicitly
believed, that the Hebrew text was free from error, and that
in all the MSS. of it, no instance of any various reading of
importance could be produced. The first person, who seems
to have combated this notion in the way of a regular attack,
was Ludovicius Capelius. From the differences he observed
between the Hebrew text and the version of the LXX. and
between the Hebrew pentateuch and the Samaritan penta-
tuch, from the palpable and manifest corruptions, which he
thought he saw in the text itself, and from the many reasons
which induced him to suppose that the vowel points and
the Masora were both a modern and an unfeles invention, he
was led to question the general integrity of the text; and
his enemies allowed, that in his attack upon it, he discovered
much learning and ingenuity. Still, however, he acquiesced
and admitted the uniformity of the MSS. But the matter
was not brought to the test of an actual collation of any
number of MSS. and versions, and little was done, till Dr.
Kennicott's attention was directed in 1748, by the late
learned Dr. Lowth, bishop of London, to an examination of
2 Sam. xxiii. 8. This circumstance convinced him of his
former error, and he was soon satisfied that the Hebrew
text was far from being perfect, and that it was impossible
to understand this single verse, without allowing that there
were in it four corruptions. Kennicott's explanation of this
verse having been approved by Dr. Lowth, he was requested
to examine the sublequent parts of the same chapter; which
was likewise performed, and the whole was published in 1753.
He proceeded to examine two parallel chapters in the first
book of Chronicles, and the second book of Samuel, and
found an omission in the former of no less than 34 Hebrew
words. Although such great corruptions were proved from the
printed text itself, and from the ancient versions, yet it
had not at that time been suspected, that there were now
extend any Hebrew MSS. which would at all affist in cor-
recting the faulty passages of the Old Testament. In the
sequel, however, this was found to be actually the case, for
Dr. Kennicott, on examining some of the Hebrew MSS.
in the Bodleian library, found that they contained, in the
chapters above cited, several of the readings which he had
recommended as genuine, before he had inspected those
MSS. A discovery so important to sacred literature being thus
begun in 1753, and extended to 70 Hebrew and Sama-
ritan MSS. in Oxford, it was soon much improved by con-
futing a number of others at Cambridge, and in London.
The inquiry was promoted by means of a catalogue of all
the other Hebrew and Samaritan MSS., which were then
known to exist in different parts of the world, published by
Dr. Kennicott in 1756, in a second dissertation on the Hebrew
text. In this work he endeavoured to produce a general
conviction, as to the certainty of the Hebrew printed
copies being much corrupted, and the great advantages to
be derived from MSS., by furnishing many various readings
of consequence, which are the true ones; and by confirming
the ancient version in a multitude of instances of little
moment in themselves, and therefore not likely to have
originated from design. It was also proved, that the Samaritan
Pentateuch was of great importance; that its MSS. would
serve to correct a variety of typographical errors, which
disgraced the two printed editions; and that the Samaritan
copies were frequently confirmed even by the Hebrew MSS.

In consequence of these interesting discoveries, Dr. Ken-
icott was solicited by the late archbishop Secker, and many
other learned persons, and by several societies of literary men,
particularly by the university of Oxford, to whose counte-
nance and encouragement the undertaking was recommended
by the late Dr. Hunt, professor of Hebrew and Arabic in
that university, to undertake a collation of all the Hebrew
and Samaritan MSS. in our own country. Discouraged at
first by the prospect of so arduous an undertaking, he at last,
in 1760, contended to engage in it. Of his progress, and the
circumstances that attended it, we have a detailed account
in the "Dissertatio Generalis," published with the second
volume of his Bible. Having proposed ten years as the
time which, he thought, would be necessary for collating the
Hebrew and Samaritan MSS., he was enabled by his singular
affability to fulfill his own expectations and those of the
public. Patronized by his majesty, and by a great number of
liberal friends and well-wishers to the undertaking, both
at home and in foreign countries, in the lift of whom are no
fewer than seven crowned heads, several princes, cardinals,
archbishops, and bishops, besides universities, public libraries,
and many of the most eminent literati in various parts of
Europe; Dr. Kennicott instituted various and extensive in-
quiries after MSS., at Constantinople, Warsaw, Venice,
Bologna, Mantua, Pavia, Genoa, Lisbon, Geneva, Utrecht,
Erfurt, Berlin, Stockholm, and Hamburg. The numerous
Hebrew MSS. of the latter place were collated by the cele-
brated Reimarus, who not only concurred in, but applauded
the undertaking. In the prosecution of this work, it was
discovered, that the printed editions of the Hebrew Bible,
which had been suppos'd to agree, and on the agreement of
which the notion of the integrity of that text had been
founded, very much differed from one another; and particu-
larly, that the oldest editions agreed most with the oldest
and best MSS., and the modern editions with the latest and worst
MSS. As one proof of this, it is alleged, that the variations
in the first edition (in 1488) from Van der Hooght (in 1705)
amount to twelve thousand. In the year 1767, Dr. Ken-
icott derived great advantage from his own examination of the
Paris MSS., both Hebrew and Samaritan, and from

B I B L E.
Dr. Gell's collation of all the passages quoted in the Talmud. An Hebrew MS., which once belonged to a synagogue at Jerusalem, was at this time purloined by his Britannic majesty; and our author himself, hoping to obtain other treasures from the East, set out for Canton, and had nearly succeeded in procuring two MS.'s from the Jews at Calcutta, in the province of Bengal. But though he failed in China, he exchanged in Amsterdam, and procured a complete Hebrew MS. from a Jew at New York. During the tenth and last year of this undertaking, eight David MSS. were sent to Oxford for the author's own examination, as well as six others from Toledo, by Dr. Bayer. Collations of other MSS. were furnished, at the same time, from Sittika, Cologne, Strasbourg, Keut, London, Leyden, and Ireland. The indefatigable author, having thus collected materials for his noble undertaking, undertook no less honourable to his country than to himself, proceeded to digest the variations, with which he was furnished, under their several books, chapters, and verses. During this operation, he formed a plan for a more complete scrutiny of the bell MSS. through Europe, by sending some well-qualified person to re-examine the MSS. already collated, and to examine the rest in passages of greater moment, and where success seemed at all probable. Mr. (afterwards Dr.) Bruns, a learned German, was selected for this embassy; and he was honoured with letters from the secretaries of state here, to all our foreign ambassadors, as well as from the rulers of the two synagogues in London. The places in which he thus examined MSS., during a tour of three years, were Paris, Louvain, Cologne, Mantz, Worms, Mainz, Nuremberg, Augsburg, Stuttgart, Carlsruhe, Strasbourg, Bâle, Zürich, Berne, Geneva, Turin, Cafale, Verulii, Milan, Genoa, Leghorn, Sienna, Rome, Florence, Bologna, Genoa, Modena, Reggio, Parma, Mantua, Palma, Venice, Udine, Gorizia, Gradisca, Trieste, Vienna, Delfen, Lübeck, Erfurt, Jersey, Defian, Berlin, Hamburg, Helvastia, Caffel, Amsterdam, Utrecht, Leyden, and the Hague.

The variations contained in nearly 700 bundles of papers, being at last digested, including the collections made by Dr. Bruns; and the whole, when put together, being corrected by the original collations, and then fairly transcribed into 30 folio volumes, the work was put to the press in 1773; and both volumes (as we have already said, with the general deviation, were finished in July 1774. To render the lucidity as well as the utility of this work, Dr. Keeneeffi has printed it with a surpringe detail of the text, which exhibit the opinions both of the Jew and Christian, as to the Hebrew text, from the earliest times down to the present. The Jewish test monies are arranged under five distinct periods, viz. from the time of Malachi, about 420 years before the birth of Christ, to the commencement of the Christian era; from Christ to the year 500 after Christ; from the year 500 after Christ to the year 1500: from the year 1500 to the invention of printing, about 1525; and from the invention of printing to the year 1740. The first Jewish testimony is that of Josephus and Philo, who speak of the Greek version as perfectly agreeing with the Hebrew text in their time; whereas Dr. Kennicott affirms the corruption of the Hebrew text before the time of those Jews, and also the very importance of the Greek version. For the pentateuch of this version being made about 150 years before Christ, and the other books being also translated into Greek about 100 years before Christ (as is inferred from the prologue to Ecclesiasticus), this version must have had many true readings, which the Hebrew was afterwards corrupted. Although in Pf. xvi. 10, the word for "thy holy one," which is now plural in the text of every copy expressed Masoretically, yet in the Greek version it is singular, which is the case in no less than 180 copies, agreeably to the quotations of St. Peter and St. Paul. And because the argument of these apophthegms urged upon the Jews, after the resurrection of Christ, depends on this word's being truly singular, Dr. Kennicott considers this various reading as of greater moment than any other which was ever drawn forth from MSS. He observes, that as the Greek version thus helps to prove the Hebrew text corrupted when it differs from it, so where the Hebrew text is corrupted, and that version agrees, it proves the corruption to be older than the version, and its text has since been attested to the Hebrew. Such very early corruptions occur, as he conceives, in Deut. xvi. 6. Gen. xi. 32, and Gen. xxxvi. 31—43. The third instance contains 13 verses, which, not being written by Mofes, were probably inferred from some Chronicles, i. 43—54. In some MS.'s of Genesis, into the margin, and thence taken into the text. This interpolation is so old as to be found in all the versions, and likewise in the Samaritan text. In the first instance, many words are omitted in the Hebrew text, and in all the versions, which are preferred only in the Samaritan text. In the second instance, the number 145 is corrupted into 205 in the Hebrew text, and in all the versions, and it is right only in the Samaritan text. Dr. Kennicott afterwards specifies two great corruptions: one, where the Greek version has been attested to the Hebrew, by addition; and another, in which the Syriac version has been thus accommodated, by change. The first relates to 20 verses, probably interpolated in 1 Sam. xvii.; and the second, to the word for body altered to the word for ears, in Pf. xvi. 7; on which word, body, the argument is grounded, in the 10th chapter of the epistle to the Hebrews: and a very old Syriac MS. in the royal library of Paris, translated from the Hebrew, has preferred the true word for body; and another has proved, that the Jews have altered their ancient copies, wilfully, from the Hebrew text and Greek version of Isaiah, xix. 18. respecting the temple at Heloplis; and also from their turning Mofes into Mahaffs, in Judges xviii. 30. Many other instances occur in the period now under consideration.

In the interval between the birth of our Saviour and the year 500, Dr. Kennicott remarks, that though the present Masora separates our tenth commandment into two, agreeable to the division now made by the Roman Catholicks; yet the unity of this commandment, as made by Protesants, is expressly confirmed by Philo and Josephus; and the Masorets' mark of separation at Exodus, xxi. 17, is absent from all MS.'s of Hebrew copies. Josephus is farther cited, as confirming the ancient chronology in the Greek version against that now in the Hebrew text; and likewise, having a number much more credible as to the gold and silver left by David. The same historian also confirms the reading in the epistle to the Hebrews, chap. vii. 4, from Genesis xvi. 20. He confirms, too, the Syriac version, and the edition of Sixtus, reading four in 2 Sam. xv. 7, and the Vatican MS. reading four in 1 Sam. xvii. 4. And though the later Jews have taken Daniel out of their prophetic books, yet Josephus calls him a prophet, in the former termes. It appears further under this period, that the Hebrew MSS. differed at the time of the composition of the Talmud; and that some of the true readings may still be found in this work. This fact is confirmed by several instances, and particularly by Pf. xvi.

Under the third period Dr. Kennicott considers the subject of the Keri, which for. This period also includes a collection of 216 variations between the oriental and occidental MSS. Proofs of differences are likewise deduced from the old Jewish books,
books, Rabbeth, Ficke Elizert, and Cozni. Saadia, who flourished about the year 1000, is also referred to as having read differently from the printed text; and Hai, about the same period, is known to have followed those MSS., which were defective in Joshua, chap. xxii., where two whole verses, absolutely necessary, though expelled by the Mafora, have been found in 149 Hebrew copies. At the end of this period, Dr. Kennicott introduces the Arabic version, generally ascribed to R. Saadia, which has hitherto been reputed only secondary, as if it had been always taken from the Greek or the Syriac; whereas it is honoured with the title of a primary version in several places: because it is found to agree with the Hebrew MSS. where both Greek and Syriac differ from it. This Arabic version has some very important readings, particularly in preserving that word which expresses the cause of God's anger against Balnam, Num. xxii. 22. It is also important where it is only secondary; because it helps to determine the true reading of the Greek version, where the Greek MSS. are now at variance; as in Psalm xviii. 14, lviii. 9, Micah v. 1, and Zech. xiii. 7. To the close of this period, Dr. Kennicott refers the two oldest and best Hebrew MSS. now extant, one at Oxford, and the other at Vienna. Of the Babylonian MS., supposed to be 800 years old, he observes, that it contains about 14,000 variations. In the pentateuch of this MS. the Greek version is confirmed by 149 various readings: the Syriac, by 98; the Arabic, by 82; the Vulgate, by 88; and the Chaldee paraphrase, by 42. It also agrees with the Samaritan text, against the Hebrew, in 700 instances. This, it is added, is the only one which has preferred a word of great importance for understanding, 2 Sam. xxiii. 3-7; which word is confirmed by the Greek version, and recovers to us a prophecy of the Messiah.

The fourth period, from 1430 to 1550, is introduced with an observation, that the oldest Hebrew MS., which has a certain date (1160), though containing only 9120 verses, has above 6600 variations. The testimonies of Aben Ezra, Jarchi, Maimonides, and Kimchi, who all flourished between 1150 and 1250, belong to this period. After taking notice of several true readings preferred by these four Rabbies, Dr. Kennicott introduces Mirin Halkovi, who died in 1241, with his pathetic lamentation over the many variations in the Hebrew MSS.

Under the fifth and last period, from 1450 to 1780, including the printed Hebrew text, Dr. Kennicott takes particular notice of the five first editions of different parts, and of the first edition of the whole together. He adds, that the Pardus, as first printed in 1477, contain about 600 variations; and that the Hebrew Bible, as first printed in 1488, contains above 12,000 of these, and some other very early editions, agree with the older MSS. much more than the editions after the year 1500, but still more than that by Jacob Ben Chaim, in 1526, which has been in general the standard down to the present time. About the year 1500, began the struggles of regard for the Mafora; and such MSS. as had been maseoretically corrected, were preferred for the editions of Cardinal Ximenes and Felix Plantin. But the Mafora being highly venerated by Ben Chaim, he chose for his text such MSS. as had the Mafora most perfect; which MSS. were the latest and the worst: and yet, unfortunately, this text became the general standard for the Antwerp, Paris, and London Polyglotts, as well as for other editions of the New Testament. The Jews have not, however, been satisfied with the correctness of Chaim's edition. For Rabbi Lonzano was afterwards encouraged to visit many countries, and to collate ten MSS. in order to render the text more perfect; and yet this complaint of errors was again renewed in 1655, by Manasseh Ben Israel. These testimonies are concluded with the Mantuan edition, called Minchah Shai, in which are about 2000 various readings, collected from MSS. and early editions, by Solomon Menorzi, in the last century: but it was not printed till 1744.

So far, at the time when Christians were generally inflicting on the perfection of the Hebrew text, the Jews were labouring to correct it, and lamenting its great imperfection in the following terms: "Quis reliquit decus? Quis ejicit raphanos et pipinas? Horror confecudit me: qui dum nodum multitudinem varietatum, quaecceiderunt in libros! Editores sunt obcecurati, neque lax et eis: neque eft qui quiserit celfationem hujus diversitatis! Exce nos palpantes tanquam cibi, in obiecratur diversitatum! Deus auferat tenebras nostrar!"

On examining the testimonies of Christian writers with regard to the state of the Hebrew text, Dr. Kennicott begins with the Evangelists and Apostles; and here he advertes to the quotations made in the New Testament from the Old: on which subject, see QUOTATION. It appears, by unquestionable evidence, that the Old Testament has been corrupted, in many instances; and that a full correction of the Hebrew text, grounded on the authorities of Hebrew MSS., the Samaritan pataleuch, and the ancient versions, will, in many places, restore to the Old Testament that harmony with which it has long been wanted. Injunctions occur in Gen. ii. 24. ; Psal. xxxvi. xxxiv. 22. compared with John xix. 36, 37. ; 36, compared with Hebrews x.; Jeremiah xxxi. compared with Hebrews viii.; Amos ix. compared with Acts xv.: Isaiah vii. 14. ; Psal. lviii. 19. ; Hosea. xiv. 14. ; Amos v. 26. ; Deut. xviii. 5. ; and Habakkuk iii. 4. Many arguments are adduced by Dr. Kennicott to shew, that the Jews have corrupted the chronology, from the creation to Abraham, either by subtracting or by adding 1300 years; and this great corruption is not in the Greek version, but in the Hebrew text; and that it was introduced in the second century. As it was a very ancient tradition, that the Messiah was to come in the sixth chiliad, because he was to come in "the last days," (founded on a mythical application of the fixed years' creation), it was contrived to shorten the age of the world from about 5500 to 3760, and thence to prove that Jesus could not be the Messiah, because at the era of his birth the time for the advent of the Messiah was not yet come. The time of this great corruption is shewn to have been between the years 175 and 200. The Old Italian version, made from the Greek about the year 100, is ad-ducted to confirm some ancient readings of the Greek version, particularly as to the more extended chronology. Dr. Kennicott, after various pertinent quotations from Ignatius, Justin Martyr, and Irenaeus, refers more particularly to Tertullian, with a view of proving that, in his time, the passage in Hie. iv. 4. expressed the sense ascribed to it in the 5th chapter of St. Matthew, where the Evangelist quotes it as foretelling, that "the Messiah should heal bodily diseases." The Hebrew words, it is shown, admit this sense: Tertullian so expresses them; and so did the old Greek version, which has been strangely altered in this place, out of opposition to the gospel." Origen is cited, as affording many interesting particulars, with regard to the differences in the Hebrew copies, and the true readings of the Greek versions; and Eusebius, Theophilus Antiochenus, Ephraim Syrus, Jerom, Epiphanius, Augulfin, and Sulcius Severus, are quoted to the same purpose. The fifth period of the Christian writers terminates with the oldest MSS. of the Greek version, particularly the Vatican and Alexandrian MSS. written about the year 400, which fee. Dr. Kennicott proceeds to the period that elapsed between the years 500 and 1000, and avails himself
of the Syriac versions (see Syriac) for introducing some useful observations on several passages, particularly Psalm xli. 6, 7, 9, and 2 Kings viii. 16; in which last passage three words are now interpolated in the Hebrew text; which, though they are also found in the Vatican and Alexandrian MSS. are not in the Complutian and Avice editors, nor are they in a manuscript of Kings, nor in some of the best MSS. and earliest editions of the Vulgate. See Vulgate.

From the year 1500 to 1540, the testimonies of Christians are very few. Yet soon after the Jews fled from the East into Europe in 1492, the Hebrew language was studied by several Christians, particularly by Lafrance and Anselm Groedel and Roger Bacon; and this last learned man, with his French servant at Oxford, bought many Hebrew MSS. when the Jews were expelled from England in 1290. In the 15th century, Raymond Martini accused the Jews of corrupting the Hebrew text; and he speaks of MSS. differing in Zechariah iii. 10, with respect to which Dr. Kennicott observes, that the copies have here the reading expressed in John xxii. 35. Dr. Kennicott also cites Nic. Lyrantus, Radulphus Aermachamus, Tottuus, Perez de Valentia, and Marsella Vicius.

Under the last period, from 1450 to 1750, Zwinglius takes the lead; and he extols the Greek version, and remarks the corrupt addition of Jerome. It is also mentioned, and Bibliander is celebrated on account of his excellent extant MS. on Ezekiel xx. 21. As it is very improbable that the news of the capture of Jerusalem should be nearly eighteen months in reaching Babylon, it will be satisfactory to know, on the authority of the Syriac version and eight Hebrew MSS., that this period was not more than six months. Having described the editions of Sixtus and Clement, Dr. Kennicott observes, that the present English version frequently expresses, not what the translators found in their Hebrew text, but what they thought should have been there; and that the 14th psalm, inserted in the liturgy of the Church of England, contains three verses not found at present in the Hebrew text of that psalm, but which are probably genuine. We have already mentioned Capell's opinion on this subject; and yet though he proved the corruption of the Hebrew text, by every argument except that of MSS., Buxtorf, the son, following his father, who affected the 14th verse in the 1st century, and all the ancient MSS., affirmed that in Hebrew MS., the world contained any version differing which agreed either with either of the ancient versions. It is needful to notice the opinion of Mede, Morinus, Beveridge, Walton, Hammond, Bocchar, Huet, Placek, Le Clerc, &c. on this subject. We shall have only obiter, with Dr. Kennicott, that Jabobow was the first editor of an Hebrew Bible, who spoke of any Hebrew MSS.; and it was not rare, by the help of which he made a free correction. Neither is it certain the two century, in John xix. 21, that Dr. Kennicott has established that, in consequence of the corruption of the 149 copies, Opinion declares that he, he has not, disobeyed the Mabura, in consequence of the whole of the MSS. and evidence of the world. Yet Vitringa also states, and Dr. Kencott, that it cannot be ascribed to one, and it may be, that he has been influenced by the practice of many, many MSS. which we have discovered. The original text, as it existed at the 1st cent., was corrupted by 2 Cor. xxvi. 5, in which the 14th verse, as it is found in 5 copies, is deleted by a reading of Hand xii. 19, by one of the 2 Cor. xxvi. 20, by the 1st and 15th Hebrew copies. J. H. Mede, although he published many versions of great merit, probably from an undue deference to the advocates of the integrity of the Hebrew text. Among those advocates we may reckon Wolfius, who maintained that mistakes might exist in some MS. copies, but not in all; because some one MS., or some one edition, always had the true reading. Carpzovius contended, that the Hebrew text has defended to us in the same state of purity in which it was first found; not indeed in all the copies, but in the best of the better fort; nor in these separately, but in such a manner; and he thought it needful to collect these from every quarter of the world, because, in his opinion, those which are near at hand will be sufficient; a concession which abridges his former doctrine. The learned Hallet, in his notes on the Holy Scriptures, published in 1729, alleges as a reason why the quotations in the New Testament differ from those of the Old, that the Hebrew copies have been altered since the days of the apostles. Bishop Hars, with whole testimonies Dr. Kennicott concludes his catalogue of Christian writers, contends earnestly for admitting the corruption of the Hebrew text. He rejects the titles of many of the psalms as not given by the authors of the Hebrew. He condemns the practice of varnishing over, instead of correcting, the corrupted readings; and he humbles the Hebrew MSS., the chief support of criticism, were wanting.

Dr. Kennicott closes his account of his labours under taking, with evince the great use to be derived from the Hebrew MSS. and ancient versions, for amending the printed Hebrew text; and with exhorting persons in power to render such corrections subservient to the public good, by procuring a more correct and a more intelligible English translation, or rather a revision of the present English translation of the Old Testament. These MSS., he says, strongly confirm the ancient versions, and enable us to accord to the times of Jerom, of the Apollines and even of Tobi-expand Philadelphia; and, he adds, it now remains to be seen in what kingdom or country through Europe, will be manifested the greater zeal for correcting the modern translations of the Old Testament.

The work of which, for the gratification of our readers, and with a view of recording and transmitting the honour of our country, where it was undertaken, and of the age in which we live, we have given a copious account, will appear in its pre-eminent importance and utility, whenever it shall be applied to the doable purpose of aiding a public and authoritative new translation of the Bible, or at least, of an effectual revision of the common version. In the translation of particular books of Scripture, by bishops Lowth and Newcome, and by others of inferior rank in the church, &c. we observe the advantage resulting from Dr. Kennicott's labours; but the full benefit can only be enjoyed, when the translation is complete, and authoritatively introduced into common use. It has contributed eminently to the honour of the king of Sweden, that he has been the full prince in Europe, who has heard his royal commands for executing a purgator of this kind; and Dr. Kennicott thinks, it would be cruel and barbarous to show that Great Britain, which has enjoyed such distinguished blessings of Providence, will be backward to procure a design. No perjury, whatever to their rank either in the church or state, can more justly oblige this generation for the Holy Scriptures, and their concern for the reformation and benefit of the world, than by aiding and correcting them, a cure of the kind. It would have also to obviate any objections against the truth or authority of divine revelation. It has been urged by lord Bolingbroke, and by other writers on the full of the act, or the Fy, that if the Scriptures had been from God, they would always have been preserved in their pristine purity. It is pertinent to bug them of this kind, Dr. Kennicott thinks, that neither the listened for the
the goodness of the Supreme Being can be justly imputed from the supposition that many errors have crept into the present text; because the most important matters are still obscure and certain, and men have always been able to derive from the Bible a rule both of faith and practice. For the illustration of this position, he appeals to the ancient churches, both Greek and Italian, and the modern churches of both Protestants and Roman Catholics; since, amongst all these, their sacred books taught them "what they must do to be saved!" though they contained many errors, the correction of which was very desirable. Indeed, the integrity of the sacred books could not have been preferred without a "miracle," perpetual as to time and universal as to place, which would consequently be a greater miracle than any in the Bible; nevertheless as many corruptions, in transcripts made from transcripts, ever since the year 400 before Christ, were unavoidable, it is happy that several versions, made 1500 or 2000 years ago, will correct some of these corruptions; and that the Hebrew MSS. still exist, will correct others. Upon the whole, it is of great importance, that the effect of these corrections should appear in its whole extent, and as speedily as possible, not only to Christians in particular, but to the world in general.

The learned Dr. John Bernard Roffi, professor of divinity and the oriental languages in the Royal Academy of Parma, undertook to make a collection of the various readings of the Old Testament, in imitation of that of Oxford; and for this purpose he examined by himself, or his friends, 1470 MSS. or printed copies. Of foreign MSS. 210, which had been omitted by Dr. Kennicott, were collated in the most important passages; and of ancient editions, either in his own possession, or to which he had access, the number amounted to 288, of which 250 are such as had not been collated by Dr. Kennicott. M. de Roffi announced his design in a tract, entitled "Apparatus Hebreo-Biblicus," and published at Parma in 1782, 8vo.; and he proposed to compile the result of his labours in 4 vols. 4to. The first volume was published at Parma in 1784, under the title of "Variae Legiones Veteris Testamenti, &c." or the various readings of the Old Testament, drawn from an immense number of MSS. and printed editions, compared with the Samaritan text and the ancient versions, and examined and appreciated by the most accurate rules and principles of facred criticism. This volume contains the "Prolegomena," and a clavis of the books of Genesis, Exodus, and Leviticus. In the introduction we have several curious critical discussions, from which we learn that this collection averts, as Dr. Kennicott's valuable and judicious labours had before done, instead of invalidating the integrity of the sacred text in matters of the greatest importance; as all the MSS. notwithstanding the diversity of their dates, and of the places where they were transcribed, agree with respect to that which constitutes the proper essence and substance of divine revelation, namely, its doctrines, moral precepts, and historical relations. M. Roffi charges the variations not merely on the copies but on the ignorance and temerity of the critics, who have, in all ages, been too ambitious of dictating to their authors, and who, instead of correcting the pretended errors of others, frequently substitute in their place real errors of their own. This author is of opinion, that the common reading of an ancient text ought never to be changed but by the authority of MSS.; and if there be any exceptions to this general rule, they are very rare; and the conjectural alterations of critics should be thrown into the notes. M. Roffi, however, observes, that we must not confound the alterations introduced into the sacred text by the injuries of time, the negligence of transcribers, or the boldness of critics, with those which have been made by public authority. The sacred writers of ancient times left, as he says, their records to other writers, who were often their disciples, as also to public scribes, and to magistrates, who revised them. In this revision, which was executed either by sacred authors, or by the public authority of the synagogue, corrections and retrenchments were made, where they were judged necessary. This, M. de Roffi thinks, appears evident from the present state of the sacred writings; and in confirmation of his opinion, he quotes the Syriac Interpreter, who, in a note placed at the end of the Pentateuch, says, that this work was composed by Moses, but was afterwards digested and finished by Joshua. He also conjectures that Moses himself made use of ancient records, both in his history of the creation, and in that of the deluge. He thinks that the frequent repetitions and anachronisms, which are disfigured in the book of Genesis, ought rather to be attributed to a writer anterior to Moses, than to scribes in after-times; or to the confusion of the ancient records themselves, as some have imagined. This opinion was proposed and maintained with singular ingenuity and erudition, before the time of Roffi, in a French work published at Bruxelles in 1755, and entitled "Conjectures concerning the original memoirs, which Moses appears to have made use of in composing the book of Genesis, together with remarks designed to confirm or illustrate the several conjectures." The revision, says Roffi, which Ezra made of the sacred writings, with the assistance of MSS. and according to the rules of criticism, both on his own authority as a sacred writer, and that of the council of which he was a member, did not annul the MSS. that were anterior to his time, either in the hands of the Samaritans, or in those of the Jews, from which those of the Cuthites or Samaritans had been taken, or in the hands of the Egyptians, or in those of the Babylonian Jews, who did not return to the holy land. The edition of Ezra remained entire till the destruction of Jerusalem; but it underwent several alterations before the time of the Maforites, whole critical labours or attempts with a view of securing the sacred code against future injuries are well known. Yet, notwithstanding these attempts and labours, some faults, which were anterior to their time, still remained; and others, though of little consequence, afterwards crept into the sacred text. The only sources from which we can derive warrantable corrections of these faults are, according to this author, the MSS., the ancient editions, the Samaritan text, the ancient versions, the parallel places, the analogy of the text or of the history, the testimonies of ancient writers, critical conjectures, and the Masora, which De Roffi treats with more respect than Dr. Kennicott, of whom he complains on that account. He subjoins many learned and judicious observations on the various sources, from which materials are to be derived for the necessary corrections. As to the MSS. he lays down rules for ascertaining their age, of which he must observe the date; and in order to understand their dates, he takes occasion of the various methods of computing time employed by the Jews, and the different eras from which they reckon. When the dates are wanting, it becomes difficult to ascertain the time of a MS., if it be anterior to the thirteenth century, Thoae which are anterior to the twelfth century are very rare; and the author minutely indicates the marks that distinguish them. The rarity of the ancient Hebrew MSS. has been occasioned by the Jewish custom of depositing their books and phylacteries in public places, from whence, to make place for others, they have been taken and buried in wells, or under ground, where they foon rot. Thoae of a very remote antiquity, which are no longer extant,
BIBLE.

tent, are often restored, in part, by copies which fill subdiv. With regard to ancient editions, Dr. Rollin distinguishes the Masoretic from those editions without the Masor., which are anterior to the year 1750, when the rabbinical Bible of Jacob ben Chain was published. Of 242 which he has collected, he reckons 30 which belong to the fifteenth century, and above 60 which are anterior to the first Masoretic Bible. The ancient versions enumerated by the author are the Greek, Chaldaic, Syriac, Arabic, and Persian; and among these, the Greek version of the Pent.-trach has not been published, which is in the library of St. Mark at Venice, and which he supposes to have been made in the twelfth or thirteenth century, by an Hebrew, from the Hebrew of Ezra or of Palestine; and not as the Septuagint, from the Egyptian or Hebrew text. The differences which are found in these versions must not be considered as various readings; since many of these diversities are to be attributed, says De Rollin, to the translat. themselves, who have sometimes taken great liberties with the original text, by altering it in their versions. For other particulars, we refer the learned reader to the work itself. The second volume was published at Parma, in 1783, and contains the books of Numbers, Deuteronomy, Joshua, Judges, Samuel, and Kings. The third comprehends I. Sam., Jeremiah, Exod., the twelve leas prophets, with the Song of Solomon, Ruth, Lamentations, Ecclesiastes, and Esther. And in the fourth, or last, are the Psalms, Proverbs, Job, Daniel, Ezra, Nehemiah, and Chronicles. Parma. 1786. The high price of Renan's and De Rollin's valuable works, induced M. Brudet to employ Dr. Dacier and Professeur Meiller, to collect the most interesting variations from the above works, and to print them under the text of his new edition of the Septuagint, printed at Lipsie in 1753, and again in 1769, under the title of "Biblia Hebracea, olim a Christiano Reuenecio edita, nuna deno, cum variis eftioniis, ex ingenti codicis copia, a B. Kennicott & J. B. de Rollin collatorum." Lipsie, 8vo. 1793.

BIBLE, Greek. The most ancient Greek version is the Septuagint; for an account of which, the manner in which it was found, the collation of its MSS., and other circum-\n\ncias relating to it, see Septuagint; see also Alexandrianc, and Vatican. The number of editions of the Bible in Greek is very considerable; but they may be all reduced to three or four principal ones, namely, that of Compton or Arcali de Hemmes, that of Venice, that of Rome, and that of Oxford. The first or Complutian edition was undertaken by the divine of Complutum, under the direction and at the expense of cardinal Ximenes, and finished in 1514, but not allowed by Leo to be publicized till 1520; nor were the copies of it distributed to the world at large before the year 1532. It was infected in the Polyglott Bible, usually called the "Complutensian Bible." In this edition the Greek of the LXX. is said to be altered in many places, in order to accommodate it to the Hebrew text, and to the Vulgate. For a more particular account of it, see Complutensian, and Polyglott. It has been reprinted in the Polyglott Bible of Antwerp, called "Biblia Regia," by Arna Montanus, in 1572; in that of the Commales, commonly called "Vulgate's Bible," in 1595; and in De Jay's Polyglott of Paris, in 1645. See Polyglott.

The second Greek Bible is that of Venice, formed from many ancients in copies by Andrea Atanasus, and printed by Aldus Manutius in 1518, and hence called the "Aldine Edition." This edition approaches nearly to the Roman, and is said to be purer than the Complutensian. Manusi says of it, that it is a copy of the simple interpretation of the ancient LXX.: but not pure, nor free from all inter-mixture of the words of Theodotion. Other observ. that it sometimes deviates from the LXX., and adopts the readings of Aquila; and that various glosses have event into it. From this Aldine edition all the German copies have been derived, which generally adopt the words of it, but differ from it in the order of the books, chapters, and some verses. The apocryphal books are printed separately after the red. This edition was reprinted, with the Complutensian Latin version, in 1520, by And. Crandatus: and again, in 1550, by Rich. Brevlinger; at Strasburg, in 1565; at Hamb. in 1565; at Frankfort, by the Wechelians, in 1577; and in other places, with some alterations, to bring it nearer to the Hebrew. The most commodious is that of Frankfort, in which they are published, from the Complutensian edition, the four last chapters of Exodus, and a great part of the 24th chapter of the Proverbs. There are also added little Scholia, which shew the different interpretations of the old Greek translation. The author of this collection has not annexed his name, but it is commonly ascribed to Francis Junius.

The third Greek Bible is that of Rome, or the Vatican (i.e. Vatican), formed from the Vatican copy by cardinal Caraffa, and other learned persons, who were employed in this work for nine years, by the order and under the auspices of pope Sixtus V. It was printed at Rome in 1587, with the Greek Scholia, collected from the MSS. in the Roman libraries. It was afterwards printed in Latin, with learned and useful notes, by Flaminius Nobilius, at Rome, in 1588. The Greek edition, with the Latin annexed, the distinction of verses, according to the Vulgate, the Greek Scholia, and the Notes of Nobilius, was printed at Paris, in 1628, by J. Moris, priest of the Oratory. In forming this edition, Caraffa made use of several ancient MSS., besides the Vatican, and particularly one procured from the library of Cardinal Bellarion, written in large letters, and another from Magna Gracia, agreeing with the Vatican; and Caraffa professed that it was his design, not to accommodate this edition to the Latin Vulgate, or the Hebrew, but to the ancient LXX. Notwithstanding some few trivial objections, this edition has extolled for its purity, its freedom from any material corruptions, and its superiority to all other editions. From this all the English editions have been derived. The Greek edition of Rome, or as Grabe says in his Prolegomena, that of Paris, has been printed in the Polyglott Bible of London, in 1657, to which Walton has added, at bottom, the various readings of the Aldine and Complutensian editions, and of the Alexandria MS., as well as of Marchiallani's and Carol. Barbinii's. It was printed at London in 1652, in 8vo, with some deviations with regard to the order of the books, the number of the psalms, &c.; at Cambridge, in 2 vol. 12mo, with a preface by the learned Pearson, in 1665; at Amsterdam, with the same preface, in 1683, by Liefden, 8vo; and at Leipsic, in 1697, 8vo, with the Greek Schola of the Roman edition, the parallel places and various readings, and a preface by J. Trizio, of Ulm. Another Greek Bible was published at Franeker, in 1779, by Lambert Boë, who professed to adhere to the Roman edition of the Vatican copy, and to subjoin at the bottom of the page, besides the Scholia of the Roman edition, all the various readings he could find, together with fragments of the versions of Aquila, Symmachus, and Theodotion. Breitinger, however, observes, that Boë, instead of adhering to the Roman edition, has followed that of Paris by Murray, or the text in Walton's polyglott. This edition of Boë has been long the common text-book of biblical scholar.
Bible.

scholars, who cannot easily purchase the Roman edition; although it is far from being a correct copy of its prototype.

The fourth Greek Bible is that done from the Alexandrian MS., begun at Oxford by Dr. Grabe, in 1707. An edition of a similar kind had been undertaken by Patricius Junicus, or Patrick Young, who proceeded no farther than the 17th chapter of the book of Numbers, and also propounded by Vossius, but not undertaken. In Grabe's edition, the Alexandrian manuscript is not printed such as it is, but such as it was thought it should be; i.e. it is altered wherever there appeared any fault of the copyists, or any word infected from any particular dialect. This same think an excellence, but others a fault; urging, that the manuscript should have been given absolutely and entirely of itself, and all conjectures, as to the meaning, should have been thrown into the notes. For the plan of this work, and the mode of its execution, we refer to the author's Prolegomena. A valuable edition of this work, enriched with various readings from the Vatican copy, and other manuscripts, and illustrated by critical dissertations, was published by Jef. Jac. Breitinger, in 4 vols. 4to. in 1730. Tigur. Helvet. A collection of the MSS. of the most ancient Greek version of the Septuagint has, within these few years, been undertaken by Dr. Holmes, canon of Christchurch, Oxford; and the first volume was published at Oxford in 1768, folio; for an account of which, see Septuagint. Walton's Prolegomena. Grabe's Prolegom. Hodii de Bibliorum Textibus originalibus, &c. p. 658; &c. Fabr. Bib. Graec. l. iii. c. 21. § 6. Tom. ii. p. 324, &c. See Septuagint, and Testament.

Bibles, Latin, how numerous formerly, may be all reduced to three classes; the ancient Vulgate, called also 'the old Latin,' or 'Vulgar Latin,' (see Latin Version), translated from the Greek Septuagint, for the use of the Latins, soon after their conversion to Christianity; which version was allowed to be superior to all the rest, being, as St. Augustine calls it, 'tenacior verborum cum perpexituate fententia;' which version being corrupted, Jerome, between the years 370 and 380, made a new Latin version from the Hexaplar Greek; the modern Vulgate, the greatest part of which is done from the Hebrew text; and the new Latin translations, done also from the Hebrew text in the sixteenth century. We have nothing remaining of the ancient Vulgate, used in the primitive times in the Western churches, but the Pfalms, Wildom, and Ecclesiastes. Nobiles has endeavored to retrieve it from the works of the ancient Latin fathers; but it was impossible to do it exactly, because most of the fathers did not keep close to it in their citations.

As to the modern Vulgate, there are numerous editions very different from each other. Cardinal Ximenes has inserted one in the Bible of Complutum, corrected and altered in many places. R. Stephens, and the doctors of Louvain, have taken great pains in correcting the modern Vulgate. See Vulgate.

The best edition of Stephens's Latin Bible is that of 1540, reprinted in 1545, in which are added, on the margin, the various readings of several Latin manuscripts, which he had consulted. The doctors of Louvain revised the modern Vulgate after R. Stephens; and added the various readings of several Latin manuscripts. The best of the Louvain editions are those, at the end of which are added the critical notes of Francis Lucas of Bruges.

All these reformation of the Latin Bible were made before the time of pope Sixtus V. and Clement VIII. since which people have not dared to make any alterations, excepting in comments, and separate notes. Sixtus V. who was advanced to the papal see in 1587, although the Latin Bible of Gregory XIII. was declared to have been restored to its primitive integrity, formed, by the assistance of learned persons, another edition; and issued a bull in 1589, resolving and declaring that this was to be deemed, without doubt or controversy, that which was acknowledged as true, legitimate, authentic, and unquestionable; forbidding the alteration, addition, or subtraction of the least tittle of it, and declaring such a mutilated edition defitute of credit or authority. Nevertheless, after the death of Sixtus V., this edition was suppressed by succeeding popes, as inaccurate and imperfect. A new edition was undertaken by pope Gregory XIV. and completed and announced by Clement VIII. in 1592, which, though different from that of Sixtus, and even repugnant to it, is received as authentic, under the name of Sixtus V.; and it is now the standard throughout all the Roman churches. This pontiff made two reformation; but it is the first of them that is followed. See Vulgate. From this the Bibles of Plantin were done, and from those of Plantin all the rest; so that the common Bibles have none of the after-corrections of the same Clement VIII. It is a heavy charge that lies on the editions of pope Clement, viz. that they have some new texts added, and many old ones altered, to countenance and confirm what they call the Catholic doctrine; witnesses that celebrated passage of St. John, tres fast, &c. Mr. James, an English protestant, has collected above 2000 articles, some of which are indeed of no great consequence, in which Clement's edition differs from that of Sixtus. Clement has adhered more closely to the Hebrew text; and his edition, says Dupin, is much more correct than that of Sixtus. He adds, though the vulgar version be not altogether free from errors and defects, it must nevertheless be confided that the council of Trent had sufficient reason to prefer this before all the other Latin versions, as Theodore Beza, P. Pagini, L. de Dieu, Cæsabon, Grotius, Walton, and some other protestants, have allowed. This version was the most ancient of all that were extant at the time of this council; the greater part of it was done by Jerome, a very exact and faithful interpreter. It had been used for many ages in the Latin church; it was written in a simple and natural style, and yet occasionally heightened by noble expressions; and upon the whole, says Dupin, it was the best and most perfect version.

There is a great number of Latin Bibles of the third class, comprehending the versions from the originals of the sacred books made within three hundred years. The first is that of Sanctus Paginæus, a Dominicus, under the patronage of pope Leo X. printed at Lyons, in 1410, in 1528, authorized by two letters of pope Adrian VI. and pope Clement VII. prefixed to it, the former dated in 1523, and the latter in 1526, and much cherished by the Jews. He employed 25 years in the execution of this work, and finished it before the year 1518. This the author improved in a second edition. In 1542, there was a beautiful edition of the same at Lyons, in folio, with fabola, published under the name of Michael Villanovæus, i.e. Michael Servetus, author of the fabola. Those of Zurich have likewise published an edition of Paginæus's Bible in 1410. And R. Stephens reprinted it in folio, with the Vulgate, in 1557, pretending to give it more correct than the former editions. There is also another edition in 1586, in four columns, under the name of Vetusbib; and we find it again in the Hamburg edition of the Bible in four languages.
In the number of Latin Bibles is also usually ranked the version of the same Papinius corrected, or rather rendered literal, by Ario Montanus; which correction is approved of by the doctors of Louvain, &c. was inserted in the Polyglott Bible of Philip II. and since that of London. The chief aim of Montanus has been to translate the Hebrew words by the same number of Latin ones so that he has accommodated his whole translation to the most scrupulous rules of grammar, without attempting his literal; and therefore this version may be considered rather as a grammatical commentary than a true version, and adapted to interest young beginners in the Hebrew, rather than to be read separately. There have been various editions of this in folio, quarto, and octavo; to which have been added the Hebrew text of the Old Testament, and the Greek of the New. The best of them all is the first, which is in folio, 1571. The translation of Thomas Malvenda, a Spanish Dominican, is more grammatical and barbarous than that of Montanus, and not much esteemed.

Since the Reformation, there have been several Latin versions of the Bible: from the original Hebrew by Protevangelists. The most esteemed are those of Munster, Leo Judae, Caalbano, and Tremellius; the last three of which have been reprinted various times. Munster published his version at Basle in 1534, which he afterwards revised; he published a corrected edition in 1546. Without rigidly adhering to the grammatical signification of the words, like Papinius and Montanus, he has given a more free and intelligible version; but by not deviating from the sense of the Hebrew text, he has retained some of its idioms. He has also added himself to the commentaries of the best Rabbins. Hautecoeur gives him the character of a translator well versed in the Hebrew language, whose style is very exact and conformable to the original. Caihalo's free Latin pleases most people; but there are some who think it too much affected, and defective of that noble simplicity and natural grandeur, and of that inexplicable energy of style, belonging to the originals, and some other versions: the best edition of it is that of 1573. Leo Judae's version, altered a little by the divines of Salamanca, was added to the ancient Latin edition, as published by R. Stephens, with notes under the name of "Vatablus'" Bible," in 1543. It was printed at Zurich in 1543, and is more elegantly written than Munster's, but sometimes recedes too far from the literal sense. It was condemned by the Parisian doctors, but printed, with some alterations, by the Spanish divines of Salamanca. That of Junius and Tremellius is preferred, especially by the Calvinists, and has undergone a great number of editions. It possesses much more of the true natural simplicity. The chief Hebraists are preferred, and the whole is exactly conformable to the Hebrew text, without the least obscurity or barbarity. Nevertheless, it is not without defects; relative pronouns are introduced, without attention to the Hebrew text, and they are charged with adding some words to express their own sense.

We may add a fourth class of Latin Bibles, comprehending the Vulgate edition, corrected from the originals. The Bible of Hierocles Clarinus is of this number: that author, not being contented with restoring the ancient Latin copy, has corrected the translator in a great number of places, which he thought ill rendered, so as to make them conformable to the Hebrew text. Although he corrected above 8,000 passages, he has omitted some to avoid giving offence to the catholics, by making too many alterations in the vulgar version. Some protostates have followed the same method, and among others, Andrew and Luke Oland, who have each published a new edition of the "Vulgate," corrected from the originals, according to the Hebrew text. They have inserted their emendations in a character different from the text of the vulgar version, instead of throwing them into the margin, and thus they have occasioned some confusion.

BIBLES, Oriental. At the head of the Oriental versions of the Bible, must be placed the Samaritan, as being the most ancient of all, though neither its age nor author have been ascertained, and admitting no more for Scripture than the Pentateuch, or five books of Moses. This translation is made from the Samaritan Hebrew text, which is a little different from the Hebrew text of the Jews. This version has never been printed above; nor anywhere but in the Polyglott of London and Paris. See Pentateuch, and Samaritans.

BIBLES, Chaldees, are only the glosses or expositions made by the Jews at the time when they spoke the Chaldee tongue. They are the work of Nestorius, or paraphrasts, as well as any strict versions of the Scripture. They have been inserted entire in the large Hebrew Bibles of Venice and Basile, but are read more commodiously in the Polyglott, being there attended with Latin translation, See Chaldee Paraphrase.

BIBLES, Syriac. There are extant two versions of the Old Testament in the Syriac language: one from the Septuagint, which is ancient, and made probably about the time of Constantine; the other, called antiqua & simper, made from the Hebrew, as from the Phœnician, about the time of the apostles. This version is printed in the Polyglott of London and Paris.

In the year 1555, Widmannstätten printed the whole New Testament in Syriac, at Vienna, in a beautiful character, after him there were several other editions; and it was inserted in the Bible of Philip II. with a Latin translation. The best edition of the Syriac New Testament is unquestionably that of Leyden, published by Schulten in 1708, and reprinted, much improved, at Leyden, in 1717. A new Syriac and Arabic Testament was printed at Rome, in 1793, by the Propaganda, for the use of the Maronite Christians in Syria. Gabriel Sionita also published a beautiful Syriac edition of the Psalms, at Paris, in 1525, with a Latin interlinear. See Syriac Version.

BIBLES, Arabic. Although the Christian religion was preached in Arabia, as well as in other countries of the East, at an early period, it never was the established religion of the country, as in Syria and in Egypt; for even the temple of Mecca was a heathen temple till the time of Mahomet. A translation of the Bible into Arabic was therefore wholly unnecessary before the conquests of the Saracens, when the Arabic became the vernacular language of Christian countries. Historical evidence on this subject extends no further than the tenth century, when Rabbi Saadah Gaon published an Arabic version of the Pentateuch; and if conjecture may be allowed (faya Martin, in his edition of Michael's Introduction, vol. iii. p. 599), we may suppose that most of the Arabic versions were made during the period that elapsed between the conquests of the Saracens in the 7th century, and the crusades in the 11th, especially about the middle of this period, when the Saracens and the Coptic, though they had ceased to be living languages, were still understood by men of education, and Arabic literature, under the patronage of Almamun and his successors, arrived at its highest pitch. The age in which the Arabic printed version, or versions of the New Testament, were written, is wholly undetermined; for we have no knowledge of the MSS. from which the Roman edition of the four Gospels (mentioned below) was printed; and all that we know of the MSS. used by Gabriel Sionita in his edition of the Paris Polyglott, and by Lepherin in his edition of the Arabic New Testament, is that the former used a MS. brought from Aleppo and written in Egypt in the 14th century, and the latter a manuscript.
script brought from Egypt, in which the gospels were written in the 13th, and the Acts, Epistles, and Revelation in the 14th century. But we are left wholly in the dark with respect to the century in which the versions themselves were made. The Arabic versions may be divided into four classes: viz. those taken immediately from the Syriac, from the Coptic, from the Greek, and from the Latin. That various Arabic versions have been made from the Latin in modern times by oriental monks residing at Rome, who being instructed by the Romish clergy to regard the Vulgate as the standard by which all other versions should be regulated, proposed especially to serve their brethren in the East, by translating it into their native language, is evident from what is related by Prosper Adeni, in his Biblical and Critical Journey to Rome, p. 178, and an Arabic version of this kind was actually published at Rome, in 1752, by Raphael Tuki, bishop of Arfan. As for those versions which are written in parallel columns with the Syriac and Coptic, of which copies exist in the royal library at Paris, it is reasonable to suppose that they were not made from the Greek, but immediately from the ancient versions with which they are connected, as the means of understanding them, after the languages in which they were written had ceased to be spoken. For the same reason, those annexed to the Greek texts were probably taken immediately from the Greek; but of these Greek Arabic MSS. only one has been discovered, namely, that in the university library at Leyden. Walton (Prolegomena, p. 96.) says, that there are two kinds of Arabic versions, one among the eastern Christians; one called the Syriac, and the other the Egyptian, from the countries in which they are used. Both these versions, according to Aug. Justinius, bishop of Nebo, were translated from the Greek. In the year 1516, Aug. Justinius printed at Genoa an Arabic version of the Psalter, with the Hebrew text and Chaldee paraphrase, adding Latin interpretations, which, he says, were taken from the Syriac or Antiochian version. There are also Arabic versions of the whole Scriptures in the Polyglotts of London and Paris, paid for by Justinius to be taken from the Egyptian or Alexandrian versions; and we have an edition of the Old Testament entire, printed at Rome in 1671, by order of the congregation de propagando fide; but it is of little value, as having been altered agreeably to the Vulgate edition. The Arabic Bibles among us are not the same with those used by the Christians in the East. Some learned men take the Arabic version of the Old Testament, printed in the Polyglotts, to be, at least, in the main, that of Sandias, who died in the year 942, and who translated the whole Old Testament from the Hebrew into the Arabic, expelling the Arabic in Hebrew characters. Their reason is, that Aben Ezra, a great antagonist of Sandias, quotes some passages of his version, which are the same with those in the Arabic version of the Polyglotts; yet others are of opinion that Sandias's version is not extant. For though the whole Hebrew Bible was thus translated by him, the Pentateuch only has been, as yet, published from his version. The other books, now in Arabic, in the Paris and London Polyglotts, were translated at different times by different authors; partly from the Greek, and partly from the Syriac versions; and few parts, if any, excepting the Pentateuch, were translated from the Hebrew text. The Arabic version is the latest of all the ancient versions of the Old Testament; however, that part of it which has been translated from the Hebrew, will affix in detecting some corruptions that have crept into the Hebrew text since, and those parts that are made from the ancient versions will affix in establishing the true readings of those versions. In 1622, Erpenius printed an Arabic Pentateuch, called also the Pentateuch of Mauritania, as being made by the Jews of Barbary, and for their use. This version is very literal, and esteemed very exact. The four gospels have also been published in Arabic, without and with a Latin version, at Rome, in 1591, folio. The Latin translation is printed under each line of the Arabic text, and is taken from the Vulgate, though the Latin text is in some measure altered, so as to make it correspond to the Arabic. In a representation of the baptism of Christ, annexed to it, the rite appears to be performed, not according to the Oriental custom of immersion, but according to the northern practice of aspersion; for our Saviour is placed, not in Jordan, but at the brink of the river, with his feet only immersed, while John the Baptist, kneeling on a rock, pours water on his head. The MS. from which this edition of the Arabic gospels is taken, is wholly unknown. Michaelis observes, that upon comparing it with the catechism of the Druses, the passages there quoted from the gospels coincide with this edition; whence he infers that this version must have been long and generally known in Asia. But from this coincidence no other inference can be justly drawn, except that the Arabic version of the gospels, printed at Rome in 1591, was made before the 11th century; for to that age the origin of the Druses is referred. Erpenius observes, in the preface to his Arabic New Testament, that this edition bears a great resemblance to the MS. from which he printed the four gospels, except the first thirteen chapters of St. Matthew. This version, says Michaelis, was certainly taken from the Greek; but father Simon (Hist. Crit. des Versions du N.T. ch. 18.) says, that upon comparing the Arabic version of the four gospels printed at Rome, and afterwards reprinted in the Polyglotts, with an Arabic translation of the Coptic version, he found them different; but that on comparing it with an Arabic translation of the Syriac version, he perceived a great resemblance. Hence he concluded, that it was taken, not from the Greek, but from the Syriac text. This version has been since reprinted in the Polyglotts of London and Paris, with some little alteration of Gabriel Sionita. This Gabriel Sionita, a Maronite by birth, from the neighbourhood of Libanus, and one of the principal editors of the Paris Polyglott, relates, that he made use of a manuscript written in Egypt in the 14th century; but he seems to have been unacquainted both with the name of the author, and with the age in which he lived. Le Long relates, that it was brought immediately from Aleppo to Paris. From this MS. the Arabic version of the Acts and of the Epistles was taken, which was printed in the Paris, and reprinted with additions in the London Polyglott. But this version of the Acts and Epistles can lay no claim to high antiquity; and though it was probably not taken from the Syriac, yet it is not certain whether it was taken from the Coptic or the Arabic. Erpenius published an Arabic New Testament entire, as he found it in his manuscript copy, at Leyden, in 1616, from a manuscript written in the Upper Egypt, in the 14th century. From two dates, which Erpenius seems to have founded, it is probable, that the manuscript used by him was a compound of two different manuscripts, one written in the 15th, and the other in the 14th century; and this is very consistent with the opinion, that the gospels in this manuscript were translated either from the Coptic or from the Greek, and the Acts and Epistles from the Syriac. There are some other Arabic versions of late date, mentioned by Walton in his Prolegomena; particularly a version of the Psalms preferred in Sion College, London, and another of the prophets at Oxford; neither of which has been published. The English society for promoting Christian knowledge published, in 1727, an Arabic New Testament, for the use of the Christians in Asia. Ten thousand copies were printed, but were sold in Europe; so that this edition is very scarce. Two
BIBLE.

Two copies are preferred at Cambridge, one in the university library, and another in the library of St. John's college. The text is taken from the Polyglot; but the editor Solomon Negri, by order of the society, altered it in those passages which vary from the reading of our present Greek text. The editor, says Michaelis, has taken the liberty of altering 1 John v. 7, without cautioning the reader that it was not taken from any MS.

An Arabic Bible is said to have been printed at Bukhara, in 1760, and the gospels at Aleppo, in 1766. Of these, as well as of the complete editions of the Arabic version, a description is given in Le Long's Bibl. Sacr. ed Mafch. P. ii. vol. i. p. 110—137. For an account of the MSS. of the Arabic version of the N. T. preferred in the different libraries of Europe, see Boerier's edition of Le Long's Bibl. Sacr. P. i. p. 231—240, or vol. i. p. 126—132. Paris ed. 1723; Ustr's Catalogue, N. 22—34 of the Arabic MSS.; and Note i. p. 5, ch. vi. in Martin's edition of Michaelis's Introduction to the N. T. In the university library are two Arabic manuscripts of the gospels, which formerly belonged to Cyrilus Lucaris.

Bibles, Coptic. There are several manuscript copies of the Coptic Bible in some of the great libraries, especially in the library of Paris. The Coptic version of the New Testament must be regarded as a principal version of considerable antiquity, because it has given birth to several others in the Arabic language; for since Egypt was invaded by the Arabs, who extinguished the old language, the Egyptians have generally turned to the Coptic N. T., an Arabic translation, which has almost superseded the original. Nubius, in his Description of Arabia (p. 86), relates, that though the gospels are still read in the Coptic version in the public service, it is not understood even by the priests; and that immediately after the leesons have been read in Coptic, the same are read in Arabic, which is the present language both of the Upper and the Lower Egypt. Thomas M' shall had once intended to print the Coptic version, and had even prepared the four gospels for the press, but he died before they were printed. Upon which the publication was referred for Dr. D. Wilkins, a native of Monm in Prussia, who, after having studied the Coptic, made a journey to Amsterdam with this view; but induced by several advantageous circumstances, he removed to Oxford, where his Coptic New Testament was printed in 1716, at the expense of the university. Besides a long preface, he added a Latin translation of the Coptic text, which Jabob ski and La Croze have criticized with some severity. It is said, however, that Wilkins took great pains to present the world with a faithful copy, and that his endeavors were not unsuccessful. He also printed the Pentateuch, with a Latin translation, in 1731. Since then a great variety of MSS. have been collected; and if Weide had undertaken the task, a more complete edition of the Coptic version might have been expected. The title of Wilkins's edition is "Novum Testamentum Egyptianum vel, Cicorium, et MSS. Bodleianus decipitem, cum Vaticane et Parisiensi textilibi, et in Latine fomeo en converti, David Wilkins, Jacobus Aylmer Pressley," Oxon. 1716, 4to. Mag. House.

In his Paragrapha Graeca (i. vi. c. 7. p. 31.), says that the Coptic MS. which remain, are not very ancient; and that he has not seen any older than 700 years. Wilkins, in his preface, supports the accuracy of the Coptic version by several arguments, the chief of which is drawn from Antioch, who began to lead an ascetic life about the year 271. Weide, as a native of Egypt, and ignorant of Coptic, read the New Testament. To the same purpose Weide (p. 97. of his Essay, mentioned below) maintains, that the Egyptian version used by Athanasius in the third century, was written in Coptic, because he actually read an Egyptian version of the Bible, and as he understood only the dialect of his own country, he concludes that the Coptic version existed before the middle of the third century. Ludovici Picaus, or Louis Picque, who was acquainted with the Coptic language, refers this version to the fifth century. See Mill's Prolegomena, 1759.

The readings of the Coptic have a striking affinity with those of the Latin version, and sometimes with those of the Codex Cantabrinus. The story of the adjectives is found in some copies, and omitted in others; but 1 John v. 7. is omitted in all. Wettstein has also observed, that the Coptic New Testament has a very great similarity to the quotations of Origen, Eusebius, Cyril, and to the Alexandrine manuscripts. The best accounts of the Coptic version are given in Simon's Histoire Critique des versions du Nouveau Testament, ed. 12.; in the Preface to Wilkins's edition of the Coptic New Testament; in Le Long's Bibl. Sacr. ed. Mafch. P. ii. vol. i. p. 10.; and particularly by the learned Weide, in a German daily printed in 1778, in vol. iii. of the Kielische Beytrage, p. 1—10. See Coptic.

article. His second argument is deduced from a Sahidic MS., which is probably of the second century, and which contains various passages both of the Old and New Testament, coinciding with some of the fragments of the Sahidic versions. His third argument is founded on an apparent coincidence of some passages in the fragments, with a manuscript containing two books of the fabrication of the Gnostics, and evidently written in the second century. It appears then, if no objections can be made to these arguments, that proofs may be alleged of a higher antiquity in favour of the Sahidic version than can be produced in favour of any other version of the New Testament; and it must of course be of the greatest importance in the criticism of the Greek Testament. At the same time it must be acknowledged, that the oldest historical evidence for the high antiquity of an Egyptian version is that of Epiphanius and Theodore; the former quoted by Semler in his "Apparatus ad Novi Testamenti interpretationem," p. 64.; the latter by Wilkins, in the "Prolegomena" to his Coptic New Testament, p. 6. From an examination of the various readings furnished by the above-mentioned fragments, it appears, that the story of the adulteress, John vii. 1-12, is not among them; in the Acts of the Apostles, ch. xxv. 28. the Sahidic version coincides with those Greek MSS. which have extem, not in, i Tim. iii. 16. they coincide with those which read ο in stead of η, and 1 John ch. v. has the sixth and eighth verses; but the seventh, which contains the testimony of the three heavenly witnesses, is absent. We have an account of the Sahidic version of the New Testament in "Friedrich Münsteri Commentarii de indole versionis N. T. Sahidice," Hafniæ, 1789, 4to. to which are annexed some fragments of the New Testament from manuscripts in the possession of cardinal Borgiæ. Some fragments of the Sahidic version of the gospels of St. Matthew and St. John have been likewise published by Mingarelli in his "Ægyptiorum codicum reliquiae, Venetiarum in bibliotheca Namana afferentes," Bonon, 1785, 4to. MSS. or rather fragments of MSS. of the Sahidic version of the New Testament are preserved in the libraries of Rome, Paris, Oxford, Berlin, and Venice.

Bibles, Ethiopic. The Ethiopians have also translated the Bible into their language. Chrysoflos, cited by Michaelis, says, that the Ethiopians had in his time a version of the Bible; but his evidence is unsatisfactory. Ludolf, in his history of Ethiopia, relates, that the Scripture was translated into that idiom of the Ethiopian language, which was at that time more peculiar to the inhabitants of Tigre, from the Greek version of the LXX, according to a certain copy used in the church of Alexandria, which the innumerable various readings that are inserted in the English Polyglott Bible from one of the same copies, plainly prove. As for the author, and time of the translation, he is unable to ascertain either; but he notes its being at the time when the Habefians, or Abyssinians, were converted, or soon after, and that it was gradually perfected. Mr. Bruce, in his "Travels," vol. i. p. 490, says, that the Abyssinian copy of the Holy Scriptures was, in Mr. Ludolf's opinion, translated by Frumentius, a bishop in the 4th century, who first preached Christlianness in Ethiopia; but Ludolf has left the matter undecided. See Hilt. of Ethiopia, p. 262 ed. 1682. Mr. Bruce himself inclines to this opinion. They divide the Old Testament, says Ludolf, containing 46 books, into four principal parts, and mix the apocryphal with the canonical. Walton, (Proleg. vol. i. p. 100.) says, that Gaulmin had an ancient MS. of the whole Ethiopic Old Testament, which was deposited in the royal library of Sweden. Mr. Bruce informs us, (vol. i. p. 489.) that he brought with him a copy of the Ethiopic version of the O. T. which he has deposited in the British Museum; but it does not appear that he brought a copy of any part of the New. Indeed, he says, (vol. i. p. 493.) that copies of the whole N. T. are in that country very scarce; that, except in the churches, he had never seen a single MS. which comprehended all the parts of it; and that even the transcripts of the Gospels were in the hands only of men of the first distinction. The Ethiopic version of the N. T. contains the whole of it, divided, according to Ludolf, into four separate parts, viz. the Gospels, the Acts, the fourteen Epistles of St. Paul, and the seven Catholic Epistles. The Apocalypse is added as an appendix, and entitled "Abukalams." Scaliger refers the Ethiopic version to the time of Justinian, at which period he dates the conversion of the Abyssinians: but Walton refers it to a much earlier period, and not far distant from the times of the Apostles. Whichever was the translator of it, it appears to have been taken immediately from the Greek: from the frequent confutation of words which found alike in the Greek, but which have not been confounded by any other translator, and from its agreement in many of its readings with the Alexandrine MS. and with the quotations of Origen. Neither of these circumstances can appear extraordinary, as it was natural for the inhabitants of Abyssinia to procure their copies of the Greek Testament from Egypt. The translation of the Gospels is much superior to that of the Epistles. This version was first published at Rome, in 1548 and 1549, under the pontificate of Paul IV. But the editors, who were natives of Ethiopia, had a very imperfect MS. of the Acts, the chains of which they were obliged to supply from the Vulgate. To this purpose, Ludolf observes, that the Acts of the Apologists, for the most part, were translated at Rome, out of the Latin and Greek, for want of the Ethiopic original. This original seems to have been the source from which our editions of the Ethiopic version of the N. T. have flowed; and it is probably preferred in the Vatican, though, it has not yet been described. Walton reprinted this Roman edition in the London Polyglott; but his copy, being in some places illegible, the editors filled up the deficiencies according to their own judgment, so that the Roman edition retains the same value, as if no other were extant. The Latin translation was made by Dudley Loftus, and corrected by Calfell; but it is of little worth, and has led Mill, and other collectors of various readings, into error. A more accurate Latin translation of the Ethiopic version has been published by professor Bode, under the following title, "Novum Testamentum ex versione Ethiopic: Interpretis in Bibliothecis Anglicanis editum, ex Ethiopic: lingua in Latin: translatum," Brunswick, 1752, 1755. 2 toms. 4to. The best extracts from the Ethiopic version, says Michaelis, are, and must be uncertain, because we have no accurate impression of the version itself; however, his editor (Dr. Marshall) observes, that if the Ethiopic version was made immediately from the Greek, and in an early age; if its readings coincide with the quotations of Origen, and the Greek MSS. of the Alexandrine edition, it seems to be entitled to the same privileges, as other versions of equal antiquity. The principal objection applies not so much to the version itself, as to our printed text, which is probably incorrect, as not being the result of a collation of different MSS. But the same objection may be made to the old Syriac version, in which, though various MSS. have been used since the original edition of Widmanstadt, the alterations that have been made deserve rather the name of corruptions than of improvements. Of all the books of the O. T. there never was any printed, but the Psalms and the Song of Solomon, in the Ethiopic language at Rome, in 1513; at Colona, in 1518; and since that time, with
There is a very ancient Armenian version of the whole Bible, done from the Greek of the LXX, by some of their doctors, about the time of St. Chrysostom. See Armenian version. The first printed edition of the Armenian version was published in the 17th century by Ufean, bishop of Erivan; because the Bible was at that time become scarce in Armenia, that a single copy cost 1200l. Hence a council of Armenian bishops assembled in 1662, ordered the Bible to be printed in Europe. Accordingly, three distinct editions were printed at Amsterdam; the first in 1665, containing both the O. and N. T. in 4to; a second, in 1668, including only the N. T. in 8vo., and a third, in 1698, in 12mo. The two first were printed under the direction of Ufean; but the last is the most beautiful edition. A complete description, particularly of the first of these editions, is given in Le Long. Bib. sacra, ed. Machi. P. II, vol. i. p. 172—176. 180. A lift of Armenian MSS. of the N. T. is given in Dr. Boerner's edition of this work, p. 176; or, vol. i. p. 138, of the Paris edition of 1723; see also vol. i. p. 76, of the Catalogus MSS. Bib. Regiae, and note 11 to 13. chap. vii. of Marsh's Michaelis. La Croze and G. Whiston have accused the editor of the above-mentioned edition of having corrupted, in some places, the Armenian text. It is certain, however, says Michaelis, that John v. 7, was not in his MS.; for Sardus declares that he had seen the MS. from which the Amsterdam edition was printed, and that it wanted that verse. Sardus, in the place referred to by Michaelis, speaks of one ancient MS. which he had seen, in possession of the bishop of the Armenian church, and which had been collated at Amsterdam, in which this passage did not occur. It is possible, however, and even probable, that Ufean had more than one MS., and the words of Sardus do not imply that. Nevertheless, we have positive evidence, that Armenian MSS. written before the time of the council at Ccez, in 1308, have not this verse. In the manner, John v. 4, is wanting in the Armenian MS. but inserted in Ufean's edition; and Le Croze observes, that Ufean himself acknowledges, in his preface, that he had altered some passages, from the Vulgate; and, as he candidly allows, with an intention to deceive, but from ignorance and supererogation.

Bible, Georgian. The Georgian version was first printed at Moscow, in 1645, fol. and a description of it is given by the learned Echirchos, in his "Allgemeine Bibliothek," or Universal History of Biblical Literature, vol. i. p. 153—169. From the description it appears, that the Georgian text was altered from the Slavonic, in the edition of Moscow, and it would therefore be of little value, if the criticism of the N. T. Two MSS. of the Georgian version of the Gospels are preserved in the Vatican. See Le Long, Bib. Sac. tom. i. p. 140, ed. Paris, 1724.

Bible, Persian. Some of the Fathers seem to say, that all the Scripture was formerly transliterated into the language of the Persians; but we have nothing now remaining of the ancient version, which was, certainly, done from the Septuagint. The Persian Pentateuch, printed in the London Polyglott is without doubt, the work of Rabia Jacob, a Persian Jew, summoned Tavmon, Tavunis, or Tadmon, from the city Tus, where the Jews had a famous academy. It was transliterated from the Hebrew text, for the use of the Jews, who lived in Persia, and printed in the Hebrew character, with the Hebrew text, and with the version of Okehod and Sada, at Constantinople, in 1551. From the collection of this, and other versions, we may derive a satisfactory explanation of the famous prophecy of Jacob concerning the advent of the Messiah, unperverted by the glosses of the Rabbis. We have likewise two Pericope versions of the four Gospels, of which the most ancient, and that which is of course the most valued by the learned, is printed in the London Polyglott, accompanied with a Latin translation by Dr. Sam. Clarke, and notes by Dr. Thomas Gresaves, contained in the appendix. This Pericope version of the four Gospels, which is the only part of the N. T. hitherto printed, was taken from a MS. in the possession of Dr. Pococke, and written in the year 1541, as appears by a declaration annexed to it. A new Latin translation has been published by professor Dods, at Heilsstadt, in 1730, 1751, with a preface containing historical and critical remarks on the Pericope version. Dr. Gresaves has very justly observed, that the Pericope is a translation of the Syriac, for it sometimes retains even Syriac words, and subjoins a Pericope interpretation; and in other places, confounds the meaning of words, that have a similar found only in the Syriac. This is likewise probable in itself; for the Christians, who lived scattered in the Persian empire, made use of Syriac as the language of the church, and as the language of literature; and it was common for the Persians to study in the schools of Syria, especially at Edessa. The principal use then of the Pericope version is in discovering the false readings that have crept, since that period, into the Syriac. It might be added, that the Pericope omits passages, that are wanting in no MS. or version except the Syriac; as Mat. xxviii. 46. Mark vii. 34. There is another Pericope version of the Gospels, which Abraham Wheelock began to print in 1653, and which was published after his death by Pierion, in 1657. It was published in London, and three MSS. were used by the editors. Walton, in his "Prolegomena," vi. 9, p. 102, informs us, that he knew of only three MSS. of the Pericope Gospels, one in the possession of Dr. Pococke, which he used, and the other two in the libraries of Oxford and Cambridge, different from the other, and less ancient. If this be the case, Wheelock must have used MSS. containing distinct versions, and his text must be of a mixed nature, and of less value in that respect, as well as in point of antiquity, than that of the Polyglott. Wheelock, or rather Pierion, whose name is prefixed to the second title-page, was of opinion, that this Pericope version was made from the Greek, but Roumou believed it to have been taken from the Syriac. Walton mentions two Persian versions of the Psalms, that were made in the 17th century from the vulgar Latin.

Bible, Gothic. It is generally said, that Ulphilus, a Gothic bishop, who lived in the fourth century, made a version of the whole Bible, for the use of his countrymen. Philogoria (Hist. Eccles. i. c. 5.) affirms, that Ulphilus omitted the book of Kings, from an apprehension, that the moral spirit of his nation might be injured by the relation of the Jewish wars; yet this opinion has been confuted by Kaestel, in his learned commentary, p. 253. Michaelis, who was once a strenuous advocate for the opinion, that this was a Frankish version, has since changed his mind, and, in the later edition of his Int. to N. T. vol. ii. p. 130, ed. Marth, expresses his conviction, that it was Gothic. For an account of the author, see HILPERINUS; and to the account already given of this version under the article RENMESSUS CODES, we shall here subjoin the following particulars. From the martyrology of Nicea, preferred by Simeon Metaphrastes, it appears, that the version was made immediately from the Greek. Besides, independently of that evidence, it is natural to conclude, that a native Cappadocian, who was bishop of a nation in the neighbourhood of Constantinople, and was sent ambassador to the Greek emperor, would translate from the original Greek, with which he was much better
In the Gospels it agrees with the Codex Stephani more frequently than with any other Greek MS. In the Catholic epistles it agrees, in general, with the Codex Alexandrinus, and frequently in the Revelation. In the Acts and in the Epistles of St. Paul, it agrees, in general, with the most ancient MSS. but sometimes with one, sometimes with another, yet most frequently with Wetstein's Codex E. Of the readings adopted by Griesbach in the text of his Greek Testament, the Slavonian version has at least three-fourths. Where the united evidence of ancient MSS. is against the common printed reading, the Slavonian version agrees with the ancient MSS. It has not been altered from the Vulgate, as some have supposed, though the fact is itself almost incredible. It varies from the text of Theophylact, in as many instances as they agree; and their coincidence is to be ascribed, not to an alteration from Theophylact, but to the circumstance, that both Theophylact and the authors of the Slavonian version used the Greek edition. The Slavonian version has few or no readings peculiar to itself, and what the critics call "lectiones singulares."

**Bible, Spanish.** There are two translations of the Bible into this language: one done by the Jews, from the Hebrew, and first printed at Ferrara, in 1553, and at Amsterdam, in 1661; the other by Cañadore Reyna, printed at Basil, in 1569. A corrected edition of it was printed at Amsterdam, in 1602, and at Frankfort, in 1622. This translation was made from the Hebrew, or rather from the version of Paganus, and the New Testament from the Greek. There is a translation of the N.T. in Spanish done by Francis Enzinas, and dedicated to Charles V. of which there are several editions; and another different Spanish translation of the N.T. printed in 1596.

**Bibles, Italian.** There are four Italian versions: the first towards the close of the 13th century, by James de Voragine, archbishop of Genoa, who translated the whole Bible into Italian, from the Vulgate; which ancient version is quite lost; the second by Bruciolus, in 1530, who translated the Bible from the Hebrew, or rather from the version of Paganus, and dedicated it to Francis I. king of France; the third by Malherbi, a Venetian and Benedictine monk, abbot of St. Michael de Lemo, translated from the vulgar Latin towards the end of the 15th century; the first edition of which was published in 1471; one of them, in 1477, revised by friar Martin, a Dominican; and afterwards printed at Venice in 1541; and the 4th by Diodati, a Protestant, which is much esteemed, and has been often printed. This edition, which was conformable to the French edition of Geneva, was first published in 1607, and again a second time in 1641. The New Testament was translated by father Zachary, a Dominican friar of Florence, and printed apart at Venice, in 1542. An Italian edition of the Epistles and Gospels was printed in 1583.

**Bibles, French.** The most ancient translation of the Bible into French is that of Guiards de Moulins, a canon of St. Peter d'Aire, in the dioceze of Tournai, who was employed in translating the historical books of the O. and N.T. from the year 1291 till 1294. Of this translation there are several editions in the Paris library. Some historians affirm that Charles V. king of France, caused the Bible to be translated into French by Nicholas Orefme, superior of the house of Navarre, and doctor of Paris. These, and some other translations of parts of the Bible, are extant in MS. in the Paris library. The first French Bible was printed by order of Charles VIII. and dedicated to him, and consequently before the year 1498; being the translation of Guiards de Moulins. The New Testament was printed in French by Cochin, printer of Paris, in 1523. But
the first edition of the whole Bible, translated from the vulgar text into French, was published, in 1560, at Noyon, by Martin Lepetereau, with the preface by Charles V. The first edition of this Bible, in 1560, is in the Paris library; and the second, in 1564, which is larger, is extant in the libraries of St. Gemery de Bea, and of St. Genevieve. These two editions, that of Robert Olivétan, the first published by the Protos, in 1555. The translation above-mentioned was printed the third time at Antwerp, in 1560, and is preserved in the Protos’ library of the college of Louis le Grand. This translation was revised by the clergy of Louvain and was the foundation of all the French Bibles that have been published either by the Catholics or Protestants. The text is that of Robert Olivetan, a Fleming of Calais, who has copied the Antwerp translation, and merely corrected such passages as differed from the Hebrew text. A new edition was given by Calvin, which comes nearer to the vulgar Latin; and of this Bible many editions were published between the years 1560 and 1561. In 1560 was published a new edition of the Bible, revised by Theodore Beza. In the following year another French translation of the Bible, from the Latin version of Diodati, was published, and held for some time in estimation by the Calvinists. In 1566, the Geneva translation was again corrected, and rendered more conformable to the Hebrew and Greek text. This was revised by Molitor, Delfantins, ministers of Geneva, and printed with notes at Amsterdam, in 1669. In the year 1555, Sebastian Catalano published another French translation of the Bible from the Latin, the style of which is affected and offensive.

A reformation of the French Geneva Bible, by Renatus Benedict, professor of divinity in the college of Navarre, was published in 1566. This was condemned by a brief of Gregory XIII. in 1575. A new edition was undertaken some time after, altogether conformable to the Latin, and free from the errors of the Calvinists, by the doctors of Louvain, who followed the old Antwerp translation, and that of Olivetan, which they corrected: which was printed by privilege from the king of Spain, and under the sanction of the licencé of the prefect at Antwerp, in 1575; at Lyons, in 1575; and in several other places. The subsequent Bibles were for some time copies of the Louvain edition, with some corrections; such were that of Peter Bess, printed at Paris, in 1563, and that of Peter Frison, printed at Paris, in 1562. Corbin’s Bible, printed in 1564, and approved by the doctors of Pothecars, recedes more than the rest from the Bible of Louvain, and adheres more closely to the literal sense of the vulgar Latin. A new version of the diction of Louvain, revised and corrected accordantly to the text of the ancient Vulgate, was published by father Veron, in 1647, and dedicated to the clergy of France. The translation of Albert de Marrella, is done from the Greek text, and the version of Erasmus, and was first published in 1650, again in 1651, and a third time in 1652. The edition of the N. T. called the edition of Mons, was published in 1667, under the name of Jaques Migeon, printer at Mons. Father Amelot’s translation of the N. T. was first printed at Paris, in 1666. Godin’s translation was printed at Paris, in 1668. The whole Bible was also translated by Isaac de Maître, of Sacy, from the Vulgate, and partly published in his life, and afterwards continued by Peter Thomas, lord of Fosse. Du Queule’s translation of the N. T. differs little from that of Mons, otherwise than by being more conformable to the vulgar Latin. Father Bouhallon has also published a translation of the N. T. and many others have in later times translated either the whole or various parts of the Bible.

**Bibles, German.** Luther’s translation of the Bible into German, was done with the assistance of Martin, and other of his disciples, the Old Testament from the Hebrew, and the New from the Greek, in 1524, and the publication of it, in several succeeding editions, very much contributed to the progress of the reformation. This was followed by a German translation by Jeron Emser, a Catholic, who in his notes criticizes that of Luther; and by another translation, done by John of Dittenberg, from the vulgar Latin, in opposition to that of Luther. Luther’s edition, revised by the Zwinglians and Calvinists, in various editions, was published at Nuremberg in 1528, and at Worms in 1535, to the dissatisfaction of the Lutherans. The German translation of Paul Eber, a Lutheran, was printed at Wittenberg in 1534, and German translations were also printed by Leon Juda, and John Pifcator, both Calvinists. A new translation in German, by Jasper Ulenberg, a Catholic, not to mention many others, was printed at Cologne in 1650, and was much used in Germany.

**Bibles, Flemish.** The Catholics in the Netherlands had several Flemish translations of the Bible in the 16th century. One was printed in 1548, which was translated by Nicholas Van Wijngaerdt, who says that he followed a Flemish translation printed in Holland 70 years before, i.e. long before the reformation. This Bible was revised by the doctors of Louvain, and printed afterwards at Antwerp in 1599, and often since. The Protentants in the Low Countries had for a long time only a translation made after the German Bible of Luther, till in pursuance of an order issued by the synod of Dort, in 1618, they had a new translation printed in 1637, exactly conformable to the Hebrew text of the Old, and the Greek of the New Testament. The Arminians, dissatisfied with this, made another Dutch translation from the Greek, which was printed at Amsterdam in 1680.

The northern nations, who embraced the doctrines of Luther, have no other translations of the Bible besides those done in the vulgar tongue after the German of Luther. The Swedish translation was made by Laurence Perri, archbishop of Uppsal, a disciple of Luther, and printed at Stockholm in 1646. The Danes have also one in their language, published in 1654, and since revived and reprinted in 1693. There is also a translation of the Bible in the Icelandic tongue, which seems to be the ancient language of the Norwegians or Goths: and another Finnish translation in 1648. The Laplanders have also the Psalms, and some other books of the Bible, translated into their own language. In the Polish language, the Socinians have a Bible printed in 1563, and they have likewise a Polish Bible in Lithuania, printed in 1652, done from the Greek and Hebrew by Simon Budd. Sand also mentions a translation of the New Testament by Martin Czeczowicz, a Socinian, printed with notes in 1577. Pepe Gregory XIII. employed the Jesuit Vichi to make a new translation of the Bible in the Polish language, which was printed at Cracow in 1599, with the approbation of Clement VIII. The Bohemians have a Bible in their language, with notes, printed in Germany from 1572 to 1601. The Hungarians have a translation done by George Calai, a Jesuit, and printed at Vienna in 1626. They have also another more ancient, printed at Frankfurt in 1668, and at Oppenheim in 1612.

**Bibles, Indian.** A translation of the Bible into the North American Indian language, by Elliott, was published in 1610 at Cambridge, in 1615.

**Bibles, Saxon.** After the Saxon inhabitants of this country were converted to Christianity, we have reason to believe that they soon had the whole Bible in the characters of their own country, and that the four Gospels in the T

Vol. IV.
fame language were read in their religious assemblies. The whole scripture is said by some to have been translated into the Anglo-Saxon by Bede, about the year 701; though others contend that he only translated the Gospels; and others ascribe to him only the gospel of St. John.

We have certain books, or parts of the Bible, by several other translators; as, 1. The Psalms, by Aldhelm, bishop of Shireborn, contemporary with Bede, about the year 705; though by others this version is attributed to king Alfred, who lived near two hundred years after, and who is said by Mr. Fox to have translated both the Old and New Testament into his native language; and by others to have translated the greatest part of the New Testament; but the authority on which these assertions is too precarious to claim any great degree of confidence. On equally uncertain authority it has been said, that the whole Bible was translated into the Saxon language in the reign of Athelstan. Bale, however, “Script. Brit.” cent. 2. c. 27, cites the testimony of Malmesbury to this purpose; and archbishop Usher refers this to the year 950. Some books of the Bible were translated by Eadred, or Egbert, bishop of Lindisfarne, about the year 685, according to the conjecture of Mr. Sel- den. A celebrated version of the four Gospels in the Saxon language, said to be made by one Alfred, a priest, is reported to have been found in the celebrated code of bishop Eadred. Aldelin is said to have written a letter to Ead- fried, extant in “Wharton’s Autolium Hist. Dogm. Usherii,” p. 51; in which he exhorts him, for the common benefit and use of all people, to put the scriptures into the vulgar language, which Butler, in his book against the vulgar translation, says he did. And archbishop Usher, in his “Hist. Dogm.” c. 5, informs us, that the Saxon translation of the Evangelists, done by Eadred, without distribution of chapters, was in the possession of Mr. Rob. Bowyer. In the Cotton library is a book of the four Gospels, said by Wharton, in his “Anglia Sacra,” part i. p. 605, to be written by bishop Eadred himself, and which had been adorned with pictures, gold, and jewels, by Ethelwold, bishop of Winchester. Eadred, or Egbert, died in 721. But some have doubted the existence of such an Anglo-Saxon MS.

A version of the Psalms in Anglo-Saxon was published by Spelman in 1640. 2. The Evangelists, still extant, done from the ancient Vulgate, before it was revised by St. Jerom, by an author unknown, and published by Matth. Parker in 1571. This was printed from a MS. now in the Bodleian library, under the direction of archbishop Parker, by John Fox the martyrologist, with the following title, “The Gospels of the four Evangelists, translated in the old Saxon tongue out of the Latin into the vulgare tongue of the Saxons, and now published for the information of the same”; at London, by John Daye, 1571. This edition has a preface by John Fox, and is dedicated to queen Elizabeth. Another edition of this version was published at Dort in 1665, by Dr. Thomas Marshall, who tells us that he could ascertain neither his author nor age. An old Saxon version of several books of the Bible, was made by Elfric, abbot of Malmesbury, and afterwards, viz. 1299, by bishop of Canterbury; several fragments of it were published by W. Lilly, or W. L’Hote, in 1658, the genuine copy by Edw. Thomas, 1699, at Oxford.

Wm. L’Hote observes, on occasion of this publication, that if that good ordinance first enacted by God, Deut. x. 4, for the preservation of the book of the law, by keeping a copy of it in the ark, had been continued, and standard Bibles had been preferred in our cathedral churches, as it has been, since appointed by king Alfred, we might now have shewed the whole book of God, or the entire Old and New Testament in Saxon, which was the English of those times, translated both by that king, and the archbishop of Canterbury, Elfric. Elfric translated the Pentateuch, Joshua, Judges, Ruth, four books of Samuel, entitled in Latin, liber regum, a fifth book called Verba Dierum, or Chronicles, the Plasher, three books of Solomon, viz. Proverbs, Ecclesiastes, the chief of all fongs, the books of Wisdom and Ecclesiasticus, the prophets Isaiah, Jeremiah, Ezekiel, Daniel, the twelve Prophets, Ezra, Job, Tobias, Esther, Judith, and Maccabees. Hence we may conclude, with little doubt, that the books of the New Testament were before translated into Saxon, and commonly read in that language. The Pentateuch, Joshua, and Judges, of Elfric’s translation, are preserved, yeas Usher, in Cotton’s library; where is also a Plasher, with several hymns of the Old and New Testament, with the Apostles’ and Athanasian creed, with an English interlinear translation. The book appears, by a note at the end of it, to have been written in the year 1249. The Anglo-Saxon version, above-mentioned, is divided into sections, over each of which is placed a rubric, directing when it should be read; and this circumstance shows, that at this time the Holy Scriptures were read in the public four to the church in a language which the people understood. Various extracts from this version of the four Gospels were first quoted by Mill (Proleg. § 1462.), who took them from the papers of Marshall. With respect to its antiquity, the learned are not agreed: some have referred it to the sixth or seventh century, since Bede died A. D. 735, but others, more generally, to some part of the eighth century. For an account of the MSS. of the Anglo-Saxon version, see Le Long, Bibl. Sacr. tom. i. p. 422, 423, ed. 1725; and for a complete catalogue of Anglo-Saxon MSS. in general, Wanley’s Appendix to Hickes’s Theaurus, published at Oxford in 1705, folio. Lewis’s Hist. Eng. Transl. of the Bible, p. 5 &c.

Bibles, English. The first English Bible we read of was that translated by J. Wickliffe, about the year 1370, according to some, and 1360, according to others; but never printed, though there are MS. copies of it in several public and private libraries. The MS. of the Old Testament ending with the second book of the Maccabees, in St. John’s college Oxford, is said to have been written by Wickliffe himself. This circumstance, though expressed on the top of the leaf before Genesis, is very doubtful. This translation was made from the Latin Bibles then in common use, not because Wickliffe thought the Latin to be the original, or of the same authority with the Hebrew and Greek text, but because he did not understand those languages well enough, to translate from them. He likewise chose to translate word for word, as had been before done in the Anglo-Saxon translation, without observing the idioms of the several languages, so that this translation is in some places not very intelligible to those who do not understand Latin. Before the invention of printing, transcriptions were obtained with difficulty, and copies were so rare, that the price of one of Wickliffe’s English New Testament appears, from the registry of William Alnwick, bishop of Norwich, in 1429, to have been four marks and forty pence, or 21. 16s. 8d. This translation gave such offence, that a bill was brought into the house of lords, 13 Ric. II. A. D. 1509, for suppressing it. But by the opposition of the duke of Lancaster, the king’s uncle, the bill was thrown out of the house. Wickliffe’s followers were encouraged, by this favourable circumstance, to revive the translation of their master, or rather to make another not so literal and verbal, but more free and accommodated to the sense. The MS. copies of this translation are more rare than those of the other; but they are found in the Bodleian library, and in other libraries both of Oxford and Cambridge. J. de Treviri, vicar of Berkley in Gloucestershire, who died about
about the year 1538, is also said to have translated the whole Bible; but if this be true, it does not appear that any copies of his translation are now remaining. It is probable, that Trench merely translated certain sentences of the Bible, that occur in his writings, and some of which are said to have been painted upon the walls of the chapel in Brinkley castle. Another English translation has been erroneously ascribed to Reginald Pecock, bishop of Chichester, A.D. 1459, in consequence of his having translated some passages of Scripture, cited in his works. Rolla, archdeacon of Hampole in Yorkshire, who translated the Psalms about the year 1532, is supposed by Weaver, in his "Liturary Monuments," p. 151, to have been the translator of the New Testament, which translation was in reality Wickliffe's. Richard Fitz-Ralph, archbishop of Armagh, is said to have translated the Bible into Irish. He died in 1562. Dr. James, relying on a vague declaration of Sir Thomas More, in his account of the confiniments of Arundel, affirms, that the Bible had been twice translated into English; and that one of these translations is much more ancient (some hundred years) than Wickliffe's. But Lewis has shown this to be a mistake. (Hist. Eng. Trans. p. 43.) The zedolts of those times were alarmed by these English translations; and in order to prevent their increase, they urged the necessity of restoring the use of Latin Bibles; and to this purpose Chaucer represents the religions as collecting and debuting them in their libraries, and thus withdrawing them from secular priests and curates, and thus hindering them from preaching the gospel to the people. In 1537, when some secular priests were sent from the diocece of Armagh in Ireland, to study divinity at Oxford, they were obliged soon to return, because they were not able to purchase a Bible. Eneas Sylvius, afterwards pope Pius II. observed in 1548, concerning the Italian priests, that they did not seem to have ever so much as read the New Testament; and Robert Stephens, speaking of the Surbomits, five, that when they are asked in what place of the New Testament anything was written, they replied, that they had read it in Jerom, or in the Decrees, but what the New Testament was they did not know. (See Hody de Bibl. Textibus, p. 464.) Indeed, at that time, if copies of the Bible had been more frequent, the clergy were generally so ignorant as not to be able to read or understand Latin. The Latin Bibles were not only scarce, but much corrupted by the carelessness of transcribers, and the interference of profane critics. In 1547, Wickliffe's followers were become numerous, and copies of his English translation of the New Testament so common, that an English Bible was sold for 25s., whereas the price of a Portuguese, or breviary, was 6 marks. After the art of printing was introduced into England, Latin, Hebrew, and Greek Bibles, and particularly copies of the New Testament became more common; and accordingly a vear of Croydon in Surry, is said to have expressed himself to this purpose, in a sermon preach'd at Paul's Cross about this time: We must not put printing, or printing will root us out."
people; that the distribution of them, as to allowing or denying them, depended on the discretion of their superiors; and that, considering the malignity of the time, an English translation of the Bible would rather occasion the continuance, or increase of errors, than any benefit to their souls. Accordingly, the proclamation announced an intention of, if the present translation were abandoned, at a former reason, to provide that the Holy Scriptures should be given, learned, and catholic persons, translated into the English tongue, if it should then seem convenient. In the mean time, Tindal was busily employed in translating from the Hebrew into the English the five books of Moses, in which he was assisted by Miles Coverdale. But his papers being lost by shipwreck in his voyage to Hamburg, where he designed to print it, a delay occurred, and it was not put to press till the year 1532. It is a small work printed at different presses, and with different types. In the preface he complained, that there was not so much as one in his New Testament, if it lacked a little over its head, but it had been noted, and numbered to the ignorant people for an heresy, which were made to believe, that there were many thousand heresies in it, and that it was so faulty as to be incapable of amendment or correction. In this year he published an answer to Sir Thomas Mor's dialogue, containing his reason for the changes which he had introduced into his translation. The three former editions of Tindal's English New Testament being all fold off, the Dutch booksellers printed a fourth in this year, in a smaller volume and letter. In 1531, Tindal published an English version of the prophet Jonah, with a prologue, full of invectives against the church of Rome. Strype supposes that before his death he finished all the Bible but the Apocalypse, which was translated by Rogers; but it seems more probable that he translated only the historical parts. In 1534, was published a fourth Dutch edition, or the fifth in all, of Tindal's New Testament, in 12mo. In this same year, Tindal printed his own edition of the New Testament in English, which he had diligently revised and corrected; to which is prefixed a prologue; and at the end are the titles of the Old Testament, closing with the following advertisement, "Imprinted at Antwerp, by Marten Empeour, anno M.D. XXXIV." Another edition was published this year, in 1606, and printed in a German letter. Hall says, in his Chronicle, printed during the reign of Henry VIII. by Richard Grafton, the benefactor and friend of Tindal; "William Tindal translated the New Testament, and first put it into print; and he likewise translated the five books of Moses, Joshua, Judicium, Ruth, the books of Kings, and books of Paralipomenon, Nehemiah, and the first of Elisha, and the prophet Jonah; and no more of the Holy Scriptures." Upon his return to Antwerp, in 1531, king Henry VIII. and his council, contrived means to have him seized and imprisoned. After long confinement he was condemned to death by the emperor's decree in an assembly at Augsburg; and in 1536, he was strangled at Villefor, near Brussels, the place of his imprisonment, after which his body was reduced to ashes. He expired, praying repeatedly and earnestly, "Lord, open the king of England's eyes." Several editions of his Testament were printed in the year of his death. Tindal had little or no skill in the Hebrew, and therefore he probably translated the Old Testament from the Latin. The knowledge of languages was in its infancy; nor was our English tongue arrived at that degree of improvement, which it has since attained; it is not, therefore, surprising, that there should be many faults in this translation which need amendment. This, indeed, was a task, not for a single person, but requiring the concurrence of many, in circumstances much more favourable for the execution of it than those of an exile. Nevertheless, although this translation fell from being perfect, few skill, translations, says Dr. Geddes (Prospectus, p. 8.), will be found preferable to it. It is astonishing, says this writer, how little often the language of it is, even at this day; and in point of perplicity, and noble simplicity, propriety of idiom, and purity of style, no English version has yet surpassed it.

Bible, Coverdale's. In 1535 the whole Bible, translated into English, was printed in folio, and dedicated to the king by Miles Coverdale, a man greatly esteemed for piety, knowledge of the Scriptures, and diligent preaching; on account of which qualities king Edward VI. advanced him to the see of Exeter. In his dedication and preface, he observes to this purpose, that, as to the present translation, it was neither his labour nor his desire to have this work put into his hand; but "when others were moved by the Holy Ghost to undertake the cost of it," he was the more bold to engage in the execution of it. Accordingly, therefore, to define him, he set forth this "special" translation, not in contempt of other men's translations, or by way of reproving them, but humbly and faithfully following his interpreters, and that under correction. Of thes, he said, he used five different ones, who had translated the Scriptures not only into Latin, but also into Dutch. He farther declared, that he had neither walked nor altered too much as one word for the maintenance of any manner of sense, but had with a clear conscience purely and faithfully translated out of the foregoing interpreters, having only before his eyes the manifest truth of the Scripture. But because such different translations, he found, were apt to offend weak minds, he added, that there came more understanding and knowledge of the Scripture by these sundry translations, than by all the glosses of sophistical doctors; and he therefore defines, that offence might not be taken, because one translated "scribe," and another "lawyer," one "repeatence," and another "penance," or "amendment." This is the first English Bible allowed by royal authority; and also the first translation of the whole Bible printed in our language. It was called a "special" translation, because it was different from the former English translations; as Lewis has shewn (Hist. Eng. Transl. p. 98,) by comparing it with Tindal's. It is divided into fix tomes, adorned with wooden cuts, and furnished with Scripture references in the margin. The half page has these words: "Printed in the year of our Lorde M.D.XXXV. and finished the fourth day of October." Of this Bible there was another edition in a large 4to, 1556, which was re-published, with a new title, 1553 and third, according to Lewis, were all the editions of it. Coverdale, in his edition of the English Bible, prefixed to every book the contents of the several parts, and not to the particular chapters, which were afterwards the subject; and he likewise omitted all Tindal's prologues and notes. Soon after this Bible was finished, in 1536, lord Cromwell, keeper of the privy-seal, and the king's vicar-general and viceregent in ecclesiastical matters, published injunctions to the clergy by the king's authority, the extent of which was, that every parson, or proprietary of any parish church within this realm, should, before the fast of August, provide a book of the whole Bible, both in Latin and in English, and lay it in the church, for every man that would, to look and read therein; and should discourage no man from reading any part of the Bible either in Latin or English, but rather comfort, exhort, and admonish every man, to read it, as the very word of God, and the spiritual food of a man's soul, &c.

Bible, Matthew's, or Matthew's. In 1537, another edition of the English Bible was printed by Grafton and Whit.
BIBLE.

With their, at Hamburg, as timeilik, or, as other pressed at Milbrow, or Mayeng in Heff, or Marbock in the city of Wittenberg, where Tindal was superintended. It bane the name of Thomas Matthewes, and it was, in sight with the king's most gracious Ffence. Mr. Ward, in an opinion, that, to the end of the book of Chronicles, this name is Tindal's translation; and from there, to the end of prophecy, Coverdale's: but Lewis (1726, p. 327), it is probable that the prophecy of Jonah should be excepted, which Tindal finished in his lifetime, and which is the fame in this edition, and in Coverdale's Bll of 1535. Mr. Ward also observed, that the whole New Testament was Tindal's. Bake says, Rogers translated the Bible into English, from Genesis to the end of Revelation, using none of the Hebrew, Greek, Latin, Greek, and English (i.e. Tindal's) copies. This book contained Tindal's prologue and notes; and, as Hulin says (ibid. ed. 201, it was no other than the translation of Tindal and Coverdale form what altered. The name of Matthewes is allowed to have been fictitious, for reasons of prudence; one of which was, that the memory of Tindal had become odious to many. It may well be admitted, that John Rogers, a learned academic, and the first who was condemned to the flames in the reign of queen Mary, was employed by Cranmer to superintend this edition, and to furnish the few emendations and additions that were thought necessary. This must have been the general practice in 1535, as the preceding sentence preserved by Fox (Act. &c. vol. ii. 1535), is against Rogers, and his alleged Matthewes." Cranmer presented a copy of the book to Cranford, during his interview with the king for the royal licence, that it might be published and used by all. The king's seal was put on the title-page, and a great fire was burnt before the church doors, on the subject of this translation, expressing warm approbation and applause: "I doubt not," says he, "that the holy book, after this day, shall be safe, that it shall appear hereafter what high and excellent service you have done unto God and the king; which shall be most honorable to your cause, that, besides God's reward, you shall obtain perpetual memory for the same within this realm."—"The day you shall leave of at the great day, when all shall be opened and made manifest." In the year 1538, an injunction was published by the vice-chancellor of the kingdom, urging the clergy to provide, before a certain festival, on book of the whole Bible, of the largest volumes in English, and to put up in some convenient place within their churches, where their parishioners might come and read it. A royal declaration was also published, since the estate were to read the same in their several churches, informing the people, that it had pleased the king's majesty to grant and command the Bible, being translated by them, to be principally taught by them, and to be openly in all their private churches. But the creditors were very cool in this affair (fay Fox, ibid. p. 253), and read the king's declaration and letter with such a motion, that fearfully no body could know or, dare say, at the time. Johnson (Hist. Accor. &c. vol. ii. 1534, p. 934) tells, that they do not read the Bible publicly, and that they led their parishioners to believe they read, when they were compelled to re, "to do it they and in the church, and to love their children, the old."

Fox declares (Acts, &c. vol. ii. 516, that the last part of this book much offended Gardiner and his fellow bishops, both for the profane, and especially because there was a table in the book chiefly about the Lord's supper, the marriage of priests, and the.maid, which there was said yet to be found in scripture. Strype, however, says, (Life of Cranmer, p. 649), it was very, careful to see, with what this book was received, not only among these learned, and those who were noted lovers of the reformation, but generally all over England, among all the common people; and with what gladness God's word was read, and what respect there was to the places appointed for reading it. Every one that could, bought the book, and busily read it, or heard it read; and many elderly persons learned to read on purpose. During a vacancy in the fee of Hereford it was visited by Cranmer, who enjoined the clergy to procure, by the 3rd of August, a whole Bible in Latin and English, or, at least, a New Testament in these languages; to study every day one chapter of these books, conferring the Latin and English together, from the beginning to the end; and not to discourage any layman from reading them, but encourage them to it, and to read them for the reformation of their lives and knowledge of their duty. In the course of the year 1538, a quarto edition of the New Testament, in the vulgar Latin and Coverdale's English, bearing the name of Holyhunde, was printed, with the king's licence, by James Newton. Of this another more correct edition was published 1539, in 8vo., and dedicated to Lord Cromwell. In 1538, an edition in 4to. of the New Testament, in English, with Erasmus's Latin translation, was printed, with the king's licence, by R. Dina. In this year it was resolved to reissue Matthewes's bible, and to print a correct edition of it. With this view Grafton went to France, where the workmen were more skillful, and the paper was both better and cheaper than in England, and obtained permission from France. I, at the request of King Henry VIII., to copy his Bible at the expense of the French government, notwithstanding the royal licence, the Inquisition interfered, and issued an order, dated December 17, 1538, preventing the French printers, their English employers, and Coverdale the corrector of the work, and prohibiting them to proceed; and the injunction, consisting of 2500 ovals, was fixed, confused, and condemned to the fire. Some sheets, however, of these books escaped the fire, by the assiance of the person who was appointed to superintend the burning of them; and the English proprietors, who had fled on the first alarm, returned to Paris, as soon as it subsided, and not only recovered some of these copies, but brought with them to London the proofs, types, and printers, and, resuming the work, finished it in the following year.

BIBLE, Cranmer's, or the Great. As soon as the papal power was abolished in England, and the king's supremacy settled by parliament in 1534, Cranmer was very anxious in promoting translations of the Holy Scriptures into the vulgar tongue; well knowing how much the progress of the reformation depended upon this measure. Accordingly, he moved in convocation, that a petition should be presented to the king for leave to procure a new translation of the Bible. This motion was vigorously opposed by Gardiner, bishop of Winchester, and his party; but Cranmer prevailed. The arguments for a new translation, urged by Cranmer, and echoed by one Anne Boleyn, who had then great interest in the king's affections, were so much considered by him, that, notwithstanding the opposition, public and private, on the part of Gardiner and his adherents, Henry gave orders for setting about it immediately. To prevent any revocation of the order, Cranmer, whose mind was intent on introducing a free use of the English Scriptures by faithful and able translatours, proceeded without delay to divide an old English translation of the New Testament into
B I B L E.

Nine or ten parts, which he caused to be transcribed into paper-books, and to be distributed among the most learned bishops, and others; requiring that they would perfectly correct their respective portions, and return them to him at a limited time. When the allained day came, every man sent his appropriate portion to Lambeth, except Stedley, bishop of London. This laudable design of the archbishop failed; but the business was executed by other persons, whom he engaged and encouraged, as we have already stated in the preceding articles. In April 1539, Grafton and Whitchurch printed the Bible (called the "Great Bible") in large folio, "cum privilegio ad imprimitum forum." A beautiful frontispiece, designed by Holbein, and particularly described and exhibited in an engraving by Lewis, p. 122, &c. was prefixed to it: and in the text, those parts of the Latin version, which are not found in the Hebrew or Greek, are inserted in a smaller letter; such, for instance, as the three verses of the 14th psalm, which are the 5th, 6th, and 7th, in the translation of the English liturgy, and the controverted words, 1 John v. 7, 8; and a mark is used to denote a difference of reading between the Hebrew and Chaldee, afterwards explained in a separate note. In this edition Matthew's Bible was revised, and several alterations and corrections were made in the translation, especially in the book of Psalms. Tindal's prologues and notes, and the notes added by others, in the edition of 1537, were wholly omitted. Pointing hands, placed in the margin and in the text, shew the passages on which these notes were to have been written. Johnfon (ubi supra, p. 76.) calls this third edition of the Scriptures the Bible in the large or great volume, ascribes it to the year 1539, and supposes it to have been the same which Grafton obtained leave to print at Paris. He says, that Miles Coverdale compared the translation with the Hebrew, mended it in many places, and was the chief director of the work. Agreeably to this, Coverdale, in a sermon at Paul's cross, defended his translation from some slanderous reports which were then raised against it, confessing "that he himself now saw some faults, which, if he might review the book once again, as he had twice before, he doubted not he should amend; but for any hereby, he was sure that there was none maintained in his translation." This is related by Dr. Fulk, who was one of Coverdale's auditors. A second edition of this Bible seems to have been printed either this or the next year, by Edward Whitchurch; but the copy is imperfect and has no date.

In the course of the year 1539, another Bible was printed by John Byddell, called "Taverner's Bible," from the name of his conductor, Richard Taverner, who was educated at Christchurch, Oxford, patronized by lord Cromwell, and probably encouraged by him to undertake the work, on account of his skill in the Greek tongue. This is neither a bare revision of any English Bible fully delivered, nor a new version; but a kind of intermediate work, being a correction of what is called "Matthew's Bible," many of whose marginal notes are adopted, and many omitted, and others inserted by the editor. It is dedicated to the king. After the patron's death, Taverner was imprisoned in the Tower for this work; but he had the address to reinstate himself in the king's favour. Wood (Hist. et Ant. Univ. Oxon. fol. 1674. 1. l. p. 264.) gives a particular account of Taverner; attributes his imprisonment to the influence of those bishops who were addicted to the Romish religion; and informs us, that his version was read in churches by royal authority. In November 1539, the king, at the intercession of Cranmer, appointed lord Cromwell to take special care that no person, within the realm, should attempt to print any English Bible for five years, but such as should be admitted by lord Cromwell; and affirms this reason for the prohibition, that the Bible should be considered and perused in one translation in order to avoid the manifold inconveniences to which human frailty might be subject from a diversity of translations, and the ill use that might be made of it. In the year 1540, two privileged editions of the Bible, which had been printed in the preceding year, issued from the press of Edward Whitchurch. Lewis mentions three other imperfections of the "Great Bible," which appeared in the course of this year; two printed by Whitchurch, and one by Petry and Redman. Cranmer wrote a preface for the editions of the year 1540, from which we learn the opinions and practice of that time. In May of this year, the curates and parishioners of every parish were required, by royal proclamation, to provide themselves with the Bible of the largest volume before the feast of All Saints, under the penalty of 40l. for every month during which they should be without it. The king charged all ordinaries to enforce the observance of this proclamation; and he apprized the people, that his allowing them the Scriptures in their mother-tongue was not his duty, but an evidence of his goodwill and liberality to them, of which he exHORTed them not to make any ill use. In May 1541, one edition of Cranmer's Bible was finished by Richard Grafton; who, in the November following, completed also another Bible of the largest volume, which was superintended, at the king's command, by Tindal, bishop of Durham, and Heath, bishop of Rochester.

In consequence of the king's settled judgment, "that his subjects should be nurtured in Christ by reading the Scriptures," he again, on the 7th of May, published a brief, or decree, for setting up the Bible of the great volume in every parish church throughout England. However, this decree appears to have been very partially and reluctantly observed; and the bishops were charged, by a writer in 1546, with attempting to suppress the Bible, under pretence of preparing a version of it for publication within seven years. After the death of Cromwell in 1540, the bishops inclined to popery gained strength; and the English translation was represented to the king as very erroneous and heretical, and destructive of the harmony and peace of the kingdom. In the convocation, assembled in Feb. 1542, the archbishop, in the king's name, required the bishops and clergy to revise the translation of the New Testament, which, for that purpose, was divided into fourteen parts, and portioned out to fifteen bishops; the Apocalypse, on account of its difficulty, being assigned to two. Gardiner clogged this business with embarrasing instructions; and Cranmer clearly perceiving the resolution of the bishops to defeat the proposed translation, procured the king's consent to refer the matter to the two universities, against which the bishops protested; but the archbishop declared his purpose to adhere to the will of the king his master. With this, the contest of the bishops terminated; and the convocation was soon after dissolved. The Romish party prevailed also in parliament, which enacted a law that condemned and abolished Tindal's translation, and allowed other translations to remain in force, under certain restrictions. After the paffing of this act, Grafton, the king's printer, was imprisoned; nor was he released without giving a bond of 300l. neither to print nor sell any more English Bibles, till the king and the clergy should agree on a translation. In 1544, the Penticrouch was printed by John Day and William Seres; and in 1546, the king prohibited by proclamation laying and reading Wickliff's, Tindal's, and Coverdale's translations, and forbade the use of any other than what was allowed by parliament.
BIBLE.

From the history of English translations, during the reign of Henry VIII. we learn, that the friends to the reformations conducted themselves with zeal and prudence in the great work of introducing and improving English translations of the Bible; that they encountered many difficulties from the dangerous inconstancy of a despotic prince, and from the invidious prejudices of a strong Romish party; and that the English scriptures were sought after and read with avidity by the bulk of the people.

Upon the accession of Edward VI. the severe Stat. 34 & 35 Henry VIII. c. 1, was repealed, and a royal injunction was published, that not only the whole English Bible should be placed in churches, but also the paraphrase of Erasmus in English to the end of the four Evangelists. It was likewise ordered by this injunction, that every parson, vicar, curate, &c. under the degree of a bachelor of divinity, should publish the New Testament, both in Latin and English, with the paraphrase of Erasmus upon it, and that the bishops, &c. in their visitations and excommunications should examine them, how they had professed in the study of the Holy Scriptures. It was also ordered, that the epistle and gospel of the mass should be read in English; and that on every Sunday and holiday, one chapter of the New Testament in English should be read and distinctly read at matins, and one chapter of the Old Testament at evensong. But, in the year 1549, when the book of common prayer, &c. was published, what nearly resembles our present custom was enjoined, that after reading the Psalms in order, morning and evening prayer, two lessons, the first from the Old Testament, and the second from the New Testament, should be read distinctly with a loud voice. During the course of this reign that is, in less than 7 years and 6 months, eleven impressions of the whole English Bible were published, and 6th of the English New Testament, before an English translation of the whole New Testament, paraphrased by Erasmus. The Bibles were reprinted, according to the preceding editions, by Bishop Coverdale, Matthew's, Cranmer's, and Taverner's; that is, with a different text, and different notes. But it is doubted by the writer of the preface to King James's translation, whether there were any translation, or correction of a translation, in the course of this reign.

In 1562, the "Great Bible," viz. that of Coverdale's translation, that had been printed at the time of Henry VIII. and also in the time of King Edward, was reviewed by archbishop Parker, and reprinted for the use of the church; and this was to serve till the end of his reign, by his grace was ready for publication. See Bible p. 6. Bible, Geneva. Many of the principal reformers having been driven to Geneva, during the persecutions of Queen Mary's reign, they published, in 1557, an English New Testament, printed by Conrad Badius; the first in our language which contained the divisions of verses by numerical figures, after the manner of the Greek Testament, which had been published by Robert Stephens in 1551. R. Stephens indeed, published his book in the margin; whereas the Geneva editors prefixed them at the beginning of minute subdivisions with breaks, after our present manner. When Queen Elizabeth passed through London from the Tower to her coronation, a page was entitled in Cheshunt, representing Time coming out of the East, and taking a person clothed in white silk, who represented Truth, his church, Truth had the English Bible in her hand, on which was written "Verbum verum." Truth addressed the queen, and presented her with the book. She kissed it, held it in her hands, laid it on her breast, greatly thanked the king for their present, and added, that she would often and diligently read it. Upon a royal visitation in 1559, the Bible, and Erasmus's paraphrase, were referred to churches; and articles of enquiry were exhibited whether the clergy discouraged any from reading any part of the Scriptures. "Ministers were also enjoined to read every day one chapter of the Bible at least; and all who were admitted readers in the church were daily to read one chapter at least of the Old Testament, and another of the New, with good admonition, to the encrease of their knowledge."

During this year, the exiles at Geneva published the book of Psalms in English, with marginal notes, and with a dedication to the queen, dated February 10. In 1560, the whole Bible in 4to. was printed at Geneva by Rowland Hare; some of the refugees from England continuing in that city for this purpose. The translators were bishop Coverdale, Anthony Gilby, William Whittingham, Christopher Weedman, Thomas Sampson, and Thomas Cole; to whom some add John Knox, John Beilking, and John Pullum; all zealous Calvinists, both in doctrine and discipline; but the chief and the most learned of them were the three last. Prefacing to observe the sense, and to adhere as much as possible to the words of the original, and in many places to preserve the Hebrew phonoology; after the labour and industry of two years and more, day and night, they finished their translation, and published it; with an epistle dedicatory to the queen, and another, by way of prayer, to their brethren of England, Scotland, and Ireland. Besides the translation, the editors of the Geneva Bible noted in the margin the diversities of speech and reading; especially according to the Hebrew; they inserted in the text, with another kind of letter, every word that seemed to be necessary for explaining any particular sentence; in the division of the verses, they followed the Hebrew examples, and added the number to each verse; they also noted the principal matters, and the arguments, both for each book and each chapter; they set over the head of every page some remarkable word or sentence, for helping the memory; they introduced brief annotations for determining the text, and explaining obscure words; they set forth with figures certain places in the books of Mosaic, of the Kings, and Ezekiel, which could not be made intelligible by any other description; they added maps of divers places and countries, mentioned in the Old and New Testament; and they annexed two tables, one for the interpretation of Hebrew names, and the other containing all the chief matter of the whole Bible. Of this translation, there were above 30 editions in folio, 4to., or 8vo., mostly printed by the queen's and king's printer, from the year 1560 to 1616. Editions of it were likewise printed at Geneva, Edinburgh, and Amsterdam. To some editions of the Geneva Bible, e.g. to those of 1599 and of 1611, is subjoined Beza's translation of the New Testament, engrossed by L. Tompson. (See RB. Bible.) Dr. Geddes (Gen. Anwser, &c. p. 4) gives an honourable testimony to the Geneva translation; and hesitates not in declaring, that he thinks it in general better than that of King James's translators.

BIBLE, bishop's. In the year 1568, the Bible, propounded by archbishop Parker three years before, was completed. This edition, according to Le Long, was undertaken by royal command; a d is mentioned by Strype, to the honour of the archbishop, that he had resolution to perform what Cranmer, as opposed by the bishops of his days, had in vain endeavoured to accomplish. In this performance, invariable portions of the Bible, at least 15 in number, were allotted to select men of learning and abilities, appointed, as Fuller says, by the queen's command; and, accordingly, at the conclusion of each part, the editor of 1568 has the initial letters of each man's name to the end of the first epistle to the Corinthians; e.g. at the end of the Pentateuch.

W.F.
W.E. for William, bishop of Exeter, whose allotment ended there; at the end of Ruth, R. M. for Richard Menvennis, or bishop of St. David's, to whom pertained the second allotment; and so of the rest. But it still remains uncertain, who, and whether one or more, revived the rest of the N.T. Eight of the persons employed were bishops; whence the book was called the "Bishop's Bible," and the "Great English Bible." The archbishop employed other critics to compare this Bible with the original languages, and with the former translations; one of whom was Laurence, a man famous in those times for his knowledge of Greek, whose conjectures the Bishop's Bible followed exactly. His grace also sent instructions concerning the method which his translators were to observe; and recommended the addition of some short marginal notes, for the illustration or correction of the text. But the particulars of those instructions are not known. The archbishop, however, directed, reviewed, and finifhed the whole; which was printed and published in 1568, in a large folio size, and with a beautiful English letter, on royal paper, and embellished with several cuts of the most remarkable things in the O. and N. T. and Apocrypha, maps cut in wood, and other draughts and engravings on copper. It has many marginal references and notes, and many useful tables. It has numerous insertions between brackets, and in a smaller character; which are equivalent to the italics afterwards used by James's translators. Dr. Geddes is of opinion, (Letter to the bishop of London, p. 32.) that italic supplements were first used by Arias Montanus, who died in 1598. The several additions from the vulgar Latin, inserted in the "Great Bible," are omitted; and verse 7 of 1 John v. which was before distinguished by its being printed in a different letter, is here printed without any distinction; and the chapters are divided into verses. In the following year, 1569, it was again published in large 8vo. for the use of private families. This Bible was reprinted in 1572, in large folio, with several corrections and amendments, and several prolegomena; this is called "Matthew Parker's Bible." With regard to this Bible, Lewis (p. 61.) observes, that the editions of it are mostly in folio and 4to., and that he never heard but of one in 8vo.; for which he supposes to be the reason, that it was principally designed for the use of churches. In the convocation of the province of Canterbury, which met in April, 1571, a canon was made, enjoining the churchwardens to fee, that the Holy Bible be in every church in the largest volumes, if convenient; and it was likewise ordered, that every archbishop and bishop, every dean and chief residientary, and every archdeacon, should have one of these Bibles in their cathedrals and families. This translation was used in the churches for forty years; though the Geneva Bible was more read in private houses. For king James's opinion of it, see King James's Bible.

Bible. Rheimsh. After the translation of the Bible by the bishops, two other private versions had been made of the New Testament; the first by Laur. Tomson, under-secretary to sir Francis Walsingham, made from Beza's Latin edition, together with the notes of Beza, published in 1576, in 8vo. and afterwards in 1599, varying very little from the Geneva Bible; the second, by the papists at Rheims, in 1582, in 4to., called the "Rheims Bible," or "Rheims Testament." These finding it impossible to keep the people from having the scriptures in the vulgar tongue, resolved to give a version of their own, as favourable to their cause as might be. It was printed on a large paper, with a fair letter and margin. One complaint against it was, its being translated from the vulgate Latin, and retaining a multitude of Hebrew and Greek words untranslated, for want, as the editors express it, of proper and adequate terms in the English to render them by; as the words affect, translate, rational, hypocrite, profane, rejoice, etc. whence Fuller called it, in his quaint manner, "a translation which needed to be transalated," and Fuller says that "by all means they laboured to suppress the light of truth, under one pretence or other." They added large annotations, to fly, as they say, the ridiculous reader, in most places pertaining to the controversies of those times, both the heretical corruptions, and false deductions, and also the apostolic traditions, the expostulations of the holy fathers, the decrees of the Catholic church, and most ancient councils. Some have said, that it was printed in a most costly manner, in order to put it out of the power of common people to purchase it; but if any of the laity secretly procured one of these Rheims Testaments, he durst not own that he had read it, without previously obtaining from his superior a licence for this purpose. Many of the copies were seized by the queen's searchers, and confiscated; and Th. Cartwright was solicited by secretary Walsingham to refute it; but after a good progress made therein, the archbishop Whitgift prohibited his further proceedings therein, as judging it improper the doctrine of the church of England should be committed to the defence of a puritan, and appointed Dr. Fulke in his place, who refuted the Rheims with great spirit and learning. Cartwright's refutation was also afterwards published in 1618. under archbishop Abbot, together with the Rheims translation. This procedure was much more agreeable to the true spirit of Protestantism, than the act of seizing and burning the copies; "argument being the only weapon (say the truly excellent primate Newcome), which should be wielded to defend Christianity, or any mode of professing it." Other editions were printed at Antwerp, in 1600, and in 12mo. at the same place, in 1630, and at Paris, in 4to. in 1653. Within 30 years after their New Testament, the Roman Catholics published a translation of the Old, at Doway, hence called the "Downay Bible," in two 4to. volumes, the former in 1609, the other in 1610, from the Vulgate, with annotations. It is said that the translators were William Allyn, afterwards cardinal, Gregory Martin, and Richard Brilow; and that the annotator was Thomas Worthington. But some (Le Long. 418.) ascribe the version of the New Testament chiefly to William Raynold.

Bible, King James's. The last English Bible was that which proceeded from the Hampton-court conference, in 1605, where many exceptions being made to the Bishop's Bible, king James gave order for a new one; not as the preface expresses it, for a translation altogether new, nor yet to make of a bad one a good one, but to make a good one better, or of many good one best. On the second day of this conference, Dr. Reynolds, the speaker of the Puritans, moved his majesty, that a new translation of the Bible might be undertaken; because those which were allowed in the reigns of Henry VIII. and Edward VI. were corrupt, and such versions as were extant were not answerable to the truth of the original. It has been observed by learned men with regard to the translators in the reign of Henry VIII., that they followed Erasmus and Sebastian Mueller too closely; of the Geneva version, that it was formed too faithfully on the model of Beza; and of the Bishop's Bible, that it was sufficiently exact, but full of errors, because its conductors departed from the Hebrew, and trod too exactly in the footsteps of the Greek. In reply to Dr. Reynolds, the king said, that he had never yet seen a Bible well translated into English; though he considered the Geneva translations as the work. On the suggestion of Bancroft, bishop of London, he forbade marginal notes; some of the Geneva
The two from the Cambridge companies were Mr. John
Bois, fellow of St. John's college, and Mr. Andrew Downes,
professor of Greek. These daily met their fellow-labourers in
Stationers' hall, London; where, in nine months, they
completed their task, and received, each of them, by the
work 3s. from the Company of Stationers, whereas, "be-
fore they had nothing." The whole was, at first, reviewed
by Bilton, bishop of Winchewell, and Dr. Myles Smyth, after-
wards bishop of Gloucester, who prefixed arguments to the
several books; and the latter was ordered to write the pre-
face. This edition of the Bible, with the preface and a dedi-
cation to the king, was first published in London, in the
year 1611; and is commonly called "King James's Bible."
Several editions of it were published in 4to. and 8vo.;
and particularly one by R. Barker, in 1613. In some
editions of this Bible, between 1638 and 1685, an alteration
is introduced in Acts vi. 3, where, instead of "We may ap-
point," is inserted "Ye may appoint," which has been
charged on the Independents. But as the first Bible in
which it was observed is that printed at Cambridge by Buck
and Daniel, in 1638, it is probably an error of the press,
without any design to favour any particular party. In 1660,
a beautiful edition of this Bible was folio, with chorographical
cuts, engraved by Ogilby, was printed at Cambridge, by
John Field; and another edition was printed in 8vo. at
Amsterdam, in 1664, by John Cume, a leader of the Eng-
lish Brownists, with marginal notes, showing Scripture to
be the best interpreter of Scripture. The editor has pre-
pared a preface; and the Apocrypha is omitted. A very fine
edition of this Bible was published in a large folio, in 1701,
under the direction of Dr. Penfold, archbishop of Canter-
bury, with chronological dates, and an index, by bishop Lloyd,
and tables of scripture measures by bishop Cumberland; and
this edition abounds with typographical errors. After this tra-
dition, all the other versions dropped, and fell into disrepe,
except the Epistles and Gospels in the Common Prayer Book,
which were still continued, according to the Bishop's transla-
tion, till the alteration of the liturgy in 1661, and the Psalms
and Hymns, which go to this day as in the old version.

About the time when King James re-issued the trau-
slation of the Bible, another translation was finished by Mr.
Ambrose Usher, elder brother of the learned priests of
Armagh of the same name. It was never printed; but is
preserved in MS. in 3 vols. 4to. in the library of Trinity
college at Dublin. In 1764, Mr. Anthony Purver published
We have also had several translations of the New Testa-
ment, (see Testament) and of particular books and parts of the
Old and New Testament, the principal of which will be
noticed in their proper places.

Learned persons have entertained very different opinions
concerning the accuracy and value of the translation, made
by order of King James, and now in common use. Bishop New-
castle, the late much respected prince of Ireland, has given an
abstract of these opinions. Celsius recommends it as the "best
translation in the world." The committee for religion in the
time of Cromwell, A.D. 1666, whilst they pretended to dif-
serve some parts, let it be useful to the "best extract;" Welb
in his "Prolegomena," boldly gives it such; and, in his "Symposia, &c." says, that "in this royal
textual and historical learning and detail in the original
language, and of unusual accuracy and judg
ment," in the "Bible, the (Latin)," A.D. 1723, it is observed, that "it was the way by general
consent and approbation, without the intervention of a
jury to enforce it. A rare argument that it is generally
accepted the Bible we have; though it has many con-
trivances."
BIBLE.

considerable faults; and very much needs another review," Dr. Wells, in his general preface to the O. T. professes to correct it, "either where it does not give the true sense of the original, or where the true sense is not well expressed," according to the modern idiom. The author of an "Essay for a New Translation of the Bible, &c." 1772, after speaking in praise of this version, recommends the attempt to give a more exact translation than any that has hitherto appeared; and he adds, "it were indeed to be wished, that those who are, in power, did employ men of true learning, and solid piety, free from bigotry and blind zeal, in so noble and necessary a work." "Innumerable instances," says Blackwall in his "Sacred Chaff, &c." might be made (in the English Bible) of faulty translations of the divine original; which either weaken its sense, or deform and tarnish the beauty of its language." He also observs, that "a new translation can give no offence to people of sound judgment and conformation; because every body, conversant in these matters, and unprejudiced, must acknowledge, that there was no occasion to change the old version into the present, than to change the present into a new one." "Thus an accurate and admirable translation, proved and supported by sound criticism, would quasi and silence most of the objections of pert and profane cavilers, which chie fly proceed from their want of penetration and discernment of the connection of the argument, and their ignorance of the manner and phrase, of the divine writings. It would likewise remove the scrupules of many pious and conscientious Christians."—"A new division of the sacred books into chapters, sections, and periods, might be so contrived and managed as to make a new edition very commodious and beautiful; which would overbalance all inconveniences which superfluous and useless parts might arise from alterations, and make a victorious and freed way to the honour, and firm approbation, of the world." There is hardly one chapter in the N. T., says this author, that is not unfairly divided, in consequence of which, the connection and meaning of particular passages are rendered confused and obscure; whil st the style is materially injured. "It is, with pleasure and just generation," he continues, "to the memory of our learned and judicious translators, that I acknowledge their version in the main, to be faithful, clear, and solid. But no man can be so superfluous as devoted to them, but must own that a considerable number of passages are weakly and imperfectly, and not a few falsely, rendered. And no wonder; for since their time there have been great improvements in the knowledge of antiquity, and advancements in critical learning, &c." "If ever!" (says Dr. Waterland, Scripture Vindicated), "a proper time should come for revising and correcting our last English translation, which, though a very good one, and upon the whole scarce inferior to any, yet is undoubtedly capable of very great improvements, &c." Doddridge, Wellesley, Wynne, Pinkington, Purver, Wordsley, Piddley, &c. &c. express themselves to the same purpose. "To confirm and illustrate the holy scriptures," says the eminent ingenious and learned bishop Lowth (Vititation Sermon at Durham, 1758), "to evidence their truth, to shew their confidence, to explain their meaning, to make them more generally known and studied, more easily and perfectly understood by all; to remove the difficulties, that discourage the honest endeavours of the unlearned, and provoke the malicious cavils of the half-learned: this is the most worthy object that can engage our attention; the most important end to which our labours in the search of truth can be directed. And here I cannot but mention that nothing would more effectually conduce to this end, than the exhibiting of the holy scriptures themselves to the people in a more advantageous and just light, by an accu-
strongly influenced in matters of acknowledged importance, by corrupt readings or mistranslations of a few texts.

It has again been objected, that a new translation is an extremely dangerous attempt; that nothing would more immediately tend to shake the faith of the establishment; and that it would be imprudent to meddle with minds of very devout and well-meaning people, by an innovation which they could not help considering as an insult on hears.
regarded, neither the reformation, nor the revolution, could have taken place; and we should have been still subject to Roman superstition, and to despotic power. It is certainly not less the part of wisdom and meekness to give up what is wrong, than respectfully to maintain what is right.

It has been further argued, that the present translation derives an advantage from its antiquity, greatly superior to any which could arise from a correction of its inaccuracies. Hence it would follow, that the versions of Tindal, Wickliffe, and Jerome, ride in excellence. But no age or prescription can authorize error; and it is obstinately to defend in any version, however ancient or venerable, what cannot be rationally defended. Although it be defirable that the genuine ancient text should prevail; in an English translation of the Bible, a translation may nevertheless become too antiquated; and in fact our own Bible retains words and forms of such remote use, that some of them are not understood, even by intelligent readers, and many of them are rather harsh and uncouth, than venerable and majestic.

But it has been said, that the present translation ought to be retained in our churches, on account of its intrinsic beauty and excellence. The language, though simple and natural, is rich and expressive. Even in the literal translation of the Psalms, there are passages exquisitely beautiful and irresistibly transporting; and where the sense is not clear, nor the connection of ideas obvious at first sight, the mind is fascinated, and the ear ravished with the powerful yet unaffected charms of the style. These beauties, it is alleged, on the other hand, are found, in an equal, or partly in a superior degree, in our first version; and must be more or less found in every version of the Hebrew Scriptures, that is not a mere paraphrase.

King James's translators found it in their prototype; the dictum and paraphraseology they borrowed from their predecessors in translation. What is beautiful, what is excellent, what is melodious and ravishing in the present version, should unquestionably be retained by all future translators; but is there any reason for retaining its corruptions, its mistranslations, its obscurities, and its other acknowledged imperfections?

The correcting translators, it will be again urged, differ among themselves. Differences must necessarily arise among interpreters of the Scriptures. King James's translators often disagreed as individuals; and adopted in a body what seemed to be most agreeable to the found rules of interpretation. Let a like number of able judges decide, on the same principles, between biblical critics of the present age. But the new translators recede too far from the common version.

This, however, in a new version, is not necessary, nor would it be proper; whilst they recede from its errors and imperfections, they should retain its general dictum and manner, nor ever allow themselves to deviate from it without a satisfactory reason.

It has been further intimated, by those who are averse from a new version, that such as wish for additional information may have recourse to those authors, who have explained obscure and erroneous passages. But have all Christians, who meet with difficulties, time and ability to consult these writers? Or if they had, is it in any respect decent or fit that the public Scriptures, confided to want assurance, should be suffered to depend for support on these extraneous props? The national Bible is the great record of our religion; it is this which the Deil attacks, and this must supply us with our defence.

The objectors proceed with obtaining, that no translation, even of a single book, has yet appeared, preferable on the whole, to the received one. Let it be considered, however, that the attempts of individuals necessarily labour under great comparative imperfections; and yet these should be promoted by the natural patrons of sacred learning, and parts of the Scriptures should be aligned to such as are well qualified for the honourable task of translating and explaining them; because these private versions and expositions will form a most useful ground-work for a revised version of the whole Bible by public authority.

After all, it will be said by many, who are convinced that our present Bible should be revised, that this is not a proper time for the undertaking; and that we should wait till, by the further increase of light, and progress of improvement, we shall be able to carry the work to a greater degree of perfection, and, if feasible, make future revisions unnecessary. This argument may be always urged; because religious knowledge will increase in proportion as human learning improves, and as new light is obtained from versions and MSS., that are already known, and that may yet be discovered, duly examined, and compared. "But shall we, in the mean time, prolong the difficulties of the Christian, and the fancied triumph of the Infidel? The mistakes already discovered are well worthy of correction. Should others of importance be brought to light in the next or subsequent generation, let them also be corrected. The true rule in this case is, to revise as often as revision is necessary. To defer this longer is an injury to religion; to put it off till it can be done in such a way as to preclude the necessity of future revisions, is in fact to put it off for ever." "The taste of the age for sound logic, found criticism, and found philology, has acquired sufficient strength to triumph over their oppressors."

In favour of an improved version of the Bible, for national use, it has been argued, that such a translation becomes necessary by the unavoidable fluctuation of languages. The style of Wickliffe's version, and of Tindal's, very widely differs in the course of 153 years; and the English language underwent also a great change between the publication of Tindal's Bible and that of King James's, in an interval of 81 years. Since the year 1611, when the present version first appeared, our language has acquired a great degree of copiousnesses, of elegance, of accuracy, and perhaps of stability. Many words and phrases which occur in the revised version become unintelligible to the generality of readers; and many, which are intelligible, are so antiquated and debased, as to excite disgust among the serious, and contempt and derision among the lightlings. Pilkington (Remarks on several passages of Scripture, Camb. 8vo. 1759); Purver (Translation of the Bible); Dr. Synnods (Observations on the expediency of revising the present English version, &c. Camb. 4to. 1789); Dr. Wells (Pref. to Comment on the O. T.); Dr. Campbell (Four Gospels translated from the Greek, 4to. Lond. 1789); and Dr. Geddes (Prospectus) have selected many words and phrases that require correction, and that admit of obvious improvement. The style of a biblical version is a matter of importance; both as it invites the perusal of a book which the Spirit of God inspired, and as it influences the national language and taste. Whatever merit be allowed to the version now in use, with regard both to its interpretations as well as its style, it must be allowed that, since the period in which it was executed, the biblical apparatus has been much enriched by the publications of polyglots; of the Samaritan pentateuch; of ancient and modern versions; of lexicons, concordances, critical dissertations, and sermons; books of eastern travels; disquisitions on the geography, customs, and natural history of the East; accurate tables of chronology, coins, weights, and measures. Many Hebrew and Samaritan MSS.; many early printed editions of the Hebrew Scriptures, have been collated by Kennicott and
and De Rossi; the eastern languages, which have so close an affinity with the Hebrew, have been industriously cultivated at home and abroad; the Masoretic punctuation is now ranked among useful aids, but no longer implicitly followed; and the Hebrew text itself is generally allowed to be corrupt in many places, and therefore capable of concordance by the same methods which are used in restoring the integrity of all other ancient books. With such an accession of helps, with light poured in from every part of the literary world, with such important principles, and with the advancement of critical skill to apply them, it is natural to conclude that many mistakes and absurdities may be removed from the present version, and that the precision, beauty, and emphasis of the original, may be communicated to it in various places. The present date of the Hebrew text in its reference to a new version of the O. T. has been already presented in the commencement of this article; and that of the text of the New Testament will be the subject of a future article; see Testament.

Dr. Newcome, in his "Attempt towards an improved version, &c. of the Minor Prophets," published in 1785, proposed a variety of rules for conducting a new translation of the Bible. These have been face corrected and enlarged (ubi infra); and in order to render the article, the subject of which is highly important and interesting, as complete and as satisfactory to biblical readers as our limits will allow, we shall here subjoin the most material parts of them. The learned prelate proposes, in the first place, that a plan, resembling the regulations preferred to king James's translators, should be deliberately adjusted by a large committee of judicious and learned men. A more select committee, well acquainted with the original tongues, in which the Bible is written, should then be appointed by proper authority, who should invite every scholar to contribute his remarks; who should have their respective parts assigned them; and who, after the performance of their allotted tasks, should amicably unite in advancing the whole to its proper degree of perfection. The first of his rules is, that a translation of the Bible should express every word in the original by a literal, verbal, or close rendering, where the English idiom admits of it. This rule admits of some few exceptions; but it excludes unnecessary deviation from the grammatical form of the original words; unnecessary paraphrase, which obscures the force of the original, digresses its matter, and sometimes forms a wrong idea; tautological renderings; and such as are defective. The second rule directs the translator, where the English idiom requires a paraphrase, to endeavour so to form it as to comprehend the original word or phrase; and to express the supplemental part in Italian, except where hardship of language results from the adoption of this method. The third rule recommends, in cases where a verbal translation cannot thus be interwoven, the substitution of an equivalent to it, and which implies the rendering in the original, but the idiom in the text should be literally rendered in the margin. By observing the second and third rules, the utmost fidelity to the original will be given, which is the primary duty of a biblical translator; the customs and manners of the eastern nations will be explained; the peculiar genius of the original language will be exhibited; and the reader unfamilied in them will be enabled to interpret for himself. The fourth rule requires, that the language of a biblical translation should be pure, or comparable to the rules of grammar. The fifth rule directs, that the propriety should be a prevailing character in the words and phrases of a biblical translation; that is, they should have the nature of rule and the introduction given to them should be warranted by the best speakers and writers. In order to preserve the venerable turn of our present version, some few exceptions may be allowed under this general rule. The sixth rule enjoins the translators to retain the simplicity of the present version; for which purpose they should exclude foreign words, and the pomp and elegance of modernized diction. The seventh rule inculcates peripetia. The eighth rule recommends the same original word, and its derivatives, according to the different leading senses, and also the same phrase, to be respectively translated by the same corresponding English word or phrase; except where a distinct representation of a general idea, or the nature of the English language, or the avoiding of an ambiguity, or elegance of style, or harmony of sound, requires a different mode of expression. In conformity to this rule, it is proposed, that translators should previously agree on the rendering of certain words and phrases. Accordingly, the original word Elohim, which expresses the self-existence of the deity, and which, so far from being barbarous, is a grand and magnificent term, should be retained:—that it should be considered, by the help of convenient renderings, whether the same word can always be rendered in the same manner; and that when an English word fits every place, it should invariably be used:—that if the original word cannot always admit of the same rendering, of which many examples occur, the different renderings may be reduced to as few as possible, and those the fittest which the English language affords—that different words, which have the same, or nearly the same sense, should be distinguished in translating them, when the English tongue furnishes distinct and proper terms:—and that parallel passages should be rendered in the same words. The ninth rule requires that the collocation of words should never be harsh and unnatural to an English ear. The tenth rule recommends to translators of the Bible a suitable degree of beauty and elegance. This beauty, in its prevailing character, must be easy and natural, simple and severe; free from laboured ornament and artificial variety of phrase. The style, like that of the original, must be raised in the poetical parts, but not inflated, and plain in the historical parts, but not abject. "Let notings," says Dr. Symonds (ubi supra) "be admitted into the text, which we cannot read with pleasure, as well as with advantage." In the eleventh rule it is required, that dignity should characterize a version of the Bible. The opposite extreme results from the introduction of debased and offensive terms or phrases: of which fome are degenerated by familiar use, others are colloquial and vulgar Anglicisms; and modern paraphrase, as such, is undignified in a translation of the Bible. The twelfth rule prefers energy as another characteristic of a biblical translation. This quality is obtained, in a great degree, by simplicity and propriety in the words that are selected to represent the peculiar notes conveyed by the sacred writers, and by expressing the ideas contained in the original with due conciseness. The expressive style of the Scriptures is ennobled by euphony and paraphrase; but does not majestically more disdain the defect of ornament, than the excess of it. A version of the Bible will derive much force by retaining those Hebrews which the English language only admits, or to which an English ear is now at home. Obscure Hebrews, such as weaken the figurative of the original, and those which pretending its meaning, should be avoided. In the thirteenth rule it is recommended to continue the old eccentric terms, such as substantia, mystagogia, et cetera, as long as they are part of our theological language, and of which explanations perpetually occur. The fourteenth is, in general, to be retained. By observing this rule, the genius of a language, and the nature and customs of a country, will often appear;
B I B L E.

Rule fifteenth. Proper names should remain as they are now written in those places where they are most correctly represented. Rule sixteenth. The best known geographical terms should be inserted in the text; and those of the original in the margin; e.g. Syria, marg. Aram; Ethiopia, marg. Cuf. Rule fourteenth. The language, sense, and punctuation of our present version should be retained, unless when a sufficient reason can be assigned for departing from them.

Rule eighteenth. The critical sense of passages should be considered, and not the opinions of any denomination of Christians whatever; so that the translators should be philosophers and not controversy. Rule nineteenth. Passages already admitted into the common version, but which are allowed to be marginal glosses, or about the authenticity of which critics have reason to be doubtful, should be placed in the text between brackets. Rule twentieth. In the editions of the Bible, the poetical parts should be divided into lines answering to the metre of the original; or some other method should be used to distinguish them from prose. But if it should be thought advisable to exclude the poetical distribution from our Bibles, and confine it to the prolixities of the scholar, some proper mark of distinction for metrical prose, as the Hebrew Rehbiang or two horizontal points placed over a word, may be admitted into the authorized impressions of the Old Testament; or, at least, the contents prefixed may advertise the reader of the passages generally allowed to assume the tone and form of poetry. Rule twenty-first. Of dark passages, which exhibit no meaning as they stand in our present version, an intelligible rendering should be made on the principles of found criticism. Under this head of found criticism, Neechome includes that which is conjectural, the sober use of which he frequently recommends. But it admits of doubt, whether conjecture can ever be authorized in a translation which is intended for general use; for if it be exercised on flight occasions, it must be in some degree superficial; if on material ones, it must ever be indecisive. The learned prelate, however, lays down the following canons for this kind of criticism. Never suppose that the text is corrupted without the most cogent and convincing reasons. Never have recourse to conjectural criticism, until every other resource has been tried and exhausted. Let all corrections be consistent with the text, and with one another. Infer no correction, however plausible or even certain, in the text, without warning the reader, and disingenuously by it a proper note. For other instructions, more immediately designed for the editor of such a new version, we refer to the author himself; as well as to his appendix, for a list of the various editions of the Bible, together with an account of the libraries public or private, in which they are to be found. Another more complete list of this kind is prefixed to bishop Wilton's Bible. See Lewis's Translations of the Bible, 8vo. 1739. Johnson's Historical Account of the several English translations of the Bible, in bishop Watton's Collection of Theological tracts, vol. iii. p. 60—100. Newcome's Historical View of the English Biblical Translations, &c. 8vo. Dublin, 1792.

BIBLE, Welsh. There was a Welsh translation of the Bible made from the original in the time of queen Elizabeth, in consequence of a bill brought into the house of commons for this purpose in 1563. The act 5 Eliz. c. 28. reciting, that in Wales the people were popishly inclined, and very ignorant, put the direction of this work into the hands of the bishops of Hereford, St. David, Bangor, Landaff, and St. Asaph, who were to inspect the translation, and take care that such a number should be printed as would provide every cathedral, collegiate, and paroch-church, and chapel of cafe, within their respective dioceses, where Welch was commonly spoken, with one copy. It was printed in folio, in 1568. Another version, which is the standard translation for it is language, was printed in 1626. It is called Parry's Bible. An impression of this was printed in 1660, called Bishop Lloyd's Bible. There were in folio. The first octavo impression of the Welsh Bible was made in 1630.

BIBLES, Irish. The New Testament having been translated into Irish by William Danii, archbishop of Tuam, Bedell, who was advanced to the see of Kilmore and Ardagh, in 1629, first precured the Old Testament to be translated by one King; but the translator being ignorant of the original languages, and having done it from the English, the bishop himself revised and compared it with the Hebrew, the Septuagint, and the Italian version of Dioscati. He supported Mr. King to the utmost of his ability, whilst he was engaged in this work; and when the translation was finished, he would have printed it in his own house, and at his own charge, if the troubles in Ireland had not prevented it. The execution of his benevolent design was also impeded in consequence of the notice that was given of it to the lord lieutenant and the archbishop of Canterbury, who thought it disgraceful for a nation to have a Bible published, which had been translated by such a despicable person as King. However, the translation escaped the hands of the rebels, and it was afterwards, viz. in 1685, printed at the expense of the Hon. Robert Boyle.

BIBLES, Gaelic. The Bible was translated and published by the Society in Scotland for promoting Christian knowledge, in the Gaelic language, for the use of their schools, and of the people in the Highlands, at different periods, and in detached portions, as the funds of the society allowed. In 1567, the New Testament in Gaelic was published by itself; and in various successive years, and in separate volumes, the several books of the Old Testament were published. In 1756, the first edition of the New Testament being exhausted, the society published another, consisting of 20,000 copies. And as some of the first printed volumes of the Old Testament have been so much reduced in number, as to be insufficient to supply the urgent demands of the Highlands in general, and of the Society's own school in particular, a new edition of 20,000 copies has been lately undertaken (in 1820), at an expense of 2284l. 16s. defrayed by voluntary subscription. An act of charity, highly important and laudable, for whose accommodation it is designed, amount to no less than 335,000; of whom, it is computed, that 360,000 understand no other language than the Gaelic, or at least cannot comprehend a book written, or a continued discourse spoken, in any other.

BIBLE-DOCTORS, in Ecclesiastical History, a denomination by which the Schoolmen of the twelfth and thirteenth centuries were distingushed, who made the Scriptures the chief subject of their studies, and text of their lectures. However, in the course of the thirteenth century, the holy Scriptures, together with those who studied and explained them, fell into great neglect and even contempt. The Bible-Doctors were sighted as men of little learning or acumen; they had few scholars, and were not allowed an apartment, or a servant to attend them, or even a stated time for reading their lectures, in any of the famous universities of Europe. The illustrious Roger Bacon inveighed very bitterly against this abuse; and his excellent friend, Robert Grouhead, bishop of Lincoln, wrote a pathetic letter to the regents in theology in the university of Oxford, on this subject; earnestly entreating them to lay the foundations of theological learning in the study of the Scriptures, and to devote the morning hours to lectures on the Old and New Testaments. But
But all these remonstrances and exhortations had little or no effect.

BIBLIA, or BIBLIA sacra, in a military sense, denotes a machine used by the ancients for throwing stones or darts.

BIBLIANDER, Theodore, in Biography, whose true name was Ignatius, a learned Protestant divine, was born in 1504, at Bischofzell near St. Gall, in Switzerland. He offered as professor of divinity at Zurich from 1532 to 1569, when he was declared eminently, or gilt service, not because he was incapable of executing his office, but because he had advanced opinions that deviated from the standard of orthodoxy with regard to the doctrine of predestination. He died of the plague, at Zurich, in 1564. He was well acquainted with the oriental languages, and published, in 1532, an edition of the Koran; the text of which, Bayle says, he corrected by a collation of the Arabic and Latin copies; and he added marginal notes, pointing out and refuting its absurdities. But others say, that this edition is faulty, and Caprete Bibliander's fell in the oriental languages. To this edition he appended the lives of Mahomet and his successors, and prefaced an apology, by way of preface, which gave great offence by maintaining the lawfulness and utility of a free perusal of books adverse to true religion. He also wrote several other books on theological subjects, some of which are printed, and others remain in Ms. in the library at Zurich. He like wise finished the Bible of L'Abbe, called the "Zurich Bible," and printed in 1543, and translated from the Hebrew into Latin the first five books of the Bible, and the last 48 Psalms. Gen. Diet.

BIBLIOGRAPHIA, a branch of archigraphia, employed in the judging and perusing of ancient manuscripts, whether written in books, paper, or parchment. The science of it is now extended, and it figures a work intended to give information concerning the first, or best editions of books, and the ways of distinguishing and distinguishing them properly. In short, it is used for a notices, or description of printed books, either in the order of the alphabet of the times when printed, or of the subject-matters. In which sense, bibliographia amounts to much the same with what is otherwise called bibliotheca.

Literary journals afford also a kind of bibliographia.

BIBLIOLOGIUM, a kind of divination performed by means of the Bible. This amounts to much the same with what is otherwise called forta biblici, or fortes sanctorum. See Sortes. It consisted in taking passages of Scripture at hazard, and drawing indications thence concerning things future; as in Augustin's telli et legi. It was much used at the consecration of bishops. F. J. Daviades, a Jefuit, has published a bibliomania, under the borrowed name of Veriditam Christifianum.

BIBLIOMANIA, an extravagant passion for books, to a degree of madness; or a desire of accumulating them beyond all reason and need.

BIBLIOTHECA, from Skr. book, and Lat. repotter, from repeto, I lay up, properly signifies a library, or repository of books. See Library. It is also used for a compilation of all that has been written on a certain subject; or a depository of all the authors who have treated of it. In this sense, we have historical bibliotheca, as that of Diodorus Siculus; mythological bibliotheca, as that of Apollodorus; theological and sacred bibliotheca, as those of Ravenna, &c. It is also used for a catalogue of the books in a library; such as: bibliotheca Cirtifana, bibliotheca Cirtifana, bibliotheca Thomae, bibliotheca Gennaziana, bibliotheca du Boffana, &c.

L'Abbe has published a Bibliotheca biblicai, or a catalogue of the names of those who have written bibliotheca, which has since been continued and improved under another title by Tellier, from 800 writers to the number of no less than 2500. Schramius has also published a programma on the writers of theological bibliotheca.

BIBLIOTHECA is a name given to the books of the Old and New Testament, in respect of their excellence, and sufficiency for the use of the Christian life; and it is also a title given to divers journals, or periodical accounts in French of some books.

BIBLIOTHECA Patrum, or of the Fathers, is a collection of the writings of the elder fathers, printed in one or more volumes. The first of this kind was published at Paris by Marc. de Bigne in 1776.

BIBLIOTHECARIAN, a library keeper, otherwise called Librarian.

The word is also used for the author of a bibliotheca, or a catalogue of books.

In this sense, P. L'Abbe has given a bibliotheca, or catalogue of bibliothecarians. Guettier, Lepinus, Struvis, Fabricius, &c. are celebrated bibliothecarians.

BIBLIOTHEQUE Musicale. See Musical Library.

BIBLIS, in Entomology, a species of Papilio, with black dotted wings, and a band of fangious spots on the posterior ones. It is a native of America, and called papilio lepideria by Cramer, Geelnn. Obs. This must not be confounded with papilio iblis of Cramer, which is a very different insect, and seems to be a variety of papilio pentheus of Fabricius.

BIBLIS Font, in Ancient Geography, a celebrated fountain of Ionia, situate E.S.E. of Miletus. It is mentioned by Pausanias and Ovid.

BIBLIZH, biblis, an appellation given by some Romish writers to those who profess to adhere to Scripture alone as the sole rule of faith, exclusive of all tradition and the sup- posed authority of the church. In which sense, all protestants are, or ought to be, bibliesi. Biblihs, among Christians, unreservedly to Coristas or Texturaries among the Jews. The Christian doctors were divided, towards the close of the twelfth century, into two classes; viz. the biblics, and the scholasticis; the former were called doctors of the factual page, because they explained the doctrines of Christianity in their manner by the sacred writings; however, their reputation declined, and the scholastic theology prevailed in all the European colleges till the time of Luther. See Bible-Destruct.

BIBLUS, in Botany, an aquatic plant in Egypt, called also papyrus; of the skin whereof the ancient Egyptians made their paper. See Papyrus, and Paper.

Hence also the Greeks gave the denomination papyrus to books made of it. See Bible.

BIBLUS, in Ancient Geography, a river in the island of Naxia.

BIBONA, a place of Gallia Aquitania, in the route from Burdigata to Segudum.

BIBORA,Ripari, and Bay, in Geography, lie to the east of Cartage bay, on the main land of Honduras, about 8., the 14. 20. W. long, 83 45'.

BIBRA, Bera, or Blera, a town of Germany, in the circle of Upper Saxony, in Thuringia, 10 miles west of Naumburg, and 8 south of Querfurt.

BIBRACE, in Ancient Geography, a citadel of the Alatai, according to Strabo, but according to Caesar, a fortified town of Gaul, the capital of which was large and populous, now desolate; about 4 miles to the north-west of Autun, and called Borex, Bevray, and Bray.

BIBRAX, Prov., a town of Belgics, in Gaul, in the country of the Roman, north-west of Darmstadt. This town was attacked with great fury by the other Belgic nations, because it had declared for Caesar. C. R. Gal. 1. 2. c. 7.
BIC

BIERRICH, in Geography, a town of Germany, in the circle of the Upper Rhine, and principality of Nassau Saarbruck Ulingen, 3 miles S.W. of Wiesbaden.

BIBRICI, in Ancient Geography, an ancient people of Britain, who are supposed to have occupied the south-eastern part of Berkshire, from the Lodden on the west to the Thames on the east. These people undoubtedly came from that part of Gaul, where the town Bibractum was situated, and their name leads us to the discovery of their origin, as well as of the place of their residence in this island. It is not certainly known when this colony of the Bibrici left their native country, and settled in Britain, though it is probable that it was not long before Caesar's invasion, to whom, perhaps, they were engaged to submit by the influence and example of their friends and countrymen in Gaul. As the Bibrici were but a small nation, they seem to have been subdued by some of their neighbours before the invasion of Claudius, and therefore they are no further mentioned in history. The name of the hundred of Bray, in the Thanet, near Maidstone, is evidently derived from the name of their ancient inhabitants; as the ancient Bibrica, in France, now bears the name of Bray.

BICALCARATUS, in Zoology, a species of Pavo, of a brown colour, with the head lightly crested, and two spurs on each leg. Geoffrin. This is from Chineses of Buffon; l'opercule de Buffon, petit paon de Malacca de Sonnerat; crested pheasant of Edwards; and iris paeon of Latham.

This splendid bird is a native of China; in point of size it rather exceeds the common pheasant, and has a blackish bill, with the base of the upper mandible red from the nostrils; the irides are yellow; cere small, though composed of some pretty long feathers, and of a dull brown colour; the face is naked; sides of the head white; neck brown, fringed across with dusky; upper parts of the back, scapulars, and wing-coverts dull brown, dotted with pale brown, and yellow; and near the end of each feather a rich and glossy purple spot, changeable to green, to blue, or gold, in different points of view; lower part of the back and rump brown, spotted with white, and body beneath brown, fringed transversely with black; upper tail coverts longer than the tail, and each marked with a fine purple spot near the end, encircled with black and orange; legs and claws brown. This is the description of the male. The female is one third smaller; head, neck, and upper parts brown; head smooth; feathers on the upper parts marked with a dull blue spot, encircled with dull orange; and the legs have no spurs.

DICARI, in Geography, a river of Sicily, which runs into the Torni, 2 miles west of Scelfani.

BICARINATA, in Zoology, a species of Lacerta, with compressed tail of moderate length, and carinated above; out the back four rows of carinated scales. This is of greenish colour, and inhabits South America and India. Geoffrin. &c.

BICAUDALIS, in Anatomy, an appellation given by some anatomists to a muscle of the external ear, usually denominated the retracereus, or retracentus auris, which see.

BICAUDULIS, in Ichthyology, a species of Ostracion, of a triangular form, with two sub-caudal fins, and ten rays in the dorsal fin. Geoffrin. There is a supposed variety of this fish found in India, and described by Arctedi, in which the body is entirely covered with spots and tubercles.

BICE, or Bice, among Painters, a blue colour, prepared from the lapic Armenus, formerly brought from Armenia, but now from the silver mines in Germany. Phil. Trans. N° 179. p. 26. Dollis, v. i. p. 95. Bice is finally reduced to a fine powder by levigation. See SMALT.

The word comes from the barbarous Latin bice, or bicas; and that, perhaps, from the French bis, grey, grisais; whence bicus pannis. Vide Du Cange, Gloss. Lat. tom. i. p. 565: Skin. Etym. in voc.

Bice bears the body all of bright blues, used in common work; but is the palest in colour. It works indifferently well; but inclines a little to be sandy, and therefore requires good grinding on a very hard stone, and should be washed before it is used. It lies best near the eye of any blue now in use, except ultramarine. Its goodness lies in the brightness and coolness. It was formerly used in oil, and more frequently in water colours; but it is now much out of use. We have also a green bice, made of the blue, with the addition of opomum; and several compositions of indigo and verditer, with chalk and other cheap substantiae, are sold under the name of bice.

BICE, in the Mythology of the Hindoes, the name of one of their Gods, proceeding from Brahma, the immediate agent of the creation, under the supreme power. It derives its appellation from the belly or thighs, and denotes nourishment. It was also extended by its founder to provide the necessaries of life by agriculture and traffic.

BICEPS, from bis and caput, in Anatomy, is a name common to several muscles, which consist of two distinct portions, called heads. Theos which are commonly known at present by that appellation are the following.

Biceps flexor cubiti. The longer portion, or head, of this muscle, arises by a tendon from the upper part of the glæroid cavity of the femur; it then passes through the shoulder joint, and descends in the groove in the upper part of the os brachii, afterwards the fleshy fibres begin to be attached to it. The shorter portion arises tendinously and fleshy from the coraco-brachialis process of the scapula, in common with the coraco-brachialis muscle; a little below the middle of the os brachii, the heads unite and form a bulky muscle, the fibres of which terminate below in a strong roundish tendon, which is inserted into a tubercle, at the upper end of the radius, at that part which is next to the ulna. At the commencement of the lower tendon of this muscle, an aponeurosis is sent off from it, which foon expands into the fascia of the fore-arm.

The use of this muscle is numerous, and the consideration of them affords a good demonstration of the impropriety of denaminating a muscle from any single office which it may serve, as it tends to limit our idea of its utility. The action of this muscle tightens the fascia of the fore-arm; it turns the hand supine; it bends the joint of the elbow; it raises the arm towards the shoulder; and occasionally it brings the bones of the shoulder to the arm.

Biceps flexor carpi. The long portion, or head, of this muscle arises, in common with the semi-tendinosus, from the upper and back part of the tuberosity of the os ischium; the short portion arises from the linea aspera on the back part of the thigh-bone. The two portions having conjointed, produce a strong tendon a little above the external condyle of the os femoris, which forms the outer head flexing, and which is attached to the upper part or head of the ulna. The chief use of this muscle is to bend the leg upon the thigh, and when it is brought into that situation, to turn the leg outwards.

BICESTER, in Geography, a market-town of Oxfordshire, England, is situated in a valley on the banks of a small river, which falls into the Cherwell, at 11fip. It is a large respectable town, divided into two parts, called Market-end, a parish, and King's-end, a hamlet. This place and its vicinity have been pollified by the Romans, as its name implies; and many Roman coins, and other memorials of that people, have been discovered here and at Alcester, or Old Chesterton, at different times. The embankments at the latter place are nearly obliterated by the plough; but from the name, and the antiquities that have been found, it seems evidently
Barrer. 

Species. 

This is the town of Bickerston, near which the French were defeated by the Imperials in 1532; 2 miles N.E. of Milan.

BICOLOR, in *Contoholy*, a species of *Donax*, with an ovate shell marked with elevated fins, which decussate a few transverse ones; rufous, with a white ray on one side. *Circ. Gmel. &c.*

BICOLOR, a species of *Pinna* found in the Red sea. This kind is thin, inflated at the lateral margin; yellowish, with black brown rays, and a few longitudinal fins. *Chernitz.*

BICOLOR, in *Entomology*, a species of *Aphis* that inhabits Denmark. The thorax yellow and ferruginous; abdomen black and immaculate. Fabricius.

BICOLOR is also an Indian species of *Aphis*, of a black colour, with the abdomen hairy; fulvous above, and snowy-white beneath. Fabricius. This bears some resemblance to *Aphis* centuncularis, but is larger.

BICOLOR, a species of *Atilus* found in Europe. It is of a black colour, with the thorax and wing-cases reddish; feet, thighs, and tarsi black; abdomen yellow. *Linnaeus.*

BICOLOR, a species of *Buprestis*, with pointed wing-cases, of a brassy-green colour, with a yellow spot; breast and abdomen yellow. Fabricius. Inhabits South America.

BICOLOR, a species of *Cantharis*, of a yellow colour, with half of the wing-cases blue. Thunberg. Inhabits the Cape of Good Hope. Fabricius.

BICOLOR, a species of *Carabus* that inhabits North America. It is black above, and ferruginous beneath. Fabricius.

BICOLOR, a species of *Cerambyx* that inhabits Cayenne. This is ferruginous; thorax with two spines and tubercles; wing-cases beyond the middle, with the abdomen black. Fabricius.

BICOLOR, a species of *Chrysomela*, of a brassy-green above, and violaceous beneath. Fabricius. Inhabits Alexandria.

BICOLOR, a species of *Cicada* (*Cercopis*), of a greenish colour, with the upper part of the thorax fuscous. *Linnaeus.*

BICOLOR, a species of *Cryptophyllum* (*Erostyla*). This insect is of a black colour, and brassy above. Fabricius. A native of New Holland.

BICOLOR, a species of *Circulus* found in America. *Circ. Gmel. &c.*
B I C

This is of a black colour, with a rufous thorax and wing-cases. Fabricius.

Bicolor, a species of Dicrornes, of an oblong form and black colour; beneath tawny; wing-cases black. Fabricius. Inhabits Germany.

Bicolor, a species of Elater, of a brownish ferruginous colour; head and thorax brown; wing-cases fringed. Inhabits Europe. Linn. Mut. Lep.

Bicolor, a species of Gryllus (Lociulata), described by Linnæus. It is greenish, aperous, with the hinder thighs rufous beneath.

Bicolor, an African species of Ichneumon, of a ferruginous colour; tip of the abdomen, breast, and end of the upper wings black. Grinnell.

Bicolor, a species of Lampiris (Pyserchus), of a purplish colour, with the posterior end violaceous. Fabricius. Inhabits America, and lays the eggs in water cresses.

Bicolor, a species of Lampiris, of a purplish ferruginous colour, with the eyes, wings, and upper part of the head black. Smithson. New Art. Sci. Nat.

Bicolor, a species of Leptura (Dornia) that inhabits Europe. It is of a golden-colour, with the upper part of the thorax, and the wing-spots, green; the latter streaked with white; posterior thighs destitute. Grinnell. &c.

Bicolor, a species of Lcteron of a tawny dusky colour; wing-cases black at the tip. Gdinny. Inhabits France.

Bicolor, a species of Morella, described by Forster (Nov. Int.). It is of a black colour; wing-cases tawny, with the tip and band in the middle black. Very small. Inhabits England.

Bicolor, a species of Niphula found in Europe. This insect is ferruginous, with black wing-cases, having a ferruginous band at the base, and a spot of the same colour near the apex. Fabricius.

Bicolor, a species of Phalæa (Bombyx) found in Saxony. The wings are white, with a large yellow spot, with black marks. Fabricius.

Bicolor, a species of Scarceus, with the thorax very slightly arched, and on the head a single tubercle; wing-cases black; abdomen red. Fabricius.

Bicolor, a species of Silpha, of a brown colour, with rufous legs. Linn. &c. A native of Europe.

Bicolor, a species of Sphinx that inhabits New Holland. This is of a black colour; head, abdomen at the tip, and wings yellow; the latter brown at the tip. Gmelin. This insect was first described by Fabricius from a specimen in the collection of Sir Joseph Banks, under the specific name Biocorus.

Bicolor, a species of Staphilinus, of a black colour, with the antennæ, wing-cases, and legs ferruginous. Linn. A native of Europe.

Bicolor, a species of Tenthredo, of a blueish black, with the abdomen and base of the wings yellow; a band of black. Schrank. Inhabits Austria.

Bicolor, a species of Vespa that inhabits China; and in size and appearance resembles the common wasp. It is yellowish; antennæ above, crown, thorax, and vent brown. Fabricius. &c.

Bicolor, a species of Ichthyology, a species of Cardium, found in the Mediterranean sea. It is of a brown colour, with all the fins black. Brit. Fish.

Bicolor, in Ichthyology, a species of Aestus, found in the Mediterranean sea. It is of a brown colour, with all the fins black. Brit. Fish.}

This bird is native of Cayenne. Buffon calls it Martin: pele voris et rons de Cayenne: head; and Latham the rufous and green kingfisher. Length eight inches; bill black; legs reddish; breadth of the forms not banded. Buffon.

Bicolor, a species of Tinellus, that inhabits the woods of Jamaica and Bahama Islands, and is called by English writers the Bahama jaunaron. This bird and bird are black; back, wings, and tail, greenish. Grinnell. The length of this bird is four inches; its wings very monotonous. Buffon calls it Chlorus Lophopterus; and Buffon Vermivorum.

Bicolor, a species of Lanius, of a blue colour; white beneath; from black. Linn. &c. This is the Madagas- gascariænus of Linnaeus. New Vol. (part II.) Lanius Madagascar- cianus, of Buffon; Picoletla bluva Mélacgar. Bicolor, Blue$j1$blue of Lophopterus. It is about six inches and a half in length, and, as the synonyms imply, is a native of Madagascar.

The bill, head, margin of the quill-feathers, two middle tail-feathers, and exterior margin of the four next; legs and claws black. Female, forktid white beneath.

Bicolor, a species of Leuca found in the East Indies. Grinnell very briefly describes it as being of a fulvous colour, and red beneath. This is Tringa latirostris maintained by Buffon; Brunnus of Buffon; Little brown shrike of Edwards; and, gray-backed parrot of Latham. There is likewise a variety of this kind of a brownish colour, white beneath, and chin inclining to brownish. About three inches and a quarter in length; bill white; legs fulvous.

Bicolor, a species of Muscicapa, of a black colour; front, space round the eyes, throat, rump, purplish wings, band on the greater wing-coverts, tip of the tail, and under parts of the body, white. Grinnell. Buffon calls this Gobe mouches à ventre blanc de Cayenne; and Edwards and Latham Black and white-fly-catcher. A variety of this bird is white, except the hind part of the head, and neck, rump, wings, and tail, black, and legs, which are black. The female is of a uniform grey colour. Inhabits the moist meadows of Guiana.

Bicolor, a species of Picus, called by Latham, after Buffon, the Escardors scops piquer; Spithe in pie de Escardors, Buffon. This is variegated greyish and white; head crested, white on the sides; quill-feathers brown, spotted with white. Grinnell, &c.

The length of this beautiful bird is about six inches; bill lead colour; tibias white; plumage brownish-grey and white finely blended; above, the colours are intermixed transversely, and beneath in a perpendicular direction; crest on the sides intermixed with cinnamon; sides of the head white, verging to brown; legs lead head colour. The female has no crest, and is entirely brown.

Bicolor, a species of Trochilus, of a scarlet-golden colour, with the head a different blue. Grinnell. This is of the middle size, and inhabits Guadaloupe. It is Colibri No. 2. of Termin. Surin. ; Scarécoles and de Buffon; and Sapphire and emerald humming-bird of Latham. Bicolor, a species of Tucanus, of a brown colour, tinged with green; abdomen and vent white. This inhabits the Cape of Good Hope; and is ten inches long. Buffon calls it Melle brun de cap de bonne Esperance, and L. the bleu-nanpré, or blue.

BICOLORA, in Entomology, an Indian species of Phalæa (Neura). Wings yellow, with a broad brown band on margin. BICOLORATA, a species of Phalæa (Gomphus) with the wings bluish and fringed; anterior black at the tip, and spotted with white. Inhabits Surinam. Cramer. &c.

BICOLORATA, a species of Scarceus (Aelurus), found at the Cape of Good Hope. It is glorious green, beneath
of Palaemon (Crustacea) with
his head, and is distinguished by
his body, or second. In his middle,
with two horns, and a pair of feelers,
Scopli. Andants Camilla, on the na-
ture of Octopus, a species of
Hippus, is a name which has been
found in Nature, and is, in Botany, a
plant with an appearance of two horns. The term
for the part of the fragments.

BIDEFORD, or Bideford, in Devonshire, is a
place of some extent, and Extention is
considered as a term formedly to
calculate the three extant miles of the
church.

Bicerin, in E. Fr. 1792, a species of Scylla, with
two horns on the head; a rendered, single-toothed horn on
the head, and blue wings. Aubert. J. n. l. b. 14.
Inhabitants of America; of a middle age among the horned
kinds of the sea.

Bicornis, a species of Herda, with peculiar antennae;
theoh and wings. Brady. Ger. 1790.
Inhabitants of North America. Fabr. 1825.

Bicornis, a species of Corella, with acutely deno-
tated horns on the head. Fabr. 1825.
Inhabitants of New Zealand, at a distance with brown and black.

Bicornis, a species of Corella, with a single appendage on
the anterior angle of the wings. Later. Fabr. 1825.

Bicornis, a species of Mantis, found in South America, and in the
sea. The horned.

A. C. S. D. B.

BIDFORD, or Bideford, in Devonshire, a place of
the same extent, and Extention, is
considered as a term formedly to
calculate the three extant miles of the
church.

BIDER, or Bider, in the list of Coustani, denotes the
invitation of friends to drink, at force poor man's home,
who, in consideration hereof, expects some contribution be-
fore he will receive.

BIDALDI, a term kind of foot soldiers, mentioned by
the Roman historians, armed with two darts.

Hence the origin of the word, which isost retranslation
for "bidaldy" or "a bistail dart." They are also called
bidal, bidal, bidal, bidal, and bidal, and similars.

BIDASOA, or Bidas, in Geography, a river which
rises in the Pyrenees, and runs to the bay of Biscay between
Avalley and Fontoura, forming France from Spain. This
river was for a long time a subject of dispute between France
and Spain, each country lay claim to exclusive claim, but in the
11th century Louis XII of France, and Ferdinand, king of
Spain, agreed, that it should be common between the two
nations, and that the duty paid by the fisherman who passes
from Spain to France would belong to the latter, and of those
who pass the contrary way to the former. E. Franckly observes
that the inhabitants of the environs of this river have cars of
any commerce.

BIDDING, a town of the Netherlands, in the duchy
of Liège, containing two parish churches, and a
school; not far from N. and N. of Linburg.

BIDFORD, or Bideford, an ancient seat of
interest, is the town of D. of the
Great. It is situated on the north and west
of the town of Exeter, and on the north
of Exeter, and on the west of the

duchy of Liège, containing two parish churches, and a
school; not far from N. and N. of Linburg.

BIDFORD, or Bideford, an ancient seat of
interest, is the town of D. of the
Great. It is situated on the north and west
of the town of Exeter, and on the north
of Exeter, and on the west of the

duchy of Liège, containing two parish churches, and a
school; not far from N. and N. of Linburg.
BID

charter of Edward I., and afterwards represented in several
parliaments, seems to have been greatly reduced at the time
when Leland visited it, for he merely mentions the river and
the bridge. Camden, however, speaks of it as "remarkable
for its populousness." At the time of the latter antiquity,
Bideford assumed a commercial importance, and carried
on trade with America and Newfoundland. Queen
Elizabeth granted it a charter of incorporation, which vested
the government in a mayor, five aldermen, seven capital bur-
gesses, a recorder, town-clerk, and two sergeants at arms.
By this charter the inhabitants are empowered to hold a
weekly market, and three annual fairs. Another charter was
however obtained in 1610, which confirmed the former, and
granted the townmen some additional powers and liberties.
The patrimony and residence of Sir Richard Granville and Sir
Walter Raleigh proved highly favourable to Bideford; for
after these worthy knights had discovered Virginia and Caro-
lina, they returned to, and settled here. In the time of the
civil wars, the inhabitants of this place declared themselves
very early in favour of the parliament; but their success did
not prove equal to their zeal, for in attempting to relieve
Exeter, they experienced a severe and total defeat, and im-
mediately resigned Bideford, Barnstaple, and their appen-
dages, to the royalists.

In the year 1646, Bideford was ravaged by a plague,
which appears to have been occasioned by the landing of
a cargo of Spanish wool; an article which at that period con-
stituted a principal part of the trade of the town. The cre-
dularity and superstition that characterized the English in the
seventeenth century are strikingly exemplified by an occurrence
which happened here in 1682. Three poor females were ac-
cused of witchcraft, and so dire and positive was the evidence
adduced against them, at several examinations before the
magistrates, that they were committed to Exeter gaol, and
soon afterwards tried, and executed for their alleged
crime.

About the middle of the last century, the export trade of
Bideford to Newfoundland was so considerable, that only two
other ports in the kingdom employed an equal number of
vessels, and in the export trade only one port excelled it.
During the unwise administration, and injurious wars of queen
Anne's reign, these commercial transactions materially suf-
f ered, and the French privateers obtained so many valuable
prizes from Bideford bay, that it was semantically termed the
Golden bay. The number of vessels now belonging to this
port is about one hundred; these vary in burthen from
twenty to two hundred and fifty tons, and are chiefly em-
ployed in the conveyance of coal and culm; in the exporta-
tion of oak bark to Ireland and Scotland; in the herring
trade; and in the importation of fish from Newfoundland.
The quay is conveniently situated near the centre of the
town, and the body of the water at high tides will bring up
vessels of 500 tons burthen. The chief manufacture of this
place is that of coarse brown earthenware, which is made
with clay brought from Fremington near Barnstaple. The
price of this is only two shillings and sixpence per ton. The
bridge at Bideford, built of stone, consists of twenty-four
irregular arches, and was constructed about the middle of
the fourteenth century. It is 677 feet in length, and was con-
structed at the expense of Sir Theobald Granville, knt., and
at the instigation of the bishop of the diocese, who granted indul-
gences to such persons as gave money in aid of the work.
The church, a spacious building, was erected in the form of
a cross about the middle of the fourteenth century. A house
of industry has lately been erected here; and a free school,
and free grammar school are ranked among the charitable
foundations of the town. The market-place is spacious, and
the town-hall is a large convenient building with two prisons
beneath it. In the parish of Bideford are 666 houses and
2697 inhabitants. This town is 211 miles S.W. from London.

Thomas Stukeley, a defendant of the celebrated chaplain
to Oliver Cromwell, was a native of Bideford, and was distin-
guished for many eccentricities of character. John Sibb-
beare M.D. an author of some eminence, was also born here
in the year 1709.

About five miles east of this town is Tawlock, the seat of
Sir Dorouchr Wrey, Bart. This place is mentioned by dif-
ferent authors as remarkable for embracing at one view
"the bel manor, bel manor, incest church, and richest
rectory in the county." Bishop's Tawton, near Tawlock,
is said to have been the first seat of the bishop of this dioces,
Watkins's History of Bideford. Maton's Tour through the
western Counties. Prince's Worthies of Devonshire. Beau-

BIDEFORD, a port of entry and port-town of America,
in York county, and district of Mayne, on the south-west side
of Saco river, on the sea-coast, 14 miles S.W. from Port-
land, 24 N.E. from York, and 105 from Boston. It con-
tains 1068 inhabitants, and the county-courts are held here
and at York. N. lat. 43° 26'. W. long. 70° 25'. The bay
of Bideford lies at the mouth of the river Saco, and has
Black point for the N.E. point, and cape Porpose for the
S.W. point.

BIDDING, is used for proclaiming or notifying; also for
offering a price for goods put up by auction.

BIDDING of the bonds, a charge or warning which the
parish priest gave to his parishioners at certain special times,
to say to many pater-noiters, &c. on their beads.

Bishop Burnet (Hist. Ref. vol. II. p. 20.) has preserved
the form, as it was in use before the reformation, which was
this; after the preacher had named and opened his text,
he called on the people to go to their prayers, telling them what
they were to pray for; "Ye shall pray (says he) for the king,
for the pope, for the holy catholic church, &c." When this
was done, all the people said their heads in a general silence,
and the minister knelt down and likewise said his; they
were to say to a pater-noiter, an ave-maria, Deus misereatur
nostr, domine fulvam fac regem, gloria patri, &c., and
then the sermon proceeded.

BIDDLE, John, in Biography, a distinguished person
among the Socinians, and reckoned the father of the English
fæt bearing this denomination, and lately attaining that of
Unitarians, was born at Wotton-under-Edge in Gloucester-
shire, in 1615; and after a previous grammatical education,
in the course of which he exhibited specimens of his talents
and improvement, admitted, in 1632, a student of Mag-
dalen-Hall, in the university of Oxford. Here he acquired
great reputation for learning and prudence, both as a stu-
dent and a tutor: and having taken his degrees of bache-
lor of arts in 1638, and of master of arts in 1641, he was,
in this latter year, recommended by the principal persons in
the university to the magistrates of Gloucester, and appointed
by them master of the free school of St. Mary de Crypt,
in that city. In this office he completely answered the expecta-
tions of his confratres, and gave great satisfaction to the
parents of the young persons who were entrusted to his care.
But he did not long enjoy, without molestation, the advan-
tages of this situation; for he was led, by a diligent study
of the seriptures, to adopt notions that were deemed hereti-
cal, concerning the Trinity, and more particularly to deny
the deity of the Holy Spirit. Failing to give satisfaction
to the magistrates, before whom he was summoned, by his
confession in 1644, he drew up a more explicit account and
defence
defence of his sentiments on this subject in a tract, entitled "Twelve arguments, drawn out of the scriptures, wherein the commonly received opinion touching the deity of the Holy Spirit is clearly and fully refuted." A copy of this treatise, which he had shown to some of his friends, having been, by the treachery of an acquaintance, delivered to the magistrates of the city, and to the parliament committee then residing there, he was committed, in December 1643, to the common goal. He was released, however, on giving security for his appearance when called for. Six months after he had obtained his liberty, he was summoned to appear before the parliament at Westminster, and examined by a committee. As he freely professed his disbelieve of the commonly received opinion concerning the divinity of the Holy Spirit, he was committed to the custody of one of the officers, and kept in that state of restraint for five years. In the main while, his book, entitled "Twelve arguments, &c." was published, and being declared blasphemous against the divinity of Christ, the house, in 1647, ordered it to be burnt by the common hangman. In the following year, the author, persisting in his opinions, and avowing the futility of their importance, published two other tracts of a similar nature; one entitled, "A confession of Faith touching the holy Trinity, according to the scripture;" and another entitled, "The testimonies of Irenæus, Justin Martyr, Tertullian," and of several other early writers, relating to the same subject. These books excited an alarm, and were the means of procuring a severe ordinance of parliament, issued in May 1648, at the solicitation of the Assembly of divines, who acted in this instance in a manner that entailed disgrace on their memory, and denounced the penalty of death against those who held opinions contrary to those that were established respecting the Trinity, and some other doctrines, accounted blasphemies and heresies; and severe penalties on those who differed in lesser matters. By this infamous and execrable decree the fate of Biddle seemed to be inevitable. But he escaped in consequence of a diffusion in parliament, supported by a party in the army, to whose cause this ordinance would have extended. After the death of the king, the Independents acquired influence, and introduced a kind of general toleration, under which Biddle was allowed to go to Staffordshire, where he was hospitably received by a judge of the peace, who, at his death, left him a legacy. From this retired asylum, however, he was removed by order of Bradshaw to closer confinement, in which state he continued for several years, under an imputation of blasphemy and heresy, which deprived him of all society, and reduced him to such lamentable indigence, that his whole support for a considerable time was a draught of milk morning and evening. The only divine who visited him, during this period, was Mr. Peter Gunning, afterwards bishop of Ely. In these circumstances he obtained temporary relief by being employed in correcting the proofs for a Greek Scripture, printed in London by Roger Daniel; and in 1651, he regained his liberty by the general act of oblivion, published by the parliament in that year. Of this liberty he availed himself, by instituting a Sunday's lecture for reading and explaining the scripture, and thus propagating his opinions. The Presbyterian ministers were rendered uneasy by his zeal and success, more especially as they could derive no aid for restraining him from the secular power. Not satisfied with the opportunities he enjoyed of disseminating his sentiments from the pulpit, and in the intercourse of private friendship, he had again recourse to the press, and in 1654, published his "Twofold Scripture catechism," which is larger and more comprehensive, and the other more brief, for the use of children. For this publication he was called to the bar of Cromwell's parliament, and committed to the Gate-house, where he was debarred the use of pen and ink, and the access of any visitor; and his books were also ordered to be burnt. Although a bill was brought into parliament for punishing him, he obtained his liberty after six months' confinement, by due course of law. Some time after, he had a dispute with a Baptist teacher, in the course of which he made use of some expressions, for which he was thrown into Newgate, and tried for his life at the next sessions, on the ordinance above-mentioned. On this occasion, counsel was at first denied him, but afterwards granted, and the trial deferred. In the mean while Cromwell interposed, and disapproving of his kind of intolerance, contented himself at first with detaining him in prison; but afterwards, in order to silence the clamours and petitions that were preferred against him, banished him for life to St. Mary's castle in the island of Scilly, assigning him an annual subsistence of 100 crowns. In this place of exile Biddle continued three years, applying himself to cloister study, and particularly to that of the Apocalypse. His friends at length prevailed with Cromwell to recall him; and in 1658, as no charge appeared against him, he was liberated. He then became pastor of an independent society in London, and propagated his opinions without molestation, till the fear of the presbyterian parliament assembled by Richard Cromwell, and the advice of his friends, induced him to retire into the country. On the dissolution of that parliament, he returned to his former situation. After the restoration of Charles II. he withdrew from public service, and exercised his ministry in private assemblies with his select friends. However, in June 1662, their meeting was discovered, and both he and his friends were apprehended and committed to prison; and at length, by processes of law, each of his hearers was fined 20l. and Biddle himself 100l.; and they were ordered to remain in prison till these fines were paid. The close confinement and foul air of a prison, within five weeks, brought upon him a distemper, which terminated his life, September 22, 1662, in the 47th year of his age: and thus was his death hastened by the intolerance which persecuted him during the greatest part of his life. Mr. Biddle possessed a considerable degree of learning; and with the Scriptures he was so conversant, that he could repeat the New Testament from memory, both in English and in Greek, as far as the 4th chapter of the revelation of St. John. He professed also, with this retentiveness of memory, powers of reasoning, which eminently qualified him for discriminating his peculiar opinions, and gaining proclivities. In his private character he was distinguished by his piety and devotion, by his moderation and temperance, by his constancy and benevolence, and by his irreproachable virtue. As he differed in some respects from Socinians and the foreign Unitarians, his followers were for some time denominated "Biddellites," but the name did not subsist after his death. Biog. Brit. Thourot's Life of Biddle, in Unitarian Arts, vol. iv. 1791. Neil's Hist. of the Puritans, vol. i. p. 476, 480.

BIDDELS, in Geograpby, a settlement on a branch of Licking river, in Bourbon county, Kentucky, about 6 miles W. N.W. from Middles on the N.E. side of the same branch, and 32 miles N.E. from Lexington.

equal, oblone, channelled, conceave. Cer. compound, uniform, tubular; corollas hermaphrodite, tubular. Proper one-petalled, funnel-form; border five-cleft, erect. Stam.-filaments five, capillary, very short; anther exstipitate, tubular. Pist. : gyn. oblong; style simple, the length of the andrenus; stigma two, oblong, reflex. Pet. : base calyx unchangled. Seeds solitary, oblong, angular; down with two or more awns, oblong, straight, acute, rough-hooked 1/2 awards. Rac. flat, chaffy; calia deciduous, flattish. Off. in most of the species an expanding five-awned calyle surrounds the compound flowers. Verbenae differs from Bident only in having a ray. Sometimes the corolla has one or two radial florets. 

Species 1. B. tricipita, trifid water-hemp-agrimony, or bun-yargold. Lin. sp. fl. 1756. Hudson 355. With. 756. Huds. 1811. Relh. 358. Sibth. 248. Abbot 157. Curt. Lond. fasc. 4. 1. 57. Smith Br. Brit. 257. 1. Verbeina seu canabina aquitana, flore minus uniforme, et magnis radios. Rais. Synop. 18. Eschschol. canabina feminina. Ger. et. 111. B. Conya palafris. Ed. tricartio divisa. Linn. propr. 53. Le. 15. "Leaves trifid, calyces somewhat leafy, seeds erect." Root annual; item from one to three feet high, with opposite. reddish branches, patent, leafy, obtusely quadrangular, furnished and smooth; leaves opposite, smooth, deep ferate, trifid or quinquafe . flowers terminating, solitary, somewhat eract, with undivided patent leaves; leaflets of the calyx unequal, plum, smooth, freckled with brown; the florets uniform, tubulose, yellow; seeds comprized, two or three angled, the angles backward, short, two or three awns, terminating; somewhat eract, yellow, three-cornered, prickly backward; the flaps of the receptacle resembling the habscts of the calyx, but narrower. It is frequent in places inundated, and on the brinks of ditches; flowers in August and September. This plant dyes a deep yellow; for which purpose the strand or yarn must be first steeped in alum water, then dried and steeped in a decoction of the plant, and afterwards boiled in the decoction. As by a chemical analysis it is found to pellucid much the same qualities as Verbeina acmenis, it may probably have the same good effects in expelling the stone and gravel. 2. B. minima, nodding bun-yargold. Lin. sp. fl. 1165. Reich. 3702. Huds. ed. 1. 310. Fl. Dan. t. 312. Abbot 1758. With. 874. 2. Curt. Lond. 3. 55. B. tricipita. 3. Huds. 355. B. Canus. 5. Smith Br. Br. 357. Verbeina minima. Dill. in Rais Synop. 128 t. 7. f. 2. Giff. 167. App. 66. "Leaves lanceolate sessile; flowers and seeds erect." This was first marked by Dillenius for a distinct species. Halls thought it to be no more than a variety of the cernua, in which he has been followed by all our British botanists. Found in dried marshes. 3. B. nodiflora, filiform-flowered bidens. Lin. spec. 1165. Dill. ed. 1. 74. 52. Reich. 3702. "Leaves oblong, quite entire, one-toothed, item dichotomous, flowers filiform, sessile." An annual plant, rising with forms eight or nine inches high, roth dist., rough, with white hairs, purpl at the base. A native of the East Indies; cultivated at Eltham by Dr. Sherard, in 1722. 4. B. cernua. Lin. spec. 1166. Reich. 3704. Auch. 6. afr. 47. "Leaves linear, peduncles capillaries, calyces mostly four-leaved, seeds erect, five-fold." Stem fringed, purplish, subtrichotomous, six or seven inches in height. An annual, and a native of the Cape of Good Hope. 5. B. cernua, drooping water-hemp-agrimony, or bun-yargold. Sp. pl. 1165. Huds. 356. With. 705. Hall 122. Rellh. 332. Sibth. 248. Abbot 177. Curt. Lond. ed. 3. 55. Fl. Dan. 11. 843. Smith Br. Brit. 357. 2. Pet. herb. t. 20. f. 6. Rall. herb. 361. 2. 5. Verbeina pubescent more flore lateo. Rais. Synop. 18. Baud. hist. v. 2. 1759. Cons. spicis desc. Sp pl. 1281. Chrysanthemum canabina britannicum, foliis integris. Moris. hist. t. 6. 5. f. 22. Eschschol. canabina chrysanthemum. Borel. lec. t. 1259. Cons. spicis desc. Bot. propr. 51. 1. 11. "Leaves lanceolate, flore calipal, flowers nodding, seeds erect." Root annual; item from one to two feet high, or more, upright, branched, a little hairy, purplish, dotted with red, round at bottom, flattened at top, with branches opposite, nearly upright, leaves opposite, moderately coarse, undivided, or with distant ferratures. spreading, smooth on both sides; peduncles fringed; flowers yellow-green, finally deinaps, generally radiate; calyx consisting of about seven jaws, a finely serrate at the edge, ribbed, turning back, and longer than the corolla; with eight corollas in the circumference, hermaphrodite, like the central ones, but with a tube more turbinated and depressed. In places overlooked for a long time, they change into ligulate neutral con-flores; receptacle pyramidal, four-cornered; feeds with four awns, two of which are larger; the prickles pointing downwards. This flowers a month later than the tripartita and in this has a strong smell, not very disagreeable. A native of most parts of Europe. Halles observes, that coreja is distinct of Linnæus differs in no respect from B. cernua, except in having raduate florets in the circumference; here, Dr. Stokes concludes, that bidens and coreja form one genus. Found at Ditchingham in Norfolk, and Tamworth in Cheshire; frequent in Ireland. 6. B. frondosa, inchoate-flowered Biders. Lin. spec. 1166. Gartn. fr. 2. 299. 2. Reinh. 57. 3. 11. Gartn. fruct. 2. 2. 2. B. Chinchaca. Agrimonia Molacca. Rumph. Amb. 6. 58. t. 15. f. 2. "Leaves pinnate, somewhat hairy, item with bearded joints, calyces with a simple involucres, feeds diverging." A native of America, and of Tungataboo in the South Seas. B. of China resem-bles the American; but in the latter the habscts are united, in the former they are distinct, and the seeds of the American have from two to five awns, and in the Chinese always four. The American fort was cultivated in 1732 by Dr. Sherard. 8. B. l improving, hemlock-leaved bidens. Lin. spec. 1166. Reich. 3. 705. Linn. ed. 1. 74. 52. Reich. 3702. Thumb. jep. p. 307. Linn. cochen. 488. Gartn. fr. 2. 2. 2. B. Chinchaca. Agrimonia Molacca. Rumph. Amb. 6. 58. t. 15. f. 2. "Leaves pinnate, somewhat hairy, item with bearded joints, calyces with a simple involucres, feeds diverging." An annual plant; a native of Virginia; cultivated in Kew garden in 1769. Laberco fays it is a native of China and Cochinchina. 9. B. sparsa, showy bidens. Lin. spec. 1166. Reich. 3. 706. Dill. ed. 1. 74. 52. Swartz. ed. 256. 2. Dill. ed. 1. 47. 55. 3. 7. Dill. ed. 1. 36. 5. 52. "Leaves simple, corolla-ovate, acuminated, branches trichotomous, ferratures, flowers hemispherical, peduncles elongated." A native of Jamaica, is cultivated in gardens, and on the ten-coast of the southern parts. Mr. Miller says, it grows naturally in South Carolina, and also at Caspian: cultivated at Eltham in
BID

BIDENS, a species of Casurina, of a black colour. Wings-cases patterned 1.4.1.1., with an oval spot on the front of each. This is a large bee, and is an inhabitant of India.

BIDENS, a species of Cardamine, that inhabits New Zealand. Its body is black; pollens triangles, dotted with a single spot, on each of the wing-cases. Fabricius.

BIDENS, a species of Cardamine (Lanata), found in New Holland, and described by Fabricius. It is characterised by thorax acutely pointed; wings-cases black tined at the tip.

BIDENS, a species of Mantis, that inhabits America. The thorax is lemon-yellow; wings-grey green, spotted with black; winged brown, deep black in the drake.

BIDENS, a species of Cellistis (Sparreri), the thorax of which is entirely pinious; inner hind and median, and hindered veins, tinged with brown; wing-cases pale. A native of Europe, Asia, and Africa. There is also another in this section, described by Linnaeus and Gmelin, under the name of B. This is an ovate shape, and the thorax acutely spiraled, and the antennae nothing.

BIDENS, a species of Sphex, of a black colour, having the head and a narrow pinnaceous; four yellow spots on the abdomen, and two spots on the thorax. Gmelin. I. inhabits Mexico.

BIDENS, a species of Vespa, of a black colour, with two spots on the thorax, and third for post of the hind wing, with yellow margin. Fabricius. It inhabits the north of Europe.

BIDENS, a species of Formica, that inhabits Surinam. Thorax with a bidicators tubercle; head wide; antennae ferrons; back very black. Fabricius. Sp. Inf.

BIDENTALIUM, Jodilis, a plant struck with a thunderbolt, and on that account converted to the gods, and to Jupiter and Minerva, and forbidden to be used, and to have any part of the tree cut down. It is said by Plutarch that the vineyard of Jupiter at the time of the Grecian wars was laid waste by this tree. This tree is said to have been used by the Romans for the making of their wine. Hence, they are found that a vineyard is always near a temple. The vineyard is extended to thunderbolts and to prevent its being burnt.

Hence, they are found that a vineyard is always near a temple. The vineyard is extended to thunderbolts and to prevent its being burnt.
that inhabits America. The abdomen is brown, with five whitish belts; vent bidentated. Fabricius.

BIDENTATUS, a species of Bostriuchus, described by Fabricius, Herbst, &c. It is black, and tesselated, rufous beneath, and armed with two hooked spines.

BIDIA, a species of Cryptocophalus (Cricoses), of a yellow colour; wing-cases black, yellowish at the tip. Fabricius. Inhabits Africa.

BIDIN, a species of Cerambyx, that inhabits South America. The thorax is slightly fuscous; wing-cases bidentated, rough, cinereous, and brown. Fabricius.

BIDLOO, a species of Ichneumon, that inhabits Europe. It is black, fuscous, and posterior part of the thorax yellow; on the latter two teeth, and the two first segments of the abdomen ferruginous. Linn. &c. The four anterior legs are russet brown; left black; tips white.

BIDOIN, a species of Cimex (Spinophus), found in France. This is long and brown; front bent; thorax beneath armed with two teeth on the anterior part. Geoffroy, Gmelin.

BIDON, a liquid measure of about five quarts English measure; seldom used except among ship's crews.

BIDOURLE, in Geography, a river of France, which passes by S. Hippolyte, Sauge, Sommieres, &c. and runs into the lake of Peraut, 3 leagues east of Montpellier.

BIDOUE, a river of France, which runs into the Adour, near the junction of that river with the gaves of Pau and Oleron.

BIDUAI, a country of Asiatic Turkey, the south part of Syria, bounded on the north by Palestine, on the west by Egypt, and on the east and south by Arabia; it is nearly desert, and has only a few scattered villages.

BIE, ADRIAN DE, in Biography, a painter of portraits and ornamental architecture, was born at Liere, in 1594, and after being initiated in the rudiments of his art by Wouter Abts, became the disciple of Redolph Schoof, a painter of considerable reputation at Paris. He perfected himself at Rome, where he spent six years in the study of the beautiful, and received great encouragement from persons of the first distinction. He so much excelled in the neatness of his pencilling, and in the delicacy of his touch and colouring, that he was frequently employed to paint on Jasper, agate, porphyry, and other precious materials. The place and time of his death are not ascertained. Pilkington. See BIE.

BIEBER, in Geography, a town of Germany, in the circle of the Upper Rhine, and county of Hanau Munzenberg, 16 miles east of Hanau. Near this town are a mine of copper and silver, and some works of iron and coal, in which the latter is prepared into a beautiful fuel.

BIEBERICH, a small but handsome town of Germany, seated on the borders of the Rhine, and in the vicinity of Mentz. It belongs to a prince of the name.

BIEBERSBACH, a town of Germany, in the circle of Franconia, and principality of Bayreuth.

BIEBRA, a river of Poland, which runs into the Narwa, near Wizna, in Malovia.

BIECZ, a town of Poland, in the palatinate of Cracow, seated on the river Wafaloke, and famous for its mines of vitriol.
BIE Shapiro, a town of Italy, in the state of the church, and province of Patrimonio, 10 miles W. of Sutri.

BIEBROOK, BIEBROOK, a small town of Germany, in the circle of Burgundy, and duchy of Luxembourg, which was flourishing till the year 1663, but soon afterwards laid waste by the French.

BIEBROOK, or BIBROOK, a small town of Germany, in the circle of the Upper Rhine, and principality of Upper Hesse, feated on the Alhills, 16 miles N.W. of Marburg, and formerly famous for its iron works and foundry.

BIEFVERSKOW, a district of Zealand, belonging to Denmark, including 12 churches.

BIEK, BIEK, BORIQUIN, or CRAB'S ISLAND, one of the Virgin Islands in the West Indies, about 2 miles in length, and not 6 in breadth, where it is widest. It is distant about 6 miles S.S.E. from Porto Rico. The soil is rich, and it has a good road on the south side, called Great Harbour. It is claimed by the Spanish, whose interest it is to let it remain desolate. N. lat. 18° 2'. W. long. 64°. See Virgin Islands.

BIEKOW, or Jezow, a town of Poland, in the patrimony of Leczycz, 24 miles S.E. of Leczycz.

BIEL, a town of Spain, in Aragon, 6 leagues S.W. of Jaca.—Alfo, a river of Spain, which joins the Eres at Exca. See Briene.

BIELA, a town of Bohemia, in the circle of Ceslau, 6 miles N.E. of Teutsch Brud.

BIELA, or BIELA, a town of Italy, in Piedmont; the capital of a small country, bounded on the north by the Alps, on the west by the duchy of Aosta, on the east by the Vercellos and the Maifern, and on the south by the Canaves; the town is rich and populous, containing about 7,000 inhabitants, and is divided into the Upper and Lower, and has four churches and four monasteries. It is famous for an image of the Virgin Mary; distant 13 miles N. from Ivrea, and 24 N. W. from Vercelli. N. lat. 45° 22'. E. long. 8° 3'.

BIELACH, a river of Germany, in the archduchy of Austria, which runs into the Danube, near Melek.

BIEIILA, a river of Russia, which rises in the Uralian mountains, and after traversing the government of Ufa, discharges itself into the Kama, on the borders of the government of Cahan.

BIELASTENA, a town of Croatia, 10 miles north of Bihae.

BIELAY, a town of Bohemia, in the circle of Komratz, 4 miles S. W. of Branau.

BIELEK, or BIELA, a town of Siberia, 40 miles south of Eniheik.

BIELOPOL, a town of Poland, in the patrimony of Kiof, 28 miles west of Balacterkiew.

BIELEF, a town and district of Russia, in the government of Tula, feated on the Oca, 50 miles W.S.W. of Tula.

BIELEFELD, a town of Germany, in the circle of Westphalia, and county of Raverberg, divided by the Lutterbach into the old and new town, feated at the foot of a mountain, and containing about 800 houses. The inhabitants are partly Lutherans, and partly Roman Catholics. The old town has two churches, the new a convent and a chapel. This town received municipal privileges in 1287, and was formerly Hanifacit; it is distant 22 miles north from Lippstadt.

BIELEGROD, a town formerly called Sarkel, and district of Russia, in the government of Kjurk, feated on the Donetz; 50 miles S.S.W. from Kjurk. N. lat. 56° 55'. E. long. 36°. This town was built in 990, by the great duke Vladimir, and is an archbishop's see; it submitted to the arms of Potemkin, in 1790.

BIELEGROD, See Axerman and Moscow.

BIELEGRAF, a town of Croatia, 40 miles S.E. of Bibern.

BIELEPHN, a town of Russian Tartary. N. lat. 43° 20'. E. long. 66° 40'.

BIELEPHN, or BILJIN, a town of Lithuania, in the province of Vilna, feated on the Niemen, 10 miles south of Lida. N. lat. 53° 35'. E. long. 25° 40'.

BIELESKI, a town of Poland, in the patrimony of Kiof, 41 miles S.W. of Kiof.

BIELETZY, See Biltucz.

BIELEA. See Biela.

BIELEB, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Chamont, 6 miles E.S.E. of Chamont.—Alfo, a town of France, in the department of the Lower Pyrenees, and chief place of a canton, in the district of Oleron, 14 miles south of Oleron.

BIELOI, a town and district of Russia, in the government of Smolensko, on the small river Volchina, falling into the Meffn or Meza, which discharges itself into the Duna; 50 miles N.E. of Smolensko. N. lat. 55° 0'. E. long. 34°.

—Alfo, an island in the Karkoi fea, about 70 miles in circumference, 20 miles from the continent of Russia. N. lat. 73° 20'. E. long. 69° 14'.

BIELOKAMSKOJ, a fortress of Russia, in Siberia, on the east side of the Itil, 12 miles S.E. of Semipolatno.

BIELOOZERO, or WHITE LAKE, a lake of Russia, in the government of Novgorod, about 50 versts long, and 30 broad, which receives into it several small streams. The only one that flows out of it, is the Schekfa, which falls into the Volga. The water of this lake is clear, having a bottom partly of clay, and partly of stone. The clay is generally of a white colour, and in stormy weather causeth a strong white foam upon the surface of the water. From this circumference, the lake first obtained its name Bieleso, or White. It contains plenty of fish and crabs. N. lat. 59° 42'. E. long. 66° 20'.

BIELOPOLJE, a town and district of Russia, in the government of Karkoff, feated on a rivulet falling into the Seim, 85 miles N.N.W. of Karkoff.

BIELOVITZ, a town of Croatia, 11 miles S.W. of Damianovitz.

BIELOVODSK, a town and district of Russia, in the government of Voronetz, feated on the Derkul, which falls into the Doca, 130 miles south of Voronetz. N. lat. 50° 42'. E. long. 39° 20'.

BIELOW, a town of Poland, in the patrimony of Volhina, 36 miles east of Lucko.

BIELOZERSK, a town and district of Russia, in the government of Novgorod, on the south side of the lake Bielegrof, near the efflux of the river Schekfa, 64 miles N.E. of Vologda. N. lat. 59° 40'. E. long. 37° 10'.

BIELOSA, a town of Spain, in Aragon, 6 leagues from Alcuia.

BIELSK, a town of Poland, and capital of the patrimony of Podolachia, where the dietine for the district is held. It is little better than a miserable village, though called in the geographical descriptions of Poland, a large town. N. lat. 52° 48'. E. long. 23° 28'.—Alfo, a town of Poland, in the patrimony of Ploczko, 10 miles N.E. of Ploczko.

BIELTSG, a town of Bohemia, in the circle of Chrudim, 16 miles north of Chrudim.

BIELE, in Zoology, Delphinus Leucis (Genua) in Steiner's Kampfleicht, &c.

BIEUASME, John, in Biography, born in 1601 at Mazeres,
Mazeres, a city in France, where he practised surgery with much success, as to attract the notice of his sovereign, Lewis XIV., by whom he was made surgeon to the army in Flanders. He acquired great reputation, Haller says, by introducing the future of the organ, and by curing a puncture of the brachial artery in a young nobleman. He gives excellent cautions, on taking up the artery, after amputating a limb, to avoid including the nerve in the ligature. He performed the paracentesis of the thorax successfully, and appears to have been a bold and expert operator, and to have made considerable improvements in his art. He died 1681, aged 80 years. A few years after his death, viz. in 1688, a polished work was published, containing an account of these operations, under the title of "Opérations de Chirurgie, par une méthode courte et facile," 12mo. Paris. Haller Bib. Anat. Eluy. Dict. Hist.

BIENENBUTTEL, in Geography, a town of Germany, in the circle of Lower Saxony, and principality of Lunenburg, 10 miles S.S.E. of Lunenburg.

BIENNE, a small district of Switzerland, lies between a lake of the same name and a chain of the Lura mountains. It is surrounded by the cantons of Berne and Solothurn, the bishopric of Basel, and the principality of Neuchâtel. The bishop of Basle is the sovereign of this little state, but his power, even before the French revolution, was exceedingly limited; and its constitutional was neither a limited monarchy nor an independent republic, but a kind of mixed government, partaking in some degree of both. The bishop of Basle, upon his promotion to the fee, received the homage of the citizens and militia of the town of Bienna, with attendant tokens of absolute submission, but at the same time he confirmed, in the strongest manner, all their privileges and franchises. The mayor appointed by him was his representative, to whom it belonged to convene and preside in the little council, as the chief court of justice, to collect the suffrages, and to declare the sentence; but without giving any vote himself. Although justice was carried on, and executed in the name of the bishop, yet neither that prince, nor the mayor, had the prerogative of pardoning criminals, or of mitigating the sentence. All causes, civil and criminal, were brought before the council in the first instance; and in more important proceedings, an appeal lay to the sovereign council. In both cases, each party chose a member of the council to act as his advocate, which office he discharged without fee or remuneration. The sovereign's revenue amounted to about 300L. a year, nor did he possess the least share in the administration. The legislative authority resided in the great and little councils combined; the former consisting of 40 members, and the latter, to which the executive power belonged, being composed of 24; and it was required that the members of each council should be married men. Both councils elected their respective members; and therefore the constitution was altogether aristocratic. The burgomaster, or chief of the regency, was chosen by the two councils, and presided at their meetings, and retained his office during life; but it was necessary that he, as well as the several magistrates, should be confirmed annually by the two councils. The salaries annexed to these posts were small, and the general expenses of government so indifferently that the revenues of the state were sufficiently ample.

This republic, though a Protestant one, under the sovereignty of a Catholic bishop, enjoyed in the fullest extent the power of imposing taxes, contracting alliances, declaring war and peace; and, in short, of exercising every other act of absolute and independent legislation. Its singular constitution was guaranteed by Berne, Friburg, and Soleure, with which the town was closely allied, having connected itself with the former in 1352, with the second in 1456, and with the latter in 1382; in consequence of which union it became a member of the Helvetic confederacy. This alliance between the cantons and the town of Bienna was paramount to that of the same cantons with the bishop of Basle; for the town enjoyed the right of sending deputies to every general diet, ordinary or extraordinary, a privilege not possesed by the bishop. The language of the country is a provincial German; but, as the territory borders on the principality of Neuchâtel, the inhabitants speak also a corrupt French. The extent of the town and territory of Bienna is estimated at 144 square geographical miles, and its population at 5,500, or nearly 6000 persons; the people are very active and industrious. Bienna forms an important pass into the Swiss territories; accordingly, it was occupied by the French on the 8th of February 1798, and annexed to France as subject to the bishop of Basle, whose rights they assumed in consequence of having seized his territories.

BIENNE, called by the Germans Biel, the capital of the above district, is situated at the foot of mount Jura, and at a little distance from the lake of the same name. Between the town and the lake is a plain, which the sovereign council, by a kind of Agrarian law, that was honourable to the legislature, allotted, by distinct portions, to each burgher for his own exclusive use; and it is entirely laid out in small kitchen gardens. Several manufactures have been established in the town, which, considering its size, carries on a tolerable trade. The government, by adopting the liberal policy of conferring the burghership at an early rate, has contributed to increase the population of the town, and to extend its commerce. N. lat. 47° 8', E. long. 1° 4'.

BIENNE, lake of, lies to the north-east of that of Neuchâtel, with which it is connected by the Thieille, which separates the country of Neuchâtel from the canton of Berne. It is about 9 miles long, and 4 broad; its borders are pleasing and picturesque, as it is skirted with agreeable walks and country houses; and the town of Nidau forms a very beautiful object upon its eastern side. Towards the southern extremity of this lake is the island of St. Peter, sometimes called the island of La Motte, and sometimes Rousseau's island, from its having been the place of Rousseau's retirement and residence, when by the violence of the populace he was obliged to withdraw from Môtier, where Frederic king of Prussia had endeavoured to protect him. Mr. Coxe, when he visited this island, landed on the south side of it, and passed through an agreeable meadow, skirted with vineyards, to a large farm house, formerly a convent, and secularised at the reformation, but inhabited, at the time of Mr. Coxe's visit, by the steward of the general hospital at Berne, to which the island belonged. "The island," says Mr. Coxe, "is about 2 miles in circumference, and richly wooded with various shrubs and trees, particularly with large oaks, beech, and Spanish chestnuts. Its surface is gently undulating; the southern shore, covered with herbage, forms a gradual slope to the lake; the remaining borders are steep and rocky; in a few places their summits are thinly fringed with shrubs; in others their perpendicular sides are clothed to the water's edge with hanging woods. The views from the different parts of the island are beautiful and diversified; that to the north is the most extensive and pleasing. It commands the lake of Bienna, which is of an oval form; its cultivated borders spotted with villages and castles, with the towns of Nidau and Bienna standing on the further extremity. Agreeable walks are carried through the woods, and terminate at a circular pavilion placed in the centre of the island. During vintage, particularly, and on Sunday, which is the usual day of festivity, the island is filled with parties, who take refreshment at the farm-house, stray about the woods, or dance in the circular building, and animate these romantic but solitary scenes."
BIE

BIE

cenes." "Rouffec occupied an apartment in the farm-
house, the only dwelling in the island. He lived with the
flewman and his family, who are the present inhabitants
(1785). The woman informed me, that he paid for his
board and lodgings 40 shillings a month; that he usually
rose at six, dined with the family at twelve, and after
a flight supper retired to rest at nine. She added, he was ex-
tremely cheerful and agreeable; conversed with the family
with the greatest ease and complacency, and conformed to
their hours and manner of living; he amused himself entirely
in wandering about the woods, and searching for plants,
which he used to explain to them with singular satisfaction.
Rouffec mentions his residence in this delightful island with
the highest terms of rapture, and with his usual proneness to
eaggeration. "I was permitted," says he, "to remain
only two months in this delightful island; but I could have
passed there two years, two centuries, all eternity, without
suffering a moment's ennui, although my whole society con-
fined of the flewman and family, good, but plain people. I
elicited those two months the most happy period of my life;
and so happy, that I could have passed my whole existence
without even a momentary wish for another situation." 
Coxe's Travels in Switzerland, &c. vol. ii. p. 152, &c.

BIENNIAL Plants, in Botany, denote such, as the
epithet imports, that are of two years' duration. Of this
tribe there are numerous plants, which, being raised one
year from seed, generally attain perfection in the same year,
or within about twelve months, shooting up tallks, pro-
ducing flowers, and perfecting seeds in the following spring
or summer; and soon after commonly wither, or apparently
decay and dwindle, so that they soon die off. Biennials are
therefore, always in their prime the first or second summer.
They consist both of herbaceous and flower plants. Thoese
of the former sort are the cabbage, savory, carrot, parsnip,
beet, onion, leek, &c.; and thoese of the latter are the
Cauterbury bell, French honey-fucklc, wall-flower, flock
july-flower, sweet-william, China-pink, common-pink, matted
pink, carnation, frabious, holly-hock, tree-mallow, vervain
mellow, tree-primrose, honeyl, or moon-wort, &c.

BIENTINA, in Geography, a town of Italy, in the
duchy of Tuscany, on the side of a lake, called the "lake
of Bientina," or the "lake of Seffo," which lake is about
6 miles long, and 5 wide; 12 miles east of Pisa, and 28
west of Florence. The territory of Bientina lies in the
middle of a marsh, in the centre of a valley, not very
spacious, bounded by the high mountains of Pisa, and by
those of Lucca and Valdimievo, which interrupt the wind,
and prevent a renewal of air; and it is, therefore, as one
would imagine by its situation, peculiarly unhealthy and
unfavourable for inhabitants. It is nevertheless very popu-
lous, and sufficiently healthful even in summer. The
principal causes of this fulabity are said to be, the
numerous population, the extensive commerce, and the extreme
attention that is paid to the continual discharge of the rain-
waters, but, above all, the advantage of an abundant spring,
which descends from the hills of St. Colome, by means of
long aqueducts, and supplies the inhabitants with excellent
water. The situation of Bientina, therefore, duly examined,
shows how far the art of man is capable of rendering habi-
table, and even fabulous, places naturally pleasant.

BIENVILLE, D. T. De, M. D. in Biography, born in
France, practiced medicine many years in the Hague, and is
only known by the following works, which bear his name:
"La Nymphomanie, ou Traite de la fureur uterine," Amst.
1771, 8vo.; "Recherches theoriques et pratiques fur la
Petite verme," 1772, 8vo.; "Traite des erreurs populaires,
fur la fante," La Hague, 1775, 8vo.

BIER, a kind of wooden carriage, on which the bodies
of the dead are borne to their grave. The word comes from
the French bier, which signifies the same. It is called in
Latin funerus, a funeral. Among the Romans the common
bier, upon which the poorer fort were carried, was
called jandapaia; that used for the richer fort, leitra, leitra
funebri, sometimes leita. The former was only a sort of
wooden shet, solis arcu, which was burnt with the body:
the latter was weathered and gilded for pomp. It was carried
bare, or uncovered, when the person died a natural and easy
death; when he was much disfigured or distorted, it was
veiled or covered over.

BIER, is more particularly used for that on which the
bodies of fants are placed in the church to rest, and exposed
to the veneration of the devout. This is often enriched
with gold, silver, and precious stones; and furnished temper-
atons, in many instances, to pilage.

BIERG, in Geography, a hered-or district, of the diocese
of Fuenz in Denmark, including 12 churches, and several
noblemen's seats.

BIERLING, Gaspan Thophilus, in Biography,
took his degree of doctor in medicine at Padua, about
the middle of the 17th century, whence he returned to Neuge-
burg, his native city, where he was in considerable eluc-
tion. He published a "Adeferariarum curiiorum Centuria
prima," June, 1679, 4to. He describes the effects of eat-
ing the hyoeryum (henbane), drawerets, and delirium,
which are cured, he says, by taking the extract of caltars,
and the effects from the bite of a viper, cured by eating the
flesh of one of those reptiles. He had the merit of recom-
mending the cool treatnut; and even bleeding, in the small-
post, contrary to the then generally received opinion. In the
remainder of his works, which are numerous, but in little es-

BIERNE, in Geography, a town of France, in the de-
partment of Mayenne, and chief place of a canton, in the
district of Chateau-Gontier. The place contains 810, and
the canton 822; inhabitants: the territory includes 123
kilometres and 12 communes.

BIERVLIET, a small town of Flanders, on the west
side of the Scheldt, which has been much reduced by frequent
iminations, and the fortifications of which were destroyed
in 1688. William Beukelvoord, or, as others have written
his name, Beukelings, who taught the Dutch the art of
curing herring, was a native of this place, and died here in
1597. The town is 7 leagues north of Ghent, and 4 E. N. E.
of Silves. N. lat. 51° 25'. E. long. 3° 42'.

BIESOS, a large lake in the Merowe, between Dort
and Gerttudenburg, formed by the imprition of the banks
dykes.

BIELSE, a river of Germany, which rises 8 miles south-
west from Stendal, in the Old Mark of Brandenburg, and
purling its course to Seuchten, changes its name to Aland.

BIESENTHAL, a town of Germany, in the circle of
Upper Saxony, and Middle Mark of Brandenburg, 20 miles
N.E. of Berlin.

BIESIUS, Nicholas, in Biography, born at Ghent in
Flanders, March 27, 1516, studied medicine at Louvain;
thence he went to Valencia in Spain, and afterwards to Si-
enna, in Italy, where he took his degree of doctor. Re-
turning to Louvain he was advanced to the chair of pro-
fessor in medicine, which he filled with credit several
years, expounding to his pupils, as the custom then was, the
works of Galen. He was then called by the emperor Maxim-
ian II. to Vienna, and appointed his physician, which post
he held until April 1572, when he was suddenly cut off by
a fit of apoplexy. His works are, "Theoretice Medicinæ,
libri sex," Ant. 1558, 4to.; in Armenia medicinæ Gala-
ieni Commentarii," 1563, 8vo.; "De Methodo Medicinæ,"
1563. 8vo.; "De Natura libri quinque," 1573, 8vo.; the
two last works have been several times reprinted.

Y y 2
BIESMIES, in Geography, a place of France, where is a
pale across the Aine, from the department of the Meuse to
that of the Marne; 3 miles from St. Menehould, and 12 from
Grand Pre.

BIESNIN, a town of Poland, in the patalinate of
Plocko. N. lat. 53°. E. long. 20° 8'.

BIETIGHEIM, a town of Germany, in the duchy of
Wurttemberg, at the confluence of the Enz and Mettersbach;
10 miles N. of Stuttgart, and 50 S.S.E. of Heidelberg.

BIERE, a river of France, which rises a little to the
south of Verfailles, and falling towards Paris, changes its
terminating point for that of Gobelins, on account of its water
being used in that manufacture, and soon after it joins
the Seine.

BIEUZI, a town of France, in the department of Mor-
bihan, and chief place of a canton, in the district of Pontivy ;
2 leagues S.S.W. of Pontivy.

BIÉZOW, or Birdsow, a town of Boheinia, in the
circle of Koningingratz; 3 miles east of Koningingratz.

BIFARIA, Folia, in Botany, denote leaves that point
two ways.

BIFASCIANA, in Entomology, a species of Phalaena
(Tortrix). The anterior wings are teffaceous; two ob-
lique bands, spot, and arched mark at the apex brown.

BIFASCIATA, in Entomology, a species of Bulla, the
shell of which is somewhat tapering, erect, and white, with
two broad reddish bands at the aperture. Lifter. Gmelin.

BIFASCIATUS, a species of Voluta, described by Lifter
and Martini. This shell is thin, transferable, fluted, and
flesh colored, with two white bands and a fingle tooth on
the pillar. It is rather less than an inch in length; and has
a long narrow aperture. Native place unknown.

BIFASCIATA, a species of Cypraea, of an oblong form
and purplish, with a straw-coloured band, and a narrower
white one, a brown border. Gmelin. Length nearly
four inches. Country unknown.

BIFASCIATA, a species of Nerita, of a blackish colour,
with two holy bands and white tip. A native of India.
Gmelin, Chemnitz, &c.

BIFASCIATA, in Entomology, a species of Silphia, found
in Saxony. This is black, with two bands and a spot at the
apex of ferruginous colour. Fabricius. This is a small insect.

BIFASCIATA, a species of Cassida, that inhabits South
America. It is pale with two brown bands. Gmelin.

BIFASCIATA, a species of Coccinella, of a ferruginous
colour, with two bands and four dots of black. Fabricius.
This insect inhabits the Cape of Good Hope; and is Coccin-
ella flexuosa of Thunberg.

BIFASCIATA, a species of Chrysomelida of a large size,
that is found at Cayembe. It is teffaceous: wing-cafes
braly and shining: two spots and two bands of yellow.
Fabricius, &c.

BIFASCIATA, a species of Cicada (Cecropia), of a yel-
lo fgh colour, with brown wing-cafes, and two white bands.
Fabricius. This is Cicada fulca, faciscis alarum binis albis, of
Linn. Synl. Nat. XII. and Cicada trifasciata, of Degeer.
Inhabits the north of Europe.

BIFASCIATA, a species of Phalaena (Geometra), de-
b described by Linnæus as a native of Europe. The anterior
wings are cinereous, clouded, with two bands; posterior
clear white.

BIFASCIATA, a species of Libellula, that inhabits
America. The wings are hyaline, with a brown spot at the
base, and two bands of the same colour. Fabricius. Ob.
This is Libellula trinaculata of Degeer; and Libellula
patchella of Drury.

BIFASCIATA, a species of Tenthredo, that inhabits Eu-
rope. The general colour is brown; thorax black; mouth
scutal, and four spots white: on the abdomen two interrupted
yellow bands; margin of the wings and legs yellow.

BIFASCIATA, a species of Mutilla, that inhabits New
York. The colour is black; upper part of the head and
thorax, and two bands on the abdomen red: wing violence-
ous-black. Swederus, Nov. Act. Stockh. Entirely downy,
and twice the size of M. Europaea.

BIFASCIATA, a species of Tipula, of a yellowish col-
our, with transparent wings palely falcinated with brown.
Schrack, Inf. Auct. Of the middle size, with the eyes black.

BIFASCIATA, a species of Musca, that inhabits South
America. It is rufous, with two golden bands on the abdo-
men. Fabricius, &c.

BIFASCIATA, a species of Scolia, that inhabits New
York. This insect is of a black colour; two dots on the
anterior part of the thorax, scutal, and two interrupted
Stockh.

BIFASCIATUS, in Conchology, a species of Conus,
figured by Born. This kind is white with angulated
chfit lines, and two orange bands: spine rather prominent:
base surrounded with orange lines, and the intermediate
spaces with teffellated spots. Country unknown.

BIFASCIATUS, in Entomology, a species of Scarabaeus,
that inhabits Coromandel; on the thorax is a triple protuber-
ance, with an erect horn on the head; wing-cafes black,
with two rufous bands. Fabricius.

BIFASCIATUS, a species of Dermestes, of a black
colour, with two waved yellow bands: thorax teffellated
with cinereous colour. Thunberg. A native of the Cape
of Good Hope.

BIFASCIATUS, a species of Bostrichus, found in Si-
bcrina. It is of a black colour: wing-cafes yellow, with two
blueish-black denticulated bands. Gmelin. This is Der-
meses bifasciatatus de Lepech. pt.

BIFASCIATUS, a species of Cryptoccephalus, that in-
habits Africa. It is rufous, with two spots on the thorax,
and two bands on the wing-cafes of black. Fabricius.

BIFASCIATUS, a species of Cerambyx (Prionus), found
in South America. The thorax is denticulated: body
black: wing-cafes red, with two black bands: antennæ short.
Gronovius, Fabricius, &c.

BIFASCIATUS, a species of Attelabus (Cerus), of a
brassy-green and downy: wing-cafes blue, with two scarlet
lines. Fabricius. A native of Siberia.

BIFASCIATUS, a species of Gryllus (Bulla-adeidium),
of a fusco brown with white spots, and two lateral ochre-

BIFASCIATILLA, a species of Phalaena (Insea), with
glossy glossy wings: with two bands of white, the
hinder one interrupted: head rufous. Fabricius. Inhabits
Denmark.

BIFERÆ, in Botany, denote plants that flower twice a
year, or in spring and autumn.

BIFERINO, in Geography, a river of Italy, which runs
into the Adriatic, not far from Termini.

BIFED, in Middle Age Writers, a machine for casting
stones and darts, having a moveable counterpoise, which
turned round its yard.

BIFID LEAF, in Botany. See Leaf.

BIFIDUS, in Entomology, a species of Cimex (Redu-
vius), of a black colour: wing-cafes with a rufous band:
an erect bifid spine on the scutellum. Inhabits China, and is

BIFOLIUM, in Botany. See Ophrys.

BIFORIS, in Natural History, a species of Echinus,
having at the base five furrows, and ten flexuous radiated
lines;
BIG

lines; and near the vent two oblong perforations. Lekke apud Klein. Its habitat unknown.

BIFORMIS, an appellation given to Bacchus, either because he is represented sometimes as a young man, sometimes as old; sometimes with a beard, and sometimes without one; or because wine, of which he is the symbol, renders men sorrowful and frantic, or gay and pleasurable.

BIFRONS, a peron doubled-fronted, or two faced.

Bifrons is more peculiarly an appellation of Janus, who was represented by the ancients with two faces, as being supposed to look both backwards and forwards; though other reasons for it are recited by Plutarch. Sometimes he was painted with four faces, quadrifrons, as representing the four leafovs.

Bifrons, in Entomology, a species of Brenius, that inhabits Cayenne. This insect is black, with fribed wing-cases, having glabrous yellow spots. Fabriunicus.

Bifrons, a species of Ichneumon, described by Linneus: it is an European insect of a black colour, with the front white, with a black spot beneath the antennæ: tip of the petiole, and two frit segments of the abdomen, with the legs reddish. Mot. Lek.

Bifrons, in Natural History, a species of Niteris, described by O. Fabricius, and Milli, as a native of the north sea. It is deprefed; peduncles with a simple fextigeral papilla, ciliated above; those in the middle also branched. This creature is continually in motion; about an inch long, and of a fulvous or brownish colour; head white; eyes four; cirth feven; body attenuated at both ends, and confiding of fift fix joints.

BIFURCATUS, in Entomology, a species of Camex (Oblongus), that inhabits Germany. It is blackish; abdomen pale yellow, and bifurred. Schaefer. Antenna confusion of fift fix joints.

BIGA, a chariot for racing, drawn by two horfes abreast. The word ought rather to be written biges, in the plural; or, d. biges, two horfes being joined by a jugum, or yoke. Bigæ stands contradistinguished from triges, quadrages, &c. Bigæ are of very ancient standing; all the heroes in Homer, Heciod, Virgil, &c. fought in them. The invention of bigæ is attributed by Pliny (N. H. vii. 56.) to the Phrygians; by Isidore, (xvii. 35.) to Cyrtidenes of Sicyon, who first yoked two horfes together. They were first introduced into the Olympic games in the 93d Olympiad, or about the year 408 B. C. It appears, however, that the Greek heroes who celebrated the first Nemean games in honum of Archæmoros, were borne on bigæ. Bigæ were the chariots first used in the Circenian games; then triges, and afterwards quadrages. The moon, night, and the morning, are by mythologists supposed to be carried in bigæ, the fun in quadrages. Statutes in bigæ were at first only allowed to the gods, then to conquerors in the Grecian games; under the Roman emperors, the like statues, with bigæ, were decreed and granted to great and well-defering men, as a kind of half triumph, being erected in most public places of the city. Figures of bigæ were also struck on their coins, and those on which were a biga, and a Janus with a double face, were termed Bigati nummi.

The drivers of bigæ were called bigari; a marble bust of one Flosus, a bigarius, is still seen at Rome.

BIGA, or Bigata, in Writers of the Middle and Barbarous Age, a cart with two wheels, drawn often with one horfe. It was more frequently called birsa.

BIGA, in Geography, a town of Attic Turkey, in the province of Natolia, 16 miles, S. of Artaki.

BIGA, a river of North Wales, which joins the Severn in the county of Montgomery.

BIGAMY, a double marriage, or the possession of two wives at the same time. Among the ancient Romans, those convicted of bigamy were branded with a note of ignominy; and, in France, they were anciently punished with death. See Polygamy.

BIGAMY, in the Canon Law, is where a perfon either marries two virgins successively; or once marries a widow. The former kind of bigamy they call real, and the latter interpretation. Each of these the canons account impediments to be a clerk, or to hold a bishohip without a dispension: a point of discipline founded on that of St. Paul, "Let a bishop be the husband of one wife," 1 Tim. ch. iii. ver. 2. Apoll. Consil. 17, 18. By a canon of the council of Lyons, A. D. 1274, held under pope Gregory X. such were deemed "omnia privilegio clericali nudati et coercioni fori leucus addictioni." 6 Decretal. i. 12. This canon was adopted and explained in England by flat. 4 Edw. i. ft. 3. c. 5: and bigamy, in consequence of it, became no uncommon counter-plea to the claim of the benefit of clergy. M. 49 Edw. iii. 42. M. ii. Hen. iv. 11. 48. M. 13 Hen. iv. 6. Staunf. P. C. 134. The cognizance of the plea of bigamy was declared by flat. 18 Edw. iii. ft. 3. c. 2: to belong to the court of Christiun, like that of bardly. But by flat. 4 Edw. vi. c. 12. 5. 6. bigamy was declared to be no longer any impediment to the claim of clergy. See Dal. 21. Dyer, 201.

The Romanists make a third kind of bigamy, by interpretation; as, when a perfon in holy orders, o. that has taken on him some monastic order, marries. This the bishop can dispence withal, at least on some occasions.

There is also a kind of spiritual bigamy; as when a perfon holds two incompatible benefits, e. g. two bishohips, two vicariates, two canoniyes fab eodem telo, &c.

By the ecclesiastical law of England, a second marriage, while the former husband or wife is living, is simply void, and a mere nullity; nevertheless, the legislature has thought it just to make it felony, by reason of its being to great a violation of the public economy and decency of a well-ordered state. For the circumstances attending this crime, and the punishment of it, see Polygamy.

BIGARELLA, in Botany. See Prunus.

BIGARELLA, in Geography, a town of Italy, in the duchy of Mantua, 7 miles E.N.E. of Mantua.

BIGATI, in Antiquity, a kind of ancient Roman silver coins, on one side whereof was represented a biga, or chariot drawn by two horfes. The bigatus was properly the Roman demarius, whose impression, during the times of the common-wealth, was a chariot driven by Victorius, and drawn either by two horfes, or four, according to which it was either denominated bigatus, or quadratus. Bigati therefore were of different values, according to the species of demarius, &c. Several of those called consular medals are also bigati. In lieu of horfes, the chariot is represented on some bigati, as drawn by two deers, especially in the medals of the family of Axia; on those of the family of Creperine, by two hippopotami, who draw, or rather bear Neptune on their tails.

BIGBERRY, or Bigbury bay, in Geography, lies on the south coast of Devon, and is formed by the Bodi Tail on the east, and Stuke-point on the west, in the direction nearly of N.W. by W. The entrance into Plymouth found is round Stuke-point to the N.W.

BIG-BONE CREEK, an American creek in Woodford county, Kentucky, which falls into the Ohio from the east, in about N. lat. 39° 17'. W. long. 85° 54'. It is small, but has three branches; the north-westernmost interlocks with Bank Lick creek, which falls into Licking river. It is noticed on account of the large bones and falt licks in its vicinity.

BIG-BONE LICK lies on each side of the above-mentioned creek,
creek, a little below the junction of the two eastern branches, about 8 miles from the mouth of the creek. These, and also the other salt springs, in the western country, are called licks, because the earth about them is furrowed up in a very curious manner, by the buffaloes and deer which lick the earth, on account of the saline particles with which it is impregnated. A stream of brackish water runs through these licks, the foil of which is of a soft clay. The large bones found here, and in several other places near licks, and in low soft grounds, thought to belong to the Mammoth, have perplexed naturalists, in their investigation of the animals to which they belong. See Bones, fossil, and Mammoth.

BIGEMINATE LEAF, in Botany. See Leaf.

BIGGAR, in Ancient Geography, a town of Spain, which, according to Livy, was attacked by the Carthagi- ninians, because it was allied to the Romans, but it was suc- ceeded by Scipio. Ptolemy assigns it to the Bacthini, in Tarragonensis.

BIGERRONEs, a people of Gaul, so called by Cæsar, and denominated by Pliny, Biggeri; and by Antonius, Biggeritani. M. d'Anville places them at the foot of the Pyrénées, to the west of the Convent. Their name exits in that of Bigorre.

BIGGAR, the name of a town and parish of Lanarkshire, in Scotland. The parish includes an area of land, measuring about 6 miles, by 35, in transverse diameter. The surface is partly hilly, and is appropriated, in nearly equal parts, to pasture and arable. The population of the parish in 1790 was 937, but this was 161 less than when a return was made 36 years anterior. From the improved state of the roads, and of agriculture, it was found to contain 1216 persons in the year 1800. The town of Biggar has 389 inhabitants. Here are three annual fairs. At the west end of the parish are the vestiges of a large tumulus, and three encampments. Tradition says, that a desperate battle was fought here between the Scots under fir. William Wallace, and the English army, when the slaughter was very great. Sir John Sinclair's Statistical History of Scotland.

BIGGE, a river of Germany, which runs into the Lena, 3 miles north of Allendorn, in the duchy of Weptphalia.

BIGGEL, in Zoology, Anilope Tragocamelus of Gmelin, in Mandellii. it.

BIGGLESWADE, in Geography, is a large improving town of Bedfordshire, England, pleasantly situated in a fertile valley, on the eastern bank of the river Ivel. This has been rendered navigable to the town by act of parliament, and considerable quantities of coals, timber, corn, and some other commodities, are brought by this channel. An extensive weekly market, and four annual fairs, also attract various merchandize to the town. The manor belongs to the king, and the parish includes, besides the towns, the small hamlets of Stretton and Holme. These together contain an annual population of 1650 persons, who occupy 301 houses. The church, an ancient and strong edifice, was partly built in the year 1200, and was formerly collegiate. The inhabitants, being free tenants, have all equal rights in the church. In this town are two charity-schools; also a Baptist meeting-house; and being seated on a great public road, it contains several large inns. Biggleswade suffered very materially by fire, which happened on the 16th of June 1785. In a few hours 150 dwelling-houses were reduced to ashes, besides some malt houses, corn-chambers, &c. which were situated round the market-place, near the centre of the town. The damages sustained by this fire were estimated at 24,000l. Since the conflagration several new houses have been erected, and the town has assumed a more modern and improved appearance. On the 25th of February 1792, a shock of an earthquake greatly alarmed the inhabitants of this place, and its concussion was so powerful as to throw down some old houses. It lasted several seconds, and was found to extend northward into Yorkshire, and towards the sea-coast of Lincolnshire. In the manner of Stratton, a short distance south-east of Biggleswade, as a cart was ploughing the land, he discovered a yellow earthen pot, which was found to contain about 300 gold coins of Henry VI. They were nearly the size of half crown pieces each, but being very thin did not equal the weight of a guinea.

About 4 miles west of Biggleswade, are the remains of Warden-abbey, which was formerly a very extensive and considerable foundation. It was founded in 1135, by Walter Espec, for Cillerian monks; and at the dissolution its revenues were valued at 358l. 16s. 6d. per annum. England's Itinerary. Camden's Britannia. Beauties of England and Wales, vol. i.

BIGGS BAY, lies on the south side of Jamaica, and to the east of New York. It is the most southerly point of the island.

BIG-HILL CREEK, an American creek, which runs west into the Kalkakias river, 25 miles below Beaver creek, 17 miles above Blind creek, and 26 northerly from the mouth of Kalkakias.

BIGGIN SWAMP.—See Santee River.

BIGH, in the Sea Language, denotes any part of a rope, as it is taken compassing, coiled up; or the double part of a rope, when it is folded, in contradistinction to the end. It signifies also a small bay between two points of land.

BIGIN, in Geography, a town of Sicily, in the valley of Mazara, 10 miles east of Mazara.

BIGIS, in Ancient Geography, a town of Sicily, placed by Ptolemy in Drangiana.

BIGLA, in Geography, a town of Lithuania, in the plains of Wilna, 40 miles E. N. E. of Wilcomierz, near a lake from which the river Drina issues. N. lat. 55° 26'. E. long. 20° 24'.

BIGLOBATUS, in Entomology, a species of Cerac- tis, found at the Cape of Good Hope. This is of a black colour, with a camalculated snout; thorax globose, very rough with punctured dots; wing- cafes with febaceous dots, and two rows of tubercles on each side. Sparr. Nov. Act. Stockh.

BIGLUMIS, a species of vesspa, with four dots on the scutel; margin of the abdominal segments white, with two white dots on the second. Gmelin. Teneo Rupferis of Linn. Syfl. Nat. is deemed a variety of this kind.

BIGNAN, in Geography, a town of France, in the department of Morbihan, and chief place of a canton in the district of Josselin, 3 leagues S. W. of Josselin.

BIGNI, in Consolagens, a name under which Adanson describes Voluta Fringe of Gmelin.

BIGNON, Jeron., in Biography, was born at Paris in 1592, and educated by his father, who was an advocate in the parliament of Paris, and dilligently by his learning and character. Having made a surprising progress under his father's tuition, he was placed, about the age of ten years, near the person of the young prince of Condé, and about this period published, "A Description of the Holy Land," more accurate than any extant. In 1604, he composed for the use of the young duke of Vendome, a "Treatise on Roman Antiquities." These works were compilations; but his work on the "Election of the Popes," said to be composed in his fourteenth year, but not published till 1608, was of a more original kind, and displayed a degree of erudition that surprised the most learned men of the age. Bignon
BIGNON

BIGNONIA, so named by Tournefort, in honour of the abbé Bignon, Eng. trumpet flower, or scarlet jasmine, in Botany. Lin. gen. n. 759. Reich. 817. Schreb. 1018. Tourn. 72. Juli. 139. Gartn. t. 52. Cháis and Orédes, didymaria angiospermia. Nat. Ord. Peronanthes. Bignonis. Jüf. Gen. char. Cal. perianth one-leaved, erect, cup-form, five-cl. Cor. monopetalous, campanulate; tube very small, the length of the calyx; throat very long, ventricose beneath, oblong-campanulate; border five-parted, the two upper divisions reflex, lower patent. Stam. filaments four, subulate, shorter than the corolla; two longer than the other two; another reflex, oblong, as it were doubled. Fil. germ oblong; fyle filiform, situation and form of the flaments; stigma capitulate. P. s. Silique two-celled, two-valved; partition membranaceous, parallel, thickened, at the futures. Seeds very many, imbricate, compressed, membrane-winged on both sides. Obs. Catalpa has only two perfect flaments, and three very small rudiments of flaments, with a five-leaved calyx. Four, however, and even all five perfect, have been observed by Cyrillus. The form of the siliqua in this genus is indeterminate. The seeds are always winged, though some on one side only.

El. Cháis. Cal. five-cl., cup-form. Cor. throat bell-

Species, 1. B. Catalpa, common Catalpa tree. Lin. spc. 865. Reich. 3. 155. Hort. cliff. 857. 1. Ait. Hort. Kew. 2. 346. Duham. Arb. t. 104. t. 41. Cataeb. Car. t. 49. t. 29. "Leaves simple, cortate; item erect; seeds winged with membrane." A deciduous tree, with an upright stem, covered with a smooth brown bark, 30 or 40 feet high; with lateral branches, ovate leaves placed opposite at every joint, flowers in branching panicles towards the end of the branches, of a dirty white colour, with a few purple spots, and faint fringes of yellow on their inflorescence, which flowers are succeeded by long taper pods not yet produced in England. Found by Mr. Catesby growing naturally on the back of South Carolina, brought into England about the year 1726, and now not uncommon in our nurseries and plantations. In our climate the leaves come out very late; and the tree requires a sheltered situation. It flowers in August, and is known in the nurseries by its Indian name "Catalpa." The branches dye wool a kind of cinnamon colour. Thumbé mentions that the Japonese lay the leaves on parts of the body affected with pains, on a hypothesis that they are beneficial to the nerves; and that a decoction of the pods is serviceable in the asthma. 2. B. tomentifolia. Lin. Syl. 563. Thumb. Jap. 252. "Leaves simple, cortate, tomentose beneath; flowers axillary, panicle." A native of Japan. 3. B. semperflorens, Carolina yellow jasmine, Lin. Spec. 869. Reich. 3. 155. Gellumnum. Park. 1456. n. 5. Rauhill. 1769. Cataeb. Car. t. 1. t. 53. Syringa. Pluk. Alm. t. 112. f. 5. "Leaves simple, lanceolate, firn twisting." Rising with slender stalks, that twist themselves round the neighbouring plants, and mount to a considerabe height, with flage opposite leaves at every joint, that remain green throughout the year; growing naturally in South Carolina, where it spreads over the edges, and at the same time unknown to the present situation, that in the flowering, perfume the air to a great distance; and also found in some parts of Virginia; called yellow jasmine, probably from the sweet odour of its flowers. Cultivated in 1695, in Kew garden, by Parkinson. 4. B. angustifolia. Lin. Spec. 869. Reich. 3. 156. Apocyno affine. Sloan. jan. 1. 268. Clematis. Pluk. Amer. t. 94. Pluk. Alm. t. 163. f. 2. "Leaves conjugate; tendril very short, bowed, three-parted." A native of the West Indies. 5. B. equinocialis. Lin. Spec. 869. Reich. 3. 156. Stubb. Hort. 2. t. 85. Plum. Spec. 5. i. 55. f. 1. "Leaves conjugate, cirrhose; leaflets ovate and lanceolate; peduncles two-flowered; figuques linear." Received by Mr. Millar from La Vera Cruz, in New Spain. 6. B. paniculata. Lin. Spec. 869. Syll. 563. Reich. 3. 156. Jacq. amer. t. 116. Pluk. 91. t. 175. Plum. Spec. 5. i. 56. f. 1. "Leaves conjugate, cirrhose; leaflets cordate-ovate; flowers racemose; peduncles three-flowered." Sent to Mr. Miller from La Vera Cruz, by Dr. Hufdourn. Observed about Carthagena by Jacquin. 7. B. crassigera. Lin. Spec. 869. Reich. 3. 157. Vis. cliff. 69. Hort. cliff. 317. 3. Gron. virg. t. 73. 255. Plum. spec. 48. t. 58. Plundo-Apocynum. Mor. cliff. 3. 612. n. 6. f. 15. t. 3. f. 16. "Leaves conjugate, cirrhose; leaflets cortate; item muricate;" deriving its trivial name from a section of the item which represents a cros. Sent to Mr. Miller from Campeachy. 8. B. capreolata, four-leaved trumpet-flower. Lin. Spec. 872. Syll. 563. Reich. 3. 157. Vis. cliff. 59. Hort. cliff. 317. Brey. i. 33. t. 25. Duham. Arb. 1. 104. t. 46. Cataeb. Car. t. 2. 82. Clematis. Bocc. ficc. t. 31. t. 15. f. 3. Zan. cliff. 74. t. 2. ed. 2. 49. t. 33. Rauh. hist. 1259. "Leaves conjugate, cirrhose; leaflets cortate-lanceolate; bottom-simples fimbriate." Sent to Mr. Miller from Campeachy. A native of Virginia and Carolina; and cultivated in
in Kew garden in 1730. 9. B. pubescens. Lin. Spec. 870. Reich. 3. 157. “Leaves conjugate, cymose; leaflets cor- date-ovate, pubescent beneath.” Growing naturally in Virginia, and several other parts of America. 10. B. tripethylla, three-leaved trumpet-flower. Lin. Spec. 870. Reich. 3. 157. “Leaves ternate; leaflets ovate, acuminate; stem shrubby, erect.” Sent to Mr. Miller from La Vera Cruz, by Dr. Houftonn. 11. B. pentaphylla, hairy five-leaved trumpet-flower. Lin. Spec. 870. Reich. 3. 158. Hort. cliff. 497. o. “Leaves digitate; leaflets quite entire, ob- ovate.” Sent to Mr. Miller from Jamaica, by Dr. Houftonn; and introduced into Kew garden before 1733. 12. B. Leucosylen, smooth five-leaved trumpet-flower, white-wood, or tulip-flower. Lin. Spec. 870. Reich. 3. 158. Swartz Obs. 233. Plut. alm. t. 220. f. 4. Brown jam. 263. n. 1. Sloan. jam. 2. 62. n. 47. Rall. dndr. 114. 2. “Leaves digitate; leaflets quite entire, ovate, acuminate.” According to Sir Hans Sloane, this tree is as large as any in the island of Jamaica, having a large straight trunk covered with a smooth whitish bark, and a very hard white wood. According to Browne, it grows in a kind soil to a large size, and is considered as good timber-wood; but when its growth is not luxuriant, fit only for smaller and subordinate imple- ments. Its juice and tender buds are said to be an antidote to the poisonous juice of the manchineel. Mr. Miller says, that it rises with an upright fleun to the height of 40 feet, in the natural country of its growth; and that the seeds, dispersed by the winds to neighbouring lands, supply plants in great plenty. Cultivated by Mr. Miller in Kew garden, in 1759; and received by him from Barbadoes under the denomination of “white wood.” 13. B. radiana, ray-leaved trumpet-flower. Lin. Spec. 871. Reich. 3. 158. Feu. peruv. 2. 731. t. 22. “Leaves digitate; leaflets pinnatifid.” Stem three inches high; corolla pale yellow, with red dots. A native of Peru, in very dry land. 14. B. radic- centis, rooting or air-leaved trumpet-flower. Lin. Spec. 871. Reich. 3. 158. Hort. cliff. 317. 4. Upf. 178. Gron. virgin. 73. 94. Duham. arb. 1. 103. 1. Saub. hort. 2. t. 84. Pecud gellifem num filiufquom. Riv. non. 101. Pecud- Apocynum. Mor. hift. 3. 612. n. 1. i. 15. t. 3. f. 1. Park. 1679. and 385. n. 6. Gellifemnum hederaceum Indicum. Corn. can. t. 103. Rall. hift. 1678. B. fraxinii fol. cocineo fil. minore. Catef. cafr. i. 1. 65. Mill. fig. 43. t. 65. Duham. arb. 103. 2. “Leaves pinnate; leaflets gilled; stem with rooting joints.” Stems rough, branches trailing, fallingen by the roots, issuing from their joints, to the trees in their natural place of growth, and climbing to a great height; in Europe, where it is generally planted against walls, flirking into the mortar of the joints, so as to support the branches, and rising to the height of 40 or 50 feet; flowers produced at the ends of the filaments of the same year, in large bunches, with long dwelling tubes, shaped somewhat like a trumpet, unless the plant has the appellation of “trumpet-flower,” corolla of an orange colour, and opening at the beginning of August. Cultivated in Kew garden in 1640. The seeds of B. were sent from Carolina in 1724, by Mr. Catefby; and since that time many plants have been raised in England, by seeds sent from that country. 15. B. flafa, branching-flowered trumpet-flower. Lin. Spec. 871. Reich. 3. 139. Jacq. Amer. piéf. 91. t. 176. Brown. jam. 262. 3. Plum. Spec. 5. ic. 54. Sloan. jam. 2. 63. n. 49. B. fruticifera. Mill. dic. n. 3. “Leaves pinnate; leaflets bright; stem erect; firm; flowers raceme.” An upright shrub from four to eight feet in height; flowers yellow, with red lines on the inside of the tube; filiques half a foot long, with winged seeds. A native of all the fugar islands in the West Indies, chiefly in a dry, rocky, or gravelly soil. Mr. Miller says, that he received this sort first in 1729, from La Vera Cruz, where Dr. Houftoun found it in great plenty; since which time he obtained the seed from the island of Ber- muda, by the title of “candle-wood.” 16. B. grandiflora. Lin. Syll. 564. Thunb. jep. 233. Kempf. ic. fol. 21. “Leaves pinnate; leaflets ovate, acuminate, fertile; stem twining, calyx fimbriatifolii.” Stem shrubby, climbing, four-cornered; calyx five-cornered; corolla purple, the size of a rose: differing from the radicans in having a stem not at all rooting, a larger flower, and a fimbriifolii calyx. A native of Japan. 17. B. chelonaider. Lin. Syll. 564. Suppl. 282. Padri. Rhed. Mal. 6. 47. t. 26. “Leaves unequaly pinnate; leaflets ovate, quite entire, acuminate, pubescent; corollas bearded, with the rudiment of a fifth filamen.” A large tree, with a whitish ash-coloured bark; leaves spreading, petioled; panicle terminating; pedicels opposite, dichotomous; flowers solitary, from the divisions; calyx hoary; border of the corolla a little arched, rough with hairs, red, five-cleft; the two upper segments yellow, with red dots; lower segments rough with hairs, curved at the edge, disk waved, white, veins red, throat rough with hairs; the rudiment of a fifth filamen, inserted in the tube of the corolla, barren; filiques linear, flat, bent, flesched. The fresh flowers, immerced in water, give it a pleasant odour; and in the East Indies, of which it is a native, they sprinkle it over the temples in a morning, to correct the flagrant air. 18. B. fndec. Lin. Syll. 564. Suppl. 283. Nür Pongelhi. Rhed. Mal. 6. 53. t. 29. “Leaves unequaly pinnate; leaflets ovate, rough with hairs; calyx one-leaved, spotted; corolla falve-shaped.” A large tree, differing in the structure of the flower from the other species, but having didymian flowers, and a pod filled with winged seeds. It is evidently of this genus. The timber is ash- coloured, or red, smooth, and much used for a variety of utensils in India. A native of Malabar, Java, and Ceylon, in woods near waters. 19. B. peruviana. Lin. Spec. 871. Reich. 3. 159. Hort. cliff. 317. 5. “Leaves compound; leaflets gilled; stem with tendrils at the joints.” A native of America. 20. B. indica, Indian trumpet-flower. Lin. Spec. 871. Reich. 3. 159. f. zeyl. 236. Lour. cochinch. 379. Palega pajauel. Rhed. Mal. 11. p. 77. t. 43. Rall. hift. 1741. B. pajani. Rall. 79. t. 44. Rall. hift. 1741. n. 2. “Leaves bipinnate; leaflets quite entire, ovate, acuminate.” A large tree with ascending branches. A na- tive of the East Indies, and Cochinchina. Introduced in 1795 by Dr. Solander. A variety occurs near Mozambique, in Africa. 21. B. cerulea. Lin. Spec. 872. Reich. 3. 160. Catef. cafr. i. 1. 42. “Leaves bipinnate; leaflets lanceolate, entire.” Grows naturally in the Bahama islands, whence Mr. Catefby sent the seeds, in 1724; and many of the plants were raised in the gardens near London. In the country where it grows naturally, it rises to the height of 20 feet. 22. B. longiflora, wave-leaved trumpet-flower. Ait. Hort. Kew. 2. 347. Jacq. Amer. 182. t. 176. f. 78. Swartz Prod. 91. Brown. jam. 262. 4. Plum. ic. 47. t. 57. B. Quercus Lamark. Encycl. t. 417. “Leaves simple, oblong, acuminate; stem erect; seeds woolly.” An elegant, upright tree, 40 feet high and upwards. A native of the West Indies; cultivated and growing luxuriantly in many parts of Jamaica, especially in the low lands and fa- vannahs, where it grows to a considerable size, and is con- sidered as an excellent timber-tree. Its numerous flowers, and slender filiques, add a peculiar grace to its growth. In Jamaica it is known by the name of “French oak”; and in the French West Indies it is called “Chêne noir.” 23. B. cebinata. Gratt. fruct. t. 240. t. 52. Jacq. Amer. 183. t. 176. f. 52. Aublet. Guian. 2. 648. t. 263, 264.
Swartz prodr. 91. "Climbing; lower leaves pinnate; upper bipinnate, cuneate; fruit exiniate." A rambling shrub climbing to the tops of trees by its very long and numerous branches. A native of the West Indies, Carthagea, and Guiana. 24. B. parvifolia, Lour. Cochinch. 379. "Leaves bipinnate; flowers five, with two anthers in each; calyx flesh-coloured, five-toothed." A middle-sized tree, with ascending branches. A native of Cochinchina, near rivers. Loreauio has another species under the name of B. longiflora, which is a native of Cochinchina, by rivers, and which is not the B. longiflora of Jacquin (N° 221); agreeing, according to Loreauio, with the "ligum equinum" of Rumphiis (vol. iii. p. 731. 462.), or B. fustacca of the younger Linnaeus in the length and form of the corolla, but not in the pinnatifid calyx and pinnate leaves. But Reclus observes, that Rumphiis's plant is not the same with Linnaeus's, and it is very different from the "Nur-Pungedon" of the Hortus Malabaricus. Loreauio also remarks, that the three Asiatic species which he has described can by no means be adapted to the generic character formed by Linnaeus from the American species, except in the fruit; and even that is not always two-celled in the Asiatic species.

The Bigoniois are trees or shrubs, inhabitants of the hot climates, of the East and West Indies, and eminently beautiful. The leaves are opposite; in some species unilaterally pinnate or pinnate; in others, conjugate, with a two-leaved petiole between the leaflets, frequently furnished with a tenderil for climbing. Flowers in panicles, large and handsome, of various colours, red, blue, yellow, or white. The calyx should be observed, whether it be simple or double; the corolla, whether it be regular or irregular; the filaments, whether they be fertile or barren; the fruit, whether it be bony or capsular, in form of a sphaera, or ovate. There are many species, particularly from Brazil, not yet sufficiently known to admit of arrangement under this genus. B. fersinervilus does not belong to this genus, says Mr. Martyn, but to that of elliaceae.

Propagation and Cultur. — These are exotic trees or shrubs, and may be raised from seeds sown on a moderate hot-bed, in the spring. They should be soon moved to the open air, in order that their being drawn up weak. They may be also increased by cuttings, and some of them by layers. The seeds of the common Catalpa tree are annually brought over from South Carolina. The seedlings should be placed in a coldframe, till autumn, and then placed under a summer frame, to guard them from the winter frosts; exposing them in mild weather to the open air. In the following spring they should be taken out of the pots, and planted in a nursery-bed in a warm situation, where they may remain two years, and then planted where they are to remain. This tree may be also propagated by cuttings which, in the spring, should be planted in pots, and plunged into a moderate hot-bed, shading them from the mid-day sun, and occasionally, but sparingly, refreshing them with water. In about six weeks, when they have taken root, and made shoots above, they should have plenty of air, and accustom the fear being exposed to the open air; and afterwards treated like the feeding plants. The Catalpa delights in a rich moil soil, where, in a few years, it will produce flowers. The plants of the third species, not bearing cold, when young, should be sheltered in winter, planted against a warm wall, and protected from frosts by coverings of mats, and by tan covering the soil about their roots. The fourth and fifth species will live in the open air, when planted against a wall with a south aspect, and sheltered in a very severe frost. The sixth, seventh, eighth, ninth, tenth, and twelfth species, are tender, and will not thrive in this country out of the hothouse. If the ninth species be planted in the full ground against a wall, the roots should be covered in the autumn with some old tanners' bark, to keep out the frosts in winter; and in very severe frosts they should be covered with mat. The twelfth will take root from cuttings planted during summer in pots, or plunged into a hothouse: it has flowered several years in the Chelsea garden, in August. The fourteenth is so hardy as to thrive in the open air; but the trailing branches should be supported; and as they spread much and rise to a great height, they will serve to cover single buildings; and also trained against the fronts of trees, they make a fine appearance when in flower. It is propagated by seeds, but the young plants thus obtained will not flower in less than seven or eight years; and therefore those propagated by cuttings or layers are most esteemed, because they will flower in two or three years after planting. The necessary culture for these plants, after they are established, is to cut away all the small weak shoots of the former year in winter, and shorten the strong ones to the length of about two feet; and thus young shoots will be obtained for flowering in the following summer. These plants are of long duration; some of them remain vigorous after 60 years, and produce plenty of flowers every season. The fifteen species is propagated by seeds sown on a hot-bed, and by transplanting the plants into separate small pots, filled with light earth, and plunged into a trent hot-bed; by removing them in autumn into the hothouse, giving them but little water during winter, and in summer refreshing them with it sparingly; and they should remain constantly in the hothouse, and be treated like other tender plants from the hot countries. The third year from seed they will flower; but they do not produce seeds in England. The other forts have not been cultivated in England. Martyn.

BIGORNO, in Geography, a town of Contica.

BIGORRE, a country of France, in the province of Guines before the revolution, but now forming a part of the department of the Upper Pyrenees. Its capital was Tarbes. It is bounded on the N. E. by Aragon and the country of the four valleys, Nubuzan and Alarca; on the south, by the Pyrenees; and by Bear, on the west. It has been sometimes divided into the country of Ruffa, the Plain, and the Vallado, and elimated at 16 leagues in length from north to south, and in its greatest breadth at 7 leagues. From its general situation, this country might be expected to enjoy the same mild climate that is experienced in the neighbouring provinces, under the same latitude; but from local circumstances it is very different. The Pyrenees intercept the warmth of the more southern country of Spain; while, from its elevated situation, it is exposed to the chilling blasts of the north. On this account Bigorre is deprived of many fruits and vegetables, such as the orange and olive; however, the laurel, fig-tree, and myrtle, are not injured by the climate. The air of the mountains is cold and chilling, but that of the plains and
vallies more mild and salubrious. This country produces wood in considerable quantities, excellent wine, rye, barley, and miller; but not much wheat. It has good pastures, quarries of marble, and medicinal springs. The mountains of Bigorre consist of schist, marble, and granite. See Pyrenees. The inhabitants of this district posses a peculiar and characteristic phygsognomy, in which they all resemble one another; they are healthy and active, lively and cheerful, and unite impetuous courage with strength and agility. The impetuosity of their temper renders their language rapid, passionate, and full of protestations; and they sometime sink the voice an octave below the natural key, that they may suddenly raise it to the sharpest note. Their ideas abound with imagery, and their gestures are quick and violent. They are distinguished by their generality and beneficence. They practice the ring from their infancy, and can draw a bow before they speak; and those persons are regarded as the most accomplished, who are most skilled in leaping, riding, and throwing the bar. The education of the Bigorrets, who are not husbandmen, is conducted with a view to the church; and they boast of many eminent persons in science and literature.

BIGOT, a person fondly obdurate, or perversely attached to an opinion. The word is formed from the German bey, and Got, or the English by-God. Camden relates that the Normans were first called Bigutii, on occasion of their duke Rollo; who receiving Gizia, daughter of king Charles, in marriage, and with her the investiture of the dukedom, refused to give the king's foot in token of submission, unless he would hold it out for that purpose, and being urged to it by those present, answered haughtily, "No, by God," wherein the king, turning about, called him Bigot; which name failed from him to his people.

BIGOT, Emeric, in Biography, an eminent promoter of literature, was born at Rouen in 1626; and forming an early attachment to literature, he declined all public business, and employed himself in augmenting a large library bequeathed to him by his father, and in correspondence and conversation with persons of learning. Few persons conciliated, by the modesty of his temper, by the friendship and familiarity of his manners, and by his love of peace and tranquility, have maintained to his greater number of friends, who respected and esteemed him. In various parts of Europe, through which he travelled, he formed connections with literary men; but his most intimate friends of this description were Menage and Nicholas Heinius. Although he distinguished himself by aiding others in their literary performances, the only work he published in his own name was the Greek text of Palladius's life of St. Chrysofolom, found in the grand duke's library at Florence, to which he annexed a Latin translation. Having entitled his valuable library on his family, in order to prevent its dispersion, he died at Rouen in 1689. However, notwithstanding his precaution, his library was publicly sold at Paris in 1706. Gen. Diet.

BIGOT, in Italian bigonius, in Commerce, is used to denote a Venetian liquid measure, containing the fourth part of the ampulla, or half the boot.

BIG Rock, in Geography, a large rock on the S.E. bank of Au Vaze river in America; about 3 miles N.E. from its mouth in the Missippi, and about 8 miles S.E. from cape St. Antonio on that river.

Big Rock Branch, the north-eastern head branch of Alleghany river. The branch called Big Hole Town joins it, and forms the Alleghany, 85 miles N.E. from and above Venango fort.

BIG Salt lick, a garrison in the state of Tennessie, near the Salt lick, on Cumberland river, 115 miles from Knoxville; 80 from S.W. point on Clinch river, 32 from Bigelock, and 63 from Nashvile.

Big Sandy River, or Totteray, rises near the source of Cumberland river, and separating Virginia from Kentucky, discharges itself into the Ohio, opposite to the French purchase of Galloipolis, in about lat. 33° 30'. Vancouver's and Harmon's forts stand on this river. On its banks are several fort licks and springs. Little Sandy is a short small river, which falls into the Ohio, about 20 miles west of Big Sandy river, in the county of Mason, Kentucky.

BIGUABA, a town of North Africa, seated on the river Rio Grande. N. lat. 11° 15'. W. long. 13° 35'.

BIGUTTATA, a genus in Entomology, a species of Silpha, met with at Upsal. This is totally ferruginous, with a pale line and spot on the wing-cases. Thunberg. Nov. Act. Stockh.

BIGUTTATA, a species of Cassida, with a yellow thorax; reddish wing-cases; black margin, and two yellow spots. Fabricius. This insect inhabits Cayenne.

BIGUTTATA, a species of Coccinella, described by Fabricius. It is rufous, with two yellow spots. The country is unknown. Size small; thorax glossy and black, with the fides yellow.

BIGUTTATA, a species of Cantharis, found in gardens in Europe. The thorax is black in the middle; wing-cases short, black, and yellow at the tip. Linan, F. Suec. Fabricius. This is Teleborus nigri, femoribus flavis, elytris apice lateis de Geer.

BIGUTTATA, a species of Buprestis, with very entire, linear, green wing-cases, with a white dot; abdomen blue, with three white dots. Fabricius, &c. Inhabits England.

BIGUTTATA, a species of Cicada (Cerops), of a black colour, spotted with yellow; wing-cases brown, with a white marginal spot. Inhabits Germany. Fabricius.

BIGUTTATA, a species of Cicada (Ranaeta Fabr.) that is found in Europe. It is black, with a patch of finguicuous red on each side of the thorax. Fabricius.

BIGUTTATA, a species of Vespa, of the small fize, that inhabits China. It is black, and spotted with yellow; margin of the segments, and two dots of yellow on the second one. Fabricius.

BIGUTTATA, a species of Scolia, of a black colour, with two transverse white dots on the abdomen; wings black. A small species, and inhabits Spain. Fabricius.

BIGUTTATOR, a species of Ichneumon, described by Thunberg. It is black, with two dots on the feutel. Found at Upsal.

BIGUTTATUS, a species of Curculio, that is found in Germany. It is black, with elevated dots on the wing-cases; abdomen and posterior legs yellow. Fabricius.

BIGUTTATUS, a species of Cryptocoepalus, of a black colour, with the head, tip of the wing-cases, and legs yellow. Gmelin. A native of Anhria.

BIGUTTATUS, a species of Carabus, that lives under the bark of trees in Sweden, and is described by Thunberg. The head is roundish and brassy; wing-cases black, with a pale spot at the apex.

BIGUTTATUS, a species of Dytciscus, described by Lamæcus as a native of Europe. This is black; legs, end of the abdomen, antennae, mouth, two dots between the eyes, thorax, and wing-cases tattaceous, the latter spotted with brown; in the middle of the thorax two black spots.
BIDUTAT, a species of Staphylinus, that inhabits some shores of the Baltic sea. It is of a black colour, with a fulvous spot on each of the wing-cases. Limn. Fabr. &c.

BICUTTATUS, a species of Cimex (Retundatus), described by Linnaeus in his Fauna Suecica, by Scopoli, &c. It is black, with all the margins white, and a white spot on the wing-cases.

BICUTULUS, a species of Gryllus (Locyopa), with a cruciate thorax; wing-cases clouded, and marked with an oblong white spot near the tip. Limn. Fn. Suec. &c. This is Accidium bicutulums of Degeer. Very common on some barren lands in the north of Europe.

BIHACS, BISATZ, BISHT, or VIHITZ, in Geography, a town of Crisia, seated on the river Umon, belonging to the Turks; 60 miles south of Carlstadt, and 180 west of Belgrade. N. lat. 44° 47'. E. long. 16° 20'.

BIHAI, in Botany. See Strelitzia.

BIHAMATA, in Entomology, a species of Hispa, of an oblong, depressed shape, that inhabits India. It is specifically described as being unarmed, black, spotted with red; shells truncated and hooked. Gmelin.

BIHAMATZ, a species of Formica, found in the island of Joanna, having four spines on the thorax, and two curved ones on the petiole female. Fabricius, &c.

BIHAR, in Geography, an ancient town of Hungary, giving name to a district, in which are also Debretzen, Great Varadein, &c.

BIHOREAU, in Ornithology, the name of Ardea myctea- raxus, or Night heron, in Buffon's Hill. Birds. Temelle de Bihoreau of Buffon, is Ardea grisea; and Bihoreau de Cay nue of Buff. is Ardea cayennensis of Gmelin.

BIHRI, in Geography, a town of Perlia, in the country of Larifan, in the route from Ipahan to Ornus, 30 miles N.W. of Lar.

BIJNAGUR. See Binsagur.

BIJORE, called also Bejaur and Bejour, the Bazira of Alexander, a province of Hindoostan, bounded on the south by Pakhurwar, on the north by Kutore, on the east by Sewad and Bejore, which are separated from it by the Penjorek, and on the west by Guznoorgul. This province, according to the dimensions flated in the Ayen Achearee (vol. ii. p. 192, &c.) extends 25 coffes north and south, and 10 caff and west; distant about 20 coffes beyond the Cabul river, and on its western extreme; about 30 coffes from the Indus. Bijore, as well as Sewad, is very mountainous, and abounds with paffes and strong situations; so that its inhabitants have not only held themselves generally independent of the Mogul emperors, but have occasionally made very ferious inroads into their territories. In this province there is at this day a tribe of Afghans, denominated Yuzuf-zyes, which traces its origin to certain persons left there by Alexander the Great, when he passed through this country. Both Abul Pazil, the author of the Ayen Achearee, and Soojan Raas, an eastern historian of good reputation, report this tradition without any material alteration. The latter, indeed, adds that these Europeans, if we may call them so, continued to prefer that ascendency over their neighbours which their ancestors may be supposed to have possessed, when they first settled here. Although we should reject this pedegree as fabulous, yet the bare claim argues the belief of the natives, for which there must have been some foundation, that Alexander not only conquered Bijore, but also transferred that conquest to some of his own countrymen. The people of Bijore had likewise an high idea of Alexander's extensive authority; and they denominated him the "Two-horned," agreeably to the striking emblem of power in all the eastern languages. (Ayen Achearee, xi. 194.) These Yuzuf-zyes, says Mahomed Cazim, quitted their ancient habitations between Ghizni and Candahar, and after various unsuccessful attempts to obtain a settlement in Cabul, at the time when Mirza Ulug Beig, furnished Cabulees, and that kingdom, finally established themselves in Sewad and Bijore; which at this period were governed by a dynasty of princes styled "Sultani," who derived their lineage from Alexander the Great. The Yuzuf-zyes possess, in addition to Sewad and Bijore, the tracts situated between these provinces, and the rivers of Cabul and Indus; the greatest part of which is described as a desert in the Ayen Achearee, but by Bernouilli as a forest. In the time of Achar, Zine Khan was sent to chastise them; and he overran their whole territory, and even penetrated to the borders of Cashgar, and took the strong fort of Kulhal, or Guhal, seated on a mountain 17 marches north of Bijore. About the year 1670, Aurungzebe found it necessary to chastise these Yuzuf-zyes; since which period the return of Nadir-Shah, in 1739, again brought them into notice. To him they appeared formidable; but he reduced them to submission; and if they really engaged to supply his army with 40,000 men, the tribe male have increased since the time of Achar, when Bijore contained only 39,000 and Sewad 40,000 families. Kennell's Mem. p. 159, &c.

BIJORE, the capital of the above-described province, situated about 6 marches, or about 66 geographical miles, from Nilab or Attock, and at 50 of the same miles, north a little east into Pailhawur, and at the same dilinace east a little north from Iblahabad. N. lat. 34° 7'. E. long. 70° 44'.

BI JORE, the name of a river which rises in the mountains, N.E. of Bijore, and passing by it, forms a junction with the Penjorekhol, Sewad, and Kamal, and falls into the Nilab, or Sinde, at Attock.

BIISK, a town and district of Siberia, in the government of Kolyvan, seated on the river Bi, or Bis, which, by uniting with the Katunia, forms the river Ob; 150 miles S.S.E. of Kolyvan. N. lat. 53° 31'. E. long. 84° 14'.

BIJUGUM, Folium, in Botany, denotes a winged leaf, bearing two pair of foliula.

BIKULAKOVA, in Geography, a town of Ruffia, in the government of Ufa, on the river Ik, 80 miles N.E. of Orenburg.

BIKILLAM, or Beckalen, a small island in the Red sea, 8 leagues from the coast of Arabia. N. lat. 16°. E. long. 43° 25'.

BIKOU, a town of Poland, in the palatinate of Bracalw, 50 miles north of Bracalw.

BILA, a river of Bohemia, which runs into the Moldaw near Aulig.

BILA, Al, a town of Bohemia, in the circle of Leitmeritz, 10 miles W.S.W. of Kamnitz.

BILANA, or Bilbana, in Ancient Geography, a town of Arabia Felix. Ptolemy.

BILANDER, in Geography, a town of Bohemia, in the circle of Curdimum, 5 miles west of Chrudim.

BILANCIS Deferendis, in Lapo, a writ directed to a corporation, for the carrying of weights to such a harn, there to weigh the wool, which persons by our ancient laws were licenced to transport. Reg. Oriq. 1720.

BILANDER, in Navigation, a small merchant-ship with two masts; distinguished from other vessels of the same kind by the form of the main-ail, which resembles a frette-foil. The head is bent to a yard, similar to the mizen-yard of a ship, and hangs to the main-mast, as a ship's does to the mizen-mast. This method of rigging has proved inconvenient, and is now seldom used, except by the Dutch.
BILANUS, in Botany. See CRATERA.

BILARIUS, Porus. See BILARII Por.

BILATERAL CONJUNCTION, denotes kinship, or kindred, on both sides; that of the father as well as mother.

Suck is the relation of brothers, sisters. Bilateral stands contradistinguished to unilateral.

BILBA, in Ancient Geography, a town of Aia, in Babylonia. PoIemcy.

BILBAO, sometimes called Bilbao, in Geography, a port-town of Spain, in the province of Biscay, seated on the banks of the river Ybaizabal, about 6 miles from the sea. On the water-side is a large square, well shaded with pleasant walks, extending to the outskirts on the banks of the river, and containing a number of houses and gardens, which form an agreeable prospect, particularly in fulfilling up the river. The number of houses in this town is about 800, some of which are built on piles; they are solid and lofty; the streets are well paved and level; and as they may be walled as plentitude, Bilbao is one of the nestest towns in Europe. The tide that flows into the river forms a secure and much frequented harbour; and a considerable commerce is thus carried on in iron, wool, of which, it is said, 60,000 bags are annually exported to Great Britain, France, and Holland, fairs, and chefnates. Towards the close of the 16th century, the people of Biscay, having maintained their independence, together with their profession of Chiliasmity, even when the Moors gained possession of the other parts of Spain, and having about this time obtained some advantages over them, began to direct their attention to the manufacture of their own excellent iron, not only for their own use, but for the supply of other nations; and their port of Bilbao began to have shipping, and to engage in foreign trade, perhaps before any other nation to the west of the Mediterranean sea, at least in a very considerable degree. In the last year of the 13th century, this town was refounded, or new built, by Didacus Lopez, then prince, or lord of the province; and as it was the staple port for the iron and wool of Spain, its commerce rapidly increased; and it appears from Rymer's Fæderata, that in the reign of King Edward IV. A.D. 1474, the merchants of Guipuzcoa carried on, probably by the port of Bilbao, a considerable trade with England. It appears, also, that the Biscayners, availing themselves of the advantage of their shipping and port, were concerned in the whale-fishery at an earlier period than any other nation of Europe, Norway excepted. The town is supplied with flesh and poultry, and also with fish of various kinds, and particularly with a sort of eells in winter, which are small, of a pale colour, about three inches long, and without a back bone, caught in prodigious quantities at low tides, and in summer with the cuttlefish. The hamble are a Tucan building, in the centre of the town, with an open court, and a fountain in the middle, by means of which it is kept clean, and free from offensive offal and filth. The environs abound in gardens, which are fertile in legumes and fruits. This town has five churches, and several religious houses; and in its police it has one law of a peculiar kind, which renders ingratitude criminal, and subject to a penalty. Although the air is generally damp, the town is remarkably healthy, and the inhabitants are robust, cheerful, and long-lived; so that the hospital is frequently without a patient. The women are capable of enduring labour as well as the men, and are employed in unloading the ships, carrying burdens, and performing the bufines of porters. At the close of the day they return to their habitations, without any appearance of latitude, dancing and singing to the pipe and tabor. Their music is delayed at the expense of the town; and on holidays it is performed in the middle of a great concourse of persons under the trees in the great square. The women of Bilbao, though constantly exposed to the air, have good complexions, lively eyes, and fine black hair, which they curiously braid, and which they reckon peculiarly ornamental. Married women wrap a white handkerchief round their heads, so knotted as to fall down in three plaits behind, and over this they wear the Motera cap. Thoie who understand their language say it is very soft and harmonious, as well as energetic. N. lat. 43°. W. long. 2°. 45'. See Biscay.

BILBERRY, in Botany. See Vaccinium.

BILBILINAE AQUISET, in Ancient Geography, Alhana, mineral and medicinal waters of Spain, 23 miles from Bilbils, according to the Itinerary of Antoninus. The name Alhana, given by the Arabian to this place, has the same meaning with the aque calcile of the Latins. See Alhana.

BILBILIS, BAMBULA, a town of Biscay Tarragonensis, belonging to the Celtiberi, south of Tarraco; seated on a mountain surrounded by the waters ot Soloto and Xalon. Bilbils was a municipal town, and bore the title of Augusta, which is found on several medals. The poet Martial was of this city, called by Poleney Bilbils.

" Municipis Augusta nabilos quos Bilbilis acri Monte creav, rapidis quo solus cingit aquis."

Martial, l. 10, epig. 143.

On most of the medals of Bilbilis, we perceive, on one side a head of Auguritus, and, on the other, a cavalier, armed with a lance and a helmet.—Alfo, a river of Spain, the waters of which were famous for tempering iron; called also Salo.

BILBOWS, in Scrophulis, a punishment answering to the flocks at land.

They consist of long bars, or bolts of iron, with shackle sliding on them, and a lock at the end, used to confine the feet of prisoners, in a manner similar to the confinement of the hands in handcuffs. See Stocks.

BILCOCK, in Ornithology, one of the eynymous English names of Rallus aquaticus, or water-rail.

BILDERVERTSCHEN, in Geography, a town of Prufil, in the province of Lithuania, 4 miles W.N.W. of Stalluponen.

BILDESTON. See BILTON.

BILDGE, or BILGE OF A SHIP, denotes the bottom of her foor; or the breadth of that part which the reels on, when she is a-ground.

Hence, when a ship receives a fracture in this place, by striking on a rock, or otherwise, she is said to be bilged, or bulged.

BILdge-Water, is that which, by reason of the flatness of the ship's bottom, lies on her foor, and cannot go to the well of the pump. This water is always, if the ship does not leak, of a dirty colour, and disagreeable smell.

The Dutch, whole ships are often of this form, use a sort of pumps, called "bilge-pumps," or, as we call them "burr-pumps," to carry off the bilge-water.

BILE, in Phvsiology, is the fluid prepared from the blood by the liver of animals. The colour of healthy bile in the human subject is probably of a deep yellow brown. In oxen, it is frequently of a yellowish green. In the gall bladder, it is of a thick thick consistency, of an uncertain feel, or like that of mucus, of a bitter taste, and peculiar smell. Its specific gravity is about 1.027. It readily mixes with water, but will not incorporate with oil, yet it takes GIFS out of cloths. Albumen may be precipitated from it by alcohol and acids; and Cadet ascertained its proportion in 160 parts of ox bile to be about 0.52. (Cadet, Mem. Par. 1757.) If a solution of bile in muriatic acid be concentrated by heat, a cephus precipitate takes place, and the solution changes its colour from a
grains green to a brown. This precipitate has the properties of a resin. From 100 parts of bile, 1.87 of crystallized soda has been obtained, and some was probably lost in the process. The residue also obtained from bile a fat of a fawtht tinte. There are other substances found in bile in small quantities: phosphated hydrogen gas, which is emitted on the addition of muriatic acid; a little muriate of soda, phosphate of lime, and phosphate of soda and of iron. Of course water is the vehicle for all these substances, and forms the largest share of the ingredients in the composition of bile. For an account of the liberation of bile, see the article LIVER, functions of.

Bile, in Chemistry. This fluid may justly be considered as equally important to the chemist as to the physiologist; and accordingly it has been examined with extreme minuteness by a great number of eminent chemists, in various countries, with a general parity of refult which is highly satisfactory. Indeed the analysis of bile, as far as relates to the detection of its leading constituent parts, is neither very complicated nor remarkably difficult.

Chemists have not been able to detect any considerable difference between the bile immediately secreted from the liver, and that which is found in the gall-bladder, excepting that the latter appears on the whole to be somewhat less watery, more bitter and more viscid than the former. The age of the animal makes a greater difference, the bile or gall of oxen being more viscid than that of calves. On account of the ease with which ox-gall is procured in considerable quantity, this has generally been selected for experiment; but its analysis does not essentially differ from that of the bile of any other animal.

Bile is a homogeneous fluid, in some animals of a deep yellowish brown, in others of various shades of green, fo viscid as not to pour by drops; of a peculiar faint smell, but not ungrateful when fresh, and not from a diluted animal: intensely bitter to the taste, even when very largely diluted with water, and somewhat pungent. It is considerably heavier than water; its specific gravity being from about 1.02 to 1.025, varying according to the age and health of the animal, and probably to the time that it has remained within the gall-bladder. When agitated, bile lathers like soap water.

When bile is gently heated, an aqueous vapor arises, which, when condensed, appears by the most delicate regents to be nothing but water, strongly impregnated however with the odorous part of this fluid, and somewhat fetid. Bile looses about seven eightths of its bulk of mere water by this evaporation; and the residue gradually thickens into the confluence of a transparent extract, which, on carefully drying, becomes a hard brittle limy mass, like wax, of a dark colour, and intensely bitter.

If this extract of bile be slowly heated in a retort to decomposition, the products are, a watery fluid, fortified with phosphated hydrogen gas, a brown fetid liquid containing ammonia, a tenebrous fuming empyreumatic oil, with more carbonated ammonia, and a copious effusion of carbonic acid, and carburetted with sulphuretted hydrogen. The mass in the retort swells up prodigiously in the process, and leaves a puffy coals easy to incinerate, the ashes of which contain a nitrate of carbonated soda, with some muriated soda, phosphat of soda and lime, and a little iron. Fontana obtained from a pound of ox-gall 45 grains of carbonated soda, and 6 grains of common salt.

The residuum, therefore, of calcined bile contains alkalii in excess; and hence water, with which it has been lixiviated, readily turns fyrup of violets green. The fame telt of an alkali is given with fresh bile, diluted with water, that the change of colour may be more apparent.

The action of acids on bile throw much light on its composition. Muriatic acid, strong or dilute, added to bile, immediately produces a coagulation, and, at the same time, renders the whole liquor of a fine light green. The coagulum, however, is partly redissolved, if the acid is concentrated. Examined chemically, it is found to be albumen, but intensely bitter. In the clear green liquor, though retaining the muriatic acid, the bitter taste also brightly predominates. Evaporated slowly, it deposits in about an hour's time another precipitate, very green, intensely bitter, and soft and tenacious like turpentine. The clear liquor is now yellowish, and, on further evaporation, yields a number of cubic crystals of muriated soda, formed chiefly, if not entirely, by the soda originally contained in the bile and the acid added. As a proof that this is the case, if the experiment is made with nitrous or sulphuric acid, instead of the muriatic, the salt will be nitrated or sulphated soda. The above decomposition is more perfect, if bile and muriated acetic acid are at first boiled together for a few minutes; the result then is a total separation of a dark green glutinous bitter mass, and a liquid now colourless and feebly bitter, from which the muriated soda may be procured by evaporation.

This glutinous coagulum, when dry, burns like a resin. Alcohol heated upon it dissolves one part, and leaves another untouched, thus entirely separating it into two distinct principles: the insoluble, which is albumen; and the soluble, which retains the colour and taste of bile, is totally precipitated from the spirit by water, is highly inflammable, insoluble in water, and has been considered as a species of resin or concrete oil, and is termed by some the resin of bile. Pouchroy, however, supposes it to be more of the nature of adipocere.

Alcohol alone is another important regent for the analysis of bile. When these two fluids are mixed together, a coagulum is immediately formed of a whitish tenacious substance, feebly bitter when well washed, and exhibiting all the properties of albumen. The remaining liquor is green, and contains, mixed with the alcohol, the resinous, fatty, and colouring matter of the bile. Alcohol equally separates albumen from bile, impalpable by evaporation, and dissolves the remainder. The alcoholic solution of bile, not previously treated by an acid, differs considerably from that which has undergone this treatment. In the latter case, as before mentioned, the solution is decomposable by mere water, and by evaporation is converted into a very resinous product. In the former case, the solution mixes uniformly with water, yields by evaporation a transparent extract like gum-arabic of a feebish tingle, a little mixed with the natural bitternes of bile, and easily soluble in water. The reason of this difference is doubtless owing to the proportion of the soda from the rear of bile by the oxed in one instance, whereas in the other they remain united in the form of a natural soap. Hence it is that the effusion of an acid upon the latter alcoholic solution decomposes it, and separates an insipid fluid, which again dissolved in alcohol is more precipitable from this solv'd by simple water, and resembles a pure resinous solution.

Some chemists have thought that they could also detect a saccharine matter in bile, but the experiments to this purpose are not conclusive.

The oxygenized muriatic acid gas passed through bile diluted with a little water, soon dyes its yellow green colour, and precipitates the albumen in white flocculi; the vapours
B I L E.

refin continues in solution without colour or smell; but the bitter principle remains. A further quantity of this acid separates the resinous oil as the muriatic acid does, but white and concrete. Any acid poured upon bile already bleached by the oxymuriatic acid, separates numerous white concrete matter much resembling adipocere, but the precise nature of the change produced by the oxymuriatic acid has not been properly ascertained.

Bile therefore may be inferred from the present state of chemical analysis to contain, 1. A large proportion of water. 2. A substance closely resembling animal albumen. 3. A peculiar resinous inflammable matter, naturally and intimately with

4. Soda, into a kind of soap, or sapenaceous extract. 5. Some neutral salts. 6. A small quantity of oxide of iron. Besides these constituents, there is a colouring and odorant matter, but it is not yet ascertained whether these are properties of any of the above-mentioned ingredients, or whether they belong to a peculiar substance.

Some chemists have also supposed a kind of saccharine mucilage, resembling the sap of milk, but the existence of this in recent masticated bile is very doubtful.

Bile has been supposed to be a powerful antiseptic, and its effects in the animal economy have been attributed to this quality, but without much foundation. Bile, left to itself in a moderate temperature soon becomes putrid (though not so speedily as blood); it then exudes a very fetid odour, but after this point it decomposes but very slowly, and at last assumes a strong, not very unpleasant mucity smell. This partial resistance to putrefaction is probably owing to the resins ingredient, which last, when separated by acids and alcohol, in the way already mentioned, is absolutely incapable of putrefaction. M. Cadet affirms, that at no time during this process is any acid generated.

The sapenaceous quality of bile, which is very characteristic, and is owing to the intimate union of its resin with soda, renders it miscible with milk, with oil, myrrh, aloe, and other gum resins, by trituration, without curling, or ready decomposition. It is also owing to an intimate mixture with this natural soap that the albumen which bile contains is not coagulable by heat; even if an additional quantity of albumen (white of egg for example) is mixed with bile, heat will not coagulate it. Hence too, alcohol on any part ally separates the albumen, unless an acid is previously applied to engage the soda, and the alcoholic solution of the resin retains the soda so as to render the resin not separable by mere water.

Bile, or ox-gall, is employed in various ways as a cleanser of wool, cloth, &c. to get out greasy spots, to take off the greasiness of ivory in preparing it for receiving colours; and in China it is mixed with some of their varnishes. Gall a little putrid may be preferred a long time from further alteration by being boiled for a few minutes.

M. Fourcroy affirms, that he has obtained a substance, resembling bile in every property, by mixing blood with a third of water, coagulating it by heat, and slowly evaporating the serum. This experiment has, however, been repeated by others without success. See Cadet in the Mem. de l'Acad. des Sciences, for 1767 and 1768. Van Bochante, Professeur at Louvain, in the Jour. de PhyL tom. 13. Suppl. An. Chim. tom. 4, 5, and 6. Fourcroy Syst. de Conn. Chim. &c.

Bile, in Medicine, is a yellowish-green fluid, more or less viscid, and of a bitter taste, secreted in the liver, and conveyed from that viscus, by the so-called ductus communis choledochus, into the duodenum. It is a very compound fluid, being resolved by chemical analysis into a variety of ingredients: such as water, albumen, retina, fodia, muriate of fodia, phosphat of fodia, phosphat of lime and iron, besides a sweeter matter analogous to sugar of milk. In its general properties, it may be said to participate of the nature of a loast, although it will not intimately mix with oil. The Sylvic bile, or that which is contained in the gall bladder, possesses more vileness and bitternes, (i.e. is more concentrated) than that which flows directly from the biliary ducts into the duodenum, and which is termed hepatic bile.

When we see an organ of such magnitude as the liver, appropriated to the secretion of the bile, we are naturally led to infer that the fluid so secreted, must answer for some useful purposes in the animal economy; but respecting the number and kind of purposes which it answers, physiologists do not exactly agree. It may, perhaps, concur with the pancreatic juice, to the separation of the refuse part of the alimentary pulp (chyme) from the proper chyle; but, as Dr. G. For- dyce has remarked, in his treatise on the digestion of food, the bile does not unite with the chyle itself, and pass along with it, through the lacteals into the blood. Mixed with the feculent matter, and colouring it, the bile seems to prevent that matter from running into fermentation, by virtue of its alkaline nature; and perhaps, also, in consequence of the bitter principle which it contains, it may, in some degree, resist putrefaction; but its principal and most obvious use is, as a stimulus to the intestines, serving to keep up a due degree of peristaltic action, and thereby to produce a regular and natural evacuation of their contents. Hence a diminished secretion, or obstructed passage of the bile, is always accompanied with colic.

From this view of the nature and composition of the biliary secretion, and of its action upon the living body in a state of health, we proceed to the consideration of its morbid conditions, which may be reduced to four heads; viz.

1. A deficiency of bile. This is known by a pale and languid habit of body, indigestion, flatulence, acidity, colic, nausea, and pale or clay-coloured stools. It is occasioned by a sedentary mode of life, by intemperance, and by deprefling passions of the mind. It occurs in chlorosis, hypochondriasis, and chronic hepatitis. (See what is said of these diseases under their respective titles.) Whatever be its cause it may be owing, it is always attended with indigestion and colic; hence it should be specially attended to in the cure. A well-regulated diet should be prescribed, wherein spirits, drinks, high-salted meats, flatulent vegetables, and crude and acid fruits, should be forbidden. Much stews should be at the same time be laid on a plan of regular exercise; and the injurious effects of cold and damp upon the gastric and hepatic sytems, should be counteracted by suitable clothing. As a further aid to digestion, bitters and chalybeates (especially the chalybeate mineral waters), should be prescribed; and colivenes should be remedied by occasional doses of rhubarb, neutral salts, and aloe; and sometimes by the stronger cathartics. Acidity should be counteracted by alkalies, among which foda or natron preparatum answers best. Where the diminished secretion of bile has appeared to be connected with a diseased structure of the liver, and particularly where such a change of structure has arisen from inflammation, mercury (Dr. Saunders observes), has been found useful, even carried to the degree of producing a slight salivation; moderating the violence, however, of its operations by plentiful dilution, with
with gum arabic, and other vegetable demulcents. In these cases, the same author has found a tepid bath, of 90 degrees of Fahrenheit, to produce manifest good effects.

2. Obstruction of Bile. After it is secreted, the bile is sometimes prevented from passing into the duodenum. This may happen from various causes; viz. from an obliteraton of the cavities of the biliary ducts, either by a thickening of their coats, or by a tuberous flate of the liver, the consequences of inflammation; from pressure produced by enlargements of the neighbouring parts; and from a too viscid and constant flate of the bile itself; but, more than all, from gall-stones impacted in the common duct. Whenever in any of these ways, the bile, after being secreted, is hindered from passing into the duodenum, it is either taken into the a. cultating system by what is termed regimentation, or by absorption; producing great languor and opprobrium, together with a yellowness of the skin, and tunic conjunctiva of the eyes, &c. i.e. giving rise to jaundice. (See Gall-Stones and Jaundice.) The treatment must be varied, according to the variety of conditions on which the obstruction depends. In this place, it will be sufficient to remark, that saline purgatives, mercurials, faponaceous and alkaline medicines, with tepid dilution, and warm bathing, will be found suited to the majority of these cases.

3. Excess, or redundancy of Bile, is a morbid affliction, of very frequent occurrence. Among its exciting causes may be mentioned intemperance of living, the flummer and autumal heats of our own latitudes, and more especially the high temperatures of the tropical climates; in a word, whatever produces a hurried circulation, or irritates the vallcular and secreting system of the liver. A redundancy of bile makes itself known by "a general languor of the body, together with nausea, foul tongue, loss of appetite, and indigestion; or, by being directed to the intestines, excites a painful diarrhoea, ultimately rendering their tone, and disturb their regular peristaltic motion. It generally happens, that, during the excess and prevalence of bile in the first passages, some absorption of it takes place into the habit, so that the skin becomes yellow, and the urine is feebly impregnated with it. The pulse is quicker than natural, and there is a considerable degree of thirst, with an increase of heat; the usual symptoms of fever. The body becomes emaciated, and the general aspect of the patient is extremely unhealthy. It may be added, that most of the fevers of hot climates, whether intermittent, remittent, or continued, are accompanied by an overflow of bile. (See Pervers.) When the increased secretion of bile affects the flomach and bowels in such manner as to excite vomiting and purging to a violent degree, it gives rise to that form of disease which is termed oblera; of which a particular description will be found under that title; when it produces vomiting, joined with confusion and acute pains about the umbilical region, the disease is termed bilious colic (see Colic); and lastly, when the evacuation of bile is frequent and copious by food only, without frequent vomiting, it constitutes bilious diarrhoea. (See Diarrhoea.) It is the remark of that judicious writer, to whose work we have more than once referred in this account of bilious disorders, that it is more difficult to supply a deficiency of bile, than to carry off its excess. In fact, little more is required for the fulfilment of this, within, than to promote the discharge of the redundant bile by gentle saline evacuants; for the bile has generally of itself a purgative tendency), and to prevent fresh accumulations, by diluting freely with water heated to a proper temperature. For this purpose, the patient should drink every morning, according to the excellent directions of Dr. Saunders, from half a pint to a pint of water, of a temperature from 80° to 115° of Fahrenheit's thermometer, and use moderate exercise before breakfast. With the same view, the Bath and Buxton waters, (provided their use be not contra-indicated by visceral disease), and the Cheltenham water also may be recommended. At the same time, a proper diet should be prescribed, consisting of food that is easy of digestion, not over-stimulating, and free from flatulence; and spirited drinks and malt liquors should be forbidden. Pasty is particularly improper. Water, or wine and water, will be the best beverage. When the bile has been sufficiently evacuated, biters and chalybeats may be given with advantage. But where these complaints are the consequence of residing in the tropical regions, the only effectual remedy is to remove to a temperate climate. People, who have suffered in these respects from the heat of climate, and to whom it is necessary to return to this country for the recovery of their health, should endeavour (as Dr. Lind has suggested), to arrive in the beginning of summer, as they will find the winters of Great Britain, on their first arrival, too piercing and severe for their constitutions.

4. Vitiation of the Bile. In almost all cases wherein the secretion of bile exceeds the natural quantity, it is at the same time vitiated in its quality. Thus in bilious fevers, bilious diarrhoea, bilious colic, and cholera morbus, it is often vitiated both in colour and taste, appearing wholly of a pure green colour, and possessing a sharpness or acidity which sets the teeth on edge, and produces a burning and corroding inflammation in the flomach, esophagus and fauces, and at the same time violent twitchings in the intestinal canal. Such vitations of the bile are common to infants, as well as to adults. The remedial treatment consists in evacuating the offending bile by the means specified under the preceding division (3), and correcting its vitiated qualities by the employment of alkalies, and by copious dilution with aqueous and mucilaginous liquors. After due evacuations, the flomach and bowels may be protected from the irritating action of the remaining bile by opiate medicines. Lind, Clark, Winterbottom, and other writers on the diseases of hot climates, may be referred to for many excellent observations on bilious disorders; but the best and most comprehensive treatise on this subject is that of Dr. Saunders.

BLEDGIK, in Geography, a town of Atlantic Turkey, in the province of Natoone, 32 miles N.W. of Eski Shehr.

BILEDULGERID, a country of Africa, comprehending, according to some geographers, the southern part of Algiers, together with the whole tract of land that lies in this direction between the Atlantic ocean and Egypt, and in this extent, including eight large tracts or provinces, viz. Duca, Biledulgerid proper, Segelmeia, or Sijmalla, Talfeet, Tigoarina, Zeb or Zab, Dorka or Doria, and Teltel, before several inferior districts, mentioned under the name of Oudna, or Augusta, Fassan or Fersan, and Gadames or Cadamis, &c. It was known to the ancients under the name of Num. It is in a more confined and proper sense, according to the arrangement of Dr. Lief, and several modern geographers, Biledulgerid includes that tract of land which lies south of Algiers and Tunis, and is bounded on the east by a range of lofty mountains, which separates it from Tripoli and part of Cadamis, on the west by the countries of Zuidar, Mezabz, and on the south by the province of Vorgela, or Wergela. Its dimensions are not accurately ascertained; but it is from what of a square form, supposed to extend about 60 or 80 leagues every way, or from about 31° 15' to 34° 15' N. lat., and from 5° 36' to 10° 10' E. long. Some have derived the appellation Biledulgerid from Biled el ferid, or the "land of dates," under which denomination it is distinguished in Rennell's map of North Africa; but others, with
Dr. Shaw, deduces it from Blaß and Jerilu, or the "dry country." The whole province of Bledagurid, bordering to the south on Sahara, or the Great Desert, is mountainous, sandy, and barren, producing little or no sustenance but dates, which grow in such abundance, that various parts of it are covered with palm-trees bearing this fruit. The climate is hot and unhealthy; the people are meagre, sallow, and shrivelled in their complexions, and their eyes are inflamed by the reflection of the sun-beams, from the white hard soil, and by clouds of dust and sand driven by the high winds at some seasons in such abundance, as to bury men and cattle under their collected mafs. They are also subject to a febrifule complaint, of which they can afflig without probable caufe, but so inative, that their teeth drop out, and their bodies become loathfome. In other refpects they are healthy and vigorous, and live without fickness or difafe to a great age. The plague of Barbary is fearely ever heard of in this province, notwithstanding the contiguity of the two countries, and the frequent intercourse of their inhabitants. Bledagurid, properly fo called, has few rivers and towns. The natives of Bledagurid are repreffed as a low, treacherous, thievish, and Savage people, that delight in murder, blood, and rapine. They are, in general, a mixture of old Africans and wild Arabs; the former of whom lived with fome degree of regularity and civil order, in a kind of villages composed of a number of little huts, while the latter inhabited movable tents, and ranged from place to place in quell of food and plunder. These Arabs value themselves on their superiority with regard to birth and talents above the primitive inhabitants; and while they are wholly independent and free, they occaflonally hire themselves to serve in the wars of the neighbouring princes, and hence arises the chief part of their public revenue; the refl purflne no other occupations besides plundering and hunting, and particularly hunting oiffices, the fefh of which they defire for food, and the fethers they barter for corn, paffe, and other necessaries. The other parts of these birds they ufe in their religious rites, as ornaments of cloaths, or as pouches and knapsacks. Besides dates and oiffices, thev likefife ufliffi the fefh of goats and camel; and for their drink, they ufe either the broth in which the fefh is boiled, or the milk of their camels, for they feldom take water, which is not only scarce, but brackifh and unwholesome. For the character and manners of thofe who inhabit that part of Bledagurid, taken in its former extent, and bordering on the Atlantic ocean; see MONGELMINE and MONGEATS.

BILCHEFIELD. See BILFELD.

BILCHE. See BILDER.

BILGUERV, JOHN ULRICK, in Biography, born at Coire, in the country of the Grious, in Switzerland; after passing through the usual course of education, practiced surgery at Berlin, where he foon acquired such reputation, as to engage the attention of king Frederic the Great, who made him surgeon to one of his regiments, and, in progression, surgeon-general to the Prussian army. In the course of an extensive practice in this field, he had an opportunity of observing how very small a proportion of the men recovered from fractures, where the loft parts were greatly bruised, and the bones shattered, when the limb had been amputated, which in such cafes was the general practice. This induced him to try more lenient methods, which he practiced with fuch success, as to enable him to reduce the cafe in which amputation should be declared to be necessary to a very small number. In 1761, he was admitted to the degree of doctor in medicine, by the university of Hall, in Saxony, where he read for his thesis "De membrorum amputatione
BILINEATA, in Entomology, 3 species of Leptura, of a blackish-brown, with two lines on the thorax, and scattered dots on the wing-cases yellowish. Scopoli, Gmelin. Inhabits Cornwall.

BILINEATA, a species of Callacris, with a yellow thorax, with a spot, and four brown dots: wing-cases yellow, with a fuscous line. Thunberg, &c. This is native of the Cape of Good Hope.

BILINEATA, a species of Chrysomela, that inhabits Scandinavia. It is green, glistened with gold; anterior part of the thorax excavated; and a double blue line on the wing-cases. Gmelin.

BILINEATA, a species of Phalaena (Gometra), with yellowish testaceous wings, waved with a broad stripe across, having a brown and a white margin. Linn. F. Svec. &c. A very common insect in hedges during the summer months; and is called in England sometimes the elm moth.

BILINEATA, a species of Brygynæa, of a blackish colour, with brown wings, and two white lines on each margin. Inhabits the north of Europe.

BILINEATUM, in Conchology, a species of Buccinum, described by Lüter. The shell is transversely striated; spine obtuse; the whorls with a pitted band and two lines. Its native country is unknown.

BILINEATUM, in Entomology, a species of Phalangiæ, of a pale colour, with two dorsal lines and black dots. Fabricius. Inhabits Norway.

BILINEATUM, a species of Cercoæli. This insect is brown, with two white lines on the wing-cases. Inhabits Germany.

BILINEATUM, a species of Cerambix (Prionus), with a crested thorax, marked with two white-lines; wing-cases ferruginous, speckled with white, and bordered with yellow. Inhabits America. Fabricius, &c.

BILINEATUM, a species of Cryptocœphalus, of a minute size, that is found in Europe. This insect is black, with two yellowish lines on the wing-cases, and ferruginous legs. Gmelin. A native of Europe, and described by Linnaeus as chrysomela bilineata.

BILINEATUS, a species of Ichneumon. It is black, with two yellow lines in front; abdomen depressed; legs red; tips of the posterior ones brown. Linn. Mol. Lefk.

BILINEATUS, in Ichthyology, a species of Plectonectes, found in China. It is thin, long, above yellow, with a brown margin; beneath reddish-white; entirely covered with very small scales. This is specifically distinguished by having the lateral line double. Bloch.

BILINEATUS, in Zoology, a species of Cölure, of a rufous colour, with two yellowish stripes: la double-queue de Cepede, and bilineata factae of Dr. Shaw. This kind, according to the former writer, measures two feet one inch in length, of which the tail is six inches and a half; colour rufous, each scale bordered with yellow; and from the back of the head are two bright golden-yellow stripes extending to the end of the tail; scales on the head large, those on the body smooth; native country unknown; abnormally fœta 204, halfcubical scales 99.

BILINGUUS, in Law. See Meditætas Lingue.

BILINGUUS, properly denotes a person who has two tongues in his mouth; an instance of which is given by Dobule. It is also used for a person who speaks two languages.

BILINGUUS Complexion. See Complexion, and Temperament.

BILINGUUS Colic. See Colic.

BILINGUUS Diet.--See Diarrhoæ Vol. IV.

BILIOUS Fever. See Fever.

BILLIANS, in Geography, a denomination given to a class of inhabitants of the southern parts of Russia. In their origin they are Scythes, who settled in their present habitations, and now exist under the name of Tcherewachs. See BULGARIANS.

BLITZ, a town of Sliecia, in the principality of Tefene, separated from Biala by the river of the same name, and at a small distance from it. N. lat. 49° 51'. E. long. 19° 16'.

BLIZIN, a town of Poland, in the palatinate of Nogrodock, about 18 miles N.E. of Nogrodock. N. lat. 53° 55'. E. long. 25° 45'.

BILL, in Agriculture, denotes an edge-tool, of the ax kind, with a hooked point, fitted to a handle, and used to lap boughs of trees, &c. When short, it is called a "hand-bill," when long, a "hedge-bill."

BILL, in Common Language, denotes a written or printed paper pulled up in some public place, for the purpose of advertising the sale of any merchandise, ship, &c. or the failing of any verdict, &c.

Bill is also used among tradesmen and workmen for an account, of goods sold and delivered, or of work done, with the charge annexed.

Bill, in Commerce, denotes a security for money under the hand, and sometimes seal of the debtor, without any condition or forfeiture, in case of non-performance.—In which it is distinguished from a bond or obligation. See Bond.

It has been usually defined a writing, wherein one man is bound to another to pay a sum of money, on a day that is future, or presently on demand, according to the agreement of the parties at the time when it is drawn, and the dealings between them.

Bill, in Law, denotes a declaration in writing, expressing a wrong or grievance, which the complainant hath suffered by the party complained of; or else some offence committed by him against some law or statute of the realm. This bill is commonly addressed to the lord chancellor, especially for uncontrollable wrongs done to the complainant; and sometimes to others having jurisdiction, according to the law direct. It contains the facts complained of, the damages sustained, and the petition of process against the defendant for redress. This is used as well in criminal as in civil matters. In criminal cases, when the grand jury against a pre-}
is wholly without remedy at the common law," relief is therefore prayed at the chancellor's hands, and also proceeds of fines assessed against the defendant, to compel him to answer upon oath to all the matter charged in the bill. See Suit in Equity.

Bill of Exception to Evidence. See Exception.

Bill of Exchange, in Commerce and Law, a short note, or writing, ordering the payment of a sum of money in one place, to some person assigned by the drawer, or remitter, in consideration of the like value paid to him in another place. (See Remittance.) Or, it is an open letter of request from one man to another, defining him to pay a sum of money named in it to a third person on his account, or to any other to whom that third person shall order it to be paid; or it may be made payable to bearer. This kind of negotiable security for money, invented among merchants in different countries, serves to facilitate the remittance of money from one to the other, and of course the conduct of commercial transactions; so that, since its first introduction, it has extended itself to almost all pecuniary negotiations.

Bills of exchange were unknown in the ancient Roman commerce, as well as jurisprudence. According to the common opinion, they are said to have been brought into general use by the Jews and Lombards, when banished for their usury and other vices; who found means to withdraw their effects, which they had lodged in the hands of friends, both in France and England, by secret letters and bills conceived in short precise terms, like the modern bills of exchange, which they negociated by the assistance of merchants and travellers. The Jews were banished out of France by Philip Augustus, in 1143, and out of England, in 1290; but the use of paper credit was introduced in the Mogul empire in China, in 1236. It further appears, that bills of exchange were negociated at Hamburgh, in 1188; and it has been said, that the faction of the Gibelins, being expelled Italy by the Guelphe, towards the close of the 15th century, retired to Amsterdam, and ufed the same means for the recovery of their effects in Italy as the Jews had done; and hence, as fine have thought, the Dutch merchants took the hint of negociating bills of exchange, and soon spread the practice throughout Europe. The fame Gibelins are said to be the inventors of the re-exchange, of re-exchange, on account of damages, charges, and interest, when bills of exchange, which they called "polizzi di cambio," are not paid, but returned on protest. In 1307, bills of exchange seem to have been in use in England, though their nature was not well understood at a much later period; and the first reference to them in an act of parliament, occurs in 1381, when they were forbidden to be used without the king's licence. In 1394, an ordinance was issued by the city of Barcelona, that bills of exchange should be accepted within twenty-four hours after they were presented, and that the acceptance should be written on the back of the bill. Moreover, in 1404, the magistrates of Bruges requested those of Barcelona to inform them what was the common practice, in regard to bills of exchange, when the person who presented a bill raised money on it in an unusual manner, in the case of its not being paid, and by these means increased the expenses to much, that the drawer would not content to fulfill the bills. The form of the bill, such as is now used, is seen in the memorial, which also speaks of usance; and it also appears, that first and second bills were at that time drawn, and that when bills were not accepted, it was customary to protect them. Anderson's Hist. Com. vol. i. Beckman's Hist. of Invent vol. iii p. 462.

In common speech, a bill of exchange is frequently called a "draught;" but the former is the more legal, as well as mercantile expression. The person who makes or draws the bill is called the "drawer," and he to whom it is addressed is denominated the "drawee," and when he undertakes to pay the amount, he is called the "acceptor." The person to whom it is ordered to be paid is called the "payee;" and if he appoint another to receive the money, this other is called the "indecor," as the payee is, with respect to him, the "indorser;" and any one who happens for the time to be in possession of the bill is called the "holder" of it. The time at which the payment is limited to be made is various, according to the circumstances of the parties, and the distance of their respective places of residence. Sometimes the amount is made payable at sight; sometimes at so many days after sight; at other times at a certain interval from the date. See Usance.

Where the time of payment is limited by months, it must be computed by calendar, not lunar months; and where one month is longer than the succeeding, it is a rule not to go in the computation into a third. Thus on a bill dated the 28th, 29th, 30th, or 31st of January, and payable one month after date, the time expires on the 28th of February, in common years, and in the three latter years, in leap year, on the 29th; to which are to be added the "days of grace." Where a bill is payable at so many days after sight, or from the date, the day of presentment, or of the date, is excluded. Thus, where a bill payable 10 days after sight is presented on the first day of a month, the 10 days expire on the 11th, when it is dated the first, and payable 20 days after date, these expire on the 21st. (Ld. Raym 281. Str. 829.) It is a custom among merchants, that a person to whom a bill is addressed, shall be allowed a few days for payment, beyond the time mentioned in the bill, called "days of grace." In Great Britain and Ireland, three days are allowed; in other places more. If the bill of these three days happens to be Sunday, the bill is to be paid on Saturday; but these days of grace are not allowed on bills payable at sight. If bills become due on Sunday, or on such holidays, when the law forbids business to be done, payment must be demanded or protest made for non-payment on the preceding day.

Bills of exchange are either "foreign" or "inland;" the first being those which pass from one country to another, and the latter such as pass between parties residing in the same country: and by the consent of merchants, certain customs are established with regard to foreign bills, which have been adopted as part of the law in every commercial state. Inland bills of exchange do not seem to have been very frequent in England before the reign of Charles II. (6 Mod. 29.) and foreign bills were much more regarded by the law than inland ones, as being thought of more public concern in the advancement of commerce. But at length the legislature, by two statutes, 17 W. 3. c. 17, and 3 & 4 Ann. c. 9, has fet both forts of bills nearly on the same footing, so that what was the law and custom of merchants, with regard to the one, is now, in most respects, the established law of the country, with regard to the other.

Promissory notes, or notes of hand, are a plain and direct engagement in writing to pay a sum specified at the time limited in it, to a person therein named, or to his order, or to the bearer at large. These notes were at first considered merely as evidence of a debt; and it was held that a promissory note was not assignable or indorsable, within the custom of merchants; and that if such a note had been indorsed or assigned over, the person to whom it was so indorsed or assigned, could not maintain an action within the custom against the drawer of the note; nor could even the person, to whom it was in the first instance made payable, bring such an action.
B I L L.

action. (1 Salk. 120. 2 Ld. Raym. 557, 9.) But at length the legislature recognized and put them upon the same footing with bills of exchange by statute 3 & 4 Ann. c. 9. made permanent by stat. 7 & 8. c. 25. § 3: which enacts that promissory notes, payable to order or bearer, may be affixed and indorsed, and a action maintained on them, as on a bill of exchange. By stat. 15 Geo. III. c. 51. and 17 Geo. III. c. 50. made perpetual by stat. 27 Geo. III. c. 16. all negotiable notes and bills for less than 20s. are declared to be null and void; and notes or bills between that sum and 51. must be made payable within 21 days after date, must purport the name and description of the payee, must bear date at the time and place in which they are made, must be attested by a subscribing witness, and the indorsement of them must be attended with the same formalities in all respects, and made before the notes or bills become due. The omission of any of these regulations and formalities vacates the security, and is fatal to any action. Bills of exchange and promissory notes may now be drawn on blank paper; and the stamp is proportioned under stat. 21 Geo. III. c. 27. 37 Geo. III. and 41 Geo. IV. c. 10. to the amount of the bill from sixpence to five shillings for such as are payable on demand; and for those payable after date from one shilling to four shillings. If foreign bills are drawn here, the whole lot must be stamped; but bills drawn abroad are not liable to any stamp duty.

As bills of exchange were first introduced for the convenience of commerce, it was formerly thought that they could neither be drawn nor negotiated by any person who was not actually a merchant; but it has been since decided, that any person capable of binding himself by a contract, may draw or accept, or negotiate a bill of exchange, and by stat. 3 & 4 Ann. c. 9. be a party to a promissory note. However, an infant cannot be sued on a bill of exchange, nor a feme-covert, except in such cases as he is allowed to act in as a feme-co. If a bill is drawn on two joint traders, the acceptance of one binds the other, if it concern the joint trade; but it is otherwise, if the bill concern the acceptor only, in a distinct interest and respect. On the subject of procuration with regard to bills; see Procuration.

A promissory note, when indorsed, begins to resemble a bill of exchange, for the indorser of the note corresponds to the drawer of the bill; the maker to the drawee or acceptor, and the indorsee to the payee; and this resemblance being fixed, the law is precisely the same in bills of exchange and promissory notes. It is now a decided point of law, that bills and notes made payable to bearer are equally transferable with those payable to order; and the transfer in both cases equally confers the right of action on the bona fide holder. But the mode of transfer is different; as bills and notes payable to bearer are transferred by mere delivery, the others by indorsement.

There are other bills and notes which differ from those already described, and which are securities for money, because they are considered as money itself. There are "Bank-notes," "Bankers' cash-notes," and "drafts on Bankers," payable on demand. Bank-notes are regarded in ordinary transactions by common consent as cash, and they have the credit and currency of money to every effectual purpose, and from to be as lawful a tender. (Stat. 5 W. & M. c. 25. § 28. 3 saint. Rep. 534.) Banker's cash-notes, and drafts of brokers, are considered among merchants as money, and are received as payment as ready cash; and if the party receiving them do so, within a reasonable time, demand the money; he must bear the loss in case of the banker's failure. The precise time is not absolutely determined; but it is held most advisable to carry such drafts on bankers, as are payable on demand, for payment on the day in which they are received, in the situation of the parties submit to it.

Bills of exchange and promissory notes, which, according to the general principles of law, are to be considered only evidences of a simple contract, are however in one respect regarded as specialties, and on the same footing with bonds; for they are promissory, unless the contrary be shown by the defendant, to have been made on a good consideration; nor is it incumbent on the plaintiff either to show a consideration in his declaration, or to prove it at the trial.

Bills of exchange, and also notes, are assignable or negotiable without any act; and every person to whom they are transferred may maintain an action in his own name against any one, who has before him in the course of their negotiations rendered himself responsible for the payment of them. But the instrument, or writing, which constitutes a good bill or note, must have certain essential qualities. One of these is, that the bill or note should be for the payment of money only, and not for the payment of money and doing of some other act. Another requisite quality is, that the instrument must carry with it a personal and certain credit, given to the drawer or maker, not confined to credit on any particular fund. But in the application of this principle, there is a material distinction between bills and notes. With regard to the former, where the fund is stipulated to be in the hands of the drawee, the objection holds in its full force, not only because the produce-ability of the fund is contingent and precarious, but because the credit is not given to the personal of the drawer: but where the fund, on account of which the money is payable, either is in the hands of the drawer, or he is accountable for it, the objection will not hold, because the credit is personal to him, and the fund is only the consideration of his giving the bill. With respect to a note, if the drawer promise to pay out of a particular fund, then within his power, the note will be good under the statute; the payment does not depend on the circumstance of the fund's proving unproductive, or not, but there is an obligation upon his personal credit; the bare making of the note being an acknowledgment that he has money in his hands. Another essential quality of a good bill or note is, that it must be absolutely payable at all events, and not depend on any particular circumstances which may or may not happen in the common course of things. No precise form of words is necessary to make a bill of exchange or a note under the statute; any order, which cannot be complied with, or promises, which cannot be performed, without the payment of money, will make a good bill or note. As the words "value received," have been usually inserted in bills or notes, some doubt has occurred, whether they are essential. It is now understood, as a decided point, that these words are not necessary; for instruments of this kind are presumed to have been made on a valuable consideration; and therefore words, which import no more, cannot be essential. It has been queried, whether it be essential to the constitution of a bill of exchange, that it should contain words which render it negotiable, as "to order," or "to bearer:" and the point has not yet received a judicial decision. With regard to notes that have not these words, the person to whom they are made payable, may maintain an action on them, within the statute, against the maker. With regard to the acceptance of bills of exchange, see Acceptance. Forgery the acceptance of any such bill, or the number or principal sum of any accountable receipt, is made felony by stat. 2 Geo. c. 22.

The mode of transferring bills and notes is regulated according to the express terms which render them negotiable. Such as are payable to bearer, are transferred by de-
BILL.

If payable to A. B. or bearer, they are payable to bearer, as if A. B. were not mentioned. But to the transfer of these payable to order, it is necessary, in addition to delivery, there should be something, by which the person may appear to express his order. This additional circumstance is called an "indorsement." See Indorsement.

By the very act of drawing a bill, the drawer comes under an implied engagement to the payee, and to every subsequent holder, fairly entitled to the possession, that the person on whom he draws is capable of binding himself by his acceptance; that he is to be found at the place where he is described to be, if that description is mentioned in the bill; that if the bill be duly presented to him, he will accept in writing on the bill itself, according to its tenor; and that he will pay it when it becomes due, if presented in proper time for that purpose. In default of any of these particulars, the drawer is liable to an action at the suit of any of the parties before-mentioned, on due diligence being exercised on their parts, not only for the payment of the original sum mentioned in the bill, but also in some cases for damages, interest, and costs; and he is equally subject to, whether the bill was drawn on his own account, or on that of a third person; for the holder of the bill is not to be affected by the circumstances that may exist between the drawer and another; the personal credit of the drawer being pledged for the due honour of the bill.

If a man write his name on a blank piece of paper, and deliver it to another, with authority to draw on it a bill of exchange to any amount, at any distance of time, he renders himself liable to be called on as the drawer of any bill so formed by the person to whom he has given the authority. If acceptance be refused, and the bill returned, this is notice to the drawer of the refusal of the drawer; and then the period, when the debt of the former is to be considered as contracted, is the moment when he draws the bill; and an action may be immediately commenced against him, though the regular time of payment, according to the tenor of the bill, be not arrived; for the drawer, not having given credit, which was the ground of the contract, what the drawer had undertaken has not been performed. When a bill of exchange is indorsed by the person to whom it was made payable, as between the indorser and indorsee, it is a new bill of exchange; as it is also between every subsequent indorser and indorsee; the indorser, therefore, with respect to all the parties subsequent to him, stands in the place of the drawer, being a collateral security for the acceptance and payment of the bill by the drawer; his indorsement imposes on him the same engagement that the drawing of the bill does on the drawer; and the period when that engagement attaches, is the time of the indorsement. Nor will any thing discharge the indorser from his engagement, but the absolute payment of the money; not even a judgment recovered against the drawer or any previous indorser, neither is his engagement discharged by an insulitary execution against the drawer, or any prior or subsequent indorser. The engagement of the drawer and indorsers depends on certain conditions to be performed by the holder of the bill, and without the performance of which he has no remedy against them.

When the payment of the bill is limited to a certain time after sight, the holder must present it for acceptance, otherwise the time of payment will never come. Although it has never been directly determined, whether the holder of a bill, payable at a certain time after date, be bound to present it for acceptance immediately on receiving it, or whether he may wait till it become due, and then present it for payment; yet in practice it often happens that a bill is negotiated and transferred through many hands, without acceptance, and not presented to the drawer till the time of payment; and no objection is ever made on that account. If, however, on the holder presenting the bill for acceptance, this be refused, he is bound to give regular notice to all the preceding parties to whom he intends to refer for non-payment; and if, on account of the holder's delay, any losses be incurred by the failure of any of these parties, he must bear these losses. It is also the duty of the holder of a bill, whether accepted or not, to present it for payment within a limited time; otherwise the law will imply that payment has been made, and it would be prejudicial to commerce, if a bill might be produced to charge the drawer at any distance of time, when all accounts might be adjusted between him and the drawer. A protest is either for payment or acceptance must be made at a seasonable hours, which are the common hours of business in the place where the party, to whom the bill is presented, resides. If acceptance or payment be refused, or the drawer of the bill, or the maker of the note, has become insolvent, or has absconded, notice from the holder himself must be given to the preceding parties, and in this notice it must be added, that the holder does not intend to give him credit. What may be considered as a reasonable time, within which notice should be given, either of non-acceptance or non-payment, has been subject to much doubt and uncertainty. It was once held, that a fortnight was a reasonable time; but that period is now much contracted. With respect to acceptance, it is usual to leave a bill for that purpose with the drawer till the next day; but if he, when called upon the next day, delay or refuse to accept according to the tenor of the bill, it is now an established rule, where the parties, to whom notice is to be given, reside at a different place from the holder and drawer, that notice should be sent by the next post, and the same rule obtains in case of non-payment. Also in case of the drawer of the bill, or maker of the note, having absconded, or not being found, notice of these circumstances, in case either of non-acceptance or non-payment, must be sent by the first post. Considerable difficulty has occurred in establishing a general rule in this respect, where the party entitled to notice resides in or near the place in which the holder lives. The court, however, has on several occasions laid it down as a principle, that what shall be considered as a reasonable time in case of notice, and also of demand of payment, is a question of law; and this seems to have been fully established, and it is understood generally, that a demand must be made, and notice given, as soon as under all the circumstances it is possible to do so. And in the manner in which notice is given, either of non-acceptance or non-payment, there is a remarkable difference between inland and foreign bills. In the former no particular form of words is necessary to entitle the holder to recover against the drawer or indorsers, the amount of the bill, on failure of the drawer or acceptor; it is sufficient if it appear that the holder means to give no credit to the latter, but to hold the former to their responsibility. But in foreign bills, other formalities are required. If the person to whom the bill is addresed, on presentment, will not accept it, the holder is to carry it to a person vested with a public character, who is to go to the drawer and demand acceptance; and if he then refuse, the officer is there to make a minute on the bill itself, consisting of his initials, the month, the day, and the year, with his charges for minuting. He must afterwards draw up a solemn declaration, that the bill has been presented for acceptance, which was refused, and that the holder intends to recover all the damages which he, or the deliverer of the money to the drawer, or any other, may sustain on account of the non-
BILL.

acceptance. This minute, in common language, is termed the "note" of the bill; the solemn declaration, the "pro- test; and the person whose face it is to do the acts called a "public notary;" and to his protestation all foreign courts give credit. If no such notary be resident in the place where the bill is negotiated, protest may be made by any substantial inhabitant in the presence of two credible witnesses. For the circumstances attending this protest, and the difference in this respect between inland and foreign bills, see Paoretz.

When a bill is once accepted absolutely, it cannot in any cafe be revoked, and the acceptor is at all events bound, though he hear of the drawer's having failed the next moment, even if the failure was before the acceptance. The acceptor may, however, be discharged by an express declaration of the holder, or by something equivalent to such declaration. But no circumstances of indulgence shown to the acceptor by the holder, nor an attempt on his part to recover of the drawer, will amount to an express declaration of discharge. Neither will any length of time short of the statute of limitations, nor the receipt of part of the money from the drawer or indorser, nor a promise by indemnification on the bill by the drawer to pay the residue, discharge the holder's remedy against the acceptor. Although the receipt of part from the drawer or indorser be no discharge to the acceptor, yet the receipt of part from the acceptor of a bill, or the maker of a note, is a discharge to the drawer and indorsers in the one case, and to the indorsers in the other, unless due notice be given of the non-payment of the residue; but where due notice is given, that the bill is not duly paid, the receipt of part of the money from an acceptor, or maker, will not discharge the drawer or indorsers; because it is for their advantage, that as much should be received from others as may be. So the receipt of part from an indorser is no discharge of the drawer or preceding indorser. If the drawer of a note, or the acceptor of a bill, be fixed by the indorser, and the bill pay the debt and costs, this absolutely discharges the indorser as much as if the principal had paid the note or bill; and the bill cannot afterwards recover against the indorser in the name of the indorser. On the principles of several cases it has been finally settled, that to entitle the indorser to recover against the indorser of an inland bill of exchange, it is not necessary to demand the money of the first drawer.

By the Stat. 3 & 4 Ann. c. 9, § 7, it is enacted, that if any person accept a bill of exchange for and in satisfaction of any former debt or claim of money, formerly due to him, this shall be accounted and esteemed a full and complete payment of such debt; if such person, accepting such bill for his debt, do not take his due course to obtain payment of it, by endeavouring to get the face accepted and paid, and make his protest according to the directions of the act, either for non-acceptance or non-payment.

Where a privity exists between the parties in a bill of exchange, an action at debt, or of "indubitus Allanum," may be maintained; but where it does not exist, neither of those actions will lie. A privity exists between the payee and the drawer of a bill of exchange; the payee and drawer of a promissory note; the indorser and his immediate indorser of either the one or the other; and perhaps between the drawer and acceptor of a bill; provided that, in all those cases, a consideration passed respectively between the parties. But no privity is supposed to exist between the indorser and acceptor of a bill, or the maker of a note, or between an indorser and a remote indorser of either.

The action which is now brought on a bill of exchange, is a special action on the case, founded on the custom of merchants. This custom was not at first recognized by the court, unless it was specially set forth; but when this custom was recognized by the judges as part of the law of the land, and they declared they would take notice of it "ex officio," it became unnecessary to recite the custom at full length; a simple allegation that "the drawer, mentioning him by his name, according to the custom of merchants, drew his bill of exchange, &c." was sufficient. If the plaintiff, adhering to former precedents, thought proper to recite the custom in general terms, and did not bring his case within the custom so far forth; yet if by the law of merchants, as recognized by the court, the case is flated, entitled him to his action, he might recover; and the latter part of the custom was reckoned surplusage, and rejected. Whether the drawer of a bill, or the indorser of a bill or of a note, receiving the bill or note in the regular course of negotiation before it has become due, can maintain an action on it against the acceptor or maker, in the character of indorser, seems undecided; but there is a case which clearly shows that a drawer or indorser cannot maintain an action in the character of indorser, "where the indorsement is after the refusal of payment;" because when a bill is returned unpaid, either on the drawer or indorser, its negotiability is at an end. The action, therefore, in which the drawer or indorser, after payment of the money in default of the acceptor, may recover, the first against the acceptor, and the latter against any of the preceding parties, must be brought in their original capacity as drawer or indorser, and not as indorser. If the drawer, without having effects of the drawer, accept and duly pay the bill without having it protected, he may recover back the money in action for money paid, laid out, and expended to the use of the drawer. Instead of bringing an action on the custom, or on the statute, the plaintiff may in many cases use a bill or note only as evidence in another action; and if the instrument want some of the requisites for making it a good bill or note, the only use he can make of it is to give it in evidence.

The holder of the bill or note may sue all the parties who are liable to pay the money; either at the same time, or in succession; and he may recover judgment against all, if satisfaction be not made by the payment of the money before judgment obtained against all; and proceedings will not be laid in any one action, but on payment of the debt and costs in that action, and the costs in all the others in which he has not obtained judgment. But though he may have judgment against all, yet he can recover but one satisfaction; and though he be paid by one, he may sue out execution for the costs in the several actions against the others. To this action the defendant may plead the statute of limitations; and by the express proviso of the statute of Queen Anne, all actions on promissory notes must be brought within the same time as is limited by the statute of James, with respect to actions on the case. And to this plea it is no good replication, that it was on account between merchants, where it appears to be for value received.

As the action on a bill of exchange is founded on the custom of merchants, so that on a promissory note is founded on the statute 3 & 4 Ann. c. 9. In both cases, however, it is necessary, that all those circumstances should be expressly stated, or clearly and inevitably implied, which, according to the characters of the parties to the action, must necessarily concur, in order to entitle the plaintiff to recover. In filing the bill or note, regard must be had to the legal operation of each respectively. It has been decided, that the legal operation of a bill or of a note, payable to a fictitious payee, is, that it is payable to the bearer; and therefore it is proper in the statement of such a bill, to allege that the drawer thereby requested the drawee to pay the money to the bearer;
B I L L.

bearer; and in the statement of such a note, that the maker thereby promised to pay such a sum to the bearer.

As to the proof that is necessary in actions on bills or notes, we may observe, that the plaintiff must, in all cases, prove so much of what is necessary to entitle him to his action, and of what must be stated in his declaration, as is not, from the nature of the thing, and the situation of the parties, necessarily admitted. In an action against the acceptor, it is a general rule that the drawer's hand-writing is admitted; that of the acceptor must of course be proved; and that of every person, through whom the plaintiff, from the nature of the transaction, must necessarily derive his title. On a bill payable to bearer, in an action against the acceptor, he has only to prove the hand-writing of the acceptor himself; but in case of a bill payable to order, the plaintiff must prove the hand-writing of the very payee who must be the first indorser. In case of a transfer by delivery, the plaintiff may be called upon to prove that he gave a good consideration for the bill or note, without the knowledge of its having been stolen, or of any of the names of the blank indorsers having been forged. In an action by the indorsee against the drawer, the same rules obtain with respect to proof of the hand-writing of the indorsers, as in an action against the acceptors. That of the drawer himself must of course be proved; and it must also be proved that the plaintiff has used due diligence. From the rule, that in an action against the drawer or acceptor of a bill payable to order, there must be proof of the signature of the payee, first indorser, and all those to whom an indorsement has been specially made, arose the question, which long and greatly agitated the commercial world, on the subject of indorsements in the name of fictitious payees. A bill, payable to the order of a fictitious person, and indorsed in a fictitious name, is not a novelty among merchants and traders. But in the years 1786, 7, and 8, two or three houses, having connection in trade, and entering into engagements far beyond their capital, under an apprehension that the credit of their own names would not be sufficient to procure currency to their bills, adopted, to a very extensive degree, a practice which had before been found convenient on a smaller scale. For a considerable time, whilst money could be procured for the payment of these bills by the acceptors or drawers, and they had sufficient credit with the holder to have them renewed, the subject of these fictitious indorsements was not questioned. But when credit failed, and a commotion of bankruptcy became necessary, the other creditors felt it their interest to replead the claims of the holders of these bills, and inferred that they should not be allowed to prove their debts, because they could not conform to the general rule of law, requiring proof of the hand-writing of the first indorser. The chancellor, when the question came before him by petition, directed trials at law. From the decisions in consequence of these trials, the principal of which was affirmed in the House of Lords, and which have led to the custom that such bills are to be considered as payable to bearer, it follows, that proof of the acceptor's hand only is sufficient to entitle the holder to recover on the bill; and in a particular case, where the bill was drawn by the defendant and others on the defendant, it was determined that a bond fide holder for a valuable consideration might recover the amount against the acceptor in an action for money paid, or money had and received. The effect of the determination of the judges in the House of Lords, with respect to the principal case above alluded to, is as follows. If a bill of exchange be drawn in favour of a fictitious payee, with the knowledge as well of the acceptor as the drawer; and the name of such payee be indorsed on it by the drawer, with the knowledge of the acceptor, which fictitious indorsement purports to be to the drawer himself or his order; and then the drawer indorses the bill to an innocent indorser for a valuable consideration, and afterwards the bill is accepted; but it does not appear that there was an intent to defraud any particular person; such innocent indorsee for a valuable consideration may recover against the acceptor, as on a bill payable to bearer. Perhaps also, in such case, the innocent indorsee might recover against the acceptor, as on a bill payable to the order of the drawer, or on a count charging the special circumstances. On other cases, afterwards brought before the House of Lords on demurrers to evidence, the judges gave their opinion, that it was not competent to the defendants to demurr; and that on the record, as stated, no judgment could be given. The tests discordant to the general rules of bill-negotiation to the amount of a million a year, on fictitious credit, which ended in the bankruptcy of many; but which had at least the good effect of showing that the obligations of law are not so easily eluded as those of honour and confidence.

In an action by an indorsee against an indorser, it is not necessary to prove either the hand of the drawer or of the acceptor, or of any indorser before him against whom the action is brought, every indorser being, with respect to subsequent indorsers or holders, a new drawer. Where an action is by one indorser, who has paid the money, proof must be given of the payment. In an action by the drawer against the acceptor, where the bill has been paid away and returned, it is necessary to prove the hand-writing of the latter, demand of payment by him, and refusal, the return of the bill, and payment by the plaintiff. In an action on the bill by the acceptor against the drawer, the plaintiff must prove the hand-writing of the defendant, and payment of the money by himself; or something equivalent, as his being in privity of execution. Where a bill is accepted, or a bill or note is drawn or indorsed, by one of two or more partners, on the partnership's account, proof of the signature of the party accepting, drawing or indorsing, is sufficient to bind all the rest. When a servant has a general authority to draw, accept, or indorse bills or notes, proof of his signature is sufficient against the master; but his authority must be proved, as that it was a general custom for him to do so, &c. An action on a bill of exchange being by an executor, and upon a debt laid to be due to tellator, it was held necessary to prove that the acceptance was in the life-time of the tellator. Where the defendant suffers judgment by default, and the plaintiff executes a writ of inquiry, it is sufficient for the latter to produce the note or bill, without any proof of the defendant's hand; and on such judgment, a writ of inquiry seems now to be unnecessary.

As to the different subjects of defence, with regard to bills of exchange and notes, the most usual are those which arise either from the total want of consideration, or from the illegality of the consideration for which the bill or note was given. See Consideration.

If a bank-bill, payable to A. B. or bearer, be lost, and it is found by a stranger, payment to him would indemnify the bank; yet A. B. may have recover against the finder, though not against his allegiance for valuable consideration, which creates a property. If the pofferor of a bill accidentally loses it, he must caufe intimation to be made by a notary public before witnesses, that the bill is lost or mislaid, and requiring that payment be not made of the same to any person without its priory. And by flt. 9 & 10 W. III. c. 17, if any inland bill of exchange for 5l. or upwards shall be lost, the drawer of the bill shall give another of the same tenor, security being given to indemnify him, in case the bill so lost be found again. If a bill lost by the pofferor should
should afterwards come into the possession of any person, who pays a full and valuable consideration for it, without knowledge of its having been lost, the drawer and acceptor, if the bill was accepted, must pay it when due to such fair possessor, so that the provisions of the statute may, in many cases, be ineffectual to the loser of the bill. But against the person who finds the bill, the real owner may maintain an action of trover. Stealing bills of exchange, notes, &c., is felony in the same degree as if the offender had robbed the owner of so much money, &c. And the forging of bills of exchange, or notes of money, indorsements, &c., is felony, by 14. 2 Geo. II. c. 25. § 9 Geo. II. c. 18. See also 41. 31 Geo. II. c. 22. § 78. Blackst. Com. vol. ii. p. 466. Jacob’s Law Dictionary, by Tomlins, vol. i. art. Bill.

Bill of Indictment. See Bill above, and Indictment.

Bill of Interpleader. See Interpleader, and Suit in Equity.

Bill of Middlesex, which was formerly always founded on a “plaint” of trespass quam clausum friget, entered on the record of the sheriff of that county, and commanding him to take the defendant, and have him before our lord the king, at Westminister, on a day prefixed, to answer to the plaintiff of a plea of trespass. This bill of Middlesex must be served on the defendant by the sheriff, if he finds him in that county; but if he returns “non est inventum,” then there issues out a writ of “lattitum” to the sheriff of another county, as Berks; which, in the court of king’s bench, is similar to the “teutatum capias” in the common pleas, and recites the writ of Middlesex, and the proceedings thereon; and that it is testified, that the defendant “lattitit et dicturn,” lurks and wanders about in Berks; and therefore commands the sheriff to take him, and have his body in court on the day of the return. But, as in the common pleas, the “teutatum capias” may be sued out upon only a humpased, and not an actual, proceeding “capias;” so, in the king’s bench, a “lattitum” is usually sued out upon only a humpased, and not an actual, “bill of Middlesex;” so that, in fact, a “lattitum” may be called the first process in the court of king’s bench, as the “teutatum capias” is in the common pleas. Yet, as in the common pleas, if the defendant lives in the county wherein the action is laid, a common “capias” suffices; so, in the king’s bench likewise, if he lives in Middlesex, the process must still be by “bill of Middlesex.”

Bill, Navy. See Navy.

Bill, in Parliament, denotes a paper containing propositions offered to the House, to be passed by them, and then to be preferred to the king to pass into an act or law: for the mode of presenting and conducting of which, see Parliament.

Bills, Lombard, are instruments of an uncommon kind and figure, used in Italy and Flanders, and also in France; consisting of a piece of parchment, cut to an acute angle about an inch broad at top, and terminating in a point at bottom; chiefly given where private persons are concerned in the paying out a ship for any long voyage.

The manner is this: the party who is desirous to be concerned in the cargo or venture, carries his money to the merchant, who fits out the ship, where it is entered down in a bill. At the same time, the merchant writes down on a piece of parchment, upwards of an inch broad, and seven or eight inches long, the name of the bearer, and the sum lent, which being cut diagonal-wise, or from corner to corner, each party retains his half. On the return of the vessel, the lender brings his moiety to the merchant, which being compared with the other, he receives his dividend accordingly. Much the same is practised in Holland by those who lend money on pledges: the name of the borrower, and the sum, are written on a slide of parchment, which is cut in two, and half given to the borrower, and the other half fastened to the pledge; that, upon comparing them together again, the borrower may receive his goods, on paying the money stipulated.

Bill, to note on. See Note, and Bill of Exchange.

Bill, to protest. See Protest, and Bill of Exchange.

Bills, bank, are notes or obligations signed in behalf of the company of the bank, by one of their drawers, for value received. See Note, and Bill of Exchange.

Bill of credit. See Credit.

Bill of entry, an account of goods entered at the custom-house, both inward and outward; in which are expressed, the name of the merchant importing or exporting, the quantity, number, and mark of the goods, and place from or to which they are imported, or to be exported.

Bill of lading, an instrument signed by the master of a ship, acknowledging the receipt of a merchant’s goods, and obliging himself to deliver them to the place to which they are consigned, in good condition. Of such bills there are usually three: the first, kept by the merchant; the second, sent to the factor to whom the goods are consigned; and the third, kept by the master of the ship. See Charter-party.

Bills of mortality, are weekly lists compiled by the parish-clerks in and about London, containing the numbers of such as die of each disease, as well as of those that are born every week. See Mortality.

Bill of parcels, an account of the particular sorts and prices of goods bought, given by the seller to the buyer.

Bill of rights. See Rights.

Bill of sale, is an instrument or writing which a person wanting a sum of money, and delivering goods as a security to the lender, gives to him, empowering him to sell the said goods, in case the sum borrowed is not repaid, with interest, at the time appointed. See Sale.

Bill of store, a licence granted to the custom-house to merchants, to carry such furs and provisions as are necessary for their voyage, custom-free.

Bill of sufferance, a licence granted to the custom-house to a merchant, to fulfill him to trade from one English port to another, without paying custom.

Bill, or Bear, perjury, in Ornithology, the elongated horny processes or mandibles of birds. The form of the bill varies greatly in different kinds of birds, that they afford the most permanent character by which these creatures may be arranged. In the distribution of families, Linnaeus first notices the structure of the bill, the tongue, and mandibles; and these parts constitute almost exclusively (with the legs) the distinction of the genera likewise. See Ornithology, and Anatomy of Birds.

The Phoenicopeter’s bill is a true hyperbola, pointed at the end like a sword; and what is remarkable, the upper bill of this bird moves in eating, the lower being fixed, which is the contrary of what is found in all other kinds. The wood-pecker’s bill is flanging, and sharp enough to dig holes, and build in the heart of the hardest timber. See Phoenicopeterus and Picus. Phil. Trans. N. 214. p. 153. N. 35. p. 529.

In the island of Ferro, a fixed reward is given for the bills of ravens and birds. All watermen are obliged to bring a certain number yearly to the country courts, at the feast of St. Olau; when they are thrown into a heap, and burnt in triumph. Plott gives divers instances of monstrous irregularities
The grand jury indorsing a bill whereby any crime punishable in that court, is presented to them, with the words billa vera, signify thereby, that the presenter has furnished his preface with probable evidence, and worthy of farther consideration; whereupon the party presented is sued to stand indicted of the crime, and bound to make answer thereto, either by confessing or traversing the indictment. See Bill in Law, supra.

BILLANCOURT, in Geography, a town of France, 4 miles S.W. from Paris.

BILLARD, or Billet, in Ichthyology, an English name, in some places, for the young coal-fish, Gadus carbonarius, when a year old; measuring at that time from 8 to 10 or 15 inches in length.

BILLAU, in Geography, a river of Silesia, which runs into the Neisse, near the town of Neys.

BILLE, a town of France, in the department of the Ille and Vilaine, and the chief place of a canton, in the district of Fougeres, 14 leagues south of Fougeres.

BILLEKA, a town of Poland, in the palestinate of Lemberg, 10 miles east of Lemberg.

BILLERDECK, a town of Germany, in the circle of Weilphalia, and bishopric of Münster, 5 miles N.E. from Coesfeld.

BILLERICA, a township in Middlesex county, Massachusetts, in America, incorporated in 1655, containing 1200 inhabitants, being 20 miles north of Boston, and watered by Concord and the Stow and Francon rivers, which run north-easterly into Merrimack river.

BILLERICA, in Geography, a market-town of Essex, England; is built on a fine eminence, commanding a view of a rich vale between the town and the river Thames. Though enjoying the advantage of a weekly market on Tuesdays, it is only a hamlet in the parish of Great Baddow, the church of which is situate about one mile and a half south of this place. For the accommodation of the inhabitants, a chapel is endowed and supported in the town. Here are two annual fairs; and the whole parish contains 250 houses, and 1472 inhabitants. Billerica is 23 miles N.E. from London. Morant's history of Essex.

BILLESDON. See Bilston.

BILL. See Headborough.

Billet, or Billette, in Heraldry, signifies a figure whose length exceeds its breadth: when the arms are charged with several of them, they are then called Billettes. The royal arms of Navarre, prince of Orange, is Jupiter Billette fol, a bice rampart of the left. Authors differ much in regard to the antiquity of the billet, which was evidently a piece of wood cut in the form of a parallelogram, and retains that name and shape to this day.

Billet, Billette, in the French Customs, a little sign in form of a cask, hung up at places where toll is to be paid to advertisements and carriages, that before they advance farther, the dues are to be paid to the king, or the lord who is charged with the care of repairing the highways.

Billets for fuel, are small pieces of wood, which must be 3 feet 4 inches long, and 7/8 in compass, &c. Juvicles of peace shall enquire, by the oaths of six men, of the affize of billets; and these which are under size are forfeited to the poor. Stat 43 Eliz. c. 14. 9 Ann. c. 15. 10 Ann. c. 6. See Fuel.

Billets of gold, denote wedges or ingots of gold, mentioned in the text. 27 Ed. 3. c. 27.

BILLETING of jolters, in Military Language, is the lodging or quartering of them in the houses of the inhabitants of a place. This is done by a ticket, called a billet, which entitles each holder, by act of parliament, to candles, vinegar, salt, and either small beer or cider, not exceeding five pints per day, gratis; with the use of fire, and the necessary utensils fordining and eating their meat.

BILLETING, among Sportmen, denotes the ordure and dung of a fox.

BILLETINS. See Brothers of Charity.

BILL, JAMES DE, in Biography, a French Jesuit, was born in Compiegne in 1602, and entered the society of Jesuits in 1619. He taught philosophy for three years, and was a preacher for more than twenty years. He was rector of Chalons, Langres, and Sens; but he is best known by his mathematical writings, which are as follows: "Nova Geometriae Chasius Algebrar," Paris, 1613, 4to. "Tabula Lodoice de doctrina eclipson," Dijon, 1656, 4to. "Tumulos Astrallogiae Judicialis," Paris, 1650, 4to. "Dioptrum Geometria," Paris, 1650, 4to.; "Opus Astronomicum," Dijon, 1661, 4to.; "Decours de la Comite qui a para l'an 1665, au mois d'Avril," Paris, 1655. 4to.; "Chiffres Astronomico de mota Cometarum," Dijon, 1660, 8vo.; "Doctrina analytica inventum novum," Toulouse, fol. Moreiri.

BILLIARDS, an ingenious kind of game played with two small ivory balls, on an oblong table, covered with green cloth, and placed exactly level; which balls are driven by flicks made on purpose, alternately against each other, with a view to push the passive ball into hazards, or holes, on the edges and corners, according to certain laws or conditions of the game.

The word comes from the French billiard, of bile, the ball made use of; and that from the Latin pilis, a ball.

This game was invented by the French, and practised by the Germans, Dutch, and Italians; and is now a favourite diversion among persons of the first rank in many parts of England. The table on which it is played is about 12 feet long, and 6 wide, and not only covered with green cloth, but surrounded with cushions to prevent the balls from rolling off, and to make them rebound. It has six holes, nests, or pockets, which are fixed on the four corners, and in the middle, opposite to each other, for receiving the balls, which, when put into these holes, are called hazards. The making of a hazard, or putting the adversary's ball into the hole at the usual game, is reckoned for two in favour of the player.

The game is played with flicks, called maces, or with cues. The mace is a long straight stick, with a head at the end, and is the most powerful instrument of the two; the cue is a thick stick decreasing gradually to a point of about half an inch in diameter; this instrument is played over the left hand, and supported by the forefinger and thumb. This is the only instrument in vogue abroad, and is used with astonishing dexterity by the Italians, and some of the Dutch; but in England the mace is the prevailing instrument, though regarded with some degree of contempt by foreigners, as the use of it does not require so much dexterity as the cue; however, the mace is used for the peculiar advantage of "trailing," as it is called; or of following the ball with it to such a convenient distance from the other ball as to make it an easy hazard. The several degrees of trailing are variously denominated by the connoisseurs; e.g., the mace, the sweep, the long stroke, the trail, and the dead
B I L I A R D S.

trail or turn up, all which secure certain advantages to a good player; and even the butt-end of the cue becomes very powerful, when it is made use of by a good trailer. The varieties of this game are denominated the "white winning game," the "white rooting game," the "red or carambolic winning game," and the "red rooting game." The game usually played is the first of these, and 12 is the number. The rules for this game are as follows: 1. String for the lead and choice of balls; the person who does this must stand within the limits of the corner of the table, and not place his ball beyond the fringing nails or spots: the lead is won by him who brings his ball nearest the cushion. 2. If after the first person has frunged for the lead, the adversary should make his ball touch the other, he loses the lead; and if the player holes his own ball in fringing or leading, he loses the lead.

3. If the leader follows his ball with either mace or cue beyond the middle hole, it is no lead; and it is at the option of his adversary to make him lead again. 4. The striker who plays at the lead must stand with both his feet within the limits of the corner of the table, and not place his ball beyond the fringing nails; and his adversary (only) is bound to see that he stands and plays fairly; otherwise the striker wins all the points he made by the stroke.

5. When a hazard has been left in either of the corner holes, the lead is obliged, if his adversary require it, to come from the end of the table, where the hazard was left; but if the hazard was left in either of the middle holes, it is at the leader's option to lead from either end of the table. 6. If the striker does not hit his adversary's ball, he loses one point; and if he by the false stroke his ball should go into a hole, over the table, or on a cushion, he loses three points; and he also loses the lead. 7. If the striker holes his adversary's ball, or forces it over the table, or on a cushion; or if he holes both balls, or forces them over the table, or on a cushion; in either case he loses two points. 8. No person has a right to take up his ball without permission from his adversary. 9. If the striker should touch or move his own ball, without intending to make a stroke, it is deemed an accident; and his adversary, if he require it, may put the ball back in the place where it stood. 10. If the striker force his adversary's ball over the table, and his adversary should chance to stop it, so as to make it come on the table again, the striker wins two points; if the striker should force his own ball over the table, and his adversary should chance to stop it so as to make it come on the table again, the striker loses nothing by the stroke, and has the lead; but if the striker miss the ball and forces it over the table, and it should be stopped by his adversary, he loses one point, and has the lead, if he chusses. 11. If the striker, in playing from a cushion or otherwise, by touching the ball, makes his mace or cue go over or beyond it, he loses one point; and, if his adversary require it, he may put the ball back, and make him pass the ball. 12. If the striker, in attempting to make a stroke, doth not touch his ball, it is no stroke; and he must make another trial; but if when the balls are near each other, the striker should accidentally make his ball touch the other, it is a stroke, though not intended. 13. If the striker who plays the stroke should make his adversary's ball go to near the brink of a hole, as to be judged to stand still, and afterwards fall into it, the striker wins nothing, and the ball must be put upon the same brink where it stood, for his adversary to play from the next stroke. 14. If the striker's ball should stand on the brink or edge of a hole, and if in playing it off he should make the ball go in, he loses three points. 15. If a ball should stand on the brink or on the edge of a hole, and should fall into the hole, before or when the striker has delivered his ball from the mace or cue, so as to have no chance for his stroke, in that case the striker and his adversary's ball must be placed in the same position, as nearly as possible, and the striker must play again. 16. The striker is obliged to pass his adversary's ball, more especially if he misfires the ball on purpose; and it is at the option of his adversary to oblige him to place the ball where it stood, and play until he has passed. 17. If the striker plays both balls from his mace or cue, so that they touch at the same time, it is deemed a foul stroke; or if the adversary discover it, and a dispute should arise, an appeal may be made to the company present; and the marker, if required, must go round the table to each person separately, and ask if he has any bet depending, and if he understands the game and the disputed subject; and if the company and marker determine it to be a foul stroke, it is at the adversary's option (if not holed) either to play at the ball, or to take the lead; but if the adversary doth not discover it to be a foul stroke, the striker may reckon all the points he made by the false stroke, and the marker is obliged to mark them: and no person has a right to discover to the player whether a stroke be fair or foul. 18. If by a foul stroke the striker should hole his adversary's ball, he loses the lead; but by such a stroke he holesthis own or both balls, or forces his own or both over the table, or on a cushion, he loses two points. 19. If the striker plays on a ball when it is running or moving, it is deemed a foul stroke; and if he plays with both feet off the ground, without leave of his adversary, it is a foul stroke: if he plays with a wrong ball, he loses the lead, if his adversary require it. 20. If the ball should be changed in a hazard, or on a game, and it is not known by which party, the hazard must be played by each party with their different balls and then changed. 21. If the striker plays within his adversary's ball, and hole, or forces the ball at which he played over the table, &c. it is deemed a foul stroke. 22. If the striker plays with his adversary's ball and holes, or forces the ball with which he played over the table, &c. he loses two points; and if he misfires the ball, three points. 23. If the striker plays with his adversary's ball and misfires it, he loses one point; and if his adversary disavows that he hath played with the wrong ball, he may part the balls, and take the lead if he pleases. 24. In all these cases of the striker's playing with the wrong ball (if discovered), his adversary must play with the ball, at which the striker played throughout the hazard, or part of the balls and take the lead. 25. Whoever stops a ball when running with hand, stick, or otherwise, loses the lead, if his adversary does not like the ball he has to play at the next stroke. 26. Whoever retains his adversary's stick when playing, it is deemed foul. 27. If the striker drops or puts his ball out of its course, when running towards either of the holes, and, if adjudged by the marker and company to be going into a pocket, if he misfires the ball he loses one point, and if going into a hole by the same stroke, three points. 28. If the striker drops or puts his adversary's ball out of the course, when running towards or into a hole, or puts it into a hole, it is deemed a foul stroke. If the adversary does the same, in the foregoing cases, he is subject to the same penalties as the striker. 29. He who plays the ball when the ball is running, or throws his stick across the table, so as to occasion any的意见 to his adversary, or hinders the ball when running, makes in either case a foul stroke; and if his own ball was running towards or near the hole, when he blows on it, he loses two points. 30. If the striker leaves the game before it is finished, and will not sit out, he loses the game. 31. Any person, whilst playing, may change his mace or cue; and neither party has a right to object to either mace or cue being played within the said game; but when the parties agree to play mace against cue, ...
eue, the mace-player hath no right to use a cue, and vice
veris, without leave of the adversary. 32. When a person
agrees to play with the cue, he must play every ball within
his reach with its point, and if he agrees to play with the
but of the cue, he must not use the point, without permission;
when the parties agree to play point and point of the cue, nei-
ther has a right to use a butt during the match, without per-
mission; but they have a right to play with a long cue over a
mace, &c. and when they agree to play all points with the
same cue, they have no right to use any other during the
game. 33. If it be proposed to part the balls, the proposer,
if the adversary agree to it, loses the lead. 34. Two mihes
may not make a hazard, unless the contrary is previously
settled. 35. The better is to abide by the player who made
the determination of the hazard, or on the game; and they have
a right to demand their money, when their game is over,
to prevent disputes. 36. The striker has a right to com-
mand his adversary not to stand facing him, or near him, so
as to annoy or molest him in the stroke. 37. Each person
is to attend to his own game, without asking questions. 38.
No person in the room has a right to lay more than the odds
on a hazard or game; and in questionable cases appeal should
be made to the marker, or to the table of odds hung up in
the room. 39. When four persons play, the game is fif-
teen in number; and each party has a right to consult
with and direct his partner in any matter respecting the
game, &c.

The "white losing-game" is the common winning-game,
and twelve is the number. This depends entirely upon the
defence, and the knowledge of the degree of strength with
which each stroke should be played, either to defend or
make a hazard; for if a person who has a competent know-
ledge of the game should not have a hazard to play at, he
must endeavour to lay his own ball in such a position, that his
adversary may not have one to play at the next stroke. In this
game, if the striker misses the ball, he loses one, and if by the
fame stroke his ball goes into a hole, he loses three points; if
he strikes his adversary's ball he loses two points; if either or
both balls be forced over the table, or on a cushion, nothing
is reckoned, and the striker loses the lead, but if he misses his
adversary's ball, and forces his own over the table, &c. he loses
one point and the lead; if either of the parties forces either
or both balls over the tables, he reckons nothing; and the
striker loses the lead; if the striker holes his own ball, he
wins two points; if he holes both balls, he wins four points;
if he holes either ball, and forces the other over the table;
&c. he only loses the lead. The "winning and losing game"
is a combination of both games; in which all balls that are
put in by striking first the adversary's ball, reckon towards
game; and holing both balls reckon four. At this game and
the losing, knocking over, or forcing the balls over the cushion,
goins for nothing; the striker only losing the lead. The "choice of balls" is choosing each time which ball the
player pleases, which is without doubt a great advantage,
and is generally played against losing and winning.

"Bricole," is being obliged to hit a cushion, and make
the ball rebound or return to hit the adversary's ball, other-
wise the player loses a point. This is a great disadvantage,
and is reckoned between even players to be equal to receiving
about eight or nine points.

"Carambole," is a game newly introduced from France.
It is played with three balls, one being red, which is neutral,
and is placed upon a spot on a line with the striking nail,
(i.e. that part of the table from whence the player strikes
his ball at first setting off, and which is generally marked
with two brass nails). Each antagonist, at the first stroke of
a hazard, plays from a mark which is upon a line with it at
the other end of the table. The chief object at this game
is, for the player to hit with his own ball the other two balls:
which is called a carambole, and by which the player
wins two. If he puts in the red ball he gets three, and
when he holes his adversary's ball he gets two; so that seven
may be made at one stroke, by caramboiling and putting
in both balls. This game resembles the losing, depending
chiefly upon particular strengths, and is generally played
with the cue. The game is fifteen up; nevertheless it is
reckoned to be more than the common game. The
next object of this game, after making what we have distin-
guished by the carambole, is the back shot, that is, making the
white ball, and bringing the player's own ball and the red
one below the striking nail, from whence the adversaries be-
gins. By this means the opponent is obliged to play bricole
from the opposite cushion; and it often happens that the
game is determined by this situation.

"The Russian carambole," is a game that has fill more
lately been introduced from abroad, and is played in the fol-
lowing manner: The red ball is placed as usual on the spot
made for that purpose; but the player, when he begins, or
after having been holed, never places his ball on any particu-
lar place or spot; or being at liberty to put it where he
pleases. When he begins to play, instead of striking at the
red ball, he leads his own gently behind it, and his antago-
nist is to play at which he thinks proper; if he plays at the
red ball and holes it, he scores three as usual towards the
game, which is twenty-four instead of sixteen points; and
the red ball is put upon the spot again, at which he may
strike again, or take his choice which of the two balls to
use at, always following his stroke till both balls are off the
table. He is entitled to two points each time that he car-
amboles, the same as at the other game; but if he caram-
boles and puts his own ball into any hole, he loses as many
as he might have got had he not holed himself; for example,
if he strikes at the red ball, which he holes, and at the same
time caramboles and holes himself, he loses five points; and
if he holes both balls when he caramboles, and likewise his
own, he loses seven, which he would have got if he had not
holed his own ball. In other respects it is played like the
common carambole game.

"The Bar-hole," is so called from the hole being harred
which the ball should be played for, and the player striking
for another hole; when this game is played against the com-
mon game, the advantage for the latter, between equal
players, is reckoned to be about six.

The player at the one-hole, though it seems to those who
are not judges of the game to be a great disadvantage, has
in fact the best of it; for as all balls that go into the one
hole reckon, the player endeavours to lay his ball constantly
before that hole, and his antagonist frequently finds it very
difficult to keep one or other ball out, particularly on the
leads, when the one player lays his ball (which he does as
often as he can) on the brink of the hole; leading for that
purpose from the opposite end, which in reality he has no
right to do; for the lead should be given from the end of
the table at which the hazard is made; but when a person
happens to be a novice, this advantage is often taken.

"The four game," consists of two partners on each side,
as the common winning game; when play by succession after
each hazard, or two points lost. The game is fifteen up,
so that the point or hazard is an odd number, which makes
a miss at this game of more consequence than it is at another;
being as much at four, five, six, or eight, as it is at five, seven,
or nine, at the single game.

"Hazards," are so called because they depend entirely
upon the making of hazards, there being no account kept
of,
of any game. Any number of persons may play by having bells that are numbered; but the number seldom exceeds six, to avoid confusion. The person whose bell is put in, pays so much to the player according to what is agreed to be played for each hazard; and the person who misses, pays half the price of a hazard to him whose bell he played at. The only general rule is, not to lay any bell a hazard for the next player, which may be in a great measure avoided, by always playing upon the next player, and either bringing him close to the cushion, or putting him at a distance from the rest of the Lars. The table, when hazards are played, is always paid for by the hour.

BILLIAT, in Geography, a town of France, in the department of the Ain, and chief place of a canton, in the district of Nantua, 23 leagues E. of Nantua.

BILLICHA, in Ancient Geography, a river of Asia in Mesopotamia, which rises in the mountains of Osrhen, south of Edessa, and pursuing a south-easterly course, discharges itself into the Euphrates, at the town of Nice-phuron.

BILLIGHEIM, in Geography, a town of Germany, in the palatinate of the Rhine, 4 miles S. of Landau, and 16 S. W. of Spire.

BILLIGRATZ, a town of Germany, in the duchy of Camiola, 4 leagues N. of Landau.

BILLINGEN, a town of the Netherlands, in the duchy of Luxemburg, 20 miles E. of Spa.

BILLINGSGATE, a fish-market of London, kept every day, and the toll of which is appointed by statute. All persons buying fish in this market may fell the same in any other market by retail; but none but fishmongers are allowed to fell it in huge; and if any person shall buy any quantity of fish at Billingsgate for others, or any fishmonger shall engross in the market, they incur a penalty of 20l. Tins imported by foreigners shall be forfeited, and the veil &c. 10 & 11 Will. III. c. 24. 1 Geo. I. Stat. 2. c. 18. § 1. &c.

BILLINGSPORT, a place on the river Delaware, in America, situate 12 miles below Philadelphia, which was fortified in the late war, for the defence of the channel, and opposite to which were sunk frames of timber, headed with iron spikes, called chevaux-de-frise, in order to prevent the British ships from passing. After the war they were rifled by a curious machine, invented at Philadelphia for this purpose.

BILLIS, in Ancient Geography, a small river of Asia Minor, on the confines of Parthia, on the borders of which was seated the town of Tarsus, mentioned by Scalibut.

BILLITON, in Geography, one of the Zunda islands in the Indian ocean, N. E. of the lower part of Sumatra, and E. of Banca. (See Straits of Banca.) S. lat. between 2° 30' and 3° 30'. E. long. between 107° 45' and 108° 26'.

BILLOM, a town of France, and principal place of a canton, in the district of Clermont, and department of Pay-de-Dome, 4 leagues E. N. E. from Clermont. The town contains 5,110 inhabitants, and the canton 13,711. The territorial extent comprehends 115 kilometres, and 10 communes. N. lat. 45° 53'; E. long. 3° 14'.

BILLON. Billon, in Coinage, a kind of base metal, either of gold or silver, in whose mixture copper predominates.

The word is French, formed, according to Meigen, from the Latin bulla, or bulla, bullion. According to M. B. utter, bullion of gold is any gold beneath standard, or twenty-one carats; and bullion of silver, all below ten penny-weights. But, according to others, and among the rest, M. Berard, gold and silver beneath the standard, as far as twelve carats, and six penny-weights, are properly base gold and silver, and all under those billion of gold, and billion of silver, because copper is the prevailing metal. The writers on numismatic science appropriate the term billion to signify metals of copper alloyed with a very small quantity of silver.

BILLES, in Geography, a rock in the Atlantic, near the west coast of Ireland, 6 miles N. W. from the island of Clare, and 6 S. E. from Achill-head.

BILLY, JAMES de, in Biography, was born in 1535, at Gwy in Picardy, and devoting himself to study, he entered the church, in which he possessed some benefices. After suffering considerably in the civil wars, he retired to Paris, and died in the house of his friend Gilbert Gearnbruch, in 1581. His works, both in prose and verse, were numerous; but the most valuable and his Latin translations of the Greek fathers are: "S. Gregorii Nazianzeni opera omnia," fol. 1569 and 1583; "Interpretatio latina in priorum libri S. Irenee. adv. Haeret. capitum," fol. 1577; "S. Joh. Damascenii opera," fol. 1577; "Sidorli Pelabonii Epistolae, Gr. & Lat. (3 scril books)," fol. 1577." and translations of some pieces of St. Chrysostom, inserted in the Paris editions of his works, in 1581, &c. Morei.

BILLY, in Geography, a town of France, in the department of the Allier; 13 leagues N. E. of Gannat.

BILMA, a defter country in the north of Africa, being a part of the Great Desert, or Sahara, and a prolongation of the Libyan desert to the S. W. bounded on the N. by the Tibesti mountains, and the desert of Berdaou, on the E. by Kawar or Kuur, on the S. by Boroum, and on the W. by Zegzag, Agades, Aoulou, Ganat, &c. N. lat. about 23 to 25. W. long. about 20°. The salt lake of Dumaroo, the Chelondes Pulus of Potonomy, is said to be situated in the desert of Bilma.

BILLOBUS, in Entomology, a species of Scarabeus, with two prominent lobes on the thorax; a simple horn on the head, and wing-cases frilled. Inhabits the south of Europe. Fabricius.

Bilobus, a species of Dysiscus, of an oblong-ovate form and black; mouth, vertical two-lobed spot, thorax, futural line, base, and margin of the wing-cases yellow. Linn. Mon. Lep.

BILLOBUS, a species of Cicindela (Sphingus), with an obtusadiated thorax; wing-cases greyish or reddish; vent with two lobes. Linn. Mon. Lep. A native of Europe.

Bilobus, or Oribatella, a species of Scarabaeus, called the Warted Plosopher, by Lathan. It is an inhabitant of the coast of the Malabar. The bill and legs are yellow; frontal skin naked, and procumbent in two pointed lobes; body above yellowish green; beneath white. Griselin, &c. The crown, band on the tail, and quill-feathers are black; broad across the eyes, greater wing-coverers, and some of the tail-feathers at the end white. This is Physicus a Lomberg of Buff. Hist. Ort. and Plutarco de la clef de Malabar, p. 124. of the same author. Length nine inches and a half.

BILLOCULAR, in Botany, a term applied to a cappula, having two cells.

BILLYAR, in Geography, a town of Russia, in the government of Simbirsk, on the left side of the Volga, 10 miles S. E. of Simbirsk.

BILGISUS, or BILLYHUS, Louis de, of Rotterdam, in Holland, in Biography, acquired much fame for a town, about the middle of the 17th century, for a supposed new method of preserving bodies from putrefaction, and of digesting them without occasioning an effusion of blood. By his method of preparing the bodies, they were said to preserve their flexibility as well as freedom from putridity for ages; so that the
they might be distracted during the summer, and remain
under the demagoguer’s hands for weeks, months, or
years, if necessary, without emitting any offensive
fume. De Bilis had the art of gaining such credit to his
professions, that he is said, by Heller, to have sold his
secret to the university of Louvain for 22,000 ducats.
He demanded a much larger sum, and certainly he had
his preparations answered the high ene who believed on them by their favours, the secrect
would have deferred it. Prior to the sale he had sent one
of his bodies to the theatre at Leyden, at which Denungius,
one of his warmest admirers says, “De fided fuperat omnem,
exceptum humanis cadaver, recente mortuorum disces, tanto
theatro digantmillinopos.” De admirandum famam, nobilis
nimi viri L. D. Bilis, p. 362. But not contented with the
fame and money acquired by his secret, for he sold his pre-
bared bodies at high prices, he pretended to have made dis-
covers in the structure of the liver, and in the lymphatics,
by which he exposed himself to deserved contempt, it ap-
ppeared that he was totally ignorant of the art of anatomy,
in which he affected to be a master. He is said to have died
phthisical from the effects of the putrid air inhaled while
preparing his bodies, and in a few years his preparations,
which were to have lasted for ages, were totally destroyed.
His productions, which were numerous, and excited
much interest at the time, were collected and published
in 1692, in 4to, under the title of, “De Bilis inventa
anatomica antiquo-nova cum clarissimis virorum epito-
is, et testimoniis, ab Ioannis ab Horrorn, et Pauli Barhette, reftan-turant, interprete Geocome Bueno.
Amit.

BILSAH, in Geography, a city of Hindostan, and capi-
tal of a circle in the Malwa country; 416 miles S. W. of
Penares, 867 N. W. of Calcutta, by Guru Mundhah, 560
N. W. of Hydrabad, 357 S. W. of Lucknow, 249 N. W.
of Nagpur, 110 nearly E. of Ougine, and 496 N. E. of
Poonah. Bilsah, which is almost in the heart of India,
affords tobacco of the most fragrant and delicious kind
throughout that whole region, and which is distributed ac-
cordingly. N. lat. 23° 30’. Long. 77° 53’.

BILSEN, a town of Germany, in the circle of Wëf-
phalia, and bishopric of Liege, chief place of a canton in
the district of Maerfich, and department of the Lower Meuf,
feated on the Deemer, possessing the privileges of a city, but
of no great consideration. 14 miles N. of Liege. The town
contains 1925 persons, and the population of the canton in-
cludes 9388. The territory comprehends 170 kilometres,
and 16 communes.

BILSKOJ, a town of Siberia, on the Bilain, 90 miles
N. W. of Irkutik.

BILSON, Thomas, in Biography, a learned prelate of
the English church, was born at Winchester, and educated
at Wykeham’s school near his native city. In 1565, he
was admitted fellow of New College, Oxford, after having served	
two years of probation. He took in due course his severa-
la degrees of bachelor and master of arts, and also of bachelor
and doctor of divinity; the half of which was conferred on
him in 1580. In his earlier years he was fond of poetry,
philosophy, and physic; but after having entered into orders
he confined himself wholly to divinity, and became an excel-
lent preacher. His first preference was the masterhip of
Winchester school; and he afterwards became prebendary of
Winchester, and at length warden of the college, in which office
he was instrumental in preserving the revenues of it,
when they were likely to have been lost by forgery. In 1583,
he published a treatise entitled “The true Difference be-
tween Christian Submission and unchristian Rebellion,” dedi-
cated to queen Elizabeth, and composed for the purpose
of confuting those catholic writers who attacked her right
to the throne, and to the allegiance of her subjects. In this
treatise paffages occur that are favourable to refrinace in
certain cafes, and which have not escaped the censure of later
advocates of passive obedience. This was succeeded, in 1593,
by his “Perpetual Government of Christ’s church, &c.” de-
signed to shew, that from the Mosaic institution to the modern
ages of Christiarty, the church has been governed by
pastors and teachers of different ranks, superior and subor-
dinate, and esteemed one of the beast books in favour of epis-
copy. In consequence of this publication he was promoted
to the see of Worcester in 1596, from which he was tran-
fledged in 1597 to that of Winchester, where he was also ap-
pointed a privy councillor. About this time he delivered a
course of sermons at Paul’s crofs, against some of the tenets
of the Puritans, on the subject of redemption, and the de-
cent of Christ into hell, which occasioned a controversy with
the leaders of that sect. In the course of this controversy
the bishop maintained the actual descent of Christ into hell,
or the place of the damned, an opinion which was then deemed
orthodox, but which has since been rejected by the best ex-
positors of the 39 articles, and by every rational divine.
This prelate took a lead in the Hampton-court conference,
where he was distinguished by his learning; and in general
he was one of the most able advocates in favour of the church
of England. To him, in conjunction with Dr. Smith, after-
wards bishop of Gloucester, was committed the care of revi-
ving and finishing the new version of the Scriptures, called
king James’s Bible. He was also one of the delegates who
pronounced the sentence of divorce between the earl of
Effex and his countess. This learned bishop, whose life was a
course of incessant labour for the public good, and whose pri-
ivate character uniformly corresponded with his high flation,
died in 1616, and was buried in Welminter Abbey. Biog.
Frat.

BILSTEIN, in Geography, a town of Germany, in the
circle of the Lower Rhine, and capital of a bailiwick, in
the duchy of Westphalia, seated on a mountain; 42 miles E.
of Cologn.

BILSTON, a large village, or chapelry, of Staffordshire,
England, is remarkable for the number of its houses and
inhabitants, without having the advantage of a chartered
market or fair. From its proximity to Birmingham and
Wolverhampton, and having the advantage of a navigable
canal near it, Bilston abounds with manufactures, among
which those for japanned and enamelled goods are the
principal. Furnaces for melting iron ore, forges and flitting
mills, mostly worked by steam engines, also abound here.
In the vicinity of the town are several coal mines, which pro-
duce great quantities of that fossil. An orange coloured
sand is also abundant, and is in much request by the artizans,
as a sand to cast metals in. Here is a quarry of remark-
able bones, lying horizontally in twelve strata, each pro-
gressively increasing in thickness from the top downwards.
The bone is mostly appropriated to the making of ciffers,
troughs, &c. Bilston is in the parish of Wolverhampton,
but is a distinct township for all parochial proceedings. There
is a chapel of modern erection; also two meeting-houses,
and a free-school. This chapelry is within the exempt jurid-
diction of the dean of Wolverhampton, and is a perpetual
curacy. Bilston is 127 miles N. W. from London; it con-
tains 1305 houses, and 6914 inhabitants. Shaw’s History
of Staffordshire.

BILTON, or BILSTON, a small manufacturing town of
Suffolk, England. The making of blue cloths, blankets,
and yarn, give employ to most of the inhabitants. Here
was formerly a consideruble market on Wednedays, but it
is nearly defecated, and the whole tins is much reduced. 
were two annual fairs. The parish contains 121 houses, and 744 inhabitants.

BILL, in Natural History, a name given by many of the Arabian writers to a genus, which though they often mention, yet they have no where given us a description of. Some have imagined it to be the *oppa* and others the *kibry*; but it appears more probable to have been a species of crystal; probably the pebble-crystal of the East Indies, which is considerably finer than the common flint-crystal; and is often sold under the name of the white sapphire, though considerably inferior, both in lustre and hardness, to the true white sapphire.

BIMA, in Geography, a river of Hindoostan, so called by Mr. Pennant. See Benmah.

BIMACULARIS, in Entomology, a species of Phalena (Pylarita, Gmel.), found in Europe. The anterior wings are glaucous brown, with two brown spots. Linn.

BIMACULATA, in Conchology, a species of Tellina, found in the European and American seas. This shell is of a somewhat rounded triangular shape, rather broad, smooth, white, with two triangular spaces within. It is a small shell, being usually half an inch in length, and sometimes, though rarely, of a yellowish colour. Linnæus, Donovan Brit. Shells, &c. On the English coast this is a scarce species.

BIMACULATA, in Entomology, a species of Silpha, found in Barbary. It is ovate and black; head of the antennae, globule; legs ferruginous. Gmelin. The margin of the thorax is rather ferruginous, and the middle of each wing is marked with a red spot.

BIMACULATA, a species of Chrysomela, of an oblong shape, and black; wing-cases tesselate, with a black spot on each. Inhabits America. Fabricius.

BIMACULATA, a species of Leptura, of a rufous colour, with cylindrical thorax; wing-cases dotted, with a spot and undulated break of white on each. Schaller, &c.

BIMACULATA, a North American species of Cantha- ris, with a ferruginous thorax; having a black spot, wing-cases tesselate, with a black spot at the tip. Fabricius.

BIMACULATA, a species of Neoclista, of a large size, that is found in Hungary. It is ferruginous, with the breast black; wing-cases tesselate, with a black spot on each. Fabricius. Mant. Inf.

BIMACULATA, a species of Durostis, that inhabits India. The wings are very entire, fringed, with a red spot; body brown, green. Linn. Fabr. &c.

BIMACULATA, a species of Sphinx (Zygna), of the middle size, that inhabits America. The wings are above and beneath black, with two yellow spots on the anterior wings. Gmel. Fabr. &c.

BIMACULATA, a species of Phryganea, described by Degener. The wings are brown, with a double yellow lateral spot. Linn. &c.

BIMACULATA, a species of Tipula, found in Europe. The wings are hyaline, with two brown spots; abdomen spotted, with ferruginous in the middle; antennae feathered. Linn. Fr. Suec. Off. This specific character is liable to some exception, for it is only the female which has the abdomen spotted with ferruginous; that of the male is immaculate.

BIMACULATA, a species of Musca, found in New Holland, and described by Swederus, Nov. Act. Stockh. The colour is light blue, with a whitish spot on each side of the breast: abdomen green, and blue at the base.

BIMACULATA, a species of Scolia, described by Fabricius. It is black, hairy, with two pale yellow spots, posterior yellow. A variety of this insect with fulvous instead of yellow spots, is mentioned by Pelag. Inf. Calibr. The former inhabits North America.

BIMACULATA, a species of Aranea, of a small size, that is found in Europe. The abdomen is subretund, cheetish, with two white spots. Gmelin. Abdomen rather depressed.

BIMACULATA, a species of Tentredo, of a pale colour, with the eyes, base of the abdomen above, and two spots on the breast, black. Linnæus Musc. Lich.

BIMACULATA, in Zoology, a species of Lacerta, described by Sparrmann, Nat. Aed. Stockh. The tail is carinated, toothed, and twice the length of the body: all the toes lobed. Inhabits the woods of St. Enlace and Pennsylvania, living under ground, or in the hollows of trees, and depositing its eggs in the earth. The body is blue, tinged with green, and thinly spotted with black, but having two larger than the rest on the shoulders, from whence it is specifically named bimaculata; on each foot are five toes.

BIMACULATUM, in Entomology, a species of Pha- langium, with the abdomen black, and two white spots. A native of England and Norway. Gmelin.

BIMACULATUS, a species of Scarabæus, with three flight tubercles on the head; wings-cases frilled, with two red spots at the base. Inhabits Germany. Fabricius.

BIMACULATUS, a species of Hister, of a black colour, with the posterior end of the wings-cases red. Linn. Fr. Suec. Found in the dung of oxen. This is Hister jennerius of Scopoli; and Atelous toto niger; cf. latres loris nonnulli friciatis; in celerarii noth de Geoffrey.

BIMACULATUS, a species of Curculio, of a brown colour: wings-cases dotted with cinereous; front and legs black. Inhabits Saxony; and resembles Curculio colus, but is rather smaller.

BIMACULATUS, a species of Cryptoccephalus, of a dusky black, with fulvous thorax, and tesselate wing-cases, with two spots of black. Fabricius. Off. This is Chrysomela melanocephala of Schaller, &c. A native of Italy and Saxony.

BIMACULATUS, a species of Carabus, of a black colour, with a common interrupted band; antennae and feet teeta- ceus. Mant. p. 532. Gmel. Inhabits India. The thorax of this insect is yellow, or black, and sometimes spotted in different specimens.

BIMACULATUS, a species of Dytsicus, of a tesselate colour, with a blackish spot on the wing-cases. Inhabitants France. Size of a grain of rice. Gouan. Gmelin, &c.

BIMACULATUS, a species of Gryllus (Bulla acridum) found in Europe, and described by Herbst. The thorax is brown, with an ochraceous hamule on each face.

BIMACULATUS, a species of Ichneumon. Colour black; front, legs, antennae beneath, anterior part of the thorax, two spots on the wings, and posterior margin of the abdominal segments, except the second, yellow. Linn. Mus. Low. Breeds in the larva of phalana umbria. Scutell raised behind. Inhabits Europe.

BIMACULATUS, is also a species of Ichneumon, that inhabits Austria, and is described by Schrank. It is black, with a yellowish feutel; two last segments of the abdomen with a single gypseous spot on each above.

BIMACULATUS, in Ichthyology, a species of Salmo, the body of which is compressed, and marked with two spots; anal fin with thirty-two rays. Gmelin. This is a native of South America. Seba calls it Tigrus ornamentatus; and Arndt Cerozgonides Ambisniffs.

BIMACULATUS, a species of Labrus, found in the Mediterraean
The dorsal fin is filamentous, body marked with a brown spot in the middle, and another near the tail. Cnid. &c.

**BINACULOSA**, in Entomology, a species of Cocciella, with fulvous wing-cases, having two obsolete white, spiral patches. Herb. Lind. &c.

**BINACULOSA**, a species of Phalana, that inhabits Germany. Colour whitish grey; anterior wings rather clouded; posterior ones with two black spots. Fabricius, &c.

**BIMATRA**, in Ancient Geography, a town of Achaia in Messenia. Prolemi.

**BIMELE** ou finière Linné, in Ornithology, a name given by Buffon to a species of motacilla, likewise called by Linnaeus the palum seneburi, and motacilla palmarum by Gmelin.

**BIMEDIAL**, in Mathematics. When two medial lines, as AB and BC, commensurable only in power, and containing a rational rectangle, are compounded; the A | | B C whole AC shall be irrational, with respect to either of the two, and is called a first bimedial line. But if two medial lines, commensurable only in power, and containing a medial rectangle, be compounded, the whole will be irrational, and is called a second bimedial line. Eucl. lib. x. prop. 28 and 39.

**BINIMI**, in Geography, one of the Bahama islands on the west side of the great Bahama bank, near the gulf of Florida. Its compass is about twenty miles, and it has a good harbour. N. lat. 25°. W. long. 76° 54'.

**BIMPLEPAKAM, or BIMIPATAN**, a sea-port town of Hindooom, on the western side of the bay of Bengal, in the island of Ciecoro, 35 miles S.S.W. of Ciecoro. N. lat. 18° 10'. E. long. 83° 15'.

**BIMOCRATUS**, in Entomology, a species of Scara- na, that inhabits Amborea. It is tesselaceous; flanks of the anterior legs large, and bearded; and it is an inhabitant of both the West and East Indies. BINA, in Geography, a town of Italy, in the Cremonese, 10 miles N.E. from Cremona.

**BINACLE**, in Sea-Language. See Bittacle.

**BINAGARA**, in Ancient Geography, a town of India, on this side the Danube. Prolemi.

**BINARD ISLAND, in Geography**, a long and narrow island on the north coast of France, to the east of Roteneuf point, having entrances at both the east and west ends, and within it a found or bay. It lies to the east of St. Malo, towards Cancale.

**BINAROS, or Vinaros, a town of Spain**, in Valencia, on the confines of Catalonia, near the coast of the Mediterranean, at the mouth of a river, which forms a small harbour, with anchorage at about a cannon-shot from the town, in 6 to 9 fathoms. It is surrounded with walls, and defended by four canons; 5 miles north of Pennecola, and 20 south of Tortosa.

**BINARY NUMBER**, which is composed of two units.

**Binary Arithmetic**, a method of computation first proposed by M. Leibnitz; whereof, in lieu of the ten figures in the common arithmetic, and the progression from 10 to 10, he has only two figures, and uses the simple progression from two to two.

Jof. Pelican, of Prague, has more largely explained the principles and practice of the binary arithmetic, in a book entitled, "Arithmeticae perfectionis, qui tria numerum secut. 1712." All his characters used in this arithmetic are 0 and 1; and the cipher, here, multiplies every thing by 2, as it does in the common arithmetic by 10. Thus, 1 is one; 10, two; 11, three; 100, four; 101, five; 110, six; 111, seven; 1000, eight; 1001, nine; 1010, ten; &c. being founded on the same principles with the common arithmetic. Hence immediately appears the reason of the celebrated property of the duplicate geometrical proportion in whole numbers; viz. that one number of each degree being had, we may thence compose all the other whole numbers above the double of the highest degree. It being here, v. gr. as if one should lay 111 is the sum of 11, 2, and 1, which property may serve allies to weigh all kinds of matter with a little weight; and may be used in coins, to give several values with small pieces. This method of expressing numbers once established, all the operations will be easy; in multiplication particularly, there will be no need for a table, or getting anything by heart. The author, however, does not recommend this method for common use, because of the great number of figures required to express a number; adding, that if the common progression were from 12 to 12, or from 16 to 16, it would be still more expedient: but its use is in discovering the properties of numbers, in constructing tables, &c. What makes the binary arithmetic the more remarkable is, that it appears to have been the same with that used 4000 years ago among the Chinese, and left an enigma for Poli, the founder of their empire, as well as of their sciences. M. Logny has proposed a new system of logarithms, on the plan of the binary arithmetic; which he finds shorter, more easy, and natural than the common ones.

**Binary**, a time in Music, consisting of two crotchets, or two minims in a bar.

**BINASCO**, in Geography, a town of Italy, in the Milanese, 10 miles south of Milan.

**BINATED LEAF, in Botany. See Leaf.**

**BINCHE**, in Geography, a town of the Netherlands, in the county of Hainaut, situated in a fertile country on the river Haie; and, according to the French distribution, a place and canton in the district of Charleroi and department of Jemappe. The town contains 3798 perfons, and the population of the canton is estimated at 13,968. The extent of the territory comprehends 153 kilometres and 16 communes. Bimche was burnt by Henry II. of France in 1554, and soon after rebuilt. In 1578, it was taken by John duke of Austria, and retaken in the same year by the duke of Alençon. The Spaniards regained possession of it, and ceded it to France at the peace of Aix-la-Chapelle, but the peace of Nimeguen restored it, together with its jurisdiction, including 51 towns and villages, to Spain. It is distant 8 miles E. S. E. from Mons.

**BIND**, in Commerce, contains 10 strikes of eels, each strike including 25.

**BIND-Weed, in Botany. See Convolvulus.**

**BIND-Weed, black. See Tamus.**

**BIND-Weed, rough. See Stilax.**

**Bind-With. See Clematis.**

**BINDEN, in Geography**, a town of Swisserland in the Valais, near the river Binna. N. lat. 46° 13'. E. long. 7° 58'.

**BINDER-Ooze, the weakest kind of tan-oze. See Tanning.**

**BINDING JOISTS, in Architecture. See Joists.**

**Binding, in the Art of Defence**, a method of securing or crowning the adversary's sword, with a prefecture, accompanied with a spring from the wrist. See Beating. Unlefs a man, by some kind of crofs, secure, as it were, or render his adversary's sword incapable to find him during the time of his performing a lefion upon him, it is impossible for him to be certain, but that he may receive from his adversary, either a fortuitous contretemps, or an exchanged thrust,
BIN

thrust, before the recovery of his body, or going off after a
thrust.

The great objection made by some people, particularly
those time-catching, against the frequent use of binding, is,
that when a man, in performing it, cleaves too much to his
adversary's fault, he is liable to his adversary's slipping
of
him, and consequently of receiving either a plain thrust, or
one from a feint.

Binding is a term in Falconry, which implies tiring, or
when a hawk seizes.

Example.

BINETTA, in Geography, a town of Italy, in the king-
dom of Naples, and country of Bari, 4 miles W.S.W. of
Bidetto.

BINGAZI. See Bengazi.

BINGE, a town of France, in the department of the
Cote d'Or, and chief place of a canton in the district of
Dijon, 10 miles east of Dijon.

BINGEN, a town of Germany, in the circle of the Lower
Rhine, and electorate of Mayence, and by the
French arrangement, the principal place of a canton in the
district of Mayence, and department of Mont-Tonnerre.
The town is said to contain 2663 inhabitants, and the canton
5638. It includes 10 communes. The town is noted for
the conflux of the Nahe and Rhine. The stone bridge over
the former is a noble structure, and the adjoining country is
delightful. Bingen is a very ancient town, and was once
imperial. The fortifications were destroyed by Lewis XIV.
in 1689. A great part of the corn, which is carried into
the Rhine-gan, the neighbouring palatinate, comes through
this place, which, on the other hand, supplies the palatinate
with drugs, and various foreign commodities. Besides this
traffic, it has in its vicinity very fruitful vineyards, which
produce excellent wine. Near this town the Rhine is com-
prefixed into a narrow channel, between two rocks; about a
mile and a half below it is a kind of whirlpool, called the
"Bingen-loch," the passage of which is dangerous. At a
small distance is also an island on the Rhine, denominated
"Maulbush," or tower of rats; from a tradition, that an
archbishop of Mentz was there devoured by these animals,
in the tenth century, as a judgment executed on him for his
cruelty to the poor, whom he compared to rats eating up the
abundance of the rich. Bingen is 19 miles W. of Mentz,
30 S. of Coblienz, and 54 E. of Treves. N. lat 49° 54'.
E. long 7° 33'.

BINGENHEIM, a town of Germany, in the circle of
the Upper Rhine, and principality of Hesse, 16 miles N.E.
from Frankfort on the Main.

BINGHAM, Joseph, in Biography, a learned English
divine, was born at Wakefield, in Yorkshire, in 1668. Having
acquired the rudiments of classical learning at a school
in his native town, he was admitted, in 1682, into University-
college at Oxford, and in 1687 became fellow. Having
taken.

BINNING Book. See Book-Binding.

BINNING-Notes, in Music, imply two or more sounds on
the same line or space, that are linked together by a semi-
circle; and which, though written or printed twice, are not
to be separated, but sustained like a single sound.
The first of these tied or binding-notes, as in preparing
discords, is usually struck on the unaccented part of a bar,
and continued on the accented part. See Ligature, and
Syncopation.

BINNING, in Geography, a town of Italy, in the king-
dom of Naples, and country of Bari, 4 miles W.S.W. of
Bidetto.

BINGAZI. See Bengazi.

BINGE, a town of France, in the department of the
Cote d'Or, and chief place of a canton in the district of
Dijon, 10 miles east of Dijon.

BINGEN, a town of Germany, in the circle of the Lower
Rhine, and electorate of Mayence, and by the
French arrangement, the principal place of a canton in the
district of Mayence, and department of Mont-Tonnerre.
The town is said to contain 2663 inhabitants, and the canton
5638. It includes 10 communes. The town is noted for
the conflux of the Nahe and Rhine. The stone bridge over
the former is a noble structure, and the adjoining country is
delightful. Bingen is a very ancient town, and was once
imperial. The fortifications were destroyed by Lewis XIV.
in 1689. A great part of the corn, which is carried into
the Rhine-gan, the neighbouring palatinate, comes through
this place, which, on the other hand, supplies the palatinate
with drugs, and various foreign commodities. Besides this
traffic, it has in its vicinity very fruitful vineyards, which
produce excellent wine. Near this town the Rhine is com-
prefixed into a narrow channel, between two rocks; about a
mile and a half below it is a kind of whirlpool, called the
"Bingen-loch," the passage of which is dangerous. At a
small distance is also an island on the Rhine, denominated
"Maulbush," or tower of rats; from a tradition, that an
archbishop of Mentz was there devoured by these animals,
in the tenth century, as a judgment executed on him for his
cruelty to the poor, whom he compared to rats eating up the
abundance of the rich. Bingen is 19 miles W. of Mentz,
30 S. of Coblienz, and 54 E. of Treves. N. lat 49° 54'.
E. long 7° 33'.

BINGENHEIM, a town of Germany, in the circle of
the Upper Rhine, and principality of Hesse, 16 miles N.E.
from Frankfort on the Main.

BINGHAM, Joseph, in Biography, a learned English
divine, was born at Wakefield, in Yorkshire, in 1668. Having
acquired the rudiments of classical learning at a school
in his native town, he was admitted, in 1682, into University-
college at Oxford, and in 1687 became fellow. Having
taken.
taken his master's degree in 1699, he was soon after presented by Dr. Radcliffe, the celebrated physician, to the rectory of Headbourne-Worthy, near Winchester; a preferment which, though not exceeding in value £100 a year, afforded him access to the valuable library at Winchester, and enabled him to prosecute the arduous undertaking, to which, in this retirement, he devoted much of his time and labour. Accordingly, the first volume of his learned work, entitled "Origines Ecclesiasticae, or the Antiquities of the Christian Church," appeared in 1708. It was completed in ten volumes, 8vo, and contains a judicious and candid, as well as ample account of the Christian clergy and churches from the earliest times. Besides this work, which was the result of much reading and indefatigable application, he published, in 1706, "The French Church's Appeal for the Church of England; or the objections of the Dissenters against the Articles, Homilies, Liturgy, and Canons of the English Church, considered and answered upon the principles of the Reformed Church of France," 8vo. His avowed design in this work was to reason Dissenters "into union upon such principles as are common to all the churches of the reformation." However laudable the design, uniformity of sentiment is not likely to be produced by any reasoning, as long as men are allowed to exercise the right of private judgment, and the only practicable union seems to be that which results from mutual forbearance and benevolence. Mr. Bingham likewise published "A Scholastic History of Lay-Baptism," in two parts, 1712, 8vo.; and "A Discourse concerning the Mercy of God to Penitent Sinners." All his works were collected and published in 2 vols. fol. Lond., 1725. Notwithstanding the acknowledged learning and meritorious services of Mr. Bingham, he had no other preferment besides that above-mentioned, till the year 1713, when he was collated to the rectory of Havant near Portsmouth. He died in 1723, and was buried in the church-yard of Headbourne-Worthy, without any monument, of which he declared his dislike in his last will.

Biog. Brit.

Bingham, in Geography, a town of Nottinghamshire, in England, stands nearly in the centre of the vale of Belvoir. It consists principally of two streets, running nearly parallel to each other, with some smaller streets branching from them. Near the centre of the town is a spacious market-place, where a weekly market is held every Thursday; it has also three annual fairs, and a large statute fair yearly for hiring of servants. Bingham is flated by Thoroton to be much reduced since the reformation, as, previously to that event, it contained three chapels, exclusive of the parish church. The latter was collegiate, and is still a large handsome structure, with a tower and spire, side aisles and chancel. It contains numerous monuments, among which is a plain one inscribed to the memory of Robert White, a native of this place, where he died, in 1773, at the advanced age of eighty. He was author of an annual publication, entitled "The Ecclesiastical Atlas, or New Ephemeris." The rectory of Bingham is esteemed one of the most valuable in the county of Nottingham, and is in the gift of lord Chetfield, who is lord of the manor. This town is 124 miles north from London. It contains 220 houses, and 1082 inhabitants.

At Allithorn, about two miles east from Bingham, archbishop Cranmer was born. About two miles north from Bingham is East-Bridgeford, where are the remains of an entrenchment, and some coins, urns, &c. have been found. Horley places the Roman station, Margidunum, "near East-Bridgeford," from its situation near the ford, and from the agreement of distances, between this and the other stations named in the Itinerary, Thoroton's History of Nottinghamshire.

BINGUM, in Ancient Geography, a town of Gaul, in Germania Prima, west of Moguntiacum; now Bingen, which see.

BINGLESTEIN, in Geography, a town of Germany, in the circle of Welfphalia, and bishopric of Paderborn, 3 miles south of Buren.

BINGO, a small country of Japan, in the island of Ni-pon, situate in N. lat. about 34° 30'. E. long. 134°.

BINGUM, a town of Germany, in the circle of Welfphalia, and county of Earl Friedland, one mile north-west of Oit.

BINGUT Cape and Bay, lie about E. by N. from Algiers, on the coast of Africa, in the Mediterranean. The town of Bingut is at the bottom of the bay of its name, about 12 or 13 leagues from Algiers.

BINIESZKY, a town of Lithuania, in the patriciate of Wilna, 44 miles S. E. of Wilna.

BINN, binna, a sort of chest or cupboard, wherein to lock up bread, meat, or other provisions.

The word is also used for a place boarded up to put corn in. The pulse and oatmeal, tied at top, are apt to spoil in casks. Dr. Hales propounds to prevent this by putting them into large bins, with false bottoms of haircloth laid on bars, whereby fresh air may be blown upwards through them, at proper times, with small ventilators.

BINNA, in Ancient Geography, a town of Assyria, according to Prolemy.

BINNINGER, John Nicholas, in Biography, born at Montbellow, in 1628, studied medicine at Padua, and then went to Bafle, where he was admitted to the degree of doctor in that art in 1652. Returning to his own country, he soon acquired so much fame for his skill in his profession, that he was appointed professor of medicine, and physician to the family of the duke, his sovereign. He left "Observationum et Curationum medicinalem, centuriae quinque," 8vo. 1673. Month, containing some curious and valuable observations. Haller, Bib. Med. Elov, Dict. Hill.

BINNIGUET, in Geography, a small island near the west coast of France, about a league south-west of Le Conquet, and ¾ west of St. Matthew's point. N. lat. 48° 29'. E. long. 1° 5'.

BINN-Na-BAIRD, and BINN-na-MUIKE-DUNDE, are the names of two lofty mountains, in the parish of Crathy, Aberdeenshire, in Scotland. These eminences are conically covered with snow, and extending in the same ridge with the Cairngorm mountain, contain the same species of topaz, which bears the name of Cairngorm flones. Emeralds have been sometimes discovered here; also a species of brown fissional stone, which bears a very fine polish.

BINOCLE, or Binocular Telescope, from binus, double, and oculus, eye, in Optics, that to which both the eyes may be applied, and consequently the same object be observed at the same time by both. It consists of two tubes, with two sets of glasses of the same power, and adjusted to the same axis; and some have pretended that it represents objects much larger and clearer than a single or monocular glass. But this is perhaps only an illusion, occasioned by the stronger impression, which two equal images alike illuminated make upon the eyes. This method of construction was invented by father Rheita, and brought into use by father Cherubin of Orleans. There are also microscopes of the same kind, but very seldom used.

BINODIS, in Entomology, a species of Formica, described by Fabricius as a native of Egypt. It is black; head
BINOMIAL.

Head large and rufous; with two tubercles on the petiole.

BINOMIAL, or BINOMIAL, from his, twice, and numer, name, in Algebra, a quantity consisting of two terms or members, connected by the sign $+$ or $-$ minus.

Thus $a + b$ and $a - b$ are binomials, consisting of the sum or difference of those quantities; though the latter is often called residual, and by Euclid, apotome.

The terms binomial and residual are said to have been first introduced by Robert Recorde. See ALGEBRA.

The powers of a binomial are found by a continual multiplication of it by itself, as often as an unit is contained in the index of the power required. Thrice of a binomial, $a - b$, are obtained in the same manner, only with this difference in the result, that the terms in which the exponent of $b$ is an odd number, will be negative.

If a root have three parts, as $a + b + c$, it is called a trinomial; if more, a multinomial.

BINOMIAL, impossible, or imaginary, in Algebra, is used for a binomial, one of the terms of which is an impossible or imaginary quantity; as $a + \sqrt{-1} b$ is an impossible binomial.

Dr. Markelyne, the astronomer royal, has given (in his Introduction to “Taylor’s Tables of Logarithms,” p. 56,) the following method of finding any power of an impossible binomial, by another similar binomial. The logarithms of $a$ and $b$ being given, it is required to find the power of the impossible binomial $a + \sqrt{-1} b$ whose index is $n$, that is to find $(a + \sqrt{-1} b)^n$ by another impossible binomial; and hence the value of $(a + \sqrt{-1} b)^n + (a - \sqrt{-1} b)^n$, which is always positive, whether $a$ or $b$ be the greater of the two.

Solution. Put $b - a = \tan z$.

Then

$$(a + \sqrt{-1} b)^n = (a + b)^n \times (\cos \frac{m}{n} z + i \sin \frac{m}{n} z).$$

Hence

$$(a + \sqrt{-1} b)^n + (a - \sqrt{-1} b)^n = (a^2 + b^2)^n \times 2 \cos \frac{m}{n} z,$$

or $2 \cos \frac{m}{n} z$, where the first or second of these two last expressions is to be used, according as $z$ is an extreme or mean arc; or rather, because $\frac{m}{n}$ is not only the tangent of $z$ but also of $z + 360^\circ$, $z + 720^\circ$, &c., therefore the factor in the answer will have several values, viz.

$$2 \cos \frac{m}{n} z; 2 \cos \frac{m}{n} (z + 360^\circ); 2 \cos \frac{m}{n} (z + 720^\circ);$$

&c.; the number of which, if $m$ and $n$ be whole numbers, and the fraction $\frac{m}{n}$ in its least terms, will be equal to the denominator $n$; otherwise infinite.

By Logarithms. Put $\log (a + b) = \log \tan z$.

Then

$$\log (a + \sqrt{-1} b)^n \times (\log (a + b) + n \log (\cos \frac{m}{n} z + i \sin \frac{m}{n} z).$$

and

$$\times (1 + \log (a + b) + n \log (\cos \frac{m}{n} z - \log \tan z) + 1 + \log \cos \frac{m}{n} z - 10 = \frac{m}{n} z + 10 \cos \frac{m}{n} z,$$

where the first or second expression is to be used, according as $z$ is an extreme or mean arc. Moreover, by taking successively, $1 \log \frac{m}{n} z$; $1 \log \frac{m}{n} (z + 360^\circ)$; $1 \log \frac{m}{n} (z + 720^\circ)$, &c., there will arise several distinct answers to the question, agreeably to the remark above.

BINOMIAL SURD, is used for a binomial, the terms of which are surds; as $a + \sqrt{b}$ or $a - \sqrt{b}$, if $m$ and $n$ be fractions. The term binomial surd is also applied to any quantity having a rational part and a surd part, as $25 + \sqrt{68}$. Euclid enumerates fix kinds of binomial surds or surds in the ioth book of his “Elements,” which are exactly similar to the six residuals or apotomes, of which he has also treated in the same place. See APOTOME.

Thee apotomes become binomials by merely changing the sign of the last term from minus to plus, and they are as follows: 1st. $\pm \sqrt{3} \pm 5$; 2d. $\sqrt{18} + 4$; 3d. $\sqrt{24} + \sqrt{18}$; 4th. $4 + \sqrt{3} 5$; 5th. $\sqrt{2} + 6$; 6th. $\sqrt{6} + 2$.

For the extraction of roots of binomial surds, see Newton’s Arithmetica Universalis; St. Graevrande’s Commentary, and Mac Laurin’s Algebra, p. 114–120. See SUND.

BINOMIAL CURVE, is used for a curve, the ordinate of which is expressed by a binomial. Thus, if the ordinate of a curve be of this form $z = \pm \sqrt{\frac{x}{y} + \frac{y}{x}}$, the curve is called a binomial curve. Stirlig Method. Diff. p. 58.

BINOMIAL Theorem, is a general algebraical expression, or formula, by which any power or root of a quantity, consisting of two terms, is expanded into a series.

It is also frequently called the Newtonian theorem, or Newton’s binomial theorem, on account of his being commonly considered as the inventor of it, as he undoubtedly was, at least in the case of fractional indices, which includes all the other particular cases of powers, divisors, &c.

This celebrated theorem, as proposed in its most general form, may be exhibited in a manner nearly similar to that of Newton, as follows:

$$a + x = a \times \left[1 + \frac{x}{a} \left(\frac{x}{a} - \frac{a}{x}\right) + \frac{x}{a} \left(\frac{x}{a} - \frac{a}{x}\right)^3 + \frac{x}{a} \left(\frac{x}{a} - \frac{a}{x}\right)^5 + \frac{x}{a} \left(\frac{x}{a} - \frac{a}{x}\right)^7 + \ldots \right].$$

Where $a, x$ are the two terms of the binomial, $\frac{m}{n}$ the index, and $A, B, C, D, &c.$ each preceding term, including their signs $+$ or $-$, the terms of the series being all positive when $x$ is positive, and alternately positive and negative when $x$ is negative, independently however of the effect of the coefficients made up of $m$ and $n$, which may be any numbers whatever, positive or negative.

A few easy cases, in the extraction of roots, will be sufficient to shew the application of the theorem in all similar cases. For this purpose, let it be required to find the square root of $a + b$, or $a + b\frac{1}{2}$, and the cube root of $a - b$, or $a - b\frac{1}{3}$; in the first of which $m = 1$ and in the second $m = \frac{1}{3}$.

Then

$$a + b\frac{1}{2} = a \left[1 + \frac{1}{2} \left(\frac{b}{a}\right) - \frac{1}{2^2} \left(\frac{b}{a}\right)^2 + \frac{3}{2^4} \left(\frac{b}{a}\right)^3 \right].$$

$$\left(\frac{b}{a}\right)^\frac{1}{3} = \frac{3}{2} \cdot \frac{3}{2^4} \cdot \frac{3}{2^4} \left(\frac{b}{a}\right)^\frac{1}{3},$$

&c.
And \( (a + b)^3 \) = \( a^3 + \frac{1}{3} \left( \frac{b}{a} \right) - \frac{1}{3^3} \left( \frac{b}{a} \right)^3 \) \( \frac{5}{3^3} \), &c.

And, in the same manner, if 1, divided by the cube root of the square of \( a + b \), be converted into a series, we shall have

\[
\frac{1}{a + b} = \frac{1}{a^3} \left[ 1 + \frac{2}{3} \left( \frac{b}{a} \right) + \frac{2^2 5}{3^3} \left( \frac{b}{a} \right)^3 \right] + \frac{2^5 7}{3^3} \left( \frac{b}{a} \right)^4, &c.
\]

But these series are only commodious in calculation, in proportion to their degree of convergency. For if \( N \) be made to represent the rank which any term holds in the series arising from the binomial \( a - b \) being refered to the nth power, then that term will be to the following one as \( \frac{m}{m-N+1} \), from which it is evident, that for the terms of the series to go on decreasing, \( b \times m - N + 1 \), taken positively, must be always less than \( aN \).

With respect to the history of this theorem, the prevailing opinion, till within these few years, has been, that it was not only invented by Newton, but first given by him in that state of perfection, in which the terms of the series, for any assigned power whatever, can be found, independently of the terms of the preceding powers; viz. the second term from the first, the third from the second, the fourth from the third, and so on, by a general rule. But it has since been found, that in the cafe of integral powers, the theorem had been described by Briggs, in his "Trigonometria Britannica," long before Newton was born; and that, by the general law of the terms, independently of those of the preceding powers. For, as far as regards the generation of the coefficients of the terms of one power from those of the former ones, succedively one after another, it was remarked by Vieta, Oughtred, and many others; and was not unknown to much more early writers on arithmetic and algebra, as will be manifest by a digest inspection of their works, as well as the gradual advance the property made both in extent and perfection, under the hands of the latter authors, most of whom added something more towards its perfection.

The knowledge, indeed, of this property of the coefficients of the terms of the integral powers of a binomial, is, at least, as old as the practice of the extraction of roots, of which it is both the foundation and principle. And as the writers on arithmetic became acquainted with the nature of the coefficients in the higher powers, they extended the extraction of roots accordingly, still making use of this property. At first, they appear to have been only acquainted with the nature of the square, the coefficients of which are the three terms, 1, 2, 1; and, by their means, extracted the square roots of numbers, but went no farther. The nature of the cube next presented itself, which consists of the coefficients, 1, 3, 3, 1; and, by means of these, they extracted the cube roots of numbers, in the same way as is practised at present. And this was the extent of their extractions, in the time of Lucas de Burgo, who, from 1470 to 1500, wrote several tracts on arithmetic, containing the substance of what was then known of this science.

It was not long, however, before the nature of the coefficients of all the higher powers became known, and tables formed for constructing them indefinitely. For, in the year 1543, Michael Stifelius, a German, published an excellent work on arithmetic and algebra, under the title of "Arithmetica Integra," in which he gives the following table, for constructing both figurate numbers and the coefficients of the terms of the various powers of a binomial, which, since his time, has been often used for these and other purposes; and more than a century after, was, by Pascal, otherwise called the arithmetical triangle, and of which he has commonly been called the inventor, though he only mentioned some of its additional properties.

\[
\begin{array}{c|cccccccc}
& 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\hline
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
2 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\
3 & 3 & 6 & 9 & 12 & 15 & 18 & 21 & 24 \\
4 & 4 & 8 & 12 & 16 & 20 & 24 & 28 & 32 \\
5 & 5 & 10 & 15 & 20 & 25 & 30 & 35 & 40 \\
6 & 6 & 12 & 18 & 24 & 30 & 36 & 42 & 48 \\
7 & 7 & 14 & 21 & 28 & 35 & 42 & 49 & 56 \\
8 & 8 & 16 & 24 & 32 & 40 & 48 & 56 & 64 \\
\end{array}
\]

In this table Stifelius observes, that the horizontal lines furnish the coefficients of the terms of the correspondent powers of a binomial; and teaches how to use them in extracting the roots of all powers whatever. The same table was also used, for a similar purpose, by Cardan, Stevin, and other writers on arithmetic; and it is highly probable that it was known much earlier than the time of Stifelius, at least as far as regards the proportions of figurate numbers, which had been amply treated of by Nicomachus, who lived, according to some, before Euclid, but not till long after him, according to others; and whose work on arithmetic was published at Paris in 1538, and is supposed to have been chiefly copied in the treatise on the same subject by Boethius.

The contemplation of this table has also, probably, been attended with the invention and extension of some of our most curious discoveries in mathematics, both with respect to the powers of a binomial, the consequent extraction of roots, the doctrine of angular sections by Vieta, and the differential method of Briggs, and others. For a few of the powers or sections being once known, the table would be of the greatest use in discovering and constructing the rest; and accordingly it appears to have been used, on many occasioned of this kind, by Stifelius, Cardan, Stevin, Vieta, Briggs, Oughtred, Mercator, Pascal, &c.

But although the nature and construction of this table were thus early known, and employed in raising powers and extracting roots, it was yet only by raising the numbers from one another, by continual additions, and taking them from the table for use when wanted; till Briggs first pointed out the way of raising any horizontal line in the table, by itself, without any of the preceding lines; and thus teaching to raise the term of any integral powers of a binomial independently of any other powers; which was, in fact, giving the substance of the binomial theorem in words, but wanting the notation in symbols.

It may, however, be fairly questioned, whether Briggs knew how, even in the case of an integral exponent, to exhibit the law of the formation of the coefficients, under the form \( \frac{1 \cdot 2 \cdot 3 \cdot \ldots \cdot n}{m^{m-1} (m-2) \ldots (m-n+1)} \); for, though his method of forming the successive coefficients amounts to nearly...
nearly the same thing, yet the advancement in analysis depended on the circumstance of the law which they observe, being expressed by means of a general symbol \((n)\); without which, its extension would never have been made to those cases in which the index is negative or fractional: so that Briggs, even in the case of integral powers, does not appear to be fully entitled to the invention of the binomial theorem, properly so called.

But however this may be, it is universally agreed that no one before Newton had ever thought of extracting roots by means of infinite series. He was the first who happily discovered, that, by considering roots as powers having fractional exponents, the same binomial series would equally serve for them all, whether the index should be fractional or integral, or the series finite or infinite; and from this extension of the theorem, some of the most important improvements, in the higher departments of mathematics, have arisen; particularly in the construction of logarithms, and the doctrine of series in general, which have since been carried to a great degree of perfection, and now form some of the most curious and interesting branches of analysis.

It may also be farther observed, with respect to the claim of Newton as an original inventor of this highly useful theorem, that he had probably never seen the Arithmetica Logarithmica of Briggs; for it is well known that he was not an extensive reader of mathematical works, depending more on the powers of his own genius than upon any helps of this kind: so that there can be but little doubt of his having made the discovery himself, without receiving any light from what had been done by Briggs; and that he conceived the theorem to be new for all powers in general, as it was for roots and quantities with fractional indices.

But though this appears to be the case with respect to Newton, it is yet surprising that Dr. Wallis, who was a general reader of most mathematical works, and who had actually seen Briggs's Arithmetica Logarithmica, as he mentions it in page 60, chap. xii. of his Algebra, should not have attended enough to this curious treatise, to know that it contained such a new and excellent theorem, as it fully appears he did not; since, in the 85th chapter of the above-mentioned work, he affirms the invention entirely to Newton; and adds, that he himself had thought after such a rule, but without success. It is also no less singular, that John Bernoulli, not half a century since, should first dispute the invention of this theorem with Newton, and afterwards give the discovery of it to Paseal, who was not born till long after it had been taught by Briggs. (See Bernouilli's works, vol. iv. p. 173.)

Dr. Wallis's Algebra was published in the year 1685; and it was here, for the first time after Newton's discovery of it, that the binomial theorem, according to his general manner of expressing it, appeared in print, and was made known to the learned world; though Leibnitz, and probably Dr. Barrow (who was Newton's great friend and patron in his youth), as well as some other mathematicians of that time, had seen it, in a letter addressed to Mr. Oldenburgh, of October 24th 1676, (which was given in the Commercium Epistolicum), long after the said letter was written. But he no where tells us his manner of investigating it; nor is any demonstration of it to be found, even in the case where the index is a whole number, in any part of his works. He says, indeed, in his next letter to Oldenburgh, to be found in the same work, that the occasion of its discovery was as follows:

"Not long (he observes) after I had ventured upon the study of the mathematics, whilst I was perusing the works of the celebrated Dr. Wallis, and considering the series of universal roots, by the interpolation of which we exhibit the area of the circle and hyperbola: for instance, in this series of curves, whole common base or axis is \(x\), and the respective ordinates \(1-x^2/3, 1-x^4/3, 1-x^6/3, 1-x^8/3, \ldots\), &c. I observed that if the areas of the alternate curves, which are \(x, x^2, x^3, \ldots\), could be interpolated, we should, by this means, obtain the areas of the intermediate ones, the first-of which is \(1-x^2/3\) is the area of the circle. In order to this it was evident, that in each of these series the first term was \(x\), and that the second terms \(\frac{2}{3}x^2, \frac{4}{3}x^3, \ldots\), were in arithmetical progression; and consequently the first three terms of the series to be interpolated must be \(x-\frac{1}{3}x^3, x-\frac{2}{3}x^3, x-\frac{3}{3}x^3\), &c.

"Now, for the interpolation of the rest, I considered that the denominators \(1, 3, 5, 7, \ldots\), were, in all of them, in arithmetical progression; and consequently the whole difficulty confined in discovering the numerical coefficients: but there, in the alternate areas which are given, I observed were the same with the figures of which the several ascending powers of the number \(1\) composed, viz. \(11, 11, 11, 11, 11, \ldots\), &c. that is, the first, \(1\); the second, \(1, 1\); the third, \(1, 2, 1\); the fourth, \(1, 3, 3, 1\); the fifth, \(1, 4, 6, 4, 1\), &c.

"I applied myself, therefore, to discover a method by which the first two figures of these series might be derived from the rest; and I found, that if for the second figure, or numeral term, I put \(m\), the rest of the terms would be produced by the continual multiplication of the terms of this series, 

\[
\frac{m}{1} \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} \times \frac{m-4}{5}, \ldots
\]

"For instance, if the second term be put for \(4\), there will arise \(4 \times \frac{m-1}{2} = 6\), that is \(6\), which is the third term; the fourth term will be \(6 \times \frac{m-2}{3} = 10\), that is \(4\); the fifth term will be \(4 \times \frac{m-3}{4} = 10\), that is \(4\); and the sixth term will be \(4 \times \frac{m-4}{5}, \ldots\), that is \(0\), which shows the series is here terminated, in this case.

"This being found, I applied it, as a rule, to interpolate the above-mentioned series. And since, in the series which expresses the circle, the second term was found to be \(\frac{1}{3}x\), I therefore put \(m = \frac{1}{3}\); and there was produced the terms \(\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} = \frac{1}{8}\), or \(-\frac{1}{4}\); and \(-\frac{1}{8} \times \frac{1}{2} = \frac{1}{16}\); and to obtain the hyperbola. Hence I found that the area of the segment of the circle-fought is \(x = \frac{1}{3}x - \frac{1}{3}\); and \(-\frac{1}{3}\); and \(-\frac{1}{16} \times \frac{1}{2} = \frac{1}{128}\); and to an infiniteness. Hence I found that the area of the segment of the circle-fought is \(x = \frac{1}{3}x - \frac{1}{3}\); and \(-\frac{1}{3}\); and \(-\frac{1}{16} \times \frac{1}{2} = \frac{1}{128}\); and to an infiniteness. Hence I found that the area of the segment of the circle-fought is \(x = \frac{1}{3}x - \frac{1}{3}\); and \(-\frac{1}{3}\); and \(-\frac{1}{16} \times \frac{1}{2} = \frac{1}{128}\); and to an infiniteness.

"In the same manner, the areas to be interpolated of the other curves might be produced; as also the area of the hyperbola,
BINOMIAL.

hyperbola, and the rest of the alternate curves in the series
\[1 + x^2, 1 + x^4, 1 + x^6, \ldots, 1 + x^n, \ldots\]; and in a similar
way might other series be likewise interpolated, and that
even if they should be taken at two more intervals.

"This was the way by which I first opened an entrance
into these speculations, which I should not have re-
membered, but that, in turning over my papers, a few weeks
ago, I, by chance, cast my eyes upon those relating to this
matter.

"After I had proceeded so far, it immediately occurred
to me that the terms \(1 - x^2\), \(1 - x^3\), \(1 - x^4\), \(1 - x^5\), \&c.
that is, \(1 - \sqrt[3]{x}\), \(1 - \sqrt[4]{x}\), \(1 - \sqrt[5]{x}\), \(1 - \sqrt[n]{x}\), \&c.
might be interpolated in the same manner as I had done in
the case of the areas generated by them; and for this, there
required nothing more than to leave out the denominators, \(1,
3, 5, 7, \&c.
\) in the terms that express the areas; then the co-
efficients of the terms to be interpolated \((1 - x^2)\), \(1 - x^3\),
or universally \(1 - x^n\) will be had by the continual multi-
plication of the terms of the series \(m \times \frac{m - 1}{2} \times \frac{m - 2}{3} \times \frac{m - 3}{4} \&c.

"Thus, for example, \(1 - \sqrt[4]{x}\) \(\frac{1}{10} \quad x^6 \&c.
and \(1 - \sqrt[5]{x}\) \(\frac{1}{9} \quad x^7 \&c.

"Thus, I discovered a general method of reducing radial
quantities into infinite series, by the binomial theorem,
which I set in my last letter, before I observed that the
same thing might be obtained by the extraction of roots.

"But after I had discovered this method, the other way
could not long remain unknown; for, in order to prove the
truth of these operations, I multiplied \(1 - \frac{1}{2} x^2 - \frac{1}{3} x^3 - \frac{1}{4} x^4 \&c.
by itself, and found the product to be \(1 - x^2, \&c.
all the terms after these \(ad in\nantum\) vanishing; in like man-
ner \(1 - \frac{2}{3} x^3 - \frac{1}{2} x^4 + \frac{1}{6} x^5 \&c.
being twice multiplied
into itself, produced \(1 - x^3\). And as this was a certain proof
of the truth of these conclusions, I was thereby naturally led
to try the converse of it, viz. whether these series, that
were now known to be the roots of the quantity \(1 - x^n\),
might not be produced by the rule for extraction of roots in
arithmetick; and, upon trial, I found it success to my
wishes.

"This being found, I laid aside the method of interpola-
tion, and assumed these operations, as a more genuine foun-
dation to proceed upon. In the mean time, I was not
ignorant of the way of reduction by division, which was so
much easier."

From this account, as given by Newton himself, it ap-
pears that his discovery of the law for the areas, with ir-
ational ordinates, preceded that of the law for the expan-
sion of those ordinates; although the latter, as Montucla ob-
erves, might have been expected to precede the former, if
inventive genius always pursued the most easy method. But,
in tracing the progress of the human mind, it may generally
be observed, that a collection of discoveries in any branch
of science, is seldom found to be a series of regular deduc-
tions; but, on the contrary, we often discern therein many
anticipations, and sometimes even a reversion of the natural
and logical order of ideas.

It is worth while here to remark, that Newton had made
these discoveries, as well as many others, several years be-
fore Mercator had published his "Logarithmotechnia," which
contains a particular case of this theory; but, from
an excess of modesty and indifference for these fruits of his
genius, he delayed making them known to the world; and,
even after the above-mentioned work had appeared, which
would have operated as a powerful motive with most other
men, in exciting them to share in the glory of these brilliant
inventions, he was still more confirmed in the resolution he
had taken, of not making himself known as an author till
he was of a more mature age. He conceived, that Mercator
having discovered, as it was said, the series for the hyper-
bola, would not be long before he extended his method to
the circle, and other curves; or, if this should not be done
by him, the invention would be readily perceived by others.
In short, it appears rather singular, that as Mercator had
converted the expression \(\frac{1}{1 + x}\) into an infinite series, by the
ordinary method of division, he should not have tried to dis-
cover the series for \(\sqrt[3]{1 + x}\) by the known method of ex-
tracting the square root; but this, though extremely ob-
vious, escaped his notice; and many circumstances, of a
similar kind, are to be found in the history of the sciences.

Newton, as has been already observed, left no demonstra-
tion of this theorem; but appears to have formed it merely
from an induction of particular cases; and though no doubt
can be entertained of its truth, having been found to succeed
in all the instances in which it has been applied; yet, agree-
ably to the rigour that ought to be observed in the estab-
lishment of every mathematical theory, and especially in a
fundamental theorem of such general use and application, it is
necessary that as regular and strict a proof should be given
of it as the nature of the subject, and the state of analysis,
can afford.

One of the first demonstrations of this kind that appears
to have been given, is that of James Bernoulli, which is to
be found, among several other curious things, in a small trea-
tise of his, entitled "Ars Conjectandi," which has been very
improperly omitted in the collection of his works, published
by his nephew, Nicholas Bernoulli. But this is only applied
to the case of integral and affirmative powers, and is near-
ly the same with that which was afterwards given by Mr. John
Stewart, in his commentary on Sir Isaac Newton's quadra-
ture of curves. It is founded on the doctrine of combina-
tions, and the properties of figurate numbers, which are
there shewn to involve in them the generation of these co-
efficients; and in the instance before mentioned, where the
index of the binomial is a whole positive number, it is clearly
and satisfactorily explained.

Since that time, many attempts have been made to demon-
strate the general case, or that where the index of the bi-
omial is either a whole number or a fraction, positive or nega-
tive; but most of these demonstrations having been con-
ducted, either by the method of increments, the multinom-
ial theorem of De Moivre, or by fluxions, are commonly
thought to be unsatisfactorily and imperfect; and it should
seem not without reason; as, independently of other objec-
tions, it appears contrary to the principles of science, as well
as to just reasoning, to employ, in a matter purely algebraical,
notions and doctrines derived from other branches, or from
an analysis which is in some sort transcendental.

For these reasons, several eminent mathematicians have en-
deavoured to investigate this formula on pure analytical prin-
ciples,
B I N O M I A L.

The binomial theorem, in its more natural and obvious way; one of the first of these attempts being that of Landen, in his "Discourse concerning the residual analysis," and the next that of Euler, in the eighth volume of the "New Petersburg Memoirs." But the legitimacy of the former may be objected to, as depending upon vanishing fractions, and other considerations of too difficult and abstract a nature to be regarded as sufficiently convincing; and the latter, though very ingenious, is not less difficult and embarrassing; at least, it is the opinion of Euler, who having himself first given a demonstration of this theorem, in which, like Macaulay, he employed the differential calculus, or method of fluxions, was afterwards led to deduce it from the principles of algebra alone: though he does not appear to have been much more successful than either of the former.

S. Lhuiller of Geneva, perceiving the defects and obscurity of these methods, has made a new demonstration of this formula in one of the preliminary articles of his excellent work, entitled, "Principiorum calculi differentialis et integralis, &c." which is purely elementary; and abating from its length, and a fatiguing detail of particulars, which the nature of the subject does not seem to require, it appears to have accomplished his object; at least as far as the method he adopted would allow; for it must be confessed, that neither this, nor any other investigation that had hitherto appeared, have been attended with the simplicity and frictitens which could be derived.

The reason of this, as Dr. Woodhouse properly observes, in his "Principles of Analytical Calculation," seems to be, that most mathematicians appear to have sought for some high origin of this theorem, distinct from the simple operations of multiplication, division, extracting of roots, &c.; and instead of considering the nature of the operations it was known to comprehend, hoped to supercede them by deductions drawn from abstruse and fine theories: whereas it is clear that whatever imperfections these fundamental operations are attended with, are also attached to the binomial theorem, which, in a certain sense, may be said to be a method of trial and conjecture. For, as this formula is only meant to express, in general terms, the algebraical rules above mentioned, it cannot posses a greater degree of certainty than is possessed by the simple operations themselves.

To avoid entering into a too prolix investigation of the well-known and simple elements upon which the general formula depends, it is sufficient to observe that it is clearly manifest from some of the first and most common rules of algebra, that whatever is the operation which the index (m) in \(a + xn\) directs be performed upon the binomial \(a + x\), whether of continued multiplication, or elevation, or division, or of extraction of roots, the terms of the resulting series will necessarily arise by regular and whole positive powers of \(x\); and that the two first terms of this series will always be \(a^m + ma^{m-1}x\); so that the entire expansion of it may be represented under the form \(a^m + ma^{m-1}x + px^n + qx^{n+1}, \&c.\)

For, omitting the practical part of the process, which is taught by the above mentioned rules, it will constantly be found, by performing the operations at length in the usual way, that

\[
\frac{1}{a + xn} = a^{-1} + 2a^{-2}x + 3a^{-3}x^2 + 4a^{-4}x^3 + \cdots
\]

\[
\frac{1}{a + x} = a^{-1} + a^{-2}x + a^{-3}x^2 + a^{-4}x^3 + \cdots
\]

\[
\frac{1}{a + x^n} = a^{-1} + 2a^{-2}x + 3a^{-3}x^2 + 4a^{-4}x^3 + \cdots
\]

\[
\frac{1}{a + x^m} = a^{-1} + 2a^{-2}x + 3a^{-3}x^2 + 4a^{-4}x^3 + \cdots
\]

In all the inferences here given, it is apparent, that the first term of the series, in each of which is the same as the power or root of the first term of the binomial quantity to which it belongs; and that the coefficient of \(x\) in the second term is always had by multiplying the index of the first term into that term, having its index diminished by 1; and as these cases are of the same kind with those that are designed to be expressed, in universal terms, by the general formula, it is in vain, as far as regards the two first terms of the expansion, to look for any other origin of them, than what may be derived from theorems and similar operations.

Aiming therefore, \(a + xn = a^m + ma^{m-1}x + px^n + qx^{n+1}, \&c.\) it only remains to determine the value of the coefficients \(p, q, r, \&c.\) and to shew the law of their dependence on the index (m) of the operation by which they are produced.

For this purpose, let \(m\) denote any number whatever, integral or fractional, positive or negative; and let the coefficients of the 3d, 4th, 5th, \&c. terms of the nth power of any binomial be denoted by \(p, q, r, \&c.\)

Then for \(x\), in the above form, put \(y + wz\), and there will arise

\[
a + y + wz = a + y + wz = a + y + wz,
\]

which are all identical expressions; and when expanded according to the proper forms, must be equal to each other.

But \(a + y + wz = a + ma^{m-1}y + pz^m + 2y^2z, \&c.\) (omitting to let down the higher powers of \(z\), which are not wanted in the demonstration) =

\[
\frac{a + y + wz}{a + y + wz} = a + y + wz = a + y + wz,
\]

\[
\frac{a + y + wz}{a + y + wz} = a + y + wz = a + y + wz.
\]

Hence the two series being identical, \(a + ma^{m-1}y + pz^m + 2y^2z, \&c.\) = \(a + ma^{m-1}y + pz^m + 2y^2z, \&c.\) = \(a + ma^{m-1}y + pz^m + 2y^2z, \&c.\) = \(a + ma^{m-1}y + pz^m + 2y^2z, \&c.\)

And hence the coefficients of the terms involving the fame powers of the arbitrary quantities \(y\) and \(z\) must be the same.

We shall have \(2p = m + 1, \&c.\) or \(p = \frac{m + 1}{2}, \&c.\)

And hence \(p' = \frac{m - 1 - m - 1}{2} = a^{m - 1}\). Also \(3q = mp', \&c.\) when \(m, m - 1, \&c.\)
The mouth of this river is in S. lat. 36° 45', W. long. 73° 28'; and its entrance known by two remarkable hills, called the Teats of Biobio, which are situated at the north, betwixt it and the bay of Conception, and serve to both as land-marks for navigators.

The river is about one mile across at the mouth, has good depth of water in the middle, and the tide rises about seven feet and a half at the full and change of the moon.

BIOCOLYTAE, in the Byzantine Empire, an order of officers appointed to prevent the violence frequently committed by the soldiers. The word is compounded of βιος, ζωή, ζωή, ζωή, and μορφός, a hinder; and should rather be written biocolyte.

The biocolyte appear to have been much the same with the French archers of the Marshalle. They were suppressed by the emperor Julian.

BIOCULATA, in Entomology, a species of Ephemeræ, described by Geoffroy, Linnaeus, &c. The wings are white, reticulated &c. on the head two yellow tubercles, Fabr. Inhabits wet places in Europe. The tail of this kind is furnished with two bristles as long as the body.

BIOCULATUS, in Natural History, a species of Hirudo, of an elongated form and cinerous colour, with two eyes. Gmel. Müll. This is hirudo flagellis of Linnaeus. En. Succ. &c. Found in wet hollows and rivulets very common. Length of this creature is nine lines. The female bears about forty eggs at a time, which are surrounded by a pellicle circle; at first these are cinerous, afterwards brown; and the young, after exclusion, adhere by their tails to the belly of the female. Gmel.

BIOCULATUS, in Entomology, a species of Cryptocéphalus (Crioceris), found at the Cape of Good Hope. It is teltaceous; thorax immaculate; on the wing-cazes two occular white spots. Fabricius.

BIOCZ, in Geography, a township of Poland, in the paltinate of Cracow, north of the Carpathian mountains. N. lat. 49° 48'. E. long. 21° 40'.

BIOEA, in Ancient Geography, a sea-port in the southern part of the island of Sardina, according to Ptolomy.

BIOGLOIO, in Geography, a town of Italy, in the lordship of Vercelli, 23 miles N.W. of Vercelli.

BIOGRAPHER, formed from the Greek βιος, ζωή, and κοινεῖος, I describe, an author who writes a history, or life, of one or more persons. Such were Plutarch, Corn. Nepos, &c.

BIOGRAPHY, the art of describing or writing lives, is a branch or species of history more entertaining, as well as more useful in many respects, than general history, as it represents great men more distinctly, unembarrassed with a crowd of other actors, and descanting into the detail of their actions and character, their virtues and failings, gives more light into human nature, and leads to a more intimate acquaintance with particular persons than general history allows. A writer of lives may defend, with propriety, to minute circumstances and familiar incidents. From him it is expected to give the private as well as the public life of those whole actions he records; and it is from private life, from familiar, domestic, and seemingly trivial occurrences, that we often derive the most accurate knowledge of the real character. The subjects of biography are not only the lives of public or private persons, who have been eminent and beneficial to the world in their respective stations, but those also of persons notorious for their vice and profligacy; which may serve, when justly characterized, as warnings to others, by exhibiting the fatal consequences which, sooner or later, generally follow licentious practices. As for those, who exposed their lives, or otherwise employed their time and labours for the service
service of their fellow creatures, it seems but just debt, that their memories should be perpetuated after them, and that posterity should be made acquainted with their benefactors. This was no small incentive to virtue in the pagan world; and no one can be ignorant, on due reflection, how natural this passion is to mankind in general. For this reason, as Dr. Ward presumes (Orat. vol. ii. p. 525.), Virgil has placed not only his heroes, but also the ventures of useful arts and sciences, and other perils of distinguished merit, in the Elysian fields, where he describes them (Ann. l. vi. v. 661.):

"Here patriots live, who, for their country's good,
In fighting fields were prodigies of blood;
Priests of unblemished lives here make shade,
And poets worthy their inspiring god:
And searching wits of more mechanic parts,
Who grace'd their age with new-invented arts;
Those who to worth their bounty did extend,
And those who knew that bounty to command:
The heads of these with holy follets bound,
And all their temples were with gruninds crown'd."

In the lives of public persons, their public characters are principally, but not solely, to be regarded. The world is inquisitive to know the conduct of princes and other great men, as well in private as in public; and both may be of service, considering the influence of their example. But to be odd inquisitive in searching into the weaknesses and failings of the greatest or best men, is, to say no more of it, a needless curiosity.

In this species of writing Plutarch has no inconsiderable merit; and to him we are indebted for much of the knowledge which we possess concerning several of the most eminent personages of antiquity. His matter, however, is better than his manner; as he cannot lay claim to any peculiar beauty or elegance. His judgment too, and his accuracy, have sometimes been taxed; but whatever may be his defects of this kind, his lives of eminent men will always be considered as a valuable treasure of instruction. He is remarkable for being one of the most humane writers of all antiquity; let's dazzled than many of them are, with the exploits of valour and ambition; and fond of displaying his great men to us, in the more gentle lights of retirement and private life.

It has been a matter of dispute among the learned, whether any one ought to write his own history. No one, it may be said, can be so much master of the subject as the person himself; and besides, there are many infallacies, both ancient and modern, to justify that practice. But, on the other hand, it must be owned, that it is attended with many inconveniences, some of which are mentioned by Cicero: "If," says he, (Ad. fam. l. vii. ep. 12.) "there is any thing commendable, perils are obliged to speak of themselves with greater modesty, and to omit what is blamable in others. Besides, what is said is not so soon credited, and has less authority; and after all, many will not hesitate in confuting it." To the same purpose it is well observed by Pliny (l. viii. ep. 1): "Those who proclaim their own virtues, are thought not so much to proclaim them, because they did them, as to have done them, that they might proclaim them. Hence, what would appear great, if told by another, is left, when related by the party himself. For when men cannot deny the fact, they reflect upon the vanity of its author. Wherefore, if you do things not worth mentioning, the actions themselves are blamed; and if the things you do are commendable, you are blamed for mentioning them." The justice of these reflections will be allowed; and yet, considering how natural it is for men to love themselves, and to be inclined in their own favour, it seems to be a very difficult task for any one to write an impartial history of his own actions. There is scarcely any treatise of this kind that is more celebrated than Cæsar's "Commentaries," and yet Suetonius tells us (in Vit. c. 56.), that "Afinius Pollio, who lived at that time, thought that they were written neither with due care nor integrity; that Cæsar was too often credulous in his accounts of what was done by other persons, and misrepresented his own actions, either delibera	ly, or through forgetfulness; and therefore he suppokes he would have revised and corrected them." At some times, however, it may without doubt be justifiable for a perfon to be his own historian. Plutarch mentions two cases, in which it is allowable for a man to commend himself, and to be the publisher of his own merits. These are, "When the doing of it may be of considerable advantage, either to himself, or to others." "Anciently," says Tacitus (Vit. Agric. c. 1.), "many wrote their own lives, rather as a testimony of their conduct, than from pride," remarking, "that the more virtues abound, the fmrer the reports of it are credited." But the ancient writers had a method of diverting the reader's attention from themselves, when they had occasion to record their own actions, and of thus rendering what they did less injudicious, which was by speaking of themselves in the third person; thus Cæsar never says, "I did," or "I said this or that," but always "Cæsar did," or "Cæsar said," Dr. Johnson has given an account of paper on the subject of biography in the collection of papers called "The Filler;" Volney, in his "Lectures on History," remarks, that biography is the only kind of history that is proper for young people. See History.

Dr. Priestley has constructed and published a "Biographical Chart," which is very useful to students in chronology, history, and biography. This chart, which is about three feet in length, and two feet in breadth, represents the interval of time between the year 1200 before the Christian æra and 1800 after Christ, divided by an equal scale into centuries. It contains about 2000 names of persons the most distinguished in the annals of fame, the length of whose lives is here represented by lines drawn in proportion to their real duration, and terminated in such a manner as to correspond to the dates of their births and deaths, in universal time. These names are distinguished into several classes by lines running the whole length of the chart, the contents of each division being expressed at the end of it. The chronology is noted in the margin on the upper side, by the year before and after Christ, and on the lower by the Christian æra, and also by the succession of fuch kings as were the most distinguished in the whole period.

BIOLE, L.L., in Geography, the chief place of a canton, in the department of Chambéry, and territory of Mont Blanc. The population of the place is about 1208, and of the canton at 5525 persons; the territorial extent contains 223 square kilometres, and 10 communes.

BIOCYNTHIUM, formed of best, life, and xanthere, light, a name given by some physicians to a supposed principle of vitality inherent in the heart, or blood, and remaining there as long as life continues. Of this principle, or innate heat, different accounts have been given by different writers; as Galp. Hoffmann, Curnius, &c.

Beguin has defended a process for preparing from human blood a vital balsam under this denomination; and J. Ern. Burgravius has written a treatise upon it.

BION, in Biography, a native of Proconnesus, was contemporary with Thucydides, and flourished about the 55th Olympiad, or 544 years B.C. Clemens Alexandrinus informs us, that he copied the titles, and abridged the works of
of Cadmus the Mileian, who is said to have been the first writer of history in prose, and to have lived before the Trojan war.

Bion, the Philosopher, was a native of Berythines, and flourished in the reign of Antigonus Gonatas, king of Macedonia, and died about the last year of the 143d Olympiad, or the 234th year B.C. He was a pupil of Xenocrates, being the son of a Laodemonian harlot; and when young, was sold as a slave to an orator, who afterwards gave him his freedom, and left him large possessions. Thus endowed, he went to Athens, and devoted himself to the study of philosophy. He was first the disciple of Crates, then of the Cynics, afterwards of Theodorus, and last of all of Thessalathus; but he adopted and maintained the opinions of Theodorus, called the atheist. He was skilled in geometry and music, and also in poetry and rhetoric; and went about from one city to another, displaying his talents. Several of his repartees, for which he was famous, are preserved; and Horace is supposed to allude to him in his "Ille Bionis fermoebus, et fale nigro." Epist. 2. lib. ii.

To a great talker, who asked him if he would, he said, "if you should have me grant it, let some other person ask it for you." Being on board a ship belonging to pirates, which was chased by another, the pirates exclaimed, "We are undone, if they discover we are!" And I," says Bion, "if they discover who I am." He ridiculed the contradiction of burning the dead as if they were inefable, and lamenting them as if they were infable. Some of his jests were offensive to morals and decency; for neither of these did he pay much regard. Notwithstanding his avowed irreligion, he recurred, when sick, to the practice of puerile superstitions, and submitted to death with great reluctance.

Bion, a celebrated Sicilian poet, was a native of Smyrna, and a contemporary of Ptolemy Philadelphia, about 280 years B.C. In Sicily or Magna Graecia, where he is supposed to have spent the last part of his life, Mofchus was his pupil; and from the beautiful elegance of this poet, we are led to infer, that he left his life in prison, and that the persecutors of this deed did not escape just punishment. As a poet he was highly esteemed; and his performances that are extant, though inconsiderable, serve as examples of the excellence to which the Greeks had attained in similar compositions. Nothing can be more sweet and tender than his "Elegy on the death of Adonis," nor anything more elegantly ingenious than his "Cupid instructed." The works of Bion are usually printed with those of Mofchus; and the best editions are those of Paris, in 1680; of Venice, in 1749; Fleklin's, at Oxford, in 1748; Scheir's, at Leipic, in 1752; and Wakefield's, Lond. 1795. Gen. Dict. Gen. Biog.

Bios, M. mathematical instrument maker to the French king, died at Paris, in 1733, at the age of 78 years, and is known to mathematicians as the author of two works: one, On the construction and principal uses of mathematical instruments, translated into English with additions, by Mr. Edmund Stone; and another, "On the Ufe of the Globes," the fifth edition of which was published at Paris, in 1728.

Bioncourt, in Geography, a town of France, in the department of the Meurthe, and the chief place of a canton, in the district of Chateau-Salins, 2 leagues W.S.W. of Chateau-Salins.

Bisckna, in Ichthyology, a species of Cyprinus, having thirty-five rays in the anal fin. Found in the lakes of Sweden. Linnaeus. This is Cyprinus quinqualis, pinna an officulorum 23, of Ardeti.

Biondo, Flavio, (Lat. Blondus), in Biography, an antiquary and historian, and one of the first who illustrated the Roman antiquities, was born at Forli in 1388, and studied at Cremona. Being deputed in his youth on public business to Milan, he there made the first copy of Cicero's treatise on famous orators. At Rome he became secretary to pope Eugenius IV., and served the three succeeding popes in the same office. He was employed in various delegations to Venice, where he had an opportunity of cultivating an acquaintance and friendship with many learned persons in that republic. Debarred by his marriage from enjoying any church preferments, and devoted to study more than to the pursuit of wealth and honour, he preferred retirement to any public hateful, and prosecuted his literary labours till his death in 1453. His long residence at Rome enabled him accurately to describe its chief relics of antiquity in 3 books entitled "Roma impluvia," which were followed by 10 books on the laws, government, customs, religion, &c. of the Romans, under the title of "De Roma Triumphans." Another work, on its history, antiquities, and geography, was entitled "Italia illustrata." All these works display great reading and diligent research, though they are not free from many errors to which his ignorance of Greek literature must have contributed. Having undertaken to write a general history from the decline of the Roman empire to his own time, he finished three decades of it, and the first book of the fourth. He also wrote a book "De Origine et Gestis Venetiarum," and had planned an entire history of the Venetian republic; but he afterwards chose to infer the substance of it in his general history. He left several other writings in MS., which it is needless to mention. His style wants purity and elegance, and his judgment in collecting materials was superior to his talent in using them. A collection of his works was published at Bafil, in 1531, fol. Novv. Dict. Hist. Gen. Biog.

Bjorko, Geography, a town of Sweden, in the province of Upland.

Bjornesborg, a town of Finland, on the cadd side of the Gulf of Bothnia, seated on a lake, 80 miles north of Abo. N. lat. 62° 6'. L. long. 22° 35'.

Bjorse, a small island of Denmark, near the south coast of the island of Tunen.

Björnstafl, James Jonas, in Biography, a learned Swedish traveller, was born at Rotarbo in 1731, and having finished his education in the university of Uppsala, he became, in 1766, tutor to the son of baron Rudbeck, with whom he travelled for eight years through France, Italy, part of Germany, Holland, and England. At Paris, where he improved himself in the Oriental languages, he was elected, in 1770, a member of the academy of sciences, and upon the baron's return to Sweden, in 1775, Björnafalk received orders from the king to travel at his expense through the Ottoman empire, Syria, Egypt, and the northern part of Africa, and in the same year he was appointed extraordinary professor of philosophy at Uppsala. In the following year he commenced his travels; and having arrived at Constantinople, he continued there two years, improving himself in the eastern languages. In 1775, he was appointed professor of the Oriental languages at Lund. He died this year of a putrid fever at Salonic. The result of his observations in the course of his travels was communicated in a series of letters to C. G. Gjörvall, librarian to the king at Stockholm; and a complete collection of them appeared at Stockholm, in 1778, in three volumes, 8vo. under the title of "J. J. Björnafalk's Bref rörande des utländiska Refa tii utgifaren C. C. Gjörvall." A German translation of this work was published at Stralsund and Roßstock, in 1783, in six volumes, 8vo. The principal object of Björnafalk's research was Oriental MSS. from which he made many important and useful extracts. Gen. Biog.
BIPED, in Zoology, an animal furnished with only two legs. Man and birds are bipeds. Apes occasionally walk on their hind legs, and seem to be of this tribe, but that is not a natural position for them, and they rest upon all their legs like other quadrupeds. The herbivorous are also of the latter description, jumping and leaping on their hind legs, but resting on the fore legs likewise.

Plato, we are told, once described a man to be a biped without feathers; and Diogenes, in order to show what he deemed the absurdity of this definition, plucked all the feathers off a cock, and placing it in the mélée of the Academy school, exclaimed, "there is one of Plato's men!"

BIPED, BIPEDS, BIPEDS, a genus of reptiles that belong to the lizard family, in the system of La Cepede. These have, according to the character established by the author, a very long body covered with scales, and the toes of the two little feet, which are placed anteriorly, are armed with nails. La Cepede describes only one species of this genus, which he calls le canelle; it is a native of Mexico, and preserved in the museum at Paris. La Cepede, it appears, was the first writer who described this creature; but Dr. Shaw noticed it afterwards in the Naturalist's Miscellany, under the name of lacerta amblyceps, a stenodactyl lizard, which see; and a specimen of it, about half the size of that in the museum at Paris, is preserved in the British museum. This must not be confounded with lacerta hopei of Linnaeus. Pallas has described another kind of biped lizard, which is called lacerta opes, but in that the legs are very small, monodactylous, and placed far behind: some have almost doubted whether this may not rather be part of the organs of generation than legs; and in general appearance the creature approaches rather to the lizards than to the lizard tribe. It is a native of the southern part of Siberia, and also of Greece, and is of a ferruginous colour.

BIPEDUS, in Roman Antiquity, a two-edged ax, used anciently by the Amazons in fight: as also by the Samian, to cut asunder the ropes and corage of the enemy's vessels. The bipedus was a weapon chiefly of the oriental nations, made like a double ax, or two axes joined back to back, with a short handle. Some compared it to a figure of a pen, and supposed it hence to have acquired the name bipenis; the tube or barrel of the pen representing the handle, and the point or nib the head. Modern writers usually compare it to our halberd, or partisan; from which it differed in that it had no point, and that its shaft or handle was much shorter. See HALBERD.

BIPES, in Zoology, a species of Lacerta, with the body subequal, round, furnished, and pale; on each side a brown dot; no anterior feet; posterior feet with two toes unmarked. Gmelin. Anguis hopei, with Cecum abdominal, and 60 subcaudal plates. Linna. Mamm. Fr. VIII. A native of South America and India. Length about six inches; body cylindrical and slender; color pale yellow. Biped lizard.

Bipes, a species of Coluber, described by Gmelin on the authority of Scopoli, as an inhabitant of the Tyrrhenian waters, where it is said to feed on frogs and fishes; it has two feet, fulvous eyes, white under-jaw, elliptic, marginate, dorsal scales; its feet spotted with white; abdominal plates whitish, with a brown spot in the middle. Gmelin describes it specifically as having 116 plates on the belly, and 58 subcaudal scales.

BIPINNULA, in Botany. See ARTEMISIA.

BIPICULATA, in Conchology, a species of Voluta, figured by Martin only. It is of a tapering shape, smooth, white spotted with yellow, and dotted with black; lip acute; pillar with two plait.

BIPUNCTARIA, in Entomology, a species of Phalera (Geometra), the anterior wings of which are cinereous, undulated with brown; a dull black band in the middle, and two black dots. Fabricius, &c.

BIPUNCTATA, a species of Apes that inhabits Siberia. This insect is hairy and black, with two yellow belts; the firlt with two lateral black dots. Lepechin, it. Gmel.

BIPUNCTATA, a species of Aranea, with a black, globulo abdominal, marked with two excavated dots. Linna. Fa. Sur.

BIPUNCTATA, a species of Caneus, with two black spots on the thorax; wings, black at the tip. Fabricius.

BIPUNCTATA, a species of Caneus, with two black spots on the thorax; wings, black at the tip. Fabricius.

BIPUNCTATA, a species of Chrysomela, described by Fabricius as a native of the Cape of Good Hope. It is ferruginous, with a brown spot on each of the wing-cases.

BIPUNCTATA, a species of Cicada, described by Linnaeus. It is yellow, with two brown spots in front; wing-cases white, veined with yellow. A native of Europe.
BIPUNCTATA is also a species of Cicada (Deflexa), found in South America. The colour is whitish; wing-cases deflected, and greasy, with two imprinted dots on the anterior part of the margin of the thorax. Fabricius, &c.

BIPUNCTATA, a species of Coccinella, of a red colour, with two black dots. Linnaeus, Fn. Suec, &c.

BIPUNCTATA, a species of Porticula, that inhabits Italy. This is black; hind part of the head and legs rus- 

BIPUNCTATA, a species of Leptura, of a black colour, ve- 

BIPUNCTATA, a species of Tantuloides, a species of Leptura, of a black colour, ve-

BIPUNCTATA, a species of Phaenea (Tinea), wings cinerous brown, with a marginal white spot. Fabricius.

BIPUNCTATA, a species of Phaenea (Tinea), with fuscous wings, with a common de- stated white stripe; tho- 

BIPUNCTATA, a species of Chrysonella, described as a Swedish insect by Thunberg. The wing-cases are black, spotted at the tip, head and sides of the thorax yellow. Fabricius, &c.

BIPUNCTATA, a species of Coccinella, of a black colour, with red spots, and fuscous abdomen. Linnaeus, Fn. Suec.

BIPUNCTATA, a species of Coccinella, of an ovate form, and black colour, with red spot on each of the wing-cases. Fabricius and Gmelin. This is Sipho oblonga nigra, &c. of Linnaeus, Fn. Suec. and Syll. Nat. Sipho, of Degener; Denneis, of Geoffroy; and Ophoma bipustulata, of Linnaeus. Inhabits Europe, and feeds on cereals, meat, bacon, &c.

BIPUNCTUM, a species of Opalatum, that inhabits Up- 

BIPUNCTUM, a species of Opalatum, that inhabits The-

BIPUNCTA, a species of Coccinella, of an ovate form, and black colour, with red spot on each of the wing-cases. Fabricius and Gmelin. This is Sipho oblonga nigra, &c. of Linnaeus, Fn. Suec. and Syll. Nat. Sipho, of Degener; Denneis, of Geoffroy; and Ophoma bipustulata, of Linnaeus. Inhabits Europe, and feeds on cereals, meat, bacon, &c.

BIPUNCTA, a species of Coccinella, of a black colour, with red spots, and fuscous abdomen. Linnaeus, Fn. Suec.

BIPUNCTA, a species of Coccinella, of an ovate form, and black colour, with red spot on each of the wing-cases. Fabricius and Gmelin. This is Sipho oblonga nigra, &c. of Linnaeus, Fn. Suec. and Syll. Nat. Sipho, of Degener; Denneis, of Geoffroy; and Ophoma bipustulata, of Linnaeus. Inhabits Europe, and feeds on cereals, meat, bacon, &c.

BIPUNCTA, a species of Gryllus (Acrisius, Tracula), of a brownish colour; feutelus long as the abdomen. A native of Europe. BIPUNCTA, a species of Gryllus (Acrisius, Tracula), of a brownish colour; feutelus long as the abdomen. A native of Europe. BIPUNCTA, a species of Gryllus (Acrisius, Tracula), of a brownish colour; feutelus long as the abdomen. A native of Europe. BIPUNCTA, a species of Gryllus (Acrisius, Tracula), of a brownish colour; feutelus long as the abdomen. A native of Europe. BIPUNCTA, a species of Gryllus (Acrisius, Tracula), of a brownish colour; feutelus long as the abdomen. A native of Europe.

BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut. BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut.

BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut.

BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut.

BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut.

BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut.

BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut.

BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut.

BIPUNCTATA, a species of Cryptoccephalus, of a glossy black; wing-cases red with two black dots; antennae length of the body. Fabricius, Gmelin, &c. Chrysonella punctata. Linnaeus. Inhabits the northern parts of Europe; on the Nut.
ight or azure blue, rufous at the apex of the wing-cases; and the anterior of the same colour. It is an European insect, and inhabits the flowers of the Chrysanthemum. Gmelin confers it on Caryophylla media of Lichat.

**BIPUSTULATUS**, a species of *Dermestes*, that is black and glossy, with the head, thorax, and spot at the base of the wing-cases red. Thueng. This is *Ipse humanus* of Fabricius. Country unknown.

**BIPUSTULATUS**, a species of *Dytiscus*, described by Fabricius. It is smooth black, with two red spots on the posterior part of the head. This inhabits the north of Europe.

**BIPUSTULATUS**, a species of *Dytiscus*, that inhabits Germany. This kind is black, thorax and head, with two black spots; wing-cases yellow, varied with brown. Fabricius.

**BIPUSTULATUS**, a small species of *Elater*, found in woods in England and other parts of Europe; the colour is black and shining, with a yellow spot on each of the wing-cases. M. Gmelin, &c. (Bleek.) In Britain, this insect is the described by Gmelin. *Bipus*, *B. pollicillus*, *B. vulgaris*, and reference to the Fabrianian Species,sect. homonymum, in which the defect on the base of the wing-cases is laid to *Bio*.

This is *Elaterium pubescens* and *Elaterium bipustulatum* of Geoffroy.

**BIPUSTULATUS**, a species of *Gallus*, in the Section *Gallus* of a pale brown colour; found at the extremity of the abdomen, and two spots of the thym. black; wing-cases yellow, variegated with black, and smaller than the wings. Gmelin, &c. This insect makes its cell at the same length according to Schafte, the figure, exclusive of the antennae, which are thrice longer than the body. Inhabits Europe.

**BIPUSTULATUS**, a species of *Scarabaeus*, of a black colour, with a red spot on each of the wing-cases. A native of New Holland. Fabricius.

**BIPUSTULATUS**, a species of *Staphylinus*, that inhabits the northern parts of Europe. Colour black, with a ferruginous dot on each of the wing-cases. Linn.

**BIOQUADRATO**, or *Biocastaneous* *paw*, in *Algebra* and *Arithmetica*. It is the next power above the cube, or the square multiplied by itself. Thus, 16 is the bigendrate, or 4th power of 2, or it is the square of 4, which is the second power of 2; for $2 \times 2 = 4$, and $4 \times 4 = 16$.

**BIOQUADRATO**, or *Biocastaneous* *Equation*, an equation raised to the fourth power, or where the unknown quantity of one of the terms has four dimensions, thus, $x + ax + bx + cx + dx + e = 0$ is a bigendrate equation. See *Equation*.

**BIOQUADRATO**, in *Geometry*, a curve line of the third order, having two infinite legs, tending the same way. See *Equation*.

**BIOQUADRATO**, in *Arithmetic*, the square root of any number is, the square root of the square root of that number; thus, the bigendrate root of 81 is 9; the square root of 9 is 3; the bigendrate root of 81 is 9.

**BIOQUADRATICA**, or the *Geometry of the Square*, a book of the 4th of 1666. This was what the Algonquins held. The 4th, 5th, 6th, 7th, and 8th, are preferred because they are the squares of the deities, which are the realities of their religion. By giving the law of forming the cubic, and square of the Angle, they show the care of forming the forms of the several parts of the Algonquin society with neatness and exactness; so, in garrison, &c. From both these they were indebted; that is, copied of companies, or command and parts of letters.

**BIOQUADRATICA**, an aspect of the planets, when they are 144 degrees distant from each other. It is thus called, because they are difficult for each other by twice the fifth part of the 144 degrees. See *Aspect*.

**BIRACI ET BIRACIC**, in *Geography*, a town of Attica, at the mouth of the Euphrates, in a very fertile country, the residence of a boy; 100 miles S. W. of Darius.

**BIRABETANE**, in the *Botanical Writings of the Alcmaon*, a name given to *Bargent*, or *verdin*, and to other birds named in the same manner. It is only the word *birapoton*, as altered by the Gothic manner of writing and speaking in. *Microbatone* is the common Greek name of *verdin*, and other particular herds, and it is probable that the Latin name vicina came from the Gothic manner of speaking this word. All these birds, when they were laid upon the altar on solemn occasions, such as making of peace, and other solemn contracts, and were to be taken up by the contracting parties as part of the sacrifice, were called by the Greek *Birapotone*; that is, laid by the bird; and verbinon; but as the plant was particularly known by the name verbena was more frequent in the days of other on this occasion, it was afterwards changed by that name. See *Verbena*.

**BIRAKADEN**, in *Geography*, a town of Persia, in the province of Fars, about the sea of Zang."
in the pleasures of social intercourse with persons the most distinguished for their attachment to letters and science. With respect to theological subjects, his sentiments were rational and liberal, and he was a zealous friend to religious and civil liberty. In this respect his views and principles were conformable to those of the truly excellent bishop Hoadly.

In literary labour few persons have been more diligent and indefatigable than Dr. Birch. The first great work in which he engaged was, "The General Dictionary, Historical and Critical," comprehending a new translation of that of Mr. Bayle, and several thousand new lives, never before published. This valuable work was completed, principally by himself, with the co-operation of the reverend Mr. John Peter Bernard, Mr. John Lockman, and Mr. George Sala, in 10 volumes,folio. The first volume appeared in 1734, and the last in 1741. In 1737, he published "Professor Greaves's Miscellaneous Works," 2 vols. 8vo.; and in 1742, "Thurloe's State Papers," in 7 vols. folio, with a dedication to lord chancellor Hardwicke. In 1743, he edited "Cudworth's Intellectual System," his "Discourse on the Lord's Supper," and "Two Sermons," with a life of the writer, in 2 vols. 4to. His "Life of the Hon. Robert Boyle," 8vo. which has been since prefixed to the 4to. edition of that eminent philosopher's works, appeared in 1744; and in the same year he began a series of biographical sketches of distinguished persons, designed to accompany their engraved portraits by Howbraken and Vertue. The first volume of this work was completed in 1747, and the second in 1752. In 1747, he published in 8vo. "An Inquiry into the Share which King Charles I. Had in the Transactions of the Earl of Glamorgan, &c." a fact which, however overlooked, or disputed by some of our historians, was confirmed by the evidence adduced in this interesting publication, and has been since further corroborated by the Chendon plate papers. In 1748, Dr. Birch was the editor, in 2 vols. 8vo. of the "Miscellaneous Works of Sir Walter Raleigh," to which is prefixed a life of the author.

His next publication was "An Historical view of the Negotiations between the Courts of England, France, and Buffels, from the year 1592 to 1617; extracted chiefly from the MS. state papers of sir Thomas Elmore, and of Anthony Bacon, &c.; to which is added, a relation of the state of France, with the character of Henry IV. and the principal persons of his court, by sir George Carew," 8vo. 1749. To this volume Dr. Birch has prefixed a discourse on the utility of deducing history from the original letters and papers of the persons who were the principal actors in public affairs, followed by a biographical account of the three negociations above-mentioned, Mrs. Cockburn's "Theological, moral, dramatic, and poetical works," 2 vols. 8vo. with the life of that ingenious lady, were edited by Dr. Birch in 1751; and he also published an edition of "Spenser's Fairy Queen," in 4 vols. 1756. One of his most popular works, which was "The Life of Archbishop Tillotson, compiled chiefly from his original papers and letters," and dedicated to archbishop Herring, in one volume, 8vo., appeared in 1752; and in the following year he revised an edition of "Milton's Prose Works," in 2 vols. 4to. to which is prefixed a new life of the author. In 1754, he published in 2 vols. 4to. "Memoirs of the reign of Queen Elizabeth, from the year 1581 till her death, &c. from the papers of Anthony Bacon, &c. and other MSS. never before published," in which, besides a full display of the temper and actions of the earl of Essex, much light is thrown on the characters of the Ceciles, Bacons, and other eminent persons of that period. Dr. Birch's next publication was "The History of the Royal Society of London," in its first volume; in which the most considerable of those papers communicated to the Society, which have hitherto not been published, are inserted in their proper order, as a Supplement to the Philosophical Transactions." The two first volumes of this work appeared in 1756, and the other two volumes in 1777; and they bring down the history to the end of the year 1687. This is unquestionably an useful book of reference, and contains many particulars which may be of occasional service both to the philosopher and the biographer.

In 1760, Dr. Birch published "Letters between Colonel Robert Hammond, Governor of the Isle of Wight, and the Committee of Lords and Commons at Derby-house, &c. concerning the King's departure at Hampton Court, and in the Isle of Wight," 8vo.; and he closed his voluminous labours with "Letters, Speeches, Charges, Advices, &c. of Francis Bacon, lord viscount St. Albans, &c. in one volume, 8vo." Soon after his death, Dr. Maty published, "The Life of Dr. Ward," which he had just lived to finish; and he had also prepared for the press, "Historical Letters, written in the reign of James I. and Charles I." which Mr. Aylefough proposed to publish. In the list of his printed works we might also comprehend some papers communicated to the Royal Society, and some accounts of books in the works of the learned; but besides these, such was his unwearied affability in collecting every fragment pertaining to literature, and deemed by him of importance, that he left behind him 24 volumes 4to. of various papers copied by himself from the Lambeth library. Upon the whole, whatever may be thought of Dr. Birch's judgment in his election of materials, of the minutudes of his researches, of the justice and faithfulness of his inferences from the facts which he produces, and of the want of elegance and animation in his style, it must be allowed, that literature has already derived, and may yet further derive, great benefit from his labours. Biog.-Brit.
are as highly prized from furnishing occupation to the sportsman, or a delicacy to the epicure.

The anatomical characters of this class of animals are not less deserving of attention than their other properties. In the scale of animated existence, birds can scarcely be considered inferior to mammals; and yet many of their functions are exercised upon a very different plan, and almost constantly by organs differently constituted. It is in birds that we perceive the first general deviations from the scheme of organization pursued in the human subject: this will be found most remarkably exemplified in the apparatus for the preparation and digestion of food, the secretion of urine, the mode of generation, and the growth and economy of the young animal, the anatomy of the brain, the structure of the eye and ear, the mechanism of the organs of sound, and the construction of the instruments of loco-motion.

The anatomy of birds has been much professed both by the older authors and in modern times, as the means of physiological knowledge, and in aid of the several purposes for which these animals are so much esteemed. The information, however, communicated in this way, falls far short of a systematic account of the subject; to supply which, therefore, much original matter is necessarily introduced into the present article, more particularly in the descriptions of the blood-vessels, of the organs of motion, and of the minute structure and uses of parts. Many errors of the older writers are also corrected; and wherever the descriptions of others are followed, they have been, as far as it has been practicable, revised by a comparison with the recent subject or authentic preparations.

**Organs Concerned in the Exercise of the Vital Functions.**

**The Mouth and its contained Parts.**

In the other classes of animals, these parts are constructed to effect the division of the food previous to its passage into the stomach, but in birds the process of mastication is either imperfectly performed, or carried on by a peculiar mechanism to be afterwards described. Birds are unprovided with those soft and flexible parts called lips; the aperture of their mouth is made by the protrusion of the two jaws, which are covered with a hard and horny substance. These are named the upper and the lower mandibles, and together form the beak or bill. The bone which enters into the composition of the bill, will be considered along with the other parts of the skeleton. The external or horny part is produced, like other similar structures, from a vascular and spongy membrane, which is interposed between it and the bones; it corresponds exactly in shape with the jaws, which serve it as a mould.

The bill is defined for many different purposes, and consequently is subject to great variety in its constitution. In the birds of prey it is strong, hooked, sharp, and furnished with a tooth-like preciss on its edge, to enable them the better to seize and lacerate their prey; those birds which inhabit small grain, are provided with short, pointed, sharp-edged bills for picking up and breaking their food; the parrots also use their bills for dividing their meat: in those in which the bills can be compared, as it is incapable both from its thin edges, and from the nature of the articulation of the lower jaw, of performing any thing like the grinding motion in which poultry mastication consists.

The **pigeon** birds have commonly large and extended bills, which become necessary to them, in order to secure their prey; these birds almost always swallow their food without chewing it. **Swallows** and **goat-jack** ty have short bills, but opening very wide, suitable to their mode of procuring their food, which consists in taking flies while the bird is on the wing.

The **wood-pickers**, ***, **, &c., use the bill as an instrument for perforating the bark of trees, and breaking nuts; for which purpose it is constructed like a wedge.

It may, in fine, be given as a general remark, that the form and structure of the bill indicate the peculiarities and economy of the birds; they have therefore always been employed by naturalists as classificatory distinctions, and to their works we refer the reader for a more detailed account of the peculiarities observed in the bills of birds.

In consequence of a particular mechanism, arising from two additional bones, the upper jaw of birds is capable of a certain degree of motion. In general this is very confined, but the parrots tribe are able to move the upper jaw with considerable freedom. The bones and muscles upon which this peculiarity depends, will be described with the organs of motion.

The cavity of the mouth is lined with a thick vascular membrane, behind which are placed a great number of follicular glands, which discharge a mucous liquor upon every part of the surface of the mouth. They are, however, not abundant in those parts which fulminate motion, as the commencement of the oesophagus, and surrounding the aperture of the nares, in the upper and back part of the mouth.

A cuticular membrane is spread over the glandular membrane, which is as useful to soft and delicate, that it cannot without difficulty be detected.

The tongue of birds can hardly be considered an instrument of mastication; its motions are very limited, in consequence of its containing a bone which runs through its whole length, and the lingual bone being articulated with the hyoides, which determines the extent of its movements. The only birds, in which the tongue is immediately considered in the division of the food, are those **peppers** living upon seeds that are included by a bill. In such the tongue is employed to convey the food between the edges of the bill, and secure it there until it is broken, which is not unlike the action of the tongue of mammals during mastication.

The tongue of the **wood-pickers** and **cary-nests** is an organ of curious structure, and enables these birds to transfer their prey at some distance from the mouth; the mechanism by which this is accomplished, and the bones and muscles which belong to the tongue in general, will be particularly described with the other organs of motion. The varieties in external form, and the structure and integuments of the substance of the tongue, will be considered under the head of the organ of taste.

Salivary glands have been ascribed by most authors to birds; but, as it would appear, without due considering the uses of these parts. Birds, as already observed, do not communicate their food by mastication in the mouth, for which purpose the saliva is employed by other animals; and the glandular bodies, which have been described as salivary, appear to yield a fluid of rather a mucous than an aqueous nature. The internal surface of the mouth of birds is lined with mucous, in order to facilitate the passage of the food, which would not be necessary, if the aliment were licked by saliva.

The reputed salivary glands of birds are situated within the angle formed by the anterior part of the lower jaw, and between the skin and the inner membrane of the mouth. They are two in number, and appear to be composed of granular mucus, or sordes, closely connected to each other. They discharge their secretion into the lower part of the mouth, by means of some foramina arranged on each side of
the tongue. They would seem to be of the greatest size in proportion to the bird, where the food is hard and dry grain; they are larger in the common fowl than in the goose.

The Parian academicians observed these glands in almost every bird they dissected. In the goshawk they describe them as being situated towards the pharynx; and in the buffard, they found several glandular bodies.

**Oesophagus.**

The tube, which conveys the food into the stomach of birds, is not situated exactly on the fore part of the neck, but a little on the right side. It is partially covered by the trachea, and is connected to all the neighbouring parts by loose cellular substance; in consequence of which, and the want of a fixed bony attachment, the neck is much bent, it does not take the same degree of flexure, but falls a little off to the right side. This effect is best observed in some of the birds which have long and flexible necks, as the gosling and water birds.

The form of the oesophagus varies according to the habits of the bird, and the nature of its food. In the capacious birds, and those which sball on fish, it is of great capacity throughout its whole length, generally extending in width the stomach itself. The magnitude of the oesophagus not only enables those birds to swallow their prey whole, but answers the purpose of a repository for their food, and thus counterbalances the disadvantages arising from their precarious means of subsistence.

*H. ronie, the common Oystercatcher, &c.* will devour as much fish at once as will be sufficient to support them for a considerable time; and an ool is often obliged to exist for days or weeks upon a rat or mouse, which being swallowed, is conveyed by degrees into the stomach, until the whole is digested.

All the pescivorous birds have the oesophagus most capacious at its commencement, or next the faucæ, for the more convenient swallowing of their prey, which is always gulped down.

The *Pisces,* furnishes a most remarkable instance of a dilatation of the faucæ, in the pouch which is placed beneath the lower jaw. This bag, if full, is very conspicuous externally; but when it is empty, the bird has the power of contracting it very considerably; when completely distended, it is said to be capable of containing ten quarts of water. The internal part of the pouch appears to possess the same structure as the rest of the oesophagus; the skin covering it externally, is clothed with a short down, smooth and soft, like silk.

The *Pelican* derives a double advantage from this enlargement of the faucæ; it enables it to provide a supply of food and water for future necessity, and to transport nourishment to its young, until they can acquire it for themselves; in digorging the food for its family, the parent presses the bottom of the faek against her breast, and thus discharges its contents; from which probably arose the absurd fable of her opening her breast, and feeding her young with her blood.

A very remarkable provision of this kind has been described in the buffards, by Dr. James Douglas. In this animal there is a membraneous bag, extending for some way down the fore part of the neck, capable of containing several quarts of water; it communicates with the mouth by an aperture beneath the tongue. See *Plate I.* fig. 1. in the *Anatomy of Birds,* in which this part is represented, as it has been figured in Edward's *Natural History of Birds,* vol. ii. p. 73. *a* the pouch, upon which a ligature is fastened near its connexion with the mouth, *b* the trachea, and *c* the oesophagus.

The pouch of the buffard is confined to the male bird, according to most authors; some have, however, ascribed it to the female, and others have doubted its existence altogether. The Parian academicians dissected six buffards, and do not describe the throat sac, although all their subjects were males.

The buffard is said to use the pouch as a temporary reservoir of water, from which it supplies the female during the period of incubation, and likewise the young brood, until they can move from the nest. It has been also occasionally employed as the means of defence. Barington relates in his *Miscellanies,* p. 553, that at Morocco, where it is usual to fly the hawk at the buffard, the latter has been known to eject the water contained in the sack against his affianant, who is not uncommonly battered in the pursuit.

The crop, or coeexus, is a term applied to another species of dilatation of the oesophagus of birds. When this enlargement is single, it is situated upon the right side of the oesophagus, and placed so low on the neck, that a portion of the bag is accommodated in the space left at the upper part of the thorax, within the fold-shaped bone. Its form is in general globular, but rendered somewhat irregular, from its connexion with the oesophagus, which enters at the superior part, and appears again on the middle, by which means the greater part of the crop is formed into a cul de sac.

It is obvious, that the effect of this structure is not only to receive a greater quantity of food than can be digested, but also to detain it in the crop until it has suffered some change.

The birds in which the crop is found of the figure just described, feed usually upon grain or other hard substances, which require to be softened by maceration in the mucous secretion of the oesophagus. Of these we may mention the turkeys, the pheasants, the common fowl, the pinnate, the turkeys, the Indian fowl, the parrots, &c.

*Fig. 2.* of Plate I. in the *Anatomy of Birds,* exhibits the crop of the *Pheasant,* the *Ostrich,* and the common *Crawl,* the crop of the *Pheasant,* the *Ostrich,* and the common *Crawl,*

The Parian anatomists found the oesophagus very much enlarged in the goshawk, but to close to the gizzard that these two parts appeared to be confounded with each other; so that it was difficult to mark the superior orifice of the ventriculus; the situation of the bag also was very unsafe, being lower than the gizzard, into which the entrance was by the bottom, and thus what is commonly called the superior orifice, was really the inferior.

It is somewhat remarkable, that the *Buffard,* which is a graminivorous bird, and in most respects resembles those which have crops, should be quite without this provision, its oesophagus consisting of an equal and regular tube.

The *Parrot* has a dilatation of the lower part of the oesophagus, which is commonly reckoned to be a crop, though perhaps improperly, as the enlargement is neither so readily produced, nor in such a degree, as to obstruct the passage of the food into the stomach; the crop of the parrot is only calculated, therefore, to afford a temporary accommodation to its food.

Some carnivorous birds are furnished with a crop, which only serves the purpose of a reservoir, as their food does not stand in need of maceration to soften it, which is so necessary with hard and dry grain.

The most singular kind of crop is that found in the *Pigeon* genus. The oesophagus in these birds is of great capacity, from its very commencement, and at its lower part it swells out into two large fleshy masses, between which and the stomach it suffers a considerable contraction. See *Plate I.* of the *Anatomy of Birds,* fig. 3. *a* the upper portion of the oesophagus.
In some species, as the *pigeon*, the esophagus above the crops, is of such great dimensions, that the latter are hardly discernible; the birds also have the power of distending their esophagi with air, which gives them that grotesque appearance from whence they derive their name.

A crop is more necessary to the pigeon than other birds, both because its food requires long maceration, and because the young, and even, on some occasions, the females, draw their sustenance from this repository.

The extraordinary change which occurs in the structure of the inner membrane of the crops of the pigeon, by which a milky fluid is secreted, for the nourishment of the young birds, will be described in its proper place.

Although there is no distinction in the form of the esophagi we have described, the internal structure appears to be the same in all birds. It forms the external cellular covering, by which it is connected to the adjacent parts; it possesses a muscular coat, an internal vascular tunic, and a cuticular lining. The mucous layer consists of two layers of fibres; in the exter al layer these are not clearly, or properly circular; the other, thinner, is composed of longitudinal fibres. The muscular coat is only strongly marked at the top of the tube, where the actions of deglutition commence; and on the crops, where support and motion are required. The internal coat resembles in structure what is usually met with upon the inner parts of cavities; with the difference, that it is provided in birds with an extraordinary number of follicular glands, which pour out their fluid through numerous foramina, resembling pinholes, upon the external surface. These glands secrete a quantity of mucus, which is employed in macerating the food, while it is detained in the esophagus, or crop. This secretion is remarkably copious. Spallanzani introduced a piece of sponge into the crop of a pigeon; and after it had remained there twelve hours, he expressed from it above an ounce of mucus, and the quantity obtained from a turkey, amounted to seven ounces in ten hours.

The follicular glands are most numerous at the commencement of the esophagus, and towards the termination of this tube in the stomach, the inner surface of the crop is but sparingly furnished with them. See Plate I. of the *Aviary of Birds*, fig. 2, in which the esophagus and crop are inverted, for the purpose of exhibiting the surface of the mucous follicles, and in fig. 3, they assume a longitudinal and regular appearance below the dilated parts of the esophagus. It is very common for the mucous gland, to be assembled in a regular and marked manner round the very termination of the esophagus, as in Plate II. fig. 2, of the *Aviary of Birds*.

The tube, which constitutes the esophagus, is generally thin and tender, but in some cases of great size, it is also strong and firm, and in others, it is also smooth and elastic. The intestinal part of the esophagus terminates abruptly at the zone of gastric juice.

It may be remarked with respect to the esophagus of birds, that it is covered on the outside with a smooth and semi-transparent mucous coat, which is produced and secreted by numerous glands. These are, in fact, entirely dependent upon the very cellular structure of the stomach, which we shall next describe.

The organ of digestion in birds consists of two parts; one for producing the digestive fluid, and the other the receptacle in which the conversion of the food is effected. This apparatus for the secretion of the gastric juice is called

The *Belullus glanduliferus*, or the Zone of Gastric Glandules—This part is situated at the termination of the esophagus, and appears in some instances to be the continuation of that tube. It has the same cellular and muscular coats, which obscure its real structure, when perceived externally, especially in the granivorous birds, which have strong muscles upon the esophagus. When the outer tunic are removed, a number of small, hollow bodies are exposed, arranged with the most perfect regularity, and closely applied to each other. They assume an indistinct granular appearance in small birds generally, and even still more so in those which feed on animal food, as the *aphisinae* and *pehacranes* birds; but in the *oiures*, and the large *granivorous* birds, as the *pigeon*, etc., the gastric glands, when divested of their coats, are readily discovered, by the naked eye, to be small cylinders, or tubes, placed horizontally with respect to the posterior of the stomach; the external end is closed and of a rounded form; the internal extremity of the tube is sometimes cleft, and contains a small foramen, which is applied to a corresponding hole in the internal membrane of the bulbous glandules. See Plate II. in the *Aviary of Birds*, fig. 1. It represents a number of the gastric glands, with their external extremity expanded, by a portion of the muscular coat being removed; and in fig. 2. shows the oriiffes of these glands upon the internal coat of the stomach, by which the cut edge of the bulb, with the cylinder as they are placed between the muscular and internal coats. The subject of both the figures is the *callous zone*.

The gastric glands commonly commence the beginning of the stomach as a perfect and equal zone. In some instances, however, where they are not large, as in the *caprimulgus* and *fissipavine* birds, they are more numerous at one part of the stomach than another; see Plate III. fig. 2, which exhibits the stomach of the *hare*, *B. b*. The glandular bands of the stomach are not quite regular in the *sph 칼*; the structure of the glands also is not the same as in other birds; indeed being placed in regular and definite order, they are disposed in masses of an unequal form and size, separated for some distance from each other. On making a section of the mucus, they are found divided, or interrupted by processes of strong white cellular fibres; from which it would seem, that they are composed of several glands, although there is but one or two belonging to each mass on the internal tunic of the bulb. The magnitude of the orifices of the gastric glands, even exceeds the proportion to be expected from the size of the bird; being capable of receiving the head of a large pin, they stand at a distance of about 1/8 of an inch asunder, and do not appear with perfect regularity upon the internal surface of the stomach, being most crowded towards the centre, where their apertures are largest; the internal tunic of the stomach, from these circumstances, exhibits a worm-eaten appearance.

The gastric glands in all birds, like other parts, which produce an important secretion, are endowed with an extreme degree of variegability.

Some authors have described a cuticular coat, on the internal surface of the bulbous glandules, which they have compared to select on account of its soft and flamy texture; it appears, however, very doubtful, whether this covering should be considered a tunic or not; we have observed the tissues deeply stained, and wholly water; it certainly bore no resemblance to the epidermis of the esophagus, and filled the substance which invests the remaining portion of the stomach, or gizzard.

No very fatal experiments have yet been made upon the nature of the digestive fluids of birds. When it is exposed from the gastric glands, which is the only mode of obtaining. 
obtaining it pure, it is observed to be of an ash or pale yellow colour, turbid, and of a tenacious consistence, like mucus. Spallanzani found it in several birds to have a bitter and salt taste, which he attributed to a mixture with some of the fluids contained in the intestines; he discovered also, that the turbidity and the colour were produced by the existence of a number of yellow particles, too minute to be distinctly seen without the aid of the microscope, and which in a few hours subsiding to the bottom, left the supernatant liquor as transparent as water. He has remarked the yellow tinge to vary in intensity, according to the species; in the eagle, for instance, it is chasitrous, and in the crow a reddish yellow colour, like the yolk of an egg.

A number of the experiments performed by Spallanzani, although in some instances he failed, showed that the gastric fluid of carnivorous birds will act upon vegetable matters; and upon the other hand, that graminivorous birds can digest animal food; but his most interesting and important experiments on the properties of the gastric fluid, is that made to determine its powers of reftilling the operation of cold. "On a very cold day in winter," he says, "I exposed a small quantity (of the gastric juice of the eagle) in a glaft, on a window, along with two other glasses containing water, in one of which was diffolved a quantity of common salt, sufficient to give it a stronger tinge than the gastric fluid had. The thermometers placed beside the glasses stood at five degrees below o (twenty and threefourths, Fahrenheit). Of the three liquids, the first that was frozen, was the common water, the next was the salt water, and the last was the gastric fluid.

When I carried them into my apartment, where the temperature was three and half deg. above o, the first that thawed was the gastric fluid, next the brine, and lastly the water." The conclusion which necessarily results from this experiment is, that the gastric juice of birds, and from analogy, that of other animals, is capable of reftilling the effects of cold more than common fluids, or even those impregnated with a great quantity of salt; and therefore it may be considered as possessing some degree of vitality. If this supposition be admitted, it determines the nature of the digestive processes, so long a question in physiology.

The gastric fluid of the crow has been submitted to chemical examination by Scopoli, by which he discovered that it contained a quantity of gelatine and serous substance, some muriate of ammonia, and plophate of lime, with a large proportion of water.

The second part of the organ of digestion of birds, is not less singular than the structure just described; it immediately succeeds the zone of gastric glands, and when in the natural situation, occupies the left region of the abdominal cavity, in which position it is retained by the several reflexions of peritoneum, which constitute the air cells. From being the part into which the food is received in order to undergo the process of digestion, it has commonly received the distinctive appellation of stomach; but it would seem more confident, not only with the form of the digestive organ in some birds, and with its functions in other animals, to apply the term stomach, both to the gastric glands, and to the mucous bag which immediately receives their secretion, and the food; or for the greater convenience and clearness of description, the lower portion of the stomach, from the name of ventricle.

The greatest variety exists with respect to the structure of this part of the organ of digestion in birds: when it possesses a certain degree of mucularity, it is well known under the name of the gizzard; and when its mucus are so thin as to give it the appearance of a sappy bag, it is commonly, though erroneously, called a membranous gizzard.

Tournoy attempted to establish three classes of birds, according to the formation of their stomachs, calling the one Gastrulorum, and the other Hymenobrachia, but these terms were only applicable to the two extremes.

Vie d'Azir has admitted three distinctions in the structure of the stomach: the first that of the true gizzard, which gives infusions in the galle, the fowm, the goofy, &c.; the second where the muscles which compose the gizzard are not distinct from the other parts, nor very strongly marked, as in the thrush and jog; the third is the membranous stomat which it is called, which is found in the brm, eagle, cor- morant, &c. See the Introduction to Vie d'Azir's great System of Anatomy.

These distinctions are not, however, just; the gradation from the most muscular gizzard to the thinest ventricle, is regular and uninterrupted; in order to understand which, and the other variations in structure, it is necessary that the true gizzard, or muscular stomach, be first described.

The external form of this organ is usually an irregular oval, the two ends of which are made of the great lateral or digastric muscles.

This muscle constitutes the principal mass of the gizzard; its attitude with respect to the bulbous glandulofus is oblique. The two fleshy portions are united by means of a strong tendon, on each side of the gizzard, which in the centre is distinct from the portion of the ventricle.

The portion of the gizzard, which separates between the two fleshy masses of the digastric muscle, and which is covered by the tendon, belongs to the cavity of the ventricle; it is composed of fleshy fibres, passing in several directions, as may be most convenient for diminishing the cavity. Many of these fibres are continued into the substance of the digastric muscle, and others are in its outer margin, thus giving integrity and connexion to these two portions of the ventricle. See Plate II. fig. 1, in the Anatomy of Birds, which represents the external appearance of the stomach of the wild fowm, bb, the fleshy parts of the digastric muscle, a, the tendon connecting them to each other, dd, the parietes of the ventricle on the superior part, e, the same, inferiorly, f, the margins of the digastric muscle, with fibres passing along them.

The disposition of the fibres in the interior of the digastric muscle is exceedingly curious. They appear, upon a superficial view, to be arranged in thin concentric laminae, separated from each other by the most delicate tendon. These layers pass to the lateral tendons on the circumference, so that their force is exerted upon them. See Plate III. fig. 1, which is the section of the gizzard of the goofy, a a, the two great masses of the muscular substance, bb, the tendons by which they are connected to each other. But if another section be made, parallel to the sides of the gizzard, or across the concentric layers, we have found each of the laminae to be divided by a great number of delicate tendinous processes which form with each other squares and triangles of various shapes, producing a reticulation, not unlike a honeycomb. The extraordinary multiplication of muscular fasciculi, which arises from the lamellated and reticulated structure of the gizzard, creates a force which almost surpasses calculation.

On laying the gizzard open by cutting through the tendon, which is the thinnest part, it is observed to be covered internally with a rude, callous fibres, of a dark brown colour; this is thin and pliable upon the portion of the ventricle, not included by the digastric muscle, and partakes of the motions of the cavity; but when it covers that muscle, it becomes as tough and inelastic as the hoof of a quadruped: two oval surfaces are seen to project beyond the other parts; they are raised upon the interior of the thickest portions of the digastric muscle, and the horny integument when
when passing over them acquires nearly the thickness of an
eight of an inch. Plate II. fig. 2, in the Anatomy of Birds,
shews the gizzard of the wild fowm laid open, $d$ the divided
tendon, $e$ the cuticular or horny covering of the gizzard,
ending decidedly at the commencement of the intellec,
and below the zone of gastric glands; at the latter place the edge
is shewn detached, $f$ the two prominent oval surfaces, $g$ the
origin of the intellec, which being cut off short on the
outside permits the light to appear through it.
The cavity of the gizzard differs very much in shape and
extent from what might be expected, from the external
figure of that organ. When all foreign matter has been
removed, the two prominent oval surfaces approach each
other, leaving only a slit between them; any thing that de-
serves the name of a cavity, is situated above and below the
place where the tendons cross (see Plate II. fig. 2.), for just
within the tendon there is not cavity sufficient to contain the
end of a finger. See Plate III. fig. 1, which shews a section
in which the two oval surfaces are applied to each other,
leaving at either end the appearance of a round hole, by
means of which the superior and inferior cavities of the ver-
tricle have communication.

When the horny or insensible lining is removed, there ap-
pears another coat to the gizzard. This is soft, somewhat
spongy, and endowed with vacularity; it is intimately united
to the muscular substance of the ventricle, on one side, and
on the other affords a surface for the adhesion of the horrry
coat; the connexion with which appears to depend upon the
mutual insertion of villous processes, too fine to be distinctly
perceived by the naked eye.

Such is the description of the muscular ventricle, or true
gizzard, as it exists in the swan, the goose, the duck, the phe-
sant, and common fowl, the pintado, the turkey, and a few
others. In few of the greater number of birds, there is a
deviation from the structure of the gizzard. The digialtric
muscle is less powerful, its tendon is incorporated with the
parietes of the ventricle; the oval, or grinding surfaces, are
little or not all distinguishable from the rest of the cavity,
which is therefore of larger capacity; and, lastly, the sub-
fintance lining the ventricle is less tough, thick, and hard,
approaching more to the nature of cuticle. It would be
collass to enumerate all the different instances of intermediate
structure, which we and others have observed; suffice it to
say, that it exists in almost all the fowlfes, or small birds which
fobbit upon a mixed food, such as grain, worms, insects, and
fruits; also in most of the order fowlfes, and in many of the
gralle and afnere, which are parivated as game. In all which
instances the deviation from the true structure of the gizzard
varies in degree according to the nature of the food fuced by
the bird; may, differs from this cause in the same individual.
Thus the gull has a strong muscular ventricle, when fed upon
grain, which, if the bird be supported by fill, becomes so
thin as to approach the membranous stomach.

It is remarkable, that many birds which live upon grain
and hard substances, have neither a very muscular ventricle,
or the horny integument very thick. This is the case with
all the fleshfes birds, and some gallines, as the buffard.
The stomach of the officin is capacious; the digialtric
muscle is thin, considering the size of the bird, and the na-
ture of its food; and the cuticular coat is so folt, that it has
been aptly compared by several authors to flannel. The
Parisian anatomists describe the stomach of the caffenerary
as being thinner than that of the officin, and divided into
two parts by a valvar projection of the inner coat.

When the digialtric muscle becomes so thin as to form a
mere layer of fibres, in close union with the other coats of
the stomach, and its tendons only fine aponeuroses, expanded
on each side, the ventricle is termed membranous; an im-
proper appellation, inasmuch as the very same parts exist,
which belong to the powerful and mitful gizzard, although
in a diguized and diminished form, and unequal to the same
functions; affording thus a curious example of the uniformity
with which nature copies her own works.

This species of stomach is almost confined to the accipitres,
or rapacious birds, and those on which the galle and afnere,
which feed on fish. The woodpecker also posfesses it, and prob-
ably it may be found in some foreign birds, which live on
insects and fruit.

The subfintance lining the membranous stomach is much
thicker than common cuticle. It is occasionally folt, and
almost of a glutinous consistence, and easily detached from
the internal coat of the ventricle.

The shape of this kind of stomach is usually a semi-oval,
or the section of an egg. Several of the officinaria birds, as
the heron, bittern, pelican, &c. have, however, a second
chamber, through which the food passes in its way to the
intellec. See Plate III. in the Anatomy of Birds. Fig. 2.
is the stomach of the bezon; $a$ the lower part of the esoph-
gagus, appearing smaller than it really is, from being thrown
into foids; $b$ the zone of gastric glands, distinctly seen through
the coats of the stomach, in consequence of the cavity being
dented with a transparent fluid, and afterwards placed against the light. If Spallanzani had em-
ployed the same expedient, he could not have denied the
existence of a distinct glandular structure to the bezon; $c$
the inferior part of the stomach, chiefly composed of muscular
fibres, spreading in a radiated manner from the lateral spon-
necrals; $d$, which supplies the place of the great tendons
of the digialtric muscle; $e$ the second stomach, furnished
with circular muscular fibres; $f$ the first intellec arising
from the additional ventricle. The communication between
the two stomachs is very straight in the pelican.

Having described the structure of the digestive organ
of birds, it remains to consider its functions. In those cases
where the muscle power of the stomach is inconsiderable,
and the cuticular coat thin and foft, digestion is carried on
in the same way as in man and other animals, with this dif-
fERENCE only, that the gastric fluid is furnished by a distinct
apparatus of glands, instead of being secrected by the whole
surface of the cavity. In the true gizzard, however, we
perceive an extraordinary departure from the common
structure of the organs of digestion. This part supplies
the place of the teeth of other graminivorous animals. In its
mechanic powers and action it resembels a mill; the upper
part serves as the receptacle for the grain; the two internal
projecting oval surfaces correspond to the mill stones, and
the intellec lining receives the substances in the ground or
divided state. The experiments made at the academy of
Cimento, and those of Reanurn, Spallanzani, and others,
shew that the gizzard is a machine of no ordinary powers.
These experiments confided in compelling birds to swallow
hard and unyielding substances, and, after some hours, ex-
amining what effect were produced upon them.

When bills of glass, or other brittle substances, were em-
ployed, they were speedily reduced to powder; metals and
precious stones were conibined or reduced. Spallanzani in-
roduced into the gizzard of the turk and common fowm,
leaden balls, armed in one instance with two sharp needles,
one quarter of an inch long; and in another, ft with as
many lance points. Upon destroying the birds 18 hours
afterwards, the needles and balls were found broken off,
and marks of impaction appeared even upon the balls them-
selves; and, what be considered more extraordinary, the
coat of the gizzard were perfectly unfurst. When we con-
side
BIRD.

Sider the immense strength which is obtained by the arrangement of the muscular fibres in the gizzard, and the horny consistency of its inner coat, there appears nothing incredible in these effects. And there is still another circumstance, not before mentioned, which fully accounts for such extraordinary powers of triturating: every muscular bosom or gizzard contains a number of small stones or pebbles; the size of the stones is proportioned to that of the bird. Their number is subject to vary from many accidental causes. Two hundred have been reckoned in a turkey-ben, and above a thousand have been taken from the gizzard of one goose.

Spallanzani denied that these stones were at all required for the comminution of the food. He has endeavoured to support his opinion by several experiments, which are, however, not clear or convincing with each other, and in contradiction to general observation; for it is well known, that birds do not thrive when they cannot obtain small stones, and that it is part of the duty of the parent to provide them for their young, before they leave the nest. Spallanzani acknowledges that he could not procure any bird so young, that it had not some stones in its gizzard; and therefore he was obliged to rear pigeons and turkeys even from the shell, before he was able to succeed. Birds, far from swallowing stones from kennels of appetite, or in mirth for food, seek out and select those most suitable to their purpose, which are almost all bits of quartz, of an equal size, and a roundish figure, with many small sharp angles.

Large birds, as the feralious bird, the bufard, &c. are in the habit of swallowing coins and pieces of metal, which necessarily suffers a reduction by the friction to which they are exposed; and hence has arisen the ridiculous notion of the offish digesting iron.

We have no hesitation in deciding, that the extraneous bodies found in the gizzard are absolutely required for the perfect division of the food used by those birds that employ them. In further proof of which opinion it may be mentioned, that they are proportioned in quantity to the degree of muscularity possessed by the ventricle, and the nutritive quality of the food; and that those birds which have thin stomachs, and live upon animal food, never designedly swallow stones, or other indigestible substances.

In order to ascertain the mode of operation of the gizzard in the living body, Reaumur opened several fowls during the process of digestion. One instance alone threw any motion in the part, which consisted in alternate contractions and dilatations, slowly and gradually performed. Spallanzani instituted similar experiments upon several birds, with no better success, being seldom able to detect the least motion; and when he did perceive any, it was irregular, partial, and indistinct. This he attributed to the violence committed by opening the animal's body, which no doubt causes the motions to be less strong and regular; but the gizzard's exhibiting externally so little action, depends upon the disposition of the fibres in the interior of the digestive muscle, which are calculated, not for performing extensive motions, but for exerting an immense concentrated force upon whatever may come within their influence.

The most satisfactory, as well as convenient, mode of examining the actions of the living gizzard, is to provide a very lean, young bird, which has thin parites to the abdomen. The side of the belly being deprived of feathers, all the motions of the gizzard can be both felt and seen. We have thus ascertained them to consist in alternate contractions of the digestive muscle, and of the intermediate parts of the ventricle. When the muscle acts, its figure is not perceptibly changed, but it feels as hard as a stone; upon its relaxation, the parites of the ventricle urge their contents again between the two grinding surfaces, when the muscle repeats its powerful contraction, by which the substances interposed are submitted to a pressure like that of a vice, accompanied by a slight rolling motion of the surfaces upon each other. These alternate actions succeed each other very slowly, but with regularity.

When the food and stones roll under the pressure of the digastric muscle, a sound is heard exactly like what is produced by the tide coming upon a shore, where there are many loose stones. This occurs with the same intervals of time, also, which are observed between the flux and reflux of the tide; and if the ear be applied to the body of the bird, during the time that the gizzard is in action, the sound of the ebbing and flowing of the tide is imitated so perfectly in loudness, and every other respect, that it is difficult to conceive it is occasioned by any other cause.

During the time that the food is undergoing a very minute division, in the manner described, the gastric juice is diffiluted from the bulbus glabulinosus in greater quantity than usual, and a more intimate mixture is formed of the digestive fluid and the triturated food, than could be accomplished under any other circumstances; and therefore we may look upon the process of digestion in granivorous birds, as not only more complicated, but more perfect than it is in animals in general.

Intestines.

These are divided in birds, as in other animals, into great and small, although the terms are not very appropriate; there not being in general any material difference in the magnitude of each.

The small intestines exceed the large very much in length; they are situated chiefly in the anterior and right side of the abdomen, where they are strictly confined by the processes of peritoneum, which form the sinews. The convolutions of the intestines are very regular, and consist in successive doublings one shorter than another, which give the appearance, on opening the abdomen, of a coil of rope, particularly in those birds which have the small intestines of considerable length. This effect depends upon the figure of the mesentery, which is not composed in quite the same manner as in mammalia.

The division of the small intestines into duodenum, jejunum, and ilium, is at all times to a certain degree arbitrary, and is still less allowable in birds. The only portion which deserves to be distinguished from the rest of the tube, is the fist coil; which ascends on the right side of the stomach, including in its reflection the pancreas, and receives the biliary and pancreatic ducts.

The length of the intestines is determined usually according to the nature of the food upon which the bird lives; they are longest in the granivorous, and very short in the accepites. Many birds, however, which use a mixed food, or even live altogether upon fish, have the small intestines of great length; this is the case with the heron, and several others. The whole of the intestines of the corvornant, according to the Parisian anatomists, measured seven feet long; and what is difficult to explain, those of the bufard and capercay, although large and granivorous birds, were only four feet in length. The different offish distillated by the Academy, varied materially with respect to the length of the intestinal canal, one subject measuring fifty feet, another forty-two, a third thirty-three, and a fourth twenty-nine feet.

There is very little peculiar to be noticed in the structure of the small intestines. They are, as in other animals, covered externally by peritoneum, have two layers of muscular fibres, and their internal surface is furnished with those innumerable fine vascular processes called vili. The granivorous.
true birds have commonly the longest villi; in the goose and
swan they are irregularly beautiful, floating a considerable
way into the cavity of the intestine. The birds of prey, and
those which feed on fish, have the villi in general too small and
insignificant, that on a slight injection, the inner surface of
the intestine appears quite smooth. The coel, however, forms
a remarkable exception to this observation in having long and
pendulous villi.

The vascular processes upon the internal surface of the
small intestines of the sdf'k do not possess the usual villous
or hair-like form, but consist of very thin plates, or lamellae.
These are short, with the edges somewhat round, and placed
not in succession, but alternately one with respect to another,
so that each lamella stands opposite to the interstice of the
two adjoining, by which means the surface of the intestine
presents very exactly the appearance of twilled cloth. The struc-
ture producing this effect cannot be seen completely, as
may be supposed, without a magnifying glass.

We have not observed in birds any thing analogous to
those projections of the internal coat of the small intestines,
which in other animals are called culda enuniventres. The
Academicians, however, relate that they found in the buffal
the inner tunic of the ilium folded longitudinally, in the
manner of the left flamach of ruminating animals, and that
the two extremitics of this extintine there were some trans-
verse wrinkles, which supplied the place of the valve of the
colon.

Throughout the tract of the intestinal tube, we have dis-
covered several clusters of mucous glands; where these are
situated, the internal coat appears as if slightly ulcerated, or
not unlike a dyenteric intine, instead of that regular
dotted figure which the mucous glands commonly exhibit in
mammalia.

The great intestines, as they are called, bear no fort of pro-
portion to the small, in point of length: in many instances,
even where the latter are of considerable extent, they do not
exceed a few inches. They only admit of division into two
parts: the coccal appendages, and the continuation of the
tube until it terminates at the anus. The first correspond
with the intestinum cocceum of mammalia; and the other
takes the place of the colon and rectum; but which from its
extreme shortness and direct course to the anus, would
appear to deserve only the name of rectum.

The coccal appendages are subject to as much variety as
perhaps any other part of the structure of birds. Generally,
they are two in number; in which case, they arise rather ab-
ruptly from opposite sides of the intestinal tube, about the
place where the convolutions cease, and the intine becomes
straight.

It may be received as a general rule, to which, however,
there are some striking exceptions, that the magnitude of the
cocca is in proportion to the musculature of the ilamach; we
accordingly meet with this organ of the greatest size, and the
strongest characters in the gallinae and other gramar-es-
new birds, from which it will be found most convenient first
to take the description.

The cocca in these birds commonly ascend for some way
quite close to each side of the intine, from which they
arise; during which they are left on the other parts of the
intestinal canal; they then make a flight curve outwards,
and become somewhat enlarged, and towards the superior
extremity they again diminish before their termination in the
col desoe. These parts reach up in the abdomen to near the
iver, and often make a flight curve round the ilium; they
are connected to each other, and to the intine between them,
and also retained in their relative situation in the ab-
domen, by reflections of peritoneum, of which some are ana-
lagous to the meso-colon and meso-rectum, and other con-
tribute to the formation of the air-vells. See Plate III, in
the Anatomy of Birds. Fig. 3, represents those parts in the
pinata, or guinea hen; a the small portion of the small intesti-
ne placed between the two cocca, b the coccal, c the rectum, d
the peritoneum connecting these parts, e a processes of perito-
neum pulling out from the top of one cocce to another.
If the cocca be slit open, it is found that they communicate
with the return by an aperture which is smaller than their
own cavity at the place; and consequently, any substance
will pass with difficulty into them from the other intestines,
and likewise be obstructed in its return.

Just within the entrance of each cocceum, there is a clus-
ter of mucous glands, which appear like two spots of ulceration.
These are particularly useful in this situation to smooth
the passage of habitations in and out of the cocceum.

The contracted parts of the cocce are in some degree vil-
ous on the inner surface, and ressemble in structure the out-
let of the intestinal caudal; but the dilated parts are deprive-
of villous, possess very little vincterality, appear to have few, if any,
mucous fibres, are without mucous glands, and are little
better than simple membranous tubes. These parts contain
the exuviae of the food.

All the uiles which the cocce serve to animals are certainly
not yet known; and the functions of these organs in birds are
amongst the least understood. The magnitude of their
cocce is not always in proportion to the apparent necessity
for such referors; often, when they might be expected
large, they are small, or absent altogether, and sometimes,
where the nature of the food would not seem to need these
repositories, they are of considerable size. With the view of
determining their uiles, they were removed from the living
hen, and the consequent is said to have been, that the ani-
mal would not admit any food from the crop into the gizz-
yard, from which it might be inferred, that these organs
serve other and more important purposes in the animal
economy, than mere referors of excrement; that, how-
ever, they are employed as a sort of temporary fewers, to
receive the undigested parts of the food, is obviously true;
and that in doing so, they answer an useful purpose, appears
to be proved, in the instance of some exceptions, by the more
numerous instances of their bearing a decided relation to the
digestive organs, and the quality of the food.

The same structure which has been described in the guinea
hen, or pinata, is to be found with little variation in all
the gallinae except the pigeon, and in the hermaphroditic anates,
such as the fowal, the goose, &c.

Daudin describes the cocce of the heath-cook (tetrao wog-
gallus), and of the sobic grous (terraethioprop), as grooved or
fluted longitudinally.

The cocce of the furttich are different from those of other
birds; they are large where they commence, and diminish
gradually towards their termination; they suffer many con-
volutions in consequence of a longitudinal band upon the
abdominal side, which is only two-thirds of their length; they
are faceted, or divided into lobes, throughout their whole
extent, by means of a circular projection of the internal
capsule, which is laid in a spiral manner, similar to the valve of the
diaphragm in the hare and rabbit in mammalia, or the ray
and flank kind amongst birds.

The spiral lamina is about five lives in breadth, but be-
comes somewhat less towards the extremities of the cocce.
This lamellated structure is continued for some way into the
other great intestines, and even into the small intestines; no-
ever, however, as one spiral valve, but in several transverse pro-
genctions, which have a semicircular figure, and are placed alter-
nately, so that one lamella is received between two others,
in the manner of the diaphragm of the bivalve shells. Plate
III, fig. 4, is a portion of the first part of the great intestine.
er colon of the ostrich, represented of the natural size and cut across, to show the semicircular lamina on the inside.

The effect of this structure is obviously the retention of the excrementsitious part of the food for a longer time in the ceca, which is accomplished in other instances by the smallness of the aperture through which these parts communicate with the rest of the intestines. This organ is not similar in the other Fruticibus birds. According to the Pariagan dissectors, the ceco-nary is not provided with any rectum. In the ceco-nary, or (with more propriety) ostrich, of New Holland, we have found two cecal appendages, which opened into the rectum by orifices not much larger than pin-holes. The internal surfaces had none of the laminae, or villar projections, but were furnished with fine villous felci, similar to those of the small intestines of the ostrich; with this difference, that in the New Holland bird, they are placed longitudinally, and are more loose and pendulous, looking somewhat like lacerated portions or shreds of the inner coat of the intama.

In the greater number of birds the cecal appendages are too small to serve any purpose, and appear only as useless imitations of the structure described in the graminivorous kinds. Many, that live on a mixed food, and whose stomachs are of an intermediate strength, amongst the larger passeres, the pica of Linnaeus, the gralle, and the affins, have two ceca measuring in length usually about twice or thrice the width of the alimentary canal from which they take their origin. See Plate III. fig. 5, which exhibits these parts in the gallina. Ceca of this size have hardly any cavity, and seldom receive any of the contents of the other intestines; in the small passeres, which feed upon seeds, as the sparrow and finch tribes, the ceca bear a still less proportion to the size of the rest of the alimentary canal; see fig. 6 of Plate III. in which the ceca are represented as they are commonly found in those birds.

In the pigeon the cecal processes are so small, that they escaped the notice of Sew accurate an anatomist as Severinus, who described the pigeon as wanting them altogether. Fig. 7 of Plate III. exhibits their appearance in the dove.

The carnivorous birds of all others have the ceca of the same length; so much so, in many instances, that their existence has been often denied. Fig. 8 of Plate III. is copied from the Memoirs of the Royal Academy of Paris; it shows the cecal dilatation which was found in the bald buzzard (juco hollinser, Linna.) in place of the cecal processes. On the internal side, however, this enlargement was furnished with a villous membrane, by which a pouch was formed on each side.

The coel appears a very remarkable exception to the common structure of the acceptors, which respect to the formation of the ceca, which both in figure and magnitude are similar to those parts in the gallina. It is difficult to account for this singularity, unless it be supposed necessary to receive the indigestible parts of the animal, which this bird swallows entire.

Some of the piscivorous birds, as the heron, &c. have only one cecal process; it is very short, and in the heron terminates in a pointed manner. See Plate III. fig. 9.

There are instances of the cecal appendages being altogether wanting. They have not been found in the confomy, the cormorant, the bittern (ardna fallaria), the parrot, and the wood-pecker.

That portion of the intestinal canal which corresponds to the colon and rectum of mammalia, as already observed, is very short in birds. In its external characters, it resembles the rest of the intestinal canal, of which it appears to be simply the continuation. The internal surface is provided with villi, which however, are not so long and delicate as those of the small intestines. They are rather very minute eminences than villous processes, especially towards the termination of the rectum, at which place they often assume a decided granular appearance. The inner surface of the rectum in the New Holland ostrich, however, presents an exception to this observation; it is covered with fine and truly hairy-like processes; in this bird also the internal coat of the great intima is slightly folded or wrinkled transversely, in a manner somewhat similar to the valvule conniventes of the small intestines of the human subject.

The termination of the rectum in birds is very usually called the cloaca, on account of its receiving, as a common sink or sewer, both the excrements of the intestines and the urine. There is at this place a dilatation of the gut, which is often only a flight and gradual enlargement just within the margin of the anus; but sometimes it swells out suddenly into a pouch or fack. A remarkable example of which occurs in the parrot; see Plate IV. in the Anatomy of Birds. fig. 1 a the rectum, b the pouch.

The cloaca of the bryall has been found large enough to contain an egg. It is of an oval form; it is situated about an inch from the anus, and the rectum again experiences a contraction previous to its termination in the vent. See fig. 2 of Plate IV. in the Anatomy of Birds; a the rectum before it enters the pouch; b the pouch laid open to expose its interior; c, the contraction within the anus.

In the ostrich, this dilatation is of great size; being capable of receiving one's two fists, according to the report both of the anatomists of the French academy, and of Mr. Warren, who published a dissection of this bird, in the Philosophical Transactions, see No. 354. p. 113.

The use which the anal pouch answers is almost too obvious to be mentioned, which is that of a temporary accommodation to the excrements of the bird, by which their ejection is rendered less frequent.

The cloaca is furnished with somewhat larger muscular fibres than the rest of the intima, and is invested with a reflection of cuticle, which in the larger birds is very palpable. Connected with the cloaca, there is a bag, or pouch, which, taking the name of the anatomist who first described it, is called burfa Fabrici.

The purse of Fabricius is usually of an oval or round figure, depressed on the anterior and posterior sides, and thence always appearing empty. It is furnished with a narrow process, or neck, which is most contracted about its middle. Its situation is on the back part of the cloaca, to which it is closely connected, being inclosed in the same reflection of peritoneum which envelops the rectum. When the peritoneum is dissected off, it is found to be a distinct bag or sack, united only to the rectum by means of its neck, which passing obliquely in the coats of the cloaca, opens into the intima by a slit-shaped aperture. The internal coat of the cloaca projects over the opening like a pouch, and performs the office of a valve, readily allowing the contents of the bag to pass out, but standing in the way of any regurgitation from the intima. See Plate IV. of fig. 2, and the purse of Fabricius in the bryall which is of an oblong shape in this bird; e, the slit by which it communicates with the cloaca.

The size of this bag is in general fairly proportioned to that of the bird in which it is found. In the bryall it has been rated to be two inches long; in the goose, it measures about an inch and a quarter in length, and half an inch in breadth; and in the sparrow, it is about a quarter of an inch long, and half as broad.

The external side of the burfa is smooth and equal, but the internal part is thrown into deep rugae. The folds are disposed in an arborecent form, and branch off with great width.
regularly from a slit which is lodged in the neck of the bag. See Plate IV. fig. 3. in which the purse of the goose is delineated, with its cavity laid open, to exhibit the folds upon the inner surface.

When more closely examined, the structure of this part is very curious. Under the peritoneal covering, it is surrounded by a very delicate expansion of muscle, the fibres of which take a transverse direction. The internal tunics of the purse are made of a thin pellicular membrane, and the folds which have been described, consist entirely of glandular bodies, which are too minute to be distinguished with the naked eye. By employing a lens of common magnifying powers, we have discovered them to bear a great resemblance to the gal- tric glands, being, like them, little cylinders, which are perforated at one extremity to give passage to their secreted fluid; indeed, the only difference which appears between them, is, that the glands of the purse are shorter, being so much compressed in some instances, that they are nearly of an annular form. Fig. 4. of Plate IV. exhibits a portion of the purse of the goose, highly magnified; a, a, the glands composing the folds; b, b, the spaces left between the folds, which consist only of the tunics of the purse.

The fluid produced by these glands, and of which the purse always contains a greater or less quantity, appears to differ in no respect from common mucus. The necessity, however, for example a supply of mucus, as the glands of the peritoneum are capable of furnishing, does not seem very plain, especially when it is considered that the purse of Fabriusc is not met with in all birds. Amongst others, the parrot is without it, as appears by fig. 1. of Plate IV. in the Anatomy of Birds; and yet the parrot has a very large cloaca, and might thence be supposed to need this glandular apparatus, even more than many birds, admitting its use to be the secretion of a mucous fluid, to sheath the cloaca against the action of the excrement and urine.

Although the functions of the purse of Fabriusc cannot be flated with certainty, it may be conjectured that they are not unimportant, from the delicacy of its organization, and its being to rarely wanting. There are a number of black points to be seen within the anus of the parrot, which appear like the orifices of mucous glands; may not these supersede the necessity of the purse in this bird?

The excrements of birds have been ascertained by Vaquer- lin and others, to polish an acid. This is increased by fer- mentation, into which excellent matters rapidly tend, and as it proceeds, the acid gives place to ammonium, which is evolved, towards the end of the process, in great abundance. The dung of the pigeons is found to contain an acid of a peculiar kind, which is increased by the mixture of the faces with water. It is from its chemical properties that the dung of pigeons becomes so serviceable as a manure, and that it is employed in the procefs of some manufactures, and for domestic purposes, as cleansing clothes, &c.

Vaquerlin has also analyzed the fixed parts of the excre- ments of fowls, which being compared with those of the food, afforded some very singular and important results.

For this purpose he fed a hen for ten days upon oats, of which she consumed during that time 111,118,843 grains troys weight; these contained

136,509 grains of phospate of lime, 219,548 silica,

359,657.

In the course of these ten days the hen laid four eggs; the shells of which yielded 98,770 grains of phospate of lime, and 453,417 grains of carbonate of lime. The whole quantity of excrement ejected during the ten days contained:

175,529 grains of phospate of lime, 58,494 grains of carbonate of lime, and 185,666 grains of silica. The amount, therefore, of the fixed parts discharged from the sytem during this period were as follows:

274,328 grains of phospate of lime, 511,911 grains of carbonate of lime, 185,666 silica,

Given out 971,482
Taken in 359,657

Surplus 615,425

Hence it appears, that the quantity of solid matter parted

by the sytem during these days, exceeded the quantity taken in by 615,425 grains.

The amount of the silica received was 219,548 grains,
The quantity given out was only 185,666 grains,

Deficient 34,882 grains.

Consequently there disappeared, during ten days, 34,882

grams of silica.

The quantity of phospate of lime taken in was 136,509 grains,
That given out was 274,328 grains,

137,796.

There must have been formed, by digestion in this fowl no less than 137,796 grains of phospate of lime, as well as 511,911 grains of the carbonate of lime. It may thence be presumed, that lime (and perhaps phosphorus) is not a simple substance, but compounded of ingredients which exist in uce, water, and air, which are the only matters that could be introduced into the body of this fowl; as a quantity of silica had disappeared, it might be supposed, that it had contributed to the formation of the additional products; but if so, it must have entered into combination with a great quantity of some other substance. See Annal. de Chim. xxix. 16.

Notwithstanding these experiments were conducted by the ablest chemist of the age, they ought not perhaps to be at- tended to without being repeated under every circumstance which could lead to the detection of any error that might possibly arise.

This is not only necessary on account of the extraordinary nature of the results, which could only be produced by a creative power in the assimilating organs of the animal, but from other analogous experiments yielding results of a contrary kind. Dr. Fordyce, for instance, found that a cer- tain quantity of calcareous matter was required by birds during the period of laying; and if the bird was deprived of this, the shell never was formed, and the bird frequently died from the eggs not coming properly forward. The method he adopted to prove this was simple and satisfactory: he took a number of canary birds, when about to lay; some he inclosed, so that they could have no access to any cal- careous matter; and to others he gave a piece of old mortar, which they swallowed with avidity, and they laid their eggs as usual; whilst, on the other hand, those birds he had not furnished with the mortar were unable to produce eggs, and in several instances died. See Fordyce on Digestion, p. 25 & 26.

Liver.

This viscus is situated about the middle of the common cavity of birds. Its form, as in other animals, is much influenced by the shape of the parts which are immediately ad- jacent. The left side lies on the ramach, the right covers the
the intestines, and the apex of the heart is accommodated in the middle, and wherever the liver comes into contact with these parts, it receives in a degree an impression of their form.

Vie d'Azir, in his great system of anatomy, says, that the liver of birds is divided into only two lobes; and Cuvier has repeated the assertion in his Tableau Élémentaire de l'Histoire Naturelle. The observation, nevertheless, is not in all cases strictly true. In many birds there is a third lobe, situated at the back of the liver, between the right and left lobes: this appears to be analogous to the lobulus epiglottis of the human subject, both from its most usual figure, and from its position. See Plate IV. of the Anatomy of Birds. Fig. 5. represents the liver, &c. of the goose reviewed on the posterior, or reverse side; a the right lobe reaching lower down than the other, and exhibiting impressions corresponding to the convolutions of the intestines; b the left lobe, with two prominent parts, and a depression extending along the lobe between them; c the third, or intermediate lobe. In the common fowl, the left lobe is on the anterior part of it, as deeply as almost to form two lobes on the left side. The French academicians allow three lobes to the liver of the coromorant; they are all very small. A third lobe has been described also in the pigeon by Borrichius, and in the swan by Bartholine. The liver of the gryzib consists of four imperfect lobes.

There is considerable variety in the shape and relative size of the two principal lobes; generally the right lobe much exceeds the other in bulk, and is somewhat longer. This character of the lobes is to be seen in the liver of the goose, Plate IV. fig. 5. but is more remarkable in the coquim, and even still more so in the buffards, in which the right lobe descends to the bottom of the belly; both lobes are short in the eagle, the Indian cock, the parrot, the owl, and many others; and in the eagle the left lobe has the greater bulk.

The two lobes are nearly of equal size in the coromorant kind, and both long-shaped. However much the livers of birds may differ in external forms, the internal structure is the same in all cases, as we have proved by numerous observations. The secretory vessel is produced from the veins of the neighbouring viscera, as in mammalia, and after entering the liver by the depression or fissure on the lower surface, which corresponds to the porta or gate of the human liver, it is distributed throughout the substance of the organ, and terminates in the same manner as the vena portae, i.e. in fine radii, or penicilli towards the surface of the liver.

As there is no muscular septum between the thorax and abdomen of birds, their liver has not the advantage of that mode of connection, which is called in mammalia the coronary ligament: it is however amply supplied by the duplication of peritoneum, which corresponds to the faliform ligament; this process divides the two principal lobes, passing deeply between them; it is connected to the peritoneum, which forms the air cells, in the sides and back part of the abdomen, is incorporated with the pericardium, and joins the sternum and the linea alba on the front part of the abdomen, and then becomes reflected on each side of the common cavity, which is thus divided almost for its whole extent, in the same manner as the mediastinum divides the thorax in mammalia. The extended attachment, which is in this way procured for the liver, renders this viscus more firmly in its situation than it is in other animals, which birds require on account of the rapid and violent motions of their bodies during the act of flying. As the faliform ligament goes on to the fore part of the cavity, the margins which forms the round ligament is necessarily wanting, but the remains of the umbilical vein may be traced running between the duplicature of the peritoneum.

The gall-bag, or reservoir of the secreted fluid of the liver, in almost every instance where it exists, is situated upon the lower surface of the right lobe, somewhat nearer its central than its external edge. It is commonly received into a slight depression of the liver, so that about one-half of the bag is brought into contact with that viscus, nothing being interposed between them but the connecting cellular substance. The surface of attachment is occasionally less extensive; thus in the eagle, buffard, and coromorant, the bag stands out from the liver being only united to it by one end.

The form of this bag is commonly that of an egg, or a globe, or often something between these two figures. In a few instances it is elongated, as in the buffard and coquim; it measured in the latter bird only one inch in diameter, although it is seven inches in length.

The structure of the gall-bag appears to differ in no respect from that described in mammalia; its coats discover no trace of mucular fibres, and its internal surface exhibits the same kind of reticulation or net-work which is found in the gall-bladder of the human subject. See Plate IV. and fig. 5. in the Anatomy of Birds; the letter d indicates the gall-bag of the goose viewed particularly in its natural position; the reticulated structure is visible on the outside, but to bring it more perfectly into view the cavity is exposed by the removal of a portion of the bag.

The bile does not flow into the gall-bag by regurgitation from the common duct, but is conveyed directly thither by means of a particular tube designed for that purpose. This duct arises from the right lobe, passes on the sides of the bag, which is in contact with the liver, then becomes involved in the coats of the cyst, which it perforates about the distance of one-third from the posterior end.

The orifice by which the duct opens into the cavity of the bag, is very small, and is surrounded by a smooth projection of the inner membrane, which added to the obliquity of the duct, affords the effect of a valve, and entirely prevents any return of the fluid upon the liver; for the more the cyst is distended, the more pressure will be laid upon the duct, in its passage.

It would seem that the cysto-hepatic duct is situated nearly in the same way in all birds, where it exists, but the present description is taken from the goose. See Plate IV. and fig. 5. in which e points out the termination of the duct in the gall-bag, upon the papilla above-mentioned, and the course of the duct also is to be indistinctly seen behind the tunics of the cyst.

The ducts which carry the bile to the intestines, are two in number, the hepatic and the cystic. The first arises by two branches, generally from the right and left lobes of the liver, and while within the fissure or porta of the liver, they unite to form the trunk which proceeds to its insertion in the intestine, and usually crosses the duct of the gall-bag in its way thither.

The cystic duct comes forth abruptly from the most posterior part of the gall-bag, which is not prolonged into a neck, as in other animals. The duct makes a turn round the end of the bag, along the side of which it then proceeds so closely applied, that upon a flight examination it might be supposed to commence from that part, or even from the anterior end of the cyst.

The cystic and hepatic ducts never unite to form the ductus communis, as in many animals; but proceed directly to the intestine, into which they always enter separately; sometimes very near each other, and at others removed to a little distance. Two hepatic ducts have been found
found in the Indian coot or *fusaffo*, which also had a distinct insertion in the intestine.

The part of the intestines where the biliary ducts penetrate, is commonly at the conclusion of the first doubling or convolution, which occurs after the origin of the intestine from the stomach; or, in other words, it might be said to be at the termination of the duodenum. The bile duct of the *girich* is very large and enters the intestine near the stomach.

As in mammalia, the passage of the ducts through the coats of the duodenum is somewhat oblique, and they open upon a papilla or prominence of the internal coat, thus gaining the effect of a valve, and preventing the regurgitation of their fluid. In addition to which, the *bylhard* is described as having a fold of the inner coat of the intestine projecting over the orifices of the biliary and pancreatic ducts.

Plate IV. and fig. 5. in the Anatomy of Birds, exhibits the origin, course, and termination of the biliary ducts in the goose; *f* the hepatic duct, formed of two branches in the nature of the liver; *g* the origin of the cystic duct from the end of the bag, appearing internally like a puckered hole; *h* its course behind the hepatic duct, beyond which it terminates in the intestine; *i* the first convolution of the intestine; *k* the portion from which the gizzard has been cut away; *l* the commencement of the second fold of the intestines, or the beginning of the jejunum.

Both the cystic and hepatic ducts of the *gull* become slightly enlarged just at their insertion in the intestine, which is produced not so much from a dilatation of their cavity as a thickening of their coats. The more minute structure and the functions of the bile ducts are in every respect analogous to those of the same parts in other animals. A very curious observation has been made on this subject by Borrichius, which deserves to be mentioned. He opened a pigeon while yet alive, and discovered in the hepatic duct a pulsatory motion, by which it was alternately distended and emptied of its contents, the intervals between each contraction were somewhat longer than they occur between the pyloric and diaphragm of the heart. If this had been related by a less accurate anatomist than Borrichius, one would be led to suspect that a blood-vein had been mistaken for the biliary duct; but he watched the moment that the action of the heart subsided, and still the duct was alternately emptied and distended with a green fluid as before.

The gall-bag is occasionally wanting in birds, and it should be remarked, that this irregularity is not governed by any general rules of structure, as two species which agree in every other respect, are observed to differ in this; nay, according to the French academicians, the gall-bag is not constantly found even amongst the individuals of the same species; thus in dissecting six *dendrolibes* of *Numidia (orden singo*), it was absent in two of them, and the others had it very small. Amongst ten *pintados*, also, they only met with the gall-bag twice, and differing very much both in size and shape; and in these instances where the bag was absent the hepatic duct was found very large.

The species known to be deprived of the gall-bag, are the *girich*, the *parrot*, the *pigeon*, the *bittern*, the *crane*, and the *cock*: in some of these, dilatations of the ducts have been observed which may be supposed to supply in a degree the office of the gall-bag, which appears from this, as well as from other circumstances, to be simply a reservoir for the bile, and not an organ for working any change in the properties of that fluid. Being, therefore, a convenient, rather than a necessary structure, its absence need not be expected to be marked with any clear relation to the other functions of the animal economy.

No experiments have yet been instituted with the design of procuring a chemical analysis of the bile of birds; it is most probable, however, that these would discover nothing peculiar, as in soluble properties such as colour, taste, &c., it perfectly resembles the bile of mammalia.

The Pancreas.

Consists of two distinct glands, for the most part, in birds. Their common situation is between the coils of the first intestines, to which they are very firmly bound by their peritoneal coat; they have a very elongated figure, furnished with decided sides, angles and edges, which are irregularly notched or indented. These ducts mark out imperfectly the original lobules of which the glands are composed. They appear to possess the same internal structure which is described in mammalia, though not so palpably as to be discovered without some pains; to a light observation their substance seems to be a white homogeneous mass, instead of that conglomerate of lobules, cells, blood-veins, and ducts, which really enter into its composition. Each of the glands produces a principal duct, which separately runs in the reflection of peritoneum, into which intestine they are inferred, at a variable distance from each other, in the manner of the two biliary ducts. Their entrance is, with scarce an exception, adjacent to that of the bile ducts, and often so near that one projection of the inferior coat of the intestine serves for the termination of all the ducts.

See Plate IV. in the Anatomy of Birds, in fig. 5. the letters *cm* indicate the two pancreatic glands of the *gull*, a little separated from each other, and their other peritoneal connections, to exhibit more clearly their figure; *m* the ducts from each gently curved in their passage to the intestine. The pancreatic and biliary ducts are at a considerable distance in the *girich* and the *gull*. In the first, as already mentioned, the hepatic duct enters the intestine near the stomach; but the pancreatic duct pusses as usual into the last portion of the duodenum. The pancreatic ducts of the *gull* penetrate the duodenum at its commencement, whilst the biliary precede nearly the common situation. It is not very usual for these ducts to enter the intestine alternately, or for the two pancreatic to pass between the two biliary; this may be observed in the *eagle*, the *heron*, &c.

Considerable varieties have been described in the number, external figure, and magnitude, &c. of the pancreas in different birds. The French academicians have represented it as a single gland, with only one duct in the *girich* and *caffo-voary*. In the latter it was extremely small in proportion to the size of the bird, being only two inches long, and its duct a line and a half in length. In the *eagle* it appeared to be single, although in one instance it sent forth two ducts, and in another three; it was enlarged and round at the head, at which place it was perforated by the hepatic duct in its way to the intestine. They also describe that this gland varies in different individuals of the same species; thus in one *cauffo-voary* they found the pancreas double, and in another single. De Groot in most *fau* found three pancreatic ducts, and also in the *pigeon*, and Bartholin observed only one pancreatic duct in the *peacock*.

The Spleen.

Has been described as occupying different situations by different authors. Thus Cuvier, and other anatomists, have stated its common position to be the middle of the mesentery. The French academicians found it closely adhering to the side of the ventricle, in one species of eagle (*falco chry-soleus*) and in another (*falco loxatilis*), it was met with under the right lobe of the liver; and Severinus mentions the spleen of the *crow* being situated upon the first intestine. In every bird, however, which we have examined with the view of
affecting the situation of the spleen, it has been uniformly discovered beneath the left lobe of the liver, placed a good deal backwards, and on the right side of the zone of gastric glands. Its peritoneal connections to the neighbouring parts are loose and permit it to be displaced, when the other viscera are removed from their situations, which circumstance may have occasioned some difference in the observations made upon the subject. The situation we have described is the most convenient for its being supplied with blood, which it receives from the gastric artery, and is besides consistent with general analogy.

The figure of the spleen is most commonly round; it is, however, in some birds, a little different in form. The most usual deviation is the oval or kidney shape, which has been observed in the corvoraent, the eagle, the pintado, the common fowl, &c. In the fowl it is cylindrical, and in the caymaway it has been likened in figure to a flat fish. In the gull it is much elongated and pointed at both ends, as it is shown in Plate IV. in the Anatomy of Birds, and § 6.

The spleen assumes rather an irregular form in the goose; it is slightly compressed and round on the one side, and flat on the other. The outline presented on either side is triangular, and one of the angles is prolonged as a mammillary process, which is distinguished from the rest of the spleen by a flat cleft or fissure. This is represented in fig. 7, of Plate IV. of the Anatomy of Birds; a the body of the spleen viewed on the flat surface; b the papilla-shaped process; c the entrance of the splenic artery, upon the edge; d the vein penetrating the flat surface.

The texture of the spleen is so much more close and firm in birds than in mammalia, that one might be easily led to suppose its structure was different; but when prepared by being injected with coloured substances, and submitted to examination through a lens, we have discovered, as in mammalia, the splenic artery to terminate in numerous minute branches, and the veins to take their rise from cells. The only difference which exists, is with respect to the magnitude of the cells which are extremely minute; and thence arise the peculiar compactness and density of the spleen of birds.

The structure of this organ being so very similar to that of the spleen in mammalia, it is fair to conclude that their functions are also analogous. The situation of the vices in birds might be confedered, therefore, as affording an objection to that theory, which supposes this organ designed to regulate the quantity of blood employed by the arteries of the stomach during the secretion of the gastric fluid; for, in birds, the spleen receives no supply as occurs in mammalia, by the introduction of food into the stomach, and consequently, cannot affect the distribution of the blood in the collateral arteries, more under the circumstance of a full stomach than an empty one. In order to put the spleen of birds in the same conditions to which it is subject in man and quadrupeds, it should be placed under the crop in the granivorous tribe, or between the ventricle and the ribs in the other kinds.

Although it would be often wrong to determine the uses of an organ in one class of animals, from the circumstances in which it may be placed in another; yet no theory can be considered as well founded, unless it be framed in the contemplation of all the varieties of comparative structure.

Absorbents.

One of the most remarkable and inexplicable circumstances in the anatomy of birds is, that the nutritious fluid of the intestines, or the chyle, is as transparent as the lymph which is taken up from the common interstices, or the surface of the body. The absorbents of the intestines, therefore, do not deserve to be called lachetals, an appellation they have received in man and quadrupeds, in consequence of the opacity and milky appearance of their contents.

The discovery of the lymphatic system in birds may be reckoned amongst the modern improvements in anatomy. Before Mr. Hunter, about the middle of the last century, described the absorvent of the neck, it was generally supposed that the office of these vessels was fulfilled in birds by the minute branches of veins. This opinion was rendered more probable as several able anatomists had fought in vain for those white vessels, and their glands, which are so easily detected in the mecatomy of the smallest quadruped. It was not then known, however, that the lymphatic vessels of the intestines were always pellucid in birds, and unprovided with glands, and accordingly Mr. Hunter's discovery was not generally admitted as decisive on the question, until some years afterwards the whole of the lymphatic system had been described by Mr. Hewson; he employed for this purpose a young and very lean goose, which had been recently fed, and having secured it upon a table, he opened the abdomen whilst the bird was yet alive, and passing a ligature round its mecanteric vessels, as near to the root of the mecantery as possibl, the lymphatics of this part became apparent in a few minutes. The same method also was pursued to expose the absorbents of the neck. A ligature was placed round the jugular vein at the lower part of the neck; and to be more certain of including the lymphatics which are near it, a sufficient quantity of the surrounding substance was included by the ligature. In this way he succeeded in tracing the lymphatic vessels, in more instances than one, after having filed the vessels with quicksilver. He published a description of the absorbents, illustrated by two drawings, in the Philosophical Transactions for the year 1748, and in his Experimental Inquiries into the lymphatic system.

As no accounts or figures of the absorbents of birds have been offered to the public since Mr. Hewson's time, we cannot do better than adopt the description, and copy the representation left to us by that indefatigable anatomist; in doing which, we shall transcribe his own words.

"This system consists in birds, as it does in the human subject, of three parts, viz. the lachetals, the lymphatic vessels, and their common trunk, the thoracic duct. The lachetals indeed, in their strictest sense, are in birds, the lymphatics of the intestines, and like the other lymphatics, carry only a transparent fluid; and instead of one thoracic duct there are two, which go to the two jugular veins. In these circumstances, it would seem, that birds differ from the human subject, so far at least as I may judge from the dissection of a goose, which was the bird I chose as most proper for this inquiry, and from which I took the following description, after previously injecting its lymphatic system with quicksilver.

"The lachetals run from the intestines upon the mecanetic vessels. Those of the duodenum pass by the side of the pancreas, and probably receive its lymphatics: afterwards they get upon the celiac artery. Whilst they are upon this artery they are joined by lymphatics from the liver. Here they form a plexus which surrounds the celiac artery: at this part they receive a lymphatic from the gizzard; and a little farther, another from the lower part of the esophagus (or zone of gastric glands). Having now got to the root of the celiac artery, they are joined by the lymphatics from the glandular renoi, or renal capsules; and near the same place, by the lachetals from the other small intestines, which vessels accompany the
the mesenteric artery. Thosc left mentioned lacoids, before they join those from the duodenum, receive from the rectum a lymphatic, which runs with the blood-veins of that gut. Into this lymphatic some small branches from the kidneys seem to enter, which, coming from those glands upon the mei entered, at last open into its lymphatics. At the root of the coeliac artery, the lymphatics of the lower extremities probably join those from the intestines. The former," he says, "I have not yet traced to their termination, though I have distinctly seen them on the blood-veins of the thigh; and in one subject which I injected, some vessels were filled, contrary to the course of the lymph, from the network near the root of the coeliac artery. These vessels ran behind the cava, and down upon the aorta, near to the origin of the cranial arteries; and I presume they were the trunks of those branches which I had seen in the thigh. At the root of the coeliac artery, and upon the contiguous part of the aorta, a net-work is formed by the lacoids and lymphatics above-described. This network consists of three or four transverse branches, which make a communication between those which are lateral.

In the subject from which this description was taken there were four. From this net-work arise the two thoracic ducts, of which one lies on each side of the spine, and runs up to the lungs obliquely up towards the jugular vein, into which it opens, not indeed into the angle between the jugular and subclavian vein, as in the human subject, but into the inside of the jugular vein, nearly opposite to the angle. The thoracic duct of the left side is joined by a large lymphatic which runs upon the aorta-plugus, and can be traced as far as the lower or glandular part of that canal, from which part, or from the gizzard, it seems to issue. The thoracic ducts are joined by the lymphatics of the neck (and probably by those of the wings), just where they open into the jugular veins.

The lymphatics of the neck generally consist of two pretty large branches on each side of the neck, accompanying the blood-veins. These two branches join near the lower part of the neck; and the trunk is in general as small, if not smaller, than either of the branches. This trunk runs close to the jugular vein, gets on its inside, and then opens into a lymphatic gland. From the opposite side of this gland a lymphatic comes out, which pours the lymph into the jugular vein. On the left side, the whole of this lymphatic joins the thoracic duct of the same side; but, on the right, one part of it goes into the inside of the jugular vein a little above the angle, whilst another joins the thoracic duct, and with that duct, forms a common trunk, which opens into the inside of the jugular vein, a little below the angle which that vein makes with the subclavian.

To this description it may be necessary to add, that though it be taken from one subject, yet in three others of the same species, which I examined carefully, I saw nothing which differed with it. I particularly attended to the number of the thoracic ducts, suspecting that possibly in this subject the two that I had seen might be only a variety, which is a circumstance that, as we are told, has occurred even in the human body. But in three others of this species, which I likewise successfully injected, I still saw two ducts; and therefore I am inclined to believe, that this is the constant number. I likewise carefully attended to the epigastrium coming from the gland on the right side; and in the only two subjects in which the lymphatics of the neck were properly filled, Vol. IV.

I observed that one part of it opened immediately into the vein, and the other joined the thoracic duct. In all the four subjects I evidently saw that the thoracic ducts opened into the inside of the jugular veins.

"This s ystem in birds differs most from that of quadrupeds. I, in the chyle being transparent, the vessels of the thoracic ducts, 3 dly, in there being no visible lymphatic glands, neither in the course of the lacoids, nor in that of the lymphatics of the abdomen, nor near the thoracic ducts; 3 dly, in the several parts of this system in birds being more frequently enlarged, or varicose, than in quadrupeds. In particular, this appears to be the case of the vessels which constitute the network at the root of the coeliac artery, in that subject from which the drawing was taken. The lacoids are frequently enlarged in some places; 3 dly the thoracic ducts; and the lymphatics on each side of the neck are commonly, when taken together, larger than their trunks, which opens into the lymphatic gland. In one subject, when, instead of two lymphatics on the left side, I found only one, that vessel was as large as a crew quill, whilst the lower part of it, which entered the gland, was much smaller."

The figures which explain the foregoing description are to be found in Plate V. of the Anatomy of Birds. Fig. 1, shews the abscesses in their natural situation, with respect to the other parts of the body; A, the neck; B, the clavicle divided near its middle; C, the left subclavian artery; D, D, the jugular veins; E, E, the pulmonary arteries; F, F, the two branches of the trachea; G, G, the lungs; H, the aorta; I, the carotid artery; L, the oesophagus joined to one side; M, M, the renal capsules; N, a small part of the liver fixed to a rib by a thread; O, O, O, ileal vessels; P, the duodenum; Q, the pancreas fixed to a rib by a thread; R, the gizzard. Fig. 2, exhibits the abscesses, and their more immediate connections with the vessels, in outlines: a, the lateral, or more properly lymphatics, which come from the duodenum; b, the lymphatics of the liver, N; c, aplexus formed by the above-mentioned lacoids and lymphatics, which surrounds the coeliac artery, 1; d, a lymphatic from the gizzard; e, a lymphatic from the lower part of the oesophagus; f, f, a network formed by the lymphatics upon the aorta; H, H, the two thoracic ducts; i, i, the trunks of the lymphatics of the neck; k, k, the glands through which the lymphatic vessels of the neck pass; that of the left side is oblong, and could not well be represented in a Figure; l, the thoracic duct of the left side, and the lymphatic vessel of the neck, opening together into the inside of the jugular vein; m, a part of the lymphatic of the right side of the neck, opening into the jugular vein, D; n, the thoracic duct of the right side, joined by a part of the lymphatic vessel of the right side, and then opening into the inside of the jugular vein.

Heart.

This organ occupies the centre of the superior portion of the common cavity of birds. It is placed usually in the line of the body, as in quadrupeds; the heart, however, is inclosed in the slightest degree to the left side in some influences, and in others a little to the right side. The apex of the heart is commonly received between the two chief lobes of the liver, which are hollowed out for its accommodation.

The membranous bag, which contains the heart, is formed like the pericardium of other animals, and is reflected in the common manner upon the origin of the great vessels, and the heart. The pericardium of birds is generally considerably larger than the heart, and especially at the lower part, which
which is often prolonged for some way between the lobes of the liver. It deserves remark, that notwithstanding the great size of the pericardium, the air, which pervades almost all the cavities of birds, is not admitted into this. The Parian anatomists, it is true, observed the pericardium to swell when they inflated the lungs and air-cells of the pinta
du, and thence concluded that the air had admission to the heart, for which they assigned some curious reasons; such as the heart requiring compression and evaporation from its surface. They appear, however, to have been equally in error with respect to the fact and the reasoning; for, in a great number of species we have examined for the purpose, the pericardium was uniformly found to contain a certain quantity of water, and had not the least communication with either the lungs or air-cells. The Parian anatomists must have been led into this mistake by the division of the air-cells around the pericardium.

The heart is of a longer figure in birds than in other ani
def; and the outline of the right side is slightly concave, in consequence of the parietes of the right ventricle being relatively thin. In the girrbz, the heart has been described as nearly round; measuring six inches from the base to the apex, and five inches across.

Birds have, like mammals, four distinct cavities in the heart, which bear the usual proportions in magnitude with respect to each other. The auricles however, and especially the right, are commonly more muscular than in other ani
def; and the left ventricle is always much stronger than the right.

The internal surface of the auricles is very irregular, in consequence of the shape and size of the muscular fasciculi. There is one very strong portion of muscle, which enters into the composition of the auricular part of both cavities, from which the other fasciculi proceed in a regular and radiated manner, at least in the right auricle. See Plate V. in the Anatomy of Birds, fig. 3.

The principal muscular fasciculus of the auricular portion of the cavity passing backwards towards the left auricle; the feu

The blood of the viscera and lower limbs is conveyed into the right auricle by a vein corresponding to the inferior vena
cava of mammals. There is, however, no vein strictly ana
gous to the superior cava, the veins of the right wing and that side of the head and neck, form a distinct trunk, which enters the upper part of the auricle; while those of the opposite side also produce another trunk, which passes along the posterior surface of the left auricle, to which it is closely united, and opens into the right auricle before the inferior cava.

The anatomists of the French academy observed, in most of the birds they dissected, a valvular projection of the inner membrane of the heart, over the entrance of the interior vena cava into the right auricle. This valve resembles in form that of the coronary vein of the human heart, and by its means, the orifice of the cava, which is really very large, is guarded by the appearance of a narrow slit. A similar valve hangs over the entrance of the veins which return the blood of the wings and head to the auricle. See Plate V. in the Anatomy of Birds, fig. 3.

The analogy between the valves of the veins entering the right auricle of birds, and the Eustachian valve of the human heart, is very obvious, and demonstrates, as far as analogous structure can, that the latter serves the purpose of a valve to the vena cava in the human subject.

There are commonly two or three orifices for the coro

nary veins in birds, one is always larger than the rest, and transmits the blood of the principal vein of the heart. They are each provided with a slight projection of the inner membrane, which acts imperfectly as a valve.

The right ventricle is of a triangular figure, and is quite smooth on the internal surface; there being none of those processes of muscle which are called carneae columnae.

The valve, which is placed at the mouth of the right ventricle, is of a peculiar shape and structure in birds. Instead of those thin and membranous folds, which usually surround the orifice of the ventricle, and are moved by means of their connexion with the carneae columnae, and which from their figure in the human subject are called the triangular valves; there is a single projection of the flesh of the heart, of a triangular figure, and nearly as thick as the parietes of the cavity in which it is contained. The triangular valve is joined by its superior edge to the margin of the orifice of the ventricle, and is united by another of its edges to the right side of the cavity almost to the bottom. The third edge is unconnected, except by a small process, which goes off near one of the superior angles to the parietes of the ventricle on the left side. See Plate V. in the Anatomy of Birds, fig. 3.

b the triangular valve, exposed by means of the anterior pa
eries of the right ventricle being cut off, a bristle is passed under the valve from the auricle; d d the external surface of the heart; e the process connecting the floating edge of the valve to the parietes of the ventricle, with a bristle lying under it.

The triangular valve, from its thickness and mincullarity, would seem to operate chiefly by means of the contraction of its own fibres changing its figure, and thus obstructing the return of the blood into the auricle. Barrois discovered a foramen in the septum of the heart of the pigeo

large enough to admit a bristle, by which the two ventricles had a direct communication with each other. See Act. Dan. anni 1. obser. 96.; and we have observed the same foramen at the upper part of the septum of the heart of the go 
in one instance; it was of sufficient size to receive a crow quill. Such a communication does not appear, however, to be an uniform or natural structure, as we failed to disco

ver it in other go 

and in different species of Birds examined for the purpose. Indeed, a ready communication between the ventricles of an adult bird, would be inconsistent with the mode in which the functions of respiration and cir

culation are carried on in this class of animals.

The pulmonary artery is provided with three semicircu

lar valves, as in mammals. It divides also, as usual, into a vesel for each lung, and that of the right side passes under the arch of the descending aorta.

The blood is returned from the lungs by two pulmonary veins, which open very near each other into the upper and posterior part of the left auricle.

The mechanism of the cavities of the left side of the heart more nearly resembles that which exists in mammals.

The sinus, or membranous part of the left auricle, is however very small, and of an oblong shape; and at the place where the pulmonary veins enter into the auricle, there appears to be a projection of the internal membrane, which performers the office of a valve to their orifices.

The valve of the left ventricle is thin and membranous, and resembles to much the mitral valve of the human heart, that the same name might with propriety be given to it.
Bird.

The tendinous cords, however, which are attached to the margins of the valve, are not moved by distinct muscular flescelli, or corona constrictoria, but proceed immediately to be left in the films of the ventricle. The lower part of the cavity is flescellated, although not so remarkably as the internal surface of the ventricle of man or quadrupeds.

The aortic or semicircular valves are to be found at the oriæ of the great arterial trunk from the left ventricle.

The above account of the mechanism of the heart of birds shows that this organ is calculated to exercise its functions precisely in the same manner as in mammals; and that the pulmonary and general circulations are maintained by different chambers of the heart; consequently every particle of blood is expelled to the influence of the air in the lungs, previous to its distribution throughout the system for the purposes of nutrition, excretion, &c. Before the description of the vessels of general circulation is entered upon, it is in order therefore to treat of the organs of respiration, or the lungs.

These bodies are situated on each side of the dorso-lumbar spine, upon the surface of the ribs and intercostal spaces, usually reaching in length from the second rib to the last intercostal space but one, and extending in breadth from the spine to about that part of the ribs, where the processes are bent from one to the other. In the sparrow, the lungs were found to measure ten inches long, and three and an half broad, and were one and an half in thickness.

The lungs of birds never move from their position, as they adhere to the inside of the chest, and are covered over by a strong membrane or aponeurosis.

They are smooth and even on the anterior part; but their figure posteriorly exactly corresponds with that of the parts upon which they are laid. The ribs and intercostal spaces serve as a mould, of which the lungs are the perfect cell, presenting a remarkable formation for each depression between the ribs. These eminences are of course most striking next the spine; and towards the anterior edge of the lungs, which is very thin, they are feebly visible.

The lungs have two coverings; one is somewhat analogous to the pleura, though not exactly similar to it in structure, being more like condenised cellular substance. It closely invests each lung, and appears to be flescellous on some parts of its surface, and to adhere to the parietes of the chest. The other coat is common to both lungs; it is extended from each side of the chest to the dorso-lumbar spine across the anterior surface of the lungs. It is connected in a direct to the fore part of the spine, and extends at this place the trunk of the defending aorta, forming the calcaneal artery to pass through. It has an intimate union with the proper tubes of the lungs except at the openings of the air-cells, and around the entrance of the great trunks of the lungs. The texture of this coat appears to be tendinous; its fibres all run in the transverse direction; and in large birds they are evidently white. This aponeurosis is not equally strong upon every part of the lungs; at the upper part, and especially above where the vessel enter, it is so weak as often to be hardly visible.

In all birds there would appear to be some muscular fibres passing from the side of the chest upon the aponeurosis of the lungs. These are very distinctly to be seen in the larger species, in some of which the muscles of the lungs are of considerable strength. The anatomy of the French academy observed in fowl strong slips of muscle on each side of the body in the aircelle and cafta overy. They arise from the ribs which come from the spine, near their junction with the face which belong to the sternum, and run to the aponeurosis which covered the lungs. M. Poupart discovered eight muscular bands in the lungs of the eagle, and had the appearance of distinct slips, as in birds, aponeurosis, but were spread as a single layer upon each lung.

It is difficult to speak with certainty of the uses of the pulmonary muscles. This fact, in itself, appears to be the tenor of the great muscles, and it is usually, the deviation of it into a flat fibrous which is ordinarily enveed, or deprived. This would naturally produce some dilatation of the lungs; and therefore these muscles might be reckoned amongst the agents of inspiration, although their operation in this way would be very trifling.

The Purifier anatomists attribute several uses to them; they supposed that these muscles had the power of depressing the anterior part of the thorax, in consequence of their attachment to the movable angle of the ribs, and their oblique course upward to the spine. If such be allowed to perform this effect, they must be considered as muscles of expiration.

They imagined also that they could, when it was often, a contraction of the foramina through which the air is admitted into the great air-cells of the thorax or upper part of the body, and thus enabled the bird to maintain a continued dilatation of these cells, in order to diminish the specific gravity of its body during the time it remained on wing; or (what the academicians thought more probable) furnished the bird with a supply of common air to carry with it into the regions of the atmosphere, in which the air would be too thin and light for respiration; in the last conjecture, however, they seem to have forgotten the effect that the temperature of the bird's body would produce in the rarefaction of the air contained in the cells.

When the lungs of birds are stripped of their coverings, they are still found to be a connected, uniform substance, and not reducible to lobes or lobules as in mammalia; they appear, to a superficial view, solid and firm, but if examined more clearly, are seen to be made up of the ramifications of the great blood-veins, the bronchial, and very minute air-cells.

When the bronchial enter the lungs, their chief branches, instead of being regularly and equally distributed, pass directly to certain points upon the surface of the lungs, and there terminate in several foramina, which communicate with the great air-cells of the body; these branches also of the bronchial retain in their structure, almost throughout their extent, some cardinaugous rays. The ramifications of the air-tube which really supply the substance of the lungs, are but branches of those which go to the cells. They are comparatively few, and entirely composed of membrane. This structure accounts for the flabby appearance and solidity of the lung, and explains why birds are able to fill their air-cells with much ease and rapidity.

Although physiologists are not agreed with respect to the uses which these parts have in birds; yet as to the immediately connected with the lungs, it seems most proper to describe them in this place. It is one of the most remarkable and peculiar circumstances in the anatomy of birds, that the atmospheric air has a ready passage to almost every part of the interior of their bodies.

The above according to their situation, may be divided into
The Parilian anatomists describe all these cells as being formed of distinct tunices, so that each is a separate bag, instead of being made by continuous and reflected membranes. They represent the bags to be distinct also from the great membranous partitions of the cavity. See Plate V. in the Anatomy of Birds; fig. 4, is copied from the memoirs of the French academy, and exhibits the air-cells, &c. of the ostrich: a the trachea; b the two bronchi passing to the lungs; e the heart; and dd the liver, seen in the inferior division of the cavity; e the transverse membrane which separates, like the diaphragm, the common cavity into two parts; f the stomach; and ggg the convolutions of the intestine, seen in the lower or abdominal portion of the cavity, bbb the lateral partitions which include the four superior cells; 12345 indicate the different cells; the air-holes are apparent in each, except the inferior or abdominal cells, which cannot be brought into view, as they lie behind the fourth cells.

The air-cells of birds in general do not exactly accord with the description given of the ostrich and cassowary, by the members of the Royal Academy; we shall therefore proceed to give an account of what we have observed on this part of the anatomy of birds in the goose, duck, common fowl, pigeon, &c.; and in order to make this description more intelligible, we shall take the liberty of naming the cells according to their situation with respect to other parts, although some of the terms must be adopted upon the strength of analogy, as the divisions of thorax and abdomen do not with fowlce belong to birds.

The first is the superior thoracic, or jugular air-cell. When it is distended with air, it becomes evident upon the outside of the thorax, between the two branches of the fork; it is large enough in the goose to contain an apple in its anterior part, and posteriorly it extends on each side of the basis of the heart, over the lungs. This cell contains the divisions of the trachea into the bronchiae and the trunks and primary branches of the blood-vessels which supply the wings and head. A great number of membranous septa pass through it in various directions, which serve to connect and keep steady the different vessels, and also divide this cell into several chambers, which, however, have all a free communication with each other. The air is transmitted from the superior part of each lung by two openings which are placed in the posterior chambers of this cell. These chambers do not appear to extend so far upon the lungs in other birds as they do in the goose; it is from this cell that the air passes into the cells of the axils, and under the fork-shaped bone, into the deep seated cells of the neck, and to those about the shoulder.

The next cells may be called the intermediate thoracic. They are generally two in number, one to each side; they lie immediately upon the lungs, and are in a degree covered by the anterior thoracic cell. That of the right side is usually larger than the one on the left; the latter is particularly small in the goose, being almost concealed by the two adjoining cells, and extending under the posterior part of the liver. The cell of the right side is of an oblong square figure, and is prolonged under the termination of the inferior vena cava in the right auricle, as far as the left side of the bulbus glandulosus. The intermediate thoracic cells receive their air through a large foramen, situated upon the inner edge of each lung, just at the basis of the heart. At the upper and inner angle of these cells also there is an opening which appears to lead to some small cells under the pericardium and oesophagus, and to communicate indirectly with the anterior thoracic cell.
The lateral thoracic cells are amongst the largest of the body. They are of a pyramidal figure, their bases being applied to the intermediate thoracic cells, and their point reaching as far down as the bones of the pelvis; they cover the inferior portion of the lungs, and occupy a space between the ribs and the lobes of the liver. They have a very free communication with the branches of the bronchise, at the external edge of the lungs.

As the intermediate thoracic cells are small on the left, and large on the right side, these cells are larger on the left side than on the right: this disproportion is more observable in the goose, and very striking in the duck, in which the two intermediate thoracic cells are nearly of an equal magnitude.

The air-cells, which are found in the lower or abdominal portion of the cavity of birds, are composed of thinner membranes than the others; in some parts they are so tender, that they are ruptured with the slightest touch, from which they become very difficult to examine.

Underneath the lateral thoracic cells, at the very lowest part of the lungs, on each side of the spine, the branches of the bronchise open into the cavity of the abdomen, by which means air is conveyed directly into the two great lateral abdominal cells, and from these it would appear that it passes into the others.

The lateral abdominal cell of the right side is by much the largest in the body; it receives from the last ribs to the anus, and lies over and includes almost all the small intestines, the rectum capsule, and the kidney. It appears in the goose to be divided from the opposite cell by a membrane which passes obliquely from the right side of the anus to the lower part of the gizzard.

The left lateral abdominal cell contains the intestines of that side; it is attached to the margin of the gizzard, under which it is prolonged as far as the lungs, where it is supplied with air, as already mentioned.

The lateral abdominal cells transmit air to the inguinal cells, and to several chambers formed by the most delicate membrane, amongst the intestines. One of these being somewhat stronger than the others, there was an opportunity of observing it more distinctly. It makes a circuit around the right side of the gizzard to which it is attached, and includes the duodenum and pancreas; it might thence receive the name of the duodenal cell.

Interposed between the peritoneum of the belly and the lateral cells there are frequently found a considerable quantity of tender fat; especially in aquatic birds, such as the goose, etc. By this means a soft cushion is provided for the small intestines to press and move upon, thus supplying the use of the omentum, which is a part not met with in birds.

The structure of the air-cells of birds in general does not appear to be the same described in the gurich and caffonare by the academicians. The membranes composing them, instead of being distinct bags, as they relate, resemble rather the pleura or the peritoneum, and like them, seem to produce all the different cavities by the means of reflection. It must be confessed, however, that the membranes of the cells, especially in the abdomen, are very easily separable into different lamina, or layers, which, it might be supposed, could be ultimately resolved into distinct flacks.

It deserves to be mentioned, that each of the air-holes in the surface of the lungs opens obliquely into the air-cells; there being a slight projection of thin membrane over the aperture. The Parifian anatomists ascribed a valvarul effect to this structure, which they supposed of great consequence, as it would serve to continue the diffusion of the air-bags, after they were once inflated. The projection of the membrane over the air-holes does not however appear to be sufficient to cause any obstruction to the regurg of the air from the cells; nor would it seem necessary or convenient to interrupt in the least degree the expulsion of the air contained in the cells.

The membranes of which the air-cells are composed, are reflected into the apertures of the air-holes, and are there perforated by a great number of small foramina, which correspond to the termination of the ramifications of the bronchise, through which the air has a ready passage. When these foramina are brought into view, by detaching of the coverings of the lungs, they give the anterior surface an appearance of being pierced by pins.

The air-cells which are found amongst the muscles and integuments of the external parts of the body, vary in number and magnitude, according to the structure and economy of the bird. In every instance, perhaps, the anterior thoracic or jugular cell is continued along with the vessels and nerves into the axilla, making what may be called an axillary cell, and in most birds others go off from this anteriorly under the pectoral muscle, and backwards under the muscles of the thorax, forming pectoral and sub-pleural cells. In the eagle, buzzard, firk, bird, and other large flying birds, these cells are very large, and in many of these birds there are still larger cells, extending under the integuments of the neck, and passing beneath the skin of the side of the arm, and the back of the shoulder. In the firk we found these cells large enough to admit the finger to pass a considerable way down upon the side and back of the wing. They are also large in the seal and other birds of prey.

Mall birds of flight have a number of cells placed under the lateral muscles of the neck. These are opposite to the bones of the cervical vertebrae, and communicate with one another. It is from the different cells about the axilla and neck, that the bones of the shoulder, the humerus, and the vertebrae, receive the air which they contain.

The inguinal and gluteal cells are filled from the great lateral cells of the abdomen, with which they have a communication, where the blood vessels of the lower extremities pass out of the pelvis. The inguinal and gluteal cells surround the neck of the femur; they are in small birds very small, but in those which are much employed in flight, especially if the thigh bones receive air, they are larger, extending for some way amongst the muscles behind the femur.

Camper observed two air-bags between the gluteal muscles of the genus Patalca, although no air was transmitted into the femur.

The subcutaneous air-cells of the pelican are very large, and were described long ago by Mery, in the early Memoirs of the Academy of Sciences of Paris.

Several means have been employed to prove that the air is permitted to enter the cavity of the bones in birds. The air-cells and the lungs have been inflated from the bones, and injection being thrown into the trachea, was found, after detaching the air-cells, to have passed into the interior of the bones. A still more decisive experiment (although a cruel one) is to cut the humerus across in a living bird, and introduce the extremity of the divided bone into water, in which some soap has been dissolved, when it is perceived that bubbles are produced by the exit of the air from the end of the bone. This expedient not only averteth the eXistence of air in the bone, but shews that there is a motion or circulation of it, which is the effect of the actions of inspiration and expiration.

This subject has been very extensively investigated by Camper.
per, he discovered the communications between the cavities of the bones and the air-cells of the soft parts, and ascertained in a great number of species what bones were filled with air.

The result of both his observations and our own tends to shew, that the bones of birds are supplied with air, according as they are employed in the locomotion of the animal's body. In birds of flight, therefore, almost all the bones are hollow, and receive air; thus in the eagle Camper found the air-cells connected with the thigh bones, those of the pelvis and coxys, all the vertebrae, the femur, clavicles, scapula, and fork-shaped bone, and the bones of the wing. The air was also admitted into the bones of the head from the cavity of the tympanum. We have observed the bones in the breast and fork to want marrow in the same manner as those of the eagle. Most of the bones are hollow in the cold, but the os femoris is filled with marrow. The pigeon kind in general also have no air in their thigh bones, although the crested pigeon has been observed by Camper to possess it.

Birds even of moderate powers of flight, receive some air into the femur and other bones of the trunk, and between the plates of the cranium; and all birds, whose wings are not capable of flight, have the humeri filled with air, with the exception of the woodpigeon, which has been observed to possess marrow in the humerus; but to counterbalance this impediment to the velocity of its motion, it is provided with pectoral muscles of unusual strength.

Those birds which are unable to transport themselves for any distance by the effort of their wings, are deprived of air in the humerus; of these may be included all the frugibous kind, the penguin, the puffin, &c. It is worthy of remark, however, that these frugibous birds, which run with great rapidity, have most of their other bones hollow; Camper discovered the air to pass into the thigh bones and lower jaw of the gryllus, and we have observed that it fills not only these bones, but the femur, the ribs, the vertebrae, and the bones of the pelvis, in both the common pigeon and that from New Holland.

The internal surfaces of those bones which contain air, have been described by Camper as being in some cases lined with perioleum, and in others entirely deprived of it; thus he states the internal part of the femur of the eagle to be cancellated and furnished with a perioleum, upon which several blood-vessels are ramified, and the humerus of the same bird to be a simple osseous tube, without membrane, vessels, or cancelli. It appears to us, however, that the membranes of which the air-cells are composed, are continued in every instance into the interior of the bone, to which they may serve, it is true, the purpose of a perioleum, although in structure they are much more firm and delicate, and when these membranes cease to be vascular, they become dry, and adhere so closely to the surface of the bone, that they are not easily perceived.

The internal parts of the bones of birds which are filled with air consist of cells, like those of other animals; the only difference that can be observed is, that the cancellated structure is less close, and that the tube of the cylindrical bodies, such as the humerus and femur, is larger than usual.

It has been already mentioned, that the bones derive their air in general from those cells which are placed next them amongst the musclos. Some, however, are filled immediately from the lungs, or the large internal air-cells, and the bones of the head and jaws have communications with the Eustachian tube, the cavity of the tympanum, and the sinuses of the nose.

The humerus is supplied with air by the axillary cell, by means of an opening situated at the inner and back part of the head of the bone. See Plate VI. in the Anatomy of Birds; fig. 1., represents the superior half of the humerus of the 
American turkey (meleagræ); a, the air-holes, which lie in the air-plates of the lung, does not open immediately into the cavity of the bone, but contains a number of smaller foramina, that are produced by the cancelli, and have a direct communication with the internal part of the humerus.

The fork-shaped bone is filled from the jugular air-cell, from which also the superior dorso-lateral, and the lowest cervical vertebra, receive some air, through several small holes scattered upon their lateral and anterior parts. The air-holes of the fork is placed upon the side of its fleshy extremity, next the spine. See Plate VI. in the Anatomy of Birds; fig. 2. is the one half of the fork-shaped bone of the fork viewed upon the inside, a, the air-hole.

The clavicle appears to obtain its chief supply of air from the cells which are continued from the jugular air-cells backwards upon the shoulder joint.

The principal foramen is found on the inside of the clavicle, where that bone is connected to the branch of the fork. There are, besides this, some minute holes upon the outside of the clavicle, immediately above the shoulder joint; and on each side of the fleshy extremity of the bone, there is a hole large enough to admit a bristle. See Plate VI. in the Anatomy of Birds. Fig. 5. shows an internal view of the clavicle of the fork; a, the larger air-hole at the joint of the shoulder; b, one of the small foramina which opens into the shell containing a bristle.

The scapula derives air also from the process of the jugular cell behind the joint. It is transmitted through several holes upon the very extremity of the bone. See fig. 4. of Plate VI. of the Anatomy of Birds, a the air-holes.

We have discovered the openings by which the air is conveyed into the femur, to be exceedingly numerous. The principal foramina are situated all along the middle line of the bone, upon the internal surface, which appears reticulated, or made of cancelli. Towards the anterior part there is one hole much larger than any of the rest; and in addition to those of the middle of the bone there are many others passing into the edges of the femur to which the ribs are articulated. All these foramina would appear to communicate with the thoracic cavities. See Plate VI. in the Anatomy of Birds; fig. 5. exhibits the internal surface of the femur of the fork; a, a small foramina in the middle of the bone, b the principal air-hole near the top of the femur, c c c e e many little foramina seen between the femoral ribs which lead to the lateral parts of the bone.

The vertebrae of the back seem to procure air immediately from the lungs; the foramina are numerous, and placed along the sides of the bodies of the vertebrae and at the roots of their transverse processes. The foramina which conduct the air into the cervical vertebrae, occur with as little regularity; the three first have their largest holes upon the sides of their bodies, and in the rest they are to be found within the canal of the transverse processes for lodging the vertebral artery, and along the course of the spinal canal, at least so they have appeared in the fork. See Plate VI. in the Anatomy of Birds. Fig. 6. shews one of the cervical vertebra of that bird, a, the body of the bone, b the spinous processes, c c the transverse processes forming a portion of the vertebral canal, on the sides of which are perceived several foramina leading into the substance of the bone, d the tube behind the body of the vertebra for containing the spinal marrow, exhibiting many small holes upon its internal
The foramina of the cervical vertebrae have communication with the lateral air-cells of the neck.

The air-holes of the anterior ribs are placed upon the ends of these bones, where they are joined to the sternum. They are supplied from the intermediate and lateral thoracic air-cells. See Plate VI., in the Anatomy of Birds, for a detailed description of the openings upon the sternal ribs.

The air-palies into the posterior or vertebral ribs by a number of foramina, situated upon the internal surface of their extremities next the spine. These foramina appear to have from their situation a direct communication with the posterior surface of the lungs. See Plate VI., in the Anatomy of Birds. Fig. 7, is a vertebral rib of the fowl seen upon its inner side, a the process which communicates with the bodies of the dorsal vertebra, b the part joined to the transverse processes, c e the several air-holes.

The air-holes of the bones of the pelvis are so numerous, and occur with so much irregularity, that they do not admit of a particular description. They are all situated upon the internal surface of the bones, and appear to be confined to that space covered by the kidneies, under which the air must infiltrate itself from the abdominal cells, in order to reach them.

The passage of the air into the femur of the eagle and fork is through an opening upon the fore part of the bone, just within the process corresponding to the great trochanter. It is a round depression, under the which the apertures leading to the cavity of the bone are situated. See Plate VI., and fig. 8. of the Anatomy of Birds, which represents the femur of the eagle seen upon the anterior side; a the air hole, b c the cavity of the bone laid open, exhibiting a number of odorous processes, passing in all directions, dividing the bone upon the inside into many irregular cells; there are most numerous towards the extremities of the femur, and are hardly to be seen in the centre; c an artery distributing its branches to the membrane which lines the internal part of the bone. The air-hole of the femur in these birds communicates with the glutinous cells.

In the struthious birds the air-holes of the femur are placed upon the posterior part, and are found upon both the upper and lower portions of the bone. See Plate VI., in the Anatomy of Birds. Fig. 7, shows the posterior surface of the femur of a young ostrich; a a depression on the upper part of the bone, containing a number of air-holes, b the inferior depression with only three foramina.

The air-holes of the lower jaw have been observed in the African and New Holland ostrich, the fork, the bustard and bustard riberis, and the crow; and in all these they consist of two holes situated upon the two extremities of the jaw behind the articulation. See Plate VI., in the Anatomy of Birds. Fig. 10, is the lower jaw of the crow; a b the two air-holes. These foramina communicate by a tube with the cavity of the ear.

The air does not penetrate the bones of the head and jaws in water-fowls.

Having described the distribution of air, which takes place throughout the bodies of birds, it remains to assign an use to this most curious and peculiar circumstance in their anatomy. It has been already stated, that the opinions of anatomists upon the subject are divided. The members of the French academy supposed that the air-cells were necessary to carry on the actions of respiration in birds. Camper thought that air was admitted into the bodies of birds for the purpose of diminishing their gravity in relation to their bulk, and thus facilitate their motion; while Mr. Hunter, the greatest physiologist of this or any other country, felt unwilling to confine the functions of the air-cells to any one purpose, and suspected they might be useful in giving tone and strength to the long limbs.

The observations of the academics appear to us perfectly satisfactory with respect to the connection between the existence of the air-cells, and the office of the lungs. They have related, that during the act of inspiration the sternum was elevated, and the thoracic air-cells distended at the same moment with the lungs, and that when the air was expelled from the lungs and thoracic cells, by the depression of the sternum, one portion of it was expired by the trachea in the usual way, and the rest was urged into the cells of the abdomen, the two parts of the cavity thus becoming alternately enlarged and diminished. In order to effect this, the more certainty the condition of the air-cells during respiration, the academicians subjected several large birds, such as the turkey, goose, etc. to the experiment, of having the parr of the body disconnected without injuring the cells, while the animal was still alive, by which they had an opportunity of observing, that the air-cells below the sternum were rendered tenet during the time the thorax was diminished for expiration, and that as soon as the sternum was raised to increase the capacity of the thorax, the abdominal air-bags become filled. We have made an experiment of a similar kind, with the same result; the abdomen of a living goose was laid open, from which no air proceeded during inspiration, but while the air was discharged from the lungs, it passed into the abdominal cells and through the opening of the belly with so much force as to blow out a candle. The necessity of having the cavity filled with air in birds, obviously arises from the circumstance of the lungs being confined to the posterior part of the thorax, and consequently not capable of suffering any compression from the contraction of the chest, but by the interposition of some other parts.

Many have supposed that the air-cells were not only mechanically subservient to the actions of respiration, but answered another important purpose by collecting a quantity of air, which in repelling the lungs effected a further change upon the blood, thus producing a sort of double respiration; but the free communication which exists between the lungs and the cells, renders it probable that the air on its return passes directly by the air-holes into the branches of the bronches, and, consequently, is never brought into contact with the blood. It would therefore appear that the only part the cells perform in the process of respiration is to supply an elastic medium, by means of which the motion of the sternum and ribs, equally and regularly affect every part of the lungs.

The air-cells making part of the mechanism of the organs of respiration, does not preclude them from answering other purposes in the animal economy. It is plain to demonstration that the bodies of birds lose much of their relative weight by containing air in their cavities, and still more from its admission into the external parts and the bones; the advantages of which in transporting themselves through the air light a medium to the air, or even in locomotion upon a solid surface, are too obvious to be mistaken upon.

The air, while it remains in the body, necessarily acquires the temperature of the living bird, which renders it much lighter even than atmospheric air, and therefore it acts like that retained in the swimming-ladder of fishes.

A comparison of the structure of one bird with another proves that the quantity of air is in proportion to the rapidity and continuance of the animal's motion, all other circumstances being the same; and that the air is distributed always in preference to those members which are most employed in locomotion, as has been already pointed out.
BIRD.

The organs of circulation in birds have obtained but little of the attention of comparative anatomists. The larger branches of the arteries and veins, which lie near some of the viscera, have alone received any description: and that rather from being involved in the account of other parts, than for their own sake. The distribution of the blood vessels of birds, notwithstanding this, is not the least interesting part of their anatomy, as will appear from the ensuing description, which has been taken chiefly from the fowls, geese, ducks, birds, and common fowl, in which it was found to much alike, that it may be premised the same arrangement of the blood vessels prevails with little variety in all birds.

The Arteries

Proceed from a trunk: which arises from the left ventricle of the heart. This trunk is so short, that it is concealed by the other parts on the base of the heart, and is only brought into view after the reflections of the pericardium, and the adjoining vessels are detached by dissection. It is from thence, that as the parts are commonly beheld, there appear to be three great arteries issuing together from the middle of the heart, which are the primary branches into which the aorta is divided. The first branch is to the left side, and after it is sent off, the trunk affects to turn over the aorta, before it gives the branch of the right side: these two branches pass in a curved manner from the heart towards the axillary, in the form of horns, and each is analogous to the arteria innominata of the human subject, so that instead of one, there may be reckoned two arteria innominata in birds. After these branches are parted with, the arterial trunk is continued over the aorta, and on reaching the back part of the heart, becomes the descending aorta.

The arteria innominata first sends off the common trunk of the carotid and vertebral arteries, which before its division gives off one or two small branches; one of these runs down upon the lungs in company with the par vagum, and appears to supply branches to the aponemotysis of the lungs, and the air-cells at the upper part of the thorax; the other branch, after supplying the lymphatic gland of the neck with several small arteries, ascends upon the side of the cephagus, to which, and the inferior larynx, the divisions of the trachea, and to the parts and integuments of the side of the neck, its branches are distributed, anastomosing with the superior cephagoidal and tracheal arteries. This branch is often not sent off until the trunk divides into the vertebral and carotid, in which case it comes from the latter artery. Sometimes in the duck, the suprascapular artery, which is usually derived from the vertebral, is a branch of the common trunk.

The carotid artery, after parting from the vertebral, proceeds to the middle of the neck, and soon disappears; being covered by the muscles of the anterior part of the neck, under which it lies hidden, and in close contact with its fellow of the other side, to very near the head. If, during its course in this situation, it gives any branches, they are too insignificant to be noticed.

The carotid artery emerges from between the muscles of the neck, at about the third or fourth vertebra from the head; and after giving a branch downwards, amongst the lateral muscles of the neck, it runs along the outer edge of the rectus major anteicus musculo, to behind the angle of the jaw, where it divides into its several branches.

An artery first goes off posteriorly, which passes a little forwards under the branch of the os hyoides, and after sending
ing some blood to the muscles of the neck, makes a turn backwards, enters the foramen in the transverse procus of the second vertebra, and terminates by a singular anatomical branch in the vertebral artery.

The next branch is analogous to the internal carotid; it goes forward also under the os hyoides, and passes behind the muscles of the jaws close upon the lower part of the skull, at which place it sends a branch upwards, which appears to penetrate the bones of the outside of the ear, and supply the organ of hearing, feeds a branch into the skull, and another through the articulation of the jaw, to unite with the ophtalmic, and contribute to the plexus at the back of the orbit. The internal carotid then enters an oculose canal, which runs along the bals of the cranium, between the tables of the bone, and at the lower and back part of the orbit, the artery receives a remarkable anastomosing branch of the internal maxillary, which almost equals in size the carotid itself; and these two vessels produce by their union, one, which passes almost directly into the cranium at the actual place for the entrance of the carotid artery. This vessel forms within the skull an anamolism similar to the circle of Willis; but the branch which occupies the place of the baso-
fary artery, is very small, and appears to be furnished entirely from the anamolism of the carotids, and designated only to supply the medulla oblongata and spinal marrow.

The branches of the internal carotid are thickly spred in an arborescent form upon the surfaces of the brain, some on the outside, and others on the internal superficies of the ventricles, and the sulci between the two hemispheres. The carotid also, as usual, sends off the ophtalmic artery, which, besides supplying the eye and the parts in the orbit, produces several anastomoses with the branches of the external carotid, which will be noticed hereafter.

After the trunk of the carotid has parted with the two branches just decribed, it passes for a little way downwards and forwards behind the angle of the jaw, and divides at once into different branches, corresponding to those of the external carotid in mammalia, the first of which might be called the ophosphageal or basophygeal artery. This vessel feeds a branch to the muscles upon the horn of the os hyoides, and then turns downwards and divides into two branches, one to the trachea, and the other to the esophagus, upon the side of which parts they descend to near the thorax, where they anastomose with the tracheal and esophagal branches of the common trunk of the carotid and vertebral arteries.

The external carotid artery dips in between the ptery-
goid muscle, and that which is situated at the back of the lower jaw for opening the mouth; it then passes behind the articular bone, and gives twigs upwards to the muscles of the jaws, and to the plexus at the back of the orbit; upon emerging from behind the articular bone, it lies under the subgastomy procus of the jaw, and feeds an artery upwards, which is distributed to the temporal and masticeter muscles; and proceeding under the triangular tendon that comes from the inferior margin of the orbit to the lower jaw, it divides into two principal branches: one of these passes along the side of the upper jaw, gives a branch upwards to the fore part of the orbit which unites with the ophtalmic artery, and is lost at the top of the head. This branch is very large in birds with combs, as in conjunction with the ophtalmic, it furnishes numerous vessels to the vascular parts. The artery then goes on and supplies branches to the sides of the head before the orbits, and to the integuments and subcutaneous of the upper mandible, inastomosing with the palatine branches of the internal maxillary artery. The second portion of the external maxillary proceeds to the lower jaw, to which, and the lower part of the masticeter muscle, it is distributed. The external maxillary supplies the place of the temporal, labial, angular, nasal, and mental arteries of mammalia.

The lingual, or posterior palatine artery is a little branch of the external carotid, which is sent off posteriorly opposite to the external maxillary artery. Its branches are exalted upon the back part of the fauces, the muscles for moving the upper jaw, and posterior nares.

The lingual, or sub-maxillary artery passes under the muscles which connect the os hyoides to the lower jaw, and close upon the back of the membrane of the lower part of the mouth, it sends a branch to the esophagus and trachea, supplies the muscles of the os hyoides, the tongue, the lower surface of the mouth, and furnishes the artery which enters the subcutaneous of the lower jaw.

Just at the origin of the sub maxillary artery, there is another little branch of the carotid, which is lost upon the muscles of the os hyoides.

The internal maxillary artery is, as usual, the continuation of the trunk of the external carotid; it runs forwards between the pterygoid muscles, and the lining of the mouth, upon the side of the long muscle for moving the upper jaw, and divides into two principal branches; one of them proceeds under the tendon of the long muscle to get upon the palate, where it forms two branches, of which one runs along the external side of the palate, between the membrane and the bone of the mandible to the extremity of the bill, where it becomes united to the same branch of the opposite side, as also to the middle artery of the palate. The other branch lies also superficially under the membrane which lines the mouth. It passes onwards to meet its corresponding vessel of the opposite side with which it becomes actually incorporated, and by their union a single artery is generated, which runs along the middle line of the palate to the end of the mandible, where it unites with the lateral branches as already mentioned. At the junction of the vessel of each side to form the middle palatine artery, two branches go off, which are lost upon the lining of the mouth, and the interior of the organ of smell.

The other branch of the internal maxillary artery is reflected upwards towards the orbit, below which it divides and unites again forming a triangle, through which the vein passes; at this place it produces a remarkable plexus of vessels, like the rete mirabile of the carotid artery of quadrupeds, which is increased by branches from the ophtalmic and the palatine arteries, and from which the back part of the organ of smell receives its supply of blood.

The internal maxillary artery then runs directly backwards below the orbit, passes between the radiated or fan-shaped muscle which moves the upper jaw, and the pterygoid process; and turning inwards round the basis of the cranium becomes incorporated with the internal carotid artery just as it enters the boney canal, which conducts it to the brain.

The vertebral artery, soon after it parts from the carotid, sends off a branch backwards, which passes over the neck of the scapula and is lost among the muscles on the posterior part of the shoulder, inastomosing with the articular and other arteries about the joint; this branch might be called the supra-vertebral. In the duck we have observed it forms the turn over the scapula to form an artery upwards along the muscles of the neck.

The trunk of the vertebral artery proceeds obliquely upwards, and having entered the carotid in the transverse processes of the third cervical vertebra, gives off a large branch downwards, which is distributed to the vertebrae, and to the spinal canal in the manner of the intercostal arteries, with which it anastomoses upon arriving in the index.
The remainder of the vertebral artery is continued upwards in the canal formed in the transverse processes of the cervical vertebrae, diminishing gradually in consequence of branches it sends off between each vertebra to the spinal marrow and the muscles of the neck. Near the head, the artery is found considerably reduced; and within the last foramen in the transverse processes, terminates entirely by insinuation with the reflected branch of the carotid, as before noticed.

The extraordinary anamolies and theplexuses which are to be observed in the arteries of the head in birds are not easily accounted for. It seems possible that they may be required in consequence of the great length of the neck in these animals; it being well known that frequent communication amongst the vessels, although it diminishes the impetus of the circulation, infuses a free and uninterrupted motion of the blood.

After the common trunk of the carotid and vertebral is detached from the artery innominate, this vessel may assume the name of the subclavian. While passing under the clavicle, it sends off some important branches; the first might be called a **piral artery**, it proceeds upwards upon the internal surface of the pectoralis major muscle, which it supplies; and then dividing into two branches, one passes over the anterior edge of the clavicle, and under the pectorals major, between which and the sternum it runs, detaching its branches to the muscle; the other sends first along the under side of the clavicle a branch which is again subdivided and distributed to the outside of the shoulder joint and to the deltoid muscles, in which it invests with the articular artery. The vessel then passes between the clavicle and the fork-shaped bone, and on a ligament which connects the head of the clavicle to that of the scapula, and divides its branches upon the upper part of the shoulder joint forming anamolies with the neighbouring arteries.

The next branch of the subclavian is the **humeral artery;** it arises from the upper side of the vessel, and makes a flight curve to reach its situation on the inside of the arm, in order to dispense its branches in the manner hereafter described.

The **interomary artery** is given off just as the subclavian leaves the chest. It divides into three branches, one ramifies upon the inner surface of the sternum; another upon the internal ribs, and the intercostal muscles; and the third runs along the anterior extremities of the vertebral ribs, supplying the intercostal muscles, &c.

The peculiarugary of the arteries of the superior extremity in birds, consists in the great magnitude of the vessels which supply the pectoral muscles; these, instead of being inconsiderable branches of the axillary artery, are the continuations of the trunk of the subclavian, of which the humeral is only a branch.

The great **pectoral or thoracic artery** passes out of the chest over the first ribs, and close to the sternum, and immediately divides into two branches. One of them ramifies in the superior part of the pectoralis major, and the other is exhausted in the lower part of the muscle, and sends off a branch analogous to the long thoracic artery of mammalia.

The **humeral artery,** while within the axilla, gives a small branch backwards to the muscles, under the scapula, and upon reaching the inside of the arm produces an artery, that soon divides into the articular and the profunda humeri. The **articular artery** passes round the head of the humerus, underneath the extensors; its branches penetrate the deltoid muscle, and anamolies with the other small arteries around the joint.

The **profunda humeri** as usual turns under the extensor muscles, to reach the back of the bone, at which place, in birds, it separates into two branches, of which one descends upon the inside, and the other upon the outside of the circulation of the humerus with the radius and ulna, and there insinuates with the recurrent branches of the arteries of the fore arm.

After the humeral artery has bent off the profunda, it descends along the inner edge of the biceps muscle, detaching some branches to the neighbouring parts; upon arriving at the fold of the wing it divides into two branches, one of these is analogous to the ulnar artery, and the other from its position derives to be called rather the interosseous than the radial artery.

At the place where the humeral produces the two arteries of the fore arm a small branch is bent off, which is lost upon the fore part of the joint, and it anamolies with the recurrent of the ulnar, and the profunda humeri.

The **ulnar artery** is the principal division of the humeral; it proceeds superficially over the muscles which are analogous to the pronator, lends a large recurrent branch under the flexor humeri to the back of the joint upon which it ramifies and forges anamolies with the profunda humeri. The artery then proceeds along the inner edge of the ulnar muscles, to which it distributes branches. It is afterwards seen passing over the carpal bone of the ulnar side, and under the annular ligament, at which place it bends off some branches which spread upon the joint and indent with similar ones of the interosseous artery. Very soon after the ulnar artery gets upon the metacarpus it dips in between the bones and re-appears upon the opposite side lying under the roots of the quills, to each of which it lends an artery; it prefers this situation to the end of the metacarpal bones, where it passes between the fly analogous to the little finger and the principal or fore finger, and pursues its course along the edge of the latter, to the extremity of the wing, supplying each of the true quills with an artery and fending at each joint of the wing, a crofs branch to communicate with the anamolies branches on the opposite side.

The **interosseous artery** detaches first a branch of some size to the membrane which is spread in the fold of the wing, upon which it forms several ramifications. After this the artery dips down behind the pronator muscles to get into the space between the ulna and radius. It here gives a branch backwards to communicate with the others about the joint, and proceeds in the interosseous space as far as the carpal joint, during which course they become much diminished from giving off several branches which are distributed to the integuments and the quills placed upon the outside of the ulna. The remainder of the interosseous artery is expended in small branches upon the back of the carpal joint, the ballast quills, and along the radial edge of the metacarpus and bones of the fore finger, where it forms communications with the crofs branches of the ulnar artery already mentioned.

From this description it will be perceived, that no artery exists in birds strictly analogous to the radial; that there are no palmar arches; and that the fize of the interosseous artery, and the course of the ulnar along the outside of the metacarpus are peculiarities which arise from the necessity of affording a large supply of blood to the quills during their growth.

The **defending aorta** makes a curve round the right auricle in order to get upon the posterior surface of the heart, after which its course is close along the spine, in which situation it is bound down by cellular sub stance, and the long membrane or aponurosis, which covers the lungs on their anterior part. The first branches which this vesse appears to send off are **branchial arteries**; they arise from the fore part of the aorta just when it arrives upon the spine; and having entered
entered the lungs, their ramifications accompany those of the pulmonary arteries. They appear also to send branches to the spaces, and the spaces between the ribs.

The _arteriae intercostales_ do not take their origin from the aorta in mammals and regular branches as in mammalia, but could originally be of but few vessels, which are multiplied by many ramifications with each other, and with the arteries which come out of the spinal canal. An arterial plexus is thus formed round the heads of the ribs, from which a vessel is sent to each of the intercostal spaces. Many of these branches, besides supplying the intercostal muscles and ribs, are continued into the muscles upon the outside of the body, and the integuments. The anatomical of the intercostal arteries round the ribs is very similar to the plexus which is produced by the great sympathetic nerve in the same situation.

The aorta produces no branch which deserves the name of the _phrenic_ artery, as birds do not possess that muscular septum of the body, to which the artery of this name is distributed in other animals.

The _celiac artery_ is a very large single trunk, and arises from the left part of the aorta, even higher than the zone of gastric glands. It descends obliquely for a short way and then gives off a branch which soon divides into two or three others, that are spread upon the lower parts of the esophagus, and the side of the zone of gastric glands, uniting with the other arteries of the esophagus above, and extending downwards upon the posterior side of the ventricle, and anastomosing with the anterior gastric artery. The trunk of the celiac now divides into two very large branches, which from their distribution we have chosen to call the posterior and the anterior gastric arteries.

The _posterior gastric artery_, almost as soon as it is formed, detaches the _esophageal_ artery; and very soon after, it furnishes from the posterior side of the vessel, the _left hepatic artery_. This branch proceeds to the right side of the liver, which it enters on the side of the hepatic duct; after having divided into two or three minute arteries on its way to the liver, it supplies the hepatic duct with a branch which accompanies the duct to the intestine, and is there lost. The posterior gastric artery then runs down upon the back of the gizzard, and opposite to the origin of the first intestine it sends off an artery which proceeds directly to one of the oviduct, upon which and the side of the neck to which it is expanded, filling at the end of the excreta, with branches of the mesenteric artery, which are distributed to the adjacent portion of the small intestine. The posterior gastric then furnishes a large vessel which runs upon the gizzard and divides into two chief branches, which penetrate the substance of the digastric muscles, in which they are lost.

The next branch of the posterior gastric artery is the _pancreatic_. It runs between the two pancrea, and, dividing branches to each, and to the duodenum. After this, the trunk of the posterior gastric artery divides into two other branches which furnish twigs to the mucous partitions of the duodenum, and run along the margins of the upper and lower portions of the digastric muscles, supplying them with numerous twigs, and anastomosing with the ramifications of the other gastric arteries.

The _anterior gastric artery_ descends to the angle formed by the bulbus glaecicoliis and the gizzard, and from that point, off a small branch which spreads upon the zone of gastric glands, and moulcules with the first ramifications of the esophagus. Immediately afterwards it sends a large artery, which runs round the superior margin of the digastric muscle, in which it furnishes with many twigs, and communicates freely with the corresponding branch of the posterior gastric artery.

Three small _hepatic arteries_ take their origin from this branch of the anterior gastric, just as it passes over the highest part of the margin of the gizzard; these vessels enter the lirate in the left lobe of the liver. The anterior gastric artery now proceeds along the front part of the gizzard, sending one or two branches into the molecular substance, and near the tendon it terminates in two large vessels, one of which is distributed upon the left side of the digastric muscle and the other passes between the tendon and then divides into two small vessels, which produce several branches that disappear in the substance of the gizzard, and between the digastric muscles and the parietes of the ventricle, anastomosing with the vessels of the posterior side.

The _superior mesenteric artery_ takes its origin from the front part of the aorta a little below the celiac, and proceeds for some way without detaching any branches; after which it experiences the same kind of division and subdivision that takes place in mammalia; and the numerous arteries which are thus ultimately produced are sent upon the small intestines. One of the first and largest branches of the superior mesenteric, however, is allotted to supply one of the ceca, and establish a communication with the inferior mesenteric, and gastric arteries. This branch, soon after it leaves the trunk of the superior mesenteric, divides into two. One descends upon the rectum, where it meets with the inferior mesenteric artery, with which it produces a very remarkable anastomosis, similar to the mesenteric arch in the human subject: this united artery supplies the rectum and origin of the ceca. The second portion of this branch of the superior mesenteric, runs in the space between the last part of the small intestine, and the excreta of one side, sending numerous branches to each, and at the end of the ceca, communicates in a palatable manner with another branch of the superior mesenteric, which runs upon the adjoining part of the small intestine.

A branch arises from the anterior part of the aorta, just below the lungs; it is designed for the nutrition of the organs of generation, and except in the female for propagation, is so small as to be discovered with difficulty; but when the chicks become enlarged, it is considerably increased in size in the male bird, and much more so in the female, when the ovary and oviduct are developed for producing eggs. It nearly equals the superior mesenteric artery during the period of laying, in which flat we shall describe it. It is a single artery like the celiac and the mesenteric, proceeds at a right angle from the aorta, and soon teads off a branch which goes into the kidney of the left side, to which it gives a large twig, and farther emerging from the kidney, it runs in the membrane of the oviduct, upon which it is distributed. After this branch is detached, the artery projects a little further forwards into the cavity and divides into two branches. One of these goes to the ovary, in which it remains, and furnishes an artery of the same size to each of the tubes containing the ovaries. The other is distributed in numerous branches to the membranes and superior parts of the oviduct, and communicates with other arteries of the oviduct. It deserves to be remarked that this and all the other arteries which are furnished to the oviduct, have a tortuous and winding course, in the same manner as the vessels of the urogenital subject.

There are no regular eminent arteries in birds; the kidneys derive their blood from various sources, which will be pointed out as they occur.

The inferior extremity is supplied with two arteries, which have a separate origin from the aorta. One corresponds with the _f. mes. artery_, and the other deserves the name of _funicular artery_.

3 G 2
The femoral artery is a small trunk which takes its origin from the side of the aorta, opposite to the notch in the bones of the pelvis immediately under the left rib. This notch is formed into a round hole in the recent subject, by a ligament which is extended from it to the rib; and it is through this hole that the femoral artery makes its exit from the pelvis; just before it passes out upon the thigh, it sends off a long branch which runs backwards the whole length of the margin of the pelvis, dispensing arteries to the abdominal muscles on one side, and the obturator internus on the other. This branch also supplies a branch to the oviduct. The femoral artery, immediately after leaving the pelvis, separates into two branches; one goes upwards and outwards, ramifying amongst the muscles in that situation; the other turns downwards, and is distributed to the flexors of the limb, and round the joint, and sends an artery to the edge of the vastus internus, which can be traced as far as the knee. The kidneys appear to derive some irregular inconsiderable branches from the femoral artery while it is within the pelvis.

The iliacic artery is the principal trunk of the lower extremity, exceeding very much in size the femoral. When it is produced by the aorta, it appears to be the continuation of that trunk; the remaining part of the aorta becomes so much and so suddenly diminished, and seems as if were to proceed as a branch from the back part of the vessel.

The iliacic artery, while in the pelvis, is concealed by the kidneys, in which situation it gives a branch from its lower side, which divides into three others that are distributed to the substance of the kidneys: one of these on the left side is continued out of the kidney to be lost upon the ovulate. The artery leaves the pelvis by the ischiadic foramen, in company with the great nerve; while within the foramen, it gives a branch obliquely downwards under the biceps to the muscles lying on the pelvis; and as it passes over the adductor, it sends off another along the lower edge of that muscle, which is chiefly lost in the femoral branch. It then detaches several small branches to the muscles on the outer and fore part of the thigh, some of which anastomose round the joint with the branches of the femoral artery. Just as the ischiadic arrives in the ham, it furnishes a very large branch downwards, which divides into two; one goes under the gastrocnemius, to which and the deep seated flexors its branches are distributed as far as the heel; the other is analogous to the peroneal artery; it goes to the outside of the leg, supplies the peroneal muscles posteriorly, and passes along the outer edge of the flexors of the toes to the heel, above which, and behind the flexor tendons, it divides, running on each side of the heel, and forms several articular arteries around the joint, and communicating with the other branch, and with the anterior tibial, and the metatarsal branch of the plantar artery.

The articular arteries go off next from the artery in the ham; the two principal ones are deep seated. One proceeds under the vastus internus to the external part of the joint; the other is large, and situated upon the tibia. It forms two vessels, one is the true articular artery, and spreads upon the ligaments of the joint, the other is distributed in the substance of the flexor of the heel, which is placed upon the inside and fore part of the leg, and comes out upon the edge of this muscle to be lost in the integuments.

The posterior tibial artery is extremely small; it only supplies muscular branches to the internal head of the gastrocnemius, and some of the flexors of the toes; it is lost on the inside of the heel in anaastomoses with the peroneal artery, and other small superficial branches.

The trunk of the artery of the leg now gets upon the posterior surface of the tibia, and sends off through the deficient left between the tibia and fibula at the superior part, a branch, which is distributed to all the muscles upon the fore part of the leg. The artery then creeps along the back of the bones for some way, and passing between them above, where the fibula is anchoylofed with the tibia, it re-appears on the anterior part of the leg in the situation of the anterior tibial artery; at this place it detaches some very small branches, which frequently divide and unite again, to produce a most singular reticulation or plexus of vessels, which closely adheres to the trunk of the artery, and is continued with it as far as the articulation of the tibia with the metatarsal bone, where it disappears without seeming to answer any useful design. This plexus resembles in appearance exactly the division of the arteries of the extremities, which has been described by Mr. Carlile in the cardigrade quadrupeds, but differs from it in this circumstance, that the trunk of the artery is preferred behind it, without suffering any material diminution of its size.

The anterior tibial artery furnishes no branch of any importance during the time it is proceeding along the fore part of the leg. It passes under the strong ligament which binds down the tendons of the anterior muscles of the leg, and over the fore part of the joint on the inside of the tendon of the tibialis anticus; at which place it distributes some branches which inculcate with the other arteries round the joint; it then pursues its course in the groove along the anterior surface of the metatarsal bone, and covered by the tendon of the flexor digitorum. On coming near the foot, it sends off an artery, which divides, behind the joint of the internal toe, into two branches; one goes between the internal and middle toes, ramifies upon both their joints, and unites with the artery in the fole of the foot; the other is distributed between the internal toe and the pollux or toe, which occupies the place of the great toe; the main artery now passes to the fole of the foot through a hole in the metatarsal bone left for the purpose, when the original parts of this bone were united by osification. In this situation the artery might receive the name of the planter. It has scarcely passed through the bone, when it divides into six branches; three of these are distributed to the tendons and ligaments, &c. on the outside of the foot and the back of the metatarsus, anastomosing with the descending branches of the peroneal artery; the fourth branch supplies the pollex, and also sends a branch upon the metatarsus. The remaining branches are designed for the three principal toes; one dips in between the internal and middle toe, unites with the anterior branch of the metatarsal artery, and is distributed to the sides of these toes as far as their extremity. The other branches, divide between the external and middle toe, into two branches, which run upon the opposite side of each of these toes to the end.

When the feet are webbed, the digital arteries send off numerous branches, which ramifying in the membrane between the toes, establish a communication with each other. The present description has been taken from birds which posses three principal toes, and the back toe, or pollux; but no material difference can be expected in those with a greater number of toes.

After the trunk of the aorta has detached the ischiadic arteries, it is continued along the spine, sending small branches analogous to the lumbar arteries, one of which ascends upon the rectum, supplies the place of the inferior mesenteric, and unites with the superior mesenteric, as already mentioned. The aorta separates above the coxal vertebra into three branches; two of these proceed
B I R D.

terly, and are distributed to the neighbouring parts, and to the kidneys and oviduct; the third branch descends to the very point of the tail, upon the urocles and quills of which its branches are exhausted.

The arterial system of birds differs from that of other animals chiefly in the frequent anastomoses, which exist more especially amongst the arteries of the head and the virena. Similar communications occur between the veins, which are even in some instances more singular and unaccountable, as will be perceived by the following description, which has been taken principally from the goose, duck, and common foul.

V i e n s.

The venous system returns the blood to the heart by means of three trunks; two of these, for the convenience of description, we shall call the abdominal veins, although they do not correspond in every respect with the veins of this name in mammalia; the other trunk is analogous to the inferior vena cava.

The abdominal veins is composed of the jugular and vertebral, and the veins which belong to the inferior extremity or wing.

The vertebral vein is lodged in the same canal with the vertebral artery; it anastomoses between the vertebrae with the veins upon the sheath of the medulla spinalis which are the continuation of the maxillae of the brain; in conjunction with these, therefore, the vertebral vein may be considered as answering the purpose of the internal jugular of mammalia. It appears also to form at the base of the cranium a free communication with the jugular vein, and to receive by occasional branches, blood from the muscles of the neck.

The jugular vein is a single trunk in birds, and does not admit of the distinction into external and internal; it proceeds superficially along the side of the neck in company with the par vagum nerve. The vein of the right side exceeds the other in size; it is often twice as large. The jugular vein receives several lateral branches from the muscles and integuments of the neck, the esophagus, &c.; one of those near the head is much larger than the rest; it lies deep amongst the muscles, and appears to communicate with the vertebral vein. There is a branch of the jugular which goes amongst the muscles of the tongue and of the os hyoideum, and another for the muscles within the jaws and the integuments in the back of the mouth; these might be called the lingual and submaxillary veins.

The two jugular veins form a most remarkable communication with each other immediately below the cranium, by means of a cleft branch, generally of an equal size with the trunks themselves. From each side of the arch thus formed there issues a large vessel, which is made up of the veins of the external part of the head; one of these passes round the articular bone, and apparently penetrates the joint of that bone with the lower jaw; it appears in several branches upon the side of the cheek, and spreading from the ear, in the manner of the portio dura nerve of the human subject, and contributes to form a plexus of veins below the posterior part of the orbit, similar to the arterial plexus already described in that situation. The principal branch of the veins of the head passes obliquely round the inter-articular bone, and below the orbit divides into several larger vessels; one of which belongs to the back part of the palate; another ascends in the orbit, and mates with the ophthalmic vein; and a third is distributed to the interior of the organ of smell, the palate, and the external parts of the upper and lower jaws. These branches produce plexuses along the back of the orbit and the external edge of the palate, which correspond to those of the arteries before described.

In all the subjects we dissected for the veins we failed to discover any direct communication between the jugular vein and the maxillae of the brain; and in every instance the external veins of the head appeared to be sufficiently large of themselves to produce the trunk of the jugular. It may therefore be presumed, that if any branch analogous to the internal jugular vein passes through the posterior foramen lacerum, it is very inconsiderable, and incapable of transmitting the blood of the brain.

The finder of the brain seem to discharge their contents principally into some veins, which lie in the membrane forming the sheath of the spinal canal, and thence appear to dispose of their blood gradually, as they descend in the neck, by means of lateral communication with the vertebral veins. The maxillae, which immediately open into the spinal veins, are situated upon the back of the cerebellum, and produce by anastomoses with each other, with the larger longitudinal sinus, and with others along the sides of the brain, an union of vessels, of a diamond shape.

The maxillae of the brain in birds generally are irregular in their form, and confluent with their parts, and not only the veins on the back of the cerebellum, but the spinal veins appear to like extravasation, that accurate and repeated observations are necessary to discover them to be real vesels.

The principal maxillae, besides those upon the cerebellum, are the superior longitudinal, and one which runs along the lower edge of each hemisphere of the cerebrum; there appears to be also one upon the side of the cerebellum, corresponding to the lateral maxillae. All these maxillae communicate with each other on the back of the cerebellum as already mentioned. The superior longitudinal maxilla is continued at its anterior part under the frontal and nasal bones, and anastomoses with the opthalmic and nasoal maxillae. There are other maxillae in the several duplicatures of the dura mater, which are too small to be easily trace, or to deserve much regard.

The veins of the wing, or superior extremity, have a less curious distribution than those of the head. The branches which are derived from the parts within the chest, the muscles about the scapula, and the pectoral muscles, accompany the arteries of the same parts, so regularly that their course does not require description.

The vein lies considerably lower in the axilla than the artery, but still continues to receive corresponding branches. The trunk of the vein descends in the course of the humeral artery, but more superficially; in this situation it may be called the biceps, or more properly the humeral vein. There is no vein in birds which deserves the name of the cephalic; there are branches of the humeral vein, accompanying the articular and profunda arteries, and at the middle of the humerus, a large branch of the vein enters the bone; there are also two very small branches which lie in close contact with the humeral artery, which they accompany nearly its whole length.

The principal vein of the wing divides into two, opposite to the joint of the humerus with the forearm. One of these branches belongs to the sides of the radius; it receives blood from the muscles and skin on the upper part of the forearm, but its chief vessels lie between the integuments of the fold of the wing. The other branch of the humeral vein crosses the fore arm, just below the articulation, in company with the nerve, and running along the lateral edge of the ulna, receives a branch from between the bights of each quill, is continued along the ligament which sustains the rest of the
the quills to the extremity of the wing, receiving many veins of the joints from the opposite side of the fingers.

Besides these large superficial veins of the fore arm, there appears to be one, and sometimes two, small accompanying veins to the ulnar and interdigital arteries.

The inferior vena cava, before it enters the auricle, receives as usual the hepatic veins; these are numerous, and open into the cava, as if they passed behind the liver, or more frequently within the substance of that viscus in that back part. We have reckoned in the cæcum two large and two small hepatic veins from the right lobe, and one large branch from the left lobe, besides six minute veins, which came indifferently from both lobes.

The trunk of the vena cava is very short in the abdomen; it separates into two great branches analogous to the primary iliac veins, opposite to the renal capsules; these turn to each side, and experience a very singular distribution. On coming near the edge of the pelvis each of these two veins forms two branches; one of which collects the blood of the lower extremity, as hereafter described; the other passes straight downwards unimpeded in the substance of the kidney, and admits the several emunctory veins, which are very large, and are seen to pass for some way obliquely in the kidney, before their termination. The descending branch of the iliac also receives the ovarian veins, and when arrived at the lower end of the kidney, divides into three branches; one transmits the blood of the muscles of the tail and parts adjacent; another accompanies the ureter to the seive of the rectum, and is distributed about the anus and parts of generation, unifying to the haemorrhoidal veins; the third passes towards the middle line between the kidneys, and there unites with the corresponding branch of the opposite side. The vessel which is in this manner produced, receives all the blood of the rectum from the anus to the origin of the cæcum, anastomosing below with the branches of the haemorrhoidal veins; and at the upper part of the rectum, it becomes continuous with the trunk of the veins of the small intestines, forming the most remarkable anastomosis in the body, both on account of its consequences and the size of the vessels by which it is effected. By means of this communication, the blood of the vena cava, and the external parts of the body, flows almost indifferently into the vena cava and vena portae; for the anastomosing vessels are sufficiently large to admit the ready passage of a considerable column of blood in proportion to the whole mass which circulates in the body of the bird: for instance, in the goose, the communicating veins of the pelvis are equal in size to a goose quill, and in the ostrich and eaffowary they are as thick as a finger. The advantage which appears to result from this remarkable union of vessels, is the prevention of congestion, or the overlapping either the heart or liver with blood, as the one organ has the power of relieving the other. It would seem from this, as well as several other provisions of the same kind, that the circulation would be more liable to obstruction in birds than other animals. It is difficult to say, however, to what cause such an effect ought to be ascribed. Is it from the compression sustained by the heart and other visceræ, by means of the air-cells during respiration? Or, is the mode of progression by flight capable of impeding the motion of the blood?

The anastomosis of the pelvic veins, in being the means of conveying common venous blood into the liver, goes to prove, that the blood of the vena portæ does not require any peculiar preparation by circulation in the spleen or other visceræ, which has been conceived as necessary by some physiologists to fit it for the secretion of bile.

The vena portæ belongs almost exclusively to the right or principal lobe of the liver. It is formed by three branches. The phlegmatic vein is the smallest, and is added to the vena portæ, just as it penetrates the liver on the side of the hepatic duct. The next is made of two branches; of which one returns the blood of the posterior gastric artery, and therefore may be called the posterior gastric vein; and the other is furnished by the pancreas and duodenum, and therefore is the pancreatic vein. The third and largest branch of the vena portæ is the mesenteric vein, which not only collects the blood from all the small intestines, but likewise receives the inferior mesenteric, or vein of the rectum, which forms the communication that has been described with the pelvic veins.

The veins of the left lobe of the liver, are furnished in the goose by those which accompany the anterior gastric artery, and some branches from the head of the duodenum.

The anterior gastric veins produce two small trunks, which enter at the two extremities of the liver, in the concave surface of the left lobe of the liver, as it lies upon the edge of the gizzard; the veins from the head of the duodenum furnish a small vein which passes backwards to penetrate the posterior part of the liver in the left lobe.

In the cæcum, the veins that the left lobe of the liver derives from the anterior gastric, are more numerous than in the trunk.

The veins of the zone of gallic glands, and of the lower portion of the esophagus, do not contribute to the secretory vessels of the liver, but proceed to the superior part of that viscus to terminate in the vena cava; as does also the umbilical vein.

The vein which returns the blood of the inferior extremities, is divided in the pelvis into two branches, which correspond with the femoral and iliac arteries; the one passes through the ifchiadic foramen, and the other through the hole upon the anterior margin of the pelvis; but the proportion they bear to each other in magnitude, is the very reverse of what occurs in the arteries; for the anterior vein is the principal one, whilst the other is not a very considerable vessel, and receives its supply of blood from the muscles at the posterior part of the joint.

The femoral vein, immediately without the pelvis, gives branches on both sides, which receive the blood of the external and adductor muscles at their superior part; the trunk passes obliquely under the asccsiary muscle of the flexor digitorum, and over the os femoris, where it lies superficially; it then winds under the adductor muscles, and gets into the ham, where it receives many muscular branches, and comes into company with the artery and nerve. It here divides into the tibial and peroneal veins. The first is joined by some branches from the surface of the joint, meandering to the articular arteries; it also receives the anterior tibial vein which accompanies the artery of the same name. The tibial vein proceeds down the leg along with the artery on the inside of the deep-seated flexors of the heel; it turns over the fore part of the articulation of the tibia with the metatarsal bone, in order to get upon the inner side of the metatarses; above the origin of the pollex, it receives a communicating branch from the peroneal vein, and immediately after, two branches from the toes; one of them comes from the inside of the internal toe; the other arises from the inside of the external and middle toes, unites at the root of the toes in the sole of the foot, and is joined by a branch from the pollex, before its termination in the internal vein of the metatarsus.

The peroneal vein derives its principal branches, along with those of the peroneal artery, from the muscles on the outside of the leg. The trunk of the vein comes out from the peroneal
Birds.

These organs occupy the posterior part of the common cavity of birds, from the last rib to near the coxogen vertebrae; they fill all the cavities and depressions of the bones of the pelvis; the posterior surface, therefore, of the kidneys is extremely irregular; their anterior part is rather flat, and they are notched upon the external edge, which gives usually the appearance of their being composed of three lobes; but the inequalities of the edge seem to arise rather from the kidneys being larger at one place than at another, than from an original division into lobes: the prominences correspond to the most depressed parts on the pelvis; accordingly, the kidneys are observed to form a projection at the upper end, where they lie on the depression of the os ilium, again opposite to the hollow on the inside of the iliacal foramen, and lastly, at the lower part of the kidney, where it fills the concavity of the ilium.

The kidneys have a covering of thin peritoneum, and under this, they seem to possess another thin membranous tunic, which closely invests them, as well where they are applied to the bones, as anteriorly; this coat also appears to be reflected into the substance of the kidneys, and to form the cellular connections of the different parts which compose these organs. According to the academicians, the kidneys of the corvus corax are separated from the other parts of the lower belly, by a distinct membrane, and instead of being divided into three lobes, are toothed like a cock's comb on their gibbous part.

The texture of the kidneys is very fragile; readily giving way under the slightest injury. They yield to the pressure of the finger a granular feel, as if composed of a number of minute bodies, easily separable from each other: the surface of the kidneys also, presents the appearance of an aggregation of small glands.

The tubs and larger branches of the blood-vessels of the kidneys have been already described. The termination of the minute ramifications of the artery cannot be so clearly perceived as in mammalia. When coloured fluids are thrown in by the artery, the whole substance of the kidney appears to equally admit the injection: the minute branches of the blood vessels are too numerous, therefore, to allow of a distinct view of the figure assumed by the secretory extremity of the arteries. But it is probable, from the structure of the kidney differing in other circumstances, that it is not wound into a coil, as in man and quadrupeds.

The kidneys of birds, in general do not possess any cavity for collecting the urine, previous to its expulsion by the excretory duct: each of the little nares which form the original glands, produces a duct: these are joined by the neighbouring ducts, and thus others are generated, which terminate in the ureter or common excretory duct of each kidney. The ureter lies upon the anterior surface of the kidney, partially embedded in its substance, so that it is visible along the whole gland, except at the upper part.

The members of the academy describe the kidneys of the ostrich as being evidently composed of distinct glands, and that the ureter did not lie as in other birds, superficially, but was concealed in the glandular substance; in which situation it suffered a degree of dilatation, forming as it were, a pelvis, the whole length of the kidney, into which the different excretory ducts discharged their contents; nor, however, from pelvis, as in mammalia, but by open and plain orifices. Mr. Ranby, in his account of the anatomy of the ostrich, states, that he found the ureters occupy their usual situation on the middle line of the anterior surface of the kidney; but that the superior branch of the ureter was very conspicuous, and entered the middle of the kidney, where it formed a very large pelvis.

The structure of the ureters appears to be exactly the same which these ducts possess in the human subject.

The course of the ureters, after leaving the kidneys, is behind the rectum, to which they become connected by the peritoneum covering the intestine: they proceed, for a very little way, involved in the coats of the back of the rectum, and open usually upon two little papille, which project into the cloaca, or termination of the rectum. The orifices of the ureters in the cloaca, are much less than the width of tubes to which they belong; this, therefore, added to the obliquity with which they perforate the cloaca, answers all the purposes of a valve, and prevents any regurgitation of the urine back upon the kidneys.

The Panthian dissectors observed in the effrîches and demotelles of Numilia (ardea virgo), that the ureters became united to the excretory duct of the testicle, at the lower part of the kidney; the common duct produced by their union terminated, as usual, in the back of the cloaca. This structure certainly does not exist in the generality of birds.

The above description anticipates the observation, that birds are unprovided with any distinct reservoir for urine; analogous to the bladder: it is the cæcum throughout the whole bird, without an exception, that the feces and urine are expelled together; but the dilatation of the end of the rectum or cloaca, in some species, supplies the want of the urinary bladder, to a great degree, and renders the ejections of both the urine and feces less frequent than they would otherwise be, by affording a temporary accommodation to a considerable quantity of excrement. These dilatations are remarkably large in the effrîches, parrots, &c. See that part of the article which treats of the great intestine of birds.

It is a matter of common observation, that the excrements of birds are of a white colour, and appear as if they contained some cærenaceous substances: this effect is universally attributed to an admixture with the urine, which is supposed to be of this colour and consistence; it deserves to be mentioned, however, that if the urine be expressed from the kidneys, or examined before it has passed into the rectum, it is neither white, nor of a chalky consistence, but a limpid aqueous fluid, which exudes a jujunct smell, that is very perceptible in the larger birds, from which some quantity of the urine may be obtained, by compressing the kidneys. It would seem more probable, that the white and chalky appearance of the excrements of birds, depended upon the quantity of caelenaceous matter contained in the solid parts of the feces, than that it is derived from the urine. In proof of this supposition, it may be remarked, that

personal muscles, and passes superficially over the joint at the hock, and along the outside of the metatarsus; near the poll, or great toe, it feeds a branch round the back of the leg, to communicate with the tibial vein: after which, it is coiled upon the outside of the external toe to the extremity, receiving anastomosing branches from the tibial vein.

Where the veins run superficially upon the upper and lower extremities, they seem to supply the place of the branches of the cephalic, saphena, and the two saphenae; but the anastomosis is lost upon the upper arm and thigh: these branches forming deep-seated trunks: this constitutes the greatest peculiarity in the distribution of the veins in the extremities of birds.
that upon one occasion, where we fed a fowl with madder for a different purpose, the crotonaceous part of the excrement left its usual whitewashes, and became of the pale pink colour which madder is well known to communicate to calcareous earths.

Renal Capsules.

These bodies hold the same situation as birds as in mammalia; they also usually possess an irregularly triangular figure. The proportion which they bear in size to the kidney, is perhaps less than generally occurs in quadrupeds. In the goose, they are each about as large as a pea. The colour of the renal capsules is in every instance more or less yellow. Several of the older anatomists have described a single renal capsule in some species of birds: the mistake seems to have arisen from their being occasionally so closely applied to each other, that they appear as one body.

The renal capsules of birds do not possess any cavity or dilated part for venous blood, which renders it probable that the enlargement of the capillary vein, which has attracted so much attention in the human subject, is no way concerned with the function of these bodies.

Having discussed the structure and operations of these organs which are more immediately concerned in supporting the life of the individual, we shall proceed to consider those which are subservient to the second order of functions.

The testicles of birds are always two in number; they are situated on the insides of the body, high up in the loins, upon the superior edge of the kidneys, from which position they never descend at any period of life, as in mammalia. Consequently, birds are not provided with a foramen, or any external pouch for the accommodation of these glands. The figure of the testicles is most commonly oval; occasionally they are of an elongated form, as in the coffee-awry. The testicles are nearly round, as in the curassow, and other infaline.

The testicles appear to receive a covering from the peritoneum; but their proper tunic is remarkably strong, dense, and inelastic.

It will always be a matter of great difficulty, to exhibit satisfactorily, the intimate structure of the testes of birds, as a successful injection from the vas deferens is nearly impossible. The seminiferous tubes are so tender, that they do not sustain the least force without being ruptured; and at the period when the testes are fully developed, they are loaded with their own secretion, a circumstance highly unfavourable to the exhibition of the structure of these organs by the means of injection. The blood-veins of the testes are easily traced; some of them pass in the usual manner directly from the back part, through the glandular substance, to the surface, where they unite with others which spread in an achoracent form, under the capsules of the testes. The great mass of these glands is evidently made up of tubes, which are convoluted in all directions, and are separated into bundles or packets, by very thin cellular membranes. Their connection with the secretory extremities of the spermatic arteries, and their termination in the excretory duct, are, however, involved in obscurity, for the reasons already given.

The testicles of birds differ very much in size at different seasons of the year. When these organs are not exercised in the act of generation, they become remarkably diminished; but, during the period in which the female lays her eggs, they acquire a bulk even beyond what might be expected, from the size of the bird to which they belong. This subject has been strikingly illustrated by Mr. Hunter, in a series of figures representing the variation of bulk which takes place every spring in the testicles of the common poultin; by which it is shewn, that the testicles of this bird are ordinarly about the size of pin-heads, but, during the season of propagation, acquire nearly the bulk of pistol balls. See Plate VII. in the Anatomy of Birds; No. 1. exhibits the testes as they exist in the month of January; No. 2. as they are in the middle of February; No. 3, as they are found in the beginning of March; No. 4, their size in the latter end of March; and No. 5, the bulk they assume in the month of April.

The vas deferens, or excretory duct, arises usually from the posterior part of the testicle, and probably always suffers a certain degree of convolution or coiling upon itself, corresponding to the epididymis, which generally differs more or less in colour from the body of the gland. In the curassow and jubal, it has been observed to be black; in the coffee-awry yellow; and in the ardea virgo, a green colour. The academicians represent the epididymis of the coffee-awry as being extended for some way above the testicle, and considerably enlarged at the top. See Plate VII. in the Anatomy of Birds. Fig. 1. a the two testes; b b the epididymis of each side; c c the vasa deferentia; d d of the ureters coming from the kidney to unite with the vasa deferentia; e e the excretory ducts common to both the kidneys and the testicles.

In the offish, the epididymis turns up on the side of the testicle; and in the ardea virgo, it is pendulous from it, and only connected by one end. The vas deferens also in this bird, appears to arise from the side of the testis, instead of the epididymis; and at its lower part, the duct unites with the ureters, in the same way as is represented in the coffee-awry. The excretory duct in the coffee-awry, the epididymis is situated below the testicle, which it almost equals in size.

In most birds the vasa deferentia proceed to their termination, without undergoing any remarkable degree of convolution, or experiencing any dilatation analogous to the vesiculae femininae; but in the cock, these ducts are composed of convolutions or reflections of a tube from side to side, which are so closely applied to each other, that a longitudinal section of the duct presents the appearance of a series of cells, which seem to communicate with each other in the middle. These become larger and more numerous towards the lower part of the vas deferens, and are capable of containing a considerable quantity of semen. It may be premised, therefore, that the cock, and other falacious birds, are provided with these receptacles of semen to enable them to meet the exigency of frequent copulation; and it is also to be observed, that these birds which have the vasa deferentia more finely formed, do not perform the act of coition so rapidly as the gallinaceous fowl. See Plate VII. in the Anatomy of Birds. Fig. 2. exhibits the genital organs of the common cock; a a the testicles of an oval shape; b b the epididymis at the posterior part of each; c c the vasa deferentia, one of which is cut open to expose the loculated appearance it presents internally.

The penis, in those birds where it has been observed to exist, is fixed upon the end of the rectum, immediately within the verge of the anus; it is usually of a pyramidal figure, and in its ordinary state is twirled like a screw; its external tunic is derived from the intestine, and is formed into a number of little ruffs, or processes, giving the edges of the penis, in its contracted state, a jagged or notched appearance. The body of the penis is composed of a white ligamentous
neculous habitation, which supplies the place of the corpora cavernosa, but does not seem to contain any cells or cavity internally.

There is a groove, corresponding to the urethra, along the side of the white ligament: it takes the spiral course of the penis, and in no instance could we discover that it formed a distinct canal, the external coat of the penis appearing always to dip into the groove, so that it was visible externally: and hence it might be said that the urethra of birds is fixed upon the outside of the penis. See Plate VII. in the Anatomy of Birds, fig. 3. represents these parts as they are found in the head of the most perfect species, and shows the edges deflected, and marked by the folding of the external part of the skin. In the second figure, the urethra, commencing upon the first side of the penis, and continued upon the same side as the urethra of a frog and at the end of the penis the folds gradually disappear.

The form of the ovis's penis is not spiral; it is simply smooth upon the surface, and a slight shape has been given to it, as if the tongue. The Papian anatomists describe it as being composed of white thick membranes and of two deepish yellow ligaments or sabines. They appeared to consist of very compact transverse fibres. One of the membranes was thicker than the other, and adhered strongly to the penis; the other laid immediately on each of the laminae, which were separated from each other, and united about two fingers from the extremity. One was longer than the other, and united to the ridge of the prepuce. The origin of the penis was at thecardilagus' feet, which is situated at the junction of the bones of the penis, from whence it was turned downward, and concluded in a little pouch, which was placed at the lower part of the cloaca, in which the penis was contained in the anus. This small pouch can be distinctly separated from the large bag of the cloaca, by the contraction of the margin of its foramen. The upper pouch only permits the excrement to pass from the other occasionally, and when it is closed, forms a fort of sheath for the penis.

The penis of birds receives some distinct muscular fasciculi from the rectum, which are inserted into the root of the ligamentous body; they appear to have the power of retracting it, or rolling it into the spiral form, and may perhaps render it more erect during copulation.

The pouch of the penis is large in the ovis. The academicians describe four of them, two on each side. The two first took their origin from the internal part of the os rectum, and descended along the pouch of the rectum, for the space of two lines, which they penetrated near the extremity, and passing under the sphincter ani, were inserted at the base of the penis. The other two muscles went from the internal part of the os rectum toward the bottom of the kidneys, and defended by the sides of the ureters, and after perforating the rectum, were attached to the lateral parts of the penis.

The penis of birds is unfurnished with any structure similar to the chicken or titup; from which it might be questioned whether it is capable of receiving any peculiar sensations during the act of copulation. It would seem probable, however, that the penis is the chief seat of pleasure in birds, as well as mammals, because it changes its form during copulation, and experiences a great degree of relaxation afterwards. The pouch of the ovis is prolonged four inches out of the anus during the performance of the coition; and after the coition is consummated, it is so much relaxed, that the animal has not the power of retracting it for some minutes; in which condition the penis hangs from the anus, and so much resembles an earthworm, that the ducks must take it for one, and attempt to swallow it. It is remarkable, however, that the greater number of birds, are either provided with a penis, or have merely a rudiment of it, which is incapable of conducting the semen into the organs of the female.

In those birds which want the penis, it is very easy to perceive the manner in which the vasa deferentia terminate: thus, in the common cock they can be readily traced passing along the sides of the rectum to the back of the cloaca, into which they open at little lower than the rectum, upon two papillae, which are red and covered with a minute coat formed by the internal part of the cloaca, but within the verge of the anus. The populi may be distinguished and have pointed; and although the base of these is fixed, the tip of the organ, being upon the point of the papilla, is extremely small, that it is disposed with difficulty, and will fearfully suffer the least violence to pass through it. See Plate VII. in the Anatomy of Birds, fig. 2, of the two inner papillae, upon the point of which the vasa deferentia terminate in the cock. A little is introduced into one of them, and through it, and near the center of the papille, we see the office of the rectum designated by the letter d. d.

As all birds have no means of conveying the semen into the body of the female, a natural eversion of the extremity of the cloaca always takes place during the copulation of birds.

The termination of the excretory duct of the female is difficult to discover in most of the birds which are furnished with a penis. This arises partly from the facts of the ducts becoming extremely thin and delicate near the extremity, and partly from the papilla upon which they open into the gut, being in those cases so small as very easily escape observation.

The academicians did not succeed in tracing the vasa deferentia: their termination in any of the birds they described. They note, however, that the penis of the ovis and cophin us has no communication with the ducts, nor did they contain any tube in the internal part by which they could give passage to the semen. In all the birds we have examined, we could not perceive the least appearance of a canal in the interior part of the penis, or any means of communication between it and the vasa deferentia.

In the gender we have been able to discover the mode in which the semen is discharged from the excretory ducts. At some distance behind the root of the penis there are two papillae, surrounded by a number of small follicular glands; they are not far at distance as those of the cock, and so little prominent, that and is minutely examined, they are not distinguishable from the glandular parts of the surface of the intine line which lie next them, and might easily be mistaken for a prominent edge of one of the follicles: from the point of these papillae a duct can be traced, as in the cock, to the back of the intine line; but furnished with coats so thin that it is perfectly transparent. See Plate VII. in the Anatomy of Birds, fig. 3, of the small papilla on which the vasa deferentia terminate in the gender. Some small follicular glands are seen around them, and farther within the intine line of these papillae, as indicated by the letters d. d. at these points also there are some small mucous glands.

Mr. Home has described the penis of the drake as possessing a distinct canal analogous to the urethra of mammalia, into which the vasa deferentia open close to the origin at the verge of the anus. He treated the penis in a manner when pulled out to its full extent, fix inches long, but that when left to itself it disappar in the verge of the anus, in consequence of the contractile power of the urethra. (See Phil. Transact. vol.xxi. p. 614.) The representation of the penis of the drake is copied in Plate VII. of the Anatomy
of Birds, fig. 4, a a the verge of the fundament surrounded by feathers; b b the urethra; or femoral canal laid open throughout its whole extent; c c the orifices of the vasa deferentia; d d the external tunic of the penis laid open, and from its elasticity thrown into serpentine folds.

It deserves to be mentioned, that Blainius also supposed the vasa deferentia of the drake terminated in the penis, although he spoke doubtingly, not having actually traced them thither. See Anatome animalium Gerardii Blainii.

In the gander, swan, ceyxorby, and other birds which we have examined, the channel that runs upon the external part of the penis supplies the place of the urethra, and appears fully competent to answer the purpose of a conduit to the female, when it is introduced into the organs of the female.

Besides the mucous follicles surrounding the termination of the ureters and femoral ducts, there are some others much larger upon the margin of the anus, on each side of the base of the penis. In the gander we have noticed twelve of these, fixed on each side. They appear like masses of fat lying under the inner membrane of the intestine. The three outer glands have wide orifices which lead to a cavity within of some size; they furnish specimens of simple mucous follicles, a greater size than are almost ever met with, even amongst the largest animals. See Plate VII. in the Anatomy of Birds, fig. 5, c c. the large follicular glands on the margin of the anus of the gander; j j j the three smaller glands next the penis. The anal glands are very remarkable in the ceyxorby.

No chemical analysis of the semen of birds has yet been attempted. The undertaking will be attended with some difficulty, from the small quantity which can be collected for investigation.

**Female Parts of Generation.**

There are no parts of the structure of birds which deviate more from that of mammals, than the female organs of generation: not only their construction, but their functions, differ so much, that the same names cannot be applied to each, without extending analogy beyond what is justifiable. The genital organs of the female bird strictly confit but of two parts, an ovary and ovarian tube; for the different portions of the latter, which have received the names of uterus and vagina, perform very different functions from the same parts in other animals.

The ovary of birds is always single, which is a peculiarity of structure hardly ever met with in the other classes of animals. It is situated over the descending aorta, above the kidneys. Instead of the ovum being imbedded in a solid mass, as in mammals, they are contained in membranous cysts, which are prolonged into peduncles, or footstalks, that are attached to the balls of the ovary, thus presenting the appearance of a cluster, or bunch of fruit, from whence the older anatomists were in the habit of calling the ovary of birds, the racemus vitellorum. Before the ovary, however, is developed, the rudiments of the eggs do not project beyond the surface, but lie in close contact with each other, and are included by the external membrane of the ovary, something in the manner of the ova of fish, or amphibious. The capsules which invest the ova of birds in the mature state, appear therefore to be formed by the extension of the outer membrane of the ovary, just as the contents of a herinia obtain during their protrusion a covering of peritheatum. The membranous bags, in which the ova are included, adhere to the proper tunic of the egg at the anterior part only; for posteriorly they are quite distinct, being prolonged into a funnel, or tube, which forms the peduncle to each ovum.

The blood-veins are transmitted through this funnel, and ramify in the space left between the capsule and the back part of the ovum, distributing their branches in a similar way to the central artery of the eye upon the back of the crystalline lens in mammals. The capsules are extremely vascular at every part, except a certain portion of the anterior surface, which appears like a white streak, or broad line. When the eruption of the ovum takes place, this part of the capsule gives way, after which the cyth appears like the cup of an acorn, when the nut has been freed. The older anatomists almost universally believed that the capsules of the ova were imperfect at their anterior part, and that the white streak was owing to the proper tunic of the ovum being actually exposed at this place; they describe the capsule as being extended upon the ova in a manner similar to the internal coats of the eye, and, like them, terminating by a defined line at the anterior part. The celebrated Harvey, however, observed that the membrane composing the capsules was continued over the anterior part of the ovum, at which place it became very thin. The observations we have made on this subject confirm the assertion of Harvey; we have always been able to detect a very fine pellucid membrane extended over the white line, which has all the appearance of being the continuation of the capsule. The coat of the capsule consists of several indistinct layers; and it is one of these only which appears to pass over the white line. The separation of the tunic of the capsules into layers is probably not an original formation, but is produced by the increate which takes place in the number and size of the blood vessels, and therefore the part which lies over the white streak might be considered as more nearly resembling the membrane of the capsule as it first existed. There are many instances of parts, on changing their position, either acquiring or losing vacuarity, and becoming so much altered in their structure and appearance, that separately they could not be recognized for the same. The tunic conjunctiva of the eye affords a well known example of this fort.

The portion of the capsule corresponding to the white line, from being bereft of blood-veins, becomes thin, is easily ruptured, and is incapable of supporting any internal actions, in consequence of injury; we accordingly find, that this part suffers laceration when the ovum is fixed, without the least inflammation succeeding, or any procéd similar to that which arises upon the rupture of the ovary in mammals. There is no deposition of new substance in the cavity of the cyst, ovum lateum, formed. The lacerated portions of the membrane disappear (probably by absorption), and the edges assume the appearance of being cut, the capsules become contracted and thickened, and remain hollow, presenting very exactly the resemblance of cups or the calyces of flowers, and thence they have been often called the calices.

The base of the ovary, in which all the pedicles of the ovum terminate, is of a peculiar texture. It is porous and tough, and seems to be composed of an intermixture of vessels and strong cellular substance; it adheres firmly to the parts upon which it is placed.

The ovum, during the time they remain in the ovary, poffes only the yolk and the cicatricula; the whites and the shell being added to them during their passage through the oviduct. Many of the blood-veins which are distributed between the capsule and the ovum, penetrate the membrane of the latter, in order to supply blood for the nutrition of the egg during its growth. But when the ovum arrives at maturity, these branches degenerate, and disappear entirely before the ovum is expelled from its cyst.

For the illustration of the structure of these parts, see Plate...
The ovarian tube, or oviduct, during the season of laying, fills the greater part of the lower belly; it forms a number of curves or convolutions similar to the intestines, which, however, are not permitted the same latitude of motion amongst each other, because the prolongation of peritoneum, which includes the oviduct, is remarkably strong, and is not so long as the parts it contains, and therefore the convolutions are clove close together, and even some of them are doubled up within the peritoneum. The disproportion between the oviduct and peritoneum, which invests it, arises from the additional bulk the ovary acquires when its functions are exercised, whilst the peritoneum must preserve at its back part its original extent, i.e. the length of the left kidney, from the middle of which it is reflected.

There is no decided muscular coat belonging to the oviduct; there are, however, muscular fibres between the peritoneal and internal coats of those parts, which have received the names of uterine and vagina; upon the former they are transverse, and upon the vagina the course of the fibres appears to be longitudinal.

The internal coat of the oviduct is the most remarkable part of its structure; and upon it chiefly depends the distinctions which have been made of the tube into infundibulum, Fallopian tube, uterus, and vagina.

The infundibulum is the extreme part of the tube next the ovary; it is composed apparently of a single thin membrane; the peritoneum and the internal tube becoming both delicately fine, and so closely united to each other, at this place, that they seem to be but one. This membrane is folded longitudinally, and it is seen that the folds of a garment, and is thickened by its superior edge to the bursa or matrix of the ovary; and inferiorly it is connected to the uterus; by which means the folds of the membrane are always kept spread out, ready to catch the ova as they are discharged from the ruminating animals. The passage from the membranous expansion of the tube into the oviduct is contracted, and thence occurs the dilatation of this part to a funnel, and the application of the term infundibulum.

The next portion of the oviduct, or Fallopian tube, is of considerable length, being several times coiled backwards and forwards upon itself. It is very nearly of the same width at every part; and the inner membrane is irregularly coiled, and forms numerous thick folds, which take an oblique or spiral course. The internal surface of this part of the tube resembles very much that of the digestive stomach in ruminating animals.

Where the part termed the uterus commences, there is a contraction of the tube, to which succeeds a dilatation of an oval or egg shape; in this the internal membrane acquires more firmness, and instead of the soft white spiral piece, produces an immense number of strong vascular processes or flacciduli, which give the internal part of the uterus the appearance of being fringed or foliated.

The tube again becomes diminished in capacity, and its structure changed, to form the part considered analogous to the vagina. At the origin of this part from the ovary there are several angular contractions; after which, the canal undergoes some degree of convolution, which is concealed by the peritoneal coat. The internal membrane produces longitudinal rugae, or folds, which do not project far into the cavity of the tube.

The oviduct finally opens into the cloaca on the left side, not by a simple aperture, but the extreme of the vagina is protruded for some way into the cavity of the intestine, appearing as if a portion of the oviduct were turned inside out; and to the puckered form thus produced, the old anatomists, who were always desirous of comparing the structure of other animals with that of the human subject, gave the name of oviduct. See Figs. VII. in the Anatomy of Birds, p. 138; see the membranous expansion of the oviduct, and its attachments to the ovary and the uterus, the aperture leading from the infundibulum to the interior of the oviduct; the convoluted part of the oviduct, which is supposed to be analogous to the Fallopian tube, and a part of it laid open to exhibit the spiral folds of the internal membrane; a view of the ovary or uterus cut open, and a portion of it turned backward to expose the foliated structure of the internal membrane; the vagina detached in a degree from its peritoneal covering to bring it more into view; the cavity exposed, showing the longitudinal folds; the projection of the end of the oviduct into the cloaca, with the corrugated form; by which it opens into the gut; a portion of the rectum, left to explain the connection these parts have to each other; the ureters, through which a bridle is introduced.

The uses which the several parts of the oviduct of birds serve, are very peculiar, and can hardly be compared with the functions of the genital organs of other animals. When the ovum is shed from the vitellarium, it is but imperfectly formed; and in passing along that portion of the oviduct which has been called the Fallopian tube, it meets with an albuminous fluid, which is secreted in abundance from the plicated membrane; a certain quantity of this fluid attaches itself to the ovum, and constitutes the whites and the chalazae. The egg now attains an oval figure, and while still soft, descends into the dilated part of the oviduct, in which it is detained for some time, and obtains the calcaneous covering or shell; after which, the lower portion of the duct, or the vagina, fuses itself to be enlarged, and the egg is expelled from the body of the bird. For the further history of the formation of the ovum, we refer the reader to the article Egg. In birds, and all animals strictly oviparous, the evolution of the embryo, and the growth of the fetus, is carried on without the body of the parent, and therefore the functions of the organs of generation in these animals are confined to the development and perfection of the ovum, which, as already observed, is partly accomplished in birds, while the egg remains in the ovary; and partly while it traverses the ovarian tube. It therefore seems improper to borrow the terms applied to the organs of viviparous animals in the description of those which mainly minister to the formation and support of the ovum. The progeny of the fetus in birds: its mode of existence while in the egg, and the provisions for its subsistence afterwards, will be treated of under the head of Incubation, which see.
BIRD.

deferentia terminate, were introduced into the orifice of the oviduct within the cloaca; and it has been observed, that the hen, before coition, everts the intumescence so much, that the orifice of the vagina is visible on the outside of the body, which would render the injection of the male organ very practicable, especially in those birds which are provided with a penis. The impregnating liquor must be transmitted as far as at the part in which the egg is clothed with the shell; for afterwards, it would be incapable of exerting any influence upon it; and it is probable that it reaches the ovum even before it acquires the white, otherwise the fémur could not be immediately communicated to the cœaricula. Many have supposed, that the semen produced a vapour which was propagated to the ovary itself; but the existence and operation of the ovum are now generally disbelieved.

Upon the margin of the anus of birds there is usually observed a projection which has been considered analogous to the pecten. The academicians observed, that it possessed in the female of which the same muscles which belonged to the penis. This part, from its situation, is little exposed to agitation or friction in venereal congress, and from its covering, friction appears to be the common integument of the anus, cannot be endowed with peculiar or delicate sensation. It may therefore be looked upon as one of the examples of uniformity of plan which are so often displayed in the works of nature, without the accomplishment of any immediate or obvious effect.

The female organs of generation of birds suffer even a greater alteration than the male parts, in consequence of the castration of their functions. Before and after the period of laying has commenced, the ovary and oviduct, in which they had developed, are the largest of the vésicera, and their diminutive, that they are hardly to be seen; the ovary is a very small mass, which appears to be composed of an aggregation of minute pale yellow grains; the oviduct is a mere membranous substance, with scarcely any cavity, like a degenerated blood-vessel; and the aperture, which at one period permits the egg to pass through it, is so nearly obliterated, that it is perceived with difficulty, and so close that it does not suffer the smallest instrument, or even air, to escape from it into the intumescence.

Mr. Hunter, and others, have observed, that even the sexual characters of some female birds have entirely changed, after the time ceased to lay. This phenomenon has been remarked most frequently in the ptarmigan. Several hens of this genus have assumed the manner and plumage of the cock so nearly, that their real sex could only be decided by anatomical inspection.

Organs subservient to the Performance of the Animal Functions.

Bones.

The osseous fabric of the bodies of birds constitutes one of the most curious and characteristic parts in the anatomy of this class of animals; being in many respects so curiously formed, that the analogy between them and the same organs of other animals can scarcely be traced.

The bones of birds have been observed to vary in their colour. The water birds have them of a duller white than the other species, in consequence of their abounding with marrow. The bones which contain air, are always of the finest colour, much exceeding in whiteness the bones of any quadruped: they are also of a harder and closer texture. Beccmann, in the voyage of Dampier, has observed that the black fowl of the isles of Cape-Verd, and other birds of these islands, had black bones, and Daubenton reared some hens of this kind. The same peculiarity has been noticed in the pintado; but some preparations, which were preserved by Mr. Hunter to illustrate this subject, shewed that it is the periodium in which the blackness resides.

The chemical principles of the bones, do not differ from those of mammals, except in being there a greater proportion of the calcareous phosphat in the long bones, filled with air. The arrangement of the ossaceous particles appears to be in layers, rather than fibres, successively formed, and closely applied to each other.

The bones of the heads, as in the other animals with vertebrae, consist of those of the cranium, or brain-case; and those which contain the organs of sense, or, as they are commonly termed, bones of the face.

The external form of the cranium differs according to the species: a longitudinal and vertical section of it naturally exhibits the cavity to be somewhat of an oval shape, of which the end next the face is rather pointed. In the coel, the cavity of the cranium is oval, with the axis nearly vertical. The same bones enter into the composition of the cranium in birds, as in mammals: but the futures are obliterated at an early age in the former, that their cranium commonly appears as a single bone, and therefore, in order to examine the bones of the head separately, a very young subject must be chosen.

The ex frontis is originally made of two portions: they form the principal parts of the roof of the orbits, and a portion of the fœtus, which divides one orbit from the other. They bend down, on each side, a pointed process, almost to the base of the bill. The prominences which are seen upon the heads of the coëssurov, barnhill, pintado, and the curaffræ, &c., are attached to the ex frontis, but were originally formed by distinct ossifications, in the same manner as the bones on the tarsus, which serve as the mould for the shoes. The cañé of the coëssurov's head is filled with numerous cells; in the pintado, the texture is more like that of the other bones.

The parietal bones are also in two pieces at one period, although the distinction is but rarely seen. They resemble two semi-spheres, hollowed out on the inside, to receive the brain.

The temporal bones compose the posterior parts of the orbits, and exhibit a remarkable depression between two projecting processes, for lodgings the muscles employed in the motions of the lower jaw. The zygoma is not joined to the temporal bone.

The occipital bone originally consists of four portions: one placed superiorly, another below, and two laterally. When these are united, the bone has an annular figure, incircling the foramen magnum. The surface by which it articulates with the first cervical vertebra, is a single spheric protuberance, which is placed upon the anterior edge of the great foramen, and is received into a corresponding depression of the atlas. The mobility of the head is much encreased by this mode of articulation.

The sphênoidal bone forms the greater part of the base of the cranium, its processes are less evident in general, than in mammales, although it furnishes a remarkable one which proceeds anteriorly like a filet, and receives upon its edge the ends of the inter-articular bones, and the palatine bones and vomer, which are each adapted to fit this process, and to slip along it, as the upper jaw is moved. The sphênoidal bone wants the pterygoid processes, these belonging to the palatine bones in birds.

The internal surface of the cranium exhibits a sharp ridge, which divides the cavity into two principal fossæ. One contains the hemispheres of the cerebrum, the other, which is situated in the posterior and inferior part of the cranium, accom-
accommodates the two thalami nervorum opticorum, the cerebellum, and medulla oblongata, &c. On the surface of the inferior fossa there are two flight projections, produced by the back of the orbits, and a small spiny ridge along the top of the cranium, which marks the division of the hemispheres; the inferior fossa displays a number of depressions, corresponding to the several parts it contains. There are also two irregular projections on the side, formed by the internal organ of hearing, and anteriorly the eminence called the fosa pinnae, is to be seen, with a deep round cell for lodging the pinnae gland. The depressions on the internal part of the cranium are deepened in the parrot and certain birds.

The form of the cranium vary in many respects from what occurs in mammalia.

The formamina through which the olfactory nerves are transmitted are only two in number; they proceed from a little depression at the anterior part of the skull, and open upon the upper and posterior surface of the orbit, along the superior part of which they are continued, as a deep groove, or rather more than a fine-canal, to the upper and back part of the nose, where there is another foramen or slit, formed by the ethmoidal bone.

The optic foramina are close together on the inside of the cranium, being only separated from each other by the thin partition of the orbits; this is frequently found deficient at the posterior part, and in that case the two optic foramina are thrown into one.

The fihora-orbitar fissure does not exist in birds. The parts which are transmitted through it in mammalia, pass by distinct holes; some of these are arranged round the optic foramina, and one is found on the back of the skull.

The foramen rotundum and foramen ovale, are supplied by a single hole. It is seen on the line dividing the optic and basilar fissure.

The canalis caroticus appears to commence far back, on the outside of the cranium, and just as it turns up to open upon the fossa turcica, there is a small foramen for the transmission of the communicating branch of the internal maxillary artery.

The foramen laterum anterior does not exist, and the posterior foramen laterum is small, and placed within and under the external maxillary foramina.

The maxilla auditoria interna is a very palpable foramen in birds.

The bone of the face in birds, although they differ extremely from that of the mammalia, still preserve in general a distinct analogy, by which they can be distinguished and compared.

The fihora of the orbits, notwithstanding its structure is so diffuse, must be considered as analogous to the ethmoid bone. It is united to the os frontis posteriorly, and to the sphenoidal bone below; it is at first but a lamina, or plate of bone, so that it is nearly transparent, and in numerous instances it is in part membranous. At the back of the organ of smell there are occasionally a process which projects a little from the fihora, and then the bone forming a slit, through which the olfactory nerve passes. This process may be compared to the os planum, and the fihora itself, although it is not continued far into the nose, may perhaps be thought analogous to the nuchal bande of the ethmoid bone.

There is a bone unial of a triangular shape, which is attached to the anterior, and outer angle of the os frontis. This bone Cuvier has called the lacrymal, and others the suprachyreal. It is in a certain degree moveable on the os frontis. Its two posterior angles form the suprachyreal or anterior edge of the orbits. The superior of them is continued farther backwards in the orbital bone of prey than others, giving a considerable prominence to the upper edge of the orbit. In the alitidae, the suprachyreal arch is made of a number of small bones, which are continued from the lacrymal bone, and are distinct from the os frontis. The lower of the posterior angles of the lacrymal bone is prolonged considerately in the duck, but much more in the parrot, in which it goes so far back as to join the projection of the temporal bones, and thus completes the frame of the orbit.

The remaining bones of the face either enter into the composition of the mandibles, or are provided for the motion of these parts. The superior mandible is made up of the oss nasale, oss maxillare, and inter-maxillare, the maxillary, and palatine bones; the extremity of the mandible appears to be formed originally by a distinct bone, which is added, as it were, to all the rest. The separate parts of the mandible are not to be distinguished in the adult bird, but in young subjects they come easily alund.

The palatine bones are so thin at their connection with the posterior part of the mandible, that they readily bend. At the back part, they spread out into two wings or the pterygoid process, leaving a slit-shaped aperture for the posterior nares, in which is seen the vomer; where the palatine bones are joined above, there is a groove or gutter formed, which receives the inferior edge of the septum of the orbits, and on which the palatine bones have a degree of motion when the upper mandible is raised.

The sphenoid is one of the most remarkable parts of the head of birds. It is a very long delicate bone, extended in a straight line from the inferior and back part of the upper mandible to the outside of the articular bone immediately above the articulation of the lower jaw. It is, as in mammalia, originally composed of two pieces, which in large birds are always visible. The anterior portion has been commonly described as a process of the palatine bones, but it is really produced from the part of the mandible that corresponds to the os male or jugale, as it ought, in order to be consistent with analogy. The junction of the sphenoid to the articular bone, is in a degree movable; this, added to its general tenderness and flexibility, allows it to yield to all the motions of the superior mandible.

There are two bones belonging to the head of birds, to which there are none analogous in mammalia. One of these has been called by Dumeril the square bone, but improperly, as it is in no instance exactly square, and when its processes are eminent, it is rather of a triangular form. We have chosen, both from its office and situation, to call it the articular bone.

This bone is interposed between the articulation of the lower jaw, and the os temporis: with both of these it produces a true joint. The articular surface it presents to the temporal bone, is like the two condyles of the scapula of mammalia, and between these the end of the bone contributes to the formation of the cavity of the tympanum. The articular surface next the lower jaw is made of two irregular eminences, placed obliquely across, forming a double pulley. On the outside of this the temporal extremity of the sphenoid is attached, and on the inside there is articulated another flander bone, which, from its situation, deserves to be named the inter-articular bone. There is a process from the anterior part of the articular bone, which puffs up into the orbit, and receives the attachments of muscles.

The inter-articular bone is connected by a movable joint to the articular. It is a small, straight, three-sided bone, light
slightly enlarged at the extremities. It is directed forwards and inwards, and at the anterior extremity touches the inter-articular bone of the opposite side; at this place the ends of both are placed against the posterior extremity of the palatine bones, and are hollowed so as to encompass the lower edge of the septum of the orbits, along which they have some degree of motion, when urged forwards by the articular bones.

The effect of this mechanism is, that whenever the inferior end of the articular bone is brought forwards, which is accomplished in a degree by the opening of the lower jaw, but still more by particular muscles, to be hereafter described, the inter-articular bones press against the extremity of the palatine bones, and they communicate the impulse to the whole superior mandible, which being very thin at its junction with the os frontis, suffers itself to be pushed up or elevated from the line it commonly holds, and in this manner the mouth of birds is dilated in part by the motion of the upper as well as the lower jaw.

The parrot is remarkable for having a great degree of motion in the upper mandible; in this bird the superior mandible is at all times separate from the frontal bone, they being only connected to each other by a very flexible ligament.

The inferior mandible appears to be formed originally of four pieces; two of these correspond with the bones of the inferior maxilla, and the others produce the mould on which the lower part of the bill grows. The formation of the inferior jaw, independent of its connection with the bill, differs very much from that of mammlia. There are no condyles, nor any procres deserving the name of cornua, and the angle of the jaw is the thicket and lowest part of it. The articulation is made by two depressed surfaces placed on the side of a cavity, into which the posterior pulley of the articular bone flaps in the motions of the jaw.

The form of the bones of the mandibles is precisely the same as of the horsey bill, with which they are covered; except in some water birds, the bill attains more or less of a conic figure, sometimes compressed, sometimes arched, in some whole elongated, in others short, and varying in the degree of sharpness, strength, and solidity. As the diversity, however, which occurs in the mandibles of birds, is an external appearance, and belongs rather to the science of natural history, than to comparative anatomy, it would be improper to diffuse the subject in the present article.

The peculiarities of the fossa and foramina of the face in birds, depend chiefly upon the form and proportions of the bones.

The orbitar fossa are so large, that they appear to occupy the greatest part of the profile of the head of birds. They extend in the skeleton from the roof of the skull to the palate, and communicate with the posterior part of the organ of smell. Cuvier very aptly compares them to the impression which one would conceive might be left by pinching the skull between two fingers, provided it were in a soft state.

The nasal fossa are continuous with the orbitar. They open upwards by the two external nares, or nostrils, and below by the posterior nares. The septum nae proceeds a short way in the nose, that the nasal fossa make but one cavity. The external apertures of the nares are found in the bone, at the base of the convex surface of the bill.

The temporal fossa are not crossed by the zygoma. They vary in depth according to the strength of the muscles employed in raising the lower jaw; they are therefore most plain in the rapacious birds, and those with long or heavy bills.

The sphenoidal maxillary suture can have no existence in birds from the figure and extent of their orbits; neither have they the internal orbitar, and sub-orbitar foramina, or the sphenoid canal.

The incisive foramina are small and numerous in the hone, flamingo, eagle, &c. There is but one of a moderate size placed near the base of the bill in the duck, the euripeon, the corncrake, and the sound-bill, &c. In the ciconiary, the foramen incisivum is small, and near the end of the mandible, but in the stork it is of great size. The stork has a long slit, into which open an immense number of minute holes.

The os hyoideus possesses a singular conformation in birds. The body of the bone is in general of a short round figure, somewhat enlarged at its posterior extremity, at which place it is articulated with the two cornua. These resemble horns exactly, both in their shape and direction; they are terminated by additional pieces, which form a sort of joint with the principal part of the horn, and generally confit entirely of cartilage. To the posterior end of the body or middle bone of the hyoïdes, there is articulated a smallteryloid or dagger-shaped bone, which proceeds directly backwards, and soon terminates in a point. There is also a bone articulated with the anterior extremity of the body of the hyoïdes, which penetrates the substance of the tongue, and partakes in a certain degree of the form of that organ; it is commonly terminated by a pointed cartilage, which is attached to it by a moveable joint, and is continued to near the tip of the tongue. This bone we should choose to call the lingual.

The os hyoideus and lingual bone are singularly formed in those birds which have the power of protruding their tongue to take their food. In the woodpecker, for instance, the cartilaginous extremities of the horns of the hyoïdes are immensely long, and when the tongue is not projected, are lodged in a groove or saw, which runs over the whole head, and terminates only at the root of the bill. The lingual bone in these birds also is not cartilaginous at its extremity, but is covered with a hard or horny substance, which protrudes beyond the soft parts of the tongue for the distance of about the quarter of an inch, ending in a point, and furnished with a number of sharp barbs, or plicula, which are moveable in the posterior direction only; to that, like the teeth of some fish, they suffer the effects on which the bird preys to be easily perforated by the end of this instrument, but render it impossible for them afterwards to retreat.

The vertebræ of the different regions of the spine of birds do not bear the same proportion to each other with respect to number that is usual in other animals. The cervical portion in this class is generally composed of a much greater number of vertebra than any other division of the spine. The length of the neck is in most birds determined by the height of the legs. Those water birds, however, which procure their subsistence by fishing, are provided with long necks, and at the same time short limbs, as in the common, divers, &c. The dorsal vertebrae are usually less numerous than in quadrupeds. The vertebrae of the loins become anchylosed with the bones of the pelvis, and with each other at an early period, and consequently it is difficult to reckon them. The caudal vertebrae are most numerous in those birds which make the greatest use of the tail, such as the falcon, woodpecker, stork, &c.

The following table, which is extracted from Cuvier's Lectures on Comparative Anatomy, exhibits the variety which exists with respect to the number of the vertebra in many species.

The cervical vertebrae are joined to each other by a mode of articulation which admits of very free motion in two directions:—lateral, and backwards or forwards. This depends upon the form of the articular surfaces of the bodies of the vertebrae, which consist of two portions of a cylinder applied crossways with respect to each other, and both a little hollowed for their mutual accommodation. The cylinder on the inferior part of the vertebrae, performs by its revolution the motion to either side; and when that of the superior part revolves, the neck is bent either backwards or forwards. The cylinders at the top of the neck admit of motion forwards; but those of the middle and inferior part of the cervical spine are incapable of performing a free motion forwards; as one contains a slight depression on its anterior part, which receives the edge of the ether. The neck of birds, therefore, possesses in the contracted state, or when at rest, somewhat of the figure of an S, which is accompanied with several advantages to these animals. They are enabled by it to throw the weight of the neck and head more over their centre of gravity, without which some species would be unable to preserve their equilibrium; and by combining the S like motion with that to each side, birds acquire a greater degree of flexibility in the neck than is possessed by other animals; they can touch every point of their own body with the bill, and thus supply the want of the prehensive faculty of the superior extremity or the tail, of which they are deprived by their peculiar mode of progression.

The surfaces of the articular processes lie nearly in the direction of the bodies of the vertebrae, but in some parts they have a degree of obliquity conformable to the S like shape of the neck.

The spinoous processes are only to be observed on the superior and inferior portions of the cervical spine, where they exist both on the anterior and posterior parts of the vertebrae. In birds with long necks there is a fossa on each side of the posterior spinoous processes, for the attachment of the cervical ligament, or hypastrum medius. This space is to be observed perhaps in all birds, but is very remarkable in the bird, Soona cafionary and ophirh. In the last bird it is nearly as strong as it exists in the larger quadrupeds; the same kind of ligament is also interpolated between the spinoous processes of the dorsal vertebrae.

The transverse processes of the vertebrae of the middle of the neck spread forwards, and tend down a very procumbent process of some length. These give attachment to muscles, and form in some birds a sort of canal on the anterior part of the neck, which contains the two carotid arteries. The anterior fluted processes are little observable in the pinnia and psittacine tribes, the parrot, &c., but are usually very marked in the long-necked birds.

The dorsal vertebrae of birds have scarcely any motion, in order
order that the trunk of the body may not be affected by the 
omotions of the wings in flight.

Their famous processes are commonly analagous with each other, which sometimes occurs also with respect to the 
transverse processes. In the ostrich and caffowary, the 
processes of the dorsal vertebrae are distinct, and posses
a degree of motion from which, however, these birds cannot 
fuffer any inconveniences, as they do not fly.

The 1stel vertebrae have processes on both the 

anterior and posterior surfaces; and the transverse processes 
are usually very prominent. The last bone of the tail, 
is, in most birds, of a plough-share shape for the attachment 
of the quills. It is small and conic in the new holland 
"ostrich, and caffowary; and in the pawaal, it is thin, oval, and 

situated horizontally. It is wanting in a variety of the 
domestic cock found in America.

The sternum forms one of the most characteristic bones 
in the skeleton of birds. It is a very broad thin bone, 
covers the anterior part of the common cavity, like a buck-

ler, and produces from its middle line, in every bird which 
is capable of flying, a thin plate of bone, which resembles 
very much the keel of a ship; but it is most prominent at 
its anterior part. The upper edge of the sternum presents 
two narrow depressions, which receive the ends of the two 
clavicles; and to the most anterior point of the keel the 
keel-shaped bone is commonly attached. The posterior 
edge is thin, and in most species, contains a space on each 
side, which is filled with membranes. In the "ostrich, 
parrot, and most aquatic birds, this is an oval hole; but in 
the gallina it is an oblong vacancy. The keel appears to be 
added to the sternum, merely for the attachment of the 
great pectoral muscle. Accordingly, we find its projection 
is proportioned to the necessity there is for using this 
muscle during flight; and in the "ostrich and caffowary, 
which do not employ their wings as organs of locomotion, 
the keel is absent, and the sternum is round and smooth 
on the external surface, and is very small in proportion to the 
magnitude of these birds.

The ribs of birds have been divided, like those of mam-
mals, into true and false, or as Vie d'azir has termed them 
the femo-vertebral and vertebral. The true ribs are made 
of two pieces, which are each composed of bone; the 
posterior portion is affixed to the spine by means of two 
branches, of which one is articulated with the body, and 
the other with the transverse processes of the last dorsal 
vertebra. The anterior piece is articulated by one end, 
with the lateral edge of the sternum; and by the other, to 
the end of the vertebral portion. The lateral extremities 
of the ribs, being distinct bones, are to be called femoral 
ribs, which term we have employed in other parts of this 
article. Most of the true ribs are furnished with their 
middle, with a thin oisaceous process, which proceeds ob-
lincey backwards from the posterior edge of one rib, and 
overlaps the one next behind it, and sometimes even goes 
on to cover two ribs, as in the columnus cricatus. The 
sternebral and vertebral portions of the true ribs form, at their 
junction, an angle which points backwards, and is very 
acute in the fowl ribs, which proves that the thorax of 
birds is chiefly dilated by the anterior part of the sternum, 
being carried forwards from the dorsal spine; at 
which time, the moveable angles of all the ribs become very 
oblique. These angles are scarcely observable in the 
"fluminis birds. Their ribs affume very much the figure of 
those of mammals.

The number of the sterno-vertebral ribs is liable to vary. 
There are, on each side, four in the eucton and the caffowary; 
five in the reeaw, africam ostrich, and fork; six in the buttet; 
seven in the ecaul, the buzzard, the owl, the crane, and 
the duck; eight in the crested geese, and several other wa-
ter-fowl; and nine in the fruman.

The vertebral, or false ribs, are in most birds placed at the 
anterior part of the thorax, which is the reverse of what 
is observed in mammals. When there are any of these 
ribs situated posteriorly, they are only one or two, and 
perfectly formed; there are two pair in the "fluminin " birds, 
which do not project far from the spine.

The bones of the pelvis become confluted together at 
a very early period. Their original parts are therefore very 
difficult to distinguish. The portion corresponding to the 
afternum bears some resemblance to that bone in mammals; 
but the ilium and pubis cannot be recognized by 
their figure, and are only to be known by their relation to 
the different foramina. There is a very long, slender bone, 
originally connected to the ilium, on the fore-part of the 
acetabulum, which supplies the place of the "bida. This 
bone runs parallel to the anterior part of the ilium, with 
which it is occasionally joined towards its extremity, but 
occasionally with the ribs and ilium, except in the eight, in 
which bird the bones of the pelvis are broad at their 
shinphysis, and fused a little forwards, losing something of the appearance of the pelvis of mammals. 
The pubis unites with the ilium in the acetabules for a 
considerable way, and leaves a distinct hole analogous to the
afternum; and the space between these bones posterior 
in all birds, at the anterior part, the traces of this foramen.

The ilium is generally united to the facrum and back 
of the ilium, by the part which corresponds to the iliacal 
"bida; consequently the iliacal foramen is complete in 
the skeleton of birds. In the ostrich and caffowary, how-

ever, the ilium is separate from the facrum, and is a long, 
slider ilial bone, like the pubis. There is no tuberos-
ity to the ilium, that part being thin and extended, 
extent in the "ostrich, where it becomes somewhat enlarged. 
The ilium appears to be joined to the pubis in the new 
holland "ostrich, by the intervention of another short bone.

The bones of the shoulder are very peculiar in birds; 
besides the clavicles and scapula, there is an additional 
"ingle bone, called the fork; it usually possesses the figure 
of a V; the point is attached to the most anterior part of 
the keel of the sternum, and the ends of the branches are 
secured by a ligament on the middle of the dorsal extremities 
of the clavicles, and also to the posterior processes of the 
scapula, which is analogous to the acromion. The fork 
frequently approaches more to the figure of an U than a 
V. Its angle is idly often at some distance from the sternum, 
which it is bound by a ligament. In the gallina it 
terminates in a thin plate, from which a ligament is ex-
tended to the keel of the sternum. As a general observation, 
it may be flated, that the fork is strong and chie, 
and its branches wide, arched, and carried forwards upon 
the body, in proportion as the bird possesses strength and 
rudicency of flight; and accordingly, the "fluminis birds, 
which are incapable of this mode of progression, have the 
fork very imperfectly formed. The two branches are very 
short, and never unite in the africam ostrich; but are an-
chored together with the scapula and clavicle. The caffowary 
has here two little processes from the side of the clavicle, 
which are the rudiments of the branches of the fork. In 
the new holland "ostrich, there are two very small thin 
bones, which are attached to the anterior edge of the dor-
 sal end of the clavicles, by ligament; they are directed 
upwards towards the neck, where they are fastened to each 
other
other by means of a ligament, and have no connection whatever with the sternum.

The *clavicle* is a straight bone in birds; it does not lie in a transverse direction with respect to the trunk of the body, but proceeds upwards and forwards towards the lower part of the cervical spine, and in proportion to the length and projection of the clavicle, the bird poises its weight of wing and activity of flight. The clavicle at its articulation with the sternum is thin and broad; but the rest of the bone is of a round shape; it produces a process from the posterior part of its dorsal extremity, which is united to the head of the scapula, and in conjunction with it forms a depression analogous to the glenoid cavity, although not of the same figure. The inside of the extreme part of the dorsal end of the bone, is joined by ligament with the branch of the fork, as already mentioned.

The clavicles of the *frugibis* are remarkably short, and are anchyloved with the scapula at birth.

The *scapula* are two long, plain bones, with sharp edges, resembling, in a great degree, the blade of a knife; they lie parallel to the dorsal spine, and have no processes, except the one which contributes with the clavicle to form the cavity for lodging the head of the humerus; and a little eminence opposite to this, which seems analogous to the acromion, and is joined to the end of the branch of the fork. The scapula, like all the other bones of the shoulder, are very short in the *frugibis*, not passing beyond the first two or three ribs; although in many other birds these bones reach as far as the pelvis.

The *humerus* is a round, smooth bone, more or less enlarged, and flattened at the extremities; the surface by which it articulates with the scapula and clavicle, is at the very end of the bone, and is formed of a portion of a cylinder, instead of a sphere, which is most suitable to the motions of the humerus in birds, they being almost confined to the elevation and depression of the wing. The external tuberosity of the humerus is very small; but the spine which leads from it is greatly elevated in most species of birds. The internal tuberosity is, on the other hand, remarkably large, and furnishes a process at its upper part, which corresponds, in some respects, with the coracoid process of the scapula in mammalia. The humerus is long, in proportion to the other bones of the wing in the *African giffinich*, and takes the curvature of the bird's body. It is extremely short and small, and without processes, in the *New Holland giffinich*, and *coffiaswer.*

The humerus is connected with the bones of the fore arm by an articular surface, similar to that of the human subject.

The *radius* is usually a much more slender bone than the ulna, with which it is never observed to be anchyloved.

The *ulna* exhibits no remarkable processes; it forms a pulley on its lower end. These two bones are flat in the *maebo* (apitiprofus), and are joined by an articulation which permits motion in several directions, with two tubercles, one above, and the other below the anterior edge of the humerus. The wing of this bird, both in its structure and offices, resembles a fan. The ulna and radius are nearly of an equal size in the *frugibis*; they are both very small, and have but little motion on the humerus.

There are but two *carpal* bones in a bird; one is applied to the end of the radius, and permits the motion of the lower part of the wing beyond the line of the radius; the other moves a little upon the end of the ulna, to which its form is adapted. It has often a little process from its lower edge, which is analogous to the *piafforme*. The carpal bones are obliterated in the *frugibis* birds.

The *metacarpus* consists of two bones, which are united at their superior part by anchylophial for bone way. At this place there are some eminences which appear like the remains of the second row of carpal bones foldered together. The articulation of the metacarpus with the carpus is the segment of more than half of a pulley, which is grooved in the middle, and revolves within a corresponding surface of the lower carpal bone. This motion, for the convenience of description, is called flexion and extension; but it is in strictness a broad movement, which passes upon the arm, and is accompanied with a degree of rotation, by which the convex figure of the wing is raised in the very action of folding it. There is a hyaloid process, in the upper part of the third side of the metacarpus, which gives attachment to a small pointed bone, supplying the place of the *tub.' A similar bone is found to the external end of the small branch of the metacarpus, and corresponding to the *bick figner*. The principal, or fore finger, which furnishes the wing, is articulated with the large or radial branch of the metacarpus. It consists of two phalanges, and the first exhibits marks of having been originally two bones. The two pieces of the metacarpus are to be seen in the *African giffinich*, as also the three fingers; each of which is furnished with a hook, which is covered with a horn, like a claw; but in the *New Holland giffinich* the metacarpus is a single bone, and there is but one finger, which is also terminated with a claw. All the bones of the hand are compressed into thin plates in the *maebo*.

The *thigh* bone of birds has nothing very peculiar in its form; it wants the small trochanter; it is irregularly short, in proportion to the other parts of the limb, in such birds as have long legs; it is elongated in the *acipinere*, and shorted in some water-birds. The femur is strong in all the *galaxia*; and in the *frugibis* it is of an immense thickness; it is bent in the *cormorant* and the *little gredi*.

There is a certain portion of the ligament of the extensor muscles of the leg converted very early into bone; and this seems in general to supply the place of the patella; it is not usually precociously in skeletons.

The *tibia* resembles in its form the same bone in mammalia. There are several prominent edges on the fore part of its head for the attachment of muscles. The lower edge of the tibia forms a pulley with a groove along the middle. The head of the tibia is prolonged in a remarkable manner upon the thigh, in the *gredi* and the *diver*.

The *fibula* is a very small bone, and is soon anchyloved to the side of the tibia.

The *tarsus* and *metatarsus* confinal to the adult bird, but of one bone; it exhibits, however, grooves corresponding to the divisions which existed between its several pieces when it was first formed. These are strongly marked in the long-legged birds, and shew that the metatarsus contained originally as many bones as there are principal toes. There is usually also a prominence on the posterior part of the head of the bone which represents the *os calcis*. The inferior extremity of the metatarsal bone produces a process shaped like a pulley for the articulation with each of the principal toes.

There are three bones in the composition of the tarsus and metatarsus of the *maebo* by separate from each other in the middle; and therefore these birds are plantigrade, or walk up on the metatarsus as well as the toes.

The extraordinary length of limb which belongs to some kinds, as the *frugibis* and *sweden* birds, depends upon the extent of the tibia and metatarsal bone.

The *flork* and some others of the *grilles*, which sleep standing on one foot, possess a curious mechanism for preserving the leg in a state of extension, without any, or at least with little muscular effort. There arises from the fore part of the head of the metatarsal bone a round eminence, which presses up between the projections of the pulley on the
anterior part of the end of the tibia. This eminence affords a sufficient degree of resistance to the flexion of the leg to counteract the effect of the oscillations of the body, and would prove an insurmountable obstruction to the motion of the joint, if there were not a socket within the upper part of the pulley of the tibia, to receive it when the leg is in the bent position. The lower edge of the socket is prominent and sharp, and presents a sort of barrier to the admissio of the eminence, that requires a voluntary muscular exertion of the bird to overcome, which being accomplished, it slips in with some force like the end of a diasticated bone. Dumeril and Cuvier have described a similar apparatus to this in the knee of the fork; but they must have confounded, in an unaccountable manner, the one joint with the other; for the articulation of the femur with the bone of the leg in the common fork (ordo alta), certainly exhibits nothing peculiar in its structure. See Plate VIII. in the Anatomy of Birds. Fig. 1. represents the anterior part of the articulation of the tibia with the metatarsus in the fork; a the tibia, b the metatarsal bone, c the prominent edges of the pulley on the end of the tibia, d the round eminence of the head of the metatarsus, e the socket in the tibia, which receives the eminence during the flexion of the joint.

The bones of the toes vary in number, increasing from the inner to the external toes. Birds with four toes have the number of the phalanges in the following order, 2, 3, 4, 5; those with three toes have them, 3, 4, 5, except the raffowary and the New Holland ofrich, which have four joints to each toe. The African ofrich has only two toes, and four phalanges to both. Most birds have the three principal toes situated before, and the pollex attached to the inner and back part of the metatarsal bone near its extremity. The tuffard,萃affowary, New Holland ofrich, the plover, the puffet, and the long-legged plover, have but three toes; and the albatross, petrel, and penguin, want the pollex. All the stufhores have their toes opposed to each other, two behind and two before.

It would have rendered the description of the bones tedious and confused, to have given frequent references to the plates which represent them; the reader, therefore, will have occasion to contemplate the relation the different figures bear to each other; and to facilitate such comparison, similar letters are employed to indicate similar parts in each of the skeletons chosen to illustrate the subject.

When birds transport themselves from one place to another, it is mostly commonly by the act of flying; which consists in the successive elevation and depression of the wings; the latter motion being performed with so much force and velocity, as to comprefs a volume of air, the reaction of which is sufficient to impel forwards the whole body of the bird. The various kinds of flight depend upon the different ways of employing the wings, and the habits and economy of the individual, which it is the business of the naturalist to point out. Many birds are capable of using other modes of locomotion besides flying, for which their structure is equally well adapted; for instance, some tribes almost constantly inhabit the water, and swim with the greatest ease; others walk or run with the greatest rapidity; and others transport themselves chiefly by the effort of climbing. We have, therefore, selected a skeleton to exhibit the organs employed in each of these species of locomotion. See Plate VIII. in the Anatomy of Birds. Fig. 2. represents a skeleton of the New Holland ofrich, which was brought into this country by an ingenious young surgeon, Mr. Langhaff. It seems to partake of the structure of both the raffowary and African ofrich, but it bears the greatest likeness to the latter; and therefore we have called the bird an ofrich, although it has hitherto been considered by some naturalists as a raffowary.

This skeleton affords the best example of a running bird, which is at the same time incapable of flight. The sternal and bones of the wing are small; the centre of gravity is thrown fairly between the legs; and the inferior extremities are long, and of an immense disproportionate strength. Fig. 3. of the same plate exhibits the skeleton of the lark, which, as being a bird of high flight, forms a striking contrast with fig. 2.

Plate IX. of the Anatomy of Birds, contains the skeletons of a climbing and a swimming bird. Fig. 1. is the skeleton of the pigeon. The body is round and contracted; the neck short, strong, and flexible in different directions; the sternal and bones of the shoulder rather small; but its chief characters are the long thigh, and very short metatarsus, furnished with the climbing toes; by which means the bird can grasp any foreign substance, and apply the feet to any part of its own body, after the manner of the prehensile members of other animals.

Fig. 2. of Plate IX. shows the skeleton of the crested grue ble (columbus cretais). The neck is much bent; the parts of the upper extremity rather small; the ribs strong, and reaching far back; the sternal long; and the body poises this very much the form of a boat; the inferior extremity flattened behind, and the thigh bone very short, and the toes long and expanded; all which circumstances are necessary to the performance of the actions of swimming and diving with facility.

The separate parts of the skeletons, in Plates VIII. and IX. in the Anatomy of Birds, are indicated as follows.

Parts composing the head; a the occiput, b parietal bone, c the frontal, d temporal bone, e the lacrymal, f supraciliary bone, g nasal bone, h superior maxilla, i molar bone, j bone of the upper mandible, k palatine bone, l septum of the orbits, m articulare bone, n inter-articular bone, o zygoma, p inferior maxilla, q bone of the lower mandible, r external nares, s deficiency in the septum of the orbits where the optic foramina open, t temporal fossa, u spongy bone in the organ of smell.

Parts of the spine and trunk; v a cervical vertebra, w their transverse procusses, x the styles which depend on the forepart, d articulare procusses, e posterior spinous procusses, f spinous on the anterior part of the bodies of some of the vertebrae, g dorsal vertebra, h facral vertebra, i vertebra of the tail, k the ilf, or caudal bone, l osium, m ischium, n pubis, o foramen ovale, p ischiadic foramen, q vertebral or false ribs, r the true ribs, s the laterial portions, t intercostal procusses, u the part of the sternum next the body, v the keel, or projecting part, x deficiency at the lower part of the sternal bone.

Parts belonging to the wing; a the fork, b the clavicle, c the scapula, d the humerus, e its inner tuberosity, f the external tuberosity, g the spine for the attachment of the deltoïd and pectoral muscles, h the ulna, i the radius, k the carpal bone on the radial side, l the ulna carpal bone, m the head of the metacarpus, n the large branch, o the smaller one, r the stylie of the metacarpus, s the pollex or thumb, t the little finger, u the principal or forefinger.

The parts of which the lower extremity consists; a the femur, b its siny trochanter, c the tibia, d the elongation of the head of the tibia which occurs in the bipes, &c. e the fibula, f the metatarsus, g the prominence at the heel, h the pollex, or back toe, i the principal or anterior toe.

Muscles.

When the writing of the present article was begun, it was intended to give a full description of the muscles of birds; but as the subject has already extended beyond the
length that was expected, and if this were done, would exceed the bounds usually allotted to a single article, we shall only point out the most striking peculiarities in the muscular system, and correct some errors into which other writers have fallen in their accounts of this part of the anatomy of birds.

The muscles which move the lower jaw, do not differ essentially from those of mammalia. There is no marked distinction between the *m. temporalis* and *m. masseter*; they form two masses which arise from the temporal fossa and inferior part of the orbit; palpebros under the zygoma, and covers the side of the lower jaw from the joint to the commencement of the bill. There is a tendon which lies over the muscles on the side of the jaws, usually of a triangular figure; it is attached to the inferior bony portions of the orbit, connects them to each other, and thus completes the margin of the orbit. It is affixed to the protuberance on the outside of the lower jaw near the joint, and seems to prevent the mouth opening beyond a certain distance.

Birds have none of the muscles of the face, as they have no folds for them to move.

The lower jaw is depressed by a mucle which arises by two portions, one from the hollow behind the side of the occiput, the other from the surface behind and below the external mentus auditorius; both are inserted upon the back of the lower jaw. This muscle, although so unlike the *digastricus*, supplies its place, and fulfills its office.

There are three muscles for moving the upper jaw, which are quite peculiar to birds. The *temporalis* is of a radiated or fan shape; it arises from the septum of the orbit, and passing obliquely backwards, is inserted into the external surface of the end of the inter-articular bone, just when it becomes joined to the articular. By pulling the posterior end of the inter-articular bone upwards, the opposite end is pushed forwards, which produces the elevation of the upper jaw in the manner already described.

The *secon d* is a short thick muscle, arising from below the posterior part of the orbit, and before the external mentus auditorius, and inserted into the inner surface of the body of the articular bone and its anterior process, where it joins the inter-articular bone; it elevates the posterior end of the inter-articular bone, and thus raises the upper jaw.

The *third muscle* is for depressing the superior jaw; it is of a long taper shape, has one attachment to the inside of the lower jaw, and then becomes affixed to the inside of the inter-articular bone, the internal part of the pterygoid process, and sends a small tendon to the integument of the palate, just where the horny covering of the mandible commences. It is difficult to distinguish it from the pterygoid muscle, which appears to aid it in the depression of the superior mandible.

The tongue enjoys much less variety of motion in birds than in mammalia; it is only capable of being protruded, retracted, turned to each side; either directly or obliquely, slightly rotated, and depressed at the point. There are a great many muscles however employed in the performance of these motions; some of these act upon the os hyoideus, and others upon the lingual bone.

The drill is analogous to the *mylo-hyoideus*; arises from the upper and back part of the lower jaw, divides into two slips; one goes to the hyoid bone of the os hyoideus, where it meets its fellow; the other slip passes to the inner part of the middle bone or body of the hyoideus; it retracts the tongue.

The second corresponds to the *mylo-hyoideus*; it is a broad thin muscle, proceeds from the inside of the lower jaw, except its posterior edge, which comes from the outer part of the jaw; it is inserted upon the concave side of the cartilaginous extremity of the horn of the os hyoideus, around which it forms a muscular sheath; its use is to protrude the tongue.

The third muscle appears to answer to the *genio-hyoideus*; it comes from the superior edge of the lower jaw internally, and becomes attached to its fellow on the other side upon the hyoid bone of the hyoideus; protrudes the tongue a little from the obliquity of its direction, and seems to commence the actions of deglution by elevating the parts in the bottom of the mouth. We did not observe this muscle in the croc.

The fourth muscle of the tongue is extended from the horn of the os hyoideus at its root, to the hyoid bone, where it joins the muscle of the opposite side. They approximate the horns of the hyoideus, during the protrusion of the tongue.

The fifth is a very small muscle, lying along the internal surface of the horn of the os hyoideus; it feeds a delicate tendon to the under surface of the lingual bone, depresses the point of the tongue, and if it acts strongly, turns the tongue.

The sixth is a little short mucle, which arises from the end of the middle bone of the hyoideus, and is affixed to the under part of the lingual bone; depresses the tip of the tongue, and raises the bafe. This is a single muscle.

The seventh muscle lies upon its fellow upon the anterior surface of the superior larynx; it is attached to the root of the lingual bone. Its uses are to depress the base of the tongue, and thus elevate the point, and to retract the tongue while in the mouth.

The eighth is short; arises from the junction of all the bones of the os hyoideus on the lower surface, and is inserted into the upper and outer corner of the base of the lingual bone. It brings the tongue into a straight line, after the other muscles have depressed the tip.

The ninth muscle is the last; it is very minute, and passes from the base of the lingual bone to the very tip of the cartilage; depresses the point of the tongue without elevating its root.

The muscles which protrude and retract the tongue, are remarkably large in the woodpeckers and swans.

The muscles which move the head and neck are even more complicated in birds than in other animals. Most of these have their attachments so numerous and intermixed, that no description can convey an adequate idea of them.

The *lingual colli* begins in the thorax on the anterior spines of the dorsal vertebra; its fasciculi go from the anterior part or the cervical vertebra to the thyrohyale and transverse processes; and their tendons are longest at the superior and inferior part of the neck.

The *reitex capitis major anterior* is continued from the head as low as the fifth vertebra of the cervical spine.

On the posterior part of the spine there is a small muscle which seems to represent the superior part of the *rectus capitis*; it is extended from the transverse process of the fourth cervical vertebra to the back of the occiput; it brings the head backwards and to one side.

There are a great number of fasciculi interposed between the transverse and articular processes at the back of the neck. These tendons pass over several vertebrae before they are inserted on the middle of the neck, which is the support of the head backwards.

A muscle which has been considered analogous to the *cervicale deflexores*, is the chief extensor of the neck of birds. It arises from the spine of the back, opposite to the second
second rib by tendon, which, on coming upon the neck, receives seven slips of muscle, which descend from the spines of the seven inferior cervical vertebrae. The muscle then proceeds on the neck as a distinct slip, and at the upper part produces three tendons, which go to the back of the articular processes of the second, third, and fourth cervical vertebrae. The tendons receive muscular slips from the back of the spine as low as the seventh vertebra, or where the other slip began to descend. The ascending fasciculi furnish the tendons to the fifth and sixth vertebrae, and to the atlas. This muscle is enabled, on account of its descending and ascending fasciculi, to extend the neck even while the head is erect. Guiver describes the muscle somewhat differently in the heron and buzzard. The above account is from the gooff.

There is a curious shaped muscle along the inside of the preceding, which Guiver compares to the trachea cervicis. It commences by a slender tendon from the spinous process of the first dorsal vertebra, becomes fleshy at the lower part, tendinous along the middle, and again fleshy near the head, and is inserted into the occiput. Although it extends the whole length of the neck, it is so slender that its tendon is not thicker than a piece of twine or thread. It affords in the extension of the neck and elevation of the head.

The tracheo-manifoldus arises in birds from the anterior part of the second, third, and fourth cervical vertebrae, and is inserted upon the side of the occiput. The complexus proceeds from but a few of the articular processes of the neck; and the splenius does not exist in birds.

Guiver describes three recti capitis postici; but these muscles do not deserve to be so called.

The first, which he names the rectus maximus, arises from the spine of the dentata, and is inserted into the side and back of the occiput. It brings the head backwards, and to one side, and reenables in figure and office the splenius capitis.

The second, or rectus major posticus, proceeds obliquely from the spine of the dentata, under the preceding, to the depression on the back of the occiput.

The third, or rectus minor, is only a few fibres mixed with the ligament which connects the head with the spine.

The muscles of the back consist of a few fleshy fibres intermixed with portion of tendon, which are mostly ossified in all grown birds; they lie on each side of the dorsal spine, which they strengthen but cannot move.

The muscles of the tail are distinct, and generally large; some are calculated to raise the tail, some to depress it, others to move it laterally, and others again to unfold the quills of this part.

The first is the levator coccygis of Vie d'Azir; it arises from the back of the sacrum and the transverse and spinous processes of the last caudal vertebra, and sends distinct tendons to each of the spinous processes of the tail and the caudal bone. There is a fleshy slip also accompanying the last tendon. This muscle, as its name implies, elevates the tail.

The second, or depref coccygis of Vie d'Azir, is situated within the pelvis, and arises from the end of the sacrum and the ischium, where they join; also from the transverse processes of the bones of the tail. It is inserted by tendons into the spinous processes of the under surface of the caudal vertebrae, and distributes a number of muscular fibres in different directions on the basis of the lateral quills. This muscle depresses the tail, and appears also, from its attachment to the ligament of the quills, to be capable of converging them.

The third arises from the posterior edge of the anterior part of the pubis, and the tendon covering the lower part of the belly, and is inserted on the base of the ligament which unites the lateral quills. When this muscle acts finely, it brings the tail downwards and to one side; if, with its fellow, it depresses the tail directly; but at all times it tends to spread the quills of the tail.

The fourth is the motor lateralis coccygis of Vie d'Azir, which describes its origin different from what we have observed it to be. It arises from the last transverse process of the sacrum and the first of the coccyx, and it turns round to be inserted in common with the preceding muscle upon the root of the ligamentous substance which connects the lateral quills. It moves, when acting alone, the tail to one side; but combined with its fellow and other muscles, unloads the quills of the tail in the manner of the flicks of a fan.

The fifth muscle is in part covered by the third; it is attached to the whole of the posterior margin of the pelvis, except the extreme portion of the pelvis, and in the gooff spreads even upon the parietes of the belly round the anus; it then proceeds to be inserted, along with the depref coccygis, on the under part of the caudal or tail bone of the tail. Its office is, with its fellow and the deprefor, to lower the tail.

The sixth is the cruro-coccygis of Vie d'Azir; it arises by a thin tendon from the inner and back part of the thigh bone, where it is conjoined with one of the muscles of the thigh. It is inserted, along with the other muscles of the tail, into the under part of the caudal bone. This muscle draws the tail to one side; but when its action is combined with its fellow, it is the most powerful flexor or deprefor of the tail.

The muscles of the trunk deviate more from the structure of mammalia than the muscles of birds do in general, and have been but very imperfectly described by Guiver and others.

The pectorales are merely two slips of muscle, which descend from the next transverse processes upon the first and second ribs.

The triangularis flavi takes its origin from the superior corner of the sternum and the four superior ribs, where they join this bone, and is inserted into the moveable angles of the four superior ribs after the first. It comprises the superior part of the thorax, and thus brings forwards the lower end of the sternum; it is, therefore, a muscle of expiration.

The abdominal muscles consist of three layers. The first represents the obliquus externus, although its fibres are arranged transversely. It arises from the edge of the ilium and pubis by a very thin tendon, and from the lower edges of the ribs, by distinct tendinous processes, and is inserted into the side and lower edge of the sternum, and the middle line of the belly, as far as the umbilicus. From this muscle passing over the moveable angles of the ribs, its action influences the whole cavity of the body; for at the same time that it compresses the abdomen, it raises the anterior part of the sternum, by drawing the posterior part backwards, and thus dilates the thorax, and becomes a muscle of inspiration; by this means the effluence we have already referred to is produced upon the abdominal airs-cells.

The second is the obliquus ascendens; it is made of two portions, the one a little overlapping the other; the anterior is analogous to the rectus abdominis, and arises from the pubis and middle line of the belly; the other portion arises from the edge of the ilium and lowest rib. The fibres of each portion ascend in their proper directions to be inserted on the lower edge of the sternum, and the tendon filling the
the space between the ribs and the sternum. This muscle, like the preceding, diminishes the abdomen, and dilates the anterior part of the thorax.

The third layer answers to the transversalis abdominis. It proceeds from the oblique margin of the abdomen to the middle line, where it meets its fellow. They consist of separate fasciculi at the superior part; and the fibres are collected round a point in the centre, where the yolk passed into the belly of the chick.

There is a very thin layer of muscle, which crosses the lowest part of the belly; it is situated superficially, and lies over several of the muscles of the tail. In the goose it arises from the ischiium, where that bone joins the pubis; and in the fowl it is only attached by cellular membrane to the surface of the muscles of the thigh. It is inserted, in both cases, on the side of the anus, which it seems designed to dilate.

We have observed in the fowl two very slender fasciculi of muscle to descend from the side of the rectum, one to the ligament supporting the quills of the tail, the other to the inside of the pelvis. They are both probably intended to produce the eversion of the tailbone during copulation.

The muscles belonging to the wing do not differ in their arrangement and structure from those of the anterior extremity of mammalia so much as might be supposed, considering how little these members resemble each other in their functions.

The latissimus dorsi arises only from the spines of the dorsal vertebra; it resembles, however, the muscle of the same name in mammalia.

A muscle, analogous to the inferior portion of the trapsezius, is observed at the shoulder. It comes from the spinous processes of the three last cervical and all the dorsal vertebrae, and is inserted into the inner and back part of the fork and posterior edge of the scapula. We have not perceived the distinction of this muscle into two parts on the shoulder, as stated by Cuvier.

The serratus major anticus is only inserted into the point of the scapula. This muscle has been called by Vic d'Azir the subscapularis.

The coqo-scapularis of Vic d'Azir goes from the first ribs to the neck of the scapula. It appears to be analogous to the pectoralis minor of the human subject.

The rib lobesides is not divided into major and minor. It arises, as usual, from the spine, and is inserted in the posterior edge of the scapula.

A muscle, analogous to levator scapula, arises by three slips from the transverse processes of the last cervical vertebra and the first and second ribs. It is inserted into the middle of the scapula, which it elevates and draws backwards. The motions of the scapula are here very limited from its mode of connexion with the neighbouring bones; and its rotation is restrained by a ligament which joins the point of the scapula with the dorsal spine. It is requisite the bones of the shoulder should be kept very steady during flight.

There are three pectoral muscles.

The pectoralis medius of Vic d'Azir might be called the levator alae. It is affixed to the fore part of the body and keel of the sternum, the side of the clavicle, and the membrane which fills the interspace between those bone and the fork. It tends its tendon over the head of the scapula through the pulley formed by all the bones of the shoulder, to be inserted on the external tuberosity of the head of the humerus. By means of the pulley it elevates the humerus, and consequently the wing; and from occupying the lower part of the shelf, the weight is kept in the situation most convenient for the bird during flight.

The pectoralis minimus of Vic d'Azir, or depressor alae minor, arises from a portion of the sternum behind the articulation of the clavicle, and from the inside of the femoral extremity of the clavicle. It is inserted under the head of the humerus; depresses the wing, and brings it close to the body.

The subclavus is extended from the inside of the femoral extremity of the clavicle to the adjoining part of the inner surface of the sternum. It is impossible to conceive the use of this muscle, unless it be to strengthen the joint, as its attachments are incapable of motion towards each other. There are muscles analogous, as much as the form of the bones will permit, to the subscapularis, teres major and minor, supra scapularis, and infra scapularis.

Cuvier describes two little muscles which come from the inside of the clavicle to the head of the humerus. We have observed a muscle in the fowl which appears to correspond to one of these; it arises from the inner surface of the clavicle, and its joint with the sternum, passes over the first rib, and is affixed to the top of the inner tubercle of the head of the humerus. It rotates the wing inwards, when it has been spread in flight. The lower edge of this muscle, and the inside of the teres major, produce a most delicate tendinous cord, or fibre, which defends on the back of the upper arm, and is lost among the ligaments of the quills below the elbow. The effect of this, if any, is to bring the wing nearer the body, and perhaps spread the quills.

The deltoideus is small, and of two portions. One arises from the fork at the top of the shoulder, and sends a small tendon to the aponeurotic expansion of the fold of the wing. This tendon, as it proceeds along the edge of the expansion, acquires exactly the structure and the elasticity of the ligament nuchae; it then becomes a common tendon, pales over the end of the radius, and is inserted into the style of the metacarpal bone. It bends the fore arm, extends the hand, and, in consequence of the elasticity of the tendon, contracts the flat part of the fold of the wing. This portion of the deltoid has escaped the observation of Cuvier and other writers, although the structure of the tendon is one of the most extraordinary circumstances in the anatomy of birds. The remaining portion of the deltoid is analogous to the same muscle of the human subject, and brings the wing upwards and backwards in flight.

The muscle which represents the biceps flexor cubiti, takes its origin from the end of the clavicle, where it joins the fork; and from the sharp tubercle of the humerus, which is analogous to the coracoide process, the chief part of the muscle proceeds to be inserted into the inside of the neck of the radius; but as it descends, a small portion goes off, and is expanded in the fold of the wing, and attached to the outer side of the arm. This expansion of tendon corresponds to the aponeurosis of the biceps muscle of the human subject; but instead of lying close to the fore arm, it is spread out and covered with the common integuments.

The brachiolus internus is very small, being only attached
to the fore part of the end of the humerus between the condyles.

There is a short muscle which arises from the ligament that
conjoins the clavicle and the head of the humerus, and is in-
serted upon the flat external surface between the two tuber-
cles. It is an elevator of the wing. It is peculiar to birds, and
has not yet been described.

The extensor cubiti consists of two portions: the one, called
by Vic d'Azir the extensor longus, comes from the junction
of the fork and feapula; the other arises in a forked man-
er from the posteriour surface of the humerus, and is the
extensor brevis.

The aternus minor of Cuvier is the external and lower
part of the extensor brevis. It is a distinct muscle in the
feowl, though not in the goos.

Although the bones of the fore arm do not admit of pro-
nation and supination, the muscles which perform these mo-
tions in other animals, exit in birds, and answer different
purposes.

The supinator resembies that of the human subject. The
longus terminates on the style of the metacarpal bone, and
serves both to bend the arm on the humerus, and extend the
metacarpus, or lower part of the wing. The supinator bre-
vis bends the fore arm. The place of the pronator teres is
supplied by two muscles very much like it in shape; they act
as flexors of the fore arm. There is a triangular muscle
which in some degree fills the situation of the pronator qua-
dratus; it arises from the end of the ulna, and sends a broad
tendon over the carpus to the highest feabrous surface on the
metacarpal bone. It extends the hand, or lower part of the
wing, giving it at the same time a degree of pronation, which
the carpal joint permits, in order to render the wing con-
cave when it is extended.

The flexor, and extensors, situated on the fore arm of
birds, resemble in shape and arrangement generally those of
the human subject; but commonly have their ues changed,
and often even reversed, in consequence of the difference
in the figure of the bones and the plan of their articu-
lations.

The muscles which correspond in situation to the exten-
sor carpi ulnaris, performs the motion which is called flex-
ion of the lower part of the wing.

There is a strong muscle arising from the external condyle
of the humerus, and implanted into the side of the ulna op-
oposite the radius, for almost its whole length. It raises
the fore arm on the radius, and seems to be the muscle called
by Vic d'Azir flexor profundus.

The muscle analogous to the extensor pollicis longus, has
its tendon inserted into the style of the metacarpus, and
into the fold abductor. It extends the hand on the fore
arm.

The extensor pollicis comes from the internal condyle, is
attached to the lower carpal bone, and sends a tendon to the
base of the first joint of the principal finger, bends the
hand, but extends the finger.

The flexor digitorum profundus arises from the inner surface
of the ulna; its tendon passes over a little pulley upon the
metacarpal bone, and terminates on the end of the last joint
of the principal finger, which it extends, but bends the
wing.

The extensor communis digitorum and indicat or arise from
the external condyle and inside of the radius. They send
tendons to the first and last joints of the principal finger,
which they extend.

The fingers of birds are furnished with many short mus-

cles; and notwithstanding they are very palatable, feem to
have escaped the observation of Cuvier and other anato-
mists.

The flexor brevis pollicis comes from the side of the head
of the metacarpal bone to the flat surface of the bone of the
thumb. The extensor brevis pollicis proceeds from the trian-
gular surface of the metacarpus, behind the joint, to the base
of the thumb. The abductor pollicis is extended between the
style of the metacarpal bone and the outer edge of the bone
of the pollex. The adductor pollicis is extended between the
branch of the metacarpus and the bone of the thumb.

The extensor, or extensor brevis indicus, is extended all along
the radial edge of the metacarpal bone, and is spread upon
the root of the first joint of the principal finger. It brings
the finger into a line with the metacarpus. The adductor
indicis comes from the ulnar side of the large branch of
the metacarpus to the root of the first joint of the fore finger.

The abductor indicis, or extensor brevis indicus, is extended all along
the radial edge of the metacarpal bone, and extends the
rest of the finger.

The muscles of the lower extremity are very numerous in
birds, and pollics several peculiarities, notwithstanding the
motions of this member are so simple. The articulation of
the femur with the pelvis permits the thigh to move freely
and backwards, but does not allow it to be carried
under the body, or far outwards. The motions of all the
other joints of the inferior extremity are merely flexion and
extension.

In consequence of the form of the pelvis, the il发生变化, the
phenomena of the extensor femoris and quadratus
lumbarum do not exist in birds. Cuvier also states that the
periformis and geminis is to be wasted; but we have seen a
little muscle which paffes from the projection above the sce-
tabulum to the trochanter, which appears to supply the
place of the periformis.

The obturator internus is generally a large muscle, and
paffes over a pulley at the fore part of the foramen ovale,
where it receives two little flaps analogous to the geminis.
They are inserted into the outer part of the trochanter.

There are three glutaeal muscles, as in quadrupeds. The
glutus maximus is attached by a broad thin tendon to the
prominence along the dorsum of the ilium, covers the outs
side of the thigh, and contributes to form the extensor ten-
don on the side of the knee. The anterior part of this mus-
cle corresponds to the tendon the geminis. The glutus
medialis occupies its usual situation. The glutus minimus is
a small muscle, so much placed on the anterior edge of the
ilium, that Vic d'Azir considered it (perhaps not impro-
perly) as the iliacus. It brings the thigh directly forwards,
and rotates the knee inwards.

The muscle analogous to the quadratus femoris is large
and of a pyramidal shape. It retracts the thigh.

The extensor muscles of the leg resemble those of mam-
malia. The vastus internus sends its tendon to be distinctly
attached to the head of the tibia. The tibialis longus is an
extensor of the leg on the thigh.

There are three flexors of the leg: one, which, although
single, is, from its insertion into the back of the fibula, ana-
logous to the biceps of the human subject; another, on the
inside, is attached to the tendon of the extensors of the heel,
as well as to the tibia. This muscle might be called either
gracilis or femorallephasus, for it resembles both. The third
flexor is in the middle. It comes from the ischium; and as
it defecns, it receives a broad flip of muscle from the back of the femur. It is inserted on the back of the tibia, and the tendon covering the extensors of the heel.

There is a large muscle on the inside of the thigh, which supplies the place of the *trochlea*. It performs adduction, but it is also employed in carrying the limb backwards.

A muscle, which Cuvier appears to reckon as the second adductor, arises from the back of the ischium, and is inserted into the middle of the femur in company with the *ceratoccygis* muscle. It retracts the limb.

The muscles for extending the heel, and consequently the lower part of the leg of birds, differ in many respects from the *gastrocnemius* of mammalia. The tendo achillis is produced by three portions of muscle; and, after passing over a moveable cartilaginous pulley which is placed on the heel, it spreads on the sides of the metatarsal bone. The first portion arises from the inner and outer part of the joint of the knee, and is connected for some way with another muscle, which lies on the outside of the joint. The second portion is the infrapatellar, and from the back of the internal condyle of the femur. The third is a very strong muscle arising by tendons from the outside of the thigh bone, just above the condyle. These three heads appear to be the *external gastrocnemius*.

The *flexor* is represented by a muscle which arises from the outer part of the knee-joint, from the upper part of the tibia, and from the fore part of the fibula. It is inserted into the pulley on the heel, and sends a tendon to join that of the flexor of the first phalax of the toes, and therefore it bends the toes; while it acts on the heel.

There is also a muscle which appears to supply the place of the *planarias*. It comes from the back of the head of the tibia, and affixes its delicate tendon to the middle of the moveable pulley of the heel.

The *tibialis anticus* arises by two heads, and is inserted into the fore part of the upper end of the metatarsal bone. It bends the joint of the heel.

There is a short *peroneal muscle* which is inserted into the outside of the metatarsal bone. It merely bends the joint.

The other muscles situated along the legs, are for the flexion and extension of the toes. The *extensor longus digitorum* exhibits no peculiarity, except that its tendon goes through a hole in the end of the tibia. There is no *long extensor* for the back toe.

The *flexors* of the toes are very complicated; they may be divided into the *flexor sublunis* and *flexor profundus*. The first is composed of several portions; two of these are *peroneal* muscles, and send their tendons to the first joint of the internal toe, and the second phalanx of the middle toe; the other two portions of the *flexor sublunis* arise, one from the outside of the fibula, and the other from the back of the joint and internal condyle of the femur. The one on the fibular side is joined by the tendon of the *aetorhynchos femoralis flexorius*; a muscle, which arises from the spine of the pubis, runs along the thigh, and sends its tendon through a sheath that runs over the ligament of the patella, to arrive on the fibular side of the leg. The two portions of the *flexor* after this, unite, separate, and unite again, and at last produce three tendons, of which two go to the first phalanges of the internal and middle toes, and the third to all the joints of the outer toe except the last. Those tendons which pass beyond the first joint, are *perforating* as well as *premumare*.

The *flexor profundus* arises as two distinct muscles; the one from the back of the femur, and the other from the back of the bones of the leg. The two tendons unite on the back of the metatarsal bone, and send off tendons to the last phalanges of the toes, which perforate those of the *flexor sublunis*.

All the *flexor tendons* are included in a tendinous sheath, as they pass along the back of the metatarsus; and some of them go through the moveable cartilaginous pulley of the heel, and others run in sheaths formed in the cartilage which covers the top of the metatarsal bone.

The circumference of the flexion of the toes accompanying that of the other joints of the lower extremity of birds, was long ago observed by Borrelli, and attributed to him by the connexion the flexors of the toes have with the upper parts of the limb, by which they are mechanically dextre. This explanation has been controverted by Vic de'Azur and others, who have referred the effect to the irritability of the muscles. The opinion of Borrelli appears, notwithstanding, to be well founded; for not only the tendon of the acceller flexor pilling round the knee, but the course of the flexor tendons over the heel and along the metatarsus, must necessarily caufe the contraction of the toes, when either of these joints are bent; and if the phenomenon was not produced on mechanic principles, it would be impossible for birds to exhibit it during sleep, which they do, or to prove the effect on the limb of a dead bird, which only a thing is more easy. The utility of this contrivance is great in all birds, but particularly so to those reptious tribes, which by this means grasp their prey in the very act of pouncing on it; and it is still more useful to those birds which perch or roost during their sleep, as they could not otherwise preserve their position when all their voluntary powers are suspended.

There are six long small muscles lying on the metatarsal bone; they are long and held marked in those birds which walk most. Two of these are on the profundus surface; one goes to the base of the external toe, which it *adducit*; the other is inserted into the root of the back toe, which it *bends*. On the anterior part of the metatarsus there are four muscles; the first *extends* the back toe; the second goes to the base of the first toe, and *adactylit*; the third is spread on the root of the middle toe, which *extends*; the fourth lies along the outside of the metatarus, perforates the end of the bone, and is implanted into the inside of the external toe, and *adactylit*.

**Brain.**

This organ exhibits several deviations from the structure of the brain of mammalia, which afterwards appear in a more marked manner in the inferior classes of animals. Accordingly, in the scale of existence, or with respect to sensitive or mental faculties, the rank of birds is clearly fixed below that of mammalia, and above that of other animals. The rules which have been established to determine the degree of intelligence poised by species or individuals, according to the proportion the brain bears to the whole body, or other parts of the nervous system, do not appear to applicable in birds as in mammalia. It is, however, very difficult to appreciate the capacity of birds, as they are so much the fables of infancy, that it is often impossible to discover whether their actions arise from the impulse of this principle, or depend upon the recollection and association of external sensations. The largest birds generally have the smallest proportion of brain to the whole body; and some of the small birds have the proportion of brain to great, that they would, agreeable to the rules laid down, exceed in mental endowments man himself; for instance, the brain of the *canary bird* is equal to the one-fourth of the whole body; and in the human subject it is only the one-twenty-fifth part. The diameter of the
the brain, in relation to the medulla oblongata, has been ascertained only in a few species of birds, in which it has been observed as follows:

The brain of birds is invested with the same coverings which are described in mammals.

The form of the cerebral maps is very different from that of the human brain, which chiefly arises from the optic thalamus being visible externally. The hemispheres are therefore proportionately diminished. They assume the shape of a heart with the point turned forwards. On the lower part of the side of the hemisphere there is a depression which corresponds to the fossa of Sylvius, and is the only appearance of a division into lobes. Underneath the hemispheres the thalami nervorum opticorum are found, as two distinct tubes, each equaling in magnitude a lobe or division of the brain. They unite before the infundibulum, and send off the optic nerves; there are, therefore, six parts, or principal eminences, of the brain of birds, visible externally: the two hemispheres, the two thalami, the cerebellum, and the medulla oblongata. There are no convolutions, or winding impregnations, on the surface of any of these parts, except the cerebellum, which is transversely furrowed, but not divided into two lobes.

The medulla oblongata is round, and smooth on the under surface, being unarmed with the eminences called pars Varolii, corpora pyramidialis, and corpora olivaria.

On separating the hemispheres a little, it is perceived that they are united at their lower part, or over the third ventricle. The junction is effected by white medullary substance, which afterwards spreads in a radiated manner, on the surfaces of the hemispheres that are opposed or applied to each other, almost as high as the top of the cerebrum. In reality, this medullary union of the hemispheres corresponds to the fornicis, and can, like it, be traced to the anterior commissure in the third ventricle; but instead of being connected to the fiesium lucidum and corpus callosum, as these parts do not exist in birds, it spreads on the inner surfaces of the hemispheres, and thus contributes to form the internal parietes of the lateral ventricles.

Behind the radiated partition of the hemispheres, and without the third ventricle, the posterior commissure presents itself, and consists usually of more than one white line connected together by a white fibre, like a nerve passing obliquely across. The vault of the canalis medius is also visible, and is composed in part of a white medullary band; and behind this, another white cord runs across, which is the fourth pair of nerves at their origin.

The lateral ventricles are not prolonged posteriorly, nor possess what is called the reflected horn; the great and lesser hippocampus have therefore no existence.

The corpus striatum fills the ventricle almost entirely, projecting from the external side of it in the shape of a kidney. It does not exhibit on a section regular or strongly marked striae.

There are no tubercula quadrigemina.

The pineal gland rests upon a flat surface; it is very small, and enveloped in pia mater, and covered by a large vein. The plexus choroides also at this place divides into two tusks, or bunches, which pass into the lateral ventricles by two foramina in the back of the internal parietes.

The third ventricle possesses its usual situation between the thalami and its slit-like shape, and communicates with the canalis medius under the posterior commissure, and with the infundibulum behind the anterior commissure.

The infundibulum and pituitary gland are both large in proportion to the other parts.

The thalami nervorum opticorum contain each a ventricle, which opens into the canalis medius; therefore, there may be six ventricles reckoned in the brain of birds.

The fourth ventricle exhibits no peculiarity.

There are no eminences corresponding to the corpora quadrigemina: Cuvier has described four round eminences between the thalami and corpora frata, which are particularly plain in the alcthes. These are analogous to the tubercules of the brain of fishes.

The olfactory nerves arise, in birds, from the very points of the hemispheres, and often have a degree of enlargement at their origin, which resembles the olfactory tubercles of fishes. There are eight other pair of cerebral nerves, which have nothing very peculiar in their origin.

See Plate X. of the Anatomy of Birds. Fig. 1 presents a lateral view of the brain of the goose abstracted from the head; a the hemisphere, b the depression analogous to the fissura Sylvii, c the optic thalami, d the cerebellum, e the medulla oblongata, f the beginning of the medulla spinalis, g the infundibulum, h the pituitary gland. The different nerves are indicated by numbers, as they arise, from 1 to 9.

N° 1. the olfactory nerve, N° 2. the optic, N° 3. the oculo-muscular nerve, N° 4. the patheticus, N° 5. the trisacial nerves, N° 6. the nervus abducens, N° 7. the seventh pair, or auditory, N° 8. the eighth pair, N° 9. the hypoglossal nerve.

Fig. 2. of the same plate, shews the internal parts of the brain, as they are exposed without division, simply by pulling the hemispheres to each side, and drawing the cerebellum a little back: a the two hemispheres, b the cerebellum, c the medulla oblongata, d the radiated white lines seen arising from the junction of the hemispheres, and forming part of the parietes of the lateral ventricles, f the transverse medullary cords corresponding to the posterior commissure, g the white band of the roof of the canalis medius, b the fourth pair of nerves crossing behind it, i the pineal gland obscured by the venous galei and the plexus choroides, k the latter passing into the ventricle.

The third figure of the tenth plate of the Anatomy of Birds, gives a view of the interior of the ventricles of the thalami nervorum opticorum, and the third ventricle: a the hemispheres laid down very much to each side, by which the white partition is ruptured, and the third ventricle brought into view, they are also pulled forwards to expose the thalami; b the cerebellum; c the medulla oblongata; d the two optic thalami, that on the right side is cut open to shew the ventricle and its communication with the canalis medius; e the tract of the third ventricle and canalis medius, along which a little is puffed into the fourth ventricle; f the anterior commissure, which seems to produce the medullary radii that unite the hemispheres.

Nerves.

The olfactory nerve has been already mentioned to pass along a canal, or groove, in the upper and inner part of the orbit, to reach the naso cavity; in which its distribution will be pointed out in describing the organ of smell.

The optic nerves pursue their ordinary course, as in other animals.

The distribution of the third, fourth, and fifth pair of nerves, is almost the same as in mammals.

The branches of the fifth pair bear great resemblance to the
the same nerves in quadrupeds. They are distributed to the bill, and are therefore the nerves of the organ of touch in birds, under which head they will be farther noticed.

The portio dura of the seventh pair, or the facial nerve, is too small in birds, that it can hardly be discovered. Its offices are not required, in consequence of the structure of the parts of the face in these animals.

The portio mollis is remarkably soft; when it arises from the brain, it is a tender pulp, of a reddish colour.

The par vagum, or pneumogastric nerve of the eighth pair, sometimes pales out of the cranium in two or three filaments, which afterwards rejoin. On leaving the skull, this nerve communicates with the lingual and glossopharyngeal nerves. The par vagus, after this, pales as a distinct strong cord along the neck, in company with the jugular vein, and descending into the chest, forms the cardiac and pulmonary plexuses, as in mammalia. The two nerves unite behind the heart, and proceed along the oesophagus, to terminate in anastomoses with the great sympathetic nerve. We have not observed the recurrent branch of the eighth pair.

The glossopharyngeal nerve of the eighth pair makes its exit from the cranium through the posterior foramen lacerum in two filaments, which immediately unite to form a quadrangular ganglion, which sends off a small nerve to the anterior muscles of the neck, and another branch to anastomose with the par vagus; the nerve then descends along the oesophagus, and divides into two branches, of which one passes upwards to the muscles of the os hyoideum, which include it between them, and the other furnishes a branch to the lingual nerve, and afterwards is expanded upon the oesophagus.

The hypoglossal nerve is small where it pales through the condyloid foramen of the cranium; croffles and partly unites with the par vagus, at which place it detaches a filament towards the thora, which seems analogous to the descendens non. The trunk of the hypoglossus goes forwards under the horn of the os hyoideum, and divides into two principal branches, which are distributed to the tongue.

The cervical, dorsal, lumbar, and sacral nerves, arise from the medulla spinalis exactly as they do in quadrupeds, and only vary in their number, which is determined by the number of vertebrae belonging to each region of the spine.

The phrenic nerve is not found in birds, in consequence of the absence of the diaphragm.

The intercostal, or great sympathetic nerve, is described as entering the cranium by the foramen lacerum poebeus. It unites with the fifth and sixth pairs, and produces a lenticular ganglion below the skull, which communicates with the eighth and ninth pair of nerves. The appearance of the sympathetic nerve is, however, foot bolt on the neck; for the cervical nerves form their anastomosis with each other in the vertebral canal, from which a nerve is sent out between each vertebra to supply the muscles and integuments of the neck. These nerves are remarkably large. On coming into the thorax the great sympathetic forms a branch to the pulmonary plexus of the par vagus; it anastomoses also with the brachial plexus; and below the second rib, the sympathetic commences a series of ganglia, which are very conspicuous between each of the succeeding ribs, but become less visible along the remaining part of the spine. These ganglia are central points for the union of a number of nerves. They receive filaments from each other, which pass over the heads of the ribs; they communicate backwards with the spinal nerves; they detach on the outside the intercostal nerves, which are large, and besides supplying the intercostal spaces, give branches to the muscles and integuments upon the sides of the body; they finally send off filaments anteriorly, which anastomose with each other on the side of the dorsal spine, and form cords, which become the plexus of the nerves. In this manner there is produced on each side of the dorsal spine a reticulation of nerves which inlets in its meshes the heads of the ribs, and has a striking effect. The first dorsal ganglion unites with the brachial plexus and the cardiac plexus of the par vagus.

The splanchic nerves, after being formed by the anterior branches of the sympathetic, pass to the roots of the principal arteries of the vasa. The chief of the celare artery produces a plexus round the trunk of this vessel, and where the artery is divided, there are one, two, or three enlargements, which are analogous to the splanchnic ganglia, and the nerves which depart from these, include the arteries in a reticulated manner, and represent the solar plexus.

There are similar plexuses on the other chief arteries of the trunk, which correspond to the superior and inferior mesenteric and renal plexuses, &c.

The nerves of the splanchnic plexus accompany the branches of the celare artery to the oesophagus, spleen, liver, and pancreas, around which they continue to form numerous anastomoses, that may be compared to the flumachic, splenic, hepatic, and pancreatic plexuses.

The nerves of the wing more nearly resemble those of the superior extremity in mammalia, than Cuvier has represented. The brachial plexus is produced by the two half cervical and first dorsal, and not, as he has stated, by the last cervical and first dorsal nerves. The union of these three branches gives rise to three others, which are distributed in the following manner:—The first is a very fine filament, which runs down on the inside of the arm, and is lost about the internal part of the elbow. This is analogous to the internal cutaneous nerve. The second is a large cord; it gives off a very large branch, which divides into many others, for the supply of the pectoral muscles; it sends several smaller branches to the muscles under the clavicle, and about the joint, and then proceeds to the inner edge of the biceps muscle, along which it descends to the fold of the arm, after giving some large muscular branches. Before it reaches the joint, it divides into two branches; one of which is analogous to the ulnar nerve, and the other forms a disease in nerves which are similar to the median and musculo-cutaneous. The median dips down amongst the muscles on the middle of the fore arm, to which it gives branches, and afterwards runs along the interosseous space, pales under the annular ligament of the carpus, and is distributed to the short muscles of the digit. The branch analogous to the musculo-cutaneous nerve, is expanded upon the muscles on the upper edge of the radius.

The ulnar nerve, although it appears to be incorporated with the median on the upper arm, can be easily separated from it and traced to its proper origin in the brachial plexus. After this nerve leaves the median, it turns over the end of the foramen to get upon the edge of the ulna. It gives filaments to the muscles in this situation; but its chief branch runs down superficially upon the ligaments of the quills in company with the vein, and goes ultimately to be lost upon the ulnar edge of the hand.

The third cord furnished by the brachial plexus, supplies the place of the radial nerve. It detaches several filaments to the muscles on the inside and back of the scapula. It gives off also the articular nerve, and then winds round the humerus between the extensor muscles, to which it furnishes some large filaments. On coming to the outside of the humerus, it sends a branch between the integuments of the
of the wing. The nerve now turns round the neck of the radius, beneath the muscles, and forms two branches; of which one passes under the muscles to the outer side of the ulna, along which it runs superficially to the hand; the other branch passes on the radial side, but more deeply amongst the muscles, goes under the annular ligament of the carpus, proceeds between the branches of the metacarpus, and is finally lost on the back of the digit.

Although Cuvier has given a more accurate description of the nerves of the lower extremity, than of those of the wing, it nevertheless needs correction in several particulars, which we have supplied.

The obturator and femoral nerves arise from the same plexus which is formed by the two last lumbar nerves, by a communicating branch from the first sacral pair. The obturator nerve passes through the upper part of the foramen ovale, and is distributed to the muscles around the hip joint, especially the adductor. The femoral nerve passes out of the pelvis in company with the artery, over the upper edge of the ilium. It divides into three branches, which are divided amongst the muscles and integuments on the anterior and inner part of the thigh. Some of these filaments are long, and defend superficially for a considerable way upon the limb.

The ischiadic nerve is composed of the five superior sacral nerves; and as soon as it departs from the plexus, even within the pelvis, is easily separable into its primary branches. Immediately after it passes through the ischiadic foramen, it sends filaments to the muscles on the outer part of the thigh; it then proceeds under the biceps muscle, along the back of the thigh, about the middle of which it becomes divided into the tibial and the peroneal nerves.

The tibial nerve, even before it arrives in the ham, separates into several branches, which pass on each side of the blood-vessels, and are chiefly distributed to the muscles on the back of the leg. Two of these branches, however, are differently divided of: the one accompanies the posterior tibial artery down the leg, passes over the internal part of the pulley, and is lost in small filaments, and a few branches of the nerve, on the inner side of the metatarsus; the other branch runs down on the peroneal side of the leg, along the deep seated flexors of the toes, passes in a fibrous sheath formed for it on the outer edge of the moveable pulley of the heel, and proceeds under the flexor tendons along the metatarsal bone, to be distributed to the internal part of the two external toes.

The peroneal nerve is directed to the outer part of the leg; it dips in above the gastrocnemius muscles, and runs through the same ligamentous pulley that transmits the tendon of the biceps muscle; it then detaches some large filaments to the muscles on the anterior part of the leg, under which it divides into two branches, which proceed close together, in company with the anterior tibial artery, to the fore part of the ankle joint, at which place they separate: one passes superficially over the outer part of the joint; the other goes first under the transfere ligament which binds down the tendon of the tibialis anticus muscle on the tibia, and then over the inner part of the joint, below which it divides into two branches, the one is distributed to the inner side of the metatarsus and the tibial side of the pollex and to the next toe; the other turns towards the centre of the metatarsal bone, and penetrates the tendon of the tibialis anticus just at its insertion, and then rejoins the branch of the peroneal nerve it accompanied down the leg. They continue their course together again in the anterior furrow of the metatarsal bone; and at the root of the toes, separate once more, and proceed to the interfaces of the three anterior toes, and each divides into two filaments, which run along the sides of the toes to the nail.

**Organ of Touch.**

As the sense of touch is bestowed upon animals to enable them to discern the forms and states of aggregation of external matter, it refines more especially in the extreme parts of their bodies, and when most perfect, exists in some members which is constructed for including or taking hold of extraneous substances. There is no part of the body of birds capable of conveying an accurate impression of touch, but the feet and the bills; their upper extremities and tail being simply instruments of motion. Different species enjoy this in different degrees, and poise it more or less in the bill or feet, in proportion as they employ these parts in the pursuit or examination of their food; these being the only occasions on which birds exercise their functions of touch. The **cenfores, accipitres, and pafserines** tribe have most fehabition in their feet, while the **gralla and anferes**, especially those that have long or broad bills for feeling out their food, like the **juife, or duck**, possess a very great susceptibility of impression in their bills.

The organization of the feet of birds, as far as concerns their offices as instruments of touch, is similar to that of the digitated mammalia and reptiles. The skin on their lower surfaces is endowed with more than common vascularity, is largely supplied with nerves, and is elevated into those little regular eminences called **papille**, in which the sense of touch more immediately refines.

The structure, on which the feasibility of the bill depends, is different from the preceding. It consists in the magnitude and distribution of the fifth pair of nerves. These are divided, as in mammalia, into three branches, the **ophthalmic**, the **superior maxillary**, and the **inferior maxillary**.

The ophthalmic enters the orbit by a hole beside the optic foramen, pales for some way in an ocellous canal before it arrives in the nasal cavity, where it distributes some branches to the septum and turbinate, and to the external nare, and then goes on as two branches; one runs in the substance of the upper jaw, which it perforates at the end in many filaments, to terminate under the horny integument of the bill; the other pales between the membrane of the palate and the bill, and is lost in a number of fibres at the apex of the bill.

The superior and inferior maxillary nerves come out of the cranium by the same hole. The superior, after dispassing branches to the muscles in its course, is finally distributed to the lateral parts of the bill, which, if notched along the edge, as in some water birds, each denticulation receives several filaments. The inferior maxillary descends to the lower jaw, which it penetrates, after sending a branch to the integuments of the side of the bill; and running in the maxillary canal, sends filaments to the edge of the bill, and terminates, like the ophthalmic, on the apex of the lower mandible.

These nerves are of great size in the **goose, duck, &c.** in which they render the bill a very delicate organ of touch. See Plate X. in the Anatomy of Birds. Fig. 4 is the section of the head of a duck, made by dividing the organ of smell longitudinally, and by removing the bill and bone of the mandible, in order to bring into view the distribution of the fifth pair of nerves: a the ophthalmic nerve coming from the upper part of the orbit, and proceeding along the septum naif; b the branch which pales in the substance of the mandible, to be lost on the point of the bill, c the branch that runs on the membrane of the palate to the end of the bill; d the superior maxillary nerve dividing on the membrane of the palate, and sending its filaments to the denticuli on the side of the bill; e the inferior maxillary running...
The feathers with which the bodies of birds are clothed, render them less capable of receiving the more simple impressions of touch, than most other animals. They also serve to defend them against the excesses of temperature. The structure and mode of growth of these substances are considered in another part of the dictionary. See Feathers.

The cuticle of birds is remarkably thin, but resists generally in structure the epidermis of mammals. It is shed generally along with the feathers.

The rete mucosum is not observable, except in those parts which are surrounded by feathers, and possesses peculiar colours, as the cere and caruncles of the head, the feet, and bills; where it is of course found to vary in colour as those parts do.

The cutis is in most birds extremely thin and delicate in its texture, appearing often like a fine single lamina, instead of an intermixture of fibres as in mammals. It is, however, of some strength in the exter birds and the aceprures; it is thinned in the pappules. The external part of the cutis is never papillated, but when it covers the undersurfaces of the toes which are designed to receive the impressions of external bodies.

The muscles of the skin, in consequence of the size of the external coverings, are in general very evident, and particularly in those birds which move their feathers on the crest, neck, or tail, as the buphæus, cuculæs, herons, &c.

The following cutaneous muscles are common to all birds. TwoUf slowly slips, which arise from each side of the head behind the mentus auditorius, and go backwards to be lost in the integuments. A thin expansion of muscle along the anterior and lateral parts of the neck; it takes a longitudinal course, but is connected with some transverse fibres between the jaws; this muscle corresponds with the platysma myæder. There is a muscle, arising in a serrated manner from two or three of the lower ribs, and extending upwards to the axilla and outside of the shoulder. We have perceived, in the gooses, a very thin slip of muscle proceeding from the posterior part of the branch of the pubis to the skin on the under side of the knee; and Cuvier considers the red granular appearance under the skin on the back of the pelvis as mucular substance.

The functions of the skin of birds, as an organ of absorption and excretion, appear to be very imperfect. The clothing of feathers alone disqualifies it in a great degree for the performance of these processes. The skin favours and simple organization of the skin itself renders it probable that its secretory powers are but inconsiderable. It does not also possess those various glands which are so abundantly bestowed upon the skin of other animals for its preservation and defence against the operation of external influences. Birds are, however, provided with two peculiar glands for the purpose of furnishing an oily fluid, to keep the feathers in order and defend them against the effects of moisture.

The oil glands are two oblong or oval-shaped bodies, with one end more pointed than the other, and situated under the skin on each side of the famous processes of the cranium vertebræ. They approach each other, and touch at their point, which are directed backwards, and thus produce a common channel between them, the figure of a heart. They are covered by a strong dense white tissue, and their interior structure consists of a number of small tubes arranged in a radiated manner around a cavity, or canal, which runs nearly in the middle of the gland, into which they all open and discharge their contents, in the same way as the tubuli uriniferi do into the pelvis of the kidney. The middle canal leads to a papilla on the skin of the rump, and terminates in a simple foramen. It defies remark, that the tubes towards the circumference of the glands are soft and indistinct, and their contents liquid and pale colored; but before their termination, the tubes acquire more firmness, are a little separated into packets, their secretion becomes an opaque yellow, and of more consistence; thus affording an obvious and interesting view of the change which may be wrought upon secreeted fluids after their formation, while they are passing through their glands. The fluid produced by the glands on the rump of birds, although of an inconstant nature, is still not pure animal oil. It has more consistence, and is less affected by heat; which properties it principally acquires in the ends of the tubes, before they open into the common duct, as already mentioned. It is, however, sufficiently obnoxious to prevent the adhesion of moisture to the surface of the feathers. When birds make use of it, they turn their head round to the rump, and compress the glands with the bill, when a quantity of oily matter exudes, with which they beaten their feathers, arranging the barbs upon their shafts at the same time by means of the bill. These glands, as might be inferred from their use, are particularly large in the faviuam birds. See Plate X. in the Anatomy of Birds. Fig. 5. shews the oil glands of the duck of their natural size; a, the two glands; b, the foramina on the papilla, into each of which a bristle is introduced; c, the integuments reflected on each side to bring the glands into view. Fig. 6. of the same plate is a section of one of the oil glands somewhat magnified; a the canal in the centre into which the radiated tubes open; b, the external portion of the tubes; e, the interior extremities more distinct, and of a deeper colour.

Organ of Smell.

The shape and situation of the nares is used by naturalists as classic characters of birds; and therefore do not require particular consideration here. They consist of two slits, varying in the length and width, commonly placed on each side behind the base of the bill. There are no muscles provided for dilating and contracting their aperture, as in mammals.

The interior of the organ of smell is formed by a septum and three turbinate bodies, over which the pituitary membrane is spread.

The superior turbinate affixes in general the shape of a bell; it is formed of cartilage, and is attached to the os frontis and lacrymalis; it is hollow within, and divided by a light prominence into two apartments, which are continued for a little way in a tubular form; the external ends by a blind extremity behind the middle turbinate; the internal opens into the cavity of the nose. The superior turbinate is small in the pappules and gallina, somewhat larger in the faviuam, exceedingly in bulk in the crocoptées, and still more in the gnuves; and in the geol the it is greatest of all. According to the observations of Scarpia, the number of smell is exactly proportioned to the magnitude of this part of the organ; as it is upon it only and the septum that the olfactory serve is spread.

The middle turbinate has been likened by Scarpia to a cubiculate. It is connected on the external part to the cartilaginous plates of the maxes and the bone processes of the upper jaw, and inferiortly it is attached to the cartilaginous septum of the nose. It is composed of a cartilaginous lamina, which in the gooses makes two folds and an half; but in the geol it is compressed, and forms only one turn and an
half. Harwood has flated these turbinata to be membranous in the *Coelanthus* and *Albatross*; and Cuvier has observed them to be composed of bone in the *toucan* and *hornbill*.

The _inferior turbinatum_ is an ofens fold, continued from the pinna of the nares, and united on the other side to the septum. See Plate X. in the *Anatomy of Birds.* Fig. 7, exhibits the interior of the nasal cavity of the *goose*, the septum being removed; _a_ the canal through which the olfactive nerves pass to the nare; _b_ the cavity of the superior turbinatum; _c_ its internal tube; _d_ the external tube; _e_ the middle turbinatum; _f_ its deep or first winding; _g_ the second; _h_ two pins passed from the windings into the nasal cavity; _i_ the inferior turbinated bone; _k_ its junction with the septum; _l_ the cartilaginous appendix of the middle turbinatum; _m_ a pin introduced through the external naris; _n_ the posterior naris.

The _pinnae_ membrane is fine where it invells the superior turbinatum, and thicker and more villous over the middle one; it is covered with pores, which discharge mucus on its surface. The blood vessels on the interior of the nare are beautifully reticulated.

The _olfactory nerve_, as already described, arises from the point of the hemisphere of the cerebrum, and poises through an ofous canal to the superior part of the nasal cavity. On arriving there it breaks into a great number of filaments, some of which are spread upon the superior turbinatum, and others run about as far as on the septum nasi. See Plate X. in the *Anatomy of Birds.* Fig. 4. _g_ the nerve proceeding along the canal above the orbit; _b_ the appearance of the nerve on the septum of the *duck*; and Fig. 8. of the same plate exhibits _a_ section of the head of the *brun*, a bird with an acute fene of smell; _a_ the trunk of the olfactive nerve; _b_ its distribution on the superior turbinatum, which is very large; _c_ the middle turbinatum proportionately reduced in size; _d_ inferior turbinatum; _e_ its connection with the septum; _f_ the aperture of the external naris.

Scarpa made a number of experiments with different species of birds, in order to determine their capacity for discerning odours. He mixed various strong smelling substances with their ordinary food, which in tame were taken with indifferenoe, but in others the repugnance to the scented food was so great, that the birds peirished rather than eat it. He was thus enabled to form a scale of the different degrees of perfection in which birds enjoy the fene of smell, which accorded exactly with the extent of the surface allowed for the distribution of the olfactive nerves. The fcale he has laid is as follows: _gallinae_, _pavonis_, _picus_, _anseres_, _acetipotes_, and _gralle_.

*Organ of Taste.*

The fene of taste is so imperfect in most birds, that it might be doubted whether it existed at all or not. The form and motions of the tongue unite it for being applied to the superficies of substances; the glairy tenacious fluid, with which the surfaces of their mouths are bemearred, is not calculated for the solution of fapid bodies; and the shape and structure of the papillae of the tongue seem to render them nearly incapable of impreffion; and further it may be observed, that birds commonly swallow their food without examination, or a minute division of its parts.

The motions and internal formation of the tongue have been already discussed; it only remains, therefore, to notice the figure and integuments; but as these have been described by natural historians in almost every genus, it is only necessary to speak of them in a very general way at precent.

The _form_ of the tongue may be commonly guessed at from the shape of the bill, with which it corresponds in a certain degree. In the _gallinae_ and _pavonis_ it is an elongated triangular, the point being turned forwards; in the _gralle_ it is generally of the same figure, the triangle being however lengthened in proportion to the bill; the broad-billed birds, as the _favae_, _goose_, _&c._ have the tongue broad and round at the end.

The _parrot_ has a thick round fleshy tongue, not unlike that of mammalia.

Several birds have the tongue bilifid at the point.

The _African ostrich_ has a broad tongue, but fo short, that its existence has been often doubted. The _New Holland ostrich_ has a very thin small tongue, and nearly an equilater al triangle.

The _papillae_ or projecting points of the integument of the tongue are very various in their shape and arrangement. In most fpecies the tongue is smooth, except at its base, where it is furnished with sharp reflex papillae, which are commonly cartilaginous, and often covered with bone. In many birds there are processcs along the upper surface or the edge of the tongue, which are invested with a horny or ofeous substance. The _columba_ has cartilaginous fers along the edges of the tongue. The _toucans_ have fine hornv bristles along the sides, which give their tongue a resem bance to a feather.

On the lateral parts of the back of the tongue of the *flamingos* there are two rows of bony processcs, shaped like hooks, with their points turned backwards.

The _duck_, _goose_, _favae_, _&c._ have, besides sharp bristles and denticulations, some rows of little osseous plates with their thin edges turned toward the fauces.

Birds have frequently the edges of the posterior nares, and other prominent parts of the fauces furnished with reflected ficipulae, similar to those on the tongue; from which it is probable, that both are intended to affift in the action of swallowing the food, rather than to receive the impressions of fapid substances.

The _parrots_ is the only bird which appears to taste its food, and hence it poiffesses soft papillae, of which some are really fungiform.

It is probable, that the _humming_ birds poiffess the fenation of taste, as their tongue is flexible and tubulated, through which they suck; like insects, their fluid aliment.

*Organ of Hearing.*

Birds are unprovided with the _concha_, or that external projection of the ear which is observed in man and quadrupeds, for collecting the rays of sound; but to compensate for the want of it, some of the internal parts of the organ are formed upon a larger scale. The feathers are arranged in some species, however, around the meatus auditorius in such a way as to produce, in a degree, the effect of the concha. This is most observable in the *owls*, in which also the membrana tympani lies at the bottom of a cavity, which is lined by a reflection of the common integuments that forms folds something analogous to the projections of the human concha; and in the *white owlet*, there is a fquare membrane, which serves as an operculum to the anterior part of the cavity.

The _frame_ of the membrana tympani, or the bone which surrounds it, is more prominent in some birds than in others; but generally it does not project sufficiently to deserve the name of a canal. It is imperfect anteriorly, where the arterial bone is situated, to which the membrana tympani is in part attached. In the *white owlet*, however, the osseous frame of the meatus is completed by the bones of the head alone.

The _membrana tympani_ is always more or less of an oval figure. It poiffesses the same structure as in mammalia, but is very thin; the convex, or concave, surface, is external,
external, instead of pointing inwards, as in man and quadrapeds.

The cavity of the tympanum is irregular on the internal surface, and is widest at its outer part. Besides the usual foramina leading to the labyrinth and Eustachian tube, it contains three others which communicate with the cells of the bones of the cranium. These are widened into something like canals, where the holes open into them. The largest of the foramina is in the back of the tympanum, and leads to the posterior cells, and communicates above the foramen magnum with the cellular canal of the other side. The second opening is placed at the anterior part of the tympanum, and conducts to the cells on the lower and anterior part of the cranium. The third foramen is continued amongst the cells which surround the labyrinth. Thus the cavities of each tympanum have a communication with the interior of all parts of the cranium, and with each other, from which they might be reckoned as making only one cavity. The end of the articular bone also, where it contributes to form the parietes of the tympanum, has a foramen by which it derives its supply of air. The auditory cells of the cranium of birds are analogous to the mailbox of the human subject; but from their extent, multiply found much more. They are of the greatest magnitude in the unilateral birds of prey, and especially in the eagle; the gooseucker (coperma'la) has them also very large. They diminish in the other birds, in which the posterior canals have no direct communication with each other. They are little observable in the thrush; and the parrot appears to want them altogether, but in their place the cavity of the tympanum is enlarged posteriory.

The Eustachian tube is very large in birds; it is an offshoot canal, and terminates by a small aperture close to the one of the other side, within the fissure of the posterior nares.

The foramina, which lead into the labyrinth, are situated within a fossa. They do not merit the distinctions of foramen ovale and foramen rotundum, being both oval, and only separated by a small bony process.

The effuacula auditus are supplied by a single bone and some cartilaginous processes. The effuclum consists of a flake or pedicle, crowned by an oval plate, which is applied to the foramen that leads into the vestibule of the labyrinth. At the other extremity it becomes extended and united to two or three cartilaginous processes, which form a triangle that is attached to the membrana tympani.

The pedunculated bone of the tympanum is moved by one muscle, which comes from the occiput behind the ear, and penetrating the cavity, is affixed to the triangle that is connected to the membrana tympani. This muscle is a tenor, and draws the membrana tympani outwards. It is counteracted by two small tendinous cords that are extended to the internal parietes of the tympanum.

The labyrinth of the ear of birds consists only of the vestibule and three semicircular canals, and the renewal of the cochlea.

The vestibule is small in proportion to the other parts. The canals have been termed by Scarpa, from their graduation in bulk, canalis major, minor, and minimus. The largest is most superior, and has a vertical position. The smallest is situated horizontally. The canalis minor ascends upon the major, and opens into its side. They contain corresponding tubes of vascular membrane; and they also pollow the ampulla, on which the nerves are distributed in the same manner as in mammalia.

The place of the cochlea is supplied by a short ossicus tube, very lightly bent, and either blunt or enlarged at the extremity. Its interior is occupied by two small cylinders of fine cartilage, each a little twisted, and united at their origin and termination. They proceed from the ossicus bar, which separates the two foramina that correspond to the foramen ovale and rotundum. The fulcule, which is left between the cartilages, is dilated near the point, and accommodates the same branch of the auditory nerve which is sent to the cochlea in mammalia. This nerve spreads in fine filaments upon the united extremity of the cartilaginous cylinders. The tube is divided by the presence of the cartilages into two scales, which communicate with the vestibule and the foramen rotundum.

The struthious birds have the tube corresponding to the cochlea, very small in proportion to the other parts.

The auditory nerve is received into a fossa, and there breaks into five branches; one is the facial, or portio dura, and the others are sent to the semicircular canals and the tube. The facial nerve receives a filament from the par vagum, which traverses the ear, and is afterwards distributed to the palate.

Comparati has described two canals leading from the labyrinth of birds, which correspond with the aqueducts of the ear of mammals.

For the illustration of the organ of hearing, see Plate X. in the Anatomy of Birds, Fig. 9. represents a division of the posterior portion of the skull of the white owl (fririus sannen), which exposes both the parts of the tympanum and the labyrinth; a the membrana tympani, which is enclosed in a perfect frame of bone in this bird; b the cavity of the tympanum laid open on the other side of the head; c the pedunculated bone, or ossicum, in situ; d d d the semicircular canals; e the tube analogous to the cochlea; f the air-cells exposed by the division of the cranium. Fig. 10. shews the ossicum and the membrana tympani abstracted from their situation and magnified; a a the membrana tympani; b the flat head, or basis, of the ossicum; c the pedicle; d the extremity which unites with the cartilages, and forms the triangle that is connected to the membrana tympani. Fig. 11. exhibits a magnified view of a division of the labyrinth of the goose, in which the membranous parts and the distribution of the nerves are displayed: a the trunk of the auditory nerve; b the portio dura; c c c the three branches of the portio mollissima going to the semicircular canals; d the nerve of the cochlea running in the tuemus, and ramifying on the apex of the cartilages; e the offshoot part of the tube analogous to the cochlea; f the inner cartilaginous cylinder; g the fulcule between it and the superior, which is concealed from view by the nerve; h h b the three ampullae of the membranous semicircular canals; i the canalis major; k the canalis minor; l its communication with the major; m the canalis minimus; n the hole which corresponds to the foramen ovale. Fig. 12. is the cartilaginous body removed from the ossicus tube; a the superior cylinder; b the inferior; c their junction where they commence; c the cavity at the apex of the cylinders, laid open; G the nerve of the cochlea; f fits expansion in the cavity of the apex of the cartilaginous body.

Organ of Sight.

The peculiarities in the structure of the eyes of birds are chiefly intended to facilitate the perception of objects through a rare medium, and accommodate vision to different distances.

The form of the eye is admirably adapted in most species to promote both these effects. The anterior circle of the globe of the eye always projects more than in other animals; and in many species it is prolonged in a tubular form, and in those cases the cornea also is remarkably globous. The eyel furnishes the most striking example of the disproportion between the anterior and posterior spheres of the eye. The
axis of the anterior portion being twice as great as that of the other. The obvious consequence of this figure of the globe of the eye is to allow room for a greater proportion of the aqueous fluid, and for the removal of the crystalline lens from the field of the sensation, and thus produce a greater convergence of the rays of light, by which the animal is enabled to discern the objects placed near it, and to see with a weaker light; and hence owls, which require this fort of vision so much, possess the structure fitted to effect it in so remarkable a degree.

The felcotic coat of the eye in birds is thin and flexible on the posterior part, but anteriorly its form is maintained by the interposition of a number of bony plates between its layers. These vary from thirteen to twenty, and are arranged in a circle immediately behind the cornea, with their edges overlapping each other. They are commonly flat thin scales, and nearly of a square figure, but become elongated from before backwards in proportion as the bird possesses the power of changing the convexity of the cornea. In the owls the scales compose not only the projection of the eye (the cornea excepted), but contribute to form the posterior sphere. The scales are capable of a degree of motion upon each other, which is, however, restrained within certain limits by the attachments of their anterior and posterior edges to the felcotic coat; and by their being bound together with a tough ligamentous subfacie, which seems to be the continuation of the felcotic between the edges that overlap each other.

The cornea possesses the same structure as in mammalia, but differs with respect to form. When the posterior part of the eye is compressed by the muscles, the humours are urged forwards and distend the cornea; which, at that time becomes much more prominent in molt birds than it is ever observed in mammalia; and under such circumstances, the eye is in a state for perceiving near objects. When the muscles are quite relaxed, the contents of the eye-ball retire to the posterior part, and the cornea becomes flat, or even depressed; this is the condition in which we always find the eye of a dead bird, but we can have no opportunity of perceiving it during life. It is only practiced for the purpose of rendering objects visible that are placed at an extreme distance. From the well known effects of form upon refracting media, it must be presumed, that the cornea possesses very little, if any, convexity, when a bird, which is soaring in the higher regions of the air, and invisible to us, discerns its prey upon the earth, and descends with unerring flight to the spot, as is customary with many of the rapacious tribe.

There are other circumstances in the anatomy of the eye of birds, which have been supposed to concur with the extraordinary variation in the figure of the cornea, in producing its capacity for the perception of remote objects: these will be mentioned in their proper place.

The choroid coat differs in no material point from that of the human subject. The ciliary processes of the choroidies are very small and short; being merely irritated iris. There appears to be no tapetum.

The iris is sometimes of brilliant colours, which are employed by naturalists as distinguishing specific characters of birds. Parrots have the power of voluntarily producing a great degree of motion in the iris. It does not appear, however, that other birds are capable of commanding the motions of this part.

The pecten, or plicated membrane, is the most singular part of the structure of the eye of birds. It appears to grow from the choroidies where the optic nerve penetrates that coat; but on closer inspection it is found to have no intimate connexion with it. In structure, however, it is perfectly similar to the choroidies. The form of this part varies in different species; in general, it consists of a membrane folded backwards and forwards on itself, like the pleats of a garment, and presenting, when viewed on the side, something of the appearance of the teeth of a comb; on which account the name of pecten has been applied to it. In the fruticose birds, the folds of the pecten are larger, and collected towards the point, giving it a resemblance to a purse. The Parifian academicians therefore, in taking their description of this part from the offric, called it the marjus fund, by which name it is still very commonly known.

The plicated membrane proceeds into the substance of the vitreous humour, and usually becomes attached to the posterior part of the capsul of the crystalline lens a little to one side. In some instances it does not come into immediate contact with the capsule of the lens, but ends a very short way behind it amongst the cells of the vitreous humour: such is the case in the turkey, jayhawk, and several other birds. The number of the folds of the pecten vary. There are sixteen in the flork, fifteen in the offric, and seven in the great boned owl.

The functions of the plicated membrane have been often ascribed, but still remain involved in some degree of doubt. Hailer, and others, consider it as the medium through which the vessels are conducted to the crystalline lens; but there appears no reason for such a provision to exist in birds. Pettit was of opinion that it absorbed the lateral rays of light, in order that objects placed immediately before the eye might be more distinctly seen; which is highly improbable, as the scope of vision is full as extensive in birds as in other animals. The belief supported by this subject is Mr. Home's. The plicated membrane, according to his experiments, possesses a contractile power, and affords the means of withdrawing the lens from the anterior part of the eye, when the organ is adapted to the perception of remote objects; thus acting in concert with the change of figure in the cornea. Experiments, however, upon the operations of the eye are so delicate in their nature, that they are seldom to be relied upon, and accordingly in different hands they have afforded very different results; but the doctrine of the muscularity of the plicated membrane is almost proved by its seeming necessity for the explanation of the powers of adaptation of the eyes to different distances, which birds possess in a degree far superior to all other animals; and it seems fair to infer that if the accommodation of vision depends upon the motion of the cornea, and the recession of the lens in those animals which are so eminently endowed with it, similar means are employed for the same purpose in the other classes which possesses the faculty in a less degree. For the more ample diffusion of this subject, see Mr. Home's lectures on muscular motion, published in the Philosophical Transactions for the years 1794, 1795, and 1796; Dr. Olbers' "De oculi mutationibus internis," Gotting. 1780; "The Essays of Petit, Mem. de l'Acad." 1735; p. 163. 1736, p. 166; "Observations on the Eyes of Birds," by Mr. Pierce Smith, Phil. Transf. for 1795; and "Dr. Young's Lecture on the Mechanism of the Eye," Phil. Transf. 1801.

The optic nerve passes through an oblique sheath in the back of the felcotic coat, during which it changes from a round to a flattened shape, and as such, enters the eye, presenting on the inside an elongated white line, instead of a round disk, from which the retina is produced. The origin of the plicated membrane covers the entrance of the optic nerve.

The humours as well as the shape of the eye and the structure.
time of its coats, indicate the peculiar vision of birds and the kind of medium they inhabit. The aqueous humour, as already observed, is extremely abundant. It possesses considerable refractive powers especially in the higher regions of the atmosphere. The crystalline is remarkably flat and soft, as its offices can be so well supplied by the aqueous fluid in a rare medium. Both the form and the proportions of the humours in the eyes of all birds derive great illustration from being compared with those of fishes, which, in conformance of their continual residence in so dense a medium as water, have these parts formed upon a plan the very reverse.—Their eye is flat anteriorly; the aqueous fluid small in quantity, and of considerable consistence; and the lens spherical and hard, more especially in the centre. The cornean has the crystalline more spherical than other birds, from being obliged to seek its food under the water.

The musculi for the motion of the eye-ball are six in birds, as in the human subject; the four straight and two oblique. The tendons of the recti cannot be traced farther than the circle of imbricated bones. The operation of the straight muscles, when acting together upon the figure of the eye (which, as already observed, is so striking in birds), depends upon the bony scales of the anterior part of the sclerotic, and the thinness and pliability of that tunic posteriorly. The superior-oblique muscle does not pass through a pulley.

The external eye-lids are chiefly closed in birds by the elevation of the lower one, although there is an orbicular muscle which surrounds both. The inferior eye-lid is larger and thicker than the other, and contains internally an oval cartilaginous plate, under which the fibres of the orbicularis palpebrarum pass. There is also a peculiar muscle, which comes from the floor of the orbit, and acts as a depressor of the inferior eye-lid.

The internal eye-lid, or membrana nictitans, is a thin semitransparent membrane, which lies close to the globe of the eye. It has a vertical position, and, when not employed, is folded back by virtue of its own elasticity, and remains concealed from view in the corner of the eye next the nose. It is, however, capable of being spread over the whole of the anterior part of the organ, by means of the combined action of two curiously contrived muscles. One of them is a square figure, and thence called quadratus; it arises from the upper and back part of the eye-ball, and approaching the optic nerve, terminates abruptly in a circular edge, which contains a pulley for the passage of the tendon of the pyramidalis. This muscle arises from the side of the sclerotic next the nose a little inferiorly, and produces a line tendon, which runs through the pulley formed in the free edge of the quadratus, and afterwards returns in a cellular sheath on the lower surface of the sclerotic, and becomes attached to the margin of the membrana nictitans, along which it is continued for some way, and gradually lost.

The lacrimal gland is small in all birds. The glandula harderi exists, and is larger than the lacrymal. Cuvier describes it as being generally situated between the adductor and levator muscles, and as having a single excretory duct, which perforates the membrana nictitans, and discharges upon its inner surface a yellow tenacious fluid. Many water-birds have a hard granular body placed at the superior part of the orbit, which seems to perform the office of a lacrymal gland; and although its excretory ducts have not been yet seen, it probably furnishes a fluid of a peculiar nature, for the defence of the eye against the effects of the water and other accidents to which aquatic birds are exposed.

The figures, which serve to explain the organization of the eye, are found in Plate XI. of the Anatomy of Birds. Fig. 1, shows the cornea and imbricated bony scales of the geese, as an example of the figure these parts commonly assume in birds. Fig. 2, represents the same parts in the horned owl, in which the cornea will be seen very prominent, and the scales greatly elongated, forming the fore part of the eye into a tube. Fig. 3, exhibits a lateral view of the crystalline lens and the plicated membrane in the goose's eye; a the pecten attached to the posterior part of the lens a little to one side; b the edge of the lens marked by the ciliary processes; c the anterior part, which is particularly flat in birds. Fig. 4, shows the pecten and the lens in the relative situation they hold in the eye of the turkey; a the plicated membrane; b the lens; e the outline of the eye; d the optic nerve. Fig. 5, is a section of the eye of the emu; a the cut edges of the sclerotic coat; b the edges of the choroides; c the retina; d the plicated membrane formed like a purse. Fig. 6, presents the anterior part of the eye of the cassowary, with the membrana nictitans partially drawn over it, which is so fine a film that the parts of the eye are seen through it. Fig. 7, is the posterior view of the cassowary's eye, all the muscles, &c. being removed, but those for moving the membrana nictitans; a the muscle quadratus; b the pyramidalis at its origin; c its tendon passing through the pulley in the edge of the quadratus; d the tendon proceeding on the sclerotic coat.

Organ of Voice.

Until within these late years this part of the anatomy of birds has been involved in obscurity. Although several of the older anatomists described the structure by which birds produce sound, they were ignorant of its uses, from being misled by analogy, and supposing that this organ occupied the same situation in all animals. Even some of the descriptions of the abode of the modern anatomists have been erroneous or imperfect. The subject has been most laboriously and ingeniously investigated by Cuvier. He dissected the organs of voice of more than one hundred and sixty species of birds, and published the result of his inquiries in two memoirs; the principal one will be found in the Magazin Encyclopédique, tom. 2, to which we would refer the reader for numerous and minute details, that would be burdensome to introduce into the present work.

The true seat of the organ of voice in birds is at the bifurcation of the trachea, and not, as general analogy would dictate, at the superior larynx, which is in birds little more than a simple ring, or slit, formed, however, with somewhat differently shaped cartilages than belong to the rest of the trachea, and furnished with muscles for opening and closing the aperture. The mechanism of the inferior larynx, which fits it for the production of sound, depends upon the figure of its cartilages, and the expansion of its membranous parts.

The two branches of the bronchi are composed of feinings of cartilage; the internal surfaces, or those opposed to each other, being membranous. The feinings next the trachea are often large, and always left curved than those near the lungs. The consequence of which is, that the membranous part of the bronchus becomes expanded in proportion to its distance from the lungs, and towards the bifurcation usually assumes an oval figure, to which Cuvier has given the name of the tympaniform membrane.

Where the bronchus open into the trachea, there is the appearance internally of the reed of a musical instrument. This is produced by a thin and elastic fold of the inner membrane, which projects upwards from each side. The aperture is divided into two, sometimes by an ossicular bar extended across from before backwards, and sometimes merely by the angle produced by the union of the two bronchi.

When the air is expelled from the lungs and air-cells with force.
force through the bronchi, a lively vibration is excited in
the tympaniform membrane and the reed shaped aperture, or
glottis, upon which the production of the voice essentially
depends.

The magnitude, figure, and proportions of the inferior
larynx vary more or less in almost every species, which Cu-
vier has taken pains to point out.

The trachea is commonly enlarged, at its bifurcation, by
the expansion and union of its last cartilaginous rings, which
is designed to afford strength to the voice.

In the flute and the singing birds the last rings of the tra-
chea are united into a single piece, of which the base is wide,
and furnished with two points that are joined by a tran-
verse oblong bar in such a way, that the trachea commu-
nicates by two openings with each of the bronchi.

In the parrot, the last rings of the trachea are united, and
form a tube a little compressed on the sides. The very last
ring is almost square; it is also flattened before and behind,
and furnished posteriorly with two points. There is no par-
tition within. The sides of the bronchi, opposite to each
other, are membranous. The first semi-ring is large, flat,
and shaped like a crescent; the second, third, and fourth
semi-rings unite in one piece; and the fifth, sixth, and se-
venth are conflated into a similar plate. The edges of
both, however, present the marks of their original parts.

In the nocturnal birds of prey, the last ring of the trachea
is divided by a bone.

In the icellus rugicola, the four last cartilaginous rings
of the trachea are incomplete posteriorly, and the tympan-
iform membrane is continued up between them.

The male birds of the duck kind, and the genus mergans,
have the last rings of the trachea united, and forming a ca-
tilaginous or bony face, called by authors the ampulla, or
the larynx. This part, in the mallard, forms two dilata-
tions; the one on the right is small, and resembles a tunc-
cated cone, with a prominence from the base behind. The
left is a large vehicle irregularly rounded, and produces at
the lower part a pyramidal projection. Its right surface is
a little flattened below, and its inferior border is indented.
The cavity is interrupted by projections, or septa, in such a
manner, that the air cannot pass from the left bronchia into
the trachea, but through the capsule, although on the right
side it may. The entrance to the bronchia is provided with
a thick membrane, under which there are some glands re-
fembling the syneval, that secrete a mucous fluid.

The form and internal partitions of the ampullae of the
drakes of other species and the mergansers, are different in
every instance. Their deviations are described at length by
Cuvier. See Memoire fur le larynx inférieur des oiseaux,
Magazin Encyclopédique, tom. 2d.

Two species of cuculus (V. papa and V. aura) were ob-
served by Cuvier to be deprived of the organ of voice,
there being neither the tympaniform membrane, nor any
contraction, or projecting elastic parts at the entrance of
the bronchia into the trachea.

The voice of birds is modified, and the tones rendered
more acute or grave, by means of two deflections of mu-
cles. The first are common to all species, and have been
long known and described. They were called by Vic
d'Azir the inferior or external laryngeal. They are two flicky
cords, and arise from the triangular procieess of the sternum,
to which the inferior ribs are joined within the chest, and
proceed to the side of the trachea, above the bifurcation,
along which they ascend for its greatest length. Their ef-
ect is to depress the inferior larynx, and contract the bron-
chia, and thereby relax the tympaniform membrane, and
depress the tone of voice, and in some circumstances they
may also bring the trachea forwards. These were the only
muscles observed by Cuvier in the gallinacea, and most of the an-
terrors. It is probable, that no others are to be found also
in the rufubious birds.

The second kind of muscles are confined to the inferior
larynx; they are short, and situated upon each side of the
bifurcation of the trachea; and, except in the parrot tribe,
are all contractors, or intended to render the tympaniform
membrane tense, and thus exalt the tones of voice.

In most birds, which do not sing, there is but a single pair
of contractors, one on each side, which arises from some of
the last rings of the trachea, and is inserted into some of the
first semi-rings of the bronchia. These muscles are longest
in the nocturnal birds of prey, extending from the base of
the trachea to the seventh semi-ring. The contractors are attached
at the fifth semi-ring in the cuckoo, the heron, and bittern.
The latter birds owe their strength of voice to the elasticity
of the semi-rings, and the extent of the tympaniform mem-
brane. The goat-fuckers, kingfisher, and pelican, have the
contractor muscle affixed to the second semi-ring of the
bronchia; and the woodcocks, phalarope, celery, and the plow,
and recurvirostra, and probably all the weak billed grallae,
have it inserted into the fifth semi-ring.

The larynx of singing birds, and some others, is pro-
vided with five contractors on each side, which Cuvier
has named, according to their situation and direction.

1. The anterior longitudinal contractor.
2. The posterior longitudinal contractor.
3. The small longitudinal contractor.
4. The oblique contractor.
5. The transverse contractor.

These almost surround the bifurcation of the trachea, to
which they have all the same attachments, as near as may
be. The two first are inserted into the third semi-ring; the
two next into the second semi-ring; and the last is affixed to
the fifth semi-ring, and particularly to a little cartilage that
is joined to it.

Cuvier has observed the five pair of contractors in all the
singing birds, in the flute, in all the passeres, except the fal-
low and goat-fucker, and in the crow, raven, joy and many of
the pie kind.

The most complicated instrument of voice amongst
birds, is that of the parrot tribe. It posses five three pair of
muscles; but one pair is intended to relax the opening of
the gullet.

The principal contractor arises from the last ring but one
of the trachea, descends almost perpendicularly upon the lax-
atore, and then goes on to be inserted into the union of the
fifth, sixth, and seventh semi-rings of the bronchia. Its at-
tachment being joined to the femicircular plate, it urges the
upper part of the plate inwards, and thus contracts the
gullet.

The auxiliary contractor, occupies, for a certain distance, the
anterior part of the trachea, and sends off a tendon, which
is lost in the preceding muscle; its operation therefore, is
exactly the same.

The laxator is placed under the two other muscles; it
arises along the side of the trachea, and expands upon the
inferior concave edge of the last ring; in drawing which
outwards, the muscle enlarges the gullet.

See Plate XI. in the Anatomy of Birds. Fig. 8. shews
the external appearance of the inferior larynx in the cow; a
the lower part of the trachea; b the two bronchiae; c the
external laryngeal muscles, which are common to all birds;
d the contractors. Fig. 9. of the same plate exhibits the
organ of voice in the turabi; a the anterior longitudinal
contractor; b the transverse contractor partially exposed
under
under it: c the posterior longitudinal conductor, detached at one extremity, and curved outward; and Fig. 12. affords another view of the same subject: the posterior longitudinal conductor is turned down to expose f the face that he behind it: a the little longitudinal conductor; b the oblique conductor. Fig. 11 of Plate X. represents the anterior part of the organ of voice in the pigeon: a the principal conductor; b the auxiliary one; c the isxator; and Fig. 12 gives a lateral view of the same organ, which are indicated by corresponding letters.

The trachea, in several birds, is found to assume singular forms, and to suffer enlargements at particular places. There have long attracted the attention of naturalists. Some of the best observations on the subject have been made by Dr. Bloch of Berlin, and by Pallas, Silberfchlag, Beckmann, and Otto, who have each published in the Berlin Transactions, Feiftich. des B.-r. Nat. F. i. ii. iii. & iv. But by far the most copious account of the peculiarities of the trachea of birds, has been given by Dr. Latham in the Linnaean Transactions, vol. iv. p. 50.

The deviations from the common structure of the trachea, have been divided by Dr. Latham into two kinds. In one the wind-pipe does not alter its capacity, but possesses an uneven length, which is disposed of either in convolutions on the outer part of the body underneath the integuments, or in a cavity formed within the sternum for the purpose. The other kind of deviation consists in dilatations occurring either at the bifurcation of the trachea, or both there and in the middle of the tube.

The trachea of the wood pheasant, when arrived at the crop, takes a bend upwards for a little way, and again turns down, and pursues its course to the lungs. There has been no peculiarity observed in the other birds of this genus which visit this kingdom.

The turkey (penelope marcella.) the trachea makes a round turn on the outside of the top of the sternum, and then enters the chest.

In the male parrakeet, the wind-pipe descends under the skin more than half the length of the body, before it returns to enter the thorax.

The guan (penelope criftata) has the trachea still longer than the preceding. It passes to the very bottom of the belly, and then turns up again, before it makes the double. See Plate XI. in the Anatomy of Birds, fig. 13.

The Indian cock was observed by the academicians to have a degree of convolution in the trachea, which varies somewhat in different individuals.

The ouisoue curfus has the most remarkable convolutions of the trachea. It first descends upon the right pectoral muscle to the end of the sternum, where it makes a convolution to the left, something in the shape of a ring, after which it returns to the right pectoral muscle, and goes over the clavicle into the thorax.

The semi-palmated goose of New Holland has an extensive convolution of the trachea under the skin. Its note is said to be very musical.

The arfida wren, the wild or whistling wren, and the crane, have the winding of the trachea accommodated in the keel of the sternum. It is singular that this structure does not exist in the tame fowl, which in other respects so much resembles the wild bird. See Plate XI. in the Anatomy of Birds, fig. 14. This shows the trachea in the wild fowl, and the sternum cut open to expose the cavity which lodges the trachea. bbb the trachea; c c the fork; d d the clavicles. The above structure belongs to both sexes.

The dilatations of the trachea are confined to two genera, Vol. IV.

The bony enlargements at the bifurcation into the bronchi, which are called ampulse, or labyrinths, exist in every species of duck and merganzer. They consist of two cells, one in general much larger than the other. In some cases the partitions of the cells are in a great measure formed by a membrane spread across it, like the head of a drum. There is also a bony arch turned across to give it strength. This is the case in the duck, the pochard, tufted duck, the gnuze, &c. See Plate XI. Fig. 15, is the end of the wind-pipe of the pochard (fama formis).

The trachea of the golden eye duck is very curious. The labyrinth is more complicated than usual; and there is a singular enlargement in the middle, which is formed by cartilaginous joints, or plates, placed obliquely, and folding over each other, so that the part admits of being contracted and lengthened, as the motions of the neck may require.

The velvet duck is distinguished by two very remarkable offshoots enlargements, one is situated immediately below the superior larynx, and another in the middle of the wind-pipe. The lower part does not form the usual ampulla, but the bronchius become for a little way bony canals. See Plate XI. in the Anatomy of Birds. Fig. 16. represents the trachea of the velvet duck, a the superior, or laryngeal offshoot cell; b the bony cavity of the middle; c c the offscott parts of the bronchus.

The red-breasted merganzer has the middle of the trachea formed like that of the golden eye duck, only the plates are made of bone, and curiously sawn; indeed all the trachea of the merganzers, as Dr. Latham observes, consists little else than bone.

A very little comparison of the mechanism of wind musical instruments with the organs of voice in birds, will shew how nearly they are allied to each other; and it may be observed, that the sound produced by some of the larger birds is exactly similar to the notes that proceed from a clarion, act or harpby in the hands of an untutored musician. The inferior glottis exactly corresponds to the reed, and produces the tone or simple sound. The superior larynx gives it utterance as the holes of the instrument; but the strength and body of the note depend upon the extent and capacity of the trachue, and the hardness and delicacy of its parts. The convolution and bony cells of the wind-pipe, therefore, may be compared with the turns of a French horn, and the divisions of a bajoon; and they produce the proper effects of these parts in the voices of those birds in which they are found.

Birds, in Ancient Auditory. Prefecture, or knowledge of futurity, was supposed, among the ancients, a natural faculty of birds, owing, perhaps, to their nearer intercourse with heaven, or their breathing a purer and more celestial air than other animals. Hence it was, that divination by birds obtained among the ancient Greeks and Romans, being performed by observing, and interpreting the flight, chirping and feeding of divers birds. (See Auditory.) Birds, with regard to augury and divination, were of divers kinds, viz. Aves suspicas, or Aves, those which naturally portended good, such were the dove, fawn, &c. Aves inspctae, dire, ensima, those that boded some evil or mischief; such were the kite, raven, crow, and owl, every where, except at Athens, Admirens, that which excites and encourages the confidier to execute what he has in view. Ariona or arca, that which forbad a thing to be done; otherwise called

Dr. Bloch, who has been the subject of several odes, has given a most curious account of the bony enlargements of the trachea, and their analogies in the human organ of voice.
called clivia, clamatoria, and prohibitoria, inebra, and inhiba. Incendiaris, that which gave omen of a fire, or other calamity; or which is seen carrying a firebrand from the funeral pile to a house. Remora, that which slays or delays an action. Sinistra, that on the left hand, denoted a happy or prosperous omen; and was also called secunda, prospera. Atter, those which gave omens by their wings and flight. Offines, those by their flinging or chirping. Pulli, by their pecking. Pregestes, those by their flight, or perching, gave happy omens. Insebra, or inebra, those which in like manner gave ill omens.

Bird, William, in Musical Biography. This worthy and admirable scholar of the profound Talus, is supposed to have been the son of Thomas Bird, one of the gentlemen of Edward the sixteenth's chapel, in which he was himself a singing-boy. By the great number of his ecclesiastical compositions to Latin words, and the several portions of the Roman ritual which he so frequently set to music, and published late in life, he seems to have been long a zealous adherent to that religion. He must, however, have conformed to the church establishments of queen Elizabeth's reign; for, in 1563, he was chosen organist of Lincoln cathedral, where he continued till 1569, when, upon the accidental death of Robert Parsons, who was drowned at Newark-upon-Trent, he was appointed gentleman of the chapel royal. Notwithstanding which office, he seems to have composed the chief part of his Choral Music to Latin words, and to have published it in that language, as late as the middle of the reign of king James I.

In 1575, it appears by the title-page of the "Cantiones Sacrae," and the patent annexed to that work, that he and Talus were not only gentlemen of the royal chapel, but organists to her majesty queen Elizabeth. Indeed both must have been great performers on the organ, to have been able to give full of their pieces for that instrument as are still preferred; in which the passages, though awkward to performers who are only accustomed to modern music, must have been figured by persons that were habituated to the complicated, and now, almost, insuperable difficulties of the sixteenth century. And though the compositions for keyed-instruments by these great masters of harmony, are totally unmusical, and without grace, it is impossible not to regard their ingenuity and contrivance in the texture of the parts, with respect and wonder.

If we consider the elaborate style of composition which prevailed, particularly in the church, during the time of Bird, and that he, like his master Talus, was not only ambitious of vanquishing its usual difficulties in the construction of fugues and canons, but invented new complications, perplexities, and involutions in the motion and arrangement of the parts, the following list of his works will not only manifest diligence, but fecundity.

Beneath the great share he had in the "Cantiones Sacrae," published in conjunction with his master Talus, in 1575, when his name first appears as an author; and without enumerating many admirable compositions for the church and chamber, still subsisting, but which were never printed, or, at least, not till after his decease, he published "Psalms, Sonnets, and Songs of Sadness and Pity," of five parts, 1585; "Liber primus facrarnum Cantionum, quinque voce," 1589; "Sono, of teudiee Natures, see of Graffite, and others of Myth, fit for all Companes and Voyces," 1589; "Cantua a Canti sacrae, Lb. primus et secundus," 1607 and 1610. The last work published by himself, was entitled, "Psalms, Songs, and Sonnets: Some solennem, others joyful, framed to the Life of the Words, fit for Voyces or Viol, of three, four, five, and six partes,"

1611. Dr. Tudway's collection, in the British Museum, contains a whole service in D minor, by Bird, with responses, and the anthems, "Sing joyful unto God,"—"O Lord, turn thy Wrath,"—(all published in the second and third volumes of Dr. Boys's Cathedral Music)—"O Lord, make thy Servant,"—"Save me, O God,"—"Prevent us, O Lord,"—" Civitas sancti tuus," one of hisSacramuntum, or Sacred Songs, published 1589, has been long sung in our cathedrals to the English words, "Bow thine ear, O Lord," and is one of the admirable pieces of harmony in the second volume of Boys's printed collection.

Dr. Aldrich, who was a great admirer and collector of the works of Bird, and who adapted English words to most of his compositions which have been used in our cathedrals, and that were originally set to parts of the Romish service, in Latin, has bequeathed to Chrift Church, Oxon, beautiful and correct copies of most of his productions, in a set of books, small 4to. In this library near forty of his compositions are preserved; and in another set, many more, with those of Talus, Taverner, Tye, White, Redford, both the Mandys, Shepherd, Bull, and other contemporary English masters.

Bird's pieces for the organ and virginals are almost innumerable. In a magnificent folio manuscript, curiously bound in red morocco, formerly in Dr. Pepeliah's collection, which is generally known by the name of "The Queen Elizabeth's Virginal Book," there are near 70 of his compositions.

The first piece by Bird, in this book, and the eighth in the collection, is a Fantasia, which generally implies a Fugue, in which the subject is as frequently changed as in ancient Choral Music, where new words require new accents and intervals; for as yet, it was not the custom in composing fugues to confine a whole movement to one theme; and here Bird introduces five or six, wholly different and unconnected with each other.

The subject of the second composition, by Bird, in the Royal Virginal Book, is the tune of an old ballad, "John come kis me now," of which, with great labour and ingenuity, he has varied the accompaniments sixteen different ways; for while the treble, bass, or some inward part, is always playing the original air, three other parts are moving in fugue, or running rapid and difficult divisions. No. 53, is another Fantasia; and 56, a Pavan, by Bird; which implied a grave majestic dance, in common time, similar to the movement of the peacock. This strain was usually followed by the Galliard; which, on the contrary, was gay and lively dance, in triple time, but on the same foundation as the preceding Pavan. No. 58, is entitled, "The man's Whistle." From No. 58 to 69, the compositions are all by Bird; confiding chiefly of old tunes, with variations; among which is "Fortune," a plaintive and expressive melody, to which the ballad, called "Titus Andronicus's Complaint," is adapted in Reliques of Ancient English Poetry, vol. i. p. 204, was originally written. It has been imagined that the rage for variations, that is, multiplying notes, and diguising the melody of an air, and, generally, well-known air, by every means that a grace note, or note slitter, fits possi, was the contagion of the last century; but it appears from the Virginal Book, that this species of influenza, or corruption of air, was more excessive in the sixteenth century, than at any other period of musical history.

Crowded and elaborate as it is the harmony, and uncouth and antiquated the melody, of all the pieces in this collection by various composers, there is a manifest superiority in those of Bird over all the rest, both in texture and design. In a later age his genius would have expanded in works of invention, talent, and elegance; but, at the period in which he
he flourished, nothing seems to have been thought necessary for keyed-instruments, except variations to old tunes, in which all the harmony was crowded, which the fingers could grasp, and all the rapid division of the times, which they could execute. Even nominal fances were without fancy, and confined to the repetition of a few dry and unmeaning notes in fugue, or imitation. Invention was so young and feeble, as to be unable to go alone; and old chants of the church, or tunes of the street, were its leading-strings and guides.

Though the reformation had banished superfluous from the land, fragments of *canto fermo*, like rags of paper, still remained in our old secular tunes, and continued to have admission in the new. Indeed the melodies of all the rest of Europe had no other model than the chants of the church, till the cultivation of the musical drama; whence all the rhythm, accent, and grace of modern music, have manifestly been derived.

Besides the great number of Bird's compositions for keyed-instruments, which are preserved in the Virginal Book of queen Elizabeth, another manuscript collection of his pieces still subsists, under the title of "Lady Nevil's Music Book." It is a thick quarto, very splendidly bound and gilt, with the family arms beautifully embellished and illuminated on the first page, and the initials H N at the lowest left hand corner. The music is all written in large, bold characters, with great neatness, on four flaved paper, of six lines, by Jo. Balewine, a singing-man at Windsor, and a celebrated copyist of queen Elizabeth's time. The pieces contained in this collection, sixteen of which are entered in that queen's virginal book, amount to forty-two, with variations to many of them, of the most laboured and difficult kind. The notes, both white and black, are of the lozenge form, like those of the printed music of the same period.

BIRD.

Lady Nevil seems to have been the scholar of Bird, who professedly composed several of the pieces for her ladyship's life.

None of Bird's pieces for keyed-instruments seem to have been printed, except eight movements in a thin folio book of lessons that was engraved on copper, and published in the reign of king James I. under the following title: "Parthenia, or the Maidenhead of the Muficke that ever was printed for the Virginals. Compos'd by three famous masters: William Bird, Dr. John Bull, and Orlando Gibbons, gentlemen of his majesty's most illustrious chapel." Thse lessons, though not equally difficult with some of those in the Virginal Books of queen Elizabeth and lady Nevil, are rather more dry and ungraceful.

The canon, *Non nobis Domine*, appears in none of his works published by himself, or collected by others, before the year 1652; when Hilton inferred, and prefixed the name of Bird to it, in a collection of catches, rounds, and canons. But as no claim was laid to it by, or in favour of, any other composer, before or since that time, till about the middle of the left century, when it was given to Palefliina by Carlo Ricciotti, who published, in Holland, among his concertos, a fugue in eight parts, on the same subject, there seems to doubt remaining of our countryman Bird having been the author of that pleasing and popular composition.

Bird died in 1623, surviving his master Tallis thirty-eight years; and if we suppose him to have been twenty in the year 1575, when he was chozen organist of Lincoln, he must have been eighty at his decease. Peacham, in his Complete Gentleman, speaks of him with great reverence; "For

Motets and Musick of piety and devotion, as well for the honour of our nation, as the merit of the man; I interfere above all others our Phoenix, Master William Byrd, whom in that kind I know not whether any may equal. I am sure none excelled, even by the judgment of France and Italy, who are very sparing in their commendation of strangers, in regard to that concept they hold of themselves. His Cantiones Sacrae, as also his Gradualia, are most angelical and divine; and being of himselfe naturally disposed to gravity and piety, yet his Virginalia, and some others in his E R fett, cannot be mended by the best Italian of them all." Second Improvisation, p. 100. His pupil, Morley, in his Introduction, every professor and musical writer of his own and later times, never mention him but with the highest respect. At this remote period but little, however, can be known of his private life, which was too illustrous and sedentary to have furnished history, at any time, with events of general interest. With respect to what Ant. Wood afferts in his Fafi, that "Bird was excellent in mathematics," it is, in his usual way, supported by no proofs: and indeed mathematics have to little to do with practical music, either in composition or performance, that those musicians, who are most ignorant of the ratio or philosophy of sounds, seem constantly to have arrived at the highest degree of excellence in the seelction, combination, and refinement of them in practice, by the mere sufficiency of experience, and the gift of good ears and powerful voices. That he was a diligent cultivator of his art appears from his numerous works, which are more the productions of meditation and study than of haste and enthusiasm. That he was a pious, the words he selected, and the solemnity and gravity of style with which he set them, sufficiently evince. Of his moral character, and natural disposition, there can, perhaps, be no testimonies more favourable, or less liable to suspicion, than those of rivals professors, with whom he appears to have lived during a long life with cordiality and friendship. And, of the goodness of his heart, it is, to us, no trivial proof, that he loved, and was beloved, by his master, Tallis, and scholar, Morley; who, from their intimate connexion with him, must have seen him en rebe de chamber, and been spectacles of all the operations of temper, in the opposite situations of subjection and dominion.

Indeed, the best memorials of a professional man's existence are his surviving works; which, from their having been thought worthy of preservation by posterity, entitle him to a niche in the Temple of Fame, among the benefactors of mankind. The physician who heals the diseaese, and animates the soul of the body, certainly merits a more conspicuous and honourable place there; but the musician, who eminently foother our forefathers, and innocently diverts the mind from its cares during health, verifies his memory dear to the grateful and refined part of mankind, in every civilised nation.

Bird cherry, in Botany. See Prunus Padus.

Bird's eye. See Adonis.

Bird's foot. See Ornithopus.

Bird's foot trefoil. See Lotus.

Bird's nigl, a name used by some for the daucus, or carrot; and by others for orbs.

Bird's nigl purple. See Ochrys.

Bird's pepper. See Capsicum.

Bird's tongue. See Scenecio.

Birds. See Canary birds.

Bird of the wise, among Adonis, is the philosophical mercury; and, in general, symbolizes or signifies pure, refined by the separation of their terrestrial part.

Bird, golden, the hermetic matter partly matured.
Bird. green, the philosopher's fume, at the time when its green colour appears.

Birds, Cyprian, aves Cypris, or arvicula Cypris, is a denomination given to a kind of odoriferous candles, made of the matter of troches, and burnt for the sake of their fumes, called also, from their figure, baculi, or sticks.

Bird of Hermes, aotis, or arvicula Hermitica. Alchemists speak much of that which flies in the night without wings. Some will have the arvicula hermitica to be an universal falt prepared from dew.—It also denotes red-head.

Birds, decoy, are those which are trained up to call and allure others into the fowler's net, snares, line-twiigs, or the like. See Decoy.

Birds, Humming. See Humming-bird.

Birds, in Domestic Economy, and in reference to their use as aliments. See Fowl.

Bird, in Falconry, denotes a hawk, or falcon. See Falconry.

Nides birds, aves nidulabae, denote those taken while in the nest. Routage birds, arboruæ aves, are those only arrived at strength sufficient to fly from branch to branch. Hazard bird, is that which has lived at liberty, and is thence more wild and untractable. Bird of the fijf, is that which having been reclaimed, returns to, and perches on, the hand, without the help of a lure. Bird of lure, signifies that which comes to the lure, and by that means to the hand. Befart bird, a hawk, for instance, bred of a hawk and a lanner; or a faker, bird of a faker and a lanner. Coward birds, those which only pursue their game for their own belly, and which are not to be reduced to juff sport; as ravens, kites, &c.

Bird, in Geography, the name of a small island in Durnaus, in the county of Cork, Ireland.—Also, another small island in Strangford lough, and county of Down.

—Alfo, one of the Bermudas, islands.—Alfo, a small island in the gulf of St. Lawrence, 21 leagues W. of Cape Annequa on the island of Newfoundland. N. lat. 47° 35'. W. long. 66° 45'.—Alfo, an island in the southern Pacific Ocean, discovered by capt. Cook, in 1768, in his voyage from Cape Horn to Ophir, covered with verdure, and inhabited. S. lat. 17° 48'. E. long. 216° 24'.—Alfo, an island in the southern Pacific Ocean, near the north-west coast of the island of New Georgia, discovered by capt. Cook in 1775. S. lat. 54'. W. long. 38° 24'.—Alfo, an island of the same name, discovered, in 1788, by the commander of the Prince of Wales, and so called from its being the resort of many birds. This solitary island, or rather single rock, rising out of the immense ocean, was particularly examined by Vancouver in 1794. Its greatest extent, in a direction S. 74° W. and N. 74° E. did not exceed one mile; and its northern, eastern, and western extremities, against which the sea broke with great violence, presented a very awful appearance, rising perpendicularly from the ocean in lofty rugged cliffs, inaccessible except to its winged inhabitants; on its southern side the ascent is not so steep and abrupt; and near its western extremity is a small sandy beach, where, in fine weather, and with a smooth sea, a landing might probably be effected. At this place was the appearance of a little verdure, though it was delitute of tree or shrub; every other part was apparently without soil, and confined only of the naked rock. The whole circumference does not exceed a league, and it is situated in N. lat. 24° 6'. E. long. 158° 8'. It lies from Onehow, one of the Sandwich islands, N. 51° W. at the distance of 339 leagues; it is recognized by the natives of those islands under the appellation of "Moono Mannoo," that is, bird island; and from its great distance from all other islands, and its proximity to their islands, it seems to claim some pretensions to be ranked in the group of the Sandwich islands; which see.—Also, a small island near the north-east coast of New Holland, lying low and almost covered with birds; 4 leagues N. W. from cape Grenville. For other islands under this denomination; see Aves.

Bird fort, an American fort on Manongahela river; 40 miles south of Fort Pitt.

Birds-Key, or Round island, a small island, or rock, among the Virgin islands; in the West Indies; 2 leagues S. of St. John's island; and 3 N. E. from St. Croix, or Santa Cruz. N. lat. 17° 55'. W. long. 64° 36'.

Birds. Maffe, aves internicenes, denote those that are employed to convey letters or other dispatches, either for the sake of expedition or safety. See Carrier pigeon and Allepo.

Bird, mocking, the turdus polyglottus; which see. See also Mock bird.

Bird bolt, in Heraldry, is a small arrow with a blunt head, and often represented in armor, with two and sometimes three heads rounded, but in that case the number of heads must be noticed.

Bird call, a small fick eft at one end, in which is put a leaf of some plant, that serves to counterfiet the call of several birds, and to bring them to the net, snare, &c. by which they are taken. A leaflet fitched on the bird-call counterfets the voice of landings. A leak that of the nightingale, &c. See Call and Bird-catchling.

Bird Catching, in its most comprehensive sense, denotes the art of taking birds or wild-fowl, either for food, or for enjoying the pleasure of their song in cages, or for preventing the destruction which some species of them occasion to the husbandman. Some recur to it as an amusing pastime, and others practice it as a profitable employment; and with a view to one or other of these objects, various modes of taking birds have been adopted, and the practice is in some places reduced to a kind of system. One of these methods is denominated Bat-Fowling, or, as some term it, Bat-folding. For this purpose, five or fix persons commonly provide themselves with a large net, expanding, when open, to the extent of a man's arms, and about three yards high, and formed of meshes so small as not to allow the escape of the smallest bird. The extremities of the net are attached to two poles, held one in each hand of the person who has the management of it. With this, and a large lanthorn affixed to a pole, the party proceeds to corn-fields, out-houses, yew-hedges, thatched buildings, &c. The cords of the net being separated to their utmost extent, it is placed before any spot where birds are supposed to roost, and the light being held before the centre of the net, the affidants in this operation beat the hedges, ricks, caves, &c. with poles; and the birds, thus alarmed, fly towards the light, upon which the person who holds the net claps its poles together, and encloses the birds. From the latter circumstance, the net is called a clap net. Sparrows, larks, thrushes, and the other small birds, are thus caught in great numbers in dark nights. Another method of bat-fowling, is performed by means of a long net drawn over the ground, followed by a person bearing a light; and this net, in its passage, ensnare and confines any birds that happen to be under it. But one of the most ingenious and systematic methods of bird-catchling, is practiced principally in the vicinity of London, by persons who find a ready market for birds used as food, or who deal in fong-birds, which, at certain feasons of the year, change their situation, and are hence denominated birds of flight, in the language of this art. The birds usually taken on fuch occahions, are wood-larks, titlarks, linnets, aberdaines, gold-fitches, and green-fiches. They are principally
pally taken during what is called their flight, or while they congregate for the purpose of propagating their species. The wild birds begin to fly in the month of October, and part of the preceding and following months; and the flight in March is much less considerable than that of Michaelmas. It is to be noted also, that the several species of birds of flight do not appear exactly at the same time, but follow one another in succession. The pippet, which is a small species of lark, inferior in its song to other birds of that genus, begins his flight, every year, about Michaelmas; and then the wood-lark, linnet, gold-finch, chaffinch, green-finch, and other birds of flight succeed; all of which are not easily to be caught, or in any numbers, at any other time, particularly the pippet and the wood-lark. These birds, during the Michaelmas and March flights, are chiefly on the wing from day-break to noon, though there is afterwards a small flight from two till night; but this is so inconsiderable, that the bird-catchers always take up their nets at noon. Another circumstance worthy of notice is, that, during their flying, they always fly against the wind; hence the bird-catchers eagerly contend for that point; so that if it be westerly, the bird-catcher, who lays his nets most to the east, is sure almost of catching every thing, provided that his call-birds are good: a gentle wind to the south-west generally produces the best sport. The nets used by the bird-catchers are about 12 yards long, and 2¼ wide; which are known in most parts of England by the name of "day-nets," or "clap-nets," but the belt are those that are used in the neighbourhood of London. These nets are spread upon the ground parallel to one another, and at such a distance, that when turned over, they shall coincide. The remaining apparatus consists of lines so fastened to the nets that the bird-catcher is able, by a sudden pull, to draw the net over the birds that may have alighted in the space between their parallel sides. These birds are elicited to flight by others usually denominated "call-birds," of which there are generally five or six, linnets, two gold-finchs, two green-finchs, one woodlark, one red-poll, a yellow hammer, a titlark, and an aberdavine, and perhaps a bull-finch. These are placed at small distances from the nets in little cages. Besides these, the bird-catcher has others called "flur-birds," which are placed within the nets, raised upon the flour, and gently let down at the time the wild birds approach it. This "flur" is a movable piece to which the bird is tied, and which the bird-catcher can raise or depress at pleasure, by means of a long string fastened to it. These flur-birds generally consist of the linnet, the gold-finch, and the green-finch, which are attached to the flour by what is called a "brace," which secures the birds without injuring their plumage. This brace is a sort of bandage, formed of a flender fiken ftring, that is fastened round the body of the bird, and under the wings in such a manner as to prevent the bird’s being hurt, however it may flutter when it is raised. The call-birds are particularly trained for the service to which they are appropriated. Accordingly, the bird catchers contrive to improve the song of these birds, by causing them to mount before the usual time. For this purpose, they put them, in June and July, into a close box, under two or three folds of blankets, and leave their dung in the cage to incense their heat; and in this state they continue, being, perhaps, examined once a week to have fresh water. The air of the cage is so putrid, that they want little or no food, as they eat fearlessly any thing during the whole period of their confinement, which is about a month. The birds frequently die under this operation; and on this account the “tipped bird,” as it is called, is the more valuable. When the bird hath thus prematurely moulted, he is “in fong,” while the wild birds are “out of fong;” and his note is louder and more piercing than that of a wild once: and his plumage is by this process equally improved. The black and yellow in the wings of the gold-finch, for example, become deeper and of a more vivid color, and acquire a very beautiful gloss, which is not to be seen in the wild bird. The bill, which in the latter is likewise black at the end, becomes in the “tipped bird” white and more taper, as are also its legs; and, in short, there is as much difference between a wild and a tipped bird, as there is between a horse, which is kept in gaudy cloths, and one at grave. When the bird-catcher hath laid his nets, he departs for his "call-birds," at proper intervals; and Pennant observes, that a masculine joy appears in these call-birds, to bring the wild ones to the same flat of captivity; and this is also the case with regard to the decoy ducks. After they have seen or heard the approach of the wild birds, which they observe long before it is perceived by the bird-catchers, the intelligence is announced from cage to cage, with the utmost efficacy and joy. The note, by which they invite them down, is not a continued song, like what the bird utters in a chamber; but “short jerks,” as they are called by the bird-catchers, which are heard at a great distance. So powerful is the ascendancy of this call over the wild birds, that the moment they hear it, they alight on a spot, within twenty yards of three or four bird-catchers, which otherwise would never have attracted their notice. It also frequently happens, that if, by pulling the string, half a flock only should be caught, the others who have escaped, will immediately return to the nets, and share the fate of their companions; and if only one bird should escape, that bird will still venture into the scene of danger, till it be caught; such is the fascination power which the call-birds possess with regard to the others. A bird, acquainted with the nets, is by the bird-catchers termed a “sharper;” and this bird they endeavour to drive away, as they can have no sport, while it continues with them. These sportmen frequently levy considerable wagers, whose call-bird can “jerk” the longest, as this circumstance determines their superiority. With this view, they place them opposite to each other, near an inch of carded, and the bird that jerks the attendent, b for the cage it burnt out, wins the water. Me bird have given 170 Jerks in a quarter of an hour, and a lunet has been known, in such a trial, to perform six in its elevation, till it formed from the perch; thus, as Pinder (L. x. c. 29.) says of the nightingale, “vita morte finit foage vitam; spiritu prae-destinat quem curas.”

It is observable, that these bird catchers immediately kill the birds of every species of birds they take, as they are incapable of singing, and inferior in plumage. The pippets, like-wise, are indiscriminately dismissed, as the cock does not sing well. The dead birds are commonly sold for three pence or four pence a dozen. The flur of these is regarded as a delicate acquisition at the tables of the luxurious; and yet the table for small birds is far from being so prevalent in England as it is in Italy, where they are eaten under the name of “beccacino.” However, the luxury of the modern Italians will appear to be partaken, when compared with the extravagance of their predecessors the Romans. (See Gloina Anit.) The highest price given for singing birds in London, Mr. Pennant informs us, is about five guineas; this sum having been paid for a chaffinch, that had a particular and uncommon note, under which it was intended to train others, and five pounds ten shillings have been given for a call-bird linenet. Mr. Pennant informs us, that when the titlarks are caught in the beginning of the season, it frequently happens, that 40 are taken without one female; the cage is the same with the wheatear, and probably with respect to other birds; and this
Bird.

this circumstance confirms the observation of Linnaeus, that the male chaffinches fly by themselves, and the flight precedes the females; and the fact extends to other birds. Such birds as breed twice a year have generally in their first brood a majority of males, and in their second of females.

As the bull-finch, though it is not properly either a singing bird, or a bird of flight, its range being merely from hedge to hedge, fetches a good price on account of its learning to whistle tunes, and as it sometimes flies over the fields where the bird-catchers lay their nets, they have often a call-bird to enliven it, though most of them can imitate the call with their mouths. It is a peculiarity with regard to this bird, that the female answers the purpose of a call-bird, as well as the male, which is not to be experienced in any other bird taken by the London bird-catcher. The nightingale, though distinguished as a singing-bird, moves only from hedge to hedge, and does not take the periodical flights of other birds in October and March; and therefore it is not classified by the bird-catchers among the birds of flight. The persons who catch these birds make use of small trap-nets, without call-birds, and are considered inferior in dignity to other bird-catchers, who will not rank with them. The arrival of the nightingale is expected by the trappers in the neighbourhood of London the fist week in April; at first, none but cocks are taken, but in a few days the hens make their appearance, generally by themselves, though sometimes a few males come along with them. They are caught in a net-trap, the bottom of which is surrounded with an iron ring; and the net itself is somewhat larger than a cabbage-net. When the trappers hear or see them, they threw some fresh mould under the place, and bait the trap with a mealworm from the baker's shop. In this way ten or twelve nightingales have been caught in a day.Pennant's Zool. vol. ii. Append.

Birds are caught in traps of various kinds; and frequently by nooses of hairs. In this way, great numbers of wheat-ears are annually taken on the various downs of England. Small holes are dug by the shepherds in the ground, in each of which is placed a noose. Whenever a cloud obscures the sun, these timid birds seek for shelter under a stone, or creep into any holes that present themselves; and they are thus ensnared by the nooses which fasten around their necks. Woodcocks and snipes are taken likewise by nooses of horse-hair placed along their paths, in marshes and moor grounds. Wild ducks in all their varieties are taken in油画 numbers every winter on our coasts by means of decoys. (See Decoy.) Grouse and partridges are taken by means of nets, either at night when reeling on the ground, by observing where they slant, and when setted, drawing a net over that part of the field; or, in the day, a very steady dog is used to point at them. The attention of the birds being thus fixed, two persons, drawing the two extremities of a large net, pass it over them, and thus secure a whole pack of grouse, or a covert of partridges at once. Pheasants are sometimes taken by night, by holding flaming sulphur under the trees on which they are perched to perch, the suffocating effluvia of which make them fall fenoufels. More Pretty informs us that, during his travels in North America, he took great numbers of the passenger-pigeon in a similar manner. For various methods of taking land; see Alauda. For the use of bird-line among bird-catchers; see Bird-line.

In various parts of the world, peculiar modes are adopted for ensnaring and taking birds, some of which, whilst they are hazardous to those who practise them, excite no considerable degree of surprise, and even of anxiety, in the spectators. Thus, in the Orkney islands, where the birds that inhabit the rocks, and the eggs which they deposit among the cliffs, supply the principal food of many among the poorer inhabitants, the intrepid and adventurous fowlers climb rocky precipices more than fifty fathoms above the sea, and pass from one shelf or ledge to another, whole breadth is barely sufficient for resting places to the birds, which deposit their eggs among them. In this hazardon employment, the adventurers are commonly lowered from above by means of a rope, formed of brittle materials, and held by a single assistant. Tattered to this rope, the intrepid peafant defends, and searches all the cavities for eggs, springing from one projecting ledge to another, by the help of a pole, whilst the assistant, upon receiving the necessary signals, shifts the rope from one part of the rocky precipice to another. If the weight of the fowler and of his booty should, in these perilous circumstances, overpower his associate above, or the craggy rock cut the rope, inevitable destruction must await the adventurer; for he will either be dashed against the projecting rock, or drowned in the subjacent sea. But the most singular species of bird-catching is in the holm of Nofs, which is a huge rock fevered from the isle of Nofs by some unknown convulsion, and distant from it about 16 fathoms. The opposite cliffs are separated by the raging sea. The adventurer, having reached the rock in a boat, and ascended to the top of it, fastens several flakes in the shallow foil that is found on the surface of the rock; and similar flakes are also attached to the edge of the corresponding and opposite cliff. A rope is then fixed to the flakes on both sides, upon which a machine, called a cradle, is contrived to slide; and by the help of a small parallel cord fastened in like manner, the daring adventurer wafts himself over, and returns with his booty.

In the Feroe islands the method of bird-catching is more extraordinary and hazardous than any which has already been recited. The cliffs, to which the fowlers recur, are in many cases 200 fathoms high; and they are traversed both from above and below. In the first cafe, the fowlers provide themselves with a rope 80 or 100 fathoms long; and the adventurer fastens one end about his waist and between his legs, and having recommended himself to the protection of the Almighty, he is lowered down by fixed associates, who place a piece of wood in the margin of the rock, that the rope may be preferred from being fretted and broken by its sharp edge. To his body is fastened a small line, which scribes for enabling him to give the necessary signals, when he wishes to be raised or lowered, or shifted from one place to another. In changing his situation, he is exposed to the hazard of being raised falling flakes, which, falling on the head, must inevitably destroy him, if he were not in some degree protected by a strong thick cap. The fowlers, by their alloning dexterity, contrive to place their feet against the front of the precipice, and to dart themselves some fathoms from it, for the purpose of surveying the roofing places of the birds, and projecting themselves into the deep recesses, where they lodge. There the fowler alights; and disengaging himself from the rope, which he fixes to a stone, collects the booty at his leisure, attaches it to his girdle, and when this is done, resumes his full-shouldered cloak. He will infld when occasions require it, springing from the rock, and at this attitude, by means of a bowling net, fixed to the end of a staff, catch the old birds which are flying to and from their retreats. When this hazardous operation is finished, he gives a signal to his companions above, who pull him up, and divide the booty. The feathers are preferred for exportation; the flesh is partly eaten fresh, and the greater
BIRD.

greater part is dried for winter's provision. In fowling from below, the party have recourse to a boat, and when they have arrived at the base of the precipice, one of the boats, instead of them falls a rope about his waist, and being furnished with a long pole, with an iron hook at one end, either climbs, or is thrusted up by his companions, the piece of rope tied to the mind of a part of his reach. By means of the rope he hoists up one of the boat's crew, and the rest are drawn up in the same manner, each of them being furnished with his rope and flying-flail.

They thus pursue their journey upwards till they arrive at the region of birds; and they wander about the cliff in search of them. They next act in pairs; one falls himself to the end of his associate's rope, and, in places where birds have nestled beneath his footing, he suffers himself to be lowered down, depending on the strength of his companion, by whom he is again hauled up; but sometimes happens, that the person above is overpowered by the weight, and in this case, both inevitably perish. The fowl is flung into the boat, which attends their operations, for the purpose of receiving the booty. The fowlers often pass seven or eight days in this perilous occupation, and lodge in the crannies which they find in various parts of the precipice.

In some remote parts of Russia there is practiced a singular invention for taking great quantities of geese or grous. They choose the most open places in the birch woods, and there they plant long stakes in the earth opposite the larger trees. On their forks is laid a horizontal flock, yellow-twigs, to which are tied small bundles of ears of corn. At a small distance from this part of the contrivance, is a kind of large funnel, or inverted cone, made with long birch twigs, thin and flexible, the lower extremities of which are fluck in the earth, very near to one another; but by spreading towards the top, forms there an opening of above a yard in diameter. In this opening is placed a wheel made of two circles that intersect each other, and are surrounded with fraw and ears of corn. This wheel turns on an axis fastened to the sides of the funnel in such a manner, that there is room enough between the flocks of the cone, and the circles, to admit of the wheel's turning freely about. The birds full perch upon the transverse flock near the tree; and when they have a mind to fall upon the corn tied to the wheel, they must necessarily flind upon one of the projecting parts of the circles of which it is composed. At that instant the wheel turns, and the gelnottc falls, head foremost, to the bottom of the trap, which is there so contracted that he cannot get out. They sometimes find the machine half full of geese.

The following method of netting or catching of wild pigeons is eagerly put forth as a direction in different parts of Italy, particularly by the inhabitants of Cava, in the Hither Principiato, and is thus defended by Mr. Swinburne. The people "assemble in parties; and if any stranger chances to fray to their rendezvous, give him a most cordial welcome. I am not in the least surprized (says Mr. Swinburne), at their passionate fondness for this sport, as I found it extremely bewitching, keeping the attention constant alive, and the springs of the mind pleasantly interested by expectation; the situations where the toils are spread are incomparably beautiful. the air is pure and balmy, and every thing around breathed health and satisfaction. When the periodical flights of rock-doves return from the northern and western parts of Europe, to gain warmer regions for their winter abode, the fowler repays to the mountain, and spreads his nets across the intermediate hollows, the passages through which the birds direct their course, to avoid unnecessary elevation in their flight. These nets are hung upon a row of large trees planted for the purpose. The branches being very thick and close at top, and the boughs lofty and bare, a great opening is left below for the teals, which reach to the ground; and, by means of pulleys, fall a heap with the fowl. Sometimes they are extended from poles that exceed the height of the trees. At a small distance is a lofty circular turret, like a column with a little capital or cap, upon which a man is stationed to watch the approach of the game. As he commands a free view over all the country, and practice has made his sight as acute as that of the lynx, he disregards the birds at a wonderful distance. The doves advance with great velocity; but the alert watchman is prepared for them; and just as they approach his post, hurls a stone above them with a fling; upon this the whole flock, whose fears have birds of prey for their great object, supposing the stone to be an enemy of that kind ready to pounce them, dart down like lightning to avoid the blow by falling under the trees; but there they rush into the jaws of death, by dashing against the net, which instantly drops, and so entangles them that not one of them can escape the active hands of the fowler. These birds are sometimes taken by dozens at one fall, and are accounted fine eating. The dexterity with which the floggers manage their weapon is very remarkable: they throw the stone to a great height without any violent effort; and even without whirling the fling round before they disfigure the pellet. In the Pyrenean mountains, where the same division is followed, the watchmen use a bow and arrow, trimmed with the feathers of a hawk."

The following simple but ingenious method of catching aquatic birds is used in Mexico by the natives. The lakes of the Mexican vale, as well as others of the kingdom, are frequented by a prodigious multitude of ducks, perees, and other water-birds. The Mexicans leave some empty gourds to float upon the water, where those birds resort, that they may be accustomed to see and approach them without fear. The bird catcher goes into the water so deep as to hide his body, and covers his head with a gourd; the ducks come to pick at it; and then he pulls them by the feet under water, and in this manner seizes as many as he pleases.

Sir George Staunton, in his "Embassy to China," (vol. ii. p. 420) informs us, that water-fowl are taken upon the Wee-Cuang hoo lake in that country by a similar device. Empty jars or gourds are suffered to float about upon the water, that such objects may become familiar to the birds. The fisherman then wades into the lake with one of those empty vessels upon his head, and walks gently towards a bird; and situating up his arm, draws it down below the surface of the water, without any disturbance or giving alarm to the whole river of which he treats in the same manner, until he fills the bag which he had brought to hold his prey. This contrivance is not so singular as it is that the same device should have occurred in the New Continent, as Ulloa affirms, to the natives of Carthagena, upon the late circumnavigation of the world."

Brasses fishing with, is a singular mode of fising practiced in some of the lakes of China, and particularly described in the account of the late embassy. Upon a lake near the imperial canal were observed thousands of small boats and rafts, constructed for this singular kind of fishing. On each boat or raft were ten or twelve birds, which, as at a signal from the owner, plunged into the water; and it was amusing to observe the enormous size of the fish with which they returned, grasped within their bills. These birds appeared to be so well trained, that it did not require either ring or cord about their throats, to prevent their following any
any portion of their prey, except what the mafier was pleased to return to them for encouragement and food. The boat used by these fishermen is of a remarkable light make; and is often carried to the lake, together with the fishing birds, by the men who are there to be supported by it. The bird trained for this purpose is a species of pelican, described by Dr. Shaw, from a specimen submitted to his inspection, as "the brown pelican or corvorum, with white throat, the body whifh beneath and spotted with brown, the tail rounded, the irides blue, the bill yellow." Staunton's emhjly to China, vol. ii. p. 588.

Bird lime, a viscid substance, prepared various ways, and from various materials, for the catching of birds, mice, and other vermin.

Bird lime ordinarily used among us is made from holly-bark, boiled ten or twelve hours. When the green coat is separated from the other, it is covered up a fortnight in a moist place, then pounded into a rough paste, so that no fibres of the wood be left, and wafted in a running stream till no moles appear, put up to ferment four or five days, skimmed as often as any thing arises, and laid up for use. To use it, a third part of nut oil, or any thin grease, is incorporated with it over the fire.

The mill-toe affords a juice even superior to that of the holly; and if a young plant of the common elder be cut through a finny juice will draw out in threads, and follow the knife like bird-lime, or the juice of holly. It seems in this tree to be lodged, not in the bark, but in certain veins within the circle of the wood. The roots of all the hirnithals also afford a tough and finny juice of the same kind, and to do the aphodel, the narcissus, and the black broony root, in a surpising quantity.

The bird-lime brought from Damascus is supposed to be made of sebiano, their kernels being frequently found in it; but this does not ensue either frock or wet. That brought from Spain is of an ill smell; that of the Italians is made of the berries of mullctoe, heated, mixed with oil, as before; to make it bear the water, they add turpentine. It is said, the bark of our willow or wayfaring shrub makes bird-lime as good as the bell.

Bird-lime is a substance very apt to be congealed, and rendered unferceivirable by 4;005; to prevent which it is proper, at the cold season, to incorporate some petroleum with it, before it is used. The method of using it is to make it hot, and dip the ends of a bundle of rods in it; then to turn them about and play them together, till a sufficient quantity is extended over them all. If strings or cords are to be limed, they are to be dipped into the bird-lime, while very hot. The cords may be put in cold, but the rods should be warmed a little. Straws are to be held while the matter is very hot; a large bundle of them should be put in at once, and worked about in it, till they are well beamed. When thus prepared, they should be preferred in a leather bag till they are used. When the twigs or cords are to be put in places subject to wet, the common bird-lime is apt to have its force soon taken away: it is necessary, therefore, to have recourse to a particular sort, which, from its property of bearing water unhurt, is called water-bird lime; and is prepared thus: Take a pound of strong and good bird-lime, wash it thoroughly in spring-water, till the hardfins is entirely removed; and then beat it well, that the water may be separated from it; then dry it well, and put it into an earthen pot; add to it as much copper's grease as will make it run. Then add two spoonsfuls of strong vinegar, one spoonful of oil, and a small quantity of Venice turpentine. Let the whole boil for some minutes over a moderate fire, stirring it all the time. Then take it off; and when there is occasion to use it, warm it, and cover the slicks well with it. This is the best sort of bird-lime for snipes, and other birds that love wet places.

In order to use the common bird-lime, cut down the main branch or bough of any bushy tree, whose twigs are thick, straight, long, and smooth, and have neither knots nor prickles. The willow and the birch trees will best anwser the purpose. Trim off all the supernuous shoots; and when the twigs are made neat and clean, let them be well covered with the bird-lime, within four inches of the bottom, but without touching the main bough from which they proceed. Some sort is necessary to lay on the bird-lime properly; in that it be neither too thick, which would give the birds a diftaste, and prevent their approaching it; nor too thin, so that it would not hold them when they touch it. Having prepared the bushes, let it be placed in some dead hedge, or among growing bushes, near the outskirts of a town, a farmer's yard, or fush station, if it be in the spring, when the birds refer to such places. If it be used in summer, let the bush be fixed in the midst of a quick-set hedge, or in groves, bushes, or white-thorn trees, near fields of corn, hemp, flax, and the like; and in the winter, near thickets of corn, hovels, barns, and inch places. When the lime-bush is thus planted, the sportsman must stand as near it as he can, without being discovered, and contrive to make such forts of notes as the birds do when they call to one another. Bird-calls may be used for this purpose; but the most expert method is to imitate with the voice the notes of call of the several birds. When a single bird is thus enticed to the bush, and fastened to it, the sportsman is to wait till, by struggling to release itself, it becomes more securely atatched, and by its fluttering it has brought other birds to the bush; so that in this way several may be caught at once.

The time of the day for this sport is from sun-rise to 14 o'clock, and from one till sun-set. Another mode of bringing the birds together is by a flake; such as, a bat folded in flight at a distance, or an owl, which is followed by several small birds, which, alighting on the lime-bush, will be entangled. The skin of an owl studded, or even the image of an owl carved on wood and painted in its natural colours, has been successfully used for the same purpose.

M. Barrers, physician at Pergnias, discovered an animal bird lime, prepared of the bulbs of a foot of caterpillars, by purifying them in the earth, steeping them in water, and then pounding and mixing them with olive oil. Fontenel. Hist. Acad. Science. 1732, p. 12.

Birds, migration of. See Migration.

Birds' nefs, in Cukery, the holes of a small Indian swallow, very delicately tailed, and frequently mixed among fowls. Mr. Maitfer, in his account of Sumatra, sir George Staunton in his embassy to China, and many other travellers of more ancient and modern date, have recited several particulars concerning these edible nefs. But we have a more minute and ample description of them, as well as of the birds by which they are formed, in the third volume of the "Transactions of the Batavian Society in the Island of Java, for promoting the arts and sciences." The birds that construct them are of a blackish grey colour, somewhat inclining to green, but gradually changing on the back to the tail, and on the belly into a mouse colour. The length of the bird, from the bill to the tail, is about 4 inches; and its height, from the bill to the extremity of the middle toe, 3 inches. The distance from the tip of one wing to that of the other, when extended, is 10 inches; the largest feathers of the wings are about 4 inches in length. The head is flat; but, on account of the thickness of the feathers, appears round, and large in proportion to the size of the

ref
BIRD.

red of the body. The bill is broad, terminating in a sharp extremity, and incurved like an awl. Its width is increased by a naked piece of skin, resembling parchment, which, when the bill is shut, is folded together; but when open, is considerably extended, and enables the bird, while on wing, to catch with greater ease the insects that hover it. The eyes are small, black, and large; the tongue is shaped like an arrow, and not forked; the ears are flat, rounded, naked spots, with small oblong openings, and are wholly concealed under the feathers of the head; the neck is very short, as well as the legs and wings; the thighs are wholly covered with feathers; and the very tender lower parts of the legs, and the feet, are covered with a skin like black parchment. Each foot has four toes; three before, and one turned backwards. The toes are separate to their roots; and the middle one, together with the claw, is as long as the softer part of the leg. Each toe is furnished with a black, sharp, crooked claw, considerably longer, by which the bird can easily attach itself to crags of rocks. The tail is as long as the body, together with the neck and head; when extended it has the form of a wedge, and consists of ten large feathers; the four first of which on each side are long, and, when the tail is closed, extend almost an inch beyond the neck. The other feathers descend towards the middle of the tail, and are equal to about the length of the body. The whole bird is very light and tender; ten of them together weighed little more than 2½ ounces. The Javanese call it "lawit," but those who live in the mountains, "berongdayi," or "waked," veroon, in the Malay language, signifying in general a bird.

There are two places in particular, near Batavia, where these birds are found in great numbers. The first, Calappa Nengal, lies about 10 miles south of the city; and the other, Sampa, is somewhat more distant to the south-west; but both are in that range of high land extending towards the sea, and apparently different from the large ridge that extends over the whole island. Besides these there are also other places in the same district, or at a greater distance from the coast, which either produce a few, or are carefully concealed by the Javanese, to whom they are known. The two birds mentioned above-mentioned, called by the Javanese (goa) caverns, are inhabited rock, hollow within, and pierced with numerous openings of different sizes; but so small, that they seem to be peculiarly adapted to the security of these little animals. On the outside, these rocks are covered with various kinds of tall trees; and within, they consist of grey calcareous stone and white marble. To the sides of these caverns the birds affix their small nests in horizontal rows, and to close as almost to adhere together. They are constructed at different heights, from 50 to 100 feet; and no cavity that is dry and clean is left unoccupied. But if the sides of the caverns be in the least wet or moist, the birds deject them. At day-break these birds fly abroad from their holes, with a loud fluttering noise; and in dry weather rise insensibly to such a height in the atmosphere, for the purpose of seeking their food in distant parts, that they are soon out of sight. In the rainy season they never wander far from their holes, particularly in Java, where some rocks are situated near the shore. About 1 in the afternoon they return, and confine themselves closely to their retired habitation, that none of them are seen to fly either out or in, except those that are hatching. They feed upon all sorts of insects that hover over the stagnated water; and these, by the daily extension of their bills, readily catch. Their most deterrent enemy is a kind of hawk, which slays many of them as they issue from their holes, and which the people frighten away by shouting at them. Their nests are prepared, says this writer, from the strongest remains of the food which they eat, and not of the down of the sea; or of sea-plants, as some have alleged. On this subject, however, there have been different opinions. As the habitation in which they form their nests is the middles of sea-weeds, according to Le Peire, fish-spawn; according to Dalrymple, sea-weeds; and according to Linnaeus, the animal fabrica is often found on the sea-beach, and called by fishermen bladders or jellies. In proof of his opinion, this author states, that it is known from experience, that those birds, which build their nests in the two rocks before-mentioned, have never been found on the sea coast, and could not possibly fly thither and return again in so few hours, on account of the high intervening mountains, and the stormy winds that often prevail among them. The great difference in the colour and value of these nests proves, that their constructors depends merely on the superabundance and quality of the insects on which they feed, and perhaps on the greater or less solitude of the place where they seek nourishment. Those found in the territory of Calappa Nengal and Goagadjia are exceedingly grey, and worth one third less than those produced in the territory of Sampa; and these latter are not so far compared with an excellent fort which is every year imported from Turkestan, and which is to be found on the surrounding islands, particularly to the east of Borneo. These birds occupy two months in preparing their nests: they then lay their eggs to number in), on which they sit for 15 or 16 days. As soon as the young are hatched, people begin to collect the nests, which is regularly done every four months; and this forms the harvest of those who are the proprietors of the rocks. The buufness of taking down the nests is performed by perfons accustomed from their youth to climb these rocks. For this purpose they construct ladders of reeds and bamboo, by which they ascend to the holes; or, if the caverns are too deep, they employ ship-ropes. When they have descended to the bottom of the caverns, they place bamboo with notches in them against the sides, so that these be sufficient, in order to get up to the nests; but if they cannot thus reach them, they ascend the ladders, and pull down the nests with poles of bamboo made for that purpose. There are also certain holes to which people can ascend by means of steep made of bamboo, but these are very few. This employment is very dangerous: many lose their lives in pursuing it, and one particularly those who attempt to rob these caverns at improper seasons, for guarding against whole depredations, there are small watch-houses constructed in their vicinity. The mountaineers who engage in this occupation, never undertake their labour till they have slaughtered or fenced a buffalo; which custom is continually observed by the Javanese, at the commencement of any extraordinary enterprise. On such occasions they mutter over a few prayers, anoint themselves with aromatic oil, and fumigate the holes with odourous substances. At the chief of these caverns, in the island of Java, a particular protecting female deity is worshipped, under the name of "Raton Laut Radul," or Prince of the South Sea. She is provided with a small hut, and a covered sheltered place, together with various elegant articles of dress, which no one but a prince must approach. On every Friday, when the nests are taken down, incense is continually burnt; and the body and clothes of every one who intends to ascend the rocks must be exposed to it. In order to have light in the caverns, they light torches made of the redissed gum of a large tree called "care," and the inner bark of the arek tree. The gathering of the nests continues no longer than 2 months, and may be repeated three times a year. Some say it may be done a fourth time; but the most experienced say,
that a nest, as long as it remains entire, is continually enlarged or made thicker, until it is entirely deserted by the bird, when it has become dry or hairy in the inside. When the nests have been collected, they require only to be dried and cleaned, and then they are packed in bales and sold to the Chineese. Their price varies, and depends on their whiteness and fineness. Some of them have a grey, and others a reddish appearance; those of the best sort are exceedingly scarce. They are sold at the rate of from 800 to 1400 rix-dollars per 125 pounds. This high price, and the inimitable sample of the Chineese, give rise to much dishonesty and thievery, especially as the Chineese make no scruple of bribing the watchmen with money, opium, and clothes; nor can any vigilance prevent this fraud. Calappa Nongal and Sampia formerly belonged to the Dutch East-India company; but, in 1778, the government resolved to sell them by auction to the highest bidder, and received for them almost 100,000 rix-dollars. Besides these, there are several other places of a like kind, though less important, in the same range of mountains; and there are also two or three in the high land, in the interior parts of the country, and several small ones, which are carefully concealed. Three considerable bird-mountains, Goa Dahler, Cede, and Nangafari, are situated in the government of Samarang, in Java; and these are washed by the sea, which forms its way so deep into the latter that fish may be caught in it. In these places the nests are of an excellent quality; but the steepness of the rocks, and the violence of the surf, render it very dangerous to collect them; and, therefore, a suspended apparatus of bamboos is employed for this purpose. The quantity of these nests, collected annually in the island of Java, amounts to 2500 pounds in weight. There are also bird caverns in Bantam, and the island of Sumatra, in the Andaman and Nicobar isalands, in the island of Borneo, and also in Cochin-China. The young birds are eaten both by the Javenese and the Europeans in India; but it is difficult to procure them. They are confidered as very heating; but the nests, on the other hand, when they have been boiled to a slimy kind of soups, exposed in the night-time to the dew, and mixed with sugar, are very cooling. The Javenese, therefore, use them in violent fevers; and they are faid to be perfirblished with good success for fore throats and hoarfenes. This latter use of them has probably been derived from the Chineese, who carry on a great trade by these nests, and eat many of them in the winter, because fore throats are then very common in the northern part of the kingdom, in confequence of the people accumulating themselves to fit very much over the fire. But the author of the paper, from which these particulars are extracted, was not able to discover this nourishing and strengthening quality that has been fo much extolled, though he used a confiderable number of these nests, prepared in various ways, in order to convince himself of the fact. He cauited them to be examined by able chemifs; but nothing more could be observed than that the solution preffed a weak gum with a disagreeable tafle, which perhaps might be of some ufe in flight indignations of the breaf.

These nests are, therefore, a mere article of luxury to adorn the tables of the rich. The Chineese are remarkably fond of them. After being boiled and well cleaned, they put them, along with a fat capon or a duck, into an earthen pot closely covered, and suffer them to boil for 24 hours over a flow fire, which they call "timmer"; and, on acount of this addition, the whole dish acquires a more luscious tafle. The trade in these nests has of late much increafed. The high and advancing price of them in China makes Batavia the principal mart of this commodity, which is employed, since the company have surrendered it, very advantageously by the inhabitants, to leffen the prejudicial exportation of specie.

The species of swallow that forms these nests is not to be found in China. Linnaeus gives, as a diftinguishing mark of the *hirundo efculenta*, that it has white spots only on the feathers of the tail. But the small birds in Java that conftruct the nests, have spots neither on the tail nor on any other place. The tail feathers are entirely of one colour, blackish grey above, and a little brighter below. Rumphius says of his *capodes marinae*, that the feathers of the tail were spotted, and that the breed also was speckled black and white. Valentim, in his description of the small swallow which constructs edible nests, mentions neither spots nor speckles; and only fays, that the belly was undulated black and white. If these are to be confidered as effential differences, it will follow that there are two kinds of these swallows: one with a speckled breaf, and white spots on the tail feathers; and the other, without spots or speckles. A third kind of these swallows would be thofe called "mo- mos," or "boerongiatas." These also prepare their nests of edible fabulatata; but on account of the number of small feathers, and other impurities mixed with them, they are not fit to be used; and people, therefore, endeavour, as much as possible, to exterminate them, as they spoil the habitations of the better kinds. They are diathighed from the others merely by being larger, and having their legs down to the feet covered with small feathers.

**Birds, pictures of, prepared by means of their own feathers.** For this purpose, procure a thin board of deal or wafticot, well fefioned, that it may not warp. On this paste white paper, and let it dry: then get any bird which you would wish to represent, and draw its outline on the paper, in the defired attitude, and in its nature fize, with the addition of any landscape or back-ground, &c. which you may think fift. This outline so drawn is afterwards to be filled up with the feathers from the bird, placing each feather in that part of the drawing correfponding to the part of the bird from which it was taken. To do this, cover the outline reprefentation with feveral coats of throng gum-water, allowing it to dry between each coat, till it is of about the thicknes of a fhillng. When the ground is thus prepared, take the feathers off the bird, beginning at the tail or points of the wings, and work upwards towards the head. These feathers must be prepared by clipping off all the downy part; and the large feathers must have the ifides of their shafts pared off, fo that they may lie flat. In laying them on, hold them by a pair of small pliers, and, moistening the gunned ground with water, place each feather in its natural and proper fution. Keep each feather down, by placing upon it a small leaden weight, till you have another ready to be laid on. Care must be taken not to let the gum pass through the feathers, for as to ftrain them or to adhere to the bottom of the weight, and thus pull off or disorder the position of the feathers. When all the feathers are put on, cut a piece of round paper, and colour it to refeemble the eye of the bird, and then flick it in its proper place; but the bell fiftituations for this purpose are small eyes made of glafs. The bill, legs, and feet, must be drawn and coloured from nature. When it is finifhed and adjusted to your mind, lay a fecht of paper upon it, and upon that a heavy weight to pref it down; and after it has remained in that position till it is quite dry, it may be preferved in a glafs-frame.

**Birds, prefervation of.** Many methods have been used by naturalists for preserving dead birds from corruption, in their natural form and colour. Some have taken off the skin, with all the feathers upon it, from the body and thighs, leaving the tail, legs and wings, with the whole neck and the bill, and filled it with some soft fluff, such as hay, wool,
wood, or flux. Mr. Kuckahn (ubi infra), and Dr. Lett-
son (Naturalist’s Companion, p. 12, &c.), who approve
of this method as one of the most compleat and least trou-
bleome, direct, that after opening the bird by a longitudinal
incision from the breast to the vent, separating the fatty
parts from the bones, and removing the entrails, eyes, brain,
and tongue, the cavities and the inlets of the skin should be
sprinkled with the powders (as below): the eyes to be ex-
fected, for which purpose wax may be used, or glass-eyes of
any size or color may be cheaply procured; and the head to
be stuffed with cotton or tow. When this is done, a
wire should be made to pass down the throat, through one
of the nostrils, and fixed into the breast-Lone. Wires
should also be introduced through the feet up the legs and
thighs, and inserted into the same bone; and then the
body should be filled with cotton to its natural size, and the
skin sewed over it. The attitude should also be regarded;
in whatever position the subject is placed to dry, the
same position will be afterwards retained. The powder
which he recommends is composed of ¼ lb. of corrosive
sublimate, ½ lb. of prepared or burnt sulphur, ¼ lb. of
burnt alum, ¼ lb. of flowers of sulphur, ¼ lb. of camphor
or musk, ½ lb. of black pepper, and ½ lb. of tobacco ground
coarse. The whole should be mixed together, and kept in
a glass vessel stoppered close.

This method is particularly described by Mr. Kuckahn,
Phil. Trans. vol. ix. p. 511, &c. When the above-men-
tioned process is finished in the manner which he has mi-
nately detailed, he advises to bake the birds intended for
preservation in an oven of a due degree of heat; and he ob-
erves, that baking is not only useful in such preparations,
but will also be of very great service to old ones, as it de-
tructs the eggs of infects. And it should be, he says, a
constant practice once in two or three years to bake them
over again, and to fresh wash the cafes with a liquid made
by dissolving one pound of camphor in half a gallon of spirit
of turpentine.

Others have put them into vessels full of spirit of wine, or
strong brandy; against which it has been objected that
spirituous liquors change the colours of the feathers; but
M. Reaumur concludes from many experiments, that this
objectian is groundless, and he has given several minute
directions for preferring and conveying them in this way.
Others again, especially in countries where spices are cheap,
have embalmed dead birds. Reaumur observes, that pour-
dered alum or lime will serve the same purpose. Another
method which has been sometimes practiced, is that of dry-
ing birds for preservation in a heated oven. It is of impor-
tance, however, that dried birds should be secured in boxes
or barrels sufficiently closed, that infects may not fly in
during the voyage or journey; and all the empty spaces
left in the barrel should be filled up with hemp, flax, cot-
ton, &c. The same ingenious naturalist informs us, that
quadrupeds, fishes, reptiles, and insects, may be preserved
in the same manner with birds. For Reaumur’s directions
to this purpose, see Phil. Trans. Abr. vol. xi. page 891,
&c.

Mr. Chaptal recommends the following method of pre-
paring all kinds of animals for cabinets as exceedingly
simple, and to certain in its effect that he never found it to
fail in a single instance. The matter contained in the bow-
els of the animal must be evacuated, either by gradually priz-
ning the body towards the rectum, or by injecting some liquid
which may remove every thing that stands in its way. Af-
ter this operation, the end of the rectum should be tied with
a thread, and ether should be injected with a proper instru-
ment into the body, through the mouth or bill; and when
the bowels have been filled with it, the animal is to be hung
up by the head. One of the eyes must then be scooped
out, and the brain extracted; after which the head is also
filled with ether, which must be prevented from escaping
by plugging up the eye hole. On the second or third day
the injection of ether is to be repeated; and this process is
to be continued till the animal is completely dried. While
it is gradually drying, care must be taken to give the body
its proper position; and as soon as it is completely de-
decated, it may be put up without further care or any other
preparation. Ether is preferable to spirits of wine, be-
cause, by its evaporation, it carries with it not only its own
aqueous particles, but those also which it aborbs from the
body. Besides, this method neither destroys the form of
the animal, nor tarnishes the splendour of the feathers or
hair, and is very cheap; one ounce of ether being in gen-
eral sufficient for a small bird. The process of drying, says
Mr. Chaptal, might perhaps be a little shortened by the
application of artificial heat. The theory of this process, as
this ingenious chemist thinks, is, that ether, while it evap-
orates, volatilizes the moisture in the animal body, and
by these means effects a gradual desiccation, and thus re-
moves the only cause of corruption.

The method of preferring birds in Guiana, described by
Bancroft (p. 184.), is as follows: The birds intended for
preservation, and for being conveyed to the cabinets of
Europe, are deposited in a proper vessel, and covered with
high wines, or the first running of the distillation of rum.
In this spirit they remain for 24 or 48 hours, or longer,
according to their size; till it has penetrated every part of
their bodies. When this is done, the birds are taken out,
and the feathers, which are not at all changed by this im-
merion, are placed smooth and regular. They are then put
into a machine, made for the purpose; and the head, feet,
winges, tail, &c. are placed exactly agreeable to life. In
this position they are put into an oven, very moderately
heated, where they are slowly dried; and they will ever after retain
their natural position, without danger of putrefaction.

BIRDS, singing, are the nightingale, blackbird, thrashing,
thrush, limet, lark, thrhole, canary bird, bullfinch, gold-
hich, &c. See SONG of birds.

BIRDAM, in Ancient Geography, a town of Indi, on
this side the Ganges, which, according to Polynæus, was
the capital of a people called Parnari.

BIREMIS, from bir, double, and rem, ear, in Anti-
guity, a vessel with one or more rows of oars, ranged, as
found in two fages over each other; or a vessel, hav-
ing two ranks or rows of oars placed over, and side of each
other. But the particular fabric of those vessels seems far
from being a settled point among the learned. The Roman
biremis is the fame with what the Greeks call biremis, and
flants contradingrified from trevremis, quadrisynmis, &c.

BIRINGOCIO, or Biringuccio, Vannuccio, in
Biography, a mathematitian of Sicilia, was descenced of a
noble family, and flourished about the 16th century. After
having been employed by the duke of Parma and Ferrara,
he entered into the service of the Venetians. He is said
to have been the first Italian author who wrote on the art of
fusing and casting metals; particularly for the purpose of
making cannon. His work, entitled, “Pietrochtin, &c.,”
was printed at Venice in 1549, 420; at Bologna, in 1678,
8vo; and at the same place in 1520, 1528, a 1559, 420.
A Latin translation of it appeared at Paris in 1573, 420; and
at Cologne, 1668, 420. A French translation by Jacob Vin-
cent, was published at Paris in 1552, and 1559, 420; and at
Rouen in 1577. As a metallurgical writer, who detailed his
own observations and experiments, and gave a clear and con-
rfed account of the chief processes in metallurgy, Biringer-
cio is highly commended by professor Beckman. Gen. Biog.

BIRKAN,
BIRKAN, in Geography, a town of Arabia, 14 miles south of Jedda.

BIRKENFELD, a town of Germany, in the circle of the Upper Rhine, and county of Spohnheim, the seat of a balthic, including 32 villages and two iron foundries. It was taken by the French in 1794; and in their new arrangement, it is the principal place of a district of the same name, in the department of Sarre. The town contains 1261, and the canton 5892 persons. This district comprehends 38 communes, and its whole territorial extent includes 1619 square miles. It is situated 30 miles E.N.E. of Treves, and 10 N.N.W. of Deux Ponts.

BIRKENHEAD, or BERKENHEAD, SIR JOHN, in Biography, a political writer of some celebrity, was mainly defended, and born at Northwich, in the county of Chester, about the year 1615. In 1632 he was entered as a fervitor in Oriel College, Oxford, and afterwards became amanuensis to archbishop Laud, who recommended him in 1640 to be chosen probationer fellow of All-Souls' College. When Oxford became the head-quarters of king Charles I. in the time of the civil war, Birkenhead was elected as a proper person to write a kind of journal in support of the royal cause; which office he discharged to the satisfaction of his employers, and with reputation and advantage to himself. The king appointed him reader in moral philosophy; and this post, more honourable than lucrative, he retained till the year 1648, when he was expelled by the parliament visitors. From hence he removed to London, where he wrote several poetical pieces, chiefly of a satirical kind, levelled against the republicans in power; and on account of his steady attachment to the royal cause, he was called the "loyal poet," and suffered several imprisonments. Upon the restoration of Charles II. he was rewarded for his loyalty. In 1661, he was created doctor of the civil law, by the university of Oxford; and about the same time, he was returned to serve in parliament for the borough of Wiltton. He was knighted in 1662, and succeeded Sir Richard Fan- thaw as master of requests. The favours which he received from the court exposed him to many severe attacks from those who opposed it; but he was exalted by the learned personages of his time, and elected a fellow of the Royal Society; and his memory has been transmitted with honour to posterity by Dryden, Langbaine, and Winckless, notwithstanding the reproaches of the whimsy Wood. He died in Wilmington, in 1679. Biog. Brit.

BIRKES, in Geography, a town of Germany, in the circle of Welfphalia and county of Juliers, one mile north of Dieren.

BIRKET EL HADJIS, or LAKE OF PILGRIMS, a lake of Egypt, communicating with the Nile, and situated 10 miles E.N.E. of Cairo, near which the companies which form the caravan to Mecca assemble.

BIRKET EL KERUN, or CAOUN, a lake of Egypt, 30 miles long and broad in the middle, but of an irregular form, and narrowing towards each end; 40 miles S.W. of Cairo. See Mochis.

BIRKHEHER, Blauer Raker, in Ornithology, the name of the garrulous roller, coracius garrula in Frisch.

BIRKIN, in Geography, a river of England, which runs into the Bollin, one mile south of Altringham in the county of Chester.

BIRKOZOWKA, a town of Poland, in the patinate of Kiov, 40 miles S.E. of Bialaerkiw.

BIRLAB, a town of Egypt, in the route from Catich to El Arith, 17 miles E.N.E. of Catich, and at a small distance east of the lake of Sebaket Bardoi, or king Baldwin's lake.

BIRLAT, a town of European Turkey, seated on a river of the same name, in the province of Moldavia, 60 miles N.W. of Galata, and 116 S.W. of Bender. Alto, a river which runs into the Siret at Dubrivatsa, in Moldavia.

BIRMAN, or BURMAN Empire, comprises the kingdoms of Ava and Pegu, and derives its name from the Birman or Burmans, who have been long known as a warlike nation, in the country formerly called "India beyond the Ganges;" its capital being Ava or Aungwa. The boundaries of this empire are not exactly ascertained. Burmah, considered as distinct from Pegu, and sometimes erroneously denominated Ava from its capital, borders on Pegu to the north, and occupies both banks of the river Ava, as far as the frontiers of China. On the north-west is Meckley, and on the Wilt Aracan and Rhoanah. On the east it has the kingdom or country of Upper Siam, which begins at a small distance eastward from the city of Ava; a ridge of mountains separating it from Burmah and Pegu. But the king of Burmah is now said to possess not only the country of Meckley, in addition to those of Pegu and Burmah, but also the whole tract which lies on the north of it, between China, Thibet, and Afiam. According to colonel Symes, to whom we are much indebted for our knowledge of the Burman empire, it appears to include the space between the 9th and 26th degrees of north latitude, and between the 92d and 105th degrees of east longitude, about 1050 geographical miles in length, and 660 in breadth. Such are the ascertained limits from the Burman accounts; but it is probable that their dominions stretch still farther to the north. The breadth, however, often varies, and is in many places very inconsiderable, on what is called the eastern peninsula. To the north this empire is separated by mountains from Afiam, and further to the east it borders on Thibet and China. On the west it is divided from the British dominions in Bengal by a range of mountains, and the little river Naaf; and the limit is continued by the sea. But the southern and easterly boundaries are somewhat obscure. If it be extended to the ninth degree of latitude, it must include a considerable portion of the Malayan peninsula, or the province of Tenasserim, and city of Mergut, formerly regarded as part of Siam; and if, on the east, it be extended to the 107th degree of longitude, it might be said to comprehend almost the whole of the country called India beyond the Ganges, as far as the mouths of the Japaneese river in Cambodia. But it does not appear that Siam is regarded as a portion of the Burman empire, and even in this case it would only extend to 103 degrees. In this state of uncertainty, however, we must satisfy ourselves with observing, that this empire constitutes the fifth grand native power in India, since Hindoostan and Peria have been divided, and may probably extend its authority over Laos and Cambodia, while it remains separated by deserts and ranges of lofty mountains from the united kingdoms of Cochinchina and Tonquin.

Of the ancient state of the countries which now constitute this empire, our knowledge is very imperfect. (See Chersonees.) With regard to their modern history, Col. Symes observs, that we are indebted for our first information, principally to the Portuguese, who made themselves masters of Malacca early in the 16th century. Accordingly the Portuguese historians inform us, that in the middle of this century four powerful states divided among them the regions that lie between the south-east coast of British India, Yunnan in China, and the easterly sea; and that their territories, besides some intervening lands belonging to petty independent princes, extended from Caffay and Afiam on the N.W. as far to the S.E. as the island of Junkfeylon. There proportions...
Birman.

Rations were known to Europeans by the names of Arakan, Ava, Pegu, and Siam; which see respectively. The empire of Ava, as it was called, is situated southward of Arakan, and separated from it by a ridge of lofty mountains. (See Arakan.) On the N.W. it is divided from the kingdom of Caffay by the river Keen-dumen; on the north it is bounded by mountains, and petty independent principalities, that he contiguous to Atam; on the north-east and east it touches on China and North Siam; and on the south its limits have been so variable, that it is not easy to define them. The city of Prome, or Pe, seems to be the original and natural boundary of the Birman empire, though by conquests it has been extended much farther to the south. Pegu is the country southward of Ava, which occupies the sea-coast as far as Martaban. (See Pegu.) The kingdom of Siam extended to the south as far as Junkfeyon, east to Cambodja and Laos, and north to Ozenme, probably the Chiansse of Loubere, and Yunnah in China. (See Siam.) These boundaries, however, may be considered more as the chain than the actual possession of each state; whilst alternate victory and defeat have occasionally extended and contracted their dominions. From the Portuguese we learn, that the Birmans, though formerly subject to the king of Pegu, became afterwards masters of Ava, and caused a revolution in Pegu about the middle of the 16th century: extending their kingdom from Maravi, probably Mergui, near Tenafalere, to the province of Yunnah in China, about 800 miles from north to south, and 250 from east to west. The influence of the Portuguese, which was for some time very considerable in the Birman and Pegu countries, was enfeated by the Dutch; and it appears that, in the beginning of the 17th century, both the English and Dutch had obtained settlements in various parts of the Birman dominions, which were forfeited by the miscalculation of the latter; so that Europeans of all nations were banished from Ava. The English, however, several years after this expedition, were reestablished in their factories at Siam and Ava, where they traded more as private merchants than on the part of the India company, in whose service they were not regularly enrolled. The supremacy of the Birman over the Peguas continued till about the year 1740, when the latter, inhabiting the provinces of Dalla, Martaban, Tongo, and Prome, revolted, and a civil war ensued. In 1744, the British factory at Siam was destroyed by the contending parties. At length the Peguas, by the assistance of some Europeans, who traded to their ports, gained several victories over the Birmans, particularly in the years 1750 and 1751; and in 1752 the capital of Ava was invested, and the Birman, after a short siege, compell'd to surrender at discretion. The loss of a long line of Birman kings was taken prisoner; but two of his sons were fortunate enough to make their escape to the Siamese, where they were kindly received and allowed of security and succour. Upon this conquest the principal inhabitants of the country about Ava acknowledged themselves vassals to the victorious king of Pegu, and accepted the preferred oath. After some time, Alompra, a Birman of low extraction, who had been continued by the conqueror in the possession of a small village called Moachatoo, determined to emancipate himself from the yoke of oppression. Accordingly, having assembled 500 followers, on whose fidelity and courage he could rely, he attacked a band of 50 Pegu soldiers, who had been stationed in Monchaboo, and put every one of them to the sword; and after several previous encounters with the Pegu force dispatched against him, he gained possession of Ava in 1753. The contest was obstinate and bloody; but Alompra, purposing his conquests, founded the town of Kangan, or Dzangon, signifying "victory achieved," and soon after chastised the people of Caffay, who had revolted from the Birman authority. In 1756 he blockaded the town of Siam, which yielded to his arms; and having deprived the capital of any foreign aid by water, he advanced against the city of Pegu, invested it in January 1757, and in about three months took possession of it. He then proceeded to subdue the countries to the end of the city, as far as the Three Pagodas, which were the ancient boundary between Pegu and Siam. Tavoy, which was once an independent principality, and recognized as such by the English in 1755, has been since added to the Birman possessions in this quarter. Alompra, triumphing in his success, determined to chastise the Siamee, who had afforded an asylum to his rebellious subjects; and for this purpose he ordered a fleet to fall to Mergui, a sea-port belonging to the Siamee, which soon surrendered; and the capture of Mergui was followed by the conquest of Tenafalere. The next object of Alompra was the reduction of the capital of Siam; but whilst he was prosecuting the siege, he was seized with a disorder which proved fatal, and laid the Siamee from destruction. Alompra, apprized of his approaching end, gave orders for a retreat; when he had arrived within two days' march of Martaban, on the 15th of May 1756, he expired, very much to the regret and sorrow of his subjects, who regarded him as their deliverer, and as a wife, powerful, and victorious sovereign. By the prudence of his counsels he secured what his valour had acquired; he was not more eager for conquest than attentive to the improvement of his territories, and the prosperity of his people; he inflicted a severe edict against gambling, and prohibited the use of spirituous liquors throughout his dominions: he reformed the courts of justice; he abridged the power of magistrates, and forbade them to decide at their private houses on criminal causes, or on property where the amount exceeded a specified sum; every process of importance was decided in public, and every decree registered. His reign was short but vigorous; and if his life had been prolonged, it is probable that his country would at this day have been farther advanced in national refinement and the liberal arts. He did not live to complete his 30th year; his person, though and well proportioned, exceeded the middle size; and though his features were coarse, his complexion dark, and his countenance somber, there was a dignity in his deportment that became his high station. Alompra, the founder of the Birman empire, was succeeded by his son Nanadagru Praw, who, after suppressing several insurrections, died in 1764, and left an infant son, Monmin; whose uncle Shemhuan, second son of Alompra, assumed the regency, and afterwards the diadem. Shemhuan, having usurped the royal power, diverted the national attention from his conduct, by declaring war against Siam; and two armies entered the country from the north and south, which, being united, defeated the Siamee about seven or eight days' journey from their capital. The consequence of this defeat was the immediate invasion of Siam by the Birmans; and after a siege of two months, the capitulation of the city. The king having withdrawn during the progress of the siege, a Siamee governor was appointed, who took an oath of allegiance to the Birman monarch, and engaged to pay an annual tribute. The Chinese, having planned the subjugation of the Birman empire, and concerted measures for adding the dominion of the Jawa and the fertile plains of Ava to their empire, advanced in the beginning of the year 1767, from the western frontier of Yunnah, with an army of 50,000 men, to accomplish their object; but they were met by the Birmans, and after a conflict which lasted three days, totally routed with very dreadful carnage. The lives of the captives were spared for the benefit of the country; various employments were assigned them; and they were encouraged to marry Birman wives, and to consider themselves...
selves as natives of the country. The Siamee, however, though vanquished, remained unsubdued; and the inherent enmity that subsists between these two nations will probably prevent either servitude or alliance on the part of the one to the other, unless they are broken by such repeated defeats as might nearly amount to extermination. As soon as it was known that the Birmans had withdrawn into their own territories, a Siamee prince assumed the monarchy, and in 1771 defeated the Birmans. The king, who had puillaniously abandoned his throne and people, is said to have perished in the woods, probably by the dagger of the fugitive. Shem- buan, the Birman sovereign, who had rebuilt ancient Ava, the metropolis of the empire, which had fallen to ruin during the late commotions, pursued his favourite scheme of extending his conquests towards the west, and having advanced within two days' march of Cospoor, the capital of Cachar, forced the raja of the province to submit to his power, by the most unequivocal proofs of vaflilage, according to the custom of the country. Shem buan died at Ava in 1776, and was succeeded by his son Chenguza, whose tyrannical conduct occasioned a conspiracy, at the head of which was Shem buan Minderage Praw, the younger brother of the deceased Shem buan, and the present monarch. Chenguza was slain in 1781, and fell unamalented, as he had lived depifted. Among other acts of savage cruelty, with which he is charged, one is his conduct towards his second wife, the daughter of one of the Attawoons, or prisy counsellors, of his court, a young woman endowed with virtue, beauty, and various accomplishments. Under the impulse of sudden rage, he accused her of infidelity, and without allowing time for cool judgment, pronounced sentence of immediate death. Accordingly the trembling and innocent victim was dragged from the palace, and inclosed in a pack of scarlet cloth, richly ornamented; thus confined, she was put on board a boat, when the vessel being suspended between the narrow necks of two earthen jars, the whole was sunk in the deepest part of the river Jarivwally. Her afflicted father, overwhelmed with anguish and deprived of all his offices, retired in despair to the city of Chagang, and waited the opportunity that soon after occurred, of being avenged. When Chenguza was forcing his way towards the royal palace, the Attawoon fetched a fafie from an attendant officer, and at one stroke cut him through the bowels, and laid him breathless at his feet; nor did any person offer to prevent or avenge the cruel tyrant's death. Shem buan Minderage withdrew the fleet of government from Ava, and founded a new city called Ummerpoora; which hee. The Birman conquests having already been extended as far as Mergui to the south, and several of the northern provinces which formerly belonged to Siam, having been reduced to subjection, and tribute, Shem buan Minderage, observing the supineness of the rajas of Arracan, and the unwieldy disposition of his subjects, and allured by the fertility of its soil, and its aptitude for commerce, determined to invade the country, and to annex it as an appendage to the Birman crown. Accordingly, in 1783, this conquest was effected. (See ARAcAN.) The Birman arms were next directed towards Siam. Although the Bir- mans could not retaiu possession of its inland parts, they maintained their dominion over the sea-coast; so that all the ports on the western shore of the peninsula, as far as Mergui, in N. Lat. 1° 25', continued inferior to them. But they still wished to obtain the island of Junkfeylon, which would give them the entire dominion of the western coast, as far as the territories of the Malay prince of Queechab, and not only enable them to monopolize the commerce of the peninsula, but prevent the Siamee from a communication with India by any other channel than that of the gulf of Siam. A fleet was fitted out in 1785 for subduing this islad; but the enterprize failed. The Birman monarch, mortified by the disappointment of his views, resolved as speedily as possible to repair the disgrace; and for this purpose he marched in the spring of 1786, from his capital at the head of 30,000 men, with a train of 20 field-pieces, which army was supported by a fleet of 16 ships, that blocked up the harbor of Junkfeylon. The sovereign, confiding in his expectations, had fearlessly entered the Siamee territories, before he was opposed by the king of Siam, and, after a furious engagement, com- pletely routed. In the commencement of the ensuing year, the Siamee invaded the vicerealty of Martaban, which comprehends within its jurisdiction Tavoy, Mergui, and all the Birman possessions towards the south; but having had un- successful siege to Tavoy, they were obliged to retreat and abandon the enterprise. In 1793 overtures for peace were made on the part of the Siamee; and they were followed by a nego- ciation, which speedily terminated in the ratification of a treaty highly favourable to the Birman interests. By this compact, the Siamee ceded to the Birmans the western maritime towns as far as Mergui; thus yielding to them entire possession of the coast of Tenasserem, and the two important ports of Mergui and Tavoy; which were acquisitions of great moment, considered either in a political or commercial light. From this statement it appears, that the Birman empire can scarcely be computed to extend beyond the 102d degree of longitude, and that only in the part to the north of Siam. The Birmans are indisputably pre-eminent among the nations which inhabit the vast peninsula that separates the gulf of Bengal from the Chinese sea; they possess a territory equal in extent to the German empire; and they are blessed with a fabulous climate, and a soil capable of producing almost every article of luxury, convenience, and commerce, which the eal can supply. After their treaty with the Siamee, they enjoyed the pleasing prospect of a long exemption from the milceries of war; but their pride and re- sentment embroiled them in fresh troubles before they had time to profit by the advantages of peace, and threatened to excite against them a foe more formidable than the Chinese, Arracaners, Peguiners, Siamee, and Caffiers. The Birman monarch, conceiving that the piratical banditti who infest the Broken islands, and commit various depredations to the injury of trade, were protected by the British flag, and that they sought refuge in the British districts, ordered a body of 20,000 men to enter the territories of the company, in order to feize the delinquent fugitives, and he stationed an army of 20,000 men at Arracan for the purpose of supporting this detachment. As the Birmans had made no previous application for redress in a pacific way, a strong detachment was formed at the presidency, and entrusted to the conduct of major-general Erkine, for reftoring this aggression. On the approach of the British general, the Birman chief proposed terms of accommodation, hinting for the surrender of the fugitives as the basis of the agreement. The general declined all treaty whilst the Birmans continued on English ground; but after a representation of the case made in person by the Birman chief, he gave hopes, that if the Birmans peaceably retired, the governor-general would institute a regular in- quiry into the grievance which was the subject of complaint. The Birman chief, professing his reliance on the declaration of general Erkine, agreed to withdraw his troops, and conducted his retreat in the most orderly manner. The matter was afterwards investigated, and the guilt of the delinquents being satisfactorily proved, they were delivered over to their own laws, by whose sentence two out of the three that had been accused underwent capital punishment. The amicable termination of this difference afford favourable opportunity for acquiring a more accurate knowledge than had hitherto been obtained, of a people, whose situation, extent of terri-
BIRMAN.

tory, and commercial connections with British India, rendered a liberal interchange with them lip, Ily desirable. The trade between Calcutta, Madras, and Rangoon, the principal Birman port, had of late years so rapidly increased, as to become an object of national importance; more particularly on account of the teak timber, the produce of Ava and Pegu, whence Calcutta and Madras drew all their supplies of wood for ship building and for various other purposes. A commerce in one article so essential, and on a general scale so extensive, as to require an annual return of Indian commodities to the amount of 200,000, was an object well worth cultivating.

With this view John Shore (now lord Teigmouth) thought proper, in 1795, to send a formal deputation to the Birman court. The particulars of this embassy are described by Col. Symes, with whom the conduct of it was entrusted. "The Birman says this writer, "under their present monarch, are certainly rising fast in the scale of oriental nations; and it is to be hoped, that a long respite from foreign wars will give them leisure to improve their natural advantages. Knowledge increases with commerce; and as they are not shackled by any prejudices of caste, restricted to hereditary occupations, or forbidden from participating with strangers in every local bond, their advancement will, in all probability, be rapid. At present, so far from being in a state of intellectual darkness, although they have not explored the depths of science, nor reached to excellence in the finer arts, they yet have an undeniable claim to the character of a civilized and well instructed people. Their laws are wise, and pregnant with sound morality; their police is better regulated than in most European countries; their natural disposition is friendly and hospitable to strangers; and their manners rather expressive of manly candour, than courteous dissimulation: the gradations of rank, and the respect due to lation, are maintained with a scrupulousness which never relaxes. A knowledge of letters is so widely diffused, that there are no mechanics, few of the peafantry, or even the common watermen (usually the most illiterate class), who cannot read and write in the vulgar tongue. Few, however, are versed in the more erudite volumes of science, which, containing many Shaneferi terms, and often written in the Pali text, are (like the Hindoo Shottars) above the comprehension of the multitude; but the feudal system, which cherishes ignorance, and renders man the property of man, still operates as a check to civilization and improvement. This is a bar which gradually weakens, as their acquaintance with the customs and manners of other nations extends; and unless the rage of civil discord be again excited, or some foreign power impose an alien yoke, the Birmans bid fair to be a prosperous, wealthy, and enlightened people."

The present capital of the Birman empire is Ummerapoora, and one of its chief ports is Rangoon; which see respectively. Its other principal towns will occur in the course of this work. See Arracan, Ava, Chiangao, Martaban, Mergui, Monchabo, Moompoora, Paya, Pegu, Pernsiam, Prome, Syran, Teniferem, Tavoy, &c. The chief rivers of this country are Irrawaddy, or the river of Ava (see Ava), whole numerous mouths and Birman very ample provide the means of inland navigation, Kandaw, Mavgya, Pintag, and the Balu. Its lakes are numerous, among which one of the largest is Toungoo. The highest range of mountains is probably that which lies on the frontier of Thibet. The other ranges pass north and south, except a small range running east and west, which supplies the sources of the river of Pegu; but their names are not known, except that of Ansonee, between Ava and Arracan. The forests are large and numerous; and fully almost every description of timber that is known in Hindoo-land; and about four days' journey to the north of the capital its grow in abundance; but the principal tree of these forests is the teak, which thrives in many parts of the empire, to the north as well as to the south of the capital. The forests, as well as the mountains, of the interior, and, in general, of the whole northern frontier, remain unexplored; and the tigers that infest them, prevent their being particularly examined.

The present sovereign of the Birman empire affixes the title of "Box," or emperor; and though the form of government be despotic, yet he is accustomed to consult a council of ancient nobles. There is no country of the East in which the royal establishment is arranged with more minute attention than in the Birman court; it is splendid without being wasteful, and numerous without confusion. The queen and princes have the title of "Praw," which is both a sovereign and a sacred appellation; and is frequently used by an inferior when adorning his superior. In the application of this term, it has been suggested, that there is an obvious analogy between the Birmans and the ancient Egyptians. "Pura," it is said, was the proper name under which the Egyptians first adored the sun, before it received the allegorical appellation of Othis, and they conferred this title on their kings and on their priests. It has been further conjectured, that the title of "Philosophic," given to successive kings of Egypt, is a corruption of the word "Praw," or "Praw," in its original sense signify the sun, and applied to the sovereign and priesthood, as the representatives of an earth of that splendid luminous. However this be, "Praw" is a principly title in the Birman empire. The eldest son of the king is denominated "Engy Teekien," or "Engy Praw," or "Engy Praw," or prince real; and as the crown devolves to the male heirs in a direct line, the son takes precedence of his uncles. Next in rank to the princes of the blood royal are the "Woongees," i.e. brothers of the great baron, who are the chief ministers of state. Their established number is four, and they constitute the great council of the nation. They sit in the "Ltoy," or imperial hall of consultation, every day, except the Birman Sabbath; they judge mandates to the "Mawoons," or viceroys of the different provinces; they control every department of the state, and govern the empire in subordination to the king, whose will is absolute, and whose power is undefined. With these are associated, for the purposes of deliberation, and of the execution of public business, four other officers, called "Woundocks," whose authority is very inferior and limited. The views and wishes of the Woongees are frequently counteracted by the interference of the four "Attawoons," or ministers of the interior, who are selected by the king to be his privy-counselors, from an opinion of their talents and integrity, and who have access to him at all times, which is a privilege which even the principal Woongee does not enjoy. There are several other subordinate officers, by whom the affairs of government, in its various departments, are transacted. There are also Woones of the queen's household, and of that of the prince-real; and each of the junior princes has a distinct establishment. The Birman government has no hereditary dignities or emoluments; for on the demise of the possessor, all honors and offices revert to the crown. The order of nobility has different degrees, distinguished by the number of rings, or small chains, that compose the "Taloe," or chain, which is the badge of the order. No subject is ever honoured with a higher degree than 12; and the king alone wears 24. Rank among the Birmans is indicated by every article of life and of ornament; the shape of the beetle-box, which is carried by an attendant after a person of distinction wherever he goes, his ear-rings, cap of ceremony, horse-furniture, and even the metal of which his spic
ingt-pot and drinking cup are made, specify and distinguish the several gradations of society; and a person who assumes the insignia of a degree, which is not his legitimate right, is subject to certain penalties. The court drefs of the Birman nobility consists of a long robe, of worked satin or velvet reaching to the ankles, with an open collar and loose sleeves; over this hangs from the shoulders a scarf, or flowing mantle, and on the head is worn a high cap of velvet, either plain, or of silk embroidered with flowers of gold, according to the rank of the wearer. Ear-rings are also a part of male drefs; persons of condition use tubes of gold about three inches long, and of the thickness of a large quill, expanding at the end like the mouth of a speaking trumpet; others wear a heavy mass of gold, beaten into a plate, and rolled up, which forms a large orifice in the lobe of the ear, and by its weight drags it down to the extent sometimes of two inches. The rank of the females is also distinguished by their drefs. The hair, which is tied in a bunch at the top of the head, and bound round with a fillet, has its peculiar and discriminating embroidery and ornaments. Over a short shift, which reaches to the pit of the stomach, and is drawn tight by strings, so as to support the breasts, is a loose jacket with close sleeves; and round the waist is rolled a long piece of silk or cloth, reaching to the feet, and sometimes trailing to the ground. When women of condition go abroad, they put on a silk shawl, resembling a long thawl, which covers their bosom, and is thrown over the shoulders, gracefully flowing on each side. Women in full drefs, flatter the palms of their hands and their nails of a red colour, for which they use a vegetable juice, and dress on their bosoms powders of fumdid wood, or of a bark called funneca, with which some rub their faces. Both men and women tinge the edges of their eyelids and their teeth with black. Men of rank wear, in common dresrs, a tight coat with long sleeves, made of mullin or of very fine nankeen, which is manufactured in the country; also a silk wrapper that encircles the waist; but the working classes are naked to the middle, except that in the cold climate they use a mantle or veil of European broad cloth, which is highly prized.

With regard to religion, the Birmans are Hindoos, not as votaries of Brahma, but ofaries of Boodh; which see. The latter contend with the former for the honour of antiquity, and are undoubtedly far more numerous. The Cingales in Ceylon are Buddhists of the purest class; and the Birmans acknowledge that they originally received their religion from that island, which they call "Zeebo." It was brought, say the Rhahaans, first from Zeebo to Aracan about 600 years ago, and thence was introduced into Ava, and probably into China; for the Birmans confidently assert, that the Chinese are Buddhists. However this be, it is allowed, that the honours of China, like the Rhahaans of Ava, wear yellow as the facerdotal colour, and that in many of their customs and ceremonies we may trace a very striking similarity. Whatever may be the antiquity of the worship of Boodh, the wide extent of its reception is unquestionable. The Birmans believe in the metempsychosis, and that, after having undergone a certain number of transmigrations, their souls will at last be received into their paradise on the mountain of Meru, which is the celestial north pole of the Hindoos, round which they place the garden of Indra, and which they describe as the seat of delights. The Birmans regard mercy as the chief attribute of the deity; and they worship God by extending mercy to all his creatures. Of the religious buildings appropriate to the Birmans worship, the temple of Shocadagon, or Dagoung, near Rangoon, that of Shoemadoor Pegu, and that of Syriam, are the most considerable. (See Rangoon, Pegu, and Syriam.) Their priets are denominated Rhahaans; and they have numerous kious or convents which differ in their structure from common houses, and much resemble the architecture of the Chinees. They are made entirely of wood; the roof is composed of different shapes, supported by strong pillars; the infinite comprehends one large hall; the whole house is open at the sides; some of them are curiously carved with various symbolic representations of the divinity. They have no apartments for the private recreation of the Rhahaans; publicity being the prevailing system of the conduct of the Birmans, who admit of no seclucia either in church or plate. The convents in the neighbourhood of Rangoon are very numerous; and hence it appears that the number of Rhahaans, and of Phlonghia, priests of an inferior order, vulgarly called Tallapoums, must be very considerable, amounting to 1500. Like the Carmelites, they go barefooted, and have their heads shaven, on which they never wear any covering. The only colour of the garments worn by the priesthood is yellow: the greatest part of their bodies is covered with a long loose cloak, that is wrapped round them; they profess celibacy, and abstinence from every sensual gratification. The prescribed punishment for a Rhahaa detected in an act of incontinence, is expulsion and public disgrace. The defendant is seated on an afs, and his face is daubed with black paint intermixed with spots of white; and he is thus led through the streets, with a drum beating before him, and afterwards turned out of the city. But such instances of degradation rarely occur. The juniors are restricted from wandering about licentiously, either by day or night; nor can any go abroad without permission from the prior of the convent. The Rhahaans never perform any of the common functions of life, which would tend to divert them from the abstract contemplation of the divine essence. They perambulate the town at the dawn of the morn in order to collect supplies for the day: and these usually consist of boiled rice mixed with oil, dried and pickled fish, sweetmeats, fruit, &c. In their walks they never raise their eyes from the ground, nor do they even flop to solicit donations, and seldom even look at their benefactors, who are more desirous to bestow than they are to receive. The Rhahaans eat only once a day, at the hour of noon; and their superfluous provisions they distribute among the indigent strangers, or the poor scholars, who daily attend them to be instructed in letters, and taught their religious and moral duties. The Rhahaans are never known to take any public and active part in politics or in war; and as the Birmans and Peguans profess the same religion, the conquerors, whoever they were, equally respected the ministers of their faith. The head of the Rhahaans at Rangoon, or the "Seredaw," lives in a handsome mansion about half a mile from the town; and values himself very much on the facerdotal titles, conferred on him by the present and late king, and which he ostentatiously displays engraved on iron plates. There were formerly numeraries of virgin priests, who, like the Rhahaans, wore yellow garments, cut off their hair, and devoted themselves to chastity and religion; but these societies have been long since abolished, as being injurious to the population of the state.

The laws of the Birmans are inseparable from their religion; and, like the latter, of Hindoo extraction. They profess to have derived them from Menu, the grandson of ramah, the first of created kings, who received the sacred Biciples on which they are founded by divine revelation, and who promulgated the code. Numerous commentaries on Menu were composed by the Munis, or old philosophers, whose treatises constituted the "Dharma Sutra," or body of law. The code of Gentoo laws, translated by Mr. Halle, is said to be a compilation from the different commentaries on Menu. These laws, as well as the religion of the Birmans, found their way into the Ava country from Aracan, and
and came originally from Ceylon, about 600 years ago. The
Birman system of jurisprudence is respectful with found mo-
rality; and is distinguished above any other Hindoo commen-
tary for perspicacity and good sense. It provides specifically for
almost every kind of crime that can be committed, and adds
an ample chapter of precedents and decisions to guide the
 inexperienced in cases of doubt and difficulty. The trial by
 ordeal, however, is disgraceful to this code, but it prevails in
all countries where the Hindoo religion is professed, and is
as ancient as their records. An instance of the exercise of
this mode of trial is mentioned by Colonel Symes. Two wo-
men having litigated a small property in a court of justice;
and the judges finding it difficult to decide the question of
right, it was agreed to refer the matter to the issue of an or-
dal. The parties, attended by the officers of the court, the
Rahasans, and a multitude of people, repaired to a tank,
or pond. After certain prayers and ceremonials of a puri-
ifying nature, the two litigants entered the pond and waded
in it, till the water reached as high as their breasts; they
were accompanied by two or three men, one of whom placed
them close to each other, and put a board on their heads,
which he prefixed down till they were both immersed at the
same instant. After continuing out of fight for about one
minute and a half, one of them being nearly suffocated,
rushed her head, whilst the other continued to swing her
ham at the bottom, but was immediately lifted up by the
man, after which an officer of the court pronounced judg-
ment in her favour, and of the equity of the decision none
of the by-standers seemed to entertain the smallest doubt.
This practice, however, and that of impression, are now
lost ground, and have of late years been disentrenched by
the judicial courts both of India and Ava. Laws dic-
tated by religion are in general conscientiously administered.
The criminal jurisprudence of the Birmans is lenient in par-
cular cases, but rigorous in others. Whoever is found guilty
of an undue assumption of power, or of any crime that in-
dicates a treacherous intent, is punished by the severest tor-
tures. The first commission of theft does not incur the
penalty of death, unless the amount stolen be above 800 kiat,
or tackal, i.e. about 100 l., or attended with circumstances
of atrocity, such as murder, or mutilation. In the former
case, the culprit has a round mark imprinted on each cheek
by gunpowder and punctuation, and on his breast the word
thief, with the article stolen; for the second offence he is
deprived of an arm; but the third inevitably produces capi-
tal punishment. Decapitation is the mode by which crimi-
inals suffer, and in the performance of it the Birman execu-
tioners are exceedingly rigid. The official hall of justice,
where the members of provincial governments, and all munici-
pal officers, are accustomed to assemble for the transac-
tion of public business, in various parts of the Birman empire,
is denominated Rhoom. Every man of high rank in the em-
pire is a magistrate, and has a place of this description and
name contiguous to his dwelling; but it is always on the
outside of the inclosure of his court-yard, and not surrounded
by any fence or railing, in order to manifest publicity, and
flrew that it is the seat of majesty and justice, to which all
mankind may have free access.

The population of the Birman dominions is not easily af-
termined with accuracy; but Col. Symes was informed, by
a person on whose testimony he could rely, that the number
of cities, towns, and villages in the empire amounts to 1,500,
without including the recent addition of Arracan. Suppos-
ing, therefore, each town, on an average, to contain 300
houses, and each house 6 persons, the result will give a po-
pulation of 1,440,000. Few of the inhabitants, he says,
live in solitary habitations, but mostly form themselves into
small societies; so that their dwellings thus collected com-
pose their towns, or villages; and therefore he concludes
that if their number, including Arracan, be reckoned at 17
millions, it will not exceed the truth.

With regard to the military and naval force of the Bir-
man, we may observe, that though every man in the king-
dom is liable to military service, and war is deemed the most
honorable occupation, the regular military establishment is
very inconsiderable. When an army is to be raised, a man-
date issue from the golden palace to all viceroys of pro-
vinces, and mandarins of districts, requiring a certain number
of men at an appointed day; and the levy is proportioned to
the population of the province or district, estimated by the
number of its registered houses. Every two, three, or four,
houses are required to furnish one recruit, or to pay 300
tackal, or about 40 l. or 45 l. in money. This recruit is
supplied by government with arms and ammunition, but has
no pay. The families of these conscripts are retained in the
district which they inhabit as hostages for the good conduct
of the soldier; and in case of defection, or treachery, his
wife, children, or parents are dragged forth to execution,
and cowardice subjects the family of the delinquent to ca-
pital punishment. The infantry and cavalry compose the
regular guards of the king; the former are armed with mus-
kets and lances, and the latter with a spear about seven or
eight feet long, which they manage on horseback with great
dexterity. The royal magazines are fixed to contain 20,000
firelocks, which are of a very indifferently kind. The most
respectable part of the Birman military force is their es-
ablishment of war-boats. The king can command, at a very
short notice, 500 of these vessels, which are formed out of
the solid trunk of the teak tree, excavated partly by fire,
and partly by cutting; the largest of them are from 80 to
100 feet long, and 8 feet broad, and they carry from 50 to
60 rowers. The prow is solid, and has a flat surface, on
which is mounted a piece of ordnance. Each rower is pro-
vided with a sword and a lance; and besides the boatsmen,
there are usually 30 soldiers, who are armed with muskets.
The attack of these gun-boats is very impetuous; and those
who conduct them advance to action with a war-song, by
which they regulate the strokes of their oars, encourage one
another, and daunt their adversaries; and when they grasp-
ple, the action becomes very severe, as these people posses
singular courage, strength, and activity. As the vessels he
low in the water, their principal danger is that of being run
down by a larger boat striking on their brosidde. The
largest of these war-boats, which are managed with surpris-
ning dexterity, both in advancing and retreating, as well as
in the time of action, do not draw more than three feet
of water. The proper weapons of the country are the spear,
the javelin, which is thrown from the hand, the cross-bow,
and the sabre; the latter of which is used by the Birmans,
not only as an implement of war, but for various purposes
of manual labour.

The revenue of the Birman empire arises from one-fourth
of all produce, and of all foreign goods imported into the
country. However, as grants to princes of the blood, great
officers of state, and provincial governors, are made in pro-
vinces, cities, villages, and farms, the rest of which they
collect for their own benefit, and money is seldom disturbed
from the royal coffers, the Birman sovereign possessess im-
mensurable treasures.

The climate of every part of the Birman empire appears to
be distinguished by its salubrity; and the natives are health-
y and vigorous. In this respect they possess a decided pre-
eminence over the encrowned natives of the East: nor are the
inhabitants of any country capable of greater bodily exer-
Vol. IV.
tions than the Birmans. The seasons are regular, and the extremes of heat and cold are seldom experienced; at least, the duration of that intense heat, which immediately precedes the commencement of the rainy season, is so short, that the inconvenience of it is very little felt. The forests, however, like some other woody and uncultivated parts of India, are extremely pellinous; and an inhabitant of the champagne country considers a journey thither as inevitable destruction. The wood-cutters, who are a particular class of men, born and bred in the hills, are said to be unhealthy, and seldom of long longevity.

The soil of the southern provinces of the Birman empire is remarkable fertile, and produces as luxuriant crops of rice as are to be found in the finest parts of Bengal. Towards the north the face of the country is irregular and mountainous, but the plains and valleys, particularly near the river, are exceedingly fruitful; they yield good wheat and the various kinds of small grain which grow in Hindoostan, together with most of the excellent legumes and vegetables of India. Sugar-canes, tobacco of a superior quality, indigo, cotton, and the different tropical fruits, in perfection, are all indigenous products of this country. Besides the teak-tree, which grows in many parts of the Birman empire, as well to the north of Ummerapoora, as in the southern country, there is almost every description of timber that is known in India. The kingdom of Ava abounds in minerals; six days journey from Bamoo, which is a province near the frontiers of China, there are mines of gold and silver, called "Badoum"; there are also mines of gold, silver, rubies, and sapphires, at present open on a mountain near the Keendum, called "Wooooloottam", but the most valuable, and those which produce the finest jewels, are in the vicinity of the capital nearly opposite to Keoum-moom. Precious stones are found in several other parts of the empire. The inferior minerals, such as contain iron, tin, lead, antimony, arsenic, sulphur, &c. occur in great abundance; amber, of a confusion unusually pure and polished, is dug up in large quantities near the river; gold likewise is discovered in the sandy beds of streams which descend from the mountains. Between the Keendum and the Irrawaddy, to the northward, there is a small river called "Sloe Lien Kioop", or the stream of golden sand. Although the Ava empire produces no diamonds and emeralds, it affords amethysts, garnets, very beautiful chrysolite, Jasper, loadstone, and marble; the quarries of the latter lie a few miles from Ummerapoora; and it is equal in quality to the finest marble of Italy, and admits of a polish that renders it almost transparent. The sale of marble is prohibited; but great quantities are consumed in the manufacture of the images of Gaudma, which are fabricated in the city and district of Chagain; however, the exportation of those marble divinities out of the kingdom is strictly forbidden.

The commerce of the Birman empire is very considerable. An extensive trade is carried on between the capital and Yunnan in China. The principal article of export from Ava is cotton, of which, it is said, there are two kinds, one of a brown colour, of which nankeens are made, the other white, like the cotton of India. This commodity is transported up the Irrawaddy in large boats as far as Bamoo, where it is bartered at the common "jee", or mart, with Chinese merchants, and conveyed by the latter, partly by land, and partly by water, into the Chinese dominions. Amber, ivory, precious stones, beetle nut, and the edible nuts brought from the eastern archipelago, are also articles of commerce; in return for which the Birmans procure raw and wrought silks, velvets, gold leaf, preserves, paper, and some utensils of hardware. The commerce between the capital and the southern parts of the empire is facilitated by the noble river that waters the country. Several thousand boats are annually employed in transporting rice from the lower provinces to Ummerapoora and the northern districts. Salt, and gun-powder, a kind of fifth-fance used with rice, are also articles of internal commerce. Articles of foreign importation are mostly conveyed up the Irrawaddy; and some few are introduced by way of Arracan. See Arracan. Among the articles of foreign trade, which have found their way into the Birman country, nothing is held in higher estimation than the European glass-ware imported into Rangoon from the British settlements in India. The Birmans are so sensible of the advantages of commerce, and so desirous of improving it, and of thus increasing population, which they consider as much more efficient in the increase of a state than the extent of its territory, that they have, of late years, tolerated all fechts, Pagans and Jews, Mussulmen and Christians, the disciples of Confucius, and the worshippers of fire, and invited strangers of every nation to resort to their ports; and being themselves free from those prejudices of class, which checkle their Indian neighbours, they have permitted foreigners to intermediary and settle among them. The children of strangers, whatever be the left to which they belong, born of a Birman woman, equally become subjects of the state, and are entitled to the same protection and privileges, as if they had sprung from a line of Birman ancestry. To British India commercial intercourse with that part of the Birman empire called Pegu is of great importance. This interest involves three distinct objects; that of securing from this quarter regular supplies of timber for ship-building; that of introducing into the country as many of our manufactures as its consumption may require, and of endeavouring to explore a mart in the south-west dominions of China, by means of the great river Ava; and that of guarding with vigilance against every encroachment, or advance, which may be made by foreign nations to divert the trade into other channels, and to obtain a permanent settlement in a country so contiguous to the capital of our possessions. The teak timber for the construction of our ships in that part of the world is an article peculiarly interesting in a political and commercial point of view. Some of the finest merchant ships at Calcutta have been lately built of this timber. Madras is also supplied from Rangoon with timber for all the common purposes of domestic use; and even Bombay, although the coast of Bombay is its principal floridource, finds it worth while annually to import a large quantity of planks from Pegu. It is also of importance, not only to promote the exportation of timber from the maritime towns of Pegu, but to discourage the building of ships in the Rangoon river, in which the Birmans are making rapid progress. National security and commercial advantage demand peculiar attention to both these circumstances. The imports into Rangoon from the British settlements, in the year 1794-5, amounted, it is said, to more than 12,000,000; and these consisted chiefly of coarse piece goods, glass, hardware, and broad cloth; and the returns were made almost wholly in timber. The maritime parts of this great empire are commodious for shipping, and better situated for Indian commerce than those of any other power. Great Britain poises the western side of the bay of Bengal; the government of Ava, the eastern. From the mouth of the Ganges to Cape Comorin, the whole range of our continental territory, there is not a single harbour capable of affording shelter to a vessel of 500 tons burthen; but Ava comprehends, within her extent of coast, three excellent ports; Negrais, the most secure harbour in the bay; Rangoon, and Mergui, each of which is equally convenient and much
much more accessible than the river of Bengal, which is the only port in our possession within the bay. The entrance into this is an intricate and dangerous channel; but from the harbour of Negrais a ship launches at once into the open bay, and may work to the southward without any impediment beside that which is occasioned by the monsoon. The Burman empire presents such a variety of advantages as to attract from the natives of all countries. We therefore flatter ourselves with the idea of effecting something of importance in that part of the kingdom, and to guard it from foreign encroachment; and then the Burman government will be united to ours in bonds of reciprocal amity and confidence. The result of the embassy of Col. Smales, sent by our governor-general of India to the kingdom of Ava in 1795, has been the establishment of this kind of amity and friendship. To the memorial presented on this occasion, the Burman monarch replied: "I, the king immortal, whose philanthropy is universal, whose anxiety for the benefit and welfare of all mankind never ceases, direct, that all merchant ships of the English nation, who resort to Burman ports, shall pay customs, charges, warehouse hire, searchers, &c. agreeably to former established usage. English merchants are to be permitted to go to whatever part of the Burman dominions they think proper, either to buy or to sell, and they are on no account to be stopped, molested, or oppressed; and they shall have liberty to go to whatever part of the Burman dominions they choose, for the purpose of buying, selling, or bartering, &c. by themselves or their agents; and it is further commanded, that they shall be at liberty to fix a resident at Rangoon, &c. and that English ships driven into Burman ports by stress of weather shall be supplied with all necessaries, &c. at the current rates of the country; and that the enemies of England, European as well as Indian, shall not be allowed to purchase warlike weapons, lead, and powder, which restriction is extended to all nations."

The manufactures of the Burmans consist of cotton and silk, faltoppee and gunpowder, various kinds of pottery, and marble statues; they also excel in gilding, to which purpose the greatest part of their gold is applied, and several other ornamental manufactures. Their edifices and barges are constructed with singular oriental taste and elegance; the most remarkable edifice is the Shomadoo at Pegu. Their kiousms and temples, which are numerous, exhibit a very rich and fantastic kind of architecture; and their grand hall of audience, or Lotoo, at Ummcapooora, is as splendid an edifice as can be well executed in wood. Many of their houses are very simple in their structure, and are erected in a day, or even in a few hours. The requisite materials are bamboos, grafs for thatching, and the ground rattan. The whole edifice is constructed without a single nail; a row of strong bamboos, from right to ten feet high, are fixed firm in the ground, which form the outline, and are the supports of the building; smaller bamboos are then tied horizontally, by ropes of the ground rattan, to these upright polls; the walls, composed of bamboo mats, are fastened to the sides with similar ligatures; bamboo rafters are quickly raised, and a roof formed, over which thatch is spread in regular layers, and bound to the wood by filaments of rattan; a floor of bamboo is next laid in the edifice, elevated two or three feet above the ground; this grating is supported on bamboos, and covered with mats and carpets. A house of this kind, simple and expedient in its structure, is nevertheless a security against very inclement weather; and if it should chance to be blown down by a tempest, the inhabitants might escape without injury. They have other buildings, however, of a superior kind; and they were formerly constructed of various figures, pyramidal, triangular, or four-sided, surrounded with walls, and adorned with flowers and figures carved in wood, and built with arches. But the art of constructing arches has been lost among the Burmans. From many buildings that now remain, it appears, that they could formerly construct excellent brick arches, both circular and gothic; but now no one in the empire can be found sufficiently skilful to arch over the opening of a window. Masonry has fallen into neglect; the jealousy of the late princes having prohibited to private individuals the use of brick or stone houses. The Burmans have of late years made rapid progress in the art of building boats and ships; and these may be constructed in the Rangoon river for one third less than in the Ganges, and for nearly one half what they would cost at Bombay. It is said, however, that the ships of Pegu are not so firmly constructed as those in our ports. The Burmans, like the Chinese, have no coin; silver in bullion, and lead, are the current money of the country. What foreigners call a takaal, properly kint, is the most general piece of silver in circulation; it weighs ten pennyweights ten grains and three fourths; its subdivisions are the tubber, two of which make one moo; two moo one nath; four nath one takaal; and 100 takaal amount to one viss. Rice is sold by a measure called Thanquaung, or basket, weighing 10 viss, or about 56 pounds; and of measurement there are several subdivisions. The average price of rice at the capital is one takaal, rather more than half a crown, fr a basket and a half. At Rangoon and Martaban, one takaal will purchase four or five baskets. The Burman measures of length are a palm-gait, or inch, 18 of which compose the taim, or cubit. The founquaung, or royal cubit (varying according to the will of the monarch), is equal to 22 inches; the dha, or bamboo, consists of seven royal cubits; 1000 dha make one Burman league, or chain, nearly equal to two British miles and two furlongs; the league is also subdivided into tenths. The Burmans divide their time as follows. The interval in which the finger can be raised without depression, is called charazzi; 10 charazzi make one palm; 6 palm one bir-zaa, or about a minute. The day of 24 hours, commencing at noon, is divided into 8 portions, or yettes, of 3 hours each. These divisions of time are ascertained by a machine resembling the hour-glas, and sometimes by a perforated pan placed in a tub of water. They are announced by a stroke on an oblong drum, which is always kept near the dwelling of the chief magistrate of the city, town, or village; it is commonly raised on a high bamboo stage, under a roof of mats to protect it from the weather. The Burmans, whatever way they acquired it, have the knowledge of a solar year, consisting of 365 days, and commencing on the 18th day of April. But the common Burman year is lunar, and of course 11 days shorter than the solar year; it is divided into 12 months; but the Burman lunations confict alternately of 29 and 30 days, occasioning a difference between the Newtonian and Burman lunar account of 8 hours and 38 minutes. In order to complete a solar revolution, they intercalate in every third year a month of 30 days; in this third year the first and third months have each 30 days instead of 29; they likewise suppose one day over a day, and by these the number of days in three solar years amounts to 1075. But every fourth year will occasion the difference of a day on account of our leap-year. This, and some other defects in their mode of computation, are sources of confusion; in order to remedy which, their five, or mode of calculation,
has frequently been altered by arbitrary authority. The manner in which the Birman month is subdivided is peculiar to their nation. Instead of reckoning the days progressively from the commencement to the close of the month, they advance no farther than the full moon, from which they recede by retrograde enumeration until the month is finished. The Birman month is divided into 4 weeks of 7 days each. The 8th day of the increasing moon, the 25th or full moon, the 8th of the decreasing moon, and the last day of the full moon, are religiously observed by the Birmans as sacred festivals. On theft hebdomadal holidays no public business is transacted in the Khoon; mercantile dealings are suspended; handiwork is forbidden; and the Birkisi pno's take no fulfillment between the rising and the setting of the sun. The Birman era is said to commence in our year 638, and it is that which is used by the philosophers at Siam; and from them, as a more polihed nation, it has passed to the Birmans.

The Birmans are very fond of poetry and music; the former they call yellos; when repeated by a lute, it flows soft and measured to the ear; sometimes in saucce, and often in alternate rhymes. They have epic as well as religious poems of high celebrity, and they are fond of writing in heroic numbers the exploits of their kings and generals.

Music is a science which is held in considerable estimation throughout the Birman empire; and the royal library of Ummerapoora is said to contain many valuable treatises on the art. Some of the professional musicians display consider- able skill and execution, and the softer airs are pleasing even to an ear accustomed to such melody. The principal instruments are a foun, or o'arp, made of light wood, hollowed and varnished, resembling a canoe with a deck; at the extremity a piece of hard wood is neatly fastened, which tapers to the end, and rises in a kind of curvature over the body of the harp; from this curvature, the strings, usually made of wire, are extended to a bridge on the belly of the instrument; it has two folding holes, one on each side of the bridge. The size of the foun varies from two to five feet in length. The surf resembles our violin; it has only three strings, and is played on with a bow. It is said to be an original instrument of the country. The pullaway is a common flageloet. The kyzzoup is a collection of cymbals, suspended in a bamboo frame. The patola, or guitar, is a curious instrument, of the form of a crocodile in miniature; the body is hollow, with hollowing holes on the back; three strings of wire extend from the shoulder to the tail, and are supported on bridges at each extremity; the strings are tuned by means of pegs in the tail, to which they are fastened; it is played on by the finger, and is generally used to accompany the voice. The boudan is a collection of drums, of oblong form and different size, which are suspended perpendicularly in a wooden frame by leathern thongs. The whole machine is about five feet in diameter, and four feet high. The performer stands in the centre, and beats on the drums with a small stick. This instrument is always introduced in a full band, and much used in processions. The heem is the pipe of Pan, formed of several reeds neatly joined and founded by a common mouth-piece, and producing, when skillfully played on, a very plaintive melody. The Birmans are fond of flamboy and dancing; and the three last days of the solar year are commonly devoted to mirth and festivity. At Pegu they have a theatre, which is an open court, splendidly illuminated by lamps and torches, and in which dramatic performances are exhibited. Indeed, at all festivals they have dramatic entertainments, consisting of music, dancing, and action, with a dialogue in recitative. The subject is generally taken from the legends of their heroes, especially of Kama. The best actors are said to be natives of Siam; and in one of these we are told that the dialogue was inspired without art, and the action animated without being extravagant; the dress's of the principal performers were also flowery and becoming. By way of interlude between the acts, a clownish buffoon entertained the audience with a recital of different passages, and by grimace and frequent alterations of tone and countenance, extracted loud peals of laughter from the spectators. The Birmans delight in micking, and are very expert in the practice, polishing uncommon verity of countenance. By pantomimic looks and gestures, they exhibit a masterly display of the passions, making sudden transitions from pain to pleasure, from joy to despair, from rage to mirth, from laughter to tears, and of varying the expression of terror and of pity, with surprising effect. On the last day of the Birman year, the 17th of April, there is a kind of sport that is universally practiced throughout the Birman dominions, to wad away the impurities of the past year, and to commence the new year free from stain. Women on this day are accustomed to throw water on every man they meet, which the men have the privilege of returning. This palline is conducted with great decorum; and a woman who declines taking a part in it, is considered as avowing her pregnancy, and pausing without molestation. At the close of Lent, or during the whole seventh month, called Sadhen-guch, there are illuminations; every house has erected by it a kind of mall, from which are suspended one or more lamps. In the royal palace, a pyramid of lamps, at least 150 feet high, is supported by a bamboo festooning. At this time the nobles from all parts of the empire resort to court to pay their homage to the king. During the principal days and nights of these festivals, there is almost a constant succession of wrestling, dancing, music, processions, fire-works, and theatrical entertainments.

The Birman alphabet consists of 35 characters, having as many distinct sounds, exclusive of various marks and contractions, that supply the place of long and short vowels, diphthongs, &c. like the other alphabets of the Hindoo clafs. It has no representation of the vowel corresponding with our short a; this is nevertheless to be pronounced after every simple sound or consonant not supplied with another vowel, unless it be forbidden by a mark of elision placed over the letter, or excluded by the juncture of two or more consonants. The Birmans write from left to right; and though they have no distinguishing interval between their words, they mark the pauses of a sentence and the full stops. Their letters are distinct, and their MSS. are in general very beautiful. It has been the opinion of some of the most enlightened writers on the languages of the East, that the "Pali," or sacred language of the priests of Bodd, is nearly allied to the Shanircet of the Brahms. The character in common use throughout Ava and Pegu is a round Nagari, derived from the square Pali, or religious text; it is formed of circles and segments of circles, variously disposed and combined, whilst the Pali, which is solely applied to purposes of religion, is a square letter, chiefly consisting of right angles. Their common books, like those of the Hindoos in the southern parts of India, are composed of palmyra leaf, on which the letters are engraved with a stylus. In their more elegant books, the Birmans write on sheets of ivory, or on very fine white palmyra leaves. The ivory is flained black, and the margins are ornamented with gilding, while the characters are enamelled or glazed. On the palmyra leaves the characters are in general of black enamel; and the ends of the leaves, and the margins, are painted.
BIRMAN.

Painted with flowers in various bright colours. A hole through both ends of each leaf, serves to connect the whole into a volume, by means of two strings, which also pass through the two wooden boards that serve for binding. In the finer binding of books of this kind, the boards are lacquered, the edges of the leaves cut smooth and glazed, and the title written on the upper board; the two ends are by a knot or jewel secured at a little distance from the boards, so as to prevent the book from falling to pieces, but sufficiently distant to admit of the upper leaves being turned back, while the lower ones are read. The more elegant books are in general wrapped up in silk cloth, and bound round by a garter, on which the Birman has the art to weave the title of the book. In every Khoom or monastery, there is a library or repository of books, usually kept in lacquered chests. In the royal library the number of these chests was not less than 200. The books were regularly classified, and the contents of each chest were written in gold letters on the lid. Some of these books exhibited very beautiful writing on thin leaves of ivory, the margins of which were ornamented with flowers of gold, neatly executed. The library contained books upon various subjects; more on divinity than any other; but history, music, medicine, painting, and romance, had their separate treatises. Col. Symes thinks it not improbable, from the chests which he inspected, that his Birman majesty may possess a more numerous library than any potentate from the banks of the Danube to the borders of China. Books in the Pali text are sometimes composed of thin stripes of bamboo, delicately stained, and varnished over in such a manner as to form a smooth and hard surface upon a leaf of any dimensions: this surface is afterwards glazed, and the faced letters are traced upon it in black and shining Japan. The margin is illuminated by wreaths and figures of gold, on a red, green, or black ground. As most of the Birmanas are taught to read and write, they carry with them a fleet of thick and strong blackened paper, called a parawalk, or paruvok, in which they enter their accounts, copy fongs, till they can repeat them from memory, and take memorandums of any things that are curious. On these parawalks the scribes, or writers, in all courts and public offices, take down the proceedings and orders of the superior officers. It is about 5 feet long, and 18 inches wide, a fold up like a fan; each fold being about six inches, and in length the whole breadth of the fleet. They write on this with a pencil of jetettes; and the characters are effaced by rubbing them over with charcoal, and the leaves are a species of delicate.

In the recitation of poetry, the language is exceedingly melodious; even the proje of common conversation appears to be measured, and the concluding word of each sentence is lengthened by a musical cadence, that marks the period to the ear of a person wholly unacquainted with the meaning. Of the cosmography and astronomy of the Birmanas, deduced from their most ancient writings, the following particulars will be sufficient. They conceive that the universe, called loghia, which signifies successive destruction and reproduction, after it had been destroyed by fire, water, or wind, is again, of itself, restored to its ancient form. The earth, they suppose to be a plane, somewhat elevated in the centre, and surrounded by a chain of very lofty mountains. Its diameter is 1,203,400 juzana, each juzana being 44,300 cubits, or nearly 12 miles; its circumference is three times its diameter; and its thickness 240,000 juzana, of which one half is dust, and the other half a solid rock, and the whole supported by a double thickness of water, relying on twice its thickness of air, below which is a vacuum. Besides the earth, there are 10,100,000 others, mutually touching in three points, and forming a similar number of equilateral spaces, which, not being penetrated by the sun's rays, are filled with water intensely cold. In the middle of the most elevated part of our earth, the Birman writings place Menmon, the largest of all mountains, elevated above the surface of the sea 8,000 juzana, and descending as far below it, supported by three feet of carbuncles, having its eastern face level, the western glafs, the northern gold, and the southern pale-coloured carbuncle, and surrounded by seven chains of hills. In the middle of the ocean, opposite to the four cardinal points of this mountain, are placed four large islands, the habitations of men and other animals; and besides these, the Birman writers allow of a smaller size, 500 belonging to each of the larger ones. The ocean is in various parts of very different depths. All living beings are distributed into three classes; generating beings; those which are material, but do not generate; and immaterial beings, or spirits, each of which is subdivided into several distinct species. The Birman writings admit of transmigration, alleging, that in death, whether of man, beast, or any living being, the soul periinds with the body, and after this dissolution, out of the same materials another being arises, which, according to the good or bad actions of the former, becomes either a man, or an animal, &c., and they teach, that all beings are revolving in these changes, till they become entitled by their actions to Nieban, the most perfect of all states, in which they are free from change, misery, death, sickness, or old age. The Birman writings also announce the opinion of an infinite number of worlds in constant succession, without beginning and without end. These writings mention eight planets, viz. the Sun, Moon, Mercury, Venus, Mars, Jupiter, Saturn, and another named Rahu, which is invisible. The Sun is 50 juzana in diameter, the Moon 49, Mars 12, Mercury 15, Jupiter 17, Venus 19, and Saturn 13; and their circumferences are triple their respective diameters. They suppose that the sun, moon, and stars revolve round the great mountain Menmon in a circle, the plane of which is parallel to the earth. The stars, according to them, pursue a constant course, without declining to the north or south; but the sun, moon, and other planets have a declination; and the sun, in proceeding from the north to the south, and from the south to the north, always touches the twelve constellations, which we call the twelve signs of the zodiac, and in the space of one year returns to the same place in the heavens from which he set out. This same revolution is performed by the moon in a month. The sun's motion, they say, is quicker than that of the moon; and by his diurnal revolution, when he is in the southern island it is mid-day, in the northern it is mid-night, in the easter island the sun sets, in the western rises. Although the sun, moon, and stars appear to us round, we are not to suppose them to be spheres, but this is a fallacy of vision. The invisible planet Rahu serves the purpose of explaining eclipses; for, being a huge monster, he takes the sun and moon either into his mouth or under his chin, and thus causes either total or partial eclipses. As to the heat and cold which are experienced at different seasons of the year, the Birmanas say, that, from the vernal equinox to autumn, the sun is always tending to the north, and the moon inclining to the south; the season is then hot, because the sun's rays, which are naturally hot, then prevail; but from the autumnal equinox to the vernal, the sun inclines to the south, and the moon to the north, and the moon's rays, which are by nature cold and predominant, produce cold. They assign seven causes of rain, of which some are physical, and some moral. These astronomical and physical ideas of the Birman writings were probably brought from Hindooistan, together with their religion and laws; but for
for a more particular account of them we shall refer to the Asiatic Researches (vol infra).

Among the Birman there are several histories, containing an account of the lives and actions performed by the different families of their princes; which histories are very fabulous, and abounded with the recital of omens and prodigies. Indeed, the Birmans are much attached to divination. No person will commence the building of a house, a journey, or the most trivial undertaking, without consulting some person of skill, in order to find a fortunate day or hour. Friday is a most unlucky day, on which no business ought to be commenced. On medicine the Birmans have several books, containing a description of 96 genera of diseases, with various recipes for their cure. Mummy is with them a favourite medicine, and they are not unacquainted with the use of mercury in the cure of lues venerea; but their mode of administering it is neither certain nor safe. Most of their medicines, however, are taken from the vegetable kingdom; and they are chiefly of the aromatic kind, nutmegs being one of their most favourite medicines. Although they are well acquainted with the plants of their country, the practice of their physicians is almost altogether empirical, and they follow certain recipes and nostrums, the efficacy of which they extol, and which have been transmitted from their ancestors for several generations. They combine with their medical practice great faith in amulets and charms. In forgery, they proceed no further than draffling wounds and letting bones. Of late the inoculation for the small pox has been introduced into Arraena.

The state of agriculture in the Birman empire is not particularly illustrated by Col. Symer. It is true, however, to be pursued with considerable avidity; and the soil in many parts is capable of cultivation, and its productions, which are naturally numerous, admit of further improvement. The cattle used in some parts of the country for tillage and draft are remarkably good; they put only a pair of them to the plough, which is little different from the plough of India, and turns up the soil very superficially. In their large carts they yoke four stout oxen, which proceed with the speed of a hand-gallop, and are driven by a country-girl standing up in her vehicle, who manages the reins and a long whip with ease and dexterity. Many of the sloping grounds are planted with indigo, but the natives suffer the hills for the most part to remain uncultivated, and only plough the rich levels. They every where burn the rank grasses once a year to improve the pasture. The Birmans will not take much pains; they leave half the work to nature, which has been very bountiful to them. In the neighbourhood of Loonghee, many fields are planted with cotton, which thrives well; Sefamum is also cultivated in this soil, and is found to answer better than rice, which is most productive in low and moff grounds. In the suburbs of Pagahm, there are at least 250 mills employed in expelling oil from the sebamum feed. In this operation the grain is put into a deep wooden trough, and pressed by an upright timber fixed in a frame; the force is increased by a long lever, on the extremity of which a man sits and guides a bullock that moves in a circle; thus turning and pressing the feed at the same time. The machine is simple, and yet efficiently answers the purpose. Waggon form a caravan for travelling from the southern country towards the capital. Of these there are sometimes as many as 18, each of which is drawn by six bullocks, and is covered with a tiled roof of bamboo, overlaid with painted cloth, for throwing off the rain. They contain not only merchandize, but also whole families, the wives, children, monksies, cats, parroquets, and all the worldly subsistence of the wag-
who incurs a debt which he cannot pay, becomes the property of the creditor, who may claim him as a slave, and oblige him to perform menial service until he liquidates the debt. His immediate relations are also liable to be attached; and innocent women are often dragged from domestic comfort, and are sold to the licensed superintendents of the tallow-tree, who, if they pollute attractions, pays a high price for them, and reimburses himself by the wages of their prostitution.

On the banks of a small creek, between the town of Manda and Baffanc, is a village called Mina-Shun-Rua, or the village of prostitutes, which is inhabited altogether by women of this description. Birman wives are said to be in general chaste and faithful; their feudal employment affording no leisure for the corruption of their minds. A woman of the highest rank seldom sits in idleness at home; her female servants, under her direction and superintendence, like those of the Grecian damas of antiquity, ply the various labours of the loom. Weaving is chiefly a female occupation; and most Birman families manufacture all the cotton and silk that are required for their domestic consumption.

The women in this country manage also the most important mercantile concerns of their husbands, and attend to their interests in all out-door manufactures; they are to the greatest degree industrious, and are said to be good mothers; and they therefore merit a higher rank than that which is assigned them, and better treatment than they experience.

The Birmans, in some respects, particularly towards their enemies and invaders, display the severity of barbarians, but in others all the humanity and tenderness of polished life. At home they manifest an amiable benevolence, administering aid to the infirm, the aged, and the sick; filial piety is inculcated as a sacred precept, and its duties are religiously observed. A common beggar is no where to be seen; every individual is certain of receiving assistance, which, if he is unable to procure it by his own labour, is provided for him by others.

Among the Birmans, marriages are not contracted till the parties attain the age of puberty; the contract is purely civil; and the ecclesiastical jurisdiction has no concern with it. The law prohibits polygamy, and recognizes only one wife; however, concubinage is admitted to an unlimited extent. Concubines, who live in the same house with the legitimate wife, are obliged by law to perform menial services for her; and when the husband dies, they become the property of the surviving widow, unless she shall have emancipated them by a specific act previous to his decease. When a young man is desirous of espousing a girl, his mother, or nearest female relation, first makes the proposal in private; if the suit be well received, a party of his friends proceed to the house of the parents of the young woman, with whom they adjourn to the dotal portion. On the morning of the bridal day, the bridegroom kindles to the maiden three long oil or tallow torches; three tubbeks, or fathes; and three pieces of white muffin; such jewels also, ear-rings, and bracelets, as his circumstances will admit: a feast is prepared by the parents of the bride, and formal writings are executed: the new-married couple eat out of the same dish; the bridegroom presents the bride with some heneep, or pickled tea, which she accepts, and returns the compliment; and thus the ceremony ends.

When a man dies intestate, three-fourths of his property go to his children born in wedlock; and one-fourth to the widow, who is the guardian both of the property and the children, until the latter attain the age of maturity. A Birman funeral is solemnized with much religious parade and external demonstration of grief; besides the mourning relations, the attendants, who follow the corpse, which is carried on a bier, are women hired for the occasion, who precede the body, and chant a dirge-like air. The Birmans burn their dead; but as the ceremony of burning is expensive, the bodies of paupers are either buried or cast into the river.

The mode of burning is as follows: the bier is placed on a funeral pile six or eight feet high, made of billets of dried wood laid over one another, with intervals for admitting a free circulation of air, so as to increase the flame. The Rahaans walk round the pile, reciting prayers to Gaudama, until the fire reaches the body, when the whole is quickly reduced to ashes, which are gathered and deposited in a grave. Perfumes of high distinction are embalmed, and their bodies are preferred in some kionum, or religious building, six or eight weeks before they are committed to the funeral pile. Honey is said to be the principal ingredient used for preserving the body from putrefaction.

As to their food, the Birmans, compared with the Indians, are gross and uncouth. Although their religion forbids the slaughter of animals in general, yet they apply the interdiction only to those that are domesticated. A wild game is eagerly sought after, and in many places publicly sold; reptiles also, such as lizards, quanias, and snakes, constitute a part of the subsistence of the lower classes. They are also extremely fond of vegetables.

Among the vegetable productions of this country we may enumerate the white pandan-tree, and the aloesmum verum, much valued for the grateful odour of their smoke; the teak-tree (tectonotheca) already mentioned; the ebon-nymyum verum, producing the true jet black ebony wood; the creamore fig, Indian fig, and banyan tree; the bogh-nia indica, manica orientals, corisaraf siribus, one of the loftiest of the palm-trees, and exoycarias Cochinichinensis, remarkable for the crimson under-surface of its leaves. To the class of plants used in medicine and the arts, we may refer the ginger and cardamom, found wild on the sides of rivers, and cultivated in great abundance; the turmeric, used by the natives of the eol to tinge and flavour their rice and other food; the betel pepper, giftaria pigeen, and 3 or 4 kinds of capicum; the jallicia tinctoria, yielding a beautiful green tinge; morinda umbellata, gamboge, and earthums, furnishing yellow dye; the red wood of the lawfonia fianoa, and Cifalpina fapan, and the indigo. The bark of the nerium antidiftericum, called codogapapa, and that of the casus cahavan, the fruit of the itrychos nax vomiica, the caffia hitula, the tamarind, and the cothen tumilum, the impalated juice of the aute, the relia of the camphor-tree, and the oil of the anees, are occasionally imported from this country for the European dispensions. The crimson laurel, sometimes accompanied by the nutmeg, thefig-bane, bamboo, and spikenard, are found throughout the whole country; the leet on dry hills; and the bamboo and fig-bane in rich swamps. The sweet potato, ipomoea tuberosa, mad-apple and low-apple (colubnum melongena and lycoperdhen), cympbea melonomba, gourits, molons, water-melons, and various other excellent plants, enrich, by cultivation, this country; and the plantain, cocoo-nut, and fogo palm, are produced more copiously.

The vine grows wild in the forests, but its fruit is much inferior for want of cultivation, and through excess of heat, to that of the south of Europe; but this country is annually supplied with the mango, pine-apple, sapindus cedulis, manteigen plum, averrhoa carambola, cutlart-apple, papaw-firg, orange, lemon, and lime, and many other exquisite fruits. The animals of the Birman empire correspond with those of Hindoostan. The wild elephants of Pegu are very numerous; and, assured by the early crops of rice, commit great devastation among the plantations that are exposed to their ravages. The king
is the proprietor of these animals; and one of his Bir-
man majesty's titles is "lord of the white elephant, and of
all the elephants in the world." The forests abound with
tigers. Their horns are small, but handsome and spirited,
hardy and active; and are frequently exported in timber-
ships bound for Madras and other ports of the confi, where
they are disposed of to considerable advantage. Their cows
are diminutive, resembling the breed on the coast of Coro-
mandel; but their buffaloes are noble animals, much superior
to those of India, and are used for draft and agriculture;
some of them are of a light cream colour, and are almost as
fierce as tigers who dare not molest them. The ichneumon
or rat of Pharaoh, called by the natives Vunbai, is found in
this country; but there is no such animal as the jackal in the
Ava dominions, though they are very numerous in the ad-
joining country. Among the birds, which are the fame
with those of other parts of India, is one called the Hen-
za, the symbol of the Birman nation, as the eagle was of the
Roman empire; it is a species of wild fowl called in India
the Braminy goose; but the natives of Ava do not defy this
bird.

The Birmanse seem to be in possession of several small islands
in the gulf of Martaban, the Magnus Sinus of antiquity,
and of others to the south and west. Symes's Embassy
to the Kingdom of Ava, 3 vols. 8vo. paflim. Asiatic Re-
searches, vol. vi. p. 103—308. See Arracan, Ava, and
Paev.

BIRMINGHAM, is justly esteemed the greatest manu-
ufacturing town in England, and we may safely affirm, that in
the quantity, variety, elegance, and utility of its manu-
factured articles, it surpasses any town in Europe. To
enable the stranger and foreigner to appreciate the ge-
cral character of this place, with its various subordinate
features, we will endeavour to depict them to the fancy, in
a concise and periphrastic narrative. Its distinguishing cha-
racteristic is appropriately displayed in the following lines
by Mr. Jago, in his poem of "Edge-hill."

"This noise, and hurry all,—the throng'd street,
The close pit'd warehouse, and the busy shop.
With nimble stroke the tinkling hammers move;
While flory and weighty the vall fledge descends,
In solemn bafe responsive, or apart,
Or socially conjoint in tuneful peal.

What various use!—Nor this alone thy praise,
Thine too of graceful form, the letter'd type!
The friend of learning, and the poet's pride."

The etymology of the name of this town is not readily at-
dained, as it has been written Bromwycham, Bromw-
ycham, and various other ways; indeed, in common con-
versation, it is frequently pronounced Bromidgham. The
town lies near the centre of the island, in the north-west-
ern extremity of the county of Warwick. It is in the
diocese of Lichfield and Coventry, in the deanery of Arden,
and in the hundred of Hemlingford. The superficial con-
 tents of the parish are 2864 acres. In 1800 here were 16,403
honsefs, 1875 of which were uninhabited. The whole pop-
ulation was 73,670, of whom 34,716 were males, and 38,954
were females.

In the scale of national importance, Birmingham bears
an exalted situation: without recurring to its ancient his-
tory, the modern inhabitants have, by laudable industry,
raised it perhaps to the acme of manufacturing and com-
mercial fame. The fagacious and elegant Burke emphati-
cally pronounces Birmingham the "Toy Shop of Europe."
This designation must not, however, be taken in its literal
fence, as the articles of utility made in this town far exceed
those intended only for show and ornament. Many of our
cities are attractive for their venerable ruins and grand cathe-
cerals, but of those Birmingham is deficient. The traveller,
who delights in feering the human race profitably employed
to their own, and their country's advantage, will disregard
the smoke which sometimes envelops the town, and discern
through the veil the bright beams of industry, the lightening
vail piles of riches: justice, however, will compel him to
acknowledge, that Providence has contrived to inundate itself
within too many dwellings of the labouring classes, pro-
ducing idleness, discontent, drunkenness, and riots, of which
several instances might be cited, exclusive of that grand con-
volution which attended the commencement of that revolu-
tion in France, which in its consequences has so severely op-
prefed this, and almost every other nation. The Ikenild-
street, one of the great Roman military roads, comes within
a mile of Birmingham, and in Sutton park and Coldfield,
four miles from the town, it remains nearly as perfect as
it just completed; one of the principal evidences of the
antiquity of Birmingham is, that it is contiguous to two
Roman roads, the Ikenild, and Shirley freets.

The family of Birmingham were lords of this manor till
1537, at which period it is said to have been obtained by
the duked of Northumberland, through the success of a de-
epanned scheme. Having endeavoured in vain to purchase
it, he contrived to make Edward Birmingham appear as an
accomplice in a highway robbery, and offered him his inter-
rest to save a forfeited life, on condition of selling him the
manor. The manor-house, which is now called the mote, still remains,
though the site has been converted into a manufactory, and
an apartment is shown, where the ancient lords held their
court-leats.

The parish of Birmingham is smaller than any in its neigh-
bourhood. Mr. Hutton observes, that when Alfred founded
a town, he allotted a much smaller space of land to it, than
when he portioned a village, obviously intending the former
for trade and commerce, and the latter for agriculture; this
circumstance seems to prove that Alfred found Birmingham a
town. "The buildings occupy the fourth-eaet part of the pa-
rish, which, with their appendages, are about 800 acres. This
part being insufficient for the extraordinary increase of the
inhabitants, he has of late extended her buildings along
the Bromgrove road, near the boundaries of Edgbaston,
and on the other side planted some of her freets in the pa-
rish of Aston."

"The situation is elevated, and the soil one solid mass of
dry, reddish sand, through which the water descends freely,
thus making even the cellars comfortable habitations; the
name author adds facetiously, that though metals of various
forts are found in great plenty above the surface, we know of
nothing below except sand, gravel, flone, and water. All the
riches of the place, like those of an empiric in laced clothes,
appear on the outside. "There is not any natural river in the
parish, but in the lower parts of the town are two excellent
springs of soft water, suitable for most purposes, one at the
top of Digbeth, the other Lady well; and at the latter place
are seven of the most complete baths in the kingdom.
They cost 3000 l. in erecting, and are ever ready for the
accommodation of hot or cold bathing, for immersion or
amusement, with convenience for sweating. That appro-
priated to swimming is 18 yards by 36, situate in the centre
of a garden, in which are 24 private undressing houses, and
the whole surrounded by a wall ten feet high."

Mr. Hutton mentions several instances of longevity,
which seem to demonstrate either that the air is too pure to
be rendered unwholesome by the smoke of the town, or that
smoke
BIRMINGHAM.

Smoke and flem are not so prejudicial to health as they have been imagined; his instances are one person aged 100, a second 103, a third 104, and a fourth 107, four upwards of 92, and 13 upwards of 80.

Birmingham is not a place a gentleman would choose to make a residence. Its continual noise and smoke prevent it from being desirable in that respect.

Many ancient families who once flourished at and near Birmingham, are mentioned by Mr. Hutton to have fallen into irretrievable decay; one instance is worth transcribing: "We have among us a family of the name of Nethercliffe, of great antiquity, deductible from the conquest; who hold, the chief parishes, and the chief offices in the county, and who matched into the first families in the kingdom, but fell with the interdict of Charles I., and are now in that low ebb of fortune, that I have frequently, with a gloomy pleasure, relieved them at the common charity board of the town."

It appears upon record, that in 1731, William de Birmingham, lord of the manor, procured an additional charter from Edward III. reviving some decayed privileges, and granting others; among the last was that of the Whitmeade fair, to begin on the eve of Holy Thursday, and to continue for four days. At the alteration of the style in 1752, it was prudently changed to the Thursday in Whitsun week, that less time might be lost to the injury of the manufacturers and their workmen. The same person also procured another fair, to begin on the eve of St. Michael, (which is commonly called the Onion fair, on account of the great quantity of onions sold at the time) both of which are at this day in great repute. The horse fair, which formerly was kept in Edgbaston-street, was, in 1777, removed to Brick-kiln-lane; and that for beafts, which used to be in the High-street, into Dale-end, in 1760.

Near Birmingham, on the London road, is Camp-hill, where the army of prince Rupert were encamped, during the siege in 1642. The inhabitants are accuited of disloyalty by lord Clarendon, for feizing the carriages which contained the royal plate and furniture. The prince, with 2000 men, had been commanded by the king to open a communication between Oxford and York, but the hardy and imprudent inhabitants of this town dared to oppose this force, with only a company of foot, and a troop of horse. Though they had thrown up some flight works, and blockaded the streets, yet the king's army forced through these trifling obstructions, and entered the town sword in hand. The earl of Denbigh, a royalist, was killed in this affair, as was a clergyman, who acted as governor for the parliament, and who refuted quarter. Birmingham had a narrow escape from destruction, for the exasperated commander ordered the place to be burnt, but some favourable circumstance confined the conflagration to a few houses in Bull-street.

The plague of 1665, was imported into the town in a box of cloaths brought to the White Hart inn. Hence the fatal poison inuinated itself through the streets and houses, destroying great numbers of the inhabitants, whose bodies soon filled the church-yard, and also an acre of land at Ladywood-green, which was afterwards called the Peat-ground.

Although some degree of eminence attached to Birmingham previously to the reign of Charles II., yet it is from that period that its rapid increase must be dated. Building lees had become common, and numbers of houses arose to accommodate the increasing population which assembled, in consequence of the cultivation of the mechanical arts.

About the year 1700, the number of streets in Birmingham was only 30, but now there are nearly 250; besides, several of the oldest are considerably improved and augmented. This will, in some measure, afford the imagination in comprehending the amazing increase of the town in size, wealth, and manufactures, during that time; and it is no presumption to suppose, that it has not yet arrived at its zenith: one instance of increase will be sufficient to point out the general improvement. Between the roads to Wolverhampton and Dudley, there were only three houses March 14, 1779. By that day twelve months they increased to 55, and March 14, 1784, there were 144. The same day in 1764, there was an addition of 813.

Thomas Sherborne, bishop of London, purchased of the ladies of the manor in 1740, land worth 400l. per annum; in 1758, the income was doubled. He always refused to let it on building leases, alleging, that his successor would be compelled to remove the rubbish at the expiration of the term; sir Thomas Gough, who held the land after the above prelate, procured an act about 1766, for setting aside the prohibitory clauses of the bishop's will; immediately he let the ground, and improved the rents to 2400l per annum; it appears from the books of the poor-rates, that less than 5000 houses pay the poor-rate dues, and more than 8000 houses are exempt; this fact denotes the prevailing deficiency of population.

Manufactures, &c. The extraordinary increase in the size, population, and prosperity of Birmingham, arises principally from its proximity to the coal mines, from the nature of the foil, from its canals, from the successful exertions of a few individuals in some manufacturing speculations, and from its being exempt from borough, and corporate laws and restrictions. To investigate and detail the whole of these causes, with their effects, would occupy more space than we can conveniently appropriate. The most prominent characteristics, however, shall be narrated. To the late John Taylor, Esq. a man of great industry and ingenuity, the public are indebted for the gilt button, the japanned and gilt snuff-box, with the numerous clas of enamels; also the painted snuff-box, at which employ, one servant earned 3l. 10s. per week, by painting them at a farthing each. In his shops were weekly manufactured buttons to the amount of 800l. exclusive of other valuable productions, and eighty guineas have been given him for a single toy made at his shop. He died in 1775, at the age of 64, after acquiring a fortune of 200,000l. His son is now partner in one of the largest provincial banking houses in England.

The greatest and most noted manufacture of this place, and perhaps in Europe, is that at Soho, about two miles from Birmingham. This is the property of Mrs. Boulton and Watt, who have advanced certain pieces of mechanism and productions of art to a state of excellence, that have excited the astonishment and admiration of nations. The large warehouses, work-shops, and the elegant mansion of the former gentleman, over the declivities of a hill, which a few years back was a barren heath, tenanted only by rabbits, and a warren'r's hut; now this once defolate scene is converted into an emporium of arts and beauties. Such are the wonderful powers of human ingenuity and industry. In 1777, this spot, with some contiguous land, was leased for 99 years, to Mrs. Boulton and Evans, who erected a house and a mill for rolling metal, &c. At Lady day, 1762, Mr. Boulton bought the whole, and removing to it soon afterwards from Birmingham, commenced the present extensive premises, which were nearly completed in 1785; at an expense of 9000l. He now admitted a partner, Mr. Fothergill, into the concern, and 30 established
Established an extensive correspondence throughout Europe. To obtain and support a reputation, every encouragement was afforded to men of genius in drawing, modelling, and other branches of the arts. An imitation of or molu in vases, tripod, and cardelabras, was adopted, accompanied by so much skill and elegance, that universal approbation followed; this led to the manufacture of wrought silver, and an application was made to parliament in 1773, for an assay office, to be established at Birmingham. The polygraphic art had its origin at Soho. This method of copying pictures in oil, by a mechanical process, was conducted by F. Epinon, who has since executed a great number of fine specimens of painting, or flaining of glafs. The encavis mode of flaining glafs, or fixing the vivid and fine graduating colours upon that transparent material, was suppos’d to be loit, but it has been revived and brought to great perfection by this gentleman. Since 1784, he has executed several large windows for various cathedrals, Churches, and gentlemen’s mansions. (See Glass-Painters.) Among the various machines, &c. invented and constructed at Soho, there is one entitled to a distinguished notice for its great national utility and importance. This is the steam engine, which has acquired extraordinary force and improvements by Mr. James Watt, one of the proprietors of the Soho firm. To him the scientific world is much indebted for various other inventions and improvements in mechanics. With a vigorous comprehension of mind, he embraces every mathematical and mechanical subject from the simplest to the most complex and profound. He procured a patent for the steam engine in 1768, and seven years afterwards, entering into partnership with Mr. Boulton, began to construct those machines at Soho. Since that period, they have been generally adopted in the mines and manufactories all over the kingdom. (See Steam Engines.) The following list of curious and useful articles are manufactured at these works, which, when fully employed, give support to upwards of 600 labourers. Buttons of all kinds; polished steel, and jetinna steel-toys; polished steel watch chains; patent cork-screws, &c. Buc- kles and latches of all sorts; plated and silver goods for the dining and tea-table, side-board, &c.; medals and coins of various sizes and metals. The late beautiful new coinage of copper, and also the re-flamped dollars; all come from the Soho mint. The coinage mid or engine first erected here in 1763, has been much improved since that period, and is now adapted to work eight machines at once, each of which will strike from 70 to 84 pieces per minute, the size of a guinea, or between 4,000 and 5,000 per hour. Thus the eight machines will work between 30,000 and 40,000 coins in one hour. These machines are operated on by the steam-engine, and perform the following processes: 1st. rolling the mallefs of copper into sheets; 2nd, fine rolling of the same cold, through cylindrical steel rollers; 3rd, clipping the blank pieces of copper for the die; 4th, shaking the coin in bags; 5th, filing both sides of the coin, and milling it, at the same time displacing it, and placing another for the same operation. To its other properties, this ingenious machine adds the almoit magical one of preventing fraud, by keeping an accurate account of every coin which passes through it. Dr. Davison has described this singular apparatus in the following apposite poetical lines:

---

"Now his hard hands on Mona’s refted creff,
Bofom’d in rocks, her azure ores arref;
With iron lips his rapid rollers feize
The lengthened bars in their expansive fqueeze;
Defeating screws with ponderous fly-wheels wound
The tawny plates, the new medallion’s round;
Hard dues of steel, the cuprous circles cramp,
And with quick fall, his lofty hammers flam.
The harp, the lily, and the lion join,
And George and Britain guard the splendid coin."
---

Rolled metals of all kinds of mixtures, are prepared here; besides mechanical apparatus, large and portable; also copying machines, and in short, almost every sort of article for use or ornament.

Besides the manufactories already named, Birmingham contains several others, which are entitled to our consideration; and although we cannot allow space for particulars, yet we muft not pass them altogether unnoticed.

Melfes. Richard’s in High-street, is styled the toy-shop of Birmingham; the elegance and variety of the articles are not to be equalled, with the exception of the show-room at Soho. Mr. Clay’s Japan manufactury is not less celebrated, particularly when it is considered that the Japan is fixed on common brown paper. To those may be added Clarke and Askone’s manufactury of whips. Gill’s gun, bayonet, and sword manufactury, suppos’d to be one of the best in the world; and Gilton’s for sporting guns. Previous to the reign of William III., guns were mostly imported from Holland; but that monarch having once expressed some regret at this circumstance, and deplored the necessity of finding abroad for the article, Sir Richard Newm.-gate, M.P. for Warwickshire, being afeend, afforded the king that his constituents would undertake to supply the demands of government. An order was given, and being readily and correctly executed, Birmingham has continued from that period to be the great and principal place of manufacture for this destructive weapon. See Guns.

Leather appears to have been manufactured here in great quantities in the early periods of the history of Birmingham; but in 1793, there was but one tanner in the place.

Within the last century, the manufacture of steel into almost every kind of toy and ornament took its rise: a large street bears the name of Steel-house-lane, from the extensive works carried on there. Here are also very large brws works erected on the banks of the canal, on the road to the five ways, near which stand the ruins of the mansion built by the late John Dalkeithville, who made great improvements in the art of printing. See BARKERVILLE.

Places of Amusement and Curiosity. In New-street is a museum, or repository of natural and artificial curiosities, the property of J. Bisset, a gentleman who has published some ingenious poems and useful books. His "Magnificent Directory," is a novel, handfome, and useful work, in which are contained elegantly engraved, emblematical cards of addresses of a great number of the merchants, manufacturers, tradesmen, &c. throughout England.

The first Theatre established at Birmingham was situated in Moor-street about 1740; that in King-street was erected 1765, and enlarged 1774; in the same year it was transferred to a religious society; and another built in New-street, at an expense of 5600l. and managed with great success by Mr. Yates. In 1791, it was burnt by some incendiaries, who have never been discovered; since that period, the proprietors have rebuilt it in a very splendid manner, for 14,000l, with an assembly room and a tavern annexed to it. Mr. Macready of Covent Garden theatre, is the present manager, who generally presents his audiences with the best London performers during the summer months. Concerts and musical parties are held weekly during winter; and the summer produces a variety of public gardens, the principal of which are Vauxhall and Spring-gardens.
BIRMINGHAM.

Government. Birmingham is governed by three elected magistrates; the officers chosen annually are the high bailiff, who inspects weights and measures, and the markets; the lower bailiff, who summons juries, and chuses all the other officers; two constables and one headborough; two high tallowers, who examine the quality of beer and its measure; two low tallowers or meat coniers, who inspect the meat expeled to sale, and cause that to be destroyed which is unfit for use; two officers, and two leather-sellers, whose offices are now only nominal.

Deritend, a baunet of Birmingham, sends its inhabitants to the court leet of that town, where all the above officers are chosen and sworn, in the name of the lord of the manor.

An act of parliament passed in 1752, which established a Court of Requests, consisting of 75 commissioners, three of whom are a quorum; they sit every Friday morning in a room of the Red Lion inn; the clerks attend to give judicial assistance, who are also professors of the common law, and chosen by the lord of the manor and the commissioners for life: ten of the commissioners are ballotted out every other year, and ten others elected from among the inhabitants. The beneficial effects of a humane society for the recovery of suspended animation were first extended to Birmingham in 1790. About the same period a committee of respectable inhabitants was established to watch over the common interests, under the title of the "Commercial Committee."

In 1791, W. Villars, esq., then high bailiff, opened a market for hay, straw, &c.

A public library was founded in 1779, which has flourished greatly, and contains nearly 10,000 volumes, supported by upwards of 500 subinbers. An elegant pile of building was erected in Withering-street for the purposes of the institution in 1797. A rival made its appearance in 1795, with every prospect of success; besides these, there are medical and law libraries, and many reading factories. Birmingham contains two churches, and four chapels; besides several meeting-houses.

The St. Martin's church, denominated the Old church, was raised previously to the year 1500. It is of stone, and occupies the site of, or is the first faced building belonging to the place. In 1690, it was thought necessary to raise the church and tower with brick. The walls support the arms and monuments of several titled and ancient families. Under the south window are two of white marble, one of which is supposed to have been erected for William de Birmingham, who was captured by the French at the siege of Blegard in 1299. He wears a short mantle, &c., and bears a shield with the bend lozenge. This church was repaired and altered in 1786, at an expense of 400l. The patronage belonged to the family of Birmingham till 1517, since which period it has been possessed by the Dudleys, the crown, the Marrows, the Smiths, and finally the Tenants. The rectory was valued in the king's books 1541, at 5l. per annum, and in 1556, at 15l. 3s. 4d. The income is now upwards of 1000l. and expected to be 2000l. after the expiration of certain leases.

St. Philip's, or the New church, is a handsome pile of building, but how Mr. Hutton or any other person could fancy and say that the pile erected is after "the model of St. Paul's in London, but without its weight," is to us unconceivable, as there is not a line of it that reminds the spectator either of the dome or turrets of the metropolitan edifice. It must be allowed that the tower of St. Philip's falsifies with an attic and diminutive cupola, but there ends the resemblance. This church is advantageously situated on an eminence, and the site was given by Robert Philips, esq.

It was begun by act of parliament in 1711, under a commission consisting of 20 of the neighbouring gentry appointed by the bishop of the diocese under his episcopal seal. In 1715, it was consecrated, and finished in 1740, at the real cost of only 500l. though the estimated value was nearly 20,000l. This circumstance arose from the gift of materials, &c. The church-yard consists of four acres, and is intersected by handsome walks, shaded by trees in double and treble rows, and is surrounded by elegant buildings. Two thousand persons may be conveniently accommodated in St. Philip's church, which has contained nearly 3000. William Higg's, first rector, founded a theological library for the use of the neighbouring clergy, and bequeathed 200l. to augment it. The Rev. Spencer Maddan erected a room in 1792, adjoining the parsonage, and termed it the parochial library. The rectory is worth about 300l. per annum.

St. Bartholomew's Chapel, capable of containing 800 persons, was erected in 1749, on a site given by John Jennins, esq., an opulent landholder of Birmingham. Mrs. Jennins, through the good offices of Mrs. Weaman, added 1000l., and the remaining sum was received in contributions from pious inhabitants. The chapel and tower are handsome, and the former presents a line north and south. The altar-piece is the gift of Basil, earl of Denbigh, and the communion plate is of Mrs. Carlyle's.

St. Mary's Chapel was erected in 1774 on a spot of ground given by Mary Weaman, whose family has the patronage. The incumbency is valued at 200l. per annum.

St. Paul's Chapel is a stone building erected in 1779, by virtue of the same act which founded St. Mary's. Charles Colmore, esq., gave the ground; a steeple is intended, and the east window was decorated in 1791, with painted glass, representing the conversion of St. Paul, by Francis Eginton, who received 400 guineas for the fame.

The house of a celebrated physician of Birmingham, Dr. Afs, was purchased in 1792 by an attorney, who converted it into an elegant chapel, at the expense of his own funds, when he caused the service of the church to be conducted by a numerous choir, accompanied by an organ, Dr. Croft, and some other clergymen, afterwards purchased it, and engaged to officiate there regularly. The congregation chiefly consists of soldiers from the neighbouring barracks.

Diffenting Meeting Houses. Old Meeting-house received its name from the old meeting erected in the reign of William III, which was destroyed in 1791 by the mob. The trustees recovered 1300l. 7s. 5d. damages, and rebuilt the present building, at an expense of 2000l.

The New Meeting built 1730, shared the fate of its parent in 1791, and has never been rebuilt. The celebrated Dr. Priestley professed over the spiritual concerns of this place of worship at the period of its destruction, and narrowly escaped personal injury, or perhaps death, from the furious populace. He fled, and finally retired into exile, within the state of Pennsylvania, where he died 1804, with the fame of an excellent philosopher and experimentalist. (See Priestley.) The trustees having lost their licence, could not recover damages, but the king granted his warrant upon the treasury for 2000l.

The Union Meeting in Livery-street, originally an amphitheatre for the exhibition of equinarian excels, being unoccupied at the period of the riots, the congregations of the two meetings hired, and converted it into a place of worship. After the re-erection of the old meeting, they separated, resigning the Union meeting to the new meeting assembly.
assembly, who occupy it till their place of worship is re-built.

Carrs-Lane Meeting, a kind of chapel to the old meeting, was erected in 1748. This society has 800L. bequeathed by Mr. John England in 1771, and 40L. 18s. per annum, termed Scott's trust.

A Baptist Meeting in Canon-street, was founded in 1738, and has continued prosperously to the present period.

The Quakers have a meeting in Bull-street, frequented by a large, peaceable, and rich congregation; behind it is a spacious burial-ground. The methodists are now very numerous; previous to 1782, there was but one congregation, whose place of worship had been a theatre; whence they removed to a splendid meeting in Cherry-street, erected at an expense of 1200L. John Webbey, their chief clerk, preached in it for the first time July 7, in the above year; three others have since been erected and purchased in Coldhill-street, Deritend, and Newhall-street. The site was erected as a new Jerusalem temple, for the Swedenborgians, but in too magnificent a style for their revenues. The methodists bought it, and the original pellicorns built a smaller temple.

A small Roman Catholic chapel is situated at Eafly-hill, in the place of one destroyed during the destructive riots. A Jewish synagogue, a baptist's meeting, and an independent meeting, lady Huntington's meeting, and some other places of worship, are found in this town, which, like most manufacturing places, is distinguished for its number of dissenters of different sects.

Charities. Some of the streets of Birmingham are kept in repair by emoluments arising from small estates. William Lench, who lived in the reign of Henry VII., bequeathed certain estates to the town, in trust to sixteen inhabitants, for repairing the streets. This person founded the almshouses in Steel-house lane for poor widows. Pentham's trust is 100L. per annum, and applied to teaching poor children reading, and for clothing ten poor widows. The date of the donation is 1712. Mr. Crowley gave in 1733, six houses for the support of a school for ten girls.

The Free School was erected on the site of the gild of the holy crosses, which had an endowment of lands for the maintenance of two priests, worth twenty marks per annum, given by Thomas de Shefledon, John Colshill, John Goldsmith, and William Astilowe. In 1593, the bailiffs and inhabitants obtained a patent for augmenting the foundation, and adding a brotherhood, which flourished till the general dilution, and was then valued at 31L. 23. 10L. per annum. Edward VI. granted the lands belonging to the gild in 1552, at the suit of the inhabitants to nineteen persons, as bailiffs and governors of the free grammar school of king Edward VI., to hold in common tenure at a rent of 206. per annum. Their successors erected the present building in 1707, which is large and handsome, has a neat tower in the centre, and a statue of Edward VI. in front. The chief master's salary is 120L, the second 60L, two others 40L each for writing and drawing, and a librarian 10L. There are seven exhibitions of 5L. per annum each for the university of Oxford, and the reductions are valued at 1200L. per annum.

The Blue Coat School was erected 1724, but enlarged and improved in 1741, at an expense of 2500L. The revenues are 1250L. and 150L boys and 40 girls receive the benefit of the institution.

The Dif fillter's Clarity School was held at the old meeting, but after that was destroyed, a building was purchased in Park-street, and has been much improved. The children received are 40 boys and 20 girls.

The Workhouse erected 1733, cost 112L, a wing was added for 200L in January 1740, and another in 1779, at an expense of 1100L. The inhabitants pay a rate of 6d. in the pound, which raises 17,000L. per annum, and relief is afforded to 7000 persons. There are twelve overseers.

The General Hospital was erected 1766, and two wings were added 1791. It is supported by voluntary contributions, and many large bequests; the physicians generally give their attendance gratis.

The Prisons in Peck-lane and Deritend are disagreeable and unhealthy, and both are licensed as public houses.

The Canal between this place and Wednesbury, was made in consequence of an act obtained in 1767. It is twenty-two miles in length, uniting with the Staffordshire canal; the shares were 140L. each, and the expense 70,000L.; they sold in 1782 for 370L. each, and in 1792 for 150L. Sir Thomas Gooch leased the proprietors six acres of land at 47L. per annum, which they converted into a wharf, and erected a handsome office on it. The boats are drawn by one horse, and are about twenty tons burden. Coals are little more than half the price they were before this canal was made. Several other canals, equally beneficial, have since been completed, opening a communication between this town, and almost every principal town in the kingdom.

The Barracks stand on five acres of land, held by government at one penny per yard. They were erected in 1793 for 13,000L., and will accommodate 162 men.

There are three extensive Breweries near Birmingham, Richards's in Deritend for ale, Giles and Forreells, W.irlomelane, for ale and porter, and the Britannia, Walmer-lane, belonging to Clay and Co.

The riots, already alluded to, constitute an unpleasant feature in the history of this town, and whilst they serve to characterize the folly and intoxication of the lower classes of society, will, we trust, operate as a warning example to the rising generation. A few parsons assembled at the hotel Birmingham, July 14, 1792, to celebrate the anniversary of the French revolution. A mob collected round the house, broke the windows, and immediately proceeded to Dr. Priestley's new meeting. This, and the old meeting, were soon burnt to ashes, and the doctor's house and furniture, with his valuable library, apparatus, and MSS. thred the fame devastating fate. On July 15, the mob of John Ryland, esq. at Ealby-hill, and Bordelay-hall, the seat of Lord Tylor, esq. together with the house, flock in trade, books, furniture, &c. of Mr. Hutton, author of the "History of Birmingham," were destroyed. Saturday the 16th witnessed the destruction of Mr. Hutton's house at Stitley, the residences of George Humphreys, William Ruffel, and John Tylor, esqrs. The latter, Bordelay-hall, was occupied by lady Carhampton, mother to the duchess of Cumberland, but neither her blindness through age, nor connection with the king, could prevent the mandate of removing her furniture from the mob, who frantically offered to affilt: "She was therefore, like Lot, hallowed away before the flames arose, but not by Angels." The revered Mr. Holton's and Mr. Harwood's houses were next burnt; those of the Rev. Mr. Coates, Mr. Hawkes, and Thomas Ruffel, esqrs. were plundered. On Sunday the 17th, Kingswood meeting perished in flames, the parsonage-house, and that of Mr. Cox, licensed for public worship. The mob this day plundered Edgbaston-hall, Dr. Withering's, and attacked Mr. Male's house, but hearing in the evening, that a troop of horse approached, they gradually dispersed, after destroying property to the amount of 60,000L. To reimburse the sufferers, an act was obtained in 1793. The war succeeding, greatly injured Birmingham, and this cannot be more clearly
BIR

clearly proved than by referring to the 1875 uninhabited houses in the year 1800. There are two morning papers published at Birmingham; Art's Birmingham Gazette, and Savi-ney's Birmingham Chronicle, &c. Mr. Swinnery also carri'es on a considerable type foundry, which is the only pro-
vincial one in the kingdom. "This neighbourhood," says Mr. Hutton, "may justly be deemed the last of the arts, but not the last of the gentility. None of the nobility are near us, except William Legge, Earl of Dartmouth, at Sandwell, four miles from Birmingham. The principal houses in our environs are those of the late Sir Charles Holte at Alton; Sir Henry Gough Calverley at Edgbaston; George Birch, esq. at Handsworth; John Gough, esq. at Perry, and John Taylor, esq. at Bordesley, and at Mofly, all adjoining to the manor of Birmingham; exclusive of these, there are many retreats of our right inhabitants, acquired by com-
ercial success." Hockley Abbey, near Soho, is the resi-
dence of Mr. Richard Ford, an ingenious smith, who had the honour of presenting his Majesty with an iron carriage made by himself. It is a modern curious building, with the upper part representing a ruin, and is surrounded by beau-
iful grounds and walks, interfered with fanciful curvatures. The most confiderable feats in the vicinity of Birmingham, are Hagley, 15 miles distant; Edville, 18 miles distant; and the Leafoxes, five miles distant. The lat-
term will long be preferred in the memory of every reader of Sherf-ton, whose creation it was, and whose tale it dis-
played in an eminently degree. It now belongs to Charles Hamilton, esq. who judiciously restored the neglected beau-
ties of the place. Hagley, the seat of Lord Littleton, has been particularly celebrated in the writings of Pope, Thompson, Hammond, and other poets. Edville, the seat of the earl of Stamford, is a scene of great natural beauty. For further particulars relating to Birmingham, its manufac-
tories and neighbourhood, see Hutton's "Hist. of Bir-
mingham," 8vo. Shaw's "Hist. of Staffordshire," vol. 1. A compo-
sition to the Leafoxes, Hagley, and Edville," 12mo. Bisset's "Poetic Survey round Birmingham," 8vo. Phil-
lips's "History of Inland Navigation," 4to. &c.

BIRON, ARMAND DE GONTAULT, baron in Biogra-
phy, was born about the year 1724, and rose gradually to the con-
dition of a page to Margaret queen of Navarre, to the rank of marquis of France, which he obtained from Henry III in 1577. After the death of this king, he was one of the first to acknowledge Henry IV, as lawful prin-
cipal of the crown, and served him with advantage at the battles of Argues and Ivry. At the close of the action, to the victorious issue of which he contributed, by his com-
mand of the reserve, though he was engaged, he said to Henry, who had much expostulated himself, "You, Sir, have acted the part of Biron to day, and he has served yours." Under Henry III he occupied the post of lieu-
tenant-general of Guetemplate, in which he gained great advan-
tages over the Cavailliés; and he also reduced part of Normandy to the obedience of Henry IV. To his son, who solicited a small force for the purpose, and with the promis-
se of raising the army of the dukes of Parma and Mauvenc, he replied: "I believe you may; but then we shal-
not have nothing farther to do but to plant cabbages at Biron." Soon after, in 1592, he lost his life by a cannon ball at the siege of Epernay. In his military character, he was a rigid disciplinarian, and required prompt obedience. When an officer, whom he had commanded to burn a house, defied an order to this effect, under his own hand, Biron instantly discharged him, alleging "I would have nothing to do with people who were afraid of justice; and that every soldier who dared a pen, must tremble at a sword." He was a polite scholar, but of a mercenary and intemperate disposition. He wrote "Commentaries" of his transactions, which were lost. Gen. Dict. Nouv. Dict. Hist. Mod. Un. Hist. vol. xxi. p. 546. &c.

BIRON, CHARLES DE GONTAULT; duke of, the eldest son of the preceding, was born in 1672: and having served under his father, he distinguished himself in several battles and sieges. Henry IV. distinguished him by tokens of for-
bearance and favour, on account of his faithful and active services. He created him admiral of France in 1592, mar-
shal and governor of Burgundy in 1594, and honoured him with erecting the barony of Biron into a dukedom and peerage. He also employed him in several important diplomatic embassies; but his pride and ambition rendered him incapable of gratitude. Allured by flattering pro-
pects, he engaged with Spain and Savoy in a conspiracy against his master; and at length his haughty conduct caused him to be arrested for his treasons, tried, and con-
demned to lose his head; and the sentence was executed in the court of the battle, July 31, 1622. He submitted with reluctance, and betrayed cowardice at the time of his death. He was vain, arrogant, and malicious; he changed his religion twice before he attained the age of 16 years, and manifested a total want of principle and integrity. His passion for gaming reduced him, notwithstanding his race pertency, to various difficulties; and he was only extirpate when he was actively employed. Although the king in-

BIRON, in Geography, a town of France, in the depart-
ment of the Dordogne, 34 leagues south of Belvez.-Alto, an island in the puit of St. Lawrence, 26 leagues west of Cape Annula. N. lat. 45° 56'. W. long 61° 5'.

BIROSTRIS, in Conchology, a species of Bella, that inhabits Java. The shell has two beads, which are ellip-
soidal and smooth; margin thickened outwards. Gracilis, Liger. This species is not unlike Bussus veron, but is smaller, being only about the size of a lemon; and it is also narrower, in such a manner that it is not uniform; bic- kne equal, obliquely truncated, and one of them a little a-

BIROTA, Birodum, from bis and rata, wheel, a kind of vehicle denominated from the two wheels wherex on it moved. The biota, by the constitution of Cailantine, was drawn by three mules, and carried 100 pounds weight; by which it was distinguished from the ricka, which carried 150 pounds, and was drawn by eight, and in winter by ten mules.

BIRR, in Geography, or, as it is called by act of parlia-
ment, Parson's Town, the largest port and market town in the King's county, Ireland, situated on the river called the Little Boyne, which divides the King's county from the county of Tipperary, on the south west. This town has Breweries, Distilleries, sail-boat, cloth and forge manu-
factories, a bank, an excellent market, and a barack for two companies of foot. The castle at the western ex-
ternity of the town, belonging to the family of Parson, was besieged by Sashed, lord Lucas, general of the Irish, in the war of the revolution of 1688, and relieved by general Kirk. There is a Ruine of William, duke of Cumber-
land, standing on a stone pillar of the Doric order, erected in 1747, in honour of the victory at Cuiloden. Biron is 65 miles west by south from Dublin, 6 south from Banagher on the Shannon, and near 12 from Portumna. N. lat.
N. lat. 53° 41', W. long. 7° 52'. Beaufort. — Coote's Survey of King's County.

BIRKETUM, or BIRKETUM, in Writers of the Middle and Lower Ages, a thin black cap or cover for the head, made of linen, fitted close to the head, and pointed by a pyramid, anciently worn by priests, folders, doctors, &c. Du Cange. The word birketum, sometimes written birketum and birquetum, is also applied to a cap or coif of a judge, or ferjeant at law. The birketuilo denotes the cap worn by the novices in the Jelin order, formerly of a square, now a round figure. The birret was the ordinary cover of the head in France 500 years ago. It took its denomination from birro or birrum, the coat anciently used by ecclesiastics; with which the cap was then of a piece, and made part of it; so that the whole covered, not only the head, but the shoulders. Afterwards, when they began to retrench the lower part, it still retaining the upper, it was no longer called birro or birrum, but diminutively birret, or birretum.

BIRRUS, an ancient habit worn by the Chrlilans in Africa. The word is also written byrus, supposed to be formed from pelle, on account of its red colour. Some will have the birrus an episcopal habit. Others extend it to all the clergy. Others, on fuller grounds, make it the common use of all the Christians in that quarter.

BIRKS, or BIRSH, in Geography, a river of Switzer land, which runs into the Rhine near Basle. Near this river, and not far from the town of Basle, are the hospital and burying ground of St. James, famous in the history of Switzerland for a desperate combat in 1444, between the Swiss and the dauphin of France, afterwards Lewis XI. in which Swiss valour and intrepidity were very signally displayed. Upon this occasion 1500 Swiss charged 6000 of the enemy's cavalry with such determined and well conducted valour, as to drive them back; and when the enemy received reinforcement, the Swiss renewed the assault, and forced them to repass the river Bir, and join the main body of the army. The Swiss, encouraged by this success, and also exasperated with the most spirituated indignation against the invaders of their country, rashly attempted, against the remonstrances of their officers, to force their passage over a bridge guarded by a large body of the enemy; but this gallant effort not succeeding, they threw themselves into the river, and gained the opposite shore, in the face of a battery of cannon, that was playing against them. But they were now opposed to an army of 30,000 men advantageously posted in an open plain. In these desperate circumstances they had no alternative, but to throw down their arms, or gloriously expire. They bravely preferred death; 500 took possession of a small island near the bridge, and after resolutely defending themselves to the last extremity, were cut to pieces. A like number forced their way through the ranks of the enemy, and marched towards Basle; when they were opposed by a large party of horse posted to prevent the inhabitants of the town from fleeing forth to the relief of their countrymen. Being now surrounded on all sides, they threw themselves into the hospital of St. James, and, lining the walls of the burying-ground, resisted for some time the united assaults of the French army. At length the hospital being set on fire, and the cannon having battered down the walls of the burying-ground, they no longer fought in hopes of victory; but still resolving to fell their lives as dearly as possible, they continued to defend themselves to the last gasp.

Ennas Sylvius (afterwards pope Pius II.) relates, among other actions of singular valour excited by this heroic troop, the following instance, that deserves to be recorded. Four French soldiers assaulted a single Swif, and having killed and stripped him, proceeded to insult the corpse; one of his companions, incensed at this brutal action, seized a battle-axe, rushed upon the four, slew two of them, and drove the others to flight; then flinging the dead body of his friend upon his shoulders, carried it to a place of security; and, returning to the attack, fell by the hand of the enemy. Of the whole number, only 15 escaped from the field of battle; and thefe, agreeably to the old Spartan discipline, were branded with infamy, for not having faciliied their lives in defence of their country. Among thofe who were desperately wounded and left upon the field, only 32 were found alive. The names of many of these glorious combatants were registered, and their remains upon records. The lots of the enemy was great; and they were effectively prevented from prosecuting their designs upon Switzerland, and compelled to retire in a shattered state into Alsace. Lewis himself declared that such another victory would ruin his army. This combat may be considered as forming a remarkable era in the history of the Swiss; for it gave rise to their treaty with Charles VII.; being the first alliance which they contracted with France. The Swiss still talk of this famous action with the warmest enthusiasm; and the inhabitants of Basle, form parties every year, and go to an inn built near the hospital and burying-ground, in order to commemorate, in a red wine produced from some vineyards planted on the field of battle, the heroic deeds of their countrymen, who so gloriously faciliied their lives, This wine is highly prized by the Basleans, and called "the blood of the Swift."
Birth, Natural, when the head of the fetus presenting to the uterine orifice, the labour is completely effected by the pains, without the interference of art. See Labour, Natural.

Birth, Premature, when by any accident or derangement of the health of the woman, or of the fetus, pains are excited, and the fetus is expelled before it has attained its maturity. See Abortion, and also Labour, Premature.

Birth, Preternatural, or acrot-, when, in labour, the arm, shoulder, side, breech, or any other part of the head of the fetus present to the uterine orifice. See Labour, Preternatural, and Cross birth.

Birth, Laborious, when in labour the head of the fetus presenting, yet an account of the strength of the pervers, the pains are insufficient for its expulsion, whence recourse is necessarily had to the assistance of the laver, forceps, crotchet, &c. See Laborious Birth, or Labour.

Birth, Monglous, when the fetus is deformed or mis-shaped, and has more or fewer organs than is natural. See Monster.

Births, Seven Months, partus septemfris, children born at the end of the seventh month, or 210 days from the time of conception, being now complete in all their members, and having acquired a certain degree of strength, and firmness of constitution, are not unfrequently reared or brought up.

Births, Eight Months, partus octemfris, that is, children born at the end of the eighth month, or after completing 240 or 242 days in the womb. These were suppos'd by the ancients, but erroneously, to be less vivacious, and consequently it's likely to be preferred alive, and to grow up to manhood, than seven months children. This opinion, founded on a mistaken idea of the upright position of the fetus in utero during the former months of pregnancy, and of the necessity of its making an evolution, about the end of the seventh month, to prepare it for the birth, is considered under the article Position of the fetus in Utero, which see.

For the number of births, see Marriage, under which the proportion of births to marriages, or births to burials, and of male births to females is computed. See also Mortality.

Birth, After. See Placenta.

Birth is also used for a person's descent; and it is either high or low according to the circumstances of his ancestry.

Birth, Birth, or Bithing, among Scythians, denotes the due distance observed between ships lying at an anchor, or under sail. A convenient place a-board for a melo to put their cests, leep, &c. is also called birth.—There is usually one of these in ships of war between every two guns. And a proper place to moor a ship in is called the same name, as is also the station in which a ship rides at anchor. To take a good birth, is to remove to some distance off any point, rock, or other thing which the seamen would avoid or go clear of.

Birth, Expulsion of, among the Ancients, was where a new-born infant was exposed or cast away, and left to the mercy of the first comer, who might either take and bring it up, or suffer it to perish. See Exposing of Children.

Birth, Supplication of, partus supplicio, in the Civil Law, is a crime for which accusation may be intended by those who have interest therin, and is punished with death, like the crimes falsi, or forgery.

Birth, Supplication of, partus supplicio. See Abortion.
country, and circur of Chanderee; 55 miles east of Chand-
eree.

BIRIESCA, or BIBUSCA, or BIBIESCA, a mean and wretched town of Spain, in Old Calilte; 15 miles N. E. of Burgos.

BIREUSE, a river of Siberia, which runs into the

BIRNUCH, or KIRDI, a town and district of Russia, in the government of Voronez, fated on the river

BIRZA, or BURZ, a town of Poland, in the palatinate of

BISACUTA, a coin in Pegn, current there for half a
ducat. The denomination is also given to a kind of weight used in the same country, equivalent to two Venetian pounds five ounces, or to three pounds nine ounces of the lighter weight of that city.

BISACUTA, in Middle Age Writers, an axe with two edges, or which cuts either way; or a missile weapon pointed at both ends. Wallingham represents the *fetus bifaxata* as peculiar to the Scottish nation. See *Battle-Axe*.

BISALTE, in Ancient Geography, the name of a people who inhabited a small country bordering on the Sinus Strymonius, in the northern part of Macedonia. Their chief cities were Exponia, Osa, and Calitera.

BISALTIDE, in Entomology, a species of *Papilio* (*Dun. Fyl.*), that inhabits Surinam. The wings are slightly tailed, fulvous, black at the tips; beneath, two ocular dots on the anterior pair, and three on the posterior ones. Fabricius, &c.

BISANTHE, or RADIUS, in Ancient Geography, a town of Thrace, on the confines of the Propontis, at the bottom of a kind of gulf, and at a small distance S.W. from Parinthe.

BISANT. See *Besant*.

BISLEA, a feast celebrated by the *Misipapii*, after the pruning of their vines, to obtain of the gods that they might grow again the better. The word is formed from *Evhe*, used by some for a *vine*.

BISCANO, BARTOLOMEO, in Biography, an eminent

BISCARA, or BICCARO, in Geography, a decayed city of Africa, in the kingdom of Algiers, the capital of the district of Zeb or Zeb, belonging to the province of Constantine. It is the residence of a Turkish garrison, and has a small castle, built by Haflan, the bey of Constantine, and chiefly defended by fixed pieces of ordnance, and a few unwieldy mulkets, mounted on carriages. It is a place of great antiquity, built by the Romans, and destroyed by the Arabs, who afterwards rebuilt it. It is at present as indifferently peopled as it is weakly defended; the houses being infected by swarms of scorpions, vipers, and poisonous reptiles, and the inhabitants being obliged to cefi the city and retire into the country in the summer, when these noxious animals are intolerable. The inhabitants of this place, and its adjacent district, called "Biccaris," lead a kind of wandering life, and live in tents. Few of them can be employed in agriculture and piturage from the nature of the country; but those of the superior class carry on some commerce, notwithstanding their poverty and indigence, in negroes and other feathers. The poorest of them migrate every year to the city of Algiers, and other towns of the kingdom, and are employed in the meanest and most subordinate offices, such as cleaning of streets, emptying vaults, sweeping chimneys, and carrying burdens. Having in the course of two or three years accumulated a capital from fix to ten zecins, they return home, and on account of the scarcity of coin among them are reckoned among the wealthy of the land.

In the capital, they constitute a kind of corporation, and have even a common treasury for the purpose of mutually relieving one another. They are the only class of free servants, and are highly esteemed for their fidelity. In winter, as well as in summer, they flee wrapped up in rags, on a kind of benches before the shops, and others place themselves at the gates of the different roads, for the convenience of opening them to passengers. They are not only desirous of the confidence that is reposest in them, but their disposition is placid and obliging, and their perseverance in labour is indefatigable. Those among them who are guilty of any breach of trust, are punished by their chiefs. They are employed by the Europeans as servants, and as they can speak, besides the language of the country, the "lingua Francesa," are found singularly useful. The villages which they inhabit in their own country are small, and remarkable only for their meagre and poverty. N. lat. 34° 30'. E. long. 5° 15'.

BISCARGIS, or BISCEGIS, in Ancient Geography, a town of Spain, on the right side of the river, N.W. of Dertos.

BISCAY, in Geography, a province of Spain, called, "the lordship of Biscay," is, in its most appropriate and restricted sense, bounded on the north by the Bay of Biscay, on the fourth...
south by a chain of the Pyrenees, which separates it from Old Castile and Alava, on the west by Asturia, and on the east by Guipuzcoa; and in extent its length is about 116 miles, and breadth much less, the greatest breadth being 80 miles, but very unequal. In its more general and comprehensive extent, Biscay is divided into three parts; viz. Biscay, properly so called, Guipuzcoa, and Alava; and, accordingly, it is bounded on the west by that narrow tract of Old Castile which reaches to the sea and Asturia; and to the south of Old Castile on the south-east by the ridge of the Asturian mountain branches from the Pyrenees, and by the same mountains from Navarre, and by the river Cidario from France, on the east; and washed on the north side by the Cantabrian sea, now commonly called the bay of Biscay. The country is for the most part mountainous and barren; but its valleys produce corn sufficient for the supply of the inhabitants, and a small quantity of flax. Apples are very plentiful, of which is made cider, the common beverage of the people. They have also a weak wine, called "Chacolino," which is pleasant, though it will not keep long, and is used instead of small beer. They have also citrons and oranges in great abundance. The adjacent sea supplies excellent fish, and the forests yield great quantities of timber for shipping. But the most valuable treasure of this country consists of its inexhaustible mines of excellent iron, which is transported from hence into all parts of the world. The country has been long famous for its iron-works, and especially for its manufacture of swords and knives. Some have computed the amount of its annual manufacture of iron and steel into arms, nails, iron tools, bars, &c. at 300,000 quintals. The air of this province is mild, pure, and more temperate than that of the other provinces of Spain; and the inhabitants have been distinguished by their attachment to liberty, and willingness to oppression. Their ancestors the Cantabri, were but imperfectly subdued by Augustus, and their mountains have, in every succeeding age, afforded them a retreat from the encroachments of arbitrary power. The Biscayans are said to be of Celtic or Gothic origin; and have preferred more of their ancient genius, laws, government, and language than perhaps any other people in Europe, except the Swiss, Scots Highlanders, and wild Irish, who are probably of the same origin, and whose language much resembles the Biscayan. They have always maintained a distinguished reputation for valor; and the bold soldiery and sailors of Spain have been the natives of this country. They essentially differ from the other Spaniards in the openness of their temper, and animation of their manner; and though they are cholerics even to a proverb, and not delitute of pride and vanity, they are obliging, polite, and friendly. Their females are beautiful, lively, and cheerful. Their dress is neat and pannorial; their hair falling down their backs in long plaits, with a handkerchief twisted round it. The most singular part of the dress of the men is the covering of their legs, round which they wrap a piece of coarse grey or woollen cloth, fastening it with many folds of tape. The three provinces of Biscay, Alava, and Guipuzcoa, have been the asylum of liberty and industry, and to these causes their prosperity may be ascribed. When the king, who is styled merely "lord of Biscay," wants a supply either of men or money, he announces his will to the province; which furnishes its contingency of both; the latter being levied upon the different cities and communities, according to a certain regilier, so that in effect Biscay may be said to tax itself. In this province are no bishops. Its privileges are extensive, it has watched over with a jealous eye. The language of Biscay is accounted aboriginal; it is said to be the Cantabrian, or ancient language of Spain, which was a branch of the Celtic, and first gave way to the Roman, of which it is so totally different from the Gallican, that the peasants scarcely understand a single word of Spanish. The capital of Biscay is Bilbao, which lies. Its other chief towns are Orduna, Durango, Fontarabia, St. Sebastian, Tolosa, and Vitoria.

BISCAY, Bay of, that part of the Atlantic which lies north of the province of Biscay, between the projecting coasts of France and Spain, and extends from Cape Ortegal to Bret. It advances farthest to the land between Bayonne and St. Sebastian; and it likewise advances considerably at Rochelle and Rochefort.—Also, a large bay on the coast of Newfoundland, between Cape Race and Cape Pine. It lies in the N.E. corner of Trepassy bay, on the S.E. part of the island. N. lat. 46° 50'. W. long 53° 6'.

BISCAY, New, a province of Mexico in North America in the audience of Gaudalajara, bounded on the north by New Mexico, on the east by New Leon and the river Bravo, on the south by Chihuahua and Coahuila, and on the west by Navarre, Sonora, and Haqui, on the borders of the Gulf of California. It is computed to be about 300 miles from east to west, and 560 from north to south. The country is mountainous, but well watered, fruitful, and moderately temperate, rich in corn, cattle, and other productions; and also in mines of silver and lead. The original inhabitants have four large towns in the morasses, which are difficult of access, and by means of which they avoid total subjection; and therefore the Spaniards have built three small fortified and well inhabited towns for the defence of their silver mines. The capital is Durango. This province lies between the latitudes of 27° 33' and 33° N. and between 105° and 108° W. long.

BISCEGLIA, a town of Naples, in the province of Bari, having the see of a bishop, suffragan of Trani; it is pleasantly situated on an eminence in the midst of orchards and villas. The walls are of stone and very lofty; and it has hundreds of subterraneous referves and cellars, cut in the solid rock, and arched over with stones and floucco, in order to collect and preserve the rain-water, which is the only port with which they are supplied in a district, to totally destitute of springs. Biseglia is 4 miles distant from Trani.

BISCHBURG, or BISCHOFSHOFN, a town of Prussia, in the county of Ermeland, 54 miles south of Konigberg.

BISCHEIM, a town of Germany, in the circle of the Upper Rhine, and county of Litchenborn, on a small river which runs into the Rhine, 8 miles N.E. of Strafburg.

BISOFFLACK, or SCHAFOF, a town of Germany, in the duchy of Carniola, 27 miles N.N.E. of Trieste.

BISOFFSHEIM, a town of Germany, which lies on the Tauber, in the circle of Franconia, but belonging to the electorate of Metz, 63 miles S. E. of Metz.

BISOFFSTORF, a town of Germany, in the duchy of Slesia, 13 miles E.N.E. of Gratz.

BISOFFSHEIM, a town of Germany, in the circle of Franconia, and bishopric of Wurzburg, lying on the Kiss, 32 miles north of Wurzburg.—Also, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenberg, 3 miles W.N.W. of Hanau.

BISOFFSTEIN, or BESTIN, a town of Prussia, in the county of Ermeland, 42 miles south of Konigberg.

BISOFSWERDA, a town of Germany, in the circle of Upper Saxony, and margraviate of Meissen, seated on
BIS

an island in the river Wesenitz, the principal commerce of which is in white thread; it has two churches; 20 miles east of Dresden.

BISCHOFSWERDER, a town of Prussia, in the province of Oberland, 80 miles S.W., of Königsberg.

BISCHOFZELL, a town of Switzerland, in the Thur-gaw, seated at the confluence of the rivers Sitter and Thur; 11 miles south of Contance. This town has a castle, in which resides the bishop of the bishop of Contance, who exercises jurisdiction over the Catholics, and receives a moiety of the fines. N. lat. 47° 25'. E. long. 9° 15'.

BISCHOP, or Bishop, John de, in Biography, an excellent artist, was born at the Hague in 1642, and is much commended as a painter; and his drawings, in which he imitated with great exactness the style of the best masters, are much esteemed and sought after by the curious. But he is most generally known as an engraver. His works are chiefly etchings, harmonized with the graver; and though slight, yet free, spirited, and pleasing. He gives a richness to the colour, and a roundness to the figures, far beyond what is usually done with the point, so little affected by the graver. His figures are generally well drawn, drawn in a mannered than a correct style; but his extremities are not always well marked, nor his heads equally expressive and beautiful. His excellence was owing chiefly to his own genius, as he never studied under any master. He worked chiefly at Amsterdam, and died in 1686. The following prints are worthy of notice: viz. "Christ and the Samaritan woman" from Aumbale Caracci; "Joseph distributing corn to the Egyptians," from B. Breenberge; "the Martyrdom of St. Lawrence," from the same. Strutt.

Bishop, or Bishop, Cornelius, a painter of portrait and history, was born at Antwerp, fay fomie, or according to others, at Dort, in 1630; and was the disciple of Ferdinand Bol, whose pencil, tint of colouring, style, and manner, he reformed, and to whom he has been taught by some competent judges not to be inferior. He died in 1674. A painting by this master, consisting of a few figures by candle-light was so much admired by Louis XIV., that he purchased it at a high price, and placed it in the royal collection. The king of Denmark also admitted his works among those of the best masters. It is observed, however, that they are not worthy of that high commendation which is bestowed upon them by the Flemish writers. Pilkington.

BISCHWILER, in Geography, a town of France, in the department of the Lower Rhine, and chief place of a canton in the district of Strasbourg, seated on the Motte near the Rhine, and defended by a castle, flanked with towers, and guarded by ditches; 10 miles north of Strasbourg. The town contains 3449 inhabitants, and the canton 13,668. Its territorial extent comprehends 265 kilometres, and 21 communes.

BISCH, in Ichthyology, one of the Synonymous names among old writers for the pipe-fish, tobacco-pipe-fish, needle-fish, or trumpet-fish; and Syngnathus acus of Linneus and Gmelin.

BISCUVAARE, in Geography, a town of Norway; 48 miles east of Bergen.

BISCROMA, Ital. for a demifemiquaver, in Music. If single, it has three hooks; if two or more, they have three ties.

BISCuit. See Bisket.

Bisquit, in Pottery, a name given to porcelain, when baked and not glazed; and this is more or less beautiful, according to the nature of its composition. See Porcelain and Pottery.

BISCUTA, in Entomology, a species of Formica, with a bidentated thorax; and a double petiole scale. Inhabitats Cayenne. Fabricius Spec. inf.

BISCUTELLA, formed of bis, and the diminutive of fustum, the fruit resembling a double shield, in Botany, buckler-mustard, or bardaff Mitridate mustard. Linn. gen. 808. Reich. 872. Schreb. 1054. into Kew garden in 1784, by Msfrs. Lee and Ken-
nedy.

Propagation and Culture. These are all annual plants, ex-
cept the last, and perish soon after they have perfected 
their seeds. They should be sown in spring or autumn, upon 
the border of light earth, in an open situation, where they are to 
remain. These sown in autumn will come up about three 
weeks, live through the winter, and flower early in the fol-
lowing summer, and thus good seeds may be always ob-
tained; but those that are sown in the spring decay in bad 
seasoons before the seeds are ripe. The autumnal plants 
flower in June, and the spring plants in July, and their seeds 
ripen in about six weeks, and if they are permitted to setter, 
young plants will be produced without any care. They re-
quire only to be kept free from weeds, and to be thinned 
where they are too close, leaving them eight or nine inches 
upon. They have no great beauty to recommend them.

BISDORF, in Geography, a town of Germany, in the 
circle of Upper Saxony, and principality of Anhalt-Cotten, 
3 miles north of Cotten.

Bisection. See Bisection.

Biselliarii, or Biselliari, in Antiquity, those 
who enjoyed the honour or privilege of the bifellium.

The word occurs in ancient inscriptions. CN. PLAE-
TORIO VIVIRO AUGUSTELLI BISELIARI. Gruter, Infer. 
p. 1099.

The honor bifellii appears to have been much the same with 
what in France is called droit de fanneul; and the bisellarii 
those who in public assemblies enjoy this distinction of 
the fanneul, while other persons are obliged to flam, or sit 
on benches, rools, or ordinary chairs. Scaliger, in his 
index to Gruter, millook the bisellari for artificers who made 
these seats.

BISELLUM, from bis and fella, a chair, a kind of seat 
or chair, larger and richer than ordinary, big enough to hold 
two persons, wherein to sit in courts, theatres, and other 
public assembleys.

Biseptemguttata, in Entomology, a species of 
Coccinella, of a pale yellow colour, with fourteen white 

Bis-Ergot, in Orniology, a name given by Buffon 
to the Gmelianus tetra bicalcarata.

Biserrula, so named from the fruit, “ biserrato 
Clais and order, Diaselphia. Decandria. Nat. Ord. Papil-
lianae or leguminos. Gen. Carl. Cal. persiana, 
tubular, erect, semiquadrifid; teeth tubulate, equal, 
the two upper ones more remote. Gr. papilionaceous, 
banner larger, reflected on the sides, ascensiong, roundish; 
wings ovate-oblong, free, shorter than the banner; keel the 
length of the wings, oblong, ascensiong. Stam. filaments 
diadelphous (simple and single-cleft), ascensiong at their tips, 
inclined within the keel; antehes small. Pyl, germ, oblong, 
comprted; style tubulate, ascensiong; stigma long. Per-
legume large, linear, flat, two-celled; partition contrary 
to the valves. Seeds very many, kidney-form, comprpessed.

Eff. Carol. legume two-celled, flat; partition contrary.

Species. 1. B. Pedicinus, balfard hatchet-vetch. Atra-
galus. Mor. hist. 2. f. 21. g. 6. Securidaca. 
f. 6. Park. Theatr. 1089. f. 5. Rauh hift. 319. n. 16. 
Lunaria radiata Robinson. Bauh. hift. 2. 348. f. 2. An annual 
plant growing naturally in Italy, Sicily, Spain, and the 
loth of France. Cultivated in Kew garden in 1649.

Propagation and Culture. It is propagated by seeds, sown 
in this country in autumn, on a bed of light earth, where 
the plants will come up in about three weeks, and live 
well in the open air. They should either be sown where 
they are to remain, or transplanted when very young. After 
the plants are come up, they will only require to be kept 
free from weeds, and to be thinned to the distance of a foot 
from one another. They flower in June, and the seeds 
ripen in September. They may be also sown in spring, and 
treated in the same manner. Two or three of these plants 
may be cultivated for the lake of variety, but they have not 
much beauty. Martin’s Miller.

Biserte, in Geography, a town of Tunis, seated on a 
small river which runs into the Upha, in the government of 
Perm. So miles S. E. of Perm.

Biserta, or Bizerta, a sea-port town of Africa, in 
the kingdom of Tunis, pleasantly situated upon a canal 
which wind a extensive lake and the sea, at the bottom of a 
large gulf, about 8 miles to the southward of Cape Blanco. 
N. lat. 35° 3'. E. long. 10° 15'. It is about a mile in cir-
cuit, defended by several castles and batteries, the principal 
of which are towards the east. Bizerta is a corruption of 
the " Hippo-Diarrhytus," or " Zarius" of the ancients; 
though the present inhabitants derive its name from their 
own language, and suppose it to be the same with " Ben-
ferth," i.e. the offspring of a canal or rivulet. The lake 
upon which Bizerta is seated has an open communication 
with the sea; and, according to an observation of the 
younger Pliny (Ep. xxxiii. l. 9.), is either continually 
receiving a fresh current from the sea, or else discharging 
one into it; so that the water loy the lake by exhalations 
is foon supplied by the sea, which in hot seasons runs into it 
with a very brill current, in order to maintain the equili-
trum, in the same manner as is observed between the 
Atlantic ocean and the Mediterranean. The millets of this 
lake are reckoned the best in Barbary. Great quantities of 
their rous are dried and made into " Botargo," and sent 
from hence to the Levant, where they are esteemed a very 
dainty. The channel of communication between the lake 
and the sea is the port of " Hippo-Diarrhytus," which still 
receives small vessels; though it must have been formerly 
the salt as well as the most beautiful haven of this part of 
Africa. There are still remaining the traces of a large pier, 
that was carried out into the sea, to break off the N. E. 
winds; the want of which, together with the disinfestation 
of the Turks to repair it, will in a short time make the 
harbour useless, which, in any other country, would be in-
cilimable. Scylax calls it only " Hippo," and Diodorus 
Scilicus gives it the name of " Hippoiana."

By the di-
rection of Scipio’s marches it seems to have been the rich 
aqueduct, now called Scipion, mentioned by Livy (x. xxix. 
289.) The Turks encouraged trade and industry. It would 
become an appellation, because, besides fish and fruit of all kinds, it 
abounds with corn, pulpe, oil, cotton, and a variety of other 
valuable productions. The gulph of Bizerta, the " Sinus 
Hippenceari," of the ancients, is a beautiful sandy inlet, 
nearly four leagues in breadth. As its bottom is low, it 
affords a delightful prospect through a variety of groves 
and plantations of olive trees, to a great distance into the 
country; but to the eastward the view is bounded by a 
high rocky shore, extending as far as cape Zibech. Bizerta 
was formerly a large town, and is said to have contained 
6000 houses; whereas now the town, and its dependent 
villages, scarcely contain the same number of inhabitants.

It has, nevertheless, two capacious prisons for slaves, a large 
3 P.'
Those who are advocates for the divine right of episcopacy, and who trace its institution to the times of the apostles, maintain that, in the earliest age of the Christian church, there were three different orders of ministers appointed by the apostles for the discharge of the public offices of religion: viz. bishops, priests, or prebendaries, and deacons. In proof of this point they refer us to the testimony of ancient ecclesiastical writers, whence they deduce, as they conceive, the most satisfactory evidence, that bishops were instituted by the apostles, and that they continued afterwards as a distinct order from that of priests. To this purpose they allege, that Irenæus, a father of the second century, says (l. iii. c. 3.), "We are able to enumerate those who by the apostles were made bishops in the several churches, and their successors, to this time." He adds, "Polycarp was not only instructed by the apostles, and acquainted with many of those who saw our Lord, but was also by the apostles made bishop of the church of Smyrna in Asia." Tertullian also, a writer of the same century (De Praefer. adv. Hetzel. p. 78.), challenges certain heretics to "exhibit the order of their bishops, following each other from the beginning, that the first bishop had for his author and predecessor some one of the apostles, or of those apostolical men who persevered with the apostles; for in this manner apostolical churches assert their rights: thus, the church of Smyrna has Polycarp, who was placed there by John; the church of Rome has Clement, who was ordained by Peter; and other churches have other persons, who, by being placed in the bishoprics by the apostles, transmitted the apostolical see." Cyprian also says (Ep. 69. ad Flor.), "that the bishop, who is one and presides over the church, through the proud presumption of certain persons, is defined; and thus the man, who is honoured by the sanction of God, is judged unworthy by men." In an epistle addressed to Ignatius (Ad Antioc. c. 7.), but probably spurious, though very ancient, it is asserted, that Evodius was consecrated a bishop by the apostles. And Chrysostom says (Hom. 42. in Ignat.), "that Ignatius converted familiarly with the apostles, and was perfectly acquainted with their doctrine, and had the hands of the apostles laid upon him." In a fragment of an epistle of Dionysius bishop of Corinth in the second century, preferred by Eusebius, (H. E. l. 4. c. 23.), it is said, that Dionysius the Areopagite, who was converted by St. Paul, was appointed the first bishop of Athens. Eusebius and Socrates have given us the catalogues of the bishops of many cities, from the times of the apostles; and Epiphanius (lib. 2. Haer. 66.) has left us a catalogue of the bishops of Jerusalem, from St. James the apostle to Hilary, who was bishop in his time. It is further alleged, that bishops, priests, and deacons, are mentioned together as three separate orders. Ignatius, in his Epistle to the Magnesians (§ 2.), mentions Damas as bishop of Magnesia. Basilius and Apollonius as prebendaries, and Sotian as deacon, in the same church; and in his epistle to the Philadelphians (§ 7.), he says, "Attend to the bishop, to the presbyter, and to the deacon;" and in his epistle to the Trallians (§ 2.), he says, "Be ye subject to the bishop, as to Jesus Christ; to the presbyters, as the apostles of Jesus Christ; and to the deacons, as to ministers of the mysteries of Jesus Christ." He then adds (§ 5.), "whether there be no elect church, no congregation of holy men." The authority of Ignatius, who lived in the beginning of the second century, is considered as decisive. Clement of Alexandria, in the subsequence part of the same century, speaks of the three progressive orders of deacons, priests, and bishops (Strom. l. 6.); and there are several early instances of bishops, who had been prebendaries and deacons in the same church. Irenæus was first prebendar, then bishop of...
bishop of Lyons; Dionysius first prebyter, then bishop of Rome; and Eleutherius, first deacon, then bishop of Rome; and all these three lived in the second century. "When your captains," says Tertullian (De Fuga in Perfo.), "that is to say, the deacons, prebyster, and bishops fly, who shall teach the laity that they must be constant?" And upon another occasion, speaking of baptism, he says (De Baptism. c. 17.), "the high-priest, who is the bishop, has the chief right of administering it, then the prebyster and deacons, but not without the authority of the bishop." Origin, in many places, speaks of bishops as superior to prebyster and deacons; and many authors compare the bishops, called by the Greeks archontes, and by the Latin fathers "summi facerdotes," and "principes facerdotum," prebyster and deacons of the Christian church to the high-priest, priests, and Levites under the Jewish dispensation; and hence prebyster afterwards obtained the name of priests. Clement, a disciple of the apostles, says (Ep. ad Cor. § 40.), "To the high-priest are given his proper duties; to the prebyster their proper place is assigned; and to the Levites their proper services are appointed;" in which passage this ancient father is speaking of the bishop, prebyster, and deacons of the Christian church; and Tertullian, in the passage just cited, called the bishop the high-priest. Jerome, though he is sometimes represented as unfavourable to the cause of episcopacy, is still more expressive, and denominates (Epist. ad Evag.) the order of bishops, prebyster, and deacons, an apostolical tradition. "To what purpose," says Optatus (ib. i.), "should I mention deacons, who are in the third, and prebyster who are in the second degree of priesthood, when the very heads and princes of all, even certain of the bishops themselves, were content to redeem life with the lofs of heaven?" In the tenth canoe of the council of Sardis, held A.D. 347, it is enjoined that a person should not be rashly and lightly appointed a bishop, a prebyster, or a deacon. It is further proceeded, that episcopal power was not called in question in the three first centuries; but towards the end of the fourth century, Aecius, an Arian, wrote against it, and maintained that there ought to be no order in the church superior to that of prebyster. Nevertheless, it is alleged that no advocate is found for his opinion in the centuries immediately following; and that even Aecius allowed there had been bishops in the Christian church from the earliest period. From these several testimonies it is inferred, that bishops were appointed by the apostles; that there were three distinct orders of ministers, viz. bishops, prebyster, and deacons, in the primitive church; and that there has been a regular succession of bishops from the apostolic age to the present time; and the enemies of episcopacy are challenged to produce evidence of the existence of a single ancient independent church fairly established, which was not governed by a bishop. While the apostles lived, the churches, it is said, were subject to their authority and government; and to this circumstance it is owing that little is said concerning the distinction and power of ministers, in the Acts and Epistles; but when the gospel was spread into distant parts, and the apostles were under a necessity of discharging their visits, or rendering them less frequent, they found it expedient for the better government of the Christians, and in order to put a stop to their schisms and contentions, which began to make their appearance both among the prebyster and their congregations, to place the supreme authority in one person, who, from the superintending care which he was to execute, was called Episcopus, a bishop; and this word, which was perhaps at first applied indiscriminately to all who had any spiritual office in the church, was now conferred on him who was its chief governor.

The bishops were at first appointed by the apostles, and afterwards chosen by the prebyster and the congregations at large; and in both cases they were generally taken from the prebyster of the respective churches, except in those instances in which they were the immediate companions of the apostles. Accordingly Jerome, (De Ecclest. Script.) where he is speaking, as it is supposed, of the apostolical times in which James was made Bishop of Jerusalem by the apostles; Timothy bishop of Ephesos, and Titus bishop of Crete, by St. Paul; and Polycarp bishop of Smyrna, by St. John; observes that "churches were governed by the common advice of prebyster; but when every one began to reckon those whom himself had baptized, his own, and not Chrift's, it was decreed in the whole world, that one, chosen out of the prebyster, should be placed over the reft, to whom all care of the church should belong, and to the leads of schism should be removed." When St. Paul was at Mileitus, A.D. 58, and convened the elders of the church at Ephesos, no mention is made of the bishop; and in his address to them he calls them "bishops or overseers of the flock," hence it is inferred, that the word bishop was not then the appropriated name of the person who held the first office in the church, or rather, that there was as yet no such person in the church at Ephesos. But in the year 64. St. Paul found it necessary to place Timothy in that situation, with power to prevent the preaching of any unfound doctrine, and to ordain and exercise authority over prebyster, that is, with episcopal power; and in his epistle, written to him in that year, he speaks expressly of the "office of a bishop," and gives a detailed account of the qualifications of a bishop. See 1 Tim. i. 3, v. 19, 22. 1 Tim. iii. 1. We have also a similar account in the epistle to Titus, written in the same year; and he was invested with the further power of rejecting heretics from the churches over which he presided. See Titus iii. 10. Hence it is concluded, that in the year 64 there was such an office as that of bishop. St. Paul, addressing his epistle to the Philippians, used the word bishops in the plural number, and does not mention prebyster; whence it is thought by Chrysostom, Theodoret, Jerome, and indeed by almost all commentators, that by bishops we are here to understand prebyster; and it is therefore presumed, that there was then no bishop, in the strict sense of the appellation, at Philippi. A.D. 62. From a comparison of these different passages it has been conjectured, that Paul began to establish episcopacy immediately after his release from his first confinement at Rome. However, it is acknowledge, that at this early period there was not a bishop in every church. Nevertheless, it is inferred from St. Paul's epistles, that he gave the ministers of the churches which he founded, a certain power over their respective congregations, and as St. Paul and the twelve apostles acted equally under the influence of the Holy Ghost, it is presumed that they invested all, whom they appointed to preach the gospel, with a similar degree of power; and thus church authority is derived from the apostles themselves. This power, thus originally given, was not limited to the primitive ages; it is supposed to have been transmitted to those "faithful men who shall be able to teach others after" (2 Tim. ii. 2), and to remain in the church under different modifications, as essentially necessary for the purposes specified by the apostle, Ephes. iv. 13, 14.

At first the jurisdiction of a bishop was confined to the walls of his own city; but afterwards, when the gospel made its way into towns and villages, the concours of the Christians that inhabited them, would naturally fall under the cognizance and direction of the bishops of the neighbouring cities; and thus dioceses would be gradually formed. See Diocesis. In prose of time, it is supposed, the affairs of the church would require the consultation and co-opc-
co-operation of different bishops; and therefore, as before, one of the presbyters of a city was raised to be a bishop, and  
we have authority over other presbyters, so one of the bishops  
of a province was selected and invested with certain authority  
over other bishops, and he was called an archbishop; and  
in the appointment of archbishops, the civil importance of the  
the city seems to have been regarded, for we find the met-  
ropolitan bishops were generally archbishops, and hence  
archbishops were called metropolitan. Archbishops, it has  
been said, were first appointed in the second century; and  
they had power to assemble the bishops within their respec-  
tive provinces, to regulate the election of bishops, to confer  
them, to hear appeals from their decisions; and to take  
cognizance of their general conduct. See Archbishop  
and Patriarch.

It is sometimes urged, that bishops, priests, and deacons,  
are now, in their office and authority, very different from  
what they formerly were; but this, say the advocates of  
episcopacy, is no more than a necessary consequence of a  
change of times and circumstances. They do not contend  
that the bishops, priests, and deacons of England are at pre-  
cent precisely the same that bishops, presbyters, and deacons,  
were in Asia Minor, 1700 years ago. They maintain, how-  
ever, that there have been always bishops, priests, and dea-  
cons in the Christian church, since the days of the apostles,  
with different powers and functions in different countries and  
at different periods; but the general principles and duties,  
which have respectively characterized these clerical orders,  
have been essentially the same at all times and in all places;  
and the variations which they have undergone, have only  
been such as have ever belonged to all persons in public situ-  
ations, whether civil or ecclesiastical, and which are, indeed,  
infenparable from every thing in which mankind are con-  
cerned in this transitory and fluctuating world. A learned  
prelate, who flatters himself that, by the testimonies and  
arguments, of which we have above given a general account,  
he has proved episcopacy to be an apostolical institution,  
readily acknowledges, however, that there is no precept in  
the New Testament, which commands that every church  
should be governed by bishops. As it has not pleased the  
Almighty to prescribe any particular form of civil govern-  
ment for the security of temporal comforts to his rational  
creatures; so neither has he prescribed any particular form  
of ecclesiastical policy as absolutely necessary to the attain-  
ment of eternal happiness. And though the Scriptures con-  
tain no directions concerning the establishment of a power by  
which ministers are to be admitted to their sacred office, yet  
he conceives, that from the apostles, episcopal ordination  
has been regularly conveyed to us; and the legislature of  
this kingdom has recognized and confirmed this power to  
bishops. See Ordination. Elements of Christian Theology,  

Persons, on the other hand, who do not admit episcopacy  
to be of apostolical and divine institution, contend, that  
the terms πρεσβυτέρος and πρεσβυτέρος, that is, bishop and  
presbyter, are used promiscuously in the New Testament, to  
which they think it necessary to appeal, as to the sole au-  
thoritative rule of faith and practice, and that they de-  
note the same, and not a distinct order or office in the Christian  
cirrh. To this purpose they allege the passage already  
cited, Acts xx. 17, 28, in which the same persons are de-  
nominated presbyters and bishops. Thus also the name, of-  

go, and work of a bishop and presbyter appear to be the  

But nor is it of any con-  
sequence whether we call their pastors bishops with the apol-  

e, or preachers with Polycarp, as both speak of two or-  
ders only among them. In the whole book of Acts, the  

tated pastors of the churches are denominated presbyters;  

collection for the poor Christians is sent to the preby-  

ders, or preachers with Polycarp, as both speak of two or-  

ders only among them. In the whole book of Acts, the  

tated pastors of the churches are denominated presbyters;  

collection for the poor Christians is sent to the preby-  

ders, or preachers with Polycarp, as both speak of two or-  

ders only among them. In the whole book of Acts, the  

tated pastors of the churches are denominated pre-  

BISHOP.

The word πρεσβυτέρος, it is said, was properly the  
name of office, and πρεσβυτέρος was a title of respect, bor-  
rowed from the Jewish customs, which was analogous to that  
of other nations, of calling not only the members of the  
Sanhedrim πρεσβυτέρος, elders or seniors, but also the mem-  
ers of the city council. It has been moreover affirmed,  
that a single passage from the apologetic writings has yet  
been produced, in which it appears from the context, that  
the two terms πρεσβυτέρος and πρεσβυτέρος mean different offices;  
and that there is the strongest positive evidence, which  
the nature of the thing can admit, that in these writings the  
two terms uniformly mean the same office. The Apostle  
Paul, in the directions he gave to Timothy, about the pro-  
per supply of churches with suitable ministers, takes parti-  
cular notice, merely, of two orders, one called bishops, and  
the other deacons; and hence, it is argued, that if by bi-  

s upstairs is the author of whom we speak, it was di-  

tinct from the num-  
bers of those who, in the book of Acts, are  
called πρεσβύτερος, presbyters, or ordinary teachers. Since it  
must therefore be admitted, that in the New Testament,  
and also in this work of Clement, the words πρεσβυτέρος and  
πρεσβυτέρος are not occasionally, but uniformly, used syno-  
ymously, the discovery that there was not any distinctive  
appellation for such an office as that now called bishop, is  
adduced as affording a strong presumption, that it did not  
exist. Another testimony alleged to the same purpose is  

§
that of Polycarp, who takes notice only of two orders of ministers in the church; for in ch. v. of his epistle to the Philippians, he enjoins the people to be subject to their prebishops and deacons, as to God and Christ; hence it is inferred, that if this ancient father had known of any higher order in the church, such as was that of a bishop in less than 350 years after his time, he would have been the principal, if not the only person, to whom his subjection would have been enjoined by a Christian writer. It is observed further, that though he specifies the duties and qualifications of deacons in ch. v. and those of prebishops in ch. vi. and through the whole of the epistle, those of the people, he no where mentions what is proper in the character and conduct of a bishop. Upon the whole, it seems evident that Polycarp knew of no Christian minister superior to the prebishops.

It has been alleged by the advocates of episcopacy, that the bishops are the proper successors of the apostles, not in the general character of teachers, but in their special functions as apostles (see Stillingfleet's works, vol. i. p. 371.); whilst the prebishops and deacons were merely the successors of those who were, in the beginning, ordained by the apostles. But that the apostles could not have any proper successors has been evinced by the following considerations. The indisputable requisite in the character of an apostle, which was that of having seen Jesus Christ after his resurrection, demonstrates that their office could be but temporary. Besides, they were distinguished by prerogatives, which did not depend on any after them; of this kind were their having received their mission immediately from Christ, and not by any human ordination or appointment; the power of conferring miraculous gifts by imposition of hands; and the knowledge which they had by inspiration of the whole doctrine of Christ. Moreover, the object of their mission was altogether of a different kind from that of any ordinary pastor; and this was to propagate the gospel throughout the world both among Jews and Pagans, and not to take charge of any particular flock. Further, as a full proof that the matter was thus universally understood, both in their own age, and in the times immediately succeeding, no one, on the death of an apostle, was ever substituted in his room; insomuch that when that faceless college was extinct, the title became extinct with it. It is alike true also of the evangelists, that their office was temporary, and that their charge extended to the whole church; and their titles, like that of an apostle, were only enjoyed by those who first enjoyed it. Such were Philip, Timothy, Titus, and probably Mark, and Luke. As to the dates or postscripts subjoined to the epistles in the common bibles, and distinguishing Timothy and Titus by the appellation of bishops, it is now universally agreed among the learned, that they are of no authority. They are not found in some of our best and most ancient MSS.; and they are generally allowed to be the spurious additions of some eastern bishop or monk, at least 500 years after Christ. It is certain, however, that in the three first centuries, neither Timothy nor Titus is styled bishop by any writer. In the island of Crete, of which Titus is said to have been ordained the first bishop, there were no fewer, according to the earliest accounts and catalogues extant, than 11 bishops. Indeed, so little can the infractions given by Paul to Timothy and Titus be made to quadrate with any ordinary ministry that ever obtained in the church, that the learned Dr. Whitby (see his Preface to the epistle to Titus) concludes, that their was extraordinary as well as temporary, and that they were not succeeded in it by any that came after them. Hence it is inferred, that all the arguments alleged in favour of the distinction between bishops and prebishops in the early age of the church, by Epiphanius and others, from some passages in the epistles to Timothy and Titus, proceed upon the mistaken notion, that they were properly bishops in the modern acceptation of the term; a notion utterly unknown to that Christian antiquity, which denies the name of primitive, and also incompatible with the authentic accounts we have concerning these extraordinary ministers, who were not made bishops till about 500 years after their death.

Some have deduced an argument in favour of the apostolical antiquity of episcopacy, from the epistles to the seven churches of Asia mentioned in the Apocalypse, which are addressed to the angels of those churches separately in the singular number. From the first chapter of that book it appears, that each epistle is intended for the whole church or congregation mentioned in the direction or superscription; and yet one person, called the angel of that church, is addressed in the name of the whole. Hence some have inferred, that the person denounced as angel, was an order differing from that of other ministers, and superior to it; whilst others have considered the appellation as descriptive of the whole collective body. An intermediate opinion, advanced by some critics, is more probable. This supposes the necessity, for the sake of order, that in their controversies or congregations one should preside, both in the offices of religion, and in the consultations for the common good; and that this presiding, or chairman, is here addressed under the name of angel. This interpretation affords us also the most plausible account of the origin of the more considerable distinction, which afterwards obtained between bishop and preb. It was the distinction of one pastor in every church, marked by the apostle John, though not made by any who had written before him, which led Tertullian, whole publication first appeared about a century after the epistles, to consider him as the institutor of episcopacy. By those who deny the superiority of bishops to prebishops in the first age of the church, it is alleged, that the first reformers and founders of the church of England, as well as many of their most learned and eminent doctors, have not pretended this distinction to be of divine, but merely of human invention; not grounded upon scripture, but only upon the custom or ordinances of this realm. To this purpose, the declaration made of the function, &c. of bishops and priests, and signed by more than 37 civilians and divines, among whom were 13 bishops, Cranmer and others, affirms, that in the New Testament there is no mention made of any degrees or distinctions in orders, but only of deacons or ministers, and of priests or bishops. (See D. Burnet's Hist. Ref. vol. i. Append. p. 321.) Besides, the book, entitled "The Institution of a Christian Man," subscribed by the clergy in convocation, and confirmed by parliament, owns bishops and prebishops to be the same. Moreover, that the main ground of settling episcopal government in this nation, was not any pretence of divine right, but the convenience of that form of church government to the late and condition of the church at the time of the reformation, the learned Stillingfleet affirms (Iren. c. 8. Works, vol. ii. p. 356, &c.), and proves it to be the sentiment of archbishop Cranmer and of other reformers, in the reigns of Edward VI. and of queen Elizabeth, such as archbishop Whitgift, bishop Bridges,loe, Hooker, Sutcliffe, Hale, Challonerworth, &c. It was also the opinion of archbishop Usher, that bishop and preb. differed only in degree and not in order, and that in places where bishops could not be procured, the ordination of prebishops was valid. Subse- Order. "As for the notion of different offices of bishop and preb., says bishop Burnet, in his "Vindication of the church of Scotland," p. 336. "I confess it is not to clear
BISHOP.

clear to me, and therefore since I look upon the sacramental actions as the highest of sacred performances, I cannot but acknowledge those who are empowered for them must be of the highest office in the church.

Although, in the apostolic times, bishops and presbyters were synonymous, and co-ordinate with respect to their ministerial powers, and they were ordained to their office by prayer, accompanied with imposition of hands; yet a certain priority, or presidency, for the sake of order, or in deference either to seniority or to distinguished talents, was allowed to one of their number. But he seems to have been only a kind of moderator in their assemblies, and to have had no more power than that of giving a single vote in common with the rest of his brethren. By those who adopt this reasoning, and who trace the original of the diocesan order of bishops, which was introduced in the second and third centuries, to this practice, it is allowed that pastors were from the beginning vested with a superintendency over the congregation or church merely in spiritual matters; and it is alleged, that some of the titles that are thus given them in Scripture, such as πρεσβυτήριον, πρεσβυτερίου, guides and governors, imply this kind of superintendency. But at this time several things relating to the church were conducted in common by the pastors, the deacons, and the whole congregation. To this class we may refer all matters of scandal and offense, and also the election of their pastors and their deacons. Accordingly, Clement, in the fore-cited epistle, ch. xlvii. speaking of the pastors, uses this expression: "Those who were constituted by the apostles, and afterwards by other eminent men, with the consent of the whole congregation." It appears also, by the epistles of Cyprian, written about the middle of the third century, that for the first three ages of the church, no final resolution was taken in any affair of moment, without communicating it to the people, and obtaining their approbation. In the second century a settled distinction obtained, in several respects, between the president, chosen by a plurality of votes, and distinguished by the appropriate title of bishop, which had before been common to all the presbyters, and the other presbyters. Many other titles, besides that of bishop, which they had all enjoyed in common, were restricted to him who was regarded as their head, such as πρεσβυτήριον, πρεσβυτερίου, πρεσβυτέρου, νεάσκες, πατριάρχης, and some others. These titles, independently of the talents, virtues and services that attended them, claimed respect and deference. The concurrence of the president thus honoured, was considered as a necessary function to all ecclesiastical resolutions and measures; and by degrees every act became valid which bore the stamp of his authority. Those who presided over churches, which were established in some of the principal cities, were honoured with peculiar pre-eminence, and to this advancement analogy to the civil government did not a little contribute. It is not improbable, that the church of Jerusalem, when it became numerous, and was deprived of the ministrv of the apostles, who were gone to instruct the other nations, was the first which chose a president or bishop; nor it it less probable, that the other churches followed by degrees this example.

The first ancient author who mentions bishop, presbyter, and deacon, as three distinct orders in the church, is, as we have already observed, Ignatius, who is supposed to have written about the 16th year of the second century. But as several of the epistles ascribed to him, are spurious, no great stress can be laid upon his authority. However, he feems, with peculiar earmenfes, to inculcate obedience and subjection to the bishop, as well as to the presbyters and deacons. Mr. Dodwell accounts for his zeal in establishing the bishop's authority, by supposing that it was at that time a new thing, totally unknown in the church; and, according to this opinion, he says, that it is in vain to look for any trace of episcopal authority in the New Testament. Ireneus, who is supposed to have written about the middle of the second century, sometimes uses the names bishop and presbyter indifferently, and at other times with some kind of distinction; but it is not easy to determine, whether by these two appellations he means the same order, or two different orders. Dr. Pearson admits that these names are often interchanged by this father, and others of his time, even to the end of the century; but he affirms at the same time, that in regard to their own contemporaries, the offices of individuals are never thus confounded, inasmuch that a person who was in the time a bishop, is not called a presbyter, nor is a presbyter called a bishop. It is allowed, that the distinction of these orders began about this time generally to prevail, though the difference was not nearly so considerable as it became afterwards. Another author, by whom the three orders seem to be discriminated, and whose testimony is commonly adduced in support of their apostolical institution, is Pius, bishop of Rome, who is supposed to have written before the middle of the second century, but after Ignatius and Polycarp: he uses an expression, however, which does not indicate any high opinion of the superiority of the bishop in his time; "Let the prebendaries and deacons reverence thee (the bishop), not as their superior, but as Christ's minister." Clement of Alexandria, at the close of the second century (see his Strom. l. 1.), strongly marks the distinction between presbyter and deacon; but he seems to intimate, that the distinction between bishop and presbyter was, even in his days, comparatively not worthy of his notice. At this time, however, every church had its own pastor, or bishop, and only one under this appellation, and every bishop had only one congregation or church. Sir Peter, afterwards lord, King (ubi infra) has proved these affirmations by a variety of citations from ancient writers; he has also shown, that a bishop's diocese did not exceed the bounds of a modern parish. See DIODE. The prebendaries, according to this writer, were the curates and affilies of the bishop, and though inferior to them in degree, yet they had the same inherent right with the bishops, and were equal to them in order. "A bishop," says this author, "preached, baptized, and confirmed, he did a presbyter; a bishop excommunicated, absolved, and ordained, he did a presbyter; whatever a bishop did, the same a presbyter; the particular acts of their office were the same." In the age of Cyprian, about the middle of the third century, it appears that the prebendaries were considered as vested with the power of conferring orders. (Cyp. Epit. 5. and 75.) In the age of Hilary, about the middle of the fourth century, it appears, that the whole distinction of the episcopate is ascribed by him to seniority in the ministry, without either election or special ordination. When the bishop died, the lesser colleague succeeded of course. As to ordination it was the same in both; and bishop meant no more than a priest among the prebendaries, or a lesser presbyter. Jerome, who wrote about the end of the fourth and beginning of the fifth century, says (In Titum. l. 5. Op. vol. x. p. 1700.) that, among the ancients, priests and bishops were the same; but that by degrees the care of a church was assigned to one person, in order to prevent dispersion. In another place (Op. vol. vi. p. 198.) he says, "Let the bishops know, that they are above priests more by custom than by the appointment of Christ." He also observes (Aeneidotes, p. 24. 54.) that at the beginning, churches were governed by the common council of prebendaries, like an aristocracy; but afterwards the superintendency was given to one of the prebendaries,
BISHOP.

Who, as is then called the bishop, and who governed the church, but still with the council of the prebysters. Dr. Hammond (Ann. Acts xi. 35.) has advanced a singular opinion, viz. that the apostles instituted only the offices of bishop and deacon, and that the intermediate office of prebyster was soon afterwards introduced. But that such a middle order should be erected at once, immediately after the times of the apostles, is much more unlikely, than that it arose gradually out of an inconsiderable distinction, which had obtained from the beginning.

At the close of the third century, the ecclesiastical government, which very generally prevailed, was of that kind which might justly be denominated a parochial episcopacy. The bishop, who was properly the pastor, had the charge of a single parish; and the parishioners assembled for the purposes of public worship, and for the celebration of religious institutions, in one place, at which the bishop commonly presided; the bishop was supplied by prebysters, who formed his council in judicial and deliberative matters, and who performed religious functions both public and private. To these were added deacons. See DEACON. The next step was the extension of the oversight of one bishop to many congregations, which branched out of the original church by an accession of converts; and in this stage of the progress of episcopacy, the several prebysters had their separate parishes, and continued in subordination to the bishop, who was acknowledged as their common head. At this period, an order of bishops, called choripope, or rural bishops (see CHORIPHOI), held the middle rank between bishops and prebysters, being inferior to the former, and superior to the latter. This state of the church may be denominated dioecesan episcopacy.

Though bishops, in the opinion of those whose sentiments are now representing, were originally no other than prebysters; the manner of their originating being the same, and the prebysters discharging every part of the office of a bishop; no sooner was the distinction between them established, than the bishops began to appropriate certain functions to themselves. It appears, by the act of the third council of Carthage, A. D. 397, that, whereas, before, priests had the power of administering the time of public penance, and of giving absolution, as also of conferring virginity, and of making the churin, without the advice of the bishop, all these things were forbidden by these canons, and appropriated to the bishops. But the principal circumstance by which the bishops were afterwards distinguished, was the power of confirming the baptized, when that churin was applied. See CONFIRMATION. After the reign of Adrian, when Jerusalem was utterly destroyed, and the Jews dispersed, an opinion began to prevail among Christianans, that their ministers succeed to the characters, rights, and privileges of the Jewish priesthood; and this was another source of honour and profit to the clergy. Another circumstance, which contributed in no small degree to the progress of episcopal authority, was the constitution of provincial councils, which infallibly superseded the importance of particular churches, and enabled the bishops by an alliance with them to obtain a much larger share of executive and arbitrary power. As soon as they became connected by a feeble of their common interest, they were empowered to attack, with united vigour, the original rights of their clergy and people. "The prelates of the third century," says Gibbon (Hist. vol. ii. p. 335, &c.), "imperceptibly changed the language of exhortation into that of command, scattered the seeds of future usurpations, and flipp'd, by scripture allegories and declamatory rhetoric, their deficiency of force and reason. They exalted the unity and power of the church, as it was represented in the episcopal office, of which every bishop enjoyed an equal and undivided portion. Princes and magistrates, it was often repeated, might hold an earthly claim to a transitory dominion; it was the episcopal authority alone, which was derived from the deity, and extended itself over this and another world. The bishops were the vicegerents of Christ, the successors of the apostles, and the mystic substitutes of the high priest of the Mosaic law. Their exclusive privilege of conferring the facerdotal character invaded the freedom of clerical and popular election; and if, in the administration of the church, they still consulted the judgment of the prebysters, or the inclination of the people, they most carefully inculcated the merit of such a voluntary coöperation. The bishops acknowledged the supreme authority which reigned in the assembly of their brethren; but in the government of his peculiar diocese, each of them exacted from his flock, the same implicit obedience, as if that favourite metaphor had been literally true, and as if the shepherd had been of a more exalted nature than that of his sheep. The same caesars, which at first had destroyed the equality of the prebysters, introduced among the bishops a pre-eminence of rank, and from thence a superiority of jurisdiction. In spring and autumn, when they met in provincial synods, the multitude was governed by the will of a few; and, besides, the office of perpetual presidents in the councils of each province, was conferred on the bishops of the principal city; and these aspiring prelates, who soon acquired the lofty titles of metropolitans and primates, secretly prepared themselves to usurp over their episcopal brethren the same authority which the bishops had to lately assumed above the college of prebysters. Hence gradually arose the pre-eminence which the ambition of the Roman pontiff gained over the other provinces and churches. King's Constitution, &c. of the Primitive Church, ch. 1—v. Campbell's Eccl. Hist. vol. ii. Moth. Eccl. Hist. vol. i. p. 104, &c. Neal's Hist. Purit. vol. i. p. 670, &c. 410. Pierce's Vindication.

It is the opinion of many approved writers on this subject, among whom may be reckoned many episcopalian and dissenters in our own country, and many learned foreigners, that no particular form of church government was authoritatively preferred either by our Lord or his apostles; but that Christianans were left at liberty to choose such as might be best adapted to their circumstances and to the state of society, and most conducing to the edification and tranquillity of the church, and of individuals in future ages. See CHURCH.

When new occasions required new measures, in a little time the functions of the priesthood were divided, and the prelats distinguished into degrees; the political part of religion being assigned principally to bishops, and the evangelical to the priests, &c. or rather, as some will have it, the functions of teaching and preaching were referred to the bishop, and that of ordination superadded; which was their principal distinction, and the mark of their sovereignty in their diocese.

By the ancient discipline, bishops were to be married once, and not to put away their wives on pretence of religion; but a second marriage was a disqualification for this order. If they lived chaste, they were ranked as confessors.

Some bishops in the middle ages, on account of their regalia, or temporalities, were obliged to a military service called bojitis, by which they were to lead their valets into the field, and attend the king in his military expeditions. This Charlemagne excused, and even forbade; but the prohibition was little regarded, since we find the thing often practised afterwards. Du Cange.

The election of bishops was anciently placed in the clergy and
and the people of the parish, province, or diocese, or of the clergy and laity, as they were afterwards called; nor did any church apply to the neighbouring bishops to assist at the ordination. Trenchus was ordained by priests only; and such was the general custom of the church of Alexandria, till the beginning of the fourth century. Cyprian also says, that it belonged to the people chiefly to choose worthy pastors, and to refuse the unworthy. Thus Alexander was chosen bishop of Jerusalem. Fabianus and Cornelius of Rome, and Cyprian of Carthage. When the people had thus elected a bishop, they presented him to the neighbouring bishops for their approbation and consent; because, without their concurrent assent, no bishop could be legally instituted or confirmed. This was the case with regard to Alexander, already mentioned, and Sabinus, bishop of Emerita in Spain. After election and confirmation, the next act was the ordination or investiture of the bishop, which was done in his own church by the neighbouring bishops, who were invited to attend on the occasion. The attendance of the neighbouring bishops, which seems to have been at first voluntary on both sides, became customary, and at length necessary; and it was an established rule, that the concurrence of these was indispensible, one of whom laid his hand on the head of the new bishop, when he was recommended by prayer to the blessing of God. In the third century, this was always done by the metropolitan bishop; or at least it was never done without his consent or order. The second council of Nice ordered that bishops should be chosen by other bishops; but in the west, the people preferred the right of choosing their bishops, till after the reign of Charlemagne and his sons; and it was not taken from them till the council of Avignon, in 1550.

Under the plea of the tumult that attended popular elections, the emperors and other sovereigns of Europe, took the appointment in some degree into their own hands; referring to themselves the right of confirming these elections, and of granting investiture of the temporalities, without which confirmation and investiture, the elected bishop could neither be consecrated, nor receive any secular profits. This right was acknowledged in the emperor Charlemagne, A. D. 773, by pope Adrian I. and the council of Lateran, and universally exercised by other Christian princes; but the policy of the court of Rome contrived to exclude the laity from any share in these elections, and to confine them wholly to the clergy; but the mere form of election appeared to the people to be of little consequence, while the crown was in possession of an absolute negative, which was almost equivalent to a direct right of nomination. Indeed, princes and magnates, patriarchs and popes, have usurped the power of electing bishops. The election was to be within three months after the vacancy of the see; and the person to be chosen out of the clergy of that church. Formerly the bishop claimed a share in the election of an archbishop; but this was set aside by the popes.

In England, during the Saxon times, the right of appointing to bishoprics is said to have been in the crown, because the rights of confirmation and investiture were, in effect, though not in form, a right of complete donation. But when, by length of time, the custom of making elections by the clergy was fully established, the popes began to except to the usual method of granting these investitures, which was “per annumum et baculum,” by the prince’s delivering to the prelate a ring, and pastoral staff, or crozier; pretending that this was an encroachment on the church’s authority, and an attempt by these symbols to confer a spiritual jurisdiction; and pope Gregory VII. about the close of the 11th century, published a bull of excommunication against all princes who should dare to confer investitures, and all prelates who should venture to receive them. At length, however, when the emperor Henry V. agreed to remove all suspicion of incroachment on the spiritual character by conferring investitures for the future “per seepetrum” and not “per annumum et baculum;” and when the kings of England and France contented also to alter the form of their kingdoms, and receive only homage from the bishops for their temporalities, instead of investing them by the ring and crozier; the court of Rome found it prudent to suspend, for a while, the other pretensions. This concession was obtained from king Henry I. in England, by means of that obilinate and arrogant prelate archbishop Anselm; but king John, about a century afterwards, in order to obtain the protection of the pope against his discontented barons, was also prevailed upon to give up by a charter, to all the monasteries and cathedrals in the kingdom, the free right of electing their prelates, whether abbots or bishops; reserving only to the crown the custody of the temporalities during the vacancy; the form of granting a licence to elect, which is the original of our "congé d’élecr," on refusal whereof the electors might proceed without it, and the right of approbation afterwards, which was not to be denied without a reasonable and lawful cause. This grant was expressly recognized and confirmed in king John’s Magna Charta, and was again established by flat. 25 Ed. Ill. 6. § 3. But by flat. 25 Hen. VII. cap. 20, the ancient right of nomination was, in effect, restored to the crown. The English consecration of prelate bishops stands on this ground. The king being certified of the death of a bishop by the dean and chapter, and his leave requested to elect another, the conég d’élecr, or usual licence, is sent to them, with a letter missive, nominating the person whom he would have chosen. The election is to be within two days after the receipt of it, otherwise the king by letters patent appoints whom he pleases; and the chapter in case of refusing the person named by the king, incurs a premarvce. The election or nomination, if it be of a bishop, must be signified by the king’s letters patent to the archbishop of the province; if it be of an archbishop, to the other archbishop and two bishops; or to four bishops; requiring them to confirm, invest, and consecrate the person so elected; which they are bound to perform immediately, without any application to the see of Rome. If such archbishop, or bishops, refuse to confirm, invest, and consecrate such bishop elect, they shall incur all the penalties of a premarvce. After election, and its being accepted of by the bishop, the king grants a mandate under the great seal for confirmation, which the archbishop confers to his vicar-general, confining mostly in a solemn citation of such as have any objections to the bishop elect, a declaration of their contentious in not appearing; and an administration of the oaths of allegiance and supremacy, of homage, and canonical obedience. Sentence being read by the vicar-general, the bishop is installed in the province of Canterbury by the archdeacon; the act is recorded by a public notary; and the bishop is invested with full powers to exercise all spiritual jurisdictions, though he cannot use for his temporalities till after consecration. Then follows the consecration by the archbishop, or some other bishop appointed by lawful collations, and two suffit bishops: the ceremony of which is much the same as in the Romish church, save that, having put on the episcopal robe, the archbishop and bishops lay their hands on the new prelate’s head, and consecrate him with a certain form of words. The fees of the whole proceed are said to amount to about 600l. 1

1 The proceeds of the translation of a bishop to another bishopric.
he is then examined as to his faith; and after several prayers, the New Testament is drawn over his head, and he receives the串munion and unction on his head. The pastoral staff, ring, and Gospels, are then given him; and after communion, the mitre is put on his head: each ceremony being accompanied with proper prayers, &c. the consecration ends with Te Deum.

These last mentioned ceremonies are laid aside in the consecration of English bishops. Nevertheless, the book of consecration, composed by the bishops, and approved by Edward VI. in the third year of his reign, and two years afterwards, confirmed by act of parliament, in which some of them are enjoined, is declared to be the standard for this purpose by the thirty-sixth article. In queen Mary's reign this act was repealed, and the book of common prayer, and the book of ordination, were by same condemned. When Elizabeth came to the throne, queen Mary's act was repealed, and king Edward's prayer-book was again authorized; but the book of ordination was not expressly named, because it had been a part of the common prayer book; and therefore it was not thought necessary to specify the office of ordination any more than any other office of the common prayer book. But bishop Bonner contended, that as the book of ordination had been by common condemned in queen Mary's reign, and had not been since revived by name, it was still condemned in law; and, consequently, that all ordinations conferred according to that form, were illegal and invalid. To obviate this objection, it was declared in a subsequent session of parliament, that the office of ordination was considered as part of the common prayer book; and it was further declared, that all ordinations which had been performed according to that office, were valid; and upon the same principle a similar clause was inserted in the 36th article.

The function of a bishop in England may be considered as two-fold: viz. what belongs to his order, and what belongs to his jurisdiction. To the episcopal order belong the ceremonies of dedication, confirmation, and ordination; to the episcopal jurisdiction, by the statute law, belong the licensing of physicians, surgeons, and schoolmasters, the making small parishes (though this last privilege is now peculiar to the bishop of Norwich), assiling the civil magistrate in the execution of statutes relating to ecclesiastical matters, and compelling the payment of tithes and subsidies due from the clergy.

By the common law, the bishop is to certify the judges, touching legitimate and illegitimate births and marriages; and by that and the ecclesiastical law, he is to take care of the probate of wills, and granting administrations; to collate to benefices, grant visitation on the presentation of other patrons, command induction, order the collecting and preferring the profits of vacant benefices for the use of the beneficaries, defend the liberties of the church, and visit his diocese once in three years. To the bishop also belong suffragio, deprivation, deposition, degradation, and excommunication.

The bishops of England are all barons: barons in a three-fold manner: viz. feudal, in regard of lands and baronies annexed to their bishopries; by writ, as being summoned by writ to parliament; and also by patron and creation. When William the Conqueror thought proper to change the spiritual tenure of frank-almoign, or free alms, under which the bishops held their lands during the Saxon government, into the feudal or Norman tenure by barony; their clergies were subjected to all civil charges and alleviations, from which they were before exempt; and, in right of succession to those baronies, which were unalienable from their respective
positive dignities, the bishops and abbots were also vested their seats in the house of lords. But though these lords spiritual are, in the eye of the law, a distinct estate from the lords temporal, and are so distinguished in most of our acts of parliament, yet in practice they are usually blended together under one name of "the lords;" they intermix in their votes; and the majority of such intermixtures joins both estates. And from this want of a separate assembly, and separate negative of the prelates, some writers have argued very cogently, that the lords spiritual and temporal are now in reality only one estate; which is unquestionably true in every effectual sense, though the ancient distinction between them still nominally continues. For if a bill should pass their house, there is no doubt of its validity, though every lord spiritual should vote against it, of which Selden and Sir Edward Coke give many instances; as, on the other hand, judge Blackstone prefixes it would be equally good, if the lords temporal present were inferior to the bishops in number, and every one of those temporal lords gave his vote to reject the bill; though Sir Edward Coke seems to doubt, whether this would not be an " ordinance," rather than an "act," of parliament. El. Com. vol. i. 156. Bishops have the precedence of all other barons, and sit in the upper house as barons. They are twenty-four in number, exclusive of the bishop of Sodor and Man, who has no seat in the house of peers, besides two archbishops. Archbishops are distinguished by the titles of "Grace," and "Most reverend father in God by divine Providence;" and bishops, by those of "Lord," and "Right reverend father in God by divine permission." The former are said to be "infronied," and the latter "infallible." See Archbishop.

With respect to the order of precedence among one another, the archbishop of Canterbury takes the lead, then the archbishop of York, next to him the bishops of London, of Durham, and of Winchester. The other bishops follow according to the seniority of their consecration; excepting only, that a bishop being a privy counsellor, takes place after the bishop of Durham.

Bishops have two great privileges next to regal: the first, that in their courts they sit, and pass sentence, of themselves, and by their own authority; the bishops' courts being not like other courts, but writs are sent out in their own name, to the bishop, not in the king's name, as is done in the king's courts: the second, that, like the king, they can deputize their authority to another, as their suffragan, chancellor, commissary, &c.

They have this advantage also over lay-lords, that, in whatever Christain country they are, their episcopal degree and dignity are acknowledged; and they may, quatenus bishops, ordain, &c.

They have several immunities, as from arrest, outlawries, distress, &c. liberty to hunt in the king's forests, &c. to have certain sums of wine duty free, &c. Their persons may not be seiz'd, as lay-peers may, upon contempt, but their temporalities alone. They may qualify as many chaplains as a duke, viz. fix. But, as they have no right to be tried in the court of the lordship, as peers, they ought not to be judges there. For, though they are lords of parliament, and sit there by virtue of the baronies, which they hold "jure ecclcsiae," yet they are not ennobled in blood, and consequently not peers with the nobility, but merely lords of parliament. 3 Inst. 30, 31. Stauf. P. C. 253. In cases of capital offence, the bishops usually withdraw voluntarily, but enter a protest, declaring their right to stay. It is observable, that in the 11th chapter of the constitutions of Clarendon, made in parliament 1 Henry II. they are expressly excused, rather than excluded, from sitting or voting in trials, when they come to concern life or limb. The determination of the house of lords in the earl of Danby's case, (Lords' Journ. 15 May, 1679), which hath ever since been adhered to, is consonant to these constitutions, "that the lords spiritual have a right to stay and sit in court in capital cases, till the court proceeds to the vote of guilty, or not." This resolution, however, extends only to trials in full parliament; for to the court of the lord high steward, in which no vote can be given but merely that of guilty, or not guilty, no bishop, as such, ever was or could be summoned: and though the statute of King William regulates the proceedings in that court, yet it never intended to new-model or alter its constitution, and consequently does not give the lords spiritual any right in cases of blood which they had not before; and their exclusion is more reasonable, because having no right to be tried in this court, as we have already said, they ought not to be judges there.

By law, the crime of episcopal, which a clergyman commits by killing his bishop, is petty treason.

In Canada there is a bishop, resident at Quebec; and there are two bishops in America. In Denmark they have no archbishop, but there are five superintendents, or bishops; four in Norway, and two in Iceland. The chief see is that of Zealand, which yields about 1000l. a year; the others are those of Funen, valued at 760l., Aarhus at 600l., Aalborg at 400l., Ribe at 300l.; in Norway, Christiana or Aggerhus at 400l., Christianland at 600l., Bergen at 400l., and Drontheim at 300l. The bishoprics of Skalhol and Holm, in Iceland, are only valued each at 150l.; but though far inferior in nominal value to the others, they may be considered, on account of the cheapness of living in Iceland, equal in real profit to the largest of the other. The bishop of Zealand, who is first in rank, and the bishop of Aggerhus, are metropolitans. They have no temporalities; keep no ecclesiastical courts; have no cathedrals or prebends, &c. but are only primi inter pares, having the rank above the inferior clergy of the province, and inspection over their doctrine and manners. They are allowed two or three parishes each. Their habit is common with that of the other ministers. In Sweden are fourteen dioceses; the archbishopric of Upsala, and the bishoprics of Linkoping, Skara, Streng promotions, Wecleras, Wexio, Abo, Lund, Bor- go, Gothcberg, Calmar, Carlctad, Herionland, and Wifh-, or Gotland. The revenues of Upsala and Wecleras amount to about 1000l. a year; and those of the lowest bishoprics to 300l. There are also three superintendents, who rank as bishops, but do not sit in the house; these are the first chaplain to the king, the rector of St. Nicholas at Stockholm, and the first chaplain of the navy. The bishops are bound to reside, except during the meeting of the diet. A conßùry of the clergy of the diocese elects the archbishop and bishops, by presenting them to the king for his nomination. They have also ecclesiastical courts, &c.

Bishop-ulhor, episcopus abbas, was an abbot invested with the episcopal order; of which we meet with several in the richer and more considerable monasteries.

Bishop, acrarchibula, he who is immediately subject to the papal see, without any metropolitan over him.

Bishop, bor. It was an ancient custom in such churches as had cathedral service, for the little choristers, on St. Nicholas' day, December the 6th, to elect one of their number to be the episcopus purorum, the beam, i.e. infant, or chorister bishop; who continued to preside over the ref, with an imitation of all the episcopal functions, till Innocent's day, Dec. 28, and then, after solemn proceessions and great pageantry, he laid down his office. He was chosen.
BISHOP.

chosen on St. Nicholas' day, because St. Nicholas was the
patron saint of children; he dying, when an infant, shewn
such singular piety, as the legend says, that when he was
at his mother's breast, he would not suck on Wednesdays
and Fridays, that he might observe the fasts of the
chapel.

The ceremonies attending the investiture of the episcopus
prœorum, are prescribed by the statutes of the church of
Sarum, which contain a title de episcopo chapt¡rorum; and
also by the provincial. From these it appears, that he
was to bear the name and state of a bishop, habited, with a
crozier or pastoral staff in his hand, and a mitre on his head.
His fellows, the rest of the children of the choir, were to
take upon them the style and office of prebendaries, and
yield to the bishop canonical obedience; and farther, the
same service as the very bishop himself, with his dean and
prebendaries, had they been to officiate, were to have per-
formed, the very same, maps excepted, was done by the
choristers and his canons upon the eve and the holiday.
The use of Sarum required also, that upon the eve of Ino-
cent's day, the chorister bishop, with his fellows, should go
in solemn procession to the altar of the Holy Trinity, in
cops, and with burning tapers in their hands; and that
during the procession, three of the boys should sing certain
hymns mentioned in the rubric. The procession was made
through the great door at the west end of the church, in
such order, that the dean and canons went foremost, the
chaplain next, and the bishop, with his little prebendaries,
last; agreeably to that rule in the ordering of all proce-
cessions, which assigns the rearward station to the most honour-
able. In the choir was a seat or throne for the bishop; and as to
the rest of the children, they were disposed on each side of
the choir, upon the uttermost acent. And to careful was
the church to prevent any disorder which the rude curiosity
of the multitude might occasion in the celebration of this
singular ceremony, that their statutes forbid all persons what-
ever, under pain of the greater excommunication, to inter-
rupt or pres on the children, either in the procession or
during any part of the service directed by the rubric; or
any way to hinder or interrupt them in the execution or
performance of what it concerned them to do. Farther it
appears, that this infant-bishop did, to a certain limit, re-
cive to his own use, rents, capons, and other emoluments of
the church. In case the little bishop died within the
month, his exequies were solemnized with great pomp; and he
was interred, like other bishops, with all his ornaments.

The memory of this custom is preserved, not only in the
ritual books of the cathedral church of Salisbury, but by a
monument in the same church, with the sepulchral effigies
of a chorister bishop, supposed to have died in the exercice of
his pontifical office, and to have been interred with the
funerality above noted.

From what period we are to date the progress of this ri-
diculous ceremony, it is not easy to discover, but it seems
more than probable that it originated with the ancient
Mysteries. In the wardrobe accounts of Edward I, pub-
lished by the society of antiquaries, we find a boy-bishop, Dec.
7, 1290, saying vespers before the king, in his chapel
at Herton, near Newcastle upon Tyne, for which he, and
the boys who sung with him, received 40s.

This establishment, but with a far greater degree of buf-
foonery, was common in the collegiate churches of France.
(See Dom. Marlot. Histoire de la Metropole de Rheims,
tom. ii. p. 769.) A part of the ceremony in the church of
Noyon was, that the children of the choir should celebrate
the whole service on St. Innocent's day. (Brit. Diction-
naire des Arrets, artíc. Noyon. ed. 1727.) In a curious book,
called Voyages Liturgiques de France (Par. Soc. 1715,
p. 45) is this account of the same practice in the church of
Vienne in Dauphiny. "Le jour de Noël après Vêpres,
jour de St. Étienne, et le jour de St. Jean l'Évangéliste, on
faizoit des procéssions solennelles pour les dîners, les préces,
et les enfants de Chœur, comme autrefois à Rouen. Il y
avait aussi le lendemain à la même solennité pour eux. Les
enfans de Chœur y avoient leur Petit Evêque, qui faifoit
tout l'office, excepté à la messe." And in the statutes of the
archiepiscopal cathedral of Tyllus, given in the year 1497,
it is said, that during the celebration of the festival of
the boy-bishop, "Moralités were presented, and flown of mi-
racles, with farces and other sports, but compatible with
decorum. After dinner they exhibited, without their masts,
but in proper dresses, such farces as they were masters of
in different parts of the city." In England too, it appears,
that the boy-bishop, with his companions, went about to
different parts of the town; at least visited the other reli-
gious houses. (See the Computus Rolls of Winchester-
College, A. 1461.) And Strype records (Eccles. Memo-
rials, iii. 310. ch. xxxix. and p. 387. ch. 1.), that when this,
among other ancient ceremonies, was restored by Queen
Mary, in 1556, "on St. Nicholas' even, St. Nicholas, that is,
a boy habitcd like a bishop in punctilios, went abroad in
most parts of London, singing after the old fashion, and
was received with many ignorant but well disposed people
into their houses, and had as much good cheer as ever was
wont to be had before." In the statutes of Eton college, given in 1441,
the episcopus prœorum is ordered to perform divine service on St.
Nicholas's day; and in those of Winchester college, 1586,
pœris, that is, the boy-bishop, and his fellows, are permitted
on Innocent's day to execute all the sacred offices in the
chapel, according to the use of the church of Sarum. A
similar clause to that at Eton occurs in the statutes of King's
college, Cambridge; and Mr. Warton, oberserves, in his
History of Poetry, that the anniversary custom at Eton,
of going ad moniem originated from the ancient and pop-
rular practice here described.

In a small college, for only one provost, five fellows, and
six choristers, founded by archbishop Rotherham in 1581,
in the obscure village of Rotheram, in Yorkshire, this piece
of mummery was not omitted. The founder leaves by will,
among other bequests to the college, "a matter for the
barnes-bishop of cloth of gold, with two knoppes of silver,
674. 686.

From the passage already quoted from the Voyages Liturgiques de France, it appears that, at least in one
church, the mass was not allowed to be celebrated by the
boy-bishop; and it is also expressly prohibited in the use of
Sarum, but other and more frequent instances occur where
the buffoonery was carried even to this height. In a fragment
of the calendars Computus of Hyde abbey near Winchester,
A. D. 1397, we have a charge "pro opulnis pueri cele-
brantis in fefto Saneti Nicolaci," and late even as the reign
of Henry VIII., we find the same ceremony at St. Paul's.

It is surprising that Dean Colley, a friend to the purity of
religion, and who had the good sense and resolution to
confume the superflitions and poperies of popery in his pub-
lie sermons, should countenance this idle farce of the boy-
bishop in the statutes of his school at St. Paul's, which he
founded with a view of establishing the education of youth
on a more rational and liberal plan than had yet been known,
in the year 1512. He expressly orders, that his scholars "shall
every Childermas (that is Innocent's) day, come to Paul's
churche, and hear the childe-bishop's (of St. Paul's cathedral)
sermon
BISHOP.

BISHOPS, **regional.** See **REGIONARY.**
BISHOPS, **rural.** See **CHIEF BISHOPS.**
BISHOPS, **suffragan,** are coadjutors or vicars of diocesan bishops, authorized by commission from them.
BISHOPS, **vagus,** those without any diocese, sometimes attendant in camps, or in foreign countries, for the conversion of infidels. The like vague bishops were sometimes also granted by popes to monasteries, exempt from the jurisdiction of the diocesan, where they performed all the episcopal functions. Du-Cange.

BISHOP, **universal or catholic,** is a title given to the patriarch of Armenia.

BISHOP of the **catholic or universal church,** a title sometimes assumed by the popes.

BISHOPS, in the **Lutheran Church,** are those more usually called **superintendents,** which fee.

The Calvinites allow of no other bishops besides presbyters; but the Lutherans make some distinction, and give a superiority or pre-eminence over the rest of their "bishops," "superintendents," or "overseers."

BISHOP is also a quality sometimes attributed to secular princes, in respect of their supremacy or jurisdiction in matters belonging to religion. See **SUPREMACY.** In this sense it is that the emperor Constantine, in a letter to the bishops in his dominions, calls himself "common bishop," as being in some respects general bishop of the whole Roman world.

BISHOP of the **Jews,** the head of that people in England, chosen by themselves, to whom they submitted to be judged and governed according to their law. Prideaux's **Constit.** part ii. lib. v. p. 478. This office, which subsisted under our Norman kings, and was licensed by them, was an earl of **MAYFAIRS** in Babylon, and the **ADABACHS** in Egypt.

BISHOPS at **thefs,** a kind of piece, the third in rank, below queens, but above knights, distinguished by their cloven heads. In Latin writers of the middle age, the bishop is called *epiphanius,* and by the French *le fou,* the *fool* or *madman.* See **CHESS.**

BISHOP's **Court,** See **COURT.**

BISHOP's *fee,* or *feoff,* originally denoted the throne or chair in the church where the bishop sat. It was also denominated in **APRIS.**

BISHOP's *fee* also denotes the city or place where the residence of the bishop is fixed.

Every bishop's *fee* was anciently called "feudes apostolica;" though the appellation has since been restrained to the *fee* of Rome.

Antiently bishops seem to have had a right in England to sit as judges in the hundred and county-courts. In after-times, they were forbid to sit in secular courts, and had separate courts erected for them; which proved an occasion of much dispute between the two jurisdictions. No church tenant might be sued in any court but the bishop's. There are also traces of a separate court of the bishops much earlier, among our Saxon ancestors in the eighth century. The regard borne to the character of bishops, made them the common arbitrators even of secular causes; they had the cognizance of all causes concerning lands in "frank-almoiny;" and for ecclesiastical, were judges even in capital causes.

BISHOP's *weeds,* in Botany. See **AMNI.**
BISHOP.

BISHOP, Bird, in Ornithology. See Tanagro Episcopus.

BISHOP and His Clerks, in Geography, a cluster of dangerous rocks, near the west coast of South Wales, at the entrance of St. George's channel, four miles west of St. David's. N. lat. 51° 54'. W. long. 5° 20'.

BISHOP'S AUCTION. See AUCKLAND.

BISHOP'S CASTLE, a market and borough town of Shropshire, in England, spreads its scattered houses over the side of a considerable eminence, at the base of which runs the small river Clun. This town is an old corporation, and made its first return to parliament in the 27th of Elizabeth. Previous to that period, it belonged to the fee of Hereford, and derived its name from being one of the seats, or elevated mansions of the bishops. The corporation consists of a bailiff, recorder and fifteen aldermen, who, with about thirty other inhabitants, call themselves burgesses, elect two members for the town. Here is a large weekly market on Fridays, which is much frequented by the Welsh, as are its six annual fairs. At some of the latter a great quantity of sheep and pigs are sold. This town was formerly under the protection of a castle, which is entirely destroyed. Bishop's castle is 156 miles N. W. from London. It contains 241 houses, and 1076 inhabitants.

At Shrewsbury, about two miles and a half N. W. from Bishop's castle, a priory of black canons was founded in the time of Henry III., but was soon afterwards removed to Chester. This place, seated near the Severn, is supposed to have been built by Ethelbeda, and was afterwards pulled down by the family of the Herverts, one of whom was created Lord Herbert of Chester. This gentleman wrote an account of his own life, which has been published by Horace Walpole at his private press at Strawberry hill. Not far from this town on the borders of Montgomeryshire, is an ancient encampment called Bishop's Mount; and at Clun are the remains of an ancient castle, near which is a camp called Bryd-dybech. About three miles hence is Wolver, the seat of lord Clive, who is patron of this borough. In the vicinity of Bishop's castle, are three lofty irregular hills, respectively named Condon-hill, Church-Stoke-hill, and Squill-hill.

At Moor Park, is an respectable mansion, the grounds are finely diversified, and abound with fine woods.

BISHOP'S ISLAND, a small rocky island in Mal-bay, on the west coast of the county of Clare, in Ireland. N. lat. 52° 38'. W. long. 9° 35'. Beaufort.

BISHOP'S STORTFORD, a market town of Hertfordshire, in England, is placed on the side of a hill, near the western borders of Essex. Situated in the midst of a corn country, it is remarkable for its number of malt-houses, and for the quantity of malt annually made here; this is distinguished by the name of brown malt, and is dispensed principally to the London brewers. It is connected by the metropolis in barges, by a navigable canal, which was cut in 1779, and which joins the river Lee, at about 14 miles distance from this town. Before this navigation was opened, the malt, which is now lodged here, was carried to Ware and Stanfield, as the nearest places for water-carriage; but since the above period, Stortford has become the depot for the malt made in this town and the neighbouring villages.

This place was evidently of some note previous to the conquest, as it appears from the Domesday Survey, that the conqueror gave the town and castle to Maurice, bishop of London. From this evidence it appears, that the castle here, which bore the name of Waytemore, was standing prior to the Norman invasion, though some writers assert that it was erected by William. It was probably repaired and strengthened by him, but Mr. Salmon forms justified in the opinion, that it was constructed by the Earl Sexon to defend their borders. The lands paying castle-ward, lie between this place and the Ermine street, one of the great Anglo-Roman roads. The hill, or keep, on which the castle flour, is artificial, being evidently railed with earth brought from some distance. On the top was a well, and a breachwork of stone and mortar. A bank of earth runs from the summit across the muddy ground to the north-east. "This castle," says Salmon, "must have been of some consequence in the time of king Stephen, because of the great defence Geoffrey de Magnanville had, either to be master of it, or to have it pulled down; and Maud the empress engaged him to do one or other." The feignery derived from this fortification gave origin to the town, which had increased to some consequence in the time of king John, who created it a borough, and invested the inhabitants with certain corporate privileges. This monach seized the castle and town from W. de St. Mary, the bishop of London, who was one of the three bishops deputed to execute the pope's interdict upon England. This period was distinguished by the alarming jealousies and animosities between the king and the pope. This was a time of Edward III. the town and castle, &c. again reverted to the bishop of London, in whose fee it still continues, and who appoints a bailiff for this liberty, which includes the town and thirteen contiguous parishes. The bishop's prison was standing in Bishop Bonner's time, but that and all the other old buildings have been since demolished.

The streets of this town are disposed in the form of a cross, with two long streets intersecting each other at right angles. Though no particular manufacture is carried on here, yet the town is respectable and populous; it contains 456 houses, and 2305 inhabitants. Here are a very considerable weekly market for grain, &c. on Thursdays, and three annual fairs, which are mostly appropriated to the sale of horses and cattle.

The church, dedicated to St. Michael, is a large lofty structure, and, like most buildings, dedicated to that saint, stands on the highest ground in the neighbourhood. There were formerly three guilds and a chantry endowed here; and in the choir are nine stalls on each side. The interior of this building is decorated with a number of monuments, some of which are ancient. The great tythes of the parish are in the hands of laymen. In the town are some meeting-houses for dissenters, methodists, and quakers, also some shambles, and a school-house. The latter was built from a subscription among the gentlemen of Hertfordshire and Essex, who were invited to this act by Dr. Thomas Tooke. This gentleman zealously indefatigably in promoting and establishing the foundation, which has proved beneficial to the town and highly honourable to its founders and patrons. The building stands on arches, beneath which is a space for market and shops. Dr. Tooke revived an annual school-feast here, and charged his own estate with an annual present to the preacher. He also gave a challenge of 20l. to the church, and was a great benefactor to the school-library, which is a good one, and was first established by the Rev. Thomas Leigh, who was vicar of the church in 1685, &c. Besides other donations to this library, it is customary for every gentleman to present a book at the time of leaving the school. Bishop's Stortford derives its compound name from being the property of the bishop of London at an early period, and from its situation on the banks of the river Stort, which separates it on the east from the hamlet.
hamlet of Hockerill. At a short distance north of this town is Hadham parva, which is noted from being the burial place of the Capes, earls of Essex. Bishop's Stortford is 30 miles north of London. Salmon's History of Hertfordshire.

Bishop's Waltham, a small town of Hampshire, in England, derives a part of its name from having been a seat of the bishops of Winchester. Some of their palaces still remain at a small distance west of the town, and the site now belongs to the fee. Leland describes it as "a right ample and goodly manor place, noted aboute, and a praty brooke running hard by it. It hath been of many bishops' buildings." The celebrated William of Wykeham, bishop of Winchester, resided here during the last three years of his life, and died in this transept, A.D. 1404, in the 8th year of his age. The house was partly demolished in the civil wars of Charles I. when bishop Kyri was in possession. Bishop's Waltham is noted for its schools, both for gentlemen and ladies. It contains 191 houses, and 1733 inhabitants, and has three annual fairs.

About five miles south of the town is Wickham, a village rendered memorable from being the birth-place of the above-named bishop. See Wykeham.

BISHOPING, in Horfamomthep, is a term probably derived from Bishop, the name of a horse-dealer, and denoting a trick of the dealers in horses for making them appear younger than they are, with a view of imposing upon the purchaser.

This is done by excavating the corner tooth of the incisors with a file, gravel, or file, and afterwards blackening the cavity with a hot iron. This mark, or excavation, is deemed by many the criterion of age, and that the horse is young while this is preserved.

To avoid being imposed upon, the purchaser should consider the general figure, not only of the corner tooth, but of all the incisor teeth of the upper and lower jaw, for they all undergo a perpetual change of figure by age and wear.

An incisor tooth of the horse, at its first emerging from the jaw, has the visible part of it flat, and covered every where with enamel; the outside sharp and projecting higher than the infide, with a conical cavity in the middle, of various depth in different horses, which renders it of not much value in deciding upon the age; in some it is so short as to be obliterated by the fifth year; in others it is so long as to be found till nine or ten, or later; it is, therefore, not a certain criterion of age: the general figure of the tooth is more to be depended upon in our estimation. The lateral width of the recent tooth, and its flatness, are very remarkable, and can never be imitated; as this wears away the tooth daily increases in its transverse width, that is from front to back, and diminishes in its lateral width, forming, as the wear advances, nearly a triangle; these angles at length by age gradually disappear, and the tooth presents a rounded surface on its upper part, and at length the tooth becomes flattened on the sides, and actually wider from front to back than from side to side. For it should be recollected that the tooth is formed in its whole extent previous to its appearance externally, and that the jaw is absorbed, to allow of its wear; the enamel, like a shell, describing the figure and boundary of the tooth, which hollow shell is afterwards filled up with bone. A transverse section, therefore, of the tooth, or a series of them at different distances from its point, afford the exact figures of the surfaces of the teeth at the various periods of their wear, and allowing for contingencies which occasion the teeth to be worn with more or less rapidity, as in crib biters, &c., will afford the truest criteria of age, and render impolition in this way impracticable.

The teeth also they pretend, in some instances, to excavate on the infide, and to sharpen with a file; these bungling attempts, however, in no way resemble the natural markings or surface of the tooth; nor could impose upon any one the least experienced in observing the teeth. For what we consider the best indications of the age of horses, however, we refer the reader to the article Teeth of Horses.

BISHOPRIC, the jurisdiction of a bishop, or the district within which it is comprised, called also "diocese," which fee.

There are twenty-four bishoprics, and two archbishoprics, in England and Wales. To the old ones subsisting before the times of the Reformation, Henry VIII., by letters patent added six more bishoprics; viz. those of Westminister, Chester, Gloucester, Peterborough, Brifton, and Oxford, flat. 34 and 35 Hen. VIII., cap. 17. These fees were all founded in the course of the years 1540, 1541 and 1542.

The fee of Westminister, having never had but one bishop, was united to that of London, and its bishop translated to Norwich, by Edward VI., in 1550. The remaining bishoprics are comprehended under two provinces, those of Canterbury and York. The province of Canterbury includes the following bishoprics, viz.: 1. The bishopric of London, containing Essex, Middlesex, and part of Hertford, and extending its jurisdiction to the West India Islands. 2. Winchester, comprehending Surry, Hampshire, and the isles of Wight, Jersey, Guernsey, and Alderney. 3. Litchfield and Coventry, to which belong Stafford, Derby, and part of Warwick and Shropshire. 4. Lincoln, comprehending Lincoln, Leicester, Huntingdon, Bedford, Buckingham, and part of Hertford. 5. Ely, containing Cambridgeshire. 6. Salisbury, to which belongWilts and Berkshire. 7. Exeter, including Cornwall and Devon. 8. Bath and Wells, comprehending Somersetshire. 9. Chester, to which belongs Suffes. 10. Norwich containing Norfolk, Suffolk, and a small part of Cambridge. 11. Hereford, comprehending Worcester and part of Warwick. 12. Hereford, including Hereford and part of Shropshire. 13. Rochester, to which belongs part of Kent. 14. Oxford, including Oxfordshire. 15. Peterborough, containing Northampton and Rutland. 16. Gloucester, comprehending Gloucestershire. 17. Brifton, to which belongs the city of Brifton, part of Gloucester, and the county of Dorset. 18. London, comprehending Glamorgan, Monmouth, Brecknock, and Radnor. 19. St. David's, including Pembroke, Cardigan, and Cermany. 20. St. Andrews, containing the greatest part of Flixt, Denbigh, and Montgomery, and some part of Shropshire. 21. Bangor, to which belong the counties of Anglesey, Caernarvon, Merioneth, and part of Denbigh and Montgomery. The province of York, comprehends—22. Durham, containing Durham and Northumberland. 23. Carlisle, including great part of Cumberland and Westmoreland. 24. Chelten, to which belong Chelmsfield, Lancaster, Richmondshire, which is part of York, together with part of Cumberland and Westmoreland. 25. Isle of Man. The value of these fees is not easily ascertained, as it is very different from that which is stated in the king's books. It is a certain fact, whatever may be the primary occasion of it, that the revenues of the bishoprics are very unequal in value, and that there is also a great inequality in the patronage appertaining to the different fees. Advertising to this circumstance, Dr. Watton, the present bishop of Landaff, addressed a ' Letter to his Grace the Archbishop of Canterbury,' printed in 1783, proposing a scheme for rendering the bishoprics more equal to each other, with respect to both income and patronage, by annulling part of the estates, and part of the preferments, of the
BIS

the richer bishops, as they became vacant to the poorer.

The advantages, resulting from the accomplishment of this object, and recited by the learned prelates, are as follows: The poorer bishops would thus be freed from the necessity of holding ecclesiastical preferments "in commendam" with their bishoprics; a practice, which bears hard upon the rights and expectations of the rest of the clergy; which is disagreeable to the bishops themselves; which exposes them too much, perhaps undeservedly, obloquy; but which certainly had better not fail in the church. The bishops would also thus acquire a greater independence in the house of lords; and the metropolitan would contribute to reduce the influence of the crown in that house. This plan would likewise ensure a longer residence of the bishops in their respective dioceses, as temptations to translations would be thus removed, and prelates would of course become more attached to their particular situations, gain a more intimate acquaintance with their clergy, and serve, by their doctrine and example, to produce the best effect in the conduct both of clergy and laity. See Augmentation.

In Ireland there were 13 bishoprics, and 4 archbishoprics. Under the archbishop of Armagh, the primates, are: the bishops of Meath, Kilmore and Ardagh, Dromore, Claghgl, Raphoe, Down and Connor, and Derry. Under the archbishop of Dublin are Kildare, Foms and Langhlinia, and Offany. Under the archbishop of Cashel are Waterford and Lismore, Limerick, Kilkllnoe, Cork and Ros, and Cloyne. Under the archbishop of Tuam are Elphin, Clonye, and Killala and Achonry. The primacy is estimated at 8,000l. a year, Derry at 7,000l., and the other bishoprics from 4,000l. to 2,000l. The cathedrals have a hierarchy nearly similar; but the metropolitan and bishops are considered by the protestants as merely titular.

The ancient ecclesiastical establishment of Scotland comprised two archbishoprics, those of St. Andrew's and Glasgow, and eleven bishoprics (that of Edinburgh having been only established by Charles L.), which, in the order of antiquity, may thus be enumerated: Galloway (St. Andrew's), Dunkeld, Moray; five founded by David I., Brechin, Dumblanc, Aberdeen, Ross (Glafgow); that of Argyle, or Lismore, was founded about the year 1200, because the bishops of Dunkeld did not speak the Irish tongue; the bishops of Orkney and of the western islands date from an earlier period, while their fees were not subject to the Scotsish crown. But since the resolution in 1688, the ecclesiastical government of Scotland is of the Presbyterian form; and of courts they have no bishoprics.

Bishoprics, as well as archbishoprics, may become void by death, deprivation, and resignation; but a bishop must resign to his metropolitan. See Archibishop.

BIS, Bonaventura, in Biography, an eminent painter and engraver, and a monk, as some say, of the order of St. Francis, was born at Bologna, and became a disciple of Lucia Mussi. His chief excellence consisted in copying in miniature, the pictures of Correggio, Guido, Titian and other masters, which he finished with surpassing beauty and elegance. Many of his works, which are highly valued, are in the duke's gallery at Modena. He also adorned himself by etching some few plates from Parmigianino, Guido, etc. One, probably from his own design, was a "Holy family," painted by Elizabeth and St. John, dated 1631. He died in 1662; but his age is not known. Strutt and Pilkington.

BISIGNANO, in Geography, an inaccessible town of Naples, in the province of Calabria, Ebra, heared on a hill near the river Crati, surrounded by lofty mountains, and defended by a strong fortres. It gives the title of prince to the last remaining branch of the ancient house of San Severian, and is a bishop's see, fullingan of Rossano; distant 16 miles W. S. W. from Rossano, and about 18 miles N. from Cosenza. Lat. 39° 38'. W. long. 168° 21'.

BISK, or Bisket, Biscuit, in Cookery, a rich sort of broth or soup, made of pigeons, chickens, force-meat, mutton, and other ingredients. The word is French, formed, as some think from bicaudaeus because the bisket, consisting of a diversity of ingredients, needs several repeated coctions to bring it to perfection. There is also demi-bisket, made at a low expense, in which only half the ingredients are used; and a bisket of fifty, made of corps, mixed with their roes and bakers.

Bisket, Biscuit, or Biscuit, usually denotes a delicate kind of bread prepared by the confectioners, of fine flour, eggs, sugar, and raisins or orange water; or flour, eggs, and sugar, with self-seeds and citron peel; baked in the oven, in tin or paper moulds. The word comes from the Latin bis, twice, and the French cult, coctus, q. d. bisket. We find divers sorts of such biscuits, as feed-bisket, fruit-bisket, long-bisket, round-bisket, Naples bisket, sponge-bisket, etc.

Bisket, for a sort of bread much dried, to make it keep for the service of the sea. It was formerly baked twice or oftener, and prepared six months before the embarkation. It will hold good a whole year. To preserve sea biscuits from insects, Dr. Hales advises to make the fumes of burning brimstone pass through the caps full of bread. Bisket may be likewise preferred a long time, by keeping it in cases well called, and lined with tin.

The flip-bisket is too hard for some teeth; and in this case, it may be softened by toasting. But rusk is better; for being made of good fermented bread, sliced, and baked a second time, the pieces imbibe the water easily, soften immediately, and digest more kindly, and are therefore more wholesome than the unfermented biscuit. Rusk, says Dr. Franklin, is the true original bisket, so prepared to keep for sea, being twice baked, as its name imports. See Franklin's Maritime Observations, in Amer. Trans. vol. ii. p. 312.

The ancients had their bisket prepared after the like manner, and for the like use as the moderns. The Greeks called it επίτησι, q. d. "bread put twice to the fire." The Romans gave it the name of "panis nautici," or "capta." Playden denominates it "vetus aut nauticus panis tulus atque iternum coctus." By which it appears, that after the first baking, they ground or pounded it down again for a second. In some middle-age writers, it is called "paximis," "paximis," and "paximata." Among the Romans, we also meet with a kind of land-bisket for the camp-service, called, "buccellatum," sometimes, "expeditionalis annum," which was baked much, both to make it lighter for carriage, and less liable to corrupt; the coating being continued till the bread was reduced one-fourth of its former weight.

The procés of biscuit baking for the British navy is as follows: and it is equally simple and ingenious. The meal, and every other article, being supplied with much certainty and simlicity, large lumps of dough, containing merely of flour and water, are mixed up together; and as the quantity is so immense, as to preclude by any common process a possibility of kneading it, a man manages, or as it is termed, rides a machine which is called a horie. This machine is a long roller, apparently about four or five inches in diameter, and about seven or eight feet in length. It has a play to a certain extent, by means of a flaple in the wall, to which certain elastic kind of eye, making the action like the machine by which they cut chalk for horses. The lump of dough being placed exactly in the centre of a raised platform, the
the course of that time bake a sufficient quantity of bread for 16,000 men. The granaries are large, and well constructed; when the wheat is ground, the flour is conveyed into the upper stories of the bake-houses, whence it descends through a trunk in each immediately into the hands of the workmen.

The bake-houses, belonging to the Victualling Office at Deptford, consists of two divisions, and has twelve ovens; each of which bakes twenty sheets daily, Sundays excepted; the quantity of flour used for each sheet is two bushels, or 112 pounds, which baked produce 162 pounds of biscuit. Ten pounds are regularly allowed on each sheet for shrinkage, &c.

The allowance of biscuit in the navy is one pound for each man per day, so that one of the ovens at Deptford furnishes bread daily for 2040 men.

BISLAIN, in Geography, a town of Egypt on the Nile, 3 miles south of Damietta.

BISLEY, anciently called Bisfedge, is a small market town, and a very extensive and populous parish of Gloucestershire, in England. The parish includes an area of 6000 acres, the surface of which is diversified with steep hills and narrow valleys. On the sides of the former are some enclosed arable lands, intermixed with copses; and the latter are mostly kept for meadow pasturage. Bisley, Chalford, and some neighbouring hamlets, are chiefly inhabited by persons engaged in the woollen manufactures; and many fulling and drizzling mills are erected on the river which runs through this parish. A small weekly market is held here on Thursdays, and here are two considerable fairs yearly. The church is a large handsome building, and, being heated on a high hill, is conspicuous for many miles. Here is a small free school, and an endowment for clothing five widows yearly. The canal, which unites the Thames and Severn, passes through this parish; and near the verge of it, at Sapperton, enters a subterraneous tunnel, which is cut through the earth to an extent of two miles and five furlongs. This tunnel is lined with masonry, and arched over at top, with an inverted arch at the bottom, except at those places where the solid rock rendered it unnecessary. The expense of cutting it was about eight guineas per cubic yard; but the plan of cutting the channels of the two great British rivers induced the proprietors to encounter extraordinary expenses and trouble. The connection of the rivers Thames and Severn, by means of this canal, and also with the internal parts of the kingdom, by the Oxford and Coventry canals, which lead to Birmingham, and also to the counties of Stafford, York, Chefler, and even to Walford, forms a line of communication with the capital of the greatest importance, and which has proved of great utility to the manufacturing towns through which it passes. On the 29th of April 1759, the acting engineer, Mr. Clowes, passed through the tunnel for the first time, in a vessel of 30 tons burthen; and the junction was completed, and a vessel passed from the Severn into the Thames, for the first time, on the 19th of November in the same year, in the presence of a large concourse of people, who came to witness and rejoice at the sight. In 1788, their majesty's vessels from Cheltenham, on purpose to view this tunnel, which excited their surprise and admiration, more particularly when they learnt it had been conducted and completed by a private gentleman. The canal is 30 miles and 7 chains in length, in which course the water is raised 241 feet 3 inches, and made to fall 130 feet 6 inches. In the parish are 522 houses, and 4227 inhabitants. Rudge's History of the County of Gloucester. Phillips' History of inland Navigation.

BISLINGUA, double-tongue, in Botany, a name used by many authors for the narrow-leaved rush, or butcher's broom.
BISMARCK, in Geography, a town of Germany, in the circle of Upper Saxony, and Old Mark of Brandenburg; 12 miles west of Stendal.

BISMEOR, or Bismea, a town of Africa in the kingdom of Algiers. 25 miles west of Algiers.

BISMILLAH, in the Mahometan Customs, a solemn form, viz. in the name of the most merciful God, constantly placed at the beginning of their books and writings in general as a peculiar mark or distinguishing characteristic of their religion; it being counted an impious to omit it. The Jews, for the same purpose, make use of the form, “in the name of the Lord,” or “in the name of the great God.”

Bismilah also used among the Arabs, as a word of invitation to eat. An Arab prince will frequently sit down to eat in the street before his own door, and call all that pass, even beggars, by this word, who do not fail to come and sit down to eat with him; for the Arabs are great levelers, and let every body on a footing with themselves.

Bismuth, Bismuthum, Wallerius; Bismuth, or Bismuth, Germ; Bismuth, Fr.; Plumbum cinerum, Antimonium sinterium, tin-glows, of the older chemists.

Bismuth is a brittle metal, of a reddish white colour, and foliated fracture, is fusible at nearly the same temperature with lead, soluble with ease in nitric acid, and precipitable from it in the form of a white oxys by the addition of pure water.

§ 1. Ores of Bismuth.

The colour of this mineral is silver-white, with a white tinge of red, frequently exhibiting an iridescent appearance on its surface. It occurs very rarely in mafs, being generally disseminated, or involving; it is also met with feather-shaped, or reticular, or in lamilla of a rectangular or triangular shape, either solitary, or heaped upon each other. It exhibits a metallic lustre of considerable brilliancy. Its fracture is perfectly foliated, or broad fissated. It is semiductile, and breaks with some difficulty into irregular, somewhat blunt-edged fragments. Sp. grav. according to Kirwan = 9.47.

Native Bismuth is fusible at a very moderate temperature, often by the heat of a common candle; when exposed to the action of the blowpipe on charcoal, it volatilizes in the form of a white vapour, not unfrequently accompanied with an arsenical smell. It dissolves very easily, and with effervescence, in cold nitric acid; and is precipitable in the form of a white powder, on the addition of pure water.

The only two substances, with which native bismuth is liable to be confounded, are the sulphur of bismuth and dendritic silver; the former of these, however, is not soluable with a slight effervescence in cold nitric acid; and the latter may be distinguished by its colour and ductility.

Bismuth is one of the most partially diffused metals hitherto known; and it is chiefly found native, accompanied with kupfernickel, white and grey cobalt, black blende, native silver, and rarely galena. Its gangue is quartz, calcareous spar, or barofolinite; and it has hitherto been found only in veins in primitive mountains.

It is found at Joachimthal, in Bohemia; at Freyberg, Annaberg, &c. in Saxony; in Sweden, Transylvania, and Britain.

The colour of this substance is between lead-grey and tinge; and on the surface it is usually yellowish or iridescent. It is found either lamellar and in mafs, or disseminated, or in small acicular crystals. Its primitive figure, according to Hauty, is that of a quadrangular prism. Its internal lustre is metallic and very brillian; its fracture is broad or narrow striated, or striated like galena. Sp. gr. according to Kirwan, = 6.131. It burns the fingers in a slight degree; and when reduced to powder, is of a glimmering black.

When exposed to the blowpipe, it melts easily, giving out a sulphureous odour and a blue flame, and is almost entirely volatilized before it can be brought to the metallic state. There has been no very accurate analysis made of this ore; but from the experiments of Sage and La Peyrouse it appears to contain about 60 per cent. of bismuth, 36 of sulphur, and a little iron. There is some external resemblance between the lamellar variety of this mineral and galena; but the superior fusibility of the former is an easy and infallible characteristic.

Sulphuret of bismuth is very rare; and, where it occurs, is always accompanying native bismuth. It is found at Joachimthal, in Bohemia; Alkenen and Johann-Georgenflaadt, in Saxony; and at Bultms, near Riddarhytte, in Sweden.

This mineral is of a greenish yellow colour, passing into ash-grey, or straw-colour. It is sometimes found in mafs, but more commonly disseminated or involving. It is opaque, and possesses a slight degree of internal lustre. Its fracture is five-grained, uneven, or earthy. Sp. grav. considerable, but has not yet been accurately ascertained. It is either friable, or of the consistence of chalk, but occasionally gives fire with a blue, or a violet tint of the particles of quartz with which it is mixed.

When exposed to the action of the blowpipe on charcoal, it is very easily reducible to the metallic state. It is fusible in nitric acid without effervescence, and precipitable for the most part by the addition of water.

Oxys of bismuth is an extremely rare mineral. It has hitherto only been found at Schneeburg, in Saxony, accompanying native bismuth; in the Black Forest mines, in Swabia; and at Joachimthal, in Bohemia. It is often confounded with the green earthy iron ore; but may be at once distinguished by its easy reduction before the blowpipe. Emmerling, vol. ii. p. 454. &c. Wiedemann, p. 887. Brochant, v. 2. p. 434. Hauty, v. 4. p. 184. Kirwan, vol. ii. p. 263.

§ 2. Assay and Analysis of Bismuth Ores.

Sulphur and iron are the only substances that have been as yet detected in combination with this metal, as far as can be inferred from very imperfect analyses of the preceding ores. But Klaproth, in his examination of the bismuthic silver ore from Schafburg (Analyt. Ess. vol. i. p. 556.), found it to be a combination of lead, silver iron, copper, and sulphur, with bismuth; and from the experiments of this able chemist is deduced the following general method of analyzing the ores of bismuth.

Having reduced the ore to a tolerably fine powder, pour upon it, in a capacious flask, five times its weight of nitric acid previously diluted with one third of water. The acid will begin to act immediately, without the assistance of heat; nitrous gas will be diffused in great quantity; and the solution will assume a greenish yellow colour. When the acid has taken up as much as it can, or nearly so, pour it off, and digest the undissolved residue in a moderate heat, with equal parts of nitric acid and water, renewing the

menium
monstrum from time to time, till all the soluble parts of the ore are taken up. Add together the solutions, and red heat them by gentle evaporation to about half their bulk (if any crystals are deposited, add a little pure warm water just sufficient to take them up again); then pour the whole into a large quantity of rain water, at least twenty times the bulk of the solution. The liquor will immediately assume a milky appearance, and, by standing a short time, will deposit a white heavy precipitate (a), which, when carefully lixivated, is pure oxide of bismuth. Add all the liquors together, and concentrate them by evaporation to one half of their bulk; then drop in the strong solution of muriated ammonia, as long as any precipitate takes place; decant the supernatant fluid as accurately as possible, and, without washing the precipitate, digest it for a short time with moderately strong nitric acid; the undiluted part of the precipitate being separated, washed, and dried, is pure muria of silver (b). The nitrous solution is now to be diluted with a large quantity of cold water, and a precipitate of oxide of bismuth (c) will be thrown down. The diluted nitrous solution being mixed with the other liquor, the whole must be evaporated, till a considerable number of crystals are deposited; at this time, the addition of sulphuric acid will occasion a white deposit of sulphat of lead (d). The remainder of the solution is now to be superheated with caustic liquid ammonia, by which the iron will be deposited in the state of brown oxide (e), and the copper will form with the ammonia a blue solution; this being saturated slightly to excess with sulphuric acid, will deposit the copper (f) upon a piece of clean iron. The residue of the ore that was undissolved by nitric acid, being weighed, and exposed to a low red heat, will give it's sulphur (g), the quantity of which may be estimated with considerable accuracy by the loss of weight. It is now finally to be digested with ten times its weight of boiling muriatic acid, by which some oxide of lead will be taken up; and this, by evaporation and the addition of sulphuric acid, may be procured in the state of sulphated lead (h). The residue being washed and dried is the stony gangue of the ore (i).

Hence the ore will be decomposed into:

- Oxide of bismuth (a) and (c),
- Muriated silver (b),
- Sulphated lead (d) and (h),
- Oxide of iron (e),
- Metallic copper (f),
- Sulphur (g),
- Stony matrix (i).

§ 3. Reduction of Bismuth Ores.

The separation of this metal from the sulphuric acid with which it is found united in the mine, and the reduction of it to a marketable state, is perhaps the chiefest of all the metallurgical processes, on account of the readiness with which the ore can be reduced to the metallic state. The following were the methods practised in the time of Agricola (De Re Metallurgica, p. 440.) A round pit, two or three feet wide, was lined with well rammed clay and charcoal, and covered with billet wood, upon which were laid alternate strata of ore and wood. When the pile was thus built to a sufficient height, fire was applied to the top, and the bismuth, as the heat penetrated through the mass, became melted, and trickled down into the hole beneath, where it collected in an irregular mass; being then withdrawn, and broken into pieces, it was remelted in iron or earthen pots, separated from the impurities that floated on its surface, and finally cast into flat cakes, or leaves, for sale. Another method was to divide a large pine tree longitudinally, and cut out the central part of the wood, thus forming it into a gutter; this being placed somewhat inclined, the ore was laid in the upper end, on a bed of chips and small wood, sufficient, when let on fire, to liquify the bismuth, which flowing down, was collected in a hole or vessel placed at the end of the trough.

The selective properties of wood, has, however, put an end to these rude and extravagant methods; and the ores of bismuth are now reduced in a common reverberatory furnace, the bed of which is lined with charcoal, whence the melted metal is removed in iron holes, and cast into masses weighing twenty or thirty pounds, in which state it is brought to market.

Bismuth is a white metal with a reddish yellow tinge; is considerably hard, but brittle, exhibiting a broad foliated fracture; has a bright, almost metallic lustre; and is somewhat fusible, when burnt. Though brittle, it may be compressed very considerably by judicious hammering, and therefore varies greatly in its specific gravity. According to Mufchenbroek, its sp. gr. when fresh melted, is 8.716; but when condensed, is 9.63. Bergman fixes its gravity at 9.67; and other authors make it as high as 9.68, or even 10. The lamine, of which this metal is composed, have but little adhesion to each other; hence the primitive form of its crystals, which is that of a regular octahedron, may very easily be detached by pressure. It is fusible at 460° Fahr., and may be poured into a paper cone without burning it. If, after it has begun to solidify, the fluid part is poured off, a group of crystals is obtained in tubes, or rectangular volutes. When exposed in close vessels to a violent heat, it sublimes and attaches itself to the cooler part of the apparatus in the form of brilliant plates.

§ 5. Oxides of Bismuth.

The combined action of air and moisture upon bismuth, at the usual temperature, is very slight; it becomes covered with a reddish grey superficial tarnish, and afterwards appears to undergo no further change. At a melting heat, it shortly becomes covered with an iridescent film, and by exposing fresh substances to the air, is wholly converted into a yellowish brown oxide, weighing about \( \frac{1}{6} \) more than the original metal. This oxide melts into a yellow glass at a moderate red heat, and soon penetrates through the most compact earthen crucibles, though not quite so easily as glasses of lead does. When bismuth is exposed to a strong heat, with free access of air, it burns with a faint blue flame, and throws up at the same time a copious white oxide, which was formerly called flowers of bismuth; towards the end of the process the oxide acquires somewhat of a yellowish tinge, probably on account of a small portion of sulphur, or other impurities. The glass, or vitreous oxide of bismuth, is a very active flux for earths and the more difficultly fusible oxides; on account, however, of the superior cheapness and efficacy of lead, it is seldom used for this purpose.

1. Concentrated sulphuric acid has no action on bismuth, except when boiling hot; in this state, it is rapidly decomposed, giving out sulphureous acid gas, and reducing the metal to a white pulverulent oxide, by a low red heat the decomposition is complete, that a quantity of actual sulphur is volatilized. The white masses being washed with a little warm water, parts with nearly the whole of its acid, holding a small portion of bismuth in solution; this fluid by careful evaporation, deposits minute soft crystalline needles of sulphat of bismuth, from which, by the mere evaporation of the water, the metal may be separated in the form of white oxide. The sulphated oxide, produced in the first part
part of the process, is remarkably more difficult of reduction than any of the pure oxys of § 5.

2. Sulphureous acid is incapable of attacking metallic bismuth, but readily combines with its oxys, forming a white insoluble sulphite of a sulphurous flavour, redatable into metallic globules before the blowpipe, decomposable with effervescence by sulphuric acid, and when distilled, giving out its acid, a mass of white oxide remaining behind.

3. Nitric acid acts upon bismuth in a remarkably violent manner. If the metal is in powder, and the acid somewhat concentrated, at the instant of their mixture, even without the assistance of heat, a rapid decomposition of the acid takes place, accompanied with the production of nitrous gas, azot, and sometimes of ammonia; and the bismuth is converted into a white oxide. If the acid is previously diluted with an equal weight of water, and the bismuth is added gradually in small pieces, the decomposition goes on more quietly, the metal is dissolved in proportion as it oxidates, and the acid may be made to take up nearly half its weight of bismuth. By cautiously adding to this solution an equal bulk of distilled water (each portion being well mixed with the whole mass by stirring), before the addition of a succeeding portion, a black pulverulent precipitate takes place, which has not yet been analyzed, but has been taken for sulphur or charcoal. If the acid made use of is still more dilute, confining, for example, of four parts of water, and one of nitric acid, the black matter is not dissolved. Nitrat of bismuth, when thus purified, is clear and colourless, and by gentle evaporation crystallizes in the form of flattened rhomboids, or comprised tetrahedral prisms terminated by three yellow pyramids. This salt, when exposed to a dry air, is considerably efflorescent; but in a humid air, becomes covered with a white, somewhat moist coating of oxides of oxygen. When thrown on hot coals, it detonates feebly, giving out faint red sparks, and leaves behind a greenish yellow oxide of difficult reduction. If a crystal of nitrat bismuth is thrown into some pure water, it immediately becomes covered with a white opaque oxide; but the decomposition of this salt is more striking, if a solution of it is made use of. For this purpose, let a jar be nearly filled with clear rain water, and drop into it nitrat bismuth as long as any precipitation takes place, then mix the whole by agitation, and let it stand for an hour to settle. The bottom of the vessel will now be covered with a fine heavy powder of a dazzling white, which, when repeatedly washed and dried, is pure oxide of bismuth, formerly called magistery of bismuth, and well known as a confection under the name of blanc de fard. This preparation, if made with pure nitric acid, and well washed, is of a dead white; but if a little muriatic acid is mixed with the nitric, and the precipitate is washed with a small portion of cold water, it will be in the form of minute glittering scales with a beautiful pearly lustre, and is then called by the French blanc de perles. In both states it is extensively employed, particularly by the French ladies for whitening the skin, but is subject to turn grey, brown, and even black, by any hydrogogenous and sulphurous vapours. This oxide of bismuth does not appear to retain any nitric acid; and its component parts are fixed by Bergman at 77 of metal, and 23 of oxygen; but, by the more accurate experiments of Kilproth, its contents are ascertained to be 81 of metal to 19 of oxygen. Nitrated bismuth is not, however, totally decomposable by water; for the clear fluid, that is separated by filtration from the oxide, may still be made to yield a precipitate by a carbonated alkali, muriatic acid, or muriated ammonia. Kilproth found (Analyt. Eff. vol. i. p. 557), that 1000 grains of bismuth, dissolved in nitric acid, yielded with water 88 grains of oxide, and 35 more were obtained from the dissolved solution, by the action of muriatic acid added in drops as long as any precipitate ensued. This oxide is very easily reduced by fusion in a covered crucible, with a little nitre and tartar.

4. Bismuth in the metallic state is acted upon with difficulty by muriatic acid, even when it is concentrated and affixed by heat. During the digestion, a small quantity of fetid hydrogen gas is given out; and, by slow evaporation, small deliquescent needle-shaped crystals are deposited of muriat of bismuth. This salt, however, may be obtained in much greater quantity, and more easily, by substituting the oxide of bismuth for the pure metal. If the fleshy mats, which remains behind after evaporation to dryness, is diffused in a glass retort, nearly the whole of it comes over at a moderate heat, and concretes into a soft white mass, called formerly butter of bismuth. Butter of bismuth, like butter of antimony, is intensely caustic to the taste, deliquesces in a moist air, and when dropped into water, is decomposed, a fine white oxide being precipitated.

5. Liquid oxy-muriatic acid acts upon metallic bismuth with considerably more energy than muriatic acid does: the metal is oxydized without the deliquescence of hydrogen, and the result is muriat of bismuth. It is probable, that by substituting the oxide of bismuth for the pure metal, oxymuriat of bismuth might be produced; this, however, is not as yet confirmed by experiment. If bismuth, previously reduced to fine powder, is poured into oxymuriatic acid gas, the metal is instantly ignited and oxydized, and falls in a shower of fire to the bottom of the vessel.

6. Tincture of galls, or gallic acid, precipitates bismuth of a greenish colour from its solution, as prussian potash does of a yellowish colour.

7. There is scarcely any thing known concerning the other bismuthic salts. They are formed by digesting the yellow oxide in the various acids that have not been already mentioned, and are for the most part but little soluble in water. The proportions of their ingredients have not been ascertained with any accuracy, nor are they applied to any use.

The fixed alkalies have no effect on metallic bismuth, but unite both in the humid and dry way with its oxide. Ammonia is said to acquire a greenish yellow colour by digestion with the metal when pulverized, and certainly dissolves its oxide in considerable proportion. The action of the earths upon bismuth is unknown, except that fels and oxide of bismuth combine by fusion into a clear greenish yellow glass.

§ 8. Action of the Neutral Salts on Bismuth.

None of the neutral salts in solution appear to exert any affinity on bismuth or its oxide; but, in a dry heat, many of them are decomposed by it.

Nitre, being mixed with pulverized bismuth, and projected into a red hot crucible, is decomposed with a flight denotation; the bismuth becomes oxydized, and then unites in part with the alkaline base of the nitre.

Muriat of soda, according to Pott, is in some degree decomposable by metallic bismuth. This fact, however, is not confirmed by later chemists; and it is probable, that the salt, which Pott made use of, was not free from muriated magnesia, and that the bismuth was partly oxydized.

Muriated ammonia is totally decomposable by oxide of bismuth. On the first impression of the fire, very pure ammoniacal gas is diffused; and by a slow red heat, the muriated bismuth rises in the form of a thick white vapour, which concretes, in the receiver and neck of the retort, into butter of bismuth; if the oxid of bismuth is in very small proportion
§ 9. Bismuth with combustible Bodies.  

If one part of sulphur, and four of bismuth, are triturated together, and afterwards exposed to a full red heat in a covered crucible, a brilliant fluid metallic mass of sulphuret of bismuth is obtained, similar in its properties to the native sulphuret mentioned in § 1. It may be made to crystallize, by allowing it to cool very gradually, and pouring off the fluid part as soon as the surface is crumpled over. The cavity thus formed will be found to be lined with long tetrahedral prisms crossing each other, and occasionally of a deep iridescent blue and red colour, forming groups of exquisite beauty. The sulphuret of bismuth is much less fusible than the pure metal; it parts with nearly the whole of its sulphur by long roasting, and is decomposable by nitric acid, which dissolves the bismuth without touching the sulphur.

Sulphuretted hydrogen converts the white oxyd of bismuth into a black mass, of which neither the properties nor proportions have been ascertained.

Phosphorus has very little affinity for this metal. Pelleter tried in vain by several methods to prepare phosphuret of bismuth. In some of his experiments, the metallic globule, when red hot, gave out a faint lambent flame, but exhibited no other proof of combination with phosphorus. Fat oils, by the affluence of heat, dissolve the oxyd of bismuth, and form with it a thick tenacious phisler.

§ 10. Alloys of Bismuth.

Bismuth appears to increase remarkably the fusibility of all the metallic compounds into which it enters; but it is to be lamented, that we are greatly in want of accurate experiments on this interesting branch of inquiry.

2. Bismuth and Silver. See Silver.
4. Bismuth and Copper. See Copper.
5. Bismuth and lead. Equal parts of these two metals unite easily by simple fusion, forming an alloy of a brilliant white colour, considerably harder than lead, and, though not ductile, more malleable than pure bismuth. By diminishing the proportion of bismuth, the malleability of the mass is increased, without sensibly impairing its fusibility, hardness, and luster.
6. Bismuth and tin. A small quantity of bismuth increases the hardness and brilliancy of tin, without rendering it less ductile; hence the best foils for glass mirrors are made of this alloy, as also are some kinds of pewter.

Bismuth with lead and tin. Fusible metal. Plumbers' folder. The fusibility of the alloys of bismuth is in no instance so remarkable as in that discovered by Newton, and hence commonly called Newton's fusible metal. It is made by melting together eight parts of bismuth, five of lead, and three of tin. The mass is very brittle, and when broken exhibits a porcelainous appearance, with little or no luster; it is fusible as to become liquid when held on a piece of flint paper over a candle, without scourching the paper; and becomes as fluid as quicksilver in boiling water. If the bismuth is reduced to one part, the proportions of lead and tin remaining the same, the alloy is plumbers' folder; and it differs from the preceding in being somewhat less fusible and confiderably malleable.

§ 11. Medical Use of Bismuth.

BISNAGUR, in Geography, an ancient kingdom of Hindooftan, called Nasinaga, from the name of one of its rajahs, or sovereigns, was formerly the most extensive, powerful, and rich monarchy in the Indies, and comprehended almost all the countries in the peninsula south of the 16th parallel, or the whole of the Carnatic and some other kingdoms. Some have distinguished between the kingdoms of Bifnagur and Narfing, but it is not easy to determine, whether they were two successive, or two co-existing kingdoms. It appears, probable, however, that in the 16th century Bifnagur included the greatest part of the peninsula. The inhabitants of this ancient empire, which is said to have continued 3000 years, were Pagans, and denominated Badaguns; and spoke the Tamul, or Damul language, which is the same with the Malabaric; but the Badagun was used at court. According to the Portuguese writers, the kingdom of Charnatak had no sovereign prince till the year 1200, and the first was Boka, a shepherd, who styled himself rau or rajah, that is emperor; which title has descended to his successors. Boka, it is said, in memory of a victory which he obtained over the king of Delhi, built the famous city of Visnagur, corruptly called Bifnagur. The crown continued in his line till it was usurped by Narfing, from whom this kingdom took its name, as it did that of Bifnagur from the city. The king of Bifnagur was a powerful prince about the year 1520; and about the year 1565 the capital was returned to by merchants from all parts, as being the greatest, if not the only mart for diamonds in the east; and its riches were equal to its extent. At this time it was invaded by the king of Visnapour, and other northern princes of the Deccan; and in 1567 the rajah, or king, retired, with his court, first to Penecunda, and at a subsequent period, or about 1597, its excelling sovereign removed to Kandegheheri, or Chadegheheri, an inland city, strong by nature and fortified by art, so as to be deemed impregnable. About the middle of the 17th century, this large monarchy was again invaded and utterly destroyed, by Adel Shah, king of Visnapour, who formed a league with the king of Golconda for this purpose. The unfortunate rajah fled into the mountains, where he remained in 1667. About 2 years after, the kingdom of Bifnagur fell under the power of the Moguls, by the conquest which Aurungzebe made of the kingdoms of Visnapour and Golconda.

BISNAGUR, rather BISNAGUR, sometimes written BEJANAGUR, the capital of the above kingdom, is situated on the south bank of the Tummbu Brdr, and according to M. Bnifty's map, distant about 50 miles S. E. or S. S. E. from Biscapour, Perifits, says that it was founded by Beladeo, king of the Carnatic in 1344, and was then placed in order to guard the northern frontier of his empire. See the preceding article. This city was visited by Cesar Frederick in 1565, and was then a very large city; its circuit, as he says, being 24 miles, and containing within it a number of hills and pagodas. He reckons it 8 days' journey.
BISPINOSUS, a species of Cerambyx (Serracera) that inhabits South America. Thorax unarmed, and slightly tuberculated; wing-cases bidentated; joints of the antennae armed with two spines; and the body tellaceous. Fabricius.

BISPINOSUS, a species of Carabus that inhabits Europe. This is of a black colour, posterior part of the thorax truncated; anterior partly with two spines. Linnaeus. Muf.

BISPINOSUS, a species of Tabanus, found about Gottingen, and described by Fabricius. The colour is brown; abdomen ferruginous, and black at the base, with two spines on the front.

BISQUET. See Bisket.

BISA, in Geography, a town of Servia on the Danube, 16 miles S. S. E. of Orlova.

BISSACRAMENTALES, in Ecclesiastical History, a denomination given by some Roman writers to Protestant, on account of their only holding two sacraments, viz. baptism and the supper.

BISSAGOS, in Geography, a town of Croatia, 16 miles N. E. of Agram.

BISSAGOS, the name of a cluster of islands and islets, lying off the west coast of Africa, between the mouths of the rivers Rio Grande and Cacheo, and between about 16° 30 and 11° 30 N. lat. and 15° 10 and 17° W. long. The principal of these islands, and that which lies nearest the coast is Boolam, or Buhum, which fee. Each of the inhabited islands is governed by a chief, who assumes the title and power of a king. All these petty monarchs are independent, and frequently at war with each other, which they carry on by means of canoes, capable of containing from 25 to 40 men, with their provisions, and also their arms, which are fables, and bows and arrows. The negroes of these islands are tall, strong, and healthy, though they live only on fish, nuts, and palm-oil, and live with rice, millet, and other produce of the earth to the Europeans, than to retain their passion for trinkets and ornaments. They are idolaters, and are said to be savage in their disposition, not only to strangers, but to one another, when they happen to quarrel, which is frequently the case; and if they are disappointed in gratifying their revenge, they will drown, or ferociously stab themselves.

BISSAO, an island on the west coast of Africa, separated from the continent by a channel, which connects two bays of the sea, within the Bisgas islands, between 11° 15 and 11° 39 N. lat. and 15° 11 and 16° 30 W. long. Both the Portuguese and French began to trade at an early period with this island; the former have a fort upon it, and the latter a factory. The Dutch have in vain attempted to obtain a settlement. The island is 35 or 40 miles in circumference, and rises from the sea, of which it has an agreeable prospect, by a safe ascent to an eminence in the centre of the island. Its surface is hilly, and the lands are separated by beautiful and fertile vales, which are watered by small rivulets. The whole, a few groves of palm-trees excepted, is in a state of cultivation, and produces, besides oranges, mangoes, and bananas, and other fruits afforded by the warm climates, wheat and unice, which grow luxuriantly, and resemble, by the size to which the items rise, reeds or lantoons. Their cattle are likewise of an extraordinary size; and are amply supplied with both milk and wine. The importation of wine is prohibited, and the food does not find the rearing of horses. The inhabitants, who are in a state of almost perpetual content with those of the neighbouring islands and continent, live in cottages differed over the island, which bears no trace of a town, except where the French
French and Portuguese have established themselves. The
drews of the married women consist of a cotton girdle, and
bracelets of glass, coral, and copper; but the virgins are
altogether naked; and those of high quality mark their
bodies with lusious figures of snakes and other reptiles.
The princes of the island is only distinguished from other
females by the elegance of these paintings, and the richness
of her bracelets. The drews of the men of all ranks is merely
a skin fixed before and behind to their girdle. One figural
ornament is a large iron ring, upon which they ring changes
with a piece of iron, so as to convey as freely with their
cabinets as if they used the most polished language. This
artificial language is used only by persons of rank and
fashion. All the Biassos are idolaters, but their system of
religion is very confused and unintelligible. Besides their
chief idol, called “China,” every one creates a divinity
according to his own fancy; trees are held sacred by them,
and, if they do not adore them as gods, they worship them
as the residence of some divinity. Their government is
despotic, the will of the emperor being the law to his people;
at his death all his wives and slaves are sacrificed and
buried near his maver, in order to attend him in the
other world. Although they are at almost perpetual war
with some of their neighbours, they have among themselves
no civil discord. Before the emperor resolves to invade any
adjacent territories, he orders the “bonbalon” to be
founded, which is the general signal to arms, on which all
persons in the pay of government assemble at a fixed place,
and embark on board their canoes, each of which carries
about thirty men, and the whole fleet consists of about 30
canoes. Before the fleet sails, they offer sacrifices in great
number to their gods, which are made of wood, and the
favourable answer of the priests, when they consult these
deities, ensures their success. When they attack any towns
or villages, they carry off the inhabitants, and every article
of value, and divide the booty between the emperor and
those that have been engaged. The slaves are sold to the
Europeans, except such as are of quality or fortune, who are
removed to their friends on condition of their finding a
number of slaves in their room. The emperor is said to
allow free commercial intercourse with all strangers. The
Portuguese demolished their fort on the island in 1703. See
Balontes, Bissagos, and Bulam.

*BISSECTION, in Geometry, the division of any quantity
into two equal parts, otherwise called bipartition, which see.
See also Division, &c.

*BISSENDORF, in Geography, a town of Germany, in
the circle of Weilphalia, and bishopric of Osnabruck, 5
miles S. E. of Osnabruck.

*BISSENPOUR, a small district of Bengal in the East
Indies, which is governed by a Bramin family of the tribe
of Rajpoots, and which has uniformly preserved its
independence. In this district, it is said, the purity and equity
of the political system of the Indians are found unadul-
terated. By the singular situation of this country, its
inhabitants have been enabled to maintain their primitive
happiness, and the gentlemen of their character; and they have
been secured from the danger of being conquered, or of im-
creasing their hands in the blood of their fellow-creatures.
Nature has surrounded them with water, and they only need
to open the sluices of their rivers in order to inundate the
whole country. The armies that have been lent to subdue
them have been so frequently drowned, that the plan of en-
slaving them has been laid aside; and the projectors have
thought proper to content themselves with an appearance of
submission. In Bissenpour, liberty and property are sacred;
obduracy is unknown; and every stranger, who enters this ter-
ritory is under the protection of the laws, which provide
for his security. The guides, to whose conduct he is
committed, become responsible for his person and effects; while
he remains, he is maintained and conveyed with his mer-
chandise at the expense of the state, unless he expresses his
desire to stay longer than three days in the same place; and
should this be the case, he is obliged to live at his own
cost. In this state it is said, probity and honesty are so
prevalent, that if any one find a purse, or any other article
of value, he hangs it upon the first tree he finds, and informs
the nearest guard, who gives notice of it to the public by
beat of drum. Out of about 350,000 annually received
at an average by the government, without inquiry to agri-
culture or trade, what is not wanted to defray the unavoid-
able expenses of the state, is hid out in improvements. The
rapids is enabled to engage in these liberal employments, as
he pays the Mogul’s only such tribute, and at such times, as
he thinks proper. Raynal’s Hist. Settl. East and West Ind.

*BISSENPRAGA, a town of Afa in the country of
Siangur, situated near the base of a mountain, on which
stands the famous temple of Buddrennath. It is a place of
some importance, as being the residence of the priests and
principal Hindoos of Buddrennath. Here they hold their
durbahs, exercise their laws and the duties of their religion,
in the greatest state of security from foreign intruders, and
can at any time seclude themselves from the rest of the
world, by a removal at Bissenprag another river, proceeding
from the eastward as large as itself, called “Dood Gangy,”

houses, and is a place of some trade; the inhabitants are all

*BISSET, CHARLES, in Biography, studied medicine
several years at Edinburgh, as he informs us in his Essay
on the Medical Constitution of Great Britain, published in 1752,
and was then promoted to be second surgeon to the hospital
in Jamaica, where he continued from 1740 to 1745, when
he returned to England, and purchasing a commission in the
army, he served as lieutenant and engineer in Flanders until
the peace in 1748. He now refumed the practice of sur-
gery, and settled at Skelton in Cleveland, Yorkshire, and
soon after published “A Treatise on the Scurry,” 1755,
8vo. He had before, viz. in 1751, published “An Essay
on the Theory and Construction of Fortifications.” In
1765 he obtained a diploma from the university of St.
Andrew’s, constituting him doctor in medicine. He died at
Knayton near Thirsk, in May 1791, in the 75th year of his

*BISSEXUALIS, or Bissetualis ells, an ancient measure
or veillet, containing twelve ounces, or two Sex-
taries.

*BISSEXILE, or Leap-Year, in Chronology, a year
constituting of 366 days, happening once each four years,
by reason of the addition of a day in the month of
February, to recover the six hours which the sun spends in its
course each year, beyond the 355 days ordinarily allowed
for it.

The day thus added, is also called bissextile; Caesar
having appointed it to be introduced by reckoning the 24th
of February twice; and as this day, in the old account, was
the same as the fifth of the calend of March, which had
been long celebrated among the Romans on account of the
expulsion of Tarquin, it was called "his sextas calendar
Martii;"
Martii; and from hence we have derived the name biffex-
tile.

By the statute de anno biffextile, 21 Hen. III. to prevent
misunderstandings, the intercalary day, and that next before
it, are to be accounted as one day.

The astronomers concerned in reforming the calendar, by
order of pope Gregory XIII. in 1582, observing, that the
biffextile in four years added 44 minutes more than the
sun spent in returning to the same point of the zodiac; and
computing that these supernumerary minutes 133 years
would form a day; to prevent any changes being thus in-
sensibly introduced into the seasons, directed, that, in the
course of 400 years, there should be three biffessexile re-
trenched; so that every centennial year, which, according
to the Julian account, is biffextile, or leap-year, is a common
year in the Gregorian account, unless the number of cen-
turies can be divided by 4, without a remainder. Thus
1600 and 2000 are biffextile; but 1700, 1800, and 1900

The Gregorian computation was received in most foreign
countries ever since the reforming of the calendar; and by
act of parliament, passed anno 1751, it commenced in all the
dominions under the crown of Great Britain, in the year
following, ordering that the natural day following the
second of September, should be accounted the fourteenth;
omitting the intermediate eleven days of the common calen-
dar. See Calendar.

BISINGEN, in Geography, a town of Germany, in
the circle of Swabia, and county of Pattingen Wallerlin,
4 miles S.S.W. of Haarburg.

BISSOOLY, a principal fort of Hindooftan, lying at or
near the entrance of the hills, 42 coffes S.E. from Jummoor.
Major Remell places it in his map on the north bank of the
Ravnees, 6 or 7 coffes above Kulamore, or 413 above La-
hore, or, in other words, about 39 geographical miles
E. 35° N. from Lahore. N. Lat. 32 32. E. Long. 75.

BISNOWIE, a town of Hindooftan, in the country of
Onde, and circar of Rohilcum, 25 miles west of Bereely,
and 85 E. S. E. of Delhi.

BISTAM, a small city of Perfia, in the province of
Dashe, on the north of the Great Salt Delert, rarely
visited by travellers. N. Lat. 35 30'. E. Long. 54 32'.

BISTER, a town of Switzerland, in the Upper Vallais,
not far bank of the Rhone. N. Lat. 46 19'. E.
long. 7° 52'.

BISTI, a species of Persief money, valued at sixteen
or eighteen French deniers. Some represent the biffi as an
ancient silver coin; others, as Chardin, make it only a
money of account, and call it dinar biffi.

BISTONES, in Ancient Geography, the name of a people
who inhabited that part of Thrace, which was bounded on
the north by mount Rhodope, on the east by the Hebrus,
and on the west by the Nesseus, and on the south by the Aeg-
ian sea. Its capital was Tinda. These people were subdued
first by the Macedonians, and at length by the Romans.
Xerxes, according to Herodotus, traversed their country in
marching against Greece. Hence "Biltonius tyrannus" is
used by Lucan to denote Diodemes, king of Thrace, who
fed his horses with human flesh; and "Biltonius turbo;" ex-
pressing a wind blowing from Thrace.

BISTONIS, a lake on the southern coast of Thrace,
N. E. of Abdera.

BISTORT, or Snakeweed, in Botany. See Poly-
comum.

BISTORY, or Bistoury, in Surgery, is a cutting in-
strument, formed like a small knife. It may be either
straight or curved, double-edged or with a single edge, harp
Vol. IV.

pointed, round pointed, or with a probe point, &c. Some-
times it is made to fit within a handle; at other times the
blade is fixed and immovable. For particular purposes,
the blade is concealed, so as to project only at the mo-
ment when the instrument is used by the surgeon on
which account it is called by the French bistouri chef.
On some occasions, it is found convenient to employ a
director, or a cane, at the same time we introduce
the bissory : for example, when it is intended to pass
the cutting instrument along a narrow fissure, or under the
purse up to a certain spot before we make any incision,
(see the article's Pyromosis, and Sirius); but whenever
there is room for the introduction of a fore-finger, that mode
is preferred by modern surgeons as a guide to the bissory,
being much more convenient and secure than any artificial
director. The precise form of a bistouri must be regulated
according to the nature of the operation required, and the
end to be obtained. See the article Scalpel, and consult
the engravings of chirurgical instruments attached to this
Cyclopedia.

BISTRA, in Geography, a town of Bohemia, in the circle
of Chrudim, 6 miles S. S. E. of Politzka.

BISTRALIA, a town of Russian Tartary, on the west
side of the Donetz, 70 miles N. N. E. of Azof—also, a
river of Russian Tartary, which runs into the Donetz, 64
miles N. E. of Azof.

BISTRE, among Painters, a composition made of
the most glossy and high-well burnet foot, pulverized, and
pasted through a fine sieve, then baked in a little gum-water,
and made into cakes; or it is the burnt oil, extracted
from the foot of wood. It is a brown transparent colour,
and has much the same effect in water-painting, where
alone it is used, as brown pink in oil.

The belt is prepared from the foot of dry beech wood,
by grinding it with urine or water, into a smooth paste,
and then diluting it with more water; after the groffer sub-
stance has subided, the liquor is poured off into another
vessel, and left to settle three or four days; the fine matter
that remains is biffre.

That the biffre of our colour shops has been prepared by
a procid of this kind, and not, as some have fatypech'd, by
evaporating the infusion of foot to an extract, may be pre-
fixed, says Dr. Lewis (Com. Epit. Phil. Techn. p. 345),
both from its appearance and its qualities. He observes,
that different parcels of biffre differ considerably in their
colour, on account, probably, of the different qualities of
the roots from which they were made.

In the Handmaid to the Arts, vol. i. p. 125, we have
the following recipe for preparing it. Put the foot of dry
wood (of beech when it can be procured) into water, in the
proportion of 2 pounds, to a gallon, and boil them half an
hour. Then, after the fluid has stood some time to settle,
but while yet hot, pour off the clearer part from the earthly
sediment at the bottom; and if on standing longer it form
another earthly sediment, repeat the same method; but this
should be done only while the fluid remains hot. Evaporate
the fluid to dryness; and what remains will be good boilre, if
the foot was of the proper kind. That which is good is
transparent, when moistened with water, and of a warm,
dark brown colour.

Instead of this, some use the hatches of a pen, with a
little Indian ink, others red chalk, others black lead, &c.
See Washing.

BISTRANIA, in Geography, a town of Russian
Tartary, on the south side of the Don, 100 miles E. N.
E. of Azof.

BISTRIATA, in Entomology, a species of Cicada (Di-
S.
that inhabits France. This is yellow, with two transverse bands of brown. Geoffroy.

BISTRICZ, or BISTITZ, in Geography, a town of Transylvania, and capital of a county, to which it gives name, situate on the river Bistriz, which runs into the Simon, 4 miles SW. of Keszova. The town is 42 miles N.N.E. of Clauflenburg, and 256 E. of Vienna. N. lat. 4° 24′ E. long. 25° 3′.

BISTRIGALIS, in Entomology, a species of PHILENA (Pyralis), with cirrurous wings, and two farrigulous streaks, and a black dot. Inhabiteth Europe. Linnaeus.

BITRIGARIA, a species of PHILENA (Geometra), with cirrurous wings, undulated, with two linear streaks.

A native of Europe. Linn. &c.

BISTRIGATA, a species of PHILENA (Geometra). It is griseous, with two white streaks. Inhabiteth Europe.

BITRITZ, in Geography, a town of European Turkey, in Moldavia, on a river of the same name, which runs into the Siret, 6 miles S.E. of Baken. The town is 20 miles S.W. of Jaffa. Also, a town of Walachia, 16 miles W.S.W. of Kinnik.

BISTRIZ, a town of Moravia, in the circle of Bruna, 6 miles W.S.W. of Ely.

BISTROFF, a town of France, in the department of the Oise, and chief place of a canton in the district of Morehang, 4 miles N.N.E. of Morehang.

BISTRITZ, a town of Bohemia, in the circle of Konigigratz, 10 miles from Gmitchin.

BISUGA, a river of Russian Tartary, which runs into the sea of Azof, 48 miles S.W. of Eiskoi.

BISULCATUS, in Entomology, a species of CURCULIO that inhabits Italy. This is black, with a cirrurous border all round, and two furrows on the beak. Fabricius.

BISULCUS, a species of ICHEUMON, of a black colour, with two impressed lines before; legs rufous; sting short. Lim. Mull. Lefk.

BIT, or BITS for Horses, in the Manage, are pieces of iron of various figure and construction which, being placed in the horse's mouth, serve, by the assistance of the reins, to restrain or guide his motions.

The term BITS, or bits, is confidered by some as originating from the horse's biting or chewing them between the teeth when placed in his mouth; in the French language is used a term also of similar signification, les mords, which would seem to corroborate the above etymology of it:—another however, equally natural, presumes itself in the common word bit, or bits, that is pieces of iron; this apparatus being always made of one or more pieces of this metal.

The art of bitting horses may be said to consist in furnishing the mouth with the most proper mouth-pieces, &c. for obtaining from them an obedience to the will of the rider, and effecting a due performance of all the movements and restraints which may be desired, or at least which are dependent upon the operation of the reins. Rightly understand, and well administered, this art affords the power of communicating to the horse support and confidence, with greater ease and security to the rider. The misapplication of its rules, on the contrary, or an insattention to them, where the mouth is not totally insensible, will produce painful sensations to the horse, with disgust and rebellion, and to the rider uneasiness and perhaps danger.

It is to be lamented that the preposterous opinions of the uninformed have been too much the guide of the public in their estimation and choice of the proper bits for horses, as also in too many other things respecting these useful animals, tending often to accumulate unnecessary suffering and misery upon them. The writers on this subject are few and unsatisfactory; we shall, however, except Mr. Berenger, whose work is a noble effort to emancipate this branch of science from barbarity and ignorance; and from him we shall take occasion to make some extracts in the sequel of this article. Here it will be proper to observe, that this author, by the term bit, has designated the curved bit only, but we have ventured, for the sake of puritying a more connected view of the subject, to include in this term any piece or pieces of metal placed in the horse's mouth, for the purposes of guidance or restraint.

In our account of the different kinds of bits, and their effects, we shall begin, for the sake of order, with the description of a bit of the most easy and simple conformation possible, and then proceed to the most complicated.

A short iron rod, made rather wider than the mouth of the horse, and provided with a hook or ring at each extremity for fastening the reins to, affords us an instance perhaps of the greatest possible simplicity in the construction of a bit; and such a one only slightly curved forwards, to allow more liberty for the tongue, is at present in general use for the heavier kind of draft horses, the bearing rein being usually attached to it, passing over the hames of the collar.

A similar rod to the former, broken in two pieces, and connected by a joint in the middle, is the next in point of simplicity, and is in common use for horses of light draft, as in horse employed for the curricule, coach, &c. and is attached by the bearing rein to the hook of the sadderle, and this kind of bit is mostly termed with us a bridon.

The next in point of further complication of parts, and which scarcely can be said to differ from the former, is the common snaffle. This is provided with two crofs pieces, which rest against the lips or sides of the mouth; for as the snaffle is intended for the saddle horse, and the reins go to the hands, to the crofs pieces are useful in preventing the bits from being drawn through the mouth, which precaution is not so necessary where the bits are affixed to the bearing rein. The bridon we may observe, is also made in general smaller than the snaffle, as well as without crofs pieces.

The distinction, however, between a bridon and snaffle is insignificant and of little consequence; for on all occasions crofs pieces are the most convenient; and it will be easily seen that the bridon is merely an imperfect snaffle, poising no peculiar characters which can form a real distinction.

The term alfo, when confined to this object is misapplied: for the French, from whom we have borrowed it, by le bridon understand the snaffle and its rein, in opposition to le brie, by which they denote the curved bit and reins.

In war, and on other occasions, the bridon was used as a letter briedle, or bridle of reserve, in case of the failure of the former from any accident; and hence the origin of its name.

The number of parts of which the mouth-piece of the snaffle is composed, may be increased to any extent, as it may be made with one, two, or several joints; but as it is evident these additions will not essentially alter its properties or effects, it would be useless to pursue a distinct consideration of them.

But the condition of the snaffle admits of being further altered and changed by the variation of its figure, its substance, and its surface, as to acquire new properties and effects which will require particular attention; its gentleness or rigour will depend almost wholly on these conditions. A mouth-piece made of two entirely straight pieces will be more severe than when there are somewhat curved, as the curved bit is more apt to embrace and incline the lips between it and the bars than the
the straight one. A thin and slender bit or snaffle, it will be easily perceived, will act with more severity and sharpness upon the bars than a thick and obtuse one; the former, therefore, or the sharp bit, is employed more particularly for restraining such horses as are hard-mouthed, and too eager, while the latter is used for such as have a proper feeling of the bars, and especially for breaking in young colts.

The surface may be varied as to roughness or smoothness, producing also different effects. To give the greatest ease possible, a large and highly polished bit is necessary. This is sometimes provided with moveable rollers on the axis of the bit, which, turning with every movement of the reins, diminish the friction of the bits and render them less irritating. These rollers, however, in reality can have but little effect in the snaffle, though of pleasing effect in the mouth-piece of the curb; for this reason, that the snaffle being jointed in the middle, is drawn by the reins to a sharp angle in the mouth, so that these rollers are presented to the bars in an oblique direction, under which position it will be obvious they can have very little or no motion, but, on the contrary, they will tend to render the bits more severe by their irregularity; so that a well polished snaffle is in fact preferable to one of these: with rollers of the ordinary construction.

On the other hand, to give the greatest degree of severity to the mouth-piece of the snaffle, it is twisted while hot into a spiral form, and is made to present by this means a sharp, rough, and unequal surface to the jaw, being capable, according to the degree of sharpness to which the edges are wrought, of punishing the bars and lips with greater or less severity. The different degrees of punishment which this kind of bit is capable of inflicting, will perhaps be found sufficient for all the purposes of correction, where restraints may properly be had to actual force and punishment. For it should be always kept in view, that gentle means will produce a good mouth; while harshness and too great severity will tend to destroy it altogether.

Thus far the ancients of the most remote ages of the world, almost as far back as any history extends, were well acquainted with the use of bits. Xenophon, more than four hundred years before Christ, had described similar bits as being in common use in his time among the Greek states. He speaks of a smooth and a sharp kind of bit, the latter, if more severity was requisite, to be armed with points or teeth. In its use, however, he enjoins the greatest tenderness, and observes "that when you would wish to slacken the pace of an eager horse, which hurries on too fast, and to pacify his fury, so as to make him go more temperately, or even oblige him to stop, you should not attempt to do it at once, and with violence, but artfully, and by degrees, gently pulling him in, then yielding the bridle, and playing with his mouth with a light touch, as if you intended rather to win his consent than force his obedience." Chap. 9, 10.

Beyond the changes above described, the snaffle itself does not appear to admit of any alterations worthy of notice. It may, however, be just observed, that some horsemen add a chain to it, extending from check to check, which rolling loosely on the tongue produces irritation and flavors and, as they imagine, freshens the mouth. Such a bit is known by the name of the Rockingham snaffle.

The reins, however, must be remarked, admit of some alterations in their disposition, which will influence the effects of the bit on the mouth; as whether they are carried higher or lower. At this present time there is a practice more especially in horses of light draft, as in those for carriage, curricles, and chairs, &c. to distort and alter the bearing reins from their natural direction, and to dispose them more perpendicularly and in a line with the head; so that instead of pulling straight from the mouth to the horse's back, they are directed up the sides of the face, as high nearly as the jaw, gland, or bale of the ear, where they are passed though a ring hanging from the head stall, and from thence to the back of the faddle. The appearance is ornamental and elegant, and the reins to direct are considered as more forcibly elevating the head than if they proceeded to the back in the usual direction.

As the disposition of the reins, so the figure of the bits themselves, and the ornamental appendages attached to them, admit of almost endless variety. The manufacturers of these articles, availing themselves of this license, render their bits more lucrative by as frequent changes as possible. These are successively introduced as fashionable novelties, till again for novelty they return to the simplest practice; and this takes place without any alteration in the principal circumstances of their construction, properties, or use.

The next kind of bits in use for horses is the curved bit; which, as it is an instrument of much greater complication of parts than the snaffle, so it appears to have been of comparatively recent date.

In some of the sculptured equestrian figures of the ancients something like the branches of the curb may be found; but in no instance does there appear any thing resembling the chain, which is absolutely necessary to its effect. Their writings also appear to be silent on this subject. It was probably the invention of Italy or France, which for some centuries past have taken the lead of the other nations of Europe in teaching the arts of the manage. It was first introduced into the English army by a proclamation made in the third year of king Charles I., since which time it has got into universal use for the army, the field, and the road, so that no horseman deems himself perfectly equipped without it. Most of those writers who have treated of it in the fall, and in the century preceding that, and who wrote probably soon after the commencement of its use, have been very profuse in their various proposals for the structure of it, especially in rendering it more complicated, fierce, and cruel; though it is probable their clumsy figures and representations were never imitated in actual practice. They appear to have been much satisfied with their new invention, imagining it a pure means of reducing horses to immediate obedience, in spite of every obstacle; and true it is, it can punish with extreme severity: but is such a measure most likely to create vice, or to overcome it? Indeed, according to the opinion of one of the ablest writers that has ever considered this subject, and whose opinion we shall take an opportunity of quoting more fully hereafter, little or nothing has been really gained by its adoption; on the contrary, the snaffle polishes more simplicity, power, and perfection.

Stripped of all unnecessary trappings, this instrument consists of the following essential parts: a mouth-piece with two forked branches, or inflexible rods of iron, firmly fixed to the former, and a chain passing from side to side, behind the chin, including the jaw between two eyes or rings at the upper extremity of these branches, fixed to the head stall, and to lay it in the mouth; two other rings at the lower extremity of the above branches receive the reins, passing to the hand, or sometimes in draft horses to the hook of the faddle, as a bearing ree. These are all the parts really necessary to constitute the curb.

The bits thus formed being placed in the mouth, and the chain passed round the lower jaw, the branches, it will be

3 S 2
readily
BITS.

readily seen, become powerful levers when drawn backwards, acting upon the mouth-piece as a centre, and squeezing, by means of the chain, whatever interposes between it and the mouth-piece, with a force equal to the length of lever afforded by the lower branch.

This force, it will be perceived, is influenced and regulated not only by the length of the lever below the mouth-piece, but also by the greater or leffer distance at which the chain is placed from it. The chain is usually fixed to the eye of the cheeks-piece, where the head-hall is fastened; if, therefore, this part is very long, it is evident it must moderate or counteract the power and effect of the lower end of the branch, and render it less effective by bringing the centre of motion nearer to the middle of the lever.

It appears manifest, from the construction of this instrument, that its whole force is exerted upon the jaw itself, and that it has power to pinch the bars with cruel violence, even to the fracture of the bone, and this with very powerful branches has sometimes happened. It can also crush and bruise, and totally destroy the tender covering of the inside of the mouth, and the skin beneath the jaw.

From considering its mode of operating, it might reasonably be doubted whether it does in reality flop the horse by its power and opposed force, as is generally conceived at present, or rather by the severity of the pain it inflicts; as should the horse arm himself against this, it is totally insufficient to arrest his course; of which influences occur in runaway horses every day. And we shall venture to suggest, though contrary to the general opinion, that the snaffle, even in this respect, if the mouth has not been previously hardened and spoiled by the use of the curb, is the most powerful instrument of the two.

The mouth-piece of the curb is usually provided with an upset or arch in the middle of it, as it would, if perfectly straight, rest on the tongue, and occasion an unpleasant restraint. This passage for the tongue is often made so narrow and small by the bit makers, that one should apprehend they scarcely had a right idea of its use. From the circumstance of its allowing a passage for the tongue, it has been called by some, the liberty; and, for the same reason, by others, the porte: hence we have the porte-mouth bit, vulgarly called among the bit makers and grooms the Portsmouth bit: and by a supposed counter expression to this term, we probably get the Weymouth-bit.

In draft horses, especially for the coach, it is a frequent custom to have affixed to the upper part of the upset small chains or polished drops of iron, which hanging loose in the mouth, and falling on the tongue, occasion the horse to champ the bits, and create a copious flow of saliva, so as to slaver the lips with its white froth; and when this happens, it is considered by some a good sign of health and gaiety, and that the horse is well bitten; for, if the bits are disagreeable to him, he never plays with them, or exhibits any froth, say they. These small appendages are termed by the French les chainettes, and by the English players.

It is farther to be observed, respecting the mouth-piece of the curb, that the straight part which rests upon the bars of the jaw, is termed by the French le canon, and by the old English writers the jeive; and though a highly convenient and useful word, it is to be regretted it is at present out of use; the French term, which is not so expressive, having superseded it. This part should be well polished, and may be made of any propel figure, as that of a cylinder, cone, oval, globular, pear-shaped, &c.

It is obvious that the effect of the curb, as far as it refers to the bars, will be correspondent to the thickness or thinness, smoothness or roughness, of this part; the larger and broader it is, the more surface it covers; and thus the pleasure, by being distributed over more points, becomes less felt. This enlargement, however, of the canon or jeive should not be carried to an excess, by making it too heavy, or filling the horse's mouth with more iron than it can conveniently receive, and thus create pain, instead of greater ease.

To render these irons less irritating to the mouth, and to avoid their friction upon the bars, the jeives are provided with loose, movable rollers of well polished iron, which readily turning on the axis of the bits, very considerably diminish their severity. These moveable pieces are also particularly useful in preventing the horse from catching and holding the bit in his teeth; as the curb, under these circumstances, can full move and act with the same freedom as before.

The jeives are sometimes composed of three or four flatth knobs, united by a joint to each other, and with a joint to the upset, which is intended to render it very fever; it is obvious, however, that such an alteration must bring it nearer to the condition of the snaffle; the knobs, however, if they can be drawn transversely across the bars, might produce considerable irritation, but not so much as they would do if not jointed. This bit is not frequently used, and it is called with us the Hessian-bit.

To the curb is often fixed a ring opposite the mouth-piece, which, as it is directly in line with the axis of the bit, has no other effect when the reins are affixed to it, than a snaffle would have provided with a familiar mouth-piece. This is termed putting the reins to the cheek, and as for horses of light draft, whose mouths are not ruined, it is by much the best, as the mouth is less annoyed, and the horse obeys with more alacrity the guidance of the hand from this point, than from the extremity of the branches, which are particularly ill calculated for this purpose: this kind of construction is generally distinguished by the name of the Pelham bit.

In the older English writers, as well as those on the continent, on the subject of bits, we find an appendage described, which is not at all, at present, in use; and as it enters the mouth with the mouth-piece, it may, with propriety, be described along with it. It consisted of a chain extending from branch to branch of the bouquet, or cheek piece, being placed rather above the mouth-piece, and parallel to it, and was stretched across perfectly straight and tight. This part was called the water-chain, and by the French Trench-file: its use is not very evident. Mr. Berenger takes notice of it, and observes "that it might be useful to horses that are apt to drink or swallow the bits, as the expression is, or burry it so deep in their mouths, as to hinder it from having a due and just effect"; from its being laid aside so generally, we presume it has at least been thought useless.

It is a common belief with the grooms, that a great power refides in the upset of the mouth-piece, and that the bits are more powerful as this is longer or shorter; nothing, however, can be more fallacious than this reasoning. In the works of Laurence Reef, also a French writer, we find, in connexion with this idea, a curb, with an upset of unusual length, being defined to correct the vice "d'un Roussin qui a la bouche d'une diable?" it will be obvious, however, on a moment's reflection, that this part, from being made very lofty, and coming forcibly against the palate, would compel the horse to open his mouth, when it would cease farther to act in any way; with more reason, the same writer proposes, on the other hand, "pour donner
B I T S.

grand plaintiffs, to have a bit constructed with a low upset, and insufficiently wide, with large, conical, smooth jewes for the bars.

Of the chain. The chain is the part most essentially necessary to give effect to all the other parts of the curb, and may be placed, as we have already noticed, at any given distance above the mouth-piece; its operation being more powerful, as this distance is exceeded by the length of the branches. This position, though true as a general principle of reasoning, appears to be subject to the operation of other causes in actual practice, which it will be necessary to consider; for, in direct contradiction to this is the assertion of Mr. Berenger, who appears to be almost the only writer who has truly investigated the merits of this particular object. He observes, in regard to this, that the nearer the chain, and the longer the branches, the fatter and more indulgent its operation. This, on a first view, would appear to be in direct variance with the rules above laid down, and irreconcilable to the well known laws of the operation of the lever, and even at variance with his own preceding affirmations; when, however, we remember the experience and practical knowledge of him who affords it, it deferves a more particular consideration; let us first admit the truth of the position, as it seems founded on the sure tenet of actual experience, and then we should venture the following as the most natural explanation of it.

In proportion as the branches are longer, the more extensive is the circuit their extremities perform in their operation; and therefore, the hand that guides them must pass through a greater space to produce the same effect: and now if the chain be placed very near to, or upon the out-side of the mouth-piece, and be applied not very tight about the chin, yet, in reality, though there would be an apparent increase of power by the length of the branches, they would have little or no effect, as they would arrive at the utmost extent to which they can be drawn, before the chain would begin to pinch. On this account, the most lively effects would be produced by the chain having more sweep and extent of action, and by the branches being not quite fo long, as great length also adds something to their flexibility, though not to a degree to be worth taking into the account. Still, however, the branches must ever obey the common laws of the lever, acting with force proportioned to their length; while shorter branches act with greater quickness, and are more lively in their impression.

The chain is fastened on one side to the eye of the baquet, where the head-flall is fastened; on the other, to a hook hanging from the same part. This chain, as it is at present used, is composed of iron links or rings, so bent or indented, as to form, when put together, one uniform nearly flat surface; and these links, by twirling or untwirling, may be made to present a surface with any degree of roughness to the chin.

When great tenderness is required, this chain may be covered with leather or cloth; or where a full greater delicacy is desirable, the curb may be made wholly of leather, without any chain.

The larger and thicker the rings are, provided they are smooth and well polished, the easier the effect of the chain. In old English, this chain was called the kirble; and hence, by contraction, kir; and finally, by an easy transition of the ki into ce, we apprehend that the modern appellation of this instrument is obtained.

Of the branches. The proportion which the check part bears to the lower extremity of the branches, or rather the position of the eye, to which the chain is fixed, determines the degree of power of the bit upon the principle before advanced, that is, if the chain is fixed to the upper extremity of it as it usually is to the transverse opening or eye of the head-flall.

For the elementary view we are taking of the construction of the bits, it has been only considered as a straight, plain lever of indeterminate length; it is, however, in practice, often used, as in the army, it is used by the famous Z, with which it is incised to be rendered more powerful, as well as ornamental; at other times the branch of the bit, with a view of increasing its force, is carried forward with a sharp elbow, giving nearly the figure of the letter Z; while by others, with more reason, to prevent the horse from catching the bit in his mouth, it is made with an arch, or semicircle, in the middle of the branch, like the letter C, turned backwards for the same purpose; still, however, in fact, whether bent into that or any other space, it is the length of the lever, and its strength, which alone give the power; it is true, however, that a long curved branch, though more powerful, will render the effect somewhat fatter, as coming from a greater distance, especially if the branch is at all flexible and yielding, than it would by the quick and rigid effect of a shorter lever, made perfectly straight and inflexible; these branches may also be turned or bent, not only backward or forward, but also outwards and inwards. At their extremities, these turned outwards, are laid to be strongest of all in their operation.

As to the cheek-piece, or baquet, as it is called by the French, for an appropriate name is wanting to this part in the English language; the eye of the baquet, say the horsemens, commands and gives efficiency to the rest of the bit; or, in other words, decides the distance of the chain from the mouth-piece, or centre of motion; as however, in speaking of the other parts, we have had occasion to introduce a sufficient account of this, it will not be necessary farther to give it a separate consideration; nor will it be useful to describe the numerous mongrel herd of bits engendered of the snaffle and curb, which are reducible to the properties of one or the other, or partaking of both.

The most useful bit of the curved kind, appears to be the Weymouth-bit, which is at present in common use for draft horses of light work, as for carriages, coaches, &c. It consists of a strong, plain mouth-piece, of uniform thickness throughout, without any upset or jewes, but is simply curved forwards, to give liberty to the tongue; this kind of construction is the simplest perhaps that the curb admits of.

In concluding, it remains for us to notice the proper application and adjustment of these bits to the horse's mouth, and to treat of their real effects.

By the management of the head-flall, the snaffle bits should be so adjusted as to fall in the middle space between the tushes and grinders, resting upon the bars: the mouth-piece of the curb should also occupy the same situation when, however, it is used along with the snaffle, the bits of the snaffle should be placed highest in the mouth.

If the bits are placed too high in the mouth, the horse carries his head aloft; if too low, he floops the head, and tries to catch them in his teeth.

The thicker and more flay, and the wider or broader the bars of the horse, the rougher may be the mouth-piece for the leaner and more delicate; consequently, the bits should be left severer. Care should also be taken that the mouth-piece be well suited to the size and width of the mouth, and be not too narrow, as this would give pain by squeezing the bars together; if, on the contrary, it is very wide, it reifies with more force on the bars, without the interpolation of
of the lips, as is most usually the case. Where the tongue is large and prominent, the upper should also be in proportion, otherwise the bits could not rest upon the bars, but would press upon the tongue.

In regard to biting the horse, and the consideration of its effects, we cannot desire to see anything more conformable to truth and reason, than what has been given us by Mr. Dr. Revere, and with some useful extracts from his valuable performance, we shall conclude this article.

Of biting horses with the curb. "In the beginning of an and taking, whole aim is to founde and reclaim nature, and that at a time when she is wild, ignorant, and even wilderished as the attempts which are made upon her, it is evident that she must not be treated with levity, but firmly, with patience, and by small degrees, and that nothing should be offered that may hurt, surprise, or occasion any dissuasion.

The horseman, therefore, should not affect the part of a tyrant, but of a lover; not endeavour to force her to submission, but strive to gain her content and good will by kindness, and the gentlest attentions; for what prospect of success would rougher manners afford? To what purpose would it be to compel a colt to go forward, or turn from fear of the whip or spur, and to trot and gallop so freely as to supple his limbs, and form his paces; if the novelty of the bit, and the unaccustomed restraint to which it subjects him, should vex and confound him, so as to make him not know what to do, or how to behave in these extremes? It cannot be expected, that he will be guided, and go with ease to himself, or pleasure to the rider, if the instrument, by which he is to be conducted, offends or gives him pain; all habits and acquirements should be attained gradually, and almost imperceptibly: rigour and precipitation would ruin all; and, instead of forming the horse to the execution of what is required, may plunge him into vice and rebellion, so as to occasion much trouble and loss of time before he can be reduced.

He should therefore, at first, be considered as if he was designed to be formed to all the delicacy and exactness of the bit; and the horseman should be content, if he will endure it in his mouth, so as to grow, by little and little, accustomed to it, till the restraint becomes by habit so familiar and easy, that he not only is not offended, but begins even to delight in it; for this purpose, great care should be taken that the bit be easy and gentle in all its parts; that the mouth-piece be larger than it need be for an horse already bitted; that it in no wise impedes the bars, squeezes the lips, or galls the tongue.

The mouth-piece, called a cannon, with a joint in the middle, will be the most suitable; the ends of it should be as large and full as the size of the mouth will permit, for the thicker and more blunted they are, the easier they will be for the horse, and the appu lefs frieck and fevere.

The links of the curb should be big, smooth, and well polished; the curb somewhat long. The branches should be exactly even with a line of the banquet, to make the appu moderate and equal; they should likewise be long; nor does it signify what shape they are, for with most horses they ought to be so weak, as fearfully to have any effect; so requisite it is to guard against every thing that may annoy or disturb the horse in these first trials. In order to reconcile him to this new constraint, the reins should be held in both hands; and the horse, for some time, should only walk under the rider. Above all, upon this, and all other occasions, a firm, a light, and diligent hand, is necessary.

Such are the outlines and general principles upon which the art of biting horses is established; which art, as far as it reaches, is pure and constant; but while, in spite of all the merits and praises of which it has so long been in possession, will, upon a serious and strict trial, merit. I doubt, be found adequate to the views of a found and intelligent horseman, nor capable of bringing a horse to that degree of fitness and exactness of curbing, which the truth and perfection of the art require; these attentions seeming to have been referred for a more simple but powerful machine, called the snaffle."

"To perform his business judiciously and gracefully, the animal must first be made supple in his bone parts, and his head and neck so managed, that one may be raised, and the other arched or bent, more or less to the hand to which he is to turn. The bridle, called the bit, is so important in its endeavours to rule the head, that it even produces the opposite effect; nor from the confinement in which it keeps the horse, and the small compass it affords for the action of the rein, does it allow the rider sufficient room to bend him, without pulling down his head, and putting him upon his shoulders, both of which are incompatible with the true and sound principles of the art. The frequent use of cavesons and bridles, fully evinces the want of power in the bit to supple the horse, or raise the forepart.

The figures and representations of horses working upon different leasons, may be appealed to for the confirmation of this attention; the books of past times abound with them, especially thatboatook work of that king of horsemen, the duke of Newcastyle, whose horses are all drawn with their heads between their knees; and yet are exhibited to the equestrian world as standards of truth, and models of perfection. The successes of this duke, and of other great masters, as imitators, are generally a blind and servile herd, ran headlong into the errors, and adopted the faults of their predecessors; and always made use of bits, without reflecting upon their effects, or perceiving that they could operate to make the horse carry low, or to put him upon his shoulders, while they thought that he was all the time upon his haunches."

"If ever there was a panacea, or universal medicine, the snaffle is one for the mouths of horses; it suits all, and accommodates itself to all; and either finds them good, or very speedily makes them so; and the mouth once made, will be always faithful to the hand, let it act with what agent it will. This bridle can at once subject the horse to great restraint, or indulge it in ease and freedom; it can place the head exactly as the horseman likes to have it, and work and bend the neck and shoulders to what degree he pleases. He can raise the head, by holding up his hand; by lowering it, it can be brought down; and if he chuses to fix and confine it to a certain degree he must use for this, as well as for the purpose of bending, double reins; that is, two on each side, the ends of which must be fastened in a staple near the pomell of the faddle, or to the girths, higher or lower, as the mouth, proportions of the horse, and his manner of going require; and if properly measured and adjusted, will form and command the horse fo effectually, as in a great degree, to palliate many imperfections of the mouth, and many faults in the mould and figure."

"The reins thus fastened, or even one only, for the sake of working one jaw and one side, will operate more or less, as the branches of a bit; and the snaffle will almost be a bit, a bridon, a caveson, and martingal, in one. When the horseman would bend the horse, he must pull the rein on that side to which he is going; and lengthen that of the opposite, that they may not counteract each other. No thing
BITE

thing will awaken a dull mouth, and bring it to life and feeling, so soon as this bridle. If the mouth be hard and callous, the iron should be so twisted as to have a fort of edge, which will reach the lips, and when they will permit, the bars also; and if gently moved, or drawn from side to side, keep the mouth fresh and cold. If the twisted, or rough flannel, be thought too harsh, and the hand not skillful enough to moderate its effects, a smooth flannel may be used; or if a bit of lain be wrap round the twisted flannel, it will make it easy and smooth; and the mouth, once made fine and delicate, will be true to its feelings, will obey the flannel, and follow the hand with as much exactness and precision as the bit knows to demand, but with more freedom and boldness than it ever can allow.

Such are the properties and merits of the flannel, which long observation, and not a little experience, have taught the writer of this article to think preferable (generally speaking) to those of the bit; and which he has been therefore induced to point out and recommend with due deference to others, but with a greater deference to truth and justice.

"Detrabere autus,
Hærentem capiti multa cum laude coronam."

But is also used for a little tool, fitted to a fock or handle, for the purpose of boring. In this lenae, we say, the bit of a piercer, an augre, or the like; meaning that iron part of those tools witherewith the holes are bored.

The bit used by the block-makers, refembles the shank of a gimlet, from fix to twelve inches long, and from half an inch to an inch in diameter, and has at its end either a screw, a sharp point, or edge, for the purpose of cutting or boring holes. The centre-bit is a bit, having in the middle of its end, a small feel point, with a sharp edge on one side to cut horizontally, and a sharp tooth on the opposite side to cut vertically. Holes bored with this instrument, are not liable to split. The counterfunk-bit is a bit having two cutting edges at the end, reversed to each other, which form an angle from the point. Goose-bit is a bit formed from the centre-bit, with a hollow edge at its end, like a gouge. Nafe-bit is a bit similar to a gouge-bit, having a cutting edge on one side of the end.

Bit of a Key, is that part fitted at right angles to the shank of the key, wherein the wards are made. See Lock, &c.

Bit is also used in Commerce, for a piece of coin current in Jamaica, and valued at 7d.

Bits, or Bitts, in a ship denote a frame composed of two upright pieces of timber, called the pins, and a cross piece fastened horizontally on the top of them; used for belying cables and ropes to. Bowline and bow-bitts are situated near the masts; the fore-jer, and top-sail-bitts are situated in the fore-cable, and round the fore-mast; the main-jer, and top-sail-foot-bitts are on the quarter-deck; the rigging-bits are the largest bits in the ship, and are those to which the cable is bitted, when the vessel rides at anchor. The cable is bitted, or confined to the bits by one turn under the cross-piece, and another turn round the bit-head. In this position, it may be either kept fixed, or it may be veered away.

Bit-Stoppers, are those stoppers that are used to check the cable. See Stopper.

BITAZA, in Ancient Geography, a town of Asia, in Asia, according to Ptolemy.

BITBOURG, in Geography, a town of the Netherlands, in the duchy of Luxemburg before the revolution, but now a principal place of the canton of the same name, in the department of Forêts, containing 1658 inhabitants; the population of the canton confining of 7160 persons. Its territorial extent includes 225 kilometres, and 12 communes. N. lat. 50° 5' E. long. 6° 43'.

BITCH, in Zoology, is the female of the canine species, in contradistinction to dog. (See Canis.) It is sometimes used in a similar sense with respect to foxes, the female being termed a "bitch-fox;" though the more common appellation among sportmen is a "vixen." Bitches are sometimes spayed, to prevent their further propagation; the best time for which operation is about after the heat is gone off.

BITCHE, in Geography, a town of France, and principal place of a district, in the department of the Moselle, containing 2130 inhabitants; the number of those in the canton being 10,441. Its territorial extent is 3125 kilometres, and it includes 23 communes. It is seated on a river at the foot of the Volges mountains, on the frontiers of Deux Ponts. It was taken by Lewis XIV, and fortified by Vauban; afterwards dismantled and restored to the duchy of Loraine. In 1743, it was again fortified. Before the revolution, it was the capital of a country, including 50 villages. N. lat. 49° 5'. E. long. 7° 44'.

BITCHU, or BITZU, a province of Nipon, in the islands of Japan, between about 34° 30' and 35° N. lat. and 134° 30' E. long. Bitchys, a tribe of Tartars, visited by La Perouze in 1787, and described by him. See Orrotchys.

BITE is defined to be a solution of the continuity of a soft part, caused by the impregnation of an animal's teeth.

Bite of Madder. See Hydrophobia.

Bite of Serpents. See Poison.

Bite of Kettle-fish. See Poison.

Bite of the Tarantula. See Tarantism.

Bite is also applied, in a less proper sense, to the impregnation of other sharp or pungent bodies. Thus a file is said to bite the metal; aqua fortis bites, or eats into copper. An anchor is also said to bite, when it holds fast in the ground.

BITERLAGH, or Bitherlage, the ancient Danish military or camp law.

The word is compounded from biter, mulct, and lagh, law; q. d. the law of mulct, or eates.

Among the laws of the Danes, there are two peculiarly eminent; viz. the bier frin, or court law; and the bitherlage ract, made by Canute the Great, about the year 1035, of which an edition has been given by Rubenius.

BITETO, in Geography. See Bibetta.

BITHABA, in Ancient Geography, called also Birthama, a town of Asia, in Asia, according to Ptolemy.

BITHER, a city of Judea, called by St. Jeron, Bethor, which was the place of retreat of the impolltor Barchochebas, fortified by him, and made the capital of his New Kingdom. It was besieged by the Romans under Julius Severus, A D. 134, and after an obstinate resistance, compelled to surrender. See Barchochebas, and Bethorhon.

BITHEREMAN, a town of Prencicia, according to Sozomen, situate at the extremity of the territory of Eleutheropolis.

BITHILA, a town of Asia, placed by Ptolemy in Cilicia.

BITHIAS, a town of Asia, in Mesopotamia, according to Ptolemy. Allo, a river of Thrace, according to Appian.

BITHICA, a town of Asia, in Mesopotamia. Pro lemy.

BITHYÆ, people of Thrace, who, according to Steph.
The chief cities of Bithynia on the coast were Mytilene, Dardanos, Sais, and Nicomedea the metropolis. On the Bosporus stood the famous city of Chalcedon. In the Euxine Sea were Situnia and Apollonia. The principal inland cities of Bithynia were Prusa, Libylia, and Nicca or Nicea. Its chief rivers were the Phasis, Capus, Sangarius or Sagaris, Hippos, Rhades, and Lyecus; all discharging themselves into the Euxine Sea between Chalcedon and Hermus. As Bithynia lies between 41° and 43° of north latitude, and is watered by many rivers, it once abounded with all the necessaries of life. The ancients compared some of the inland provinces to the fruitful and delicious vales of Tempe; but at present it lies in a great degree neglected and unimproved. Bithynia was anciently inhabited by various nations, differing in their manners, customs, and language; namely, the Bebryces, the Marindini, the Caunones, the Dolliones, and the Cimerii. These different nations were anciently governed by their own kings; Bithynia being, in the earliest times, divided into as many kingdoms as nations or tribes. However, in the process of time, these petty princes were reduced by the more powerful kings of Bithynia. According to Diodorus Siculus, the Bithynians had kings from the time of Ninus; and, according to Appian, they had 49 sovereigns before the Romans obtained possession in Asia. But this high antiquity is rendered doubtful by the silence of Homer respecting the Bithynians. Strabo (l. xii.) speaks of one Prusias, who reigned in Bithynia in the time of Creusus, the last king of Lydia, by whom he was conquered. From this period, the Bithynians continued subject first to the Lydians, and afterwards to the Persians, till the reign of Alexander the Great; for we find them mentioned by Herodotus among the many nations that attended Xenocrates in his expedition into Greece. While they were subject to the Persians, they seemed to have been still governed by their own princes. Under Nicomedes I. the Gauls, whom he called to his assistance, first passed into Asia, and obtained a settlement in that part of Asia Minor, which was called from them Gallo-Grecia and Galatia. The last king of Bithynia was Nicomedes IV., who, at his death, in the year before Chr'ist 75, bequeathed his kingdom to the Romans, by whom it was reduced to the form of a province.

Bithynia, in Modern Geography, forms one of the districts of Asia Minor, and is the nearest province to Turkey in Europe, being parted from it only by the tall strait called the Thracian Bosporus. Its principal cities are Prusa, Nice, and Nicomedea.

BITHYNIARCHIA, a sort of superior priesthood in the province of Bithynia, to which belonged the superintendence of the sacred games, and which gave an exemption to

him poffessed of it, called bithyniarcha, from the care of the tuteurage.

BITHYNIUM, in Ancient Geography, the ancient name of a city of Bithynia, afterwards called Chauliodos.

BITHIS, in Zoology, a species of Coluber that inhabits Brail. Above, this creature is cinnereous, yellow, varied with white and red, and transversely brown bands; beneath, yellowish, with a middle row of very minute scales. Gen. Crot. &c. Viperidae of Laurent. Amphi.

BITON, in Cosmology, the name of the Linnean cypreas pedestris in Adanson's Senegaal, &c.

BITON, in Entomology, a species of Papilio, so named by Esper. It is papilio damen of Gmelin.

BITONTO, in Geography, a town of Naples, in the province of Bari, about 8 miles from the Adriatic, the see of a bishop, suffragan of Bari. This is a fine town, containing 16,000 inhabitants, of more early fortunes, and more polished manners, than those who dwell in the cities along the coast; its markets are well supplied, and it has an air of affluence. The country between it and Bari, at the distance of 9 miles, is much very indufed; and though thorny, fertile in corn, almonds, olives, wine, and fruit of all kinds. Near this city an obelisk was erected by the king of Spain, with some fulsome inscriptions in praise of himself, his father Philip, his soldiers, and the count of Mortemar, who was honored with the title of duke of Bitonto, for having defeated the Austrians on this spot in 1734. The monument, however, which records a trivial victory, is crumbling to ruin.

BITTACLES, or Binacle, a square box, or frame of timber, placed in the fleereage of a ship, wherein the compass is placed. The word is formed, by contraction, from the French bittacles, which signifies the name.

Large vesels have two bittacles, a leffer placed before the pilot, and a greater before the fleerman.

In the smaller vesels, the bittacle is divided into three spaces or apartments; in large vesels into five. One for the hour-glasses; another for the lamp or light; another for the compasses, &c.

Great care is to be taken in the disposition, framing, &c. of the bittacle, that it stand true, and that it be not fastened together with iron nails, but with wooden pins, because the former would affect the compasses. See Compass.

BITTENDORF, in Geography, a town of Silefia, in the principality of Neuffe, 2 miles N. of Otmutian.

BITTER, in Sea Language, denotes the turn of the cable round the bitts.

BITTER almond. See Almond.

BITTER apple. See Colocynthis.

BITTER end of a cable, that end which remains on board round the bitts, when the ship is at anchor; the other part of the cable being veered.

BITTER gourd. See Colocynthis.

BITTER place, loco amarus, a poor barren soil, by Pliny called terra amara, fove macera.

BITTER purging falls, fal catharticum amarum. See Epson Salt.

BITTER root, in Botany. See Solanum.

BITTER walnut. See Orobus.

BITTER waters. See Water.

BITTER wine. See Wine.

BITTER wood and of. See Quassia.

BITTERwort. See Gentiana.

BITTERFELD, in Geography, a town of Germany, in the circle of Upper Saxony, and electorate of Saxony, feated
BITTEN, in Ornithology, the Linnean order Dullariae to which see.

BITTERS, in the Materia Medica. The quality of bitters (a simple perception familiar to every one, and which cannot be defined) is much more frequently met with in vegetable matter, than in any other order of natural substances; and in this, it mostly refides in a certain soluble matter, with tolerably uniform chemical properties, which has by some been denominated bitter extract. This distinction, though not perfectly accurate, is of considerable use in pharmacy; for whenever a bitter taste is perceived in any part of a vegetable, we may conclude, with much probability, that it refides in this specific part of the vegetable, and especially that it gives certain medicinal properties, which experience has shown to be in the highest degree important.

The bitter principle is found in combination with a variety of other active substances, which modify, alter, correct, or impair its medicinal powers.

A pure, simple bitter vegetable (of which gentian, or quafia are good examples), is entirely void of smail, has neither acerbities nor alkaliency to the taste, nor does it excite nausea, unless in excessive quantity. The bitters are readily extracted by almost every menstruum, aqueous, as well as spirituous; and in the simple bitters, little, if any, difference, is perceived in the soluble properties of what is extracted, whatever be the menstruum. The bitter extract is not volatile by heat; hence, in the distillation of bitter plants that yield an essential oil (worm-wood, for example), the distilled oil has none of this taste, the whole remaining in the residue. A watery, or spirituous infusion of a bitter plant, insipid nearly to drynades, becomes intensely bitter, often with an empyreumatic, or a somewhat altered taste. This, when further dried, becomes solid and pulvulent. The extract is a convenient form for the substance, but the flavour is not so acceptable to the palate as the simple infusion.

The bitter extract is considerably antifeptic. Experiments have proved that the putridity of animal matters is much retarded by immersion in bitter infusions, even the watery; and substances already putrid, in some degree, lose their taint by this addition. The watery infusions of bitter vegetables mould by long keeping, and become sour. This change takes place in summer, in five or six days, when the infusion is not very strong. The newly acquired acid taint in some degree marks the bitters; but this latter quality remains extremely long, and is hardly ever lost by spontaneous decomposition.

The effect of the simple bitter on the human body, is generally considered as purely Tonic. It does not raise the pulse; nor does it directly, or constantly, produce any change in the secretions or excretions of the body. Its chief and most obvious operation is to increase the appetite, and promote the digestive powers; and hence it is with reason supposed, that its virtues depend on stimulating the fibres of the stomach. From this single effect may be derived the well known use of bitters, in giving general tone and vigour to the system, in a vast variety of cases of debility, unconnected with organic disease, in checking accezency of the stomach, heartburn, flatulence, and other symptoms indicating a deficiency of the digestive powers, and in extending its salutary operation through the whole of the alimentary canal, restoring the regular and natural action of the bowels impaired by the original defect of the digestive organs.

Bitters have been supposed to form an increase to the intoxicating powers of spirituous liquors. This however, appears to apply only to the narcotic bitters, and to be attributable to the narcotic, and not the bitter principle. On the contrary, the salutary action of bitters on the digestive powers, is well calculated to correct the extreme and peculiar debility of the stomach, induced by habitual drinking.

An anthelmintic virtue (or power of expelling worms from the human body) has been attributed very generally to all bitters indiscriminately. This does not, however, appear to be much foundation for this opinion, unless the bitters are combined with a purgative property, as in aloes, or possibly a narcotic. The contents of the intestines being always intensely bitter by the natural admixture of bile, it does not appear probable that animals, which live and grow in such a medium, can be much molested by a small addition of this principle, though from a vegetable matter.

An excetive habit of taking bitters, may at length prove detrimental to the stomach, by over-excitement, or by inducing a kind of artificial demand for food, in greater quantity than is salutary to the general health. A remarkable example of the danger of these medicines, long persifled in by persons of gouty habits, is afforded by the operation of the Portland powder in this disease.

The chief combinations of the bitter principle used in medicine are Narcotic bitters, such as opium, fufa Sancti Ignatii, bitter almonds, and the kernels of many plants: Aromatic bitters, as orange-peel, cascarilla, and wormwood: Afflucent bitters, a very large class, and generally combined both with tannin and the gallic acid, of which cinnamon, and many other barks are striking examples: Acid and purgative bitters; the fquill, colocynth, aloes, and some other combinations of thes frequency.

For medicinal use, the aromatic is always an useful addition to the bitter, and is generally employed.

The most important of the animal bitters is the bile, the properties of which have been mentioned under that article. In tonic power, it closely resembles the vegetable bitters. Late experiments make it probable, that the Prufic acid, a very peculiar animal bitter, possesses properties similar to the vegetable narcotic bitters.

A few of the mineral, or common saline combinations, are distinguished by bitters of taste; but it is doubtful how far
far this principle modifies their medicinal powers. The nitrate of silver is of this kind, a salt esteemed to be a very powerful tonic, taken internally in small doses. Some of the faine combinations of magnesia have the same taste, and it is possible on this account, that the sulphat of magnesia will often be retained by very irritable stomachs, when other faine medicines are rejected. For the pharmaceutical preparations of the several bitters, see the respective articles; as Gentian, Quassia, Columbus, &c. and that of Bitter Extract.

BITTOUR, in Orythology. See BITTERS.

BITUBERCULATA, in Lutonology, a species of Casida, of a brown colour, with a white margin; wing-cases spotted with black, and a single tuberole at the base of each. A native of Cayenne. Fabricius.

BITUBERCULATUS, a species of Curculio, that inhabits New Zealand. This is of a ferruginous colour; thorax length of the wing cases, and dotted, with two tuberole on the back. Fabricius.

BITUBERCUSULI, a species of Cryptogelalus (Grisevity), that inhabits Africa. It is fulvous; wing-cases pale, entirely bordered with fulvous. Fabricius.

BITUMEN, Bitume, Fr. The bitumens, properly so called, form a species of compound mineral inflammables, of which the following are the characters. 1. By exposure to the air, and the application of heat, they burn with a flame more or less vivid, and leave scarcely any residue. 2. By destructive distillation, they yield a liquid acid, but no ammonia, a variable but small proportion of charcoal being left behind in the retort. 3. They are either liquid, or capable of being rendered so by a moderate degree of heat. Bitumens may be divided into two families, the non-elastic and elastic. To the former belong naphthae, petroleum, mineral tar, mineral pitch, and asphaltum; to the latter belong mineral coal, cokemone, and suberiform mineral cokemone.

§ 1. Non-Elastic Bitumenes.

NAPHTHA, Bergnaphtha, Naphte, Bitume liquide blanche, is a substanee of a light brown, or wine yellow colour, perfectly fluid and transparent. It is the lighted of all liquids, its specific gravity being 69708 to 732; it has a strong penetrating bituminous smell; it takes fire with great readiness, and burns with a bluish yellow flame and copious black smoke, leaving no residue. It may be rectified by distillation with water, in the same manner as the essential oils, and then becomes colourless, and weaker in its odour. It does not combine in any considerable degree with either water or alcohol, but unites easily with ether, with turpentine, with caoutchouc, and the essential oils. When rubbed with the caustic fixed alkalies, it form a kind of Starkey's soap. The concentrated sulphuric and nitric acids are decomposed with vehemence upon it, converting it into a solid resinous substance soluble in alcohol. Even the purest naphtha, when exposed to the air, becomes friable of a yellow, and then of a brownish colour, acquires a somewhat viscid consistence, and thus passes into petroleum. Naphtha is procured for the most part from very copious springs of this substance at Baku on the shore of the Caspian sea, where it is burnt in lamps instead of oil, and is used medicinally both externally and internally in rheumatic and other complaints. It is also met with in Calabria and some parts of Italy.

Petroleum, Rock-oil. Erdohl, Stein-oil. Petroleum. The colour of petroleum is a blackish or reddish brown; it is fluid, though somewhat viscid; it is almost opaque, is unctuous to the touch, and exaltes a strong bituminous odour; its taste is pungent and acid. Sp. gr. 0.747, 0.854. Petroleum may be rectified by distillation with water, in which processes, the carbon, which thickens and colours it, is left behind in the retort, and a colourless fluid comes over, possessed of all the properties of naphtha. When petroleum is distilled per fer, there first arises some naphtha, then a watery empyreumatic acid, and lastly a thick dark-coloured oil, a spongy coal remaining in the retort. In its combinations with, and chemical actions on other substances, it perfectly resembles the preceding speciees. It is found wherever naphtha is, and in many other places among stratified mountains, in the vicinity of coal. In England, Coalbrook Dale, and Pitchford in Shropshire, are the principal places where petroleum is found; at the latter place extensive flara of sandstone are saturated with petroleum, and the naphtha, procured by distillation of the stone, is sold under the name of Betton's British oil, and is esteemed an active remedy in ulcers and rheumatism.

MINERAL TAR, Barbados Tar, Bigherith, Gondor mineral. This substance differs from the preceding only in degree; it is very vivid, more opaque, of a darker colour, and, when distilled, leaves a larger carbonaceous residue. It is found native together with petroleum, and may also be procured by the distillation of coal.

MINERAL Pitch, Maltha. The external characters of maltha are extremely similar to those of common pitch; when heated, it emits a strong unpleasant odour. In cold weather it may be broken, and exhibits a vitreous lucre; but when warm it is soft and tenacious.

ASPHALTUM, Sulphurco, Erdpech, Asphalt. The colour of this substance is black or brownish black; it is light and brittle; when broken, it displays a conchoidal fracture and vitreous lucre; it has little or no odour, unless it is rubbed or heated. It is considerably inflammable, melts easily, and burns away without leaving any residue. It is principally found on the shores of the Dead Sea, in Syria, and in the island of Trinidad in the West Indies.

The principal use of asphaltum is an ingredient in certain varnishes, especially that used by the copper-plate engravers.

§ 2. Elastic Bitumenes.

MINERAL CAOUTCHOU, Elaschiches Erdpech, Paix minerale elastique. The colour of this substance varies from yellowish brown to olive brown and blackish or reddish brown. The light coloured is often in a semiholid state, and adheres to the fingers; the olive brown is solid and elastic; the blackish and reddish brown are hard and little elastic. It occurs talacitical, or involving, or in masses. Its fip. grav. in the soft varieties is about 0.9, and in the hardest and least elastic is 1.2. It passes into asphaltum.

It is partly soluble in sulphuric ether; but the residue of the solution, after evaporation of the ether, is not elastic; thus forming an essential difference between the vegetable and mineral cokemone.

This singular mineral has been hitherto only found in the cavities of a lead mine, near Calleston, in Derbyshire, called the Odin mine, accompanied by asphaltum.

SUBERIFORM MINERAL CAOUTCHOU. This substance, when recently cut, exactly resembles fine cloke cork in its colour and texture; but by exposure for a few days to the air, it becomes of a pale reddish brown colour. It is also sometimes found friable, and passing by decomposition into an ochraceous powder. It has only been found in a rivulet near the Odin mine, whence the preceding is obtained, and appears to differ from it, merely by being penetrated with water. It occurs in nodules of various sizes, some weighing upwards of 13 pounds, the nucleus of which is very commonly the brown perfectly elastic mineral cokemone. Fourcroy Syll. vol. viii. Brochant. Mineralog. vol. ii. p. 58. Dict. d' Hist. Nat. art. Bitume. Gren. Syll. Handbucr. vol. iii. p. 1. Hatchet on Bitumens in Linnear Trans.
BITURIGES Cubi, in Ancient Geography, the name of a people who occupied a considerable part of Aquitania Prima, and who had been much more powerful before Caesar's conquest of Gaul, than they were afterwards. Livy says, that, in the time of Tarquin, they commanded the whole portion of Gaul called Celtic. Their capital was dominatized

Avenicum, which see. In the time of Caesar, these people lost their power, and became subject to the Aburi, or at least were reduced to the necessity of putting themselves under their protection.

Bituriges Virolesi, a people who inhabited the southern part of Aquitania Secunda, and are supposed to have derived their origin from the Bituriges Cubi. Their capital was

Boulogna; which see.

BITURIS, a town of Hispanic Tarraconensis, in the country of the Vacones. Ptolemy.

BITYLA, a town of the Peloponnesus, not far from the Melian gulf, S.W. of Sparta.

BITZLEER, Liwa, in Biography, a celebrated Jewish rabbi, who flourished in Bohemia about the close of the sixteenth century. He converted with the emperor Rudolph, and he was so famous, that the Jews fied of him, that all Israel drank of his waters, and walked by his light. He founded the academy, called Klauta, in 1592, which acquired such repute in his time, that it drew a vast concourse of disciples to him. He was chosen at last superintendent of all the synagogues in Poland.

BITYLA, or, in Bology, bivalvular conchae, one of the three principal sections, into which all tabellaceous animals are divided. The Limaxen genera of bivalve shells are mya, tellina, cardium, macra, conus, spondylus, chama, arca, oliva, azou, mytilus, and pinna. The arrangement of the bivalves by Cuvier, Lamarck, and other naturalists differs materially from that of Linnaeus and Gmelin. See CONCHOSCOLOGY.

BITYLA, is also applied, in Botany, to the filique, or feed-pods, of such plants as open their whole length to discharge their seeds. Such are pea, beans, &c. which the botanists say, have bivalve or bivalvular filique.

BITYLO, in Conchology, the name given by Adanson to the shell called by Linnaeus (Syst. Nat. ed. 12.) musce

fabriculatus; and vulgata cancellaria. Gmelin.

BIVENTER, from bis and venter, in Anatomy, a name given to muscles that have two flabby portions, which were called bellies, and one tendon. Such muscles are also called digastricus. The term biventer has been applied to a muscle of the lower jaw and os hyoide, which is described under its more common title of digastricus. Albimus also designates a portion of the mucus complexus of the neck, biventer cervicis. See COMPLEXUS.

BIVERI, in Geography, a lake of Sicily, near Lentini, which in summer and autumn, renders the situation of this town very uninhabitable. The waters of this lake, and of the neighbouring marshes and ponds, abound with eels and tench, of the ree of which the fishermen make a large quantity of botarga, a species of caviar; it is very fat, and has the taste of tar, but is much relished by the Sicilians.

BIVINCO, the principal place of a canton, in the department of Golo, a d island of Corfica, the population of which consists of 1573 persons.

BIVIO. See BIVIO.

BIVITTATUS, in Entomology, a species of Scarabaeus (Melobonta), that inhabits Brazil. It is yellow and very glossy; on the head and thorax two common stripes, and many abbreviated green stripes on the wing-cases. Swedenus Nov. Act. Stockhil.

BIVITTATUS, a species of Cucullo, found in St. Thomas's island. It is black; wing-cases furnished with dots; marginal and dorsal interrupted stripe of yellow. Fabricius.

BIUMBRES, from bis, double, and umbra, shadow, in Geography, an appellation given to the inhabitants of the torrid zone, because at two different seasons of the year, their shadows are projected two different ways.

The buimbres are the name for those otherwise denominated amphibia.

BIUMI, Paul Jeron, in Biography, born at Milan in 1663, studied medicine at Padua, where he was admitted to the degree of doctor in 1685. Returning thence to Milan, he soon acquired to much fame for his learning and skill in his profession, that in 1699 he was made professor of anatomy there, in which situation he continued to the time of his death, in 1731. He was author of several works, of which the following are most known:—"Encomiasticus lucis, seu lucis encomia in physiologia medicinae noven fundamentis et veterum theologis crutis, atque culto anatomico, autopsique caracteris confirmatis," Medic. 1701, 4to. "Sorrito de Natumie a de Cirurgia," Milan, 1712, 8vo. Haller. Bib. Anot. et M. Elov. Dict. Hist.

BIVONA, in Geography, a town in the kingdom of Naples, and province of Calabria Ultra, 10 miles N.E. of Nicosia.

Linnaeus has adopted the South American vernacular name of bixa from Oviedo; and it is known by the same name in Holland, Denmark, and other northern countries. In Holland it is likewise called Oripe; in German, Anott, &c. In England this name is adopted, but its orthography is various. As Arnot, Arnot, Anotta, Anoto, Anoto, and Arnotta. The French have adopted the Brazilian name. Urubu, or Ureun, spelling it Ronzyrer, Roncon, or Roncier des Indes. The Portuguese have also the same appellation.
appellation Urucu, or Urucueira. In Spanish it is Año, or Atolle. In the Mexican language, Achoti. Scalliger calls it abor fiuminum regundorum, because the Mexicans made plans, and marked the boundaries of their lands on tablets, with the colour prepared from the berries. Tournafort named it Metella, from the resemblance of the capule, when open, to a mitre. For the preparation of the drug, and its uses, see ANNO. The bark of the bixa makes good ropes for common use in the West Indies; and pieces of the wood are used by the Indians to procure fire by friction.

Propagation and Culture. This plant is propagated by seeds, may be easily cultivated, and is planted in many parts of Jamaica, Barbadoes, Cavanne, &c. in rich soils, and shady situations, shooting luxuriantly near rivulets. It is also propagated with us by seeds, which are annually brought in great plenty from the West Indies. These should be sown in a small pot filled with light rich earth, and plunged into a hot-bed of tenants' bark, where, with proper temperature, the plants will appear in about a month; when they are about an inch high, they should be taken out and separated without injuring their roots, and each planted in a pot of light rich earth, and plunged into a fresh hot bed of tenants' bark, shading them every day till they have taken root; afterwards they should be treated like other plants of the same country, by admitting fresh air to them in proportion to the warmth of the season; and when the heat of the sun declines, it should be turned up to the bottom, and if necessary, fresh tar added to renew the heat. The plants must be refreshed with water three times a week in summer, but not in great quantities, as with much wet their roots would rot. Plants that are raised early in spring, and properly managed, will be a foot and a half high in autumn, when they should be removed into the bark flore, and plunged into the tan-bed. During the winter, they must have but little water, and while the plants are young, they should be kept warm; otherwise they will call their leaves, lose their tops, and appear unhealthy. They must be kept constantly in the bark flore; some of them rife seven or eight feet high, with strong stems and large heads; but seldom produce flowers in Europe. Martyn's Miller.

BIXE, in Ent molg., a species of Papilio (Pleb. Urb.), with roundish, brown wings, greenish at the base, and a milky band on the under side of the posterior wings. Linn. Fabr &c. Inhabits America.

BIZACIUM, in Ancient Geography. See Byzantium.

BIZAM, Chat-Bizam, in Zoology, the French name of the Limnean viverra tigrina, which see.

BIZANO, in Geography, a kingdom of Abyssinia, situate between the branches of the Nile, called the White and the Blue rivers, about N. lat. 10° 15', and between 35° and 56° E. long.

BIZANTIA, a town of European Turkey, in the province of Moldavia, 40 miles south-west of Bithyn.

BIZARRE, Fr. denoting capricious, &c. a term used among Flurishes for a particular kind of carnation, which has its flowers striped or variegated with three or four colours.

BIZE, in Geography, a town of France, in the department of the Aude, and district of Narbonne, 10 miles N.W. of Narbonne.

BIZERTA. See Biserta.

BIZES, in Ancient Geography, a river of Bithynia, between Pitus and Rhecus. Annian. Marcell.

BIZOCHI, or Bischi, in Ethnological History, a sect or branch of religious Saxons, conducted by several popes.

The Bizchi were all called fraticelli, or fratre de poor, i.e. sometimes Bichini or Bichini, or Bichini. The name is formed from frater, on account of a double bank, or wallet, wherewith they begged their living. See Beggarmen, and Tertiaries.

BIZONE, in Ancient Geography, a city of Lower Me- fia, 83 stadia north of Dionysopolis, mentioned by Pliny (L IV, c. 12,) as having been destroyed by an earthquake.

BIZONIES, in Geography, a town of France in the department of the Eure, and chief place of a canton; in the district of La Tour du Pin, 12 miles north-west of Morans.

BIZU, a town of Africa, in the kingdom of Morocco, seated on a mountain in a fertile country, 25 leagues north of Morocco.

BIZYA, in Ancient Geography, a town of Thrace, and capital of the country called Asia, at some distance from the sea, N.W. of Salmydessus.

BIZYA, in Geography, a town of European Turkey, in Romania, 50 miles east of Adrianople.

BLACK, something opaque and porous, that imbibes the greatest part of the light that falls on it, reflects little or none, and therefore exhibits no colour. See Blackness.

Bodies of a black colour are found more inflammable, because the rays of light falling on them are not reflected outwards, but enter the body, and are often reflected and refracted within it, till they be fixed and lost. They are also found heavier, cotteris purpuris, than white bodies, being more porous. It may be added, that clothes dyed of this colour wear out faster than those of any other, because their substance is more penetrated and corroded by the vitriol necessary to fixle their dye, than other bodies are by the galls and alum which suffice for them.

The inflammability of black bodies, and their disposition to acquire heat, beyond those of other colours, are easily evinced. Some appeal to the experiment of a white and black globe worn in the same sun; the consequence will be a very sensibly greater degree of heat in the one hand than the other. Others allege the phenomena of burning-glasses, by which black bodies are always found to kindle sooner; thus, a burning-glass, too weak to have any visible effect at all upon white paper, will readily kindle the same paper rubbed over with ink. Mr. Boyle gives other proofs still more obvious: he took a large tile, and having whited over one half of its superflicies, and blacked the other, exposed it to the sun; where having let it lie a convenient time, he found, that while the white part remained still cool, the black part was grown very hot. For farther satisfaction, the same author has sometimes left on the surface of the tile a part retaining its native red, and exposing all the to the sun, has found the latter to have contracted a heat in comparison of the white part, but inferior to that of the black. So also on his exposing two pieces of silk, one white, the other black, in the same window to the sun, he often found the latter considerably heated, when the former has remained cool. It is observable likewise, that rooms hung with black are not only darker, but warmer than others. Boyle's Works abridg. tom. 1. p. 144. and tom. ii. p. 36. To all which may be added, that a virtuoso of uninfected credit affirmed Mr. Boyle, that, in a hot climate, he had, by carefully blackening the shells of eggs, and exposing them to the sun, then them thereby well roasted in a short time.

Dr. Watson, the prefect bishop of Landaff, covered the bulb of a thermometer with a black coating of Indian ink, in consequence of which the mercury rose ten degrees. Phil Trans. vol. liii. part 1. p. 40.

Black clothes heat more, and dry sooner in the sun, than white clothes. Black is therefore a bad colour for clothes in hot climates; but a fit colour for the linings.
of ladies' summer hats. Dr. Franklin's Experiments, Observations, &c. 5th ed. p. 483, & seq. He observes also, ibid. p. 382, that a chimney painted black, when exposed to the sun, will draw more strongly. We may add, that black mould is a hotter foil for vegetables; and garden-walls, painted black, answers better for the ripening of wall-fruit, than those of lighter colours.

Black, in matters of dress, is the distinguishing habit of avaricious and mourners. Some will have it, that the common people among the Romans were clothed in black; whence the denomination given them of tecta post hue.

Black, Joseph, in Biograpy, a celebrated teacher of chemistry, was born at Bordeaux, in France, in the year 1728. His father, who was a native of Belfast, in Ireland, but of a Scotch family, carried on the wine trade at Bordeaux, and lived in intimacy with the famed baron Montefquieu, who expressed his regret in strong terms on Mr. Black's quitting Bordeaux, when he retired from business, as appears by several of his letters which are preserved by the family. By his mother, Dr. Black was closely related to the wives of Dr. Adam Ferguson, and Mr. James Ruffel, professor of natural philosophy at the university of Edinburgh, and who was probably much of his knowledge to the instruction or information he obtained from them. In the year 1746, his father sent him to Belfast, that he might have the education of a Britsh subject; and from his letters, he appears to have been satisfied with the progress he made there. In 1746, he went to Glasgow, where he applied to the study of medicine, but particularly to chemistry, into the knowledge of which he was initiated by Dr. Cullen, who then gave lectures there on that branch of science. Under his direction he made such progress, that, in 1756, when Dr. Cullen removed to Edinburgh, Black, who had previously taken his degree of doctor, succeeded him as professor in medicine, and lecturer in chemistry. That he was qualified to fill this office, he had shewn by an ingenuous essay, containing experiments to investigate the nature of magnesia, quicklime, and some other alkaline substances, recommended as solvents of the stone in the bladder. In the course of these experiments he demonstrated the existence of an aerial fluid, which he called fixed air, the presence of which gave mildness, and its absence causticity, to alkals; and calcareous earth—an discovery which laid the foundation of the improvements since made in our knowledge of gases, or aerial bodies, by Priestley, Cavendish, Lavoisier, and other chemists. The essay, containing the account of these experiments, was published in the second volume of "The Transactions of the Royal Society, in 1755. The following year he further enriched his favourite science with his experiments on the heat, which is found to exist in all bodies; explaining in a satisfactory manner the connection of heat and fluidity, by which he established his reputation, that on Dr. Cullen's being promoted from the chemical to the medical chair at Edinburgh, in 1757, he was unanimously chosen to succeed him as professor in chemistry there. His time was now dedicated, and with increased ardour, to imparting the knowledge he had acquired to his numerous pupils; and as he was perfectly master of the subjects on which he lectured, his doctrines were fully explained, as to be easily understood by his auditors, many of whom took complete copies of his lectures. By this means the knowledge of the discoveries he had made, became widely diffused, and his claim to them secured to him, which might otherwise have been ascribed to those who improved and extended them. Having thus laid the ground-work for the improvement of the art, he seems to have been contented, without attempting to push his discoveries further. Satisfied with the attention paid him by his pupils, and the gradual extension of his fame, of which he received daily proofs, he took little notice of what Priestley, Lavoisier, and other philosophical chemists, were doing; or only noticed them when they had neglected making those acknowledgments to him which he knew to be his due. Dr. Robison, who had been his pupil, and has lately published his lectures, with an account of his life, attributes this apparent apathy to the ill state of his health, which, for several years before his death, did not permit that degree of application and study, which the farther extension of his discoveries would have required. "The slightest cold," he says (Preface to the Lectures, p. 1.) the most trifling approach to repetition, immediately affected his breath, occasioned feverishness, and, if continued two or three days, brought on a pitting of blood. In this situation nothing restored him but relaxation from thought, and gentle exercise. The sedentary life, to which study confined him, was manifestly hurtful; and he never allowed himself to indulge in any intense thinking, or puzzling research, without finding these complaints feebly increased." Hence, though he had the honour of being elected one of the foreign affiliates of the royal academy of sciences at Paris, and member of the imperial academy at Petersburg, he sent no communications to either of those learned societies. As he ranked high among the teachers of chemistry, and his name and character were extended over Europe, his pupils were numerous, and continued increasing for the whole time he lectured, more than thirty years. In the year 1774, he sent to the Royal Society in London, his observations on the effect of boiling upon water, in depositing it to freeze; and, in 1791, the Royal Society at Edinburgh published his analysis of the waters of some hot springs in Ireland, in the third volume of their Transactions. In this paper, which is drawn up with great accuracy, he treats of the formation of the effusive flame, which is deposited by these springs. His constitution becoming more and more feeble, from the frequent returns of his complaint, he was first oblig'd to make use of an assistant in his lectures, and at length, to give them up altogether; the small exertion bringing on a fit of hemorrhoea. "But he seemed," Dr. Robison says (Preface, p. 73.), "to have his complaint almost under command, so that he never allowed it to proceed far, or to occasion any distressing illates, and to spurn his thread of life to the last fibre, guarding against illates by restricting himself to a moderate diet, and meeting his increasing infirmities with a proportional increase of attention and care." On the 20th of November 1799, and in the 71st year of his age, he died suddenly, without any previous warning. Being at table, with his usual fare before him, some bread, a few prunes, with milk and water for his drink, having the cup in his hand, reposing on his knees, he expired suddenly in that posture, the cup remaining in his hand, and his countenance so composed and placid, that his servant at first imagined he was fallen asleep. He was of a cheerful and amiable disposition, and, as his mind was well stored with knowledge, an entertaining companion. His company was therefore much courted; and, as his circumstances were affluence, he dedicated as much of his time to the pleasures of society, as was consistent with his avocations. He was never married, he therefore left the principal part of his fortune, which is said to have been considerable, among the children of his brothers and sisters.

Black, in the Munger. A horse of a deep, flining, and
and lively black is called a black-more, or coal-black. Horses
black all over are commonly reckoned dull and melancholy;
but a white foot, or bar in the forehead, gives them a de-
gree of sprightliness. The Spanish gravity is said to be bett
pleased with those entirely black.

Black, blue, in the Manufactures and Arts, is the cool of
some kind of wood, or other vegetable matter, burnt in a
clothe heat, where the air can have no access; the bolt fert
is said to be made of vine-stalks and tendrils. The good-
ness of blue-black consists in the cleanliness and blue cat
of its black colour, and the perfect degree of its levigation.

That this preparation, which is sold in the colour-floos,
is no other than a vegetable coal, appeared from the fol-
lowing experiment of Dr. Lewis. (Comm. Phil. Techn. p. 358.)
Laid on a red hot iron, it burned and glowed like powdered
charcoal, and turned into white ashes; which ashes, thrown
into a roll of vitriol diluted with water, very readily dissolved
into a bitterish liquor, the characteristic by which the vegetable
earth is distinguished. From what particular vegetable mater this black-blue is procured, experiments, he says,
cannot discover; but it appears from thence how he recites,
that it may be obtained from many, and that the choice
of the vegetable subject affects rather the softness or hard-
ness than the colour of the coal. Blue-black, perfectly
good, may be prepared in the manner directed for ivory
black, from the vine filks, or tendrils, or any other
twig of wood, of an acid taste and tough texture; but the
foaming in the oil, preferred for the ivory, must be omitted.

The painters have blue-blacks, brown-blacks, &c., which
may be made by mixing pigments of the respective colours,
with simple black oils in greater or less quantity, accord-
ing to the shade required. The dyers also have different
blacks, and often darken other colours by slightly paling
them though the black dying liquor; but the term brown-
black is in this business unknown, brown and black being
here looked upon as opposite to one another. In effect,
the colour called brown-black is no other than that which
all dyed black clothes change to in wearing; and therefore
it is no wonder that it should be excluded from the cata-
logue of the dyers' colours. The true or simple blacks,
mixed with white, form different shades of grey, lighter or
darker, according as the white or black ingredient prevails
in the mix. The black pigments, spread thin upon a white
ground, have a like effect. Hence the painter, with
one true black pigment, can produce on white paper, or
on other white bodies, all the shades of grey and black,
from the slightest discolouration of the paper up to a full
black; and the dyer produces the same effect on white
wool, silk, or cloth, by continuing the subjects for a
shorter or longer time in the black bath, or making the bath
itself weaker or stronger.

M. le Blon, in his "Harmony of Colours," forms 15 k
by mixing together the three primitive colours, blue, red,
and yellow; and Mr. Caettel, in his "Optique des couleurs,"
published in 1740, says, that this compound black has an
advantage in painting above the simple ones, of answiering
better for the darkening of other colours. Thus if blue, by
the addition of black, is to be darkened into a blue-black,
the simple blacks, if used in sufficient quantity to produce
the requisite deepness, conceal the blue, while the com-
ound blacks leave it ditinguishable. Le Blon has not
mentioned the proportions of the three primitive colours
necessary for producing black. Caettel directs 15 parts of
blue, five of red, and three of yellow; and he observes, that
the colours should be the deepest and darkest of their respec-
tive kinds, and that a combination should be made to
several pigments for each colour; for the greater the contrait
of heterogeneous and discordant drugs, the more true and
beautiful will be the black, and the more capable of uniting
with all other colours, without suppreffing them, and even
without making them tawney. Dr. Lewis, in his experi-
ments, has not so far succeeded as to obtain a perfect black
by mixing different blue, red, and yellow powders; but he
procured very dark colours, such as brown-blacks and grey-
blacks.

Black, bone, is made of the bones of bullocks, cows, &c.,
well burnt and ground. To be good, it must be soft and
friable, of a glossy cast. It is in considerable use, though
inferior in goodnes to ivory-black.

The invention of bone, or ivory-black, is attributed to

Black chalk, See Chalk, and Kiln.
Black charcoal. See Charcoal, and Crayons.
Black, carriers, signifies a teint or dye laid on tanned
leather. Tanned leather is so much impregnated with the
altrigent parts of oak bark, or with that matter which
flushes a black colour with green vitriol, that rubbing it
over three or four times with a solution of the vitriol, or
with a solution of iron made in vegetable acids, is sufficient
for staining it black. Of this we may be convinced by
dropping a little of the solution on the unblacked side of
common shoe-leather. This operation is performed by the
carrier, who, after the colouring, gives a gloss to the leather
with a solution of gum-arabic and fide made in vinegar.

Where the previous altrigent impregnation is insufficient
to give a due colour, and for those forts of leather which have
not been tanned, some galls or other altrigents are added
to the solution of iron; and in many cases, particularly for
the finer sorts of leather, and for renewing the blackness,
ivory or lamp-black is used. A mixture of either of these
with linseed oil, makes the common oil-blacking. See
Currying.

Black, dyes, is one of the five simple and mother-colours
used in dyeing: and given differently, according to the
different quality and value of the stuffs to be dyed. See
Dyeing.

Green vitriol strikes a black colour with vegetable altrig-
ents, and hence it is the basis of the black dye for cloth,
leather, hats, &c. And as solutions of iron with galls, &c.
produce the same colour, a method is derived from hence
of distinguishing the minute portions of iron in mineral
waters, &c. Neumann.

The substances chiefly employed for producing black
colour with vitriol are galls. When a decoction or infun-
ation of the galls is dropped into a solution of the vitriol
largely diluted with water, the first drops produce bluish or
purplish red clouds, which mingling with the liquor tinge it uni-
formly of their own bluish or reddish colour. This differ-
cence of the colour, says Dr. Lewis (Com. Ph. Techn. p. 356.),
seems to depend on the quality of the water. With diluted
water, or the common spring waters, the mixture is always
blue. A minute quantity of alkaline salt previously diffuscd
in the water, or a small degree of putrefy in it, will render
the colour of the mixture purple or reddish. Rain-water
received from the clouds, in clear glass vessels, gives a blue,
but if it be collected from the tops of houfes, gives purplc
with the vitriol and galls. Both the blue and purple
liquors, when more of the altrigent infusion is added,
deeper to a black, more or less intense, according to the
degree of dilution; and if the mixture be a deep opaque
black, it again becomes bluish or purplish when further
diluted. If it be suffered to stand in this dilute state for
two or three days, the colouring matter settles to the
bottom in form of a fine black mud, which, by gently
shaking
black.

Making the vessel, is diffused again through the liquor, and tinges it of its former colour. When the mixture is of a full blackness, this separation does not happen, or in a far less degree, for though a part of the black matter precipitates in standing, yet so much remains dissolved, that the liquor continues black. This suspension of the colouring substance in the black liquid may be attributed in part to the gummy matter of the allringent infusion increasing the confidence of the watery fluid, for the separation is retarded in the diluted mixture by a small addition of gum arabic. If the mixture, either in its black or diluted state, be poured into a filter, the liquor passes through coloured, only a part of the black matter remaining on the paper. The filtered liquor, on standing for some time, becomes turbid, and full of fine black flakes; but being freed from these by a second filtration, it again contracts the same appearance, and thus repeatedly, till all the colouring parts are separated, and the liquor has become colourless. The colouring matter, thus separated from the liquor, being drained on a filter and dried, appeared of a deep black, which did not seem to have suffered any change on being exposed to the air for upwards of four months. When it was made red hot, it gloved and burnt, though without flaming, and became a rusty brown powder, which was readily attracted by a magnetic bar; though in its black state, the magnet had no action upon it. The vitriolic acid, diluted with water, and digested on the black powder, dissolved the greatest part of it, leaving only a very little quantity of whitish matter. Solution of pure fixed alkaline felspar dissolved very little of it; the liquor received a reddish brown colour, and the powder became blackish brown. This residuum was attracted by the magnet after being made red-hot, though not before; the alkaline tincture, passed through a filter, and mixed with solution of gum vitriol, struck a deep brownish black colour, nearly the same with that which results from mixing with the vitriolic solution an alkaline tincture of galls. For an account of the result of these experiments, see Lewis, ubi supra. See also Iron.

For broad cloths, fustains, and druggets, &c., the dyers use wood and indigo; the goodness of the colour consists in there not being above six pounds of indigo to a ball of wool, when the latter begins to cast its blue flower; and, in its not being heated for use above twice. Thus blued, the stuff is boiled with ale, or water, then madder and lafly, the black given with galls, copperas, and fumace. To bind it, and prevent its smearing in use, the stuffs are to be well scoured in the fuling mill, when white, and well washed afterwards.

For stuffs of less value, it is sufficient they be well blued with wood, and blacked with galls and copperas; but no stuff can be regularly dyed from white into black, without passing through the intermediate blue.

Yet there is a colour called coal black, or Jefuit's black, prepared of the same ingredients as the former, and sufficient of itself without the blue dye. Here the drugs are diffused in water that had boiled four hours, and flood to cool till the hand would bear it; then the stuff is dipped in it, and again taken out six or eight times. Some even prefer this black to the other. This mode of dyeing black is laid to have been invented by the Jesuits, and to have been practised in their houses, where they retained numbers of dyeing.

By 23 El. c. 9. nothing of the nature of cloth shall be madderred for a black, except it be first grounded with wood only, or with wood and ancle [blue ind.] madder be put in with fumace or galls; on pain of forfeiting the value of the thing dyed; provided it shall be lawful to dye any manner of gall-black, and fumace black [plain black], wherein no madder shall be used.

Logwood yields a black with chalybeate solutions and is employed with those liquors for staining wood black, as picture frames, &c. With the addition of galls, it is used for dyeing cloth and hats black. (Neumann's Works, p. 587.) This black colour is not permanent, though beautiful, any more than the natural violet dye of the logwood.

Black may be also obtained by a solution of silver in aqua fortis, when the previous matter stained with this liquor is exposed for some time to the sun and air; and also from solutions of lead in acids, when the subjects to which they are applied are exposed to fulphurous vapours, or washed over with alkaline solutions of sulphur. Cakes of lead, melted with sulphur, form a bluish or blackish mass, useful in taking casts from medals. (See Casts.) Besides, when a solution of silver in aqua fortis is added to a solution of sulphur made in alkaline ley, the silver and sulphur unite and precipitate together in the form of a black powder. See Dyeing, and Staining.

Black, earth, is a kind of coal found in the ground, which, well pounded, is used by painters in fresco. See Pit-coal, and Fresco.

There is also a kind of black made of silver and lead, used to fill up the strokes and cavities of things engraved.

Black, German, or Frankfort, is made of the lees of wine burnt, then washed in water, and ground in mills for that purpose, together with ivory or peach stones burnt. Some suppose, that it is the coal of vine-twiggs; but this, says Dr. Lewis (Com. Phil. Techn. p. 377.), does not appear to differ, in any great degree, from that of the fals branches of other kinds of trees; but the kernels of fruits yield coal considerably more soft and mellow, easily crumbling between the fingers into a fine meal. That the Frankfort black is no other than a vegetable coal, appeared, from its burning on a red-hot iron, like charcoal powder, into white ashes, and from the ashes, like common vegetable ashes, being plentifully dispersible by the vitriolic acid into a bitterish liquor, while the ashes of animal substances are very sparingly affected by that acid, and form with it a compound of a different kind of tafe.

This black makes the principal ingredient in the rolling-pens printers' ink, which fee. It is ordinarily brought from Frankfort, Mentz, or Strafsbourg, either in lumps or powder. That made in France is more valued than that of Germany.

Black siles. See Glass. Black, burnt, that which remains in the retort after extracting the spirit, salt, and oil of hartshorn. This refuse being ground up with water, makes a black not much inferior to that of ivory.

Black, Indian. See Indian Ink.

Black, ivory, is made of ivory burnt or charred, ordinarily between two crucibles well lit; which, being thus rendered perfectly black, and in feales, is ground in water, and made into troches, or little cakes, used by the painters; and also by the jewellers to blacken the bottom or ground of the collets, wherein they set diamonds to give them their teint or foil. Some recommend soaking the chips or shavings of ivory in hot linseed oil, before it is charred. There are particular machines and contrivances for burning the ivory for these purposes, by which the colour is rendered more beautiful than that of the coal which remains in the distillation. Neumann.

The goodnes of ivory-black, which is the dust of all the charcoals black, may be perceived by its fulness, without a blue cast; and by the finenes of the powder.
In the manufacture of this black much imposition is practiced, so that what is generally sold under this name is no other than the coal of common bones. Being applied to coercive purposes, and sold at a low price, it is very greatly levigated by the hand or horse-nails which are employed in grinding the bones, and to much adulterated with charcoal dust, which gives it a blue cast, that it is wholly exploded from delicate infes, and lamp-black, though inferior with regard to the purity and clearness of the black colour, substituted for it.

The following recipe is given in the Handmaid to the Arts (vol. i. p. 140.) for preparing it in perfection. Take plates, chips, or shavings of ivory, and soak them in hot linseed oil; or, if filings are more easily procured, they may be used moistened with the hot oil. Put them into a vessel, which will bear the fire, covering them with a sort of lid made of clay and sand; which should be dried, and the cracks repaired before the vessel be put into the fire. Let this vessel be placed in a tobacco-pipe maker's or potter's furnace, or any other such fire; and let it remain there during one of their heats. When it is taken out, the ivory will be properly burnt; and must be afterwards thoroughly well levigated on the flute with water, or to have it perfectly good, be also washed over. The ivory may be conveniently burnt in a calcing or subliming furnace.

An opake deep black for water colours is made by grinding ivory-black with gum-water, or with the liquor which seethes from the whites of eggs after they have been suffered to stand a little. Some use gum water and the whites of eggs together, and they say, that a small addition of the latter makes the mixture flow more freely from the pencil, and improves its glossiness. It may be observed, however, that though ivory-black makes the deepest colour in water, as well as in oil-painting, yet it is not on this account always to be preferred to other black pigments. A deep jet-black colour is seldom wanted in painting; and in the lighter shades, whether obtained by diluting the black with white bodies, or by applying it thin on a white ground, the particular beauty of the ivory-black is in a great measure lost.

Black, lamp, or lam Black, originally perhaps the foot collected from lamps, is generally prepared by melting and purifying reifn or pitch in iron vessels; then letting fire to it under a chimney, or other place made for the purpose, lined a-top with fleece-flins, or thick linen cloth, to receive the vapour or smoke, which is the black; in which manner they procure vast quantities of it at Paris. In England considerable quantities are prepared, particularly at the turpentine-houses, from the dreages and refuse parts of the reifnous matters which are there manufactured; but the greatest part is brought from Germany, Sweden, and Norway. Its preparation is described in the Swedish Translations for 1754, as a process dependent on the manufacture of common reifn. —

The impure reifnous juice, collected from incisions made in pines and fir-trees, is boiled down, with a little water, and strained, whilst hot, through a bag; the dregs and pieces of bark, left in the strainer, are burnt in a low oven, from which the smoke is conveyed, through a long passage, into a square chamber, having an opening in the top, in which is fastened a large fack, made of flaky or thin-woven woolly stuff; the foot, or lamp-black, concretes partly in the chamber, from which it is swept out once in two or three days, and partly in the fack, which is now and then gently struck upon, both for shaking down the foot, and for clearing the interlaces between the threads, so as to procure a sufficient draught of air through it. The more curious artificers prepare lamp-black for the nicer purposes, by hanging a large copper pan over the flame of a lamp with a long wick, supplied with more oil than can be perfectly consumed, as to receive its smoke. Soot collected in like manner from fir and other woods, by burning small pieces of them slowly under a copper pan, is of a deeper black colour than such as is obtained from the same kinds of wood in a common chimney, and little inferior to that of oils. The foot of mineral bitumens, in this close way of burning, appears to be of the same qualities with those of woods, oils, and reifns. In some parts of Germany, it is said, great quantities of good lamp-black are prepared from a sort of pit-coal.

The goodness of lamp-black lies in the fulness of the colour, and in its being free from dust or other impurities. The lightness of the subfilance furnishes the means of discovering any adulteration, to a great degree; as the bodies with which lamp-black is subject to be adulterated, are all heavier in a considerable proportion.

This subfilance is used on various occasions, particularly in the printers' ink; for which it is mixed with oils of turpentine and linseed, all boiled together.

It must be observed, that this black takes fire very readily, and when on fire is very diftinctly extinguished: the best method of putting it out is with wet linen, hay, or straw; for water alone will not do it.

A glass tube closely filled with lamp-black has been found to conduct a considerable charge of electricity instantaneously, and with fear no explosion. But a coating of this subfilance, mixed with tar or oil, is a perfect non-conductor, and has proved a preventative from lightning, by repelling the electric matter from those parts of the masts of ships which have been covered with it.

Ruffian lamp-black is prepared from the foot of fir, and is collected at Ochat near St. Petersburg, Moscov, Archangel, and other places, in little wooden hats, from reifnous fir wood, and the unctuous bark of birch, by means of an apparatus uncommonly simple, confifting of pots without bottoms, let one upon another, and is sold very cheap. It is three or four times more heavy, thick, and minute, than that kind of painters' black which the Germans call "kiennrahm," and which is called in Ruffia "Holland's black." For an account of the spontaneous accenfion of Ruffian fir-black, impregnated with hemp-oil, see Spontaneous Inflammation.

A mineral lamp-black may be procured from pit-coal, or any kind of mineral or coal tar, by prefering the blackest particles of the smoke arising from it in ignition. Mr. W. Row of Newcastle-upon-Tyne obtained a patent in 1798 for his method of manufacturing this kind of lamp-black. See the specification in the Repertory of the Arts, &c. vol. x. p. 81.

Black paint. See Paint.
Black flock. See Sand.
Black feeling wax. See Wax.
Black, foot, or chimney, is a poor colour; but ready for painting black draperies in oil. The foot blacks are in general much softer and of a more yielding texture than those of the charcoal kind, and require much less grinding, for uniting them with oily, watery, or spirituous liquors, into a smooth mass; of some of them a part is dissoln by water, or spirits of wine, while none of the charcoal blacks have been found to contain any thing dissoln. This soluble matter of foots, however, is not black like the indiffoluble parts; and in this particular, as well as in the colour of the entire mass, different sorts of foot differ from one another. Thus the foot of pit-coal collected in common chimneys, of itself rather greyish black than of a full black, being
being infused separately in rectified spirit of wine, and in water, tinged the former of a transparent reddish colour, and the latter of a paler reddish; while the deeper black font of wood gave, both to spirit and to water, an opake, dark brown. See Sorb.

Black, Spanish, so called, because first invented by the Spaniards, and most of it bought from them, is no other than burnt cork used in various works, particularly among painters.

Black狂. See Staining.

Black varnish. See Varnish.

Black vegetable pitch. See Anacardium.

Black Ad Waltham, in Essex, a name commonly distinguishing the statute of 9 Geo. I. c. 22, because it was occasioned by the devastations committed near Waltham in Essex, by persons in disguise, or with their faces blacked. By this statute it is enacted, that persons hunting, armed and disguised, or killing or wounding deer, or robbing ware, or stealing fish out of any river, &c. or any persons unlawfully hunting in his maj. fly's forests, &c. or breaking down the head of any fish-pond, or killing, &c. of cattle, or cutting down trees, or setting fire to hoo's, barn, or wood, or shooting at any person, or sending letters, either anonymous, or signed with a fictitious name, demanding mony, &c. or refusing such offenders, are guilty of felony, without benefit of clergy. This act is made perpetual by 31 Geo. II. c. 42. See farther 6 Geo. II. c. 37. and 27 Geo. II. c. 15. Blackstone's Comm. vol. iv. p. 144, 208, 232, 244. The milder punishment inflicted by that 16 Geo. III. c. 30. against deer-dealers, has been thought a virtual repeal of the punishment of the black act above-mentioned.

Lesch's Hawk. P. C. I. c. 47. § 7.

Black bay, in Geography. a bay on the south-east coast of Labrador. N lat. 51° 30'. W. long. 56° 20'.

Black bear, in Zoology. See Ursus Arctos.

Black-bellied darter, and Black-bellied anhinga of Latham, in Ornithology, is Plutos Melanoger of Gmelin.

Black-bellied grebe of Brown's Illustrations, is Loxia Alfredi of Gmelin.

Black-bellied green humming-bird of Edwards; Black-bellied American humming-bird of Bancroft; and Black-bellied humming-bird of Latham, are all the same bird; namely, Trochilus gobiferus of Linn. and Gmel.

Black-berry, in Botany. See Rubus.

Black billed awk of most English writers, in Ornithology, is Alca Fica of Linn. Syr. Nat. and Fabricius.

Black-billed tropic bird, so named in Latham's Synopsis, is Phaetan melanerhynchos of Gmelin.

Black-billed whistling duck of Sloane and Brown's Jamaica, is called Anas Arborea by Gmelin.

Black-tit. The proper acceptance of this word among the English writers of the present time, is very clearly understood; the Turdus meurula of Linnaeus and other naturalists being alone implied. The earlier ornithologists of this country are much more precise in the application of this word: with them, birds of the fame natural order were sometimes called black-birds, because they bear a remote resemblance to the common species most familiarly known by that name, as we frid, for instance, in the two kinds of turdus, torquatus, and rofocus, both of which are called, in a general manner, black-birds, white-ringed black-birds, rose-coloured black-birds, and the like. Thus far, indeed, there existed a flitting natural affinity between the species, because they all belong to the same natural order, and were, in reality, of the family they called merula, which seems to have been considered in certain instances synonymous with black-bird. But all the early writers did not confine themselves to such minute distinctions as the generic character afforded: the black-bird (razor-billed) of Catsby, being, for example, of a very dissimilar genus to that of our common black-bird; namely, the creatophaura of modern writers. Again, the black-bird (red-breasted Indian) of Willoughby, is one of the oriuus; the black-bird (red-breasted) of Edwards, belongs to the tangerina; and the black-bird, or Chinese, harling of the fame author, is a gracula. Birds of the sparrow, titmouse, and other kinds, altogether remote from the former, were also called occasionally black-birds. We may, therefore, easily perceive that the word black-bird was an indefinite term, applied, for the most part, to those birds whose plumage is of a black colour, without regard to the natural order to which they ought to have been referred, although sometimes employed to express only that which we shall distinguish by the name of black-bird. See Turdus Merula.

Black-book of the Exchequer, Eng. House, Money, Order, Star. See the several articles.

Black-bunks, a name given to those which treat of necromancy, or, as some call it, nigromancy.

The black-book of the English monasteries, was a detail of the scandalous enormities practised in religious houses, compiled by order of the visitors under king Henry VIII. to black a man, and thus halen their dissolution.

Black-bred ted grebe of Latham, in Ornithology, is Colymbus thornecap of Gmelin.

Black-bred ted grebe of Latham, is Loxia Americana of Gmelin.

Black-bred ted humming-bird of Latham, is spoken of by Buffon under the name of Hauff col vert; Gmelin calls it Trochilus gramineus.

Black-breasted Indian plower of Edwards, is a variety of Charadrius spinosus of Gmelin. The female of this bird is called by Edwards the four-winged plower, a nain retained by Latham for both sexes. In Ruell's Aleppo it is called the lapwing.

Black-bred ted thrush. Latham describes Turdus cinna
comus of Gmelin, under this name in the synopsis of birds.

Black-bred ted titmouse of Latham, is Purus afer of Gmelin.

Black-bred wood-pecker of Latham, is Picus multi
color of Gmelin.

Black-bufnch of Albin, like Pyrrhula nigra of Bliffon, and Buurenilvoid of Buffon, is nothing more than an accidental variety of the common bufnch, or Loxia pyrrhula of Latin writers. The bufnch occurs sometimes of a white colour, as well as black or dully.

Black-bufnch, (Little) of Catsby and Albin, and Black grebe of Latham, is Loxia nigra of Gmelin.

Black-canker, in Agriculture, a dicate in turnip and other crops, produced by a species of ecterpillar destroying their leaves.

It is observed by Mr. Young, in the second volume of the Annals of Agriculture, that those insects were effectually destroyed by Mr. Coke, at Holkham, in Norfolk, by turning a number of ducks among the turnips when injured by insects. On the 10th of July, says he, they were turned into thirty-three acres, having water at one corner of the field, and, in five days, they cleared the whole field completely, marching at last through the field on the hunt, essaying the leaves on both sides with great care to devour
every one they could see, and filling their crops several times in the day. The ducks, after having fattened about sixty pounds' worth of turnips, were sent to the poultry yard. With this view, it has been suggested by Mr. Middleton in his "Survey of the county of Middlesex," that this sort of poultry may often be kept with advantage by the farmer.

Black-evans, in Ecclesiastical History, a name given to the regular canons of St. Augustine, who wore a black mantle over their surplices, by way of distinction from the Premonstratensian.

Black-cap of the English, in Ornithology, the Motacilla atricapilla of Linnaeus. The same name is given likewise to the marsh titmouse, Parus palustris of Linn. and the black-headed gull, Larus atricilla of Gmelin.

Black-cap of Ceylon, or Ceylon black-cap, the name of Motacilla zeylonica of Gmelin, in Brown's Illustration of Nat. Hist.

Black-capped humming-bird of Latham, and Long-tailed black-capped humming-bird of Edwards and Barcroft, are Trochilus pygmaeus of Gmelin.

Black-capped king's-fisher of Latham, is Alcedo atricapilla of Linn.

Black-capped lory, the English name given by Latham to the Gmelinian ptiloceros lory. This is the first black-capped lory of Edwards.

Black-capped manakin of Edwards and Latham, is Pipra manucaus of Gmelin.

Black-cap, in Geography, lies on the east coast of Newfoundland, S. E. from Cape St. Francis.

Black-cattle, in Agriculture, a small, hardy breed of cattle, mostly of a black colour, occupying the high or more mountainous districts in the northern parts of the island. They are covered with a long close coat of hair, of much the same kind as the polled and long horned breeds. They feed readily in the rich pastures in the southern parts of the kingdom, where large quantities of them are annually driven and fed for sale in the London and other markets. Their beef is generally of a fine grain, well marbled, and of a good flavour; but sometimes not so fine and bright in its external appearance as that of other sorts of cattle, being occasionally, except when made very fat, spotted with black, even upon the choicest parts. From their property of becoming quickly fat, and not being of great weight, they seem well adapted to the low, rich, grazing districts in the southern counties, where the lands are liable to be poached and injured by the heavier breeds of cattle. They seldom weigh more than from twenty to thirty stone each, though some particular ones have become considerably heavier. See CATTLE and LIVE- STOCK.

Black-checked eagle, of Latham's Synopsis, in Ornithology, is Falco meruacanus of Gmelin.

Black-checked thrush of Latham, is Turdus nigerrimus of Gmelin.

Black-chin grebe of Pennant, &c. Colymbus lebriculius of Gmelin.

Black-cock of Pennant, Latham, Donovan, &c. is Tetrao tetrix of Linnaeus. The same bird is also well known by the name of black-game, or black-grons.

Black-cockatoos of Latham, and Great black cockatoos of Edwards, is called by Buffon Kakatôk noir, and by Gmelin Ptiloceros aterrimus. Black-collared finch of Latham, is Fringilla Abyginnica of Gmelin.

Black-crowned bunting of Latham, is Emberiza atricapilla of Gmelin.

Black-crowned manakin of Latham, is Pipra atricapilla of Gmelin.

Black-crowned oriole, the English name of Oriolus Meridianus of Linn. in Latham's "Synopsis of Birds."

Black-crowned plover of Arch. Zool. is Charadrius aterrimus of Gmelin.

Black-crowned oriole of South America is Lanius Americanus of Gmelin.

Black-crowned tanager of Latham, is Tangara melanotera of Gmelin.

Black-crowned parrot of Edwards, is Cacusus nigricula of Linnaeus.

Black-dove, or fester, of English ornithologists, is Anas nigra of Linn. &c. Suec.

Black-dolphin, in Agriculture, a small insect which is frequently very destructive to bean, turnip, and some other crops. Where beans are attacked with these insects, the best remedy probably is, as soon as they are first perceived, to cut off the tops by means of a scythe, as they are found to make their first lodgment, principally in those parts of the plants. See Fly and Turnips.

Black duck of Latham and other writers, in Ornithology, is called by Edwards the great black duck from Hudson's bay. This is a very distinct species from the black duck of Ray and Willughby, and velvet duck of modern naturalists. Gmelin calls it Anas perficillata.

Black-duck, or Great black duck of Ray and Willughby, is the velvet duck of later English authors, and Anas fusca of the Linnaean Fauna Suecia.

Black eagle, in Heraldry, an order of knighthood instituted in Prussia, by Frederick I. 14th Jan. 1701. The ensign of the order is a gold cross of eight points, enamelled blue; in the centre whereof are the letters F. R. in cypher, and in the four angles the eagle of Prussia, enamelled black. On collar days, it is worn pendant to a rich collar of gold, composed of round pieces of gold, each enamelled with four cyphers of the letters F. R.; in the centre of the piece is set a large diamond, and over each cypher a regal crown, all richly chased, intermixed with eagles displayed, enamelled black alternately, and holding in their claws thunderbolts of gold.

The cross of the order is worn, on ordinary days, pendant to a broad, orange-coloured ribbon, across the left shoulder. The knights have embroidered on the left breast of their coats a star of silver, like that of the ensign of the order, in the centre of which is an eagle displayed black, holding in his dexter claw, a chaplet of laurel, and in the other a thunderbolt, with the motto Swam epiyou round it. See Plate of Heraldry.

Black-eagle of Willughby, in Ornithology, is Ptilogus commune of Buffon, and Fasol melanotus of Gmelin.

Black-ears, or Black-ered lynx, in Zoology, called also the Perisan lynx, and Black-ered cat, is the Sigab giau or Sigab gijus of Charleton, and Caracal of Buffon. Gmelin mentions this animal under the name of Felis caracal. See CARACAL, and SIGAH GUSH.

Black-eared, in Agriculture, that kind of earth or mould which contains a large portion of carbonaceous or vegetable matter in its composition. Soils of this sort are capable of producing most sorts of grain and other vegetable crops in abundance. See SOIL, &c.

Black-eunuchs, in the Cyclopedia of Eastern Nations, are Ethiopians castrated, to whom their princes commonly commit the care of their women. See EUNUCH.

Black-eye, in Botany, a name given to the germ in beans, which the Romans called hilum. See GERM.
BLACK.

**Blackeye, hyposphorhena, in Medicina, a fullness of blood on the tunica albuginea, turning livid, occasioned by a blow.** See Ecchymosis.

**Black faced bunting of Latham, in Ornithology, is Emberiza quotulae ofGmelin.**

**Black-faced finch of the Arctic Zoology is Fringilla coerulea of Gmelin.**

**Black-faced ibis of Latham, is Tantalus melanopis of Gmelin.**

**Blackfish, in Ichthyology, the name under which Silurus anguillaris is described in Ruffell’s “Hist. of Alesopo.”** This fish has a long dorsal fin containing seventy rays, and eight bars at the mouth, namely, two on the upper lip, four on the lower one, and two on each side of the mouth. There is likewise a kind of perch mentioned by Borlase as being found in the rivers of Cornwall, which he calls the black fish. Pennant speaks of it on the authority of that writer; and Gmelin, after him, gives it as a species with some doubt. This species meant by Borlase is certainly ambiguous. See Perca nigra.

**Blackfly, in Agriculture, an insect of the beetle tribe, that often commits great devastation among turnip and other crops, destroying the young plants, by feeding upon their feed-leaves the moment they are protruded and appear above ground. Different remedies have been propounded for the prevention of the destructive ravages of this insect on turnips, but few of them have been attended with much success. The best method is probably, that of fowing the feed at such a season, and under such circumstances, that its early vegetation may be quick and uninterrupted, and thereby allow little time for the insects to feed upon the plants, before they become in broad leaf, and capable of resisting its injurious attack.** See Fly and Turnips.

**Blackfly-catcher of Latham, in Ornithology, is Muscicapa lacernigora of Gmelin.**

**Blackforest, mountains of, in Geography, called in German Schwartzwald, extend from near Neuenburg, in the territories of Wurttemburg, south to the four forest towns on the Rhine. The southern part is called the high, and the northern the lower forest; the length being about 80 British miles. To the east the Neckar may be considered as a boundary, and the breadth may be computed at about 20 British miles. The eastern part presents a gradual elevation, while the western exhibits precipitous summits to the inhabitants of Baden and Alsace. The appellation seems to be derived from the thick dark forests with which the affents are clothed. Besides paturage, the inhabitants, partly subject to Austria, and partly to Wurttemburg, derive advantage from the rent of the pines, and the timber, of which they make all kinds of utensils. Some parts are cultivated by spreading branches of pine, covered with sod, which, being burnt, affords an excellent manure, that prepares the ground for four abundant harvests. A branch of the black mountains spreads east from near Sulz, on the Neckar, towards the county of Oettingen, being more than 60 miles in length. This chain is called the Alp, and sometimes the Suabian Alps. Busching traces this ridge from the north-east, the source of the Brenz, to the west of the Neresheim, by Wissensteg, whereof the mountains are highest. Thence they turn north-west to Guttenberg, and west to Neissen, whence they pass by Hohenzollern to the Neckar, then bend south and west between that river and the Danube. Busching adds, that as this chain rises infenibly on Kingstrown north-east, so it gradually terminates at Ebingen south-west. The principal summits are in the north and west of the ridge; and the forests are chiefly beech; while the open spaces supply pasturage for numerous flocks of sheep. Of these two extensive ridges of mountains, the Black Forest and the Alb, a considerable portion pervades the duchy of Wurttemburg; and near Stuttgart, the capital, are the mountains of Bayreuth and Schweinfurt, and Haasen. The contiguous parts of these extensive ridges have been little detailed; but a great part is calcareous, as they supply excellent marbles. Near Freudenstadt, in the black mountains, are mines of silver and copper.**

**Black-footed penguin, or penguin, lesser penguin, cape penguin, &c. in Ornithology, are different English names of an individual species of Aptenodyta in the works of Edwards, Latham, &c. Gmelin names this bird specifically demora.**

**Black fox, in Zoology. See Canis Lycaon.**

**Black-fronted fly catcher of Latham, in Ornithology, is Muscicapa nigrifrons of Gmelin.**

**Black-fryer, in Ecclesiastical History, a name given to the Dominican order, called also Predicants and Preaching fryers; in France, Jacobins.**

**Black-game, in Ornithology. See Black-Cock.**

**Black-graves, in Agriculture, a species of American grasses, growing in meadows which border on tide-rivers, well supplied also with fresh water; for a mixture both of fresh and salt water seems to be necessary for its prolific vegetation. Its seeds are small, like those of tobacco; its colour a deep green; and it affords from three to four tons of hay by the acre. This kind of grass thrives best on a clay or strong loam; nor is the vicinity of salt water absolutely necessary. The seeds have been lately brought over into England, and distributed for trial in proper soils.**

**Black-grsebek of Edwards, in Ornithology, and the Angela greybeck of Latham are the same; Loxia angustirostris of Gmelin.**

**Black-headed bunting of Latham, is Emberiza melanocephala of Scopoli.**

**Black-headed creeper of Latham, and the Green black-cap fly-catcher of Bancroft, are of the same species, the latter being only a variety of the first. Linnaeus calls this kind Motacilla fringilla.**

**Black-headed duck of Shaw’s travels, has been since named the Domiatta duck by Latham, and Anas Domitana by Gmelin in the Linn. Syst. Nat.—The variety of Anas boschas, or wild duck, called nigris, from having the head and collar black, might be also called the black-headed duck.**

**Black-headed finch of Latham, is Fringilla melanopis of Gmelin.**

**Black-headed fly-catcher, of Arctic Zoology; and black-cap fly-catcher of Catesby, is the muscicapa fusca of Gmelin.**

**Black-headed greybeck of Latham, is loxia erythromelas of Gmelin.**

**Black-headed gull, the English name of larus rhinoceri. The same bird is also called the pewet black-cap, or sea crow, by Ray and Willughby.**

**Black-headed Indian stork of Albin and Edwards, is ibis lutosus of the tenth edition of the Linn. Syst. Nat. and erithus melanopechala of Gmelin.**

**Black-headed nut-batch, a variety of the common nut-batch found in Carolina and Jamaica. Buffon and Arct. Zool. Syst. Europea of Gmelin.**

**Black-headed piedew of Latham, is charadrius melanopechala of Gmelin.**

**BLACK.**

Black-headed frike, a species of Lanius, so called by Latham: it is the Lanius melanocephalus of Gmelin.

Black and spotted breast-cock of Edwards, and spotted grouse of Pennant and Latham, are tetrao canaden§is of Gmelin. — Off. There is another black and spotted breast-cock figured also by Edwards, pl. 71, which, in the 12th edition of the Linnaean Syd. Nat. is called tetrao canace.

Black heron of Latham, is the ardea atris of Gmelin.

Black-bodied rufset-car of Latham, is motacilla pilcata of Gmelin.

Black-bunting-bird, the Linnaean, turdulus niger, is so named in the Synopsis of Latham.

Black jacoba: the jaca jamaica nigra of Brilliant, and parra nigra of Gmelin, bears this name in Latham's Synops.

Black jack, or Blend, is a mineral, called alfo falfi galena and blende, &c.

Black-jowled sparwarth of Latham, in Ornithology, is motacilla nigricans of Gmelin.

Black island, in Geography, an island near the coast of America, belonging to the state of Rhode Island. N. lat. 41° 7'. W. long. 71° 35'.

Black islands, islands near the eft coast of Labrador. N. lat. 41° 8'. W. long. 56° 30'.

Black kite, or black-gled of Siberia, is falco ater of Gmelin, and milvus nigry of Brilliant. — Off. Gmelin mentions a black variety of falcon communis under the specific name of ater; it was previously described by Edwards under the name of black hawk or falcon.

Black land, in Agriculture, a name given to a part of soil which has a greyish black cast. This part of foil, though pale when dry, always blackens by means of rain; and when ploughed up at fuch times, it ficks to the plough fpare and the more it is wrought the mudder and deeper-coloured it appears. Thisfes of land, when fomewhat rich, yet porous, light but sufficiently tenacious, are good both for corn and grasses; but as they are mostly fituated in bottoms, the wetnels often fpoils them for corn; but when they are dry, they are extraordinarily fruitful, especially for barley; they also bear good wheat crops. When they are very rich, they may, if a deep mould, be planted with liquorice, or town with hemp, wood, clofe, or rape, madder, and other fimilar plants, that beft fit fuch lands; and afterwards with corn, when fome of their fertility is expended. They are capable of bearing excellent clover crops. The belt manure for these foils is chalk or lime, where it can be procured.

Black lark, in Ornithology. Albin describes an accidental variety of the common lark, alauda arvensis, under this name, in the third volume of his History of Birds.

Black lead, in Mineralogy &c. See Lead and Plumbago.

Black leather, in the Manufacture, is that which has paffed the curriers' hands, where from the erifht as it was left by the tanners, it is become black, by having been foonered and rubbed three times on the grain-fide with copperas-water.

Black legs, a name given in Leickeferhire to a difeafe frequent among calves and fleec. It is a kind of jelly, which fettles in their legs, and often in the neck, between the skin and flesh.

Black legs, an appellation given to thofe gamblers and sharpers who prey upon the ignorance and credulity of in-experienced and unfeafonable persons of property, with whom they contrive to associat, and who fubfift in defcription and luxury on the fpoils acquired by deception and fraud, in a variety of games and sports which they frequent for this purpoce. They are jully denominated the pelt of civilized foceity, and should be fanned by thofe who have any concern for thier property or reputation, as the moft dangerous and deftructive enemies.

Black licks, in Geography, lies in Westmorland county, Pennsylvania, about 36 miles eafe of Pittsburg.

Black lory, of Latham, in Ornithology, is phistis teres Gmelin.

Black mail, in English Antiquity, a certain rate of money, corn, cattle, or other matter, anciently paid by the inhabitants of towns in Westmorland, Cumberland, Northumberland, and Durham, to diverse persons inhabiting on or near the borders, being men of name, and allied with others in those parts, known to be great robbers and spottakers; in order to be by them freed and protected from any pillage. Prohibited as felony, by 43 El. c. 13.

The origin of this word is much contrived, yet there is ground to hold the word black to be here a corruption of blank or white, and consequently to signify a rent paid in a small copper coin called blanks. This may receive some light from a phrase fed used in Picardy, where, speaking of a perfon who has not a single halfpenny, they say, il n'a pas une blanche maile. The term is also used for rents referred in work, grain, or labour money, which were called "reditus nigra" in contradification to the blanch farms, "reditus alba".

Black martir, or waif of the English, in Ornithology, is the virid.opus of Latin writers.

Black monks, in Ecclesiatical History, a denomination given to the Benedictins, called in Latin nigri monachi, or nigromonachi; sometimes ortus nigrorum, the order of blacks.

Black mountains, in Geography. See Black Forest.

This is also a denomination given to an extensive ridge of mountains in South-Wales, separating the boundaries of the counties of Glamorgan and Brecknock; covered in summer with black-cattle and sheep.

Black-necked quail of Latham, in Ornithology, is tetrao nigricollis of Gmelin.

Black necked fwan of Pennant and Latham, stands under the name of anatis nigricollis in the Gmelinian edition of Syd. Nat.

Black-necked thruf of Latham, is turdus nigricollis of Gmelin.

Black nyes, in Geography, a fowrt point on the coast of France, and in the English channel, four leagues W. from Calais.

Black oats, in Agriculture, a species of oats much cultivated in the northern parts of England, and esteemed a very hearty food for horses. See Oats.

Black orelle, of the Arctic Zoology, and Latham's Synopis, in Ornithology, is theterus nigry of Brilliant, and orelus nigry of Linn. and Gmelin.

Black orelle (Lefter), the English name of orelus minor, in Latham's Synopis.

Black of Black's Illuftrations, &c. is fruticula camus of Scopoli, Gmelin, &c.

Black parrot of Latham, and black parrot of Madagascar, and of Edwards, are the name; the phistis nigra of Gmelin.

Black petrel of Latham, and great black petrel of Edwards, stands under the name of procellaria aquinsectalis in Gmelin's edition of the Linn. Syd. Nat.

Black poll warbler of Latham, is motacilla frivata of Gmelin.

Black point, in Geography, Eari of America, within thofe of Elizabeth and Portpoife, in the district of Maine.

Black point, is also a point on the west coast of Africa, between cape Cavallou, and cape Palmas. — Also, a point

S. E.
BLACK.

S. E. from cape Chishley, the north point of the Labrador coast. N. lat. about 50° 20'.—Also, on the coast of Spitzbergen, or East Greenland. N. lat. 78° 30'. E. long. 11° 30'. Variation 10° 42'.

BLACK POOL lies on the coast of Lancashire, about 25 miles S. from Lancaster. The beach is a beautiful level sand, with an extended sea front before it. This place is frequently visited for summer bathing.

Black process. in Ecclesiastical Writers, that which is made in black books, and with black engravings and ornaments. See Procession.

Antiquity at Malta, there was a black procession every Friday, where the whole clergy walked with their faces covered with a black veil.

Black rail of Latham, in Ornithology, is the rallus niger of Gmelin.

Black rat, in Zoology. See Mus Notatus, or Common rat.

Black red-tail of Latham, in Ornithology, is the motacilla arara of Gmelin.

Black rents. See Black mail.

Black River, in Geography, an appellation applied to two small rivers, in Vermont, America; one falling into Connecticut river, at Springfield, and the other running north into lake Mispiremagog.—Also a river in New York, which interlocks with Canada creek, and runs northward into Iroquis river, navigable with boats 60 miles.—Also, a long river, which rises in Virginia, and passes southward into Nottaway river, in North Carolina.

Black River, a British settlement at the mouth of the St. Croix river, 20 leagues to the east of cape Honduras, the only harbour on the coast of Terra Firma, from the island of Rattan to cape Gracias a Dios; and for more than sixty years it was the refuge of the logwood cutters, when the Spaniards drove them from the forest of East Yucatan. This occasioned adventurers of different descriptions to settle here, where the coast is fatly, low, and swampy; but higher up, near the rivers and lakes, which are full of fish, the soil is more fertile, and produces plantains, cacao, sugar, maize, yams, potatoes and a variety of vegetables; and the passion for drinking induced them to plant sugar-cane. The forests are full of deer, fowl, and game. The shores abound with turtle, and the woods with mahogany, zebra-wood, farfapallis, &c.: and the whole settlement Bourihrs spontaneously without cultivation.

Black River, a river of Jamaica, which passes through a level country, and is the deepest and largest in the island, so as to admit flat-bottomed boats and canoes for about 30 miles.

Black Rock, a rock in the mouth of Sligo harbour, in Ireland, which is covered about high water only, and has a conspicuous tower built on it that serves as a beacon.

Black Rock, a Rock in the bay of Galway, in Ireland, about three miles westward of Galway, which dries with spring-tide only, and requires attention in navigating that bay. M. McKenzie.

Black Rocks, rocks in the Atlantic ocean, near the coast of Ireland, about six miles N. W. from Saddlehead, in Achill island, and ten miles W. by S. from Blackfoot point. —There are rocks called by the same name in Killbeg's bay and Mulroy haven, but they are less objects of attention to the navigator. M. McKenzie.

Black Rock, a rock near the south coast of Wexford, in Ireland, about four miles W. by S. of Carnfore point, which is always above water, and may be failed round without danger. M. McKenzie. Boate.

Black Rock, a populous village, situate on the river Tawe, about a mile above Swansea, in Glamorganshire, South Wales, where are considerable smelting-houses, and whence are exported coals, &c.

Black Rock lies also near the extreme north point of the island of Antiqua, between Humphrey's bay and Boom point. N. lat. 17° 5'. W. long. 61° 35'.

Blackrod. See Gentleman Usher of.

Black rowan, a species of iron-stone, or ore, found in the mines about Dudley, in Staffordshire.

Black S.G., in Geography. See Euxine S.G.

Black sheep, in Oriental History, the enigma or standard of a race of Turkmans settled in Armenia and Mesopotamia, it is called the "dung of the black sheep." 

Black start of Latham, in Ornithology, is larius niger of Gmelin.

Black Mexican guion of Latham, is fringilla cattol of Gmelin.

Black skimmer of Latham, cut-watter of Aert. Zool., sea crow of Edwards, are all names of the same bird; the Rynchops niger of Gmelin.

Black girdrel of Catchley, is the fenara niger of Erxleben and Gmelin.

Black flumes and gams, according to Dr. Woodward, owe their colour to a mixture of tin in their composition.

Black strakes, a range of planks immediately above the wale in a ship's side; they are always covered with a mixture of tar and lamp-black.

Black swallow of Latham, in Ornithology, is the hirundo apus dominicensis of Buffon, and hirundo niger of Gmelin.

Black fawn. A bird of this description inhabits Botany Bay. Its form resembles that of the common white-fawn; but the prevailing colour of the plumage is black, instead of white; the wings are edged with white; and the bill is red. This species is described by Dr. Shaw (Nat. Mamm.) under the name of anus atrata. It is the black fawn of several writers who have lately treated on the history of Botany Bay.

Black tail, a beacon about 3 leagues distant from the Nore in the river Thames.

Black tern of modern writers, is the sterna hirundo of the old English ornithologists, and elenvis-footed gull of Willughby. Sterna fluvialis of Brunnich and Gmelin.

Black thorn, in Botany, a species of the prunus, which bear...
BLACK.

**BLACK-throated magpie**, of Latham, the _tanagra nigricollis_ of Gmelin.
**Black-throated magpie**, of Latham, the _pipra nigricollis_ of Gmelin.
**Black-throated thrush**, of Latham, is _purdus ater_ of Gmelin.
**Black-throated warbler**, of the Arctic Zoology, is _metacilla Cannatensis_, of Gmelin.
**Black tit**, in Zoology. See Felis Discolor.

**Black toad-gull** of Pennant, Latham, Walcott, &c. In ornithology, is the _larus croopedatus_ of Hawkeworth and Gmelin.
**Black toad petrel**. The Gmelinian _procellaria melanopis_ is described under this name in Latham's Synopsis of Birds.

**Black town**, in Geography, a settlement of 1200 free negroes, erected in 1783, about a mile from the town of Shalburne, in Nova Scotia.

**Black witch**, in Agriculture, a noxious weed, probably the _polygonum convolvulus_, which flourishes in even extremely dry locations, and is very injurious to many crops.

**Black实战**, in Medicine, a disease to which the inhabitants of Spanish North America are subject, said to be allied to the yellow fever of the United States, and which, at intervals, ravages the country like a pestilence. See Fever.

**Black vulture** of Willughby and Latham, in Ornithology, is _corvus niger_ of Ray, Bruffin, and Gmelin.
**Black vulture**, (crested) of Edwards, the _civorus monachus_ of Gmelin.
**Black woodpecker**, (great), Albin, Donovan, &c. the _picus martius_ of Linn. &c. Suec.

**Black woodcock**. See WADD.

**Black-winged parakeet** of Brown's Illustrations, in Ornithology, is called by Gmelin _pittacus melanopis_.
**Black-winged thrush** of Latham, is _turdus Lambla_ of Gmelin.

**Black and white butcher-bird**. Under this title the _Linn. tanais dobis_ is described and figured by Edwards in his History of Birds. Latham calls it the _pied fly-britke_.

**Black and blue creeper** of Edward's Gleanings, the _cathus frons_ of Gmelin.
**Black and violet creeper** of Latham, is _cathus Brachycephala_ of Gmelin.

**Black and white creeper** of Edwards, and small black and white bird of Ray and Sloane, are _metacilla varia_ of Gmelin.

**Black and white king's fisher** of Edwards and Latham, is the _alcedo radiata_ of Gmelin.

**Black and white wagtail** of Ray, is the _pied wagtail_ of Latham, _metacilla nudicollis_ of Bruffin, and _motacilla poeciloptera_ of Gmelin.

**Black, white, and red Indian creeper** of Edwards, is the _cathus cruentata_ of Linn. and Gmelin.
**Black and yellow creeper**. _Cathus flavicollis_ of Gmelin is described under this name both by Edwards and Latham.

**Black and yellow dwarf** of Brasili. Edwards under this title describes a variety of _tirica Perennis_. Linn.

**Black and white diver** (small) of Willughby and Edwards, is _ala alba_ of Linneus. This bird is likewise called the _Greenland dove_, or sea turtle, by Albin; and is known among later writers by the name of the little _cuckoo_. Penant.

**Donov. Brit. Birds**.

**Black and white dodo** of Edwards, is the _doby gree_ of later writers; _Colymbus adjeurn_ of Gmelin.
**Black and white duck** (little) of Edwards, and spirit of Arf. Zool., are _anas alba_ of Gmelin.

**Black and white Indian falcon**, the English name of _falco melanoleucus_ (Gmelin) in Pennant's Indian Zoology, and Latham's Birds.

**Black and orange finch** of Latham, and small black and orange bird of Sloane and Ray, is _fringilla melanistera_ of Gmelin.

**Black and white fly-catcher** of Edward's Gleanings, is _myctisaca bicolor_ of Gmelin.

**Black and white gull** of Ray, Willughby, and Albin, is the black-backed gull of modern ornithologists. Linneus calls it _larus marinus_.

**Black and blue humming-bird** of Bancroft, is called by Gmelin _trochilus cyanemas_.

**Black and yellow manakin** of Edwards, is the variety _β_ of the Gmelinian _pipra aurea_.

**Black and orange-coloured bird** (small) of Ray and Sloane, is _motacilla ruticilla_ of Linneus, and _myctisaca ruticilla_ of Gmelin. This is likewise the black-headed warbler of Latham, _small American redstart_ of Edwards, and yellow-tailed fly-catcher of Edward's Gleanings.

**Black and white Chinese phalanger** of Edwards. This is _phasianus mystellus_ of Scopoli and Gmelin. It is likewise called the _pencilled phalanger_ by Latham and other late writers.

**Black and yellow frizzled sparrow** of Edwards's Gleanings, is the _frizzled sparrow_ of Latham, and _fringilla crisp_ of Gmelin.

**Black and white starling** of Willughby, is _frurus leucomalua_ of Bruffin, which Gmelin gives as a variety of the common sparrow, or _frutus euroluris_ of Linneus.

**Black and white Indian starling** of Edwards. This is _frurus coruscus_ of Gmelin.

**Black and blue tanager** of Latham, is the black and blue _turnus_ of Edwards, and _tanagra mexicana_ of Gmelin.

**Black whistling**, in our Old Writers, bread of a middle fineness, between white and brown, called in some parts ravelbread.

In religious houses, it was the bread made for ordinary guests, and distinguished from their household loaves, or _panis conventus_, which was pure manchet, or white bread.

**Black-work**, iron wrought by the blacksmith; thus called by way of opposition to that wrought by whitesmiths.

**BLACKALL, Offspring, in Biography, an English pretender, was born at London, in 1654, and educated at Catherine hall, in the university of Cambridge. Before several promotions in London, he was appointed one of the chaplains in ordinary to king William, though his principles were adverse to the revolution government, and he refused for two years to take the requisite oaths to king William and queen Mary. On the 30th of January 1699, he preached a sermon before the house of commons, in which he animadverted on a passage in Mr. Toland's life of Milton, who, after stating the proofs that Dr. Gauden, afterwards bishop of Exeter, was the true author of the book entitled "Icon Ballicke," and ascribed to Charles I., observes, that many supposititious pieces, under the name of Chrift, his apostles, and other great persons, were published and approved in the primitive times. But as Mr. Toland, in his Aymont, published in the same year, avowed his belief of
the genuineness of the books of the New Testament, Mr. Blackall cited the dispute by the publication of a small pamphlet in 1790, entitled "Reasons for not replying to a book lately published, entitled "Antimony." In 1790 he
preached a course of sermons at Boyle's Lecture, published in
the first volume of the collection of those sermons. In
1797, he was promoted to the see of Exeter; and in
1799, he was engaged in a controversy with Hoadly, con-
cerning the institution of civil government, and the mea-
sures of submission. With respect to this controversy it is
sufficient to observe, that the bishop defends the high-church,
tory principles, as they are usually called, of the divine in-
ituation of magistracy, and unlimited passive obedience, and
non-refinance, which Hoadly opposes. This pretext, whose
private character, and style of preaching, are highly extolled
by Sir William Dawes, archbishop of York, in the preface
to his sermons, died at Exeter, Nov. 29th, 1716. His ser-
mons were collected and published in 2 vols. folio, Lond.

BLACKAMOOR'S HEAD, in Chemistry, consists of a conical vessel, surrounded with another of a cylindrical form, filled with cold water, and having a cock to draw it off, when it is become too warm. Both vessels are made of copper. In the figure, one half is left open to show the cone; the inclination of the sides of which, according to Chaptal, is most proper, when forming an angle of 75 degrees with the base. See Plate of Chemistry.

BLACKBALL HEAD, in Geography, a cape on the S.W. coast of Ireland, at the north side of the entrance into
Bantry bay in the county of Cork. N. lat. 51° 32'. W.
long. 9° 55'. McKenzie and Beaufort.

BLACKBURN, William, in Biography, an eminent
surveyor and architect, was born in Southwark, Dec. 20,
1750, and having acquired some knowledge of his pro-
fession, in the ordinary course of education, he was admitted
a student at the Royal academy. By this academy he was
prevented in 1773, with the medal for the belt drawing of
the inside of St. Stephen's church in Walbrook; and the
delivery of it by the president, Sir Joshua Reynolds, was
accompanied by a distinguished tribute of respect to his abili-
ties. About this time he entered into busines in the place of
his nativity; but a circumstance occurred in a few years
which served to establish his reputation, and to introduce
him into very general notice. In 1779 an act of parliament
was passed for the erection of places of confinement, under
the denomination of 'penitentiary houses.' Two edifices of
this kind were proposed to be erected; one for the confinement and employment of 620 males, and the other
for the accommodation of 350 females. The three super-
visors first authorized by his majesty for carrying into effect
the provisions of this act, were John Howard esq., George
Whiteley esq., and Dr. John Fothergill. The death of Dr.
Fothergill, and the resignation of Mr. Howard, dissolved
this commission; and the charge was devolved, in 1781, on
Sir Gilbert Elliot, Sir Charles Bunbury, and Thomas Bow-
ler esq. The principal object of the plan proposed was to
combine, in the buildings to be erected, solitary confinement,
with useful labour and moral reformation. Accordingly
promises were made to those who should produce the
belt plans. The highest premium of 100 guineas was unani-
mosly assigned, in 1782, to Mr. Blackburn. In con-
sequence of this distinction, he was appointed by the super-
visors to the office of architect and surveyor of the projected
buildings. The designs of government, after several pre-
paratory steps had been taken, were never accomplished.
However schemes of a similar kind were projected in various
parts of the country, and the execution of them was en-
trusted to Mr. Blackburn. Whilst he was busily employed in
the completion of various designs of this kind, and whilst
he was prosecuting a journey to Scotland, for the pur-
pose of erecting a new gaol at Glasgow, he died suddenly, Oct.
28th, 1790, at Preston in Lancashire; and his remains were
removed to London, and interred in the burying ground of
Bushell-fields.

Mr. Blackburn's skill as a draughtsman and an architect,
was not confined to prisons and penitentiary houses; but
he was occupied, as far as his time would allow, in prepar-
ing various designs for churches, houses, villas, &c.; and in
his drawings and designs he always manifested a correct
taste, and a thorough knowledge of the science to which he
was practically devoted. His friends, and the public in
general, very justly lamented, that by the corpulence to
which he was inclined from his early youth, and the increase
of which no ablution, nor any mode of regimen, would
restrain, he was removed from a scene of usefulness and re-
putation, at too early a period as the 40th year of his age.
As to his religious profession, he was a protestant dissent
of the presbyterian denomination; but he, combined with an
undistinguished and unadulterated avowal of his own sentiments, the
most liberal and candid opinion and conduct with respect to
all who differed from him. In his natural temper he was
cheerful and lively; in his conversation agreeable, animated,
and instructive; in his private character amiable and respecta-
able; and in all the relations and intercourses of domestic
and social life, esteemed and honoured. In 1783, he
married the daughter of Mr. John Habeon, an eminent builder,
of the denomination of quakers, by whom he left four
children.

BLACKBURN, in Geography, a town of Lancashire, Eng-
land, is seated in a valley surrounded with hills. It consists
of several streets, irregularly laid out, but intersected with
good houses. Befides the parish church, here are a newly
erected chapel of the establishment, and five places of
worship for so many different sects of dissenters. A free-school
was founded by queen Elizabeth, and the necissitous poor
of the town are comfortably provided with a poor-house,
which has land attached to it for the pasturage of cattle.

The market, on Mondays, is chiefly supplied with pro-
visions from Preston. Befides this, here are a fortnight
market for cattle, &c. and an annual fair. The town is
approached by four stone bridges crossing the river Derwent,
whole water, being of rather a blackish hue, is laid, by
the writers, to have given name to the town. Blackburn
has been noted for its manufactures, particularly for an
article called Blackburn-grey, which were plains of linenc-warp
flot with cotton. The prosperity of Manchester, and the
great influx of manufacturers to that town and its neigh-
bourhood, have deprived Blackburn of its usual trade; yet
some cottons, callicoco, and muslins are still made here; and
the fields around the town are frequently covered with ma-
terials to bleach.

The church of Blackburn, previous to the reformation,
was attached to the abbey of Whalley. It is now a recol-
yered, policed by the archbishop of Canterbury, who also owns
half of the town, which he lets on leases of 21 years. The
parish church of Blackburn includes 22 townships, and embraces
about a half the hundred of the name. The land round
the town is mooldy, a sandy soil, and consequently unprop-
tious to agriculture. Coal is found in the southern part of
the parish, and in great plenty at Darwen, about four miles
south of the town. An alum mine was found, and much
worked over, in the time of Fuller, but from the depth of
the strata, and consequent expense, it was afterwards neg-
lected. Sir George Colebrook, willing to monopolize all the
BLA

alam of the country, purchased this, with other mines; but failing in his unjust speculations, was obliged to relinquish the works at Blackburn. (See Alum.) Blackburn contains 2,532 houses, 11,980 inhabitants, and is 211 miles N.W. from London. Aitkin's description of the country round Manchester, 180. 1795.

BLACKBURN, the name of a river in Scotland celebrated for its romantic cascades, for the bold and picturesque scenery adorning its banks, and for a singular natural bridge which stretches across the stream, in the parish of Cartfon. The latter is deemed one of the greatest curiosities in Scotland. "It is 55 feet long, 10 feet wide, and the thickness of the arch is two feet four inches of solid stone. It is not composed of one entire rock, but has the appearance of many flakes of about one foot and a half square, set neatly together. The bridge slopes a little downwards, and the water rushes under the arch, through an opening of 31 feet. Among the cascades, which ornament and enliven this stream, is one of above 37 feet in height, and 20 feet in width; another 31 feet high, and 36 feet broad; and a third 27 feet in height. These waterfalls, combining with the romantic character of the rocks, and the constant roar of the dashing stream, present a great number of highly picturesque and interresting scenes. In this wild and romantic vale, nature appears in various forms, now beautiful, then awful, sometimes sublime, and frequently terrible." Sir John Sinclair's Statistical Account of Scotland, vol. xi.: communicated by the Rev. Mr. Arkle.

BLACKBURNE, Francis, in Biography, a clergyman of the church of England, distinguished by his firm attachment to the cause of civil and religious liberty, and by his zealous exertions in the promotion of it, was born of respectable parents at Richmond, in Yorkshire, on the 9th of June 1705. Having pursued a course of classical education, first at Kendal in Westmorland, and afterwards at the free schools of Hawkhead in Lancashire, and of Sedbergh in Yorkshire, he was admitted, in May 1722, penitent of Catherine hall, in the university of Cambridge; where he took the degree of bachelor of arts, and was chosen conduit or chaplain-fellow of the society; and on this title he was ordained deacon in March 1728. At this time he flattered himself with the expectation of a foundation-fellowship; but his avowal of sentiments with regard to ecclesiastical and civil liberty, which he had acquired by the perusal of the writings of Locke, Hoadly, &c. rendered him obnoxious to a majority of the fellows, who, being high royalists on the principle of hereditary right, set aside his just claims as the only qualified candidate, and precluded his election, by indulging Mr. Addenbrooke with an extraordinary year of grace, and thus keeping the fellowship full. This disappointment induced him to resign his conduitship, to quit the university, and to live in retirement with his uncle, Thomas Comber, esq. of East Newton, near Helmsley in Yorkshire, till some church preferment might occur. His views, indeed, were particularly directed to the living of Rich- mond, the place of his nativity; to which he was inducted upon the death of the incumbent in 1739, having previously qualified himself for it by taking prebend's orders. During the interval of his retirement at East Newton, he eacually found some old books that had formerly belonged to his great grandfather, an ovarian justice; and by the perusal of these he was led to entertain favourable sentiments of the manners and principles of many excellent old puritans, to admire their unaffected and disinterested piety, and their zeal for the spiritual good of mankind, and to cherish that moderation and liberality of temper, and that ardent concern for liberty, which distinguished his future conduct. As soon as he was invested with a parochial cure, he devoted himself with exemplary diligence to the studies and duties appropriate to his pastoral office, which he discharged, during a residence among his parishioners of 48 years, no less to their satisfaction and improvement than to his own honour. His first appearance as an author was in the year 1742, when he published an "Afflzet Sermon," preached at York. About the same time he wrote two pamphlets concerning the illegal removal of the conliliary court and its records from Richmond to Lancaster, which, in consequence of a petition from the mayor and corporation to the bishop of Chester, were restored. In 1748, he employed a young person, who was his curate, to translate Erasmus's preface to his paraphrase on the gospele of St. Matthew; and having written "A Preliminary Discourse addressed to the Roman Catholic gentry and laity of Great Britain," he circulated a cheap edition of it, recommending it to the public, partly as an antidote against popery, but chiefly as an encouragement to the common people to be diligent in reading the scriptures, for the information and improvement of themselves and families in Christian knowledge and Christian piety. It was not, however, till the year 1750, that Mr. Blackburne began to distinguish himself as a writer in defence of Christian liberty. A work had been published in the preceding year, intitled "Free and Candid Disquisitions relating to the Church of England." This work contained many pertinent observations on existing defects and improprieties in the established forms of the church, and propounded for revising the liturgy, and amending such passages, as were liable to reasonable objections. Mr. Blackburne was satisfied with many, who were acquainted with his sentiments on the subject of an ecclesiastical reform, to have had a concern in this publication. But though he had corresponded with the compiler and editor of it, and had seen the greatest part of the work in manuscript, he had neither written nor suggested a single line or word. Indeed, he disapproved the style and spirit of it; and thought them by no means adapted to the occasion, nor likely to produce effect. "He was rather perhaps too much (says his biographer), inclined to look upon those who had in their hands the means and the power of reforming the errors, defects, and abuses in the government, forms of worship, faith and discipline of the established church, as guilty of a criminal negligence, from which they should have been roused by sharp and spirited expoliations." Nevertheless, he thought it his duty to repel the attacks of the adversaries of this work; and accordingly, he published, without the knowledge of its editor, or any of his more confidential associates, an "Apology for the Authors of the Free and Candid Disquisitions," 1750. But though he engaged in this controversy, his attention was not diverted from parochial duties; for his next publication was "A Short Discourse on the Nature, Obligation, and Benefits of Family Religion," which he published at his own expense, and distributed among his parishioners. In this same year 1750, notwithstanding the publication of his "Apology," he was collated to the archdeaconry of Cleveland, and also to the prebend of Bilton, by Dr. Matthew Hutton, then archbishop of York, to whom he had been for some years titular chaplain. Towards the close of the year 1752, he had an opportunity of perusing the charge delivered by Dr. Butler, bishop of Durham, to the clergy of his diocese at his private visitation in 1751; and he found in it some doctrines which were, in his opinion, so diametrically opposite to the principles on which the protestant reformation was founded and supported, as to deserve being exposed and cenured, in order to prevent the mischief which they might do under the sanction of his name. Accordingly, he wrote six strictures upon them; and, in opposition
to the reminiscences of a friend who diffused him from publishing them, lest they might be the means of preventing his further preferment, he committed them to the press under the title of "A Serious Enquiry into the Use and Importance of external Religion, &c." This piece, which was afterwards printed by Mr. Baron, in the 4th volume of a collection of tracts, entitled, "The Pillars of Prielecraft, and Orthodoxy shaken," and ascribed to him as its author, gave great offence, particularly to archbishop Secker, and precluded all hopes of preferment in the church, if indeed he had indulged any such hopes, under episcopal patronage. The next subject of importance, which engaged his attention, was the doctrine of an intermediate state. To this he was led by an "Appendix" to Dr. Law's "Considerations on the Theory of Religion," which appeared in 1755, and which inculcated the tenet of the sleep of the soul. This opinion was attacked from several quarters, and particularly by Dr. Goddard, master of Charter-hall, in a sermon preached at St. Edmund's Bury. Mr. Blackburne defended his friend Dr. Law, in a publication entitled "No Proof in the Scriptures of an intermediate state of happiness or misery, between death and the resurrection." He also published several other pieces on the same topic; such as "Remarks on Dr. Warburton's account of the sentiments of the early Jews concerning the soul," and "A Review of some pamphlets in the last edition of the Divine Legation of Moles demonstrated," which appeared in 1759, and may be considered as a sequel to the "Remarks." He also prepared a reply to Dr. Morton, Mr. John Steffe, and Dr. Caleb Fleming, who had published tracts on Dr. Law's Appendix; and he purified the discussion of the subject more at large in a work, first published in 1763, and afterwards with considerable additions in 1774, and entitled "A Short Historical View of the Controversy concerning the intermediate state between death and the resurrection, with a prefatory discourse on the use and importance of theological controversy." In 1759, our author published "Some Sentiments of a country divine concerning the Ordinance of Baptism, &c." occasioned by letters which passed between bishop Clayton and Mr. Penn on that institution. In the correspondence between these writers, a difficulty occurs in the interpretation of the charge given by our Lord to his apostles. Matt. xxviii. 19. Our Lord, it is said, prescribes one precise form of words to be used in baptism; the apostles appear, from the Acts and Epistles, to have used another; and the evangelists Mark, Luke, and John, do not mention any precise form whatever. Various hyp thesis have been proposed by Groseby, Limborch, Lightfoot, Whitby, Clayton, &c., for reconciling the practice of the apostles with the precept of Christ. Mr. Blackburne, diffidently, with all their suggestions, that the words in question contain no baptismal form at all; and that we should rather follow the apostolical form in Acts, as being derived to us by the authority and example of men, who must be perfectly satisfied that the foundation they built upon was found and good. Accordingly, he proposes that we should read the passage in St. Matthew thus: "Πάντες οι ἀνεποίητοι τού Ἰησοῦ Χριστοῦ, ἐποίησαν στίχον: Χριστῷ τῷ παῖς, και τῷ κυρίῳ, και τῷ πνεύματι ἑως τῆς ἀποκάλυψεις." Go ye therefore, and disciple all nations (baptizing them) into the name of the Father, and of the Son, and of the Holy Ghost." By construction and parenthesis, the command to baptize refers to no particular form at all, and leaves us to suppose, what was certainly the truth of the matter, that the apostles being already well acquainted with the form used in the baptism of Jesus, it was quite superfluous to explain it here.

In 1758, Mr. Blackburne avowed the sentiments which he had for some time entertained concerning subscription to the liturgy and articles of the church of England, in "Remarks on the Rev. Dr. Powell's sermon in defence of subscriptions, &c." presented in the preceding year before the university of Cambridge, to which is prefixed "An Adress to the younger students in both our universities." The subject of subscription had indeed for some time engaged his attention; and it was not without scruples that he had qualified himself to hold the archdeaconry and prebend in 1750; but when he had reason to expect further advancement in the church, he refused the consideration of the subject, and the result was a determination never to renew his subscription. About this time he began to make collections for his famous work entitled "The Confessional, or a full and free Enquiry into the right, utility, and success of establishing Confessions of faith and doctrine in Protestant churches." This work, in the execution of which he was much encouraged by Dr. Edmund Law, afterwards bishop of Carlisle, lay by him manuscript for several years, and was at length published in 1766, 8vo, without his name. It excited, as we may naturally imagine, very general attention both among the partisans of reform and the advocates for existing establishments. A second edition appeared in 1772; and the controversy, which it occasioned, lasted for some years, and produced a great number of publications. The third edition, corrected and much enlarged, was published in 1770; and to this edition has been added from the author's manuscript, in the late collection of his works, an appendix, containing a short history of the confessions established in the church of Scotland at different periods. For a further account of the subject of this work, and of the arguments for and against subscription, see Subscription. Soon after the publication of the third edition of the "Confessional," the author was induced by several of his friends to draw up and publish "Proposals for an application to parliament for relief in the matter of subscription to the liturgy and thirty-nine articles of the established church of England; humbly submitted to the consideration of the learned and conscientious clergy of the said church." An association was formed for this purpose, for the result of which, see Association.

It was natural to imagine, that the author of such a work as the "Confessional," written with a view of examining and refuting the federal pleas that had been urged in favour of subscription, and which had convinced many persons of the insufficiency of these pleas, would have wished to withdraw himself from the established church, which imposed a subscription that appeared to him to be unjustifiable; and accordingly, as the death of Dr. Chandler, in 1766, occasioned a vacancy in the respectable congregation of dissenters at the Old Jewry, in London, some individuals of that society applied to Mr. Blackburne for information, whether such a situation would be agreeable to his views, if it were offered to him. But, with the prospect of a very considerable addition to his income, he declined accepting the proposal, for reasons that were very fatal to those who made it. The clear amount of all that he possessed, as a beneficed clergyman, never exceeded the sum of 150l. a year; whereas, if the removal that had been suggested to him had taken place, his income would have been nearly trebled. Some other circumstances also afterwards occurring, which had a tendency to detach him from the established church. Two very respectable clergymen, immediately connected with his own family, viz. the learned Mr. Theophilus Lindsey, whose excellent character those who are well versed in his theological opinions concur in applauding, and his son-in-law, Dr. Disney, no less esteemed by all who know him, surrendered their preferments, because they disapproved the doctrines and forms of the established church.

3X
Mr. Black-
Mr. Blackburne, however, though he agreed with his valued relatives in many of their objections to the liturgy and articles of the church, differed from them with regard to several doctrinal points of importance; and without seeming to advert to his past subscription, in consequence of which he still held his church prebends, he satisfied himself with refusing any further prebend, which was actually offered to him, because he was determined not to renew his subscription. His constancy in the church cannot be justly ascribed to any selfish and interested motives, because he might have left it with advantage, and he remained in it with a fixed purpose of accepting no prebend; and he refused very considerable offers of this kind. But, in order to vindicate his constancy, he thought it right to avow his motives for continuing minister in the church, while he disapproved many things in her doctrine and discipline; and with this view he drew up a short paper containing "An Answer to the question, Why are you not a Socinian?" and also his reasons for officiating in a church, whose forms of faith, worship, and discipline, he thought to be in many things highly exceptions. Those who with for faction on these points, are referred to the Appendix annexed to the Memoirs of his Life, p. 130. We shall content ourselves with observing, that Mr. Blackburne was a firm believer of the pre-existence of Christ, and that he also maintained his divinity, with limitations according to his own ideas, which he believed to be founded on the Scriptures; and with regard to the general sentiments of his creed, he is said to have more than once declared himself a moderate Calvinist. Whatever may be the inconsistency which some persons have charged upon his conduct, he manifested his election for the church, not only by continuing his own connection with it, but by educating a son for the clerical office, though the condition of performing any duties, or enjoying any emoluments in that church, was subscription, the imposition of which he had strongly repudiated and condemned. On this subject the further discussion of which would lead us beyond our province as biographers, we shall only say, "Let every one be fully persuaded in his own mind; to his own master let each one answereth."

Being accompanied from early life to regard the Roman C. tholes as dangerous foes to the government and religion of his country, Mr. Blackburne, notwithstanding the enlarged and liberal sentiments acknowledged by him on all other occasions, wrote against them with a vehemence which the friends of freedom have generally condemned. But an alarm with regard to the spread of popery, and the evils to be apprehended from it, prevailed very much at the time; and this induced him, in 1768, to publish a caution against it, under the title of "Considerations on the present state of the controversy between the Prot: and Papists of Great Britain and Ireland, particularly on the question, how far the latter are entitled to toleration upon Protestant principles."

"During the intervals of his other professional and literary engagements, he employed his self in collecting materials for the life of Martin Luther, which he proposed to write according to the pattern of Dr. J. R. N. of Erasmus; but he was diverted from accomplishing his design, first by the death of his friend Thomas Hollis, esq. of whom he published "Memoirs." in 2 volumes 4to. in 1750. and afterwards by the loss of his second son Thomas, in 1782, a physician of rising eminence in the city of Durham, which so affected him as to render him incapable of finishing several things which he had undertaken. Soon after his eye-sight failed him, and he was under the necessity of employing an amanuensis. His mind, however, was still enterprising and active; nor was he prevented by the increasing infirmities of age from prosecuting the object of ecclesiastical reformation, which seems to have occupied his thoughts to the latest period of his life, and from performing his professional duties. Having in the last year of his life prepared a charge for his 5th annual visitation in Cleveland, he caused it to be delivered by his eldest son, who flourished by him, and then took leave of his clerical brethren, with an address equally pious and affectionate, that must have deeply impressed the minds of all who heard it. At the close of his visitation circuit, he was taken ill at the house of a friend, and apprehensive of approaching dissolution, hastened to his rectory at Richmond with all the expedition which the state of his health allowed. Within a few weeks after his return, on the morning of August 7th 1872, in his 83d year, he finished the profound course of a studious and exemplary life, with the sentiment of the amiable Erasmus, and the benevolent Justin, "I have had enough of every thing in this world, and expired, as he sat in his chair, without a groan. He left a widow, who died August 20th 1793, and four children; viz: Jane, married to the Rev. Dr. Disney, now minister of the Unitarian society in Effex-street, London; the Rev. Francis Blackburne, vicar of Brignal, near Greta bridge, Yorkshire; Sarah, married to the Rev. John Hay, vicar of Chew Magna, and rector of Dundry in Somersetshire; and William Blackburne, M. D. of Cavendish square, London. Few persons have ever been more regular and afforded in the performance of professional duties, whether we consider him as a parish priest, or as an architecton, than Mr. Blackburne. Possessing naturally a strong constitution of body, and great firmness of mind, which he preferred by temperance to a very advanced period, he was capable of industry and continued application. He was likewise animated in the discharge of his clerical duties by a conviction of their importance, and by an ardent desire of promoting the best interests of those with whom he was connected. In composing for many years new discourses, whenever he offered, and also charges for his archidioecesan visitations, and in preparing for the press a variety of publications, a great part of his time must have been spent in study and retirement; and hence he is said to have acquired the appearance of austerity; nevertheles with his intimate friends and associates he was cheerful and unreserved. As a writer he was nervous and animated; and his public discourses were delivered with an unaffected earnestness, which proceeded from conviction of the importance of religious truth and duty, and which interested and impressed those who heard him. In his controversial writings, it must be acknowledged, and he himself lamented it towards the close of his life, that he was occasionally betrayed into precipitation of judgment and asperity of language; but it should be recollected, that he contended with a host of adversaries, whose mode of attack sometimes provoked and justified his resentment; and that his vehemence and ardour were always accompanied with a high sense of integrity and honour, and a laudable solicitude for serving what he conceived to be the cause of truth and liberty. The topics of his numerous publications, the principal of which we have above recited, were chiefly theological or controversial; nevertheles he was an occasional writer on political liberty, and he largely contributed to a collection of letters and essays on this subjed, published in 3 vols. 8vo. 1774. A collection of his "Works, theological and miscellaneous, including some pieces not before printed, with the account of the life and writings of the author, by himself, completed by his son Francis Blackburne, L. L. D. and illustrated by an appendix of original papers," has this year (1804) been published in 7 vols. 8vo. The following remarks..."
spectable and just tribute to his memory closes his son's account of his life and writings: "Such was Francis Blackburne; a believer of Christ and of the deep conviction of his truth;..." 

Eff. char. Cal. four-toothed; pet. four. elliptic; anh. heart-shaped; germ conic; stigma simple. Pcr. berry, with a single seed.

BLACKBURNIA, in Ornithology, a species of Motacilla, described in the Arctic Zoology under the name of the blackburnian warbler. The crown is black, with a yellow line in the middle; and through or across the eye black, as are also the, upper wing covers; greater wing-coverts. Vent and lateral tail-feathers white, the middle ones being dark; sides of the neck, chin, and middle of the belly yellow. A native of New York.

BLACKHEAD, in Geography, a cape on the east coast of Ireland, at the north entrance into Belfast Lough. N. lat. 54° 45'. W long. 5° 23'.

BLACKHEAD, a cape on the western coast of Ireland, in the county of Clare, on the south side of the entrance into Galway bay. N. lat. 53° 7'. W long. 9° 11'.

BLACKHEAD, a cape on the south coast of Ireland, within the head of Kinsale, and on the west side of Kinsale harbour. N. lat. 51° 38'. W long. 8° 30'.

BLACKHEAD, a cape on the west coast of Scotland, in the county of Wigtoun; 6 miles W.S.W. of Stranraer.

BLACKHEAD, a point of land between Falmouth haven and the Lizard point. - Also, one of the peaks between Fermoye's harbour on the east coast of Newfoundland, and Augus fort; Bald head being the other. - Also, a point on the south coast of Newfoundland, west of cape Race, and half a league further west from cape Pine. - Also, a point on the east coast of the northern island of New Zealand, N.N.E. of cape Turnagain, in about 40° 18' S. lat.

BLACKING, in the Arts, &c. is sometimes used for a faciitious black, a lamp-black, shoe-black, &c. A mixture of ivory or lamp-black with linseed oil, makes the common oil-blacking. For a flaming blacking, small beer or water is used instead of oil, in the proportion of about a pint to an ounce of the ivory black, with the addition of half an ounce of brown sugar, and as much gum Arabic. The white of an egg, substituted for the gum, makes the black more shining; but is supposed to hurt the leather, and make it apt to crack.

In 1771, a patent was granted to Mr. William Basley for preparing a composition in cakes, rolls, or bals, which, with the addition of water only, makes an excellent flaming liquid blacking for shoes, boots, &c. The recipe for this purpose is as follows: Take one part of the gummy juice that issuing, in the months of June, July, and August, from the shrub called the goat's thorn, four parts of river water, two parts of neat's head, or some other softening lubricating oil, two parts of superfine ivory-black, two parts of deep blue, prepared from iron and copper, and four parts of brown sugar-candy. Evaporate the water; and, when the composition is of a proper consistence, let it be formed into cakes of such a size, that each cake may make a pint of liquid blacking.

BLACKLOCK, Thomas, in Biography, was born in 1721, at Annan in Scotland, of parents, who were natives of Cumberland, and who occupied a humble station. At the age of 6 months he was deprived of his sight by the small-pox; and thus becoming incapable of any mechanical employment, he was in the probable cause of nature destined to be a perpetual charge to his parents. His disposition, however, as he advanced towards maturity, engaged the most affectionate attention; and the kindliness of his father was such as to impress his youthful mind, and to engage expressions of ardent gratitude. The powers of his mind were no less distinguished than the amiable habits of his temper; and he improved the actual opportunities of cultivating them, which were afforded him by the attention of his father and friends, who read to him several passages out of English authors, and particularly from the works of our most approved and popular poets. Thee he heard with avidity and delight; and at the early period of his 12th year, he began to imitate what he admired. His performances, as he advanced towards maturity, became the subjects of general conversation; and having the misfortune to lose his father in his 19th year, he was invited, at the age of 20, by Dr. Stephenfon, physician at Edinburgh, to remove thither and to pursue his studies at the university. Notwithstanding the personal disadvantages under which he laboured, he made very considerable progress in the Latin, Greek, and French languages; but upon the breaking out of the rebellion in 1745, his studies were interrupted, and he retired into the country. On this occasion he was solicited by his friends to publish a small collection of his poems at Glasgow. When the tumult of the rebellion forbade, he returned to Edinburgh, and to the prosecution of his studies for 6 years more, during which period he not only perfected himself in the languages, but made considerable progress in all the sciences, and particularly in polite literature. In 1754, he published a second edition of his poems, much improved and enlarged; and thus gained the patronage of Mr. Spence, who in his account of his life, character, and poems, brought him into general notice. By means of a subscription to a 4th edition of his poems, his circumstances were rendered easy and comfortable; and applying himself to the study of theology, he passed the usual trials, and was licensed in 1759 to be a preacher by the presbytery of Dumfries. From the discharge of the duties of his office he derived great satisfaction and reputation. On the alarm of a French invasion in 1761, he published a discourse "On the right improvement of time;" and in the same year he contributed some poems to the first volume of Donaldfon's collection of original poems. In 1762 he formed a matrimonial connection, which he regarded as the chief source of the felicity of his future life. About this time he was ordained minister of Kirkcudbright, on the presentation of the Earl of Selkirk; but in consequence of some litigations that ensued, he
thought it most expedient, within two years, to resign this preferment, and to retire upon a moderate annuity. With this slender provision he removed in 1674 to Edinburgh, and opened his house for the accommodation of young persons as boarders and students. In 1765 the medical school of Aberdeen conferred upon him the degree of doctor in divinity. From this time he continued to maintain his literary character by several publications, which it will be sufficient to enumerate. There were, "Paradisus, or Collections deduced from natural and revealed religion," in two dissertations, 8vo. 1753; "A Discourse on Great Britain," a satirical piece, 8vo. 1773; "The Graham, an heroic ballad, in four cantos," 1774; "Remarks on the nature and extent of liberty, &c. and on the justice and policy of the American war, occasioned by perusing the observations of Dr. Price on these subjects," 8vo. 1776; and a valuable article, communicated to the editors of the Encyclopaedia Britannica, "On the education of the blind," 1783. A 4to. edition of Dr. Blackock's poems was printed in 1793. This edition contains an essay on the education of the blind, being a translation of M. Hailly's celebrated essay on this subject; and prefixed to it we have a new account of the life and writings of the author by Mr. Mackenzie, author of the Man of Feeling, &c. Dr. Blackock died at the age of 70, in July, 1791. With respect to his talents, Mr. Hume observes, "that he may be regarded as a prodigy;" and to his moral character he bears this honourable testimony, that "his modesty was equal to the goodness of his disposition, and the beauty of his genius." In the depressed circumstances of his early life he was singularly contented and acquiescing; but his loss of sight deeply affected his sensibility, and he deplores it in plaintive accents in one of his poems, written on occasion of his escape from falling into a deep well. At the same time he was drenched with apprehensions of falling into extreme indigence; however he expresses his trust in Providence, and his hope that the clouds which were gathering over him would be diffipated. Next to his religious principles, were letters, conversation, and music, from which he derived his principal felicity. His poetry is easy, elegant, and harmonious; and abounds with images, deduced from visible objects, and aptly applied. He is said to have composed with rapidity, and hence it is owing that his vivacity and animation are often indulged in the expense of correctness and regularity. In sentiment he displays much benevolence and tenderness of disposition, as well as true piety and philosophy. Spence, ibid. /spra. Gen. Biog.

BLACKMORE, SIR RICHARD, M. D., an indefatigable writer, poet, and physician, was born at Corsham in Wiltshire, about the year 1652. After some years spent at a grammar school in the country, he was sent to Westminster school, and in 1668 to Edmund-hall, Oxford. In 1676 he took his degree of master of arts, and continued to reside at college three years after, but apparently without receiving much benefit from his long residence in this feast of the muses, scarcely knowing the names or situations of places, which an intimacy with classical authors must have made familiar to him. At some time in his life, probably immediately on quitting college, he kept a school, but does not seem to have remained long in that situation, as he soon after went to Paris, and to other places on the continent, with a view, it is probable, of acquiring or improving his knowledge in medicine, in which faculty he took his degree of doctor at Padua. Returning to England, after a ramble of eighteen months, he came to London, and settled at first in Cheapside, where he acquired to much reputation, that in 1697, he was admitted a fellow of the college of physicians. In 1697, he received the honour of knighthood from king William, accompanied with a present of a gold chain and medal, which, he intimates, were given him as a reward for some services performed at the revolution. The same year he was made physician in ordinary to the king; an office he held afterwards under his successor, queen Anne. He was now in the zenith of his reputation, and having as yet but little exposed himself to the fury of the critics by writing, his merit was probably rated much beyond its real standard. To his popularity as a physician, and his excellent and unimpeached moral character, it was probably owing that his first production, "Prince Arthur," an epic poem, in ten books, published a little before this time, acquired so much celebrity as to pass through three editions in the space of two years. Encouraged by this success, in 1699 he published his "King Arthur," in twelve books, with paraphrases on the book of Job, and on other parts of scripture; and in 1700, his "Satire on Wit," in which he took occasion to retort the farcifias which had been heaped with no sparing hand on his last poems by Denis, Dryden, Pope, and most of the wits of the time. Not deterred by their censures, in 1705 he published "Eliza," another heroic poem, in ten books. "This excited," Johnson says, "neither praise nor blame, but seems to have dropped dead born from the press." In 1712, appeared "Creation," a philosophical poem, certainly the belf of his productions. It had the honour of being praised by Addison, in the Spectator, and Dr. Johnson has since inferred it in his collection of English poets, with commendation much beyond its merit. This for a time revived its credit, and gave it a degree of celebrity, which seems again to be declining. Pleased with the reputation procured by this poem, he soon after produced his fourth and last epic poem in twelve books, intended to commemorate the actions of king Alfred, whose name it bore, but like Eliza, excited little notice; benevolence being ashamed any longer to patronize, and malevolence weary of inflicting, such frigid ablations. But as it was to be the late of this author to try every species of writing, and to fail in all, on the Spectator evening, he produced, in conjunction with Mr. Hinges, the "Lay Monastery;" one paper of which was published three times in the week. This was only continued to the 46th number. Soon after he gave the world two volumes of essays. As these were intended to promote the cause of virtue and religion, they met with some favour. Besides these works, Dr. Blackmore wrote several tracts on different branches of medicine; on the spleen, the gout, the rhumatism, the king's evil, the dropsy, the jaundice, the diabetes, the plague; and as inculcation for the small-pox was making some progress in his time, he thought it incumbent on him to give his decided disapproval of the practice. But as by this time he began to be esteemed scarcely a better physician than a poet, his opinion had fortunately very little weight with the public. The medical tracts are published together in an 8vo. volume, but are little known or noticed. He died on the 8th of October, 1729. Gen. Biog. Johnsooke Lives of the Poets.

BLACKNESS, the quality of a black body; or a colour arising from a texture and situation of the superficial parts of the body, which, as it were, flitte, or rather absorb, the light falling on it, without reflecting any, or very little of it, to the eye. In which case, blackness stands directly opposed to whiteness; which confinits in such a texture of parts, as indifferently reflect all the rays thrown upon it, of whatsoever colour they be.

Defeartes, says Dr. Priestley (Hist. of Vision, p. 127 and 143, &c.), though mistaken with respect to the nature of light and colours, yet distinguished jullly between black and white, observing, that black absorbs and extinguishes the
rays that fall upon it; but that white reflects them.
This, adds the historian of philosophy, is the first distinct
account I have met with of this tenable hypothesis. Mr. Boyle,
also made several observations and experiments, which de-
montate his theory in a very satisfactory manner. See
BLACK.
Sir Isaac Newton, in his Optics, shews, that for the pro-
duction of black colours, the component parts must be less
than those which exhibit any other colours; because, where the
sizes of the component particles are greater, there is too
much light reflected to constitute this colour; but, if they
be a little less than requisite to reflect the white and very
faint blue of the first order, they will reflect so little light,
as to appear intensely black; and yet may, perhaps,
reflect it variously and so within them so long, till
it happen to be it shed and lost; by which means they
will appear black in all positions of the eye, without any
transparence.
And hence it appears, why fire and putrefaction, by
dividing the particles of substances, turn them black: why
small quantities of black substances impart their colour very
freely, and intensely, to other substances, to which they are
applied; the minute particles of these, by reason of their
very great number, easily overpowers the great particles
of others. Hence also appears, why glass, ground very
excellently with sand, on a copper plate, till it be well po-
lished, makes the sand, together with what by rubbing is
worn off from the glass and copper, become very black; and
why black substances do, soonest of all others, become
hot in the sun's light, and burn (which effect may proceed
partly from the multitude of refracted actions in a little room,
and partly from the easy motion of such very small particles):
also, why blacks are usually a little inclined towards a blueish
colour; for that they do so are seen by looking white paper with light reflected from black substances, where
the paper will usually appear of a blueish white; and the
reason is, that black borders on the obtuse blue of the first
order of colours; and therefore reflects more rays of that
colour than any other.
BLACKIE, Alexander, in Biography, apothecary,
a native of Scotland, published in 1766 a dissertation on
medicines that diffuse the flame, in which Dr. Chittick's
secret is laid open, 12mo. It was reprinted in 1771, with
additions. He found the solvent to be the luvian poto-
narium, which may be given, he says, advantageously, mixed
with lime water, even when blood is voided with the urine.
When the bladder becomes ulcerated, wounded by the
asperities of the stone, he recommends the parcrea brava and
vina udi. When pain in the loin or pubis is violent, he gives
opium; and he has known, he says, persons vomit stones
in their sleep, while taking that drug. Persons who vomit
sand or gravel with their urine, are never affected, he says,
with the stone. Haller, Bib. Chirur.
BLACKS, Negroes; a people so called from the colour
of their skin. For the reason of their colour, and the com-
merce of them, see Negro.
BLACKS, de a name given to an association of disorderly
and ill-atoning persons, formerly herding chiefly about
Waltham, in Essex, who destroyed deer, robed fish-ponds,
ruined timber, &c. See BLACK a.d.
BLACKSOD BAY, in some old maps erroneously called
Black harbour, in Geography, a large bay lying between the
peninsula of the Mullet, and the main land of the county of
Mayo, Ir'ld, to the south of the Mullet. It is well
sheltered, the ground in most parts clean, and sufficiently
deep for large ships; but the ground being a hard sand, it
is not thought that it will hold well in hard gales from the west
and south-west, especially in the winter time. It is 2$ miles
wide at its entrance, and runs about 9 miles inland, with
several creeks communicating with it, of which those within
Barnacle island, and the point of Clew, are the most remark-
able. The south-west point of this bay is in N. lat. 54° 6'.
W. long. 5° 55'. Mr. Blackstone, &c.
BLACKSTONE Point, the southern point of the Muller, a
peninsula in the western part of the county of Mayo, Ire-
lund, which forms the western extremity of Blackford bays,
N. lat. 54° 6'. W. long. 5° 55.'
BLACKSTONE, J. in Biography, apothecary, of whom
nothing is known, but that he published, in 1737, "Palaegeus
Plantarium, circa His~field, fpo peascentium, cum Appen-
disse ad loci naturam frequentes," 8vo. London. Among many
common, some very rare plants were discovered by this
author, and are described in this volume. He also published,
in 1746, "Specimen botanicum, quo plantarum plurim.
Anglie indigenarum, loci naturales illustratum." 8vo. London,
BLACKSTONE, William, Sir, knight and L.L.D.,
a celebrated English lawyer, was born in London,
July 10th 1723, and received the first rudiments of
learning at the Charter-house, where he was admitted upon
the foundation in 1735, and whence he was removed, in 1738,
to Pembroke college, Oxford. At school and in the uni-
versity he was distinguished by his application and pro-
cerity; and the range of his studies, even at an early period, was
to extensive, that he is said to have composed a treatise on the
"Elements of Architecture," for his own use, at the age of
20. This treatise is was never published. As he made choice
of the profession of the law, he was entered of the Middle
Temple, and quitted Oxford in 1744 to pursue studies, very
different from those to which his taste inclined him at the uni-
versity. This change of his pursuits is feelingly commemo-
rated in the "Lawyer's Farewell to the Mufe," composed
about this time, and published in the fourth volume of
Dodley's Miscellanies. From this period he affidually
applied to his professional studies, residing occasionally in
chambers in the Temple, for the convenience of attending
the courts, and at other times in the university, to which he
was much attached. In 1742 he was elected a fellow of
All-Souls' college, and on the 24th of November 1746 he
was called to the bar, and commenced the practice of the
law. Delighted of a ready docility, and of other talents
required for a popular advocate, his progress was so
rapid; and he had leisure to discharge the duties of curate, or
reward, of All-Souls, which he did with such skill and diligence,
as to improve the revenues of the college, and to aid in
completing the magnificent structure of the Coderingtton
library. A treatise which he composed on this occasion is still
useful in conducting the peculiar concerns of this society. In
1749, he was appointed recorder of Walling-ford in Berks,
and instituted more constant residence at Oxford, he
took in the following year the degree of doctor of laws.
About this time he published an "Essay on collateral con-
finuity," particularly referring to the claim made by the
kindred of the founder of All-Souls to a preference in being
elected fellows of that society. It was written in defence
of the college, which had lately rejected some of these
claims; but the reasoning, though supported by great
learning and ingenuity, is deemed by some competent
judges inconclusive. In 1757, Mr. Blackstone, perceiving,
after a trial of seven years, that he had no prospect of suc-
cess in the courts at Westminster, determined to quit London,
and to retire to his fellowship at Oxford. This resolution
was eventually very favourable both to himself and the
public. As no public provision had been made either by
the founders of the English universities, or at any subsequent
period.
BLAckstone.

period, for teaching students the laws and constitution of their own country, Mr. Blackstone undertook to supply this defect, and opened a course of public lectures upon this interesting subject. With such reputation and success did he prosecute his plan, from Michaelmas term 1753, when his first course of lectures commenced, during a series of successive years, as probably to suggest the idea to Mr. Viner of founding by his will a very liberal establishment in the university of Oxford for the study of the common law. As soon as the plan of Mr. Viner's institution could be arranged, Mr. Blackstone was very properly elected, in October, 1758, the first Vinerian professor; and he introduced the duties of his new office by a well-written lecture, adapted both to the subject and the audience, which was soon afterwards published, and which has since prefixed to the first volume of his Commentaries.

With his engagements as a lecturer, Mr. Blackstone combined the occasional exercise of his profession as a provincial barrister; and, in 1754, he was employed as counsel in the great contested election for the county of Oxford. The fulness of his pleadings on this occasion was published in a pamphlet entitled "Considerations on Copyholders," with a view to the legislative decision of the point controverted at this election. The argument of this treatise is founded on feudal principles, and excludes copyholders from the right of voting; this right being, by his reasoning, restricted to those who have a freehold or permanent interest in land, which does not belong to copyholders, whom the feudal system considers as mere vassals, and dependent on the will of the lord. But it has been more liberally argued by others, that a series of legal decisions has given to this tenure the permanence of freehold property, and that as the reason of the distinction between the two species of tenure has ceased, the distinction itself ought no longer to exist. However, in the parliamentary discussion of this question, the technical arguments prevailed; and a declaratory act was soon afterwards passed, in conformity to the principles advanced by the professor's treatise, excluding copyholders from the right of suffrage. In 1759, Blackstone published, besides two tracts of a local and temporary nature, a new edition of the "Great Charter, and Charter of the Forest," introduced by an historical preface, which evinced a considerable knowledge of antiquities. In the same year, the reputation gained by his lectures encouraged him to return to the Temple, and to reform his attendance at Westminster; where he soon acquired professional eminence, and where he was employed for a considerable time in almost all cafes that required great learning and deep research. In 1761, he was elected member of parliament for Hinckon, and had a patent of precedence to rank as king's counsel, having before declined the office of chief justice of Ireland. In 1762, he collected and republished several of his pieces under the title of "Law Tracts," in 2 vols. 8vo. In 1763, he was appointed solicitor general to the queen, in the establishment of her majesty's household, and barrister of the Middle Temple. Having vacated his fellowship by his marriage, in 1761, he was immediately afterwards appointed principal of New Inn-hall, by lord Welfmoreland, then chancellor of the university. But in 1766, he resigned both this office and his Vinerian professorship.

The first volume of his lectures was published in 1765, under the title of "Commentaries on the Laws of England," a work which Sir William Jones has characterized as "the most correct and beautiful outline that was ever exhibited of any human science." In the execution of this undertaking, the author combines the humble duty of an expounder with the higher character of a philosophical writer on jurisprudence. Under the former character he is entitled to the highest praise. The style is correct, perspicacious, and elegant; and the author has admirably contrived to connect amicable with instruction, and to render the study of the law as agreeable as it is important and interesting. Notwithstanding the immense mass of materials of which this comprehensive work consists, few errors have been detected in it, and it has been cited as a book of authority.

It has been objected, however, that the Commentaries, excellent as they are in a variety of respects, that in those parts of them where the author examines the reasons and principles of law, he does not investigate them with a truly philosophical spirit, and that he does not rise above the ordinary level of those writers who, in every country and age, have extolled their own municipal institution as "the wisdom of ages," and "the perfection of reason." In discourse on the propriety of particular laws, it is said that "his ingenuity is always occupied by the forms of jurisprudence; and instead of referring to public convenience and general utility, the sole standard of all rational legislation, he perpetually appeals to those technical arguments which are dignified with the title of "legal reasons." He is, in all cases, the advocate and the apologists of existing institutions; and it is the constant tendency of his work to justify whatever has been established by antiquity, to defer the improvements of modern times, and to expose to contempt or indignation all proposals for further change. In his political principles he has been charged with being too much the advocate of prerogative; and his ecclesiastical opinions have been thought to incline towards intolerance. Notwithstanding the undue deference to authority, with which this writer has been charged, there are many passages in his admirable work, in which he expresses a marked disapprobation of standing armies and military barracks, and in which he eliminates the progress of the influence of the crown, and the probable effects of a further increase of the national debt. These passages, however, have been attributed, by some of those who have animadverted on his Commentaries, more to the spirit of the times, than to that of the writer. Several obnoxious passages in the ecclesiastical part of this work were pointed out by Dr. Pusey and Dr. Pusey; but though the author had not magnanimity enough explicitly to acknowledge his errors, these passages were retracted in subsequent editions. The political principles of the Commentaries were some years afterwards, viz. in 1770, more severely noticed in a treatise entitled "A Fragment on Government," by Jeremy Bentham, et seq. To the honour of Mr. Blackstone it should be mentioned, that notwithstanding the severity of this author's criticism, he afterwards became acquainted with him, and lived with him upon terms of regard and friendship.

Having given his opinion in parliament, on occasion of the debates about the Middlesex election, that an expelled member was not eligible to the same parliament, and this opinion appearing to contradict the language of his Commentaries, he was violently attacked for this inconsistency by the celebrated Junius and others; but, though he defended himself with ingenuity, he inferred the cale of expulsion in the next edition of his work, of which he had before taken no notice, as one of the disqualifications for a seat in parliament.

His distinguished talents and meritorious services entitled him, without doubt, to the notice and recompense of government. Accordingly, when he declined the offer of being solicitor-general, on the resignation of Mr. Dunning, in 1770, he was appointed immediately afterwards one of the justices of the common pleas, which office he held, except for a short interval, during which he accommodated Mr. Justice Yates by sitting as one of the justices of the king's
king's bench, till his death. Towards the end of the year 1779, a
diphthisial disease, occasioned chiefly by early application,
and by neglect of exercise, made rapid advances, and termi-
nated in his death, Feb. 14th, 1782, in his 56th year. In
private life, judge Blackstone was distinguished for mildness
and benevolence, and for every domestic and social virtue.
In studies and avocati ns that contributed to establish his own
reputation, and to benefit both his contemporaries and pos-
terity, he was eminently prolific; and the intervals of leis-
ure which he enjoyed in the later period of his life were
devoted to schemes of local improvement in the neighbour-
hood where he resided, or to great public undertakings.
The two volumes of Reports, which he left in MS. have
been published since his death, in 2 vols. folio, with a pre-
face containing Memoirs of his life; but their merit is laid
not to correspond with the fame of the author. He also
left in MS. several small poetical pieces; and his notes on
Shakespeare inserted in Mr. Malone's Supplement, shew
how well he understood, and how capable he was of appre-
ciating, the excellence of that author. Life prefixed to

BLACKSTONE, in Geography, a small river of America,
which has its source in Ramhorn pond, in Sutton, Massa-
chusetts; and, passing through Providence, discharges itself
into Narraganset bay, at Bristol, receiving in its course se-
veral tributary streams.

BLACKSTONIA, in Botany. See Chlor.

BLACKWALL, Anthony, in Biography, a native of
Derbyshire, was admitted a fellow of Emmanuel college, in
the university of Cambridge, in 1695. Having taken the degree
of M. A. in 1698, he became head-mastcr of the free-school
at Derby, and lecturer of the parish of All-hallows in that
town. In 1726, he excited notice by an edition of the
" Moral Sentences of Theogon," with a new Latin version,
together with notes and emendations. He also published, in
1718, "An Introduction to the Classics," 12mo., in which he
displays his excellence, gives directions for studying
them with advantage, and illustrates those rhetorical figures
by which language is cultivated and adorned. In 1722,
he was appointed head-master of the free-school at Market
Boicworth, in Leicestershire; and in this situation he pre-
pared for the press his principal work, entitled: "The Sacred
Classics defended and illustrated; an essay humbly offered
after proving the purity, propriety, and eloquence of the
writers of the N. T. in 2 parts 4to." This was pub-
lished in 1723; and a second edition in 8vo. appeared in
1727. After his death, a second volume was published under
the title of: "The Sacred Classics defended and illustrated,
the second and last volume, in 3 parts." 8vo. 1731. The
design of the author, in this elaborate and learned work, was
to vindicate the writers of the New Testament from the
charge of barbarism in their language, and to shew that the
words and phrases which they have used are to be found in
the most approved classical writers. Many of the obscurities
and seeming faults it attributes to transpositions and mis-
translations, and he urges the necessity of a new version.
See Bible. This book has been highly valued by biblical
scholars; and a Latin translation of it was published at
London, 1756, by Christopher Wulphus. Nevertheless it
has been thought by several very competent judges to be
written with more zeal than fidelity; and Dr. George
Campbell, in his Preliminary Dissertation to his Version of
the four Gospels, has attacked the fundamental principle
of the work, and made several particular criticisms upon it.
Mr. Blackwall was eminently distinguished as a schoolmaster,
and formed many good scholars, among whom was Richard
Dawes, author of the Miscellanea Critica. In his school he
used a Latin grammar composed by himself, and published
in 1728 without his name. Sir Henry Atkins, bart., who
had been one of his scholars, presented him, in 1726, with
the valuable rectory of Clapham, in Surrey; but he refused
it in 1726, and returned to Market Bicoworth, where he died
in 1730.

BLACKWATER, in Geography, the name of four
rivers in England and Scotland. That of England rises
near the middle of the county of Essex, and falls into
the mouth of the Thames, where it forms a spacious bay called
Blackwater bay. Thole of Scotland, 1in. in Berwickshire,
and 3d. in Berwickshire, and 3d. in Berwickshire.

BLACKWATER, the name of several rivers in Ireland, one
of which is very considerable. This river rises on the
mountains which separate the counties of Limonick and Kerry; and,
taking a southerly direction, divides the latter county from
the county of Cork for about 12 miles. After passing at
the foot of Slieve-logher mon tain, from which it receives
a large supply of water, it runs westerly across the northern
part of the county of Cork, which is about 45 English
miles. In this course it passes the flourishing towns of
Mallow and Fermoy, to the former of which it was naviga-
ble in lord Orrey's time, and receives the rivers Allo,
Aweeg, and Puncion, besides many smaller streams.
A few miles below Fermoy, it enters the county of Waterford,
and continues in the same direction for 12 miles, when, hav-
ing passed the ancient city of Lismore, it bends nearly at a
right angle to the south at Cappoquin. At this town it be-
comes navigable, and in its course receiving the river Bride,
and opening into two or three spacious loughs, it flows into
the sea a little below the town of Youghal, which is situated
on its western bank. This river passes for almost the whole
of its course, which, without making any allowance for its great
windings, is about 90 English miles, through a rich and
well-wooded country, "equally remarkable," says Mr.
Young, "for beauty of prospect and fertility of soil." The
banks are crowded with a number of fine estates, some of
which, as Dromana and Lismore castle, may vie with
those in any country, and have furnished artists with beau-
tiful landscapes. The cedar made in its neighbourhood is
held in great estimation, being preferred to the best im-
ported from England, and of course brings a very high price.
The Irish name of this river was Annulbiff, or Acoin-dub,
the black river, and also Acoin-more, the great river, to dif-
tinguish it from the Aroweg, or Acoin-beg, which runs into it.
The latter is the Mull of the immortal Spenfer, who
had an estate on its banks, where he resided for a long time.
In his marriage of the Thames, he has mentioned the
Blackwater and several of its tributary streams, though not
with geographical accuracy, as the Alto does not rise near
Slevogher, but has the Blackwater between it and that
mountain.

"Swift Aunilbiff, which of the Englishman
It is called Blackwater, and the Llalar deep,
Sad Traws that once his people overran,
Strong Alto tumbling from Slevogher steep.
And Mull of mine, who leaves Lambton taught to weep,"
—Spenfer. Tairy queen, b. v. e. 11.

—3. Another river, called Blackwater, rises in the county of
Tyrowe, and, for the greater part of its course, divi-
ses that county from those of Monaghan and Armagh.
The linen manufacture is extensively carried on in its neigh-
brbourhood, so that there are many bleach-works. The
flourishing little towns of Aughnesslo, Caledon, Blackwater
town, Moy, &e., are on its banks; and its navigation to
Longe Naugh, into the south-western angle of which it
pours its waters, has been improved at a considerable na-
tional expense, on account of the colliers at Dunglass,
in the county of Tyrone.—3. A river Blackwater rises in the
the county of Monaghan, and, having passed through Lough Ramor, unites its waters to those of the Boyne at Navan.

—There are also small rivers of this name, one in the county of Longford, which joins the Shannon near Lanesborough, and one in the county of Wexford, which flows into St. George's channel at the place where Bannow formerly stood. Smith's Cork. Beaumont's Map. Holmes's Tour in the South.

Blackwater Town, a small town in the county of Armagh, in Ireland, on the river Blackwater, which has a linen market. Distance from Dublin 66 miles.

Blackwell, Thomas, in Biography, was the son of one of the ministers at Aberdeen, and born in that city in the year 1701. He was educated at the grammar school and marischal college of his native place, of which, in 1723, he was appointed Greek professor, and in this office he contributed in no small degree to promote Greek literature, and the study of the classics in general. In 1735, his "Enquiry into the Life and Writings of Homer," 8vo, was published without his name; and by its popularity served to establish his reputation for learning and ingenuity. Of this work, discussing a variety of topics without any very obvious connection, Dr. Bentley is said to have remarked, "that when he had gone through half, he had forgotten the beginning; and that when he had finished the perusal of it, he had forgotten the whole." It is reckoned, however, the author's principal performance, and is both curious and entertaining. His "Letters concerning Mythology," 8vo, were published in 1743; and they were intended to establish a regular system of ancient fable, as an allegorical representation of the religion, laws, and philosophy of early times. The work is learned, fanciful, and delectable. In this year Dr. Blackwell was appointed principal of the Marischal college, and allowed his office of Greek professor. In 1751, he announced to the public his design of publishing a new edition of Plato's works; but this design was never executed. The first volume of "Memoirs of the Court of Augustus," 4to, was published in 1753; the second in 1755; and the third, after the author's death, in 1764. The object of this work is to exhibit, in an elegant and popular form, the principal facts of Roman history, at the commencement and during the period of the public life and reign of Augustus. It is written with vivacity, and was at first well received; but the affectation and familiarity of the style, united with a considerable degree of that pompous kind of pedantry, which displays not only erudition but a knowledge of the world, has contributed to lower its reputation. This work manifests also a republican spirit, not altogether free from party prejudice. The author's affected mode of writing increased as he advanced in years; and though it must be acknowledged, that he possesses genius and fancy, and had a relish for the beauties of ancient authors, he never acquired that simplicity of taste, which leads to the true and elegant manner of composition. This peculiar style and manner of composition have been attributed to an injudicious imitation of Lord Shaftesbury. Some years before his death Dr. Blackwell's health declined; and his disorder being of the consumptive kind, which he is thought to have increased by his sedentary mode of living, he was under a necessity of remitting his studies, and advised to travel: but with this view he could proceed no farther than Edin- burgh, where he died in 1767, the 56th year of his age. His temper was singularly mild and equable; and he retained his natural vivacity and cheerfulnes through the whole period of his illness, and till the hour of his death. In conversation he was inoffensive and entertaining; and he blended a considerable knowledge of the world and urbanity of manners with an extensive acquaintance with ancient and modern authors. But it was his foible, that he was apt to assume the appearance of universal knowledge; and this weakness betrayed him into conversations on philosophical and mathematical subjects, with which his acquaintance was very imperfect. Among his friends and correspondents were many persons of literary eminence; and it is said, that his patrons proped to introduce him into the professorship of modern history at Cambridge, if he had not died before a vacancy occurred. Biog. Britt.

Blackwell, Elizabeth, widow of Alexander Blackwell, M. D. author of "A New Method of improving cold, wet, and clayey ground," 1741, London, 8vo. Rejecting dung and other manures, he depended entirely on repeated ploughing and turning the ground. He died a miserable death in Sweden. His widow, being left in indigence, undertook, by the advice of her friends, to publish an account of 500 medicinal plants, to be drawn, engraved, and the greater part of them coloured by herself. The plants were furnished by Rant and Miller, from the botanical garden, belonging to the company of apothecaries, at Chelsea. They are, in general, Haley says, faithfully delineated. In some parts, however, she has failed. Not well instructed in the Linnean system, she has not delineated the fibres or filaments of the flowers with the accuracy now required. A short account is annexed of the medicinal virtues of each of the plants, some of which are extremely rare. The first volume of this work was first published in 1727, and the second in 1739, when the whole was published in 2 vols. fol. under the title of "A Curious Herbal, &c.;" and it is creditable to the author's to say, that this bulky and expensive work passed through several editions. The last, which came out in 1760, in 5 vols. folio, at Nuremberg, is furnished with a preface and considerable additions by James Trevor. After his death, in 1760, a supplemental volume, conducted by Ludwig, Bofc, and Boehmer, was printed in 1773. This work has been in a great measure superceded by Dr. Woodville's SS. Medical Botany, in 4 vols. 4to. Haller. Bib. Bot. Pulteney's Hist. and Biol. Sketches of the Progress of Botany in England, vol. ii. p. 254.

Blackwood, Adam, was born at Dumferline, in Scotland, in 1539, and educated at Paris under Turnebus and Dorat. He was particularly patronized by Mary queen of Scots; and when he had finished his law studies at Touloupe, he obtained the office of counsellor to the privy seal of Poitiers, which was Mary's dowry-town. In this place he settled and married; and, during the imprisonment of Mary, took several journeys to England with a view of serving her. He died in 1633. His religious and political sentiments may be deduced from the titles of his works, which were written both in verse and prose. Of these the principal were, "Caroli IX. pompa funebris veribus expressa," Paris, 1574; "De vinculo religionis et imperii, et de conjunctionum invidiae, religionis fuo adunbratis," 1573; "Adversus G. Buchananum dialogum de jure regni apud Scotas, &c.;" Poi- tiers, 1581; "Martyre de Marie Stuart, rene d'Ecoffe," &c. &c. His account of the execution of Mary Stuart is a virulent inveccive against queen Elizabeth, her parentage, her right to the crown, her government, &c. His works were collected and published in a 4to. volume by Gabriel Naudé, in 1644, with an eulogy of the author prefixed. Moret. Ger. Biol.

Bladder, in Anatomy, is a membranous bag, serving as a receptacle for some secreted fluid. That which is con- sidered as the chief receptacle of this kind, is the urinary bladder. As the anatomy of these parts, in general, will be described with that of the organ which prepares the fluid which they are intended to contain; therefore, for the sake of uniformity of method, the description of the urinary bladder
bladder is given with that of the kidneys and other urinary organs. See Kidney.

Bladder. Difficult of the, in Surgery. This wine being supplied with nerves, blood-vessels, eschariform, and mucous fibres, will be necessary lie to all the common disorders of flat parts; such as wounds, inflammation, ulceration, gangrene, palsy, coma, emaciation, rupture, &c. But, besides these affections, the bladder is subject to other morbid changes, which occur very rarely or not at all in most other parts of the body. It is sometimes included among the contents of a hernial sac. See Hernia. Partial bags, or fasciae, may likewise form in the coats of the bladder, so as to contain one or more eloxerous bodies generated in the urine. See Calculus, Cystotomy, Lithotomy, and Stone. Fungous, painful, and dangerous excrescences arise also on the inner surface of this organ, which are frequently denominaled cancers, and are perhaps equally fatal in their consequences. These disorders will, in general, produce either a retention or a preternatural evacuation of urine, and require a peculiar plan of treatment adapted to the diversity of symptoms. See Urine, Retention of, &c, &c.

Bladders, vesicles, in Botany, a kind of air bags found in some species of insects.

Vegetable bladders are found everywhere, in the structure of the bark, the fruit, pith, and parenchyma, or pulp; besides those morbid ones raised on the surface of leaves by the puncture of insects.

Bladder, swimming. See Air bladder.

Bladders, oil, in the Anatomy of Plants. See Oils.

Bladder, pelor, in Entomology. See Chermes.

Bladder-nut, in Botany. See Staphylaea.

Bladder-nut, African. See Rovenia.

Bladder nuts, laurel-leaved. See Holly.

Bladder fern. See Colutea.

Bladder shaped, inflates, denotes inflated or distended like a blown bladder; such are the cup of the bladder campion, and the blossoms of the fig-wort.

Bladder-scent. See Utricularia.

Bladder-wort, common. See Utricularia.

Blade, in Agriculture, a spike of grain, or green shoot of corn.

Blade, in Anatomy. See Shoulder-blade.

Blade of an Anchor, denotes that part of the arm on which the palm is shut.

Blades, in Commerce, a thin slender piece of metal, either forged by the hammer, or run and cast in moulds, to be afterwards sharpened to a point, edge, or the like. Sword-blades are made by the armourers, knife-blades by the cutlers, &c. The English and Dacianus blades are most esteemed. Among the French, those of Vienne and Dauphiny have the preference. The conditions of a good blade of a small sword are, that it be light and tough, apter to bend than break. When it will stand in the bend, it is called a pour mor ads blade.

Blade of a Chisel, is the iron or铁el part, as distinguished from the wooden handle.

Blade of Mace, or cinnamon, among apothecaries, are little slips or flakes of those barks.

Blade of an Oar, is that part which is plunged into the water in rowing. On the length of this do the force and effect of the car, so much the greater, measure, depend.

Blade of a Scythe, the thin part wherein the teeth are cut, which, to be good, must be thin, yet bend equally into a regular bow all the way, without yielding more in one place than another.

Vol. IV.
divisions ovate, reflex. Stem. filaments four, setaceous, the length of the tube, inserted into the receptacle; anthers oblong, compressed, erect, obtuse, emarginate. Pet. germ. four-cornered, short; style setaceous, much longer than the corolla; stigma obtuse. Per. capsule oblong, quadrangular, four-celled, gaping at the angles. Seed, none roundish. Of these the anthers are emarginate, but not horned, as in cica, allied to this.

Species, 1. B. ericoideis, heath-leaved. B. "Anthers awnless, standing out; calyces four-leaved; bract the length of the calyx; leaves in foars, oblong-acerofo, hairy, imbricate." This has the figure of the common heath. Flowers terminating, white with a tinge of purple; corollas tubulous, erect; anthers two-parted, feaceous; style capillary, longer than the anthers. Introduced into Kew garden in 1774 by Mr. F. Maffon. 2. B. eiarain, eiliated B. "Flowers in a head, calyces ciliate." Refembling the preceding, and readily known by its white calyces, most difficultly eiliate. 3. B. articulata, joined-leaved B. Penna Sarcoila. Berg. cap. 25. "Stamens protruded, two-parted; corollas cylindric." A divided shrub, of the figure of common heath. Leaves in fours, pricked to the branches; heads of flowers terminating, with white-villoso calyces; corollas flesh-coloured; anthers very narrow, black; differing from the first in having equal filaments, and leaves more imbricated. 4. B. purpurea, purple-flowered B. "Stamens included; two-parted; corollas oblong, sliight; flowers terminating, aggregate; peduncles erect." Like the third; but the heads are nodding. 5. B. pufilla, dwarf B. "Flowers scattered; corollas funnel-form." This has the figure of small heath. Branches pubescent; leaves in fours, rugged, petiolated, scorced underneath with a line; flowers minute, scattered, shorter than the leaves. B. myosotis, moss-leaved B. Att. Hort. Kew. 1. 150. "Anthers awnless, almost standing out; calyces one-leaved, hairy; corollas bell-shaped, hairy in the upper part; flowers axillary; frigmas ciliate." Found at the Cape of Good Hops by Mr. F. Maffon, and introduced in 1774; flowering from June to August.

Propagation and Culture.—These are all shrubs, inhabitants of the Cape of Good Hops, require the same treatment and shelter with other Cape plants in the dry frame, and may be increased by cuttings, like the cicas, or heaths, which they much resemble. Martyn.

BLESLING, in Ornithology. One of the surnames of the greatest of English writers, and fascina alterima of Linnaeus. Vide Günther Neft. und. Eyer. The common eoot, fulica atra of Linneaus, is also named by this author kleiner blaugreif

BLEMMUS, in Medicine. See Stammering.

BLAGAITZKI, in Geography, a town of Croatia; 10 miles N.N.W. of Slun.

BLAGNAC, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Toulouse, on the Garonne; 3 miles N.W. of Toulouse.

BLAGOVETSCHENSKOY, a town of Russia, in the government of Archangel, near the south-east coast of the White sea; 70 miles S.W. of Archangel.

BLAGRAVE, John, in Biography, an English mathematician, was born of an ancient and honourable family at Bulmash court near Sunning in Berkshire, towards the middle or close of the 10th century, and educated, first at a school in Reading, and afterwards at St. John's college, Oxford. Before he took any degree he retired from the university to his patrimonial seat at South-cote lodge, near Reading, where he diligently pursued his studies, particularly mathematics. His works, of which we have any account, are, "A Mathematicai Jew," shewing the construction and use of an instrument fo called, and its application to astronomy, cosmography, geography, &c. Lond. 1585, 4to.; "The Contruction and Ufe of the Familar Staff, &c.," performing the geometrical mensuration of all altitudes, Lond. 1596, 4to.; "Altroalbium Uranicum generale," containing the use of an instrument, or altzlobe, Lond. 1596, 4to.; and "The Art of Dallin, in two parts," Lond. 1609, 4to. Mr. Blagreave was distinguished by his benevolence, both during his life, and at his death. Having never been married, he bequeathed 50l. to each of his children, or their posterity, payable at the age of 26; and his bequests in this way were so well administered, that near 80 of his nephews and their descendants were thus benefited out of his leafhold ciate. He also bequeathed lands for producing an annual donation of 10l. to a maid-servant in the town of Reading, according to the directions of his will. These directions required, that the churchwardens of each of the three parishes should on Good Friday fend one virtuous maid, who had lived five years with her master. The three maid's were to appear in the town-hall before the mayor and aldermen, and to eat dice. She, whose throw was the greatest, received the ten pounds. The three maid's who had lost were to appear the next year, together with a third added to them. Accordingly each maid was to have by his will the chance of three annual throws; but if any failed in three successive years, he orders new persons to be prelected. On the same Good Friday, money is distributed to 50 widows in pursuance of his will, who attend a sermon, for which the preacher is to receive ten shillings. Mr. Blagreave died Aug. 9th, 1611, and was buried in the church of St. Lawrence, Reading, where a funereal monument is erected to his memory. Biog. Brit.

BLAGRE, in Ornithology. Under this name Lervailant describears the African species of eagle called by Latham falco blagre, which fee.

BLAIN, a distemper incident to beasts, consisting in a bladder growing on the root of the tongue against the windpipe, which at length swelling stops the breath.

It comes by great chilling and heating of the stomach; whereby, as some judge, it still grows and increases by more heat.

It is perceived by the beast's gaping, holding out his tongue, and forming at the mount: to cure it, call the beast, take forth his tongue, and then flitting the bladder, wash it gently with vinegar and a little salt.

BLAIN, in Geography, a town of France, and principal place of a district in the Lower Loire. The population of the place consists of 1097 persons, and of the canton of 10,274; its territorial extent is 3424 Kilometres, and it includes 4 communes; 18 miles N.N.W. of Nantes, and 40 S. of Rennes.

BLAINVILLE, in Biography, a learned musician of Paris, who proposed, in 1751, a third mode or key, which he called a mixed mode, because it participates of the modulations of the two other, or rather from its being compounded of both, a mixture which the author does not regard as an inconvenience, but rather as an advantage and source of variety both in the melody and harmony. Rou- feau. Dit. de Musique, published 1768.

BLAINVILLE, a performer on the violoncello, and violinmaker at Paris, who had many symphonies and motets performed at the Concert Spirituell, in the middle of the last century,
century, without success; but abandoning the practice of harmony or composition, in order to try his force in the theory, in 1751, he produced "L'Harmoie theorico-pratico," in 1754, "L'Esprit de l'Art Musical;" in 1765, "L'Histoire générale, critique, et philologique de la Musique." These works are no better than his symphonies. They are compositions without taste, which teach nothing new to those who know anything about music already; and not enough to those who know nothing. In 1751, he had the courage to publish as a discovery a pretended new mode, a key different from the major and minor, which, he said, was neither major nor minor, but mixed of both. He composed a symphony in this new mode, and had it performed at the Concert Spirituel, which gave birth to many discussions and criticisms, &c. Laborde, Effai sur la Musique, tom. iii. p. 577.

"Who shall decide, when doctors disagree?"
The new mode, as it was called, was attacked by the ingenious and speculative writer on music, M. Serre, of Geneva, and defended by Rouffeau in his Dictionary. Thirty years after, it became the subject of a very long article in M. Laborde's Effai sur la Musique, merely to attack Rouffeau for having defended it. In this attack of the dead lion, the able Rouffeau wasattle-bulldo to his friend Laborde. All these gentlemen were utterly ignorant of the church music of the 15th and 16th century, built on the ancient ecclesiastical modes, in which nothing was more common in the masses of the old masters, than for a movement beginning in A minor to end on the Fifth of that key, with a sharp third, which would be called now a "soft cadence." The melody of the several parts is equally in the scale of C and A natural, which, without accidental flats or sharps, produces nothing but different species of octaves in the key of C natural. But calling E the key note instead of A, it has a peculiarity in the second, instead of being a tone major above the key note, is only a major semitone.

Now Dr. Pepusch, who rigidly adhered to the laws of the ecclesiastical modes in his "Treatise on Harmony," so late as 1731, in speaking of the key of E formed of one of the species of octave in the scale of C natural, has explained the properties of this key with only a major semitone for its second, much better than Bainville, or any of his defenders or opponents, and terminates his remarks on this key, by saying that "it differs from all others; for they are introduced by the semitone major below them, but this is by the semitone major above it; they by their seventh major, but this by its second, which happens to be minor; that is from F downwards to E. It is because of this difference and peculiarity in its modulation, which makes what is composed in it to be very solenm, that this key is as it were appropriated to church-music, and called by the Italians "tono di chiesa," p. 65.

But the doctor does not call it a new key, for it is as old as counterpart; and we should suppose that Bainville had either seen Dr. Pepusch's treatise, or found in some old mas a movement that ended on the Fifth, instead of the key note, and wished to pass for an inventor. But it is plain that all the French gentlemen, who took a part in this controversy, were disputing about the "det d'or," before they had ascertained its existence. In examining the masses of Jofquin, Palestrina, and the canticles of Tallis and Bird, we find movements of the description of Dr. Pepusch's "tono di chiesa." And in Padre Martinus's "Saggio di Contrepunto," tom. i. p. 42, he calls this mode il terzo tono autentico, the third authentic mode, which Bainville calls the new or mixed mode; and Padre Martinus even calls it terzo tono milo del quarto fluo plagale, p. 44. He gives the same natural scale for its intervals as Rouffeau and Bainville, EFGABCDE, p. 51. An example of this mixed mode is given from Palestrina, in which no accidental sharps are marked, though it modulates into G major, A minor, C, and G, a second time. A sharp only is given to G upon the close note, as sharp third to the final E.

In 1756, Bainville published what he called "A general, critical, and philological History of Music;" a work for which the author's materials seem to have been so scanty, that he was reduced to fill two-thirds of this quarto with an indigent treatise on composition. See Pepusch, p. 65, and examples 53 and 76.

Bainville, in Geography, a town of France, in the department of La Manche, or the Channel, and chief place of a canton, in the district of Coutances, five miles west of Coutances, and 13 north of Granville.

Bainville sur l'Eau, a town of France, in the department of the Marne, and chief place of a canton, in the district of Luneville, four miles S.W. of Luneville, and 12 S. E. of Nancy.

BLAIR, John, in Biography, a chronologer and geographer, was born in Scotland, and educated at Edinburgh. Upon his first arrival in England, he was usher at a private school, and first appeared with regular advantage before the public by publishing, in 1746, a work intituled "The Chronology and History of the World, from the Creation to the year of Christ 1753," illustrated in 56 tables, of which four are introductory, and contain the centuries prior to the first Olympiad; and each of the remaining 52 contains in one expanded view 50 years, or half a century; by the Rev. John Blair, L.L.D." This comprehensive work, on which the author must have bestowed a very great degree of attention and labour, was published by subscription, and dedicated to Lord Hardwicke; and the author acknowledges great obligations to the earl of Bath. Dr. Blair appears at this time to have taken orders in the English church; in 1756, he was elected fellow of the Royal Society, as he was of the Antiquarian Society, in 1761. In 1756, he published a second edition of his Tables, and in 1757, he was appointed chaplain to the princes-dowager of Wales, and mathematical tutor to the duke of York. In 1761, he obtained a prebendal stall at Weilmünster, and several church preferments in very quick succession. From the vicarage of Hinckley, in Leicestershire, which he held, by dispensation, with the rectory of Burton Coggles, in Lincolnshire, he was promoted first to the vicarage of St. Bride's, in London, in 1771, and in 1776, to the rectory of St. John the Evangelist in Weilmünster, with which he held that of Horton near Colebrooke, in Buckinghamshire. During the years 1762 and 1764, he accompanied the duke of York in his travels on the continent. In 1768, he published an improved edition of his "Chronological Tables," which he dedicated to the princes-dowager; and to this edition he annexed 13 maps of ancient and modern geography, and prefixed a dissertation on the rise and progress of this science, which was also printed separately in 12mo. His death, which happened June 24th 1782, was probably accelerated by the shock that attended the news of his brother, captain Blair's death in the memorable sea-fight of April 12, 1782; more especially as he then was severely afflicted with an epidemic influenza. After his death, in 1783, his "Lectures on the canon of the Scriptures, comprehending a dissertation on the Septuagint version," were published; and a new edition of his "Chronological Tables," extended to the year 1790, appeared in that year. Biog. Dict.

BLAIR, Patrick, practised physic and surgery at Dun- dee, in Scotland, where he was probably born. He first became known, in 1706, by his account of the anatomy of an elephant, which he had the opportunity of dissecting there. It was published in the Philosophical Transactions, Nos. 346 and 352.
and 327, in the year 1710. It contains an accurate description of the proboscis and its muscles, and confirms, Haller says, the opinion formerly given, that the elephant has no gall bladder. In a subsequent number of the Transactions, he gives a description of the officia auditus, accompanied with engravings. In the rebellion, in 1715, being suspected, on account of his religious principles, of hostility to government, he was for a small time confined. He came afterwards to London, where he re-published his "Anatomy of the Elephant," in 4to; and, in 1718, published a volume of "Miscellaneous Observations on the Practice of Physic, Anatomy, Surgery, and Botany," in 8vo. This was followed, in 1720, with "Botanical Essays," in two parts, also 8vo. with figures, in which he treats of the sexes of plants, confirming the arguments adduced in proof of them by found reasoning, and some new experiments of the manner of fecundation, of the circulation of the sap, &c. This work still retains its credit among botanists, although some of the author's opinions are abandoned. About the same time, he gave an account of the abeifus, found in the county of Angus, in Scotland, printed in the Phil. Trans. N° 333; and of the dissection of an emaciated child, in which he could find no velum of the omentum, Id. N° 353; and also of a boy, who lived a considerate time without food, Id. N° 524; and in the same number is also a dissection of the means of discovering the medicinal properties of plants from their external figure. He soon after settled at Bath, and published "Pharmacoe- botanical," or an alphabetical and classical dissection on all the British indigenous and garden plants of the London Dispensary, in seven decades, 4to. 1723 and 1728, introducing some plants which he had first discovered growing near Bath. The work only proceeded to the letter H. The time of his death is not known. Haller Bb. Anat. et Bot. Tunley's Sketches, vol. ii. p. 134. &c.  

BLAIR, Chairman, an episcopal divine, was born and educated in Scotland, where he was ordained and beneficed; but meeting with some discouragements in that country, he quitted his prebendaries, and removed to England, about the latter end of the reign of king Charles II. Being introduced to Dr. Compton, then bishop of London, he prevailed on him to go, about the year 1685, as a missionary to Virginia, where, by his conduct and ministerial labours he was eminentely serviceable in promoting the cause of religion. In 1689, he was appointed by the same prelate as his commissary for the province. Intent upon doing good in the office with which he was entrusted, he observed with concern, that the want of proper seminaries for religion and learning obstructed every attempt for propagating the gospel in this colony; and he therefore formed the benevolent design of erecting and endowing a college at Williamsburg, the capital of Virginia, for professors and students in academical learning. With this view he raised a considerable sum of money by voluntary subscription; and, in order the more effectually to accomplish his purpose, he came over into England in 1693, to solicit the concurrence of government. King William and queen Mary very much approved the design, and accordingly a patent was issued for erecting and endowing a college, which was to be denominated from its founders, "the college of William and Mary." Mr. Blair, who first projected the scheme, was appointed president of the college. (See Williamshurg.) He was also rector of Williamsburg and president of the council in that colony. Having faithfully and honourably discharged the duties of his office as president of the college for about 50 years, and that of his ministerial function for above 80 years, he finished his course of laborious and useful life in the year 1754. His works, comprising "Our Saviour's divine Sermon on the Mount explained, and the practice of it recommended, in divers fictions and discourses, with a recommendatory preface, by the Rev. Dr. Waterland," were published in 1720, 4 vols. 8vo. Waterland's Preface. Burnet's Hist. of his own Times, vol. iii. p. 165. 8vo.  

BLAIR, Hugh, a distinguished preacher and writer, the descendant of an ancient family of Anstford, in Scotland, and the son of a respectable merchant at Edinburgh, was born in that city, April 7th, 1718. As his views were at an early period directed towards the church, he entered the university of his native place in 1730, and spent eleven years in the studious prosecution of those literary and scientific studies which the church of Scotland prefers to such as proffers themselves candidates for the ministerial office. During this period his application and proficiency gained repeated testimonies of approbation from the professors under whom he studied. One of his performances at this time, indicating the bent of his genius towards polite literature, was an essay on the beauty, or "On the Beautiful," which afforded such satisfaction to professor Stevenson, that it was appointed to be publicly read at the conclusion of the session. This honour, without doubt, stimulated his emulation, and proved the earnest of his future fame. The method of study, which he commenced at college, and which he occasionally practised in his mature years, contributed in a considerable degree to the accuracy and extent of his knowledge. It consisted in making abstracts of the most important works which he read, and in digesting them according to the train of his own thoughts. This was the method in which he studied history in particular; and with this view, aided by some of his youthful associates, he constructed a comprehensive series of chronological tables, in which was inferred every important fact that occurred. In conformity to this plan, his learned friend, Dr. John Blair, formed his valuable work, already noticed under his article. In 1739, Mr. Blair took his degree of master of arts; and on this occasion he printed and defended, in elegant Latin, a thesis, "De Fundamentis et Obligatione Legis Naturae." Having completed his academic course, he passed through the coltumary trials before the prebendary of Edinburgh, and was licenced as a preacher, October 21st, 1741; and in the following year he was presented to the parish of Coileffe, in Fife, where he was ordained Sept. 23d, 1742. Such at this time was his established reputation as an eloquent preacher, that when a vacancy occurred in the Canongate church of Edinburgh, he was chosen at a contested election to supply it; and accordingly he returned to his native city in July 1743. In this situation he continued for eleven years, exhibiting specimens of those talents for pulpit compositions, which have since obtained distinguished testimonies of public approbation. In 1754, he was translated from the Canongate to lady Yelter's, one of the city churches; and in 1758, he was promoted to the High Church of Edinburgh, the most important ecclesiastical charge in North Britain. To this honourable rank he was advanced at the request of the lords of council and session, and of other distinguished persons holding public offices, who attend that church; and the wisdom of their choice was amply justified by the prudence, ability, and success, with which his ministerial labours were conducted for a period of more than 40 years. Previously to his advancement to this station of public service, Mr. Blair's attention seems to have been almost wholly devoted to the attainment of professional excellence, and to the regular discharge of his parochial duties. Of the productions of his pen, we have only two sermons, preached on particular occasions; some translations, in verse, of passages of Scripture for the
was preacher. His reward. She was...tion of rhetoric and belles letters in the university of Edinburgh, and to appoint Dr. Blair, in conlerration of his approved qualifications, regius pro-
ductor thereof, with a salary of 70l. The lectures which he delivered on this occasion, were published in 1783, under the title of "Lectures on Rhetoric and Belles Lettres," in two volumes. Also; and they have been frequently re-
published in 3 vols. 8vo. Of these lectures it will be sufficient to observe, that the general voice of the public not only in our own country, but in other nations on the continent into whose languages they have been translated, has pronounced them to be a most judicious, elegant, and comprehensive system of rules for forming the style, and cultivating the taste of youth. By a happy and singular union of taste and philosophy, the author has supplied a great defect in the science of criticism, and has made a valuable addition to the polite literature of the present age. In the course of this Dictionary we shall have frequent occasions for referring to this excellent work, and availing ourselves of its interesting and useful contents. In 1763, Dr. Blair published "A Critical Dissertation on the poems of Ossian," which, for beauty of language, delicacy of taste, and acuteness of critical investigation, has few parallels. As it was partly by his solicitation, that Mr. Macpherson was induced to publish his " Fragments of Ancient Poetry," it is no wonder, that, independently of the text of criticism, he should be a zealous advocate in favour of their authenticity and antiquity; but, notwithstanding his able defence, a degree of scepticism has prevailed on this subject.

Dr. Blair's reputation as a preacher, or rather as a compend of sermons, had been for a long time acknowledged by those who had the pleasure of attending on his ministry; but it was not till the year 1777, that he could be induced to favour the world with a volume of the discourses which had so long furnished instruction and delight to his own congregation. The MS. of this volume, it is said, was received by the bookseller with some hesitation; but it was sooner published, than he found it his interest to engage the author to furnish him with other volumes. Accordingly five volumes, in the whole, have been published at different intervals; and we may venture to affirm, that liberally as the author was remunerated, no collection of sermons has ever been more profitable to the bookseller, or more acceptable to the public, than Dr. Blair's. The circulation of them was rapid and extensive. They were translated into several foreign languages; and they received a still greater reward. A pension of 200l. a year, being out of the exchequer in Scotland, was conferred, in 1780, on the author, and it was continued without any alteration till his death. These fer-

mones, though they posses various degrees of comparative excellence, and some must be allowed to be much inferior to others, are upon the whole models in their kind; and they will long remain as monuments of the piety, the genius, and found judgment of the author. Occupying a middle place between the dry metaphysical discourses or controversial speculations of one class of preachers, and the loose incoherent declamations of another, they blend the light of argument with the warmth of exhortation, the elegance of composition with judicious observations on human life, and practical knowledge with important principles of religion and virtue. The last volume was prepared for the press by the author after he had completed his eighty-second year, and delivered to the publishers about six weeks before his death. Although he left many other discourses in manuscript, he explicitly enjoined that they should be destroyed, and thus wisely prevented that injury to his reputation which has sometimes been the result of posthumous publications. The author's fame, as a preacher, depended principally, if not wholly, on the intrinsic excellence of his discourses, with respect to matter and composition: for we are informed, that his delivery, though distinct, limpid, and impressive, was not remarkably distinguished by that magic charm of voice and action, which captivates the senses and imagination, and which, in the estimation of superficial hearers, constitutes the chief merit of a preacher. Dr. Blair, in the exercise of his professional duties, as far as they regarded the government of the church, was steadily attached to the cause of moderation. Difficult and unaccustomed to extemporary speaking, he declined interfering in ecclesiastical politics, and never would consent to become moderator of the general assembly of the church of Scotland; nevertheless, his opinion, which was always guided by sound judgment, uniformly commanded deference and respect. Whilst he was anxious to preserve the church from a servile corrupting dependence on the civil power, on the one hand; it was his wish, on the other, to prevent a greater invasion of democratic influence than he thought it compatible with good order, and the established constitution of the country. His reputation in public life was well sustained by the great respectability of his private character; and he was eminently distinguished throughout life by the prudence, purity, and dignified propriety of his conduct. With a mind free from envy, and yet not insensible to the estimation in which he himself was held; inflexibly upright, and yet condescending to his friends, and disposed to enjoy the pleasures of social intercourse; few men have passed through life more universally respected by those who knew him, more sincerely esteemed in the circle of his acquaintance, or more tenderly beloved by those who enjoyed the benefit of his private and domestic connection. His wife, to whom he was married in 1748, contributed for almost half a century to his felicity, and was taken from him a few years before his death; and his two children, a son and a daughter, died, the former in infancy, and the latter in her 21st year. His constitution was naturally delicate and feeble; but he enjoyed, upon the whole, a state of good health; and by habitual cheerfulness, temperance, and care, survived the usual term of human life. He retained his faculties to the last stage; and after a short illness of three days, expired on the 27th of December, 1800, with the composure and hope of a Christian pallor; and his funeral sermon was preached by Dr. Finlayson, who has annexed to the fifth volume of his Sermons a short ac-
count of the life and character of the author, from which the preceding article is chiefly compiled.

BLAIR, in Geography. See ATHOL.

BLAIREAU, in Zoology, the common French name of
of urusus melas, or badger. A variety of a white colour found in New York is also called in France Blancoue blanc.

BLAISEAU point du Cap de Bonne Esperance. Kolbe, and after him Abbé de la Caille, have described under this title a little quadruped found in the interior of Africa, which exhales a most insupportable odour. Whether it be of the badger kind in reality, or not, is uncertain. Somnini believes it to be of the civet kind, veverra Capensis; and on the contrary, Gmelin supposes it to be of the glutton kind, perhaps a variety of urusus gulo.

BLAIRIA in Botany. See VERBENA.

BLAISE, St., Order of, was founded in Armenia, about the commencement of the twelfth century. The habit of the knights of this order was a sky-blue; and on the breast thereof was embroidered their badge, being a cros of gold.

BLAISE. St. Blaize and the Virgin Mary was an order ecclesiastical and military. The particular time of its institution is not absolutely ascertained; but it is universally agreed that it took place soon after that of the Knights Templars. The badge of the order was a red cros, on the centre of which was a medallion with the image of St. Blaize enamelled thereon. When the knights assembled in chapter, or set out on any military expedition, they wore on their breast the same badge embroidered on a white habit.

BLAISE, in Geography, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Chaumont, 12 miles N.N.W. of Chaumont.—Allo, a river of France, which runs into the Marine near Larzicourt, in the department of the Marine.

BLAISE, or BLAS, Sr., a cape on the coast of West Florida, in the gulf of Mexico. It is a promontory, which separates the bay of Apalache on the east from that of St. Joseph, forming a kind of hered's crook. N. lat. 29° 40'. W. long. 86'.

BLAISOS, a province of France before the revolution, bounded on the east by Orleanois, on the south by Berry, on the west by Bouraine, and on the north by Vendomois and Daunois. The capital was Blais, which fee.

BLAISON, a town of France, in the department of the Mayne et Loire, and chief place of a canton, in the district of Angers; 8 miles S.E. of Angers.

BLAKE, Robert, in Biography, a celebrated English admiral, was a descendant of an ancient family of the name in the parish of Saxton and county of Somerset, and born at Bridgewater, in August, 1589. Having received the rudiments of grammar learning at a free school in his native town, he became a member of St. Alban's hall, Oxford, in 1615, and translated himself thence to Wadham college, where, in 1617, he took the degree of bachelor of arts. In 1619, he left a fellowship of Merton college, for which he was a candidate, on account of his low fortune; for Henry Savile, the warden, paying particular respect to personal connexions. Soon after the year 1623, in which he wrote a copy of verses on the death of Mr. Camden, he left the university, where he had been noticed for his early rising and application to study, and lived privately at Bridgewater. Adapting himself at an early period republican principles, and prejudiced against the ecclesiastical establishment, by the severity with which Dr. Laud, then bishop of Bath and Wells, enforced uniformity in his diocese, he inclined also to those opinions that were deemed puritanical. Accordingly the puritan party prevailed in procuring his return as a member for his native town, to the parliament of 1624, but for the Long Parliament he lost his election. Upon the breaking out of the war between the king and parliament, he declared for the latter, and entering into military service, was soon appointed captain of dragoons. In this capacity he exhibited proofs of his talents by an obdurate defence of Britot against the attack of prince Rupert, which he was at length obliged to surrender. In 1644 he was appointed governor of Taunton, which he had surprised and taken possession of for the parliament, and which he defended with a small but well-disciplined garrison, during a vigorous siege by the king's forces, till he obtained relief. For this service the parliament voted Blake, who was then colonel, a present of 500 pounds. After the murder of the king, which he is said to have disapproved, he cordially joined the republican party, and was reckoned, next to Cromwell, the ablest and most successful officer in the service of the parliament. Without affecting the character of a politician, he thought it his duty to serve his country to the utmost of his power, and to execute any measures that were adopted by the party to which he was attached, and by the exiling government for this purpose. Early in the year 1649, he was appointed, in conjunction with Col. Deane and Col. Popham, to the command of the fleet; and his first naval expedition was directed, in 1649, against prince Rupert and prince Maurice, to the harbour of King'slease in Ireland; where he blocked them up for some time, and whence he purveyed them to Lilloon, whither they had fled for the protection of the king of Portugal. War being declared on this account against the Portuguese, Blake annexed their trade, and took several rich prizes; and he afterwards proceeded, first to Carthagena and then to Malaguia, in pursuit of prince Rupert. At the latter place he burned and destroyed his whole fleet, two ships excepted; and in the beginning of the year 1652, he returned with his squadron to Plymouth, where he received the thanks of the parliament, and was appointed warden of the cinque ports. In the following year he was constituted one of the admirals and generals of the fleet, and employed in reducing the islands of Scilly and the island of Guernsey. Having accomplished this service, he was elected one of the council of state; and in 1653, promoted to the rank of vice admiral for nine months, in the prospect of a Dutch war. The States, jealous of the naval power of England, determined to reduce it by a very vigorous effort. With this view they dispatched Van Tromp with 45 sail of men of war into the Downs, who was met by Blake with a much inferior force of 23 ships, and, after a very severe action, which took place May 19th 1652, obliged to retire. After several skirmishes with the Dutch ships, and the capture of many prizes, during the progress of the winter, Van Tromp appeared again in the Downs, towards the close of the year, with 80 ships, for the purpose of renewing his attack upon Blake. The English admiral, whose force was much inferior, and who had the disadvantage of an unfavourable wind, disdained however to retreat, and engaged the enemy on the 29th of November. Notwithstanding every possible exertion, he lost six ships, and was compelled to retreat into the Thames with his shattered fleet; and Van Tromp was left in triumphant possession of the channel. Blake lost no time in repairing and recapturing his fleet; and in February 1653, he fell into pursuit of his antagonist. On the 18th day of the month the English admiral, with 80 ships of war, came up off Portland with Van Tromp, who had 70, and a fleet of 300 merchant ships under his convoy. The engagement was such as seldom occurs in the history of naval combats; it lasted three days, and on both sides equal valour was displayed; at length, however, after a running fight up the channel, the Dutch anchored safely in the sands of Calais, having lost 11 men of war, 30 merchant-ships, and 1500 men who fell in the action, whilst the English lost only one ship, but as many lives as the enemy. In this action Blake was wounded in the thigh.
At this time Cromwell disunited the parliament, and assumed the supreme power; nevertheless, Blake and his colleagues declared their fixed purpose to serve their country faithfully, and to guard it, by every effort in their power, against foreign injury and infult. "It is not for us," said Blake, "to mind flare affairs, but to keep foreigners from fooling us." Accordingly, when generals Monk and Deane, on the 23d day of June, had engaged Van Tromp with a fleet of 150 men of war, with dubious success, and with the loss of several men, among whom was Deane, Blake on the next day came up to their assistance with 18 fresh ships, and gained a victory so complete, that if the Dutch had not again faved themselves on the sands of Calais, their whole fleet must have been funk or taken. After this engagement, his health being much impaired, he took his seat in the new parliament, summoned by the protector Oliver, as a representative of his native town, and he was constituted one of the commissioners of the admiralty. Cromwell indeed treated him with great respect; but he was not unapprized of the admiral's strong inclination to a commonwealth; and he was therefore the more difpofed to send him, in November 1654, with a strong fleet into the Mediterranean, for the purpose of supporting the honours of the English flag, and procuring satisfaction for any injury which the British merchants had suffered. Whilst he lay in the road of Cadiz, he was treated with great respect by the Dutch and French; and even by the Algerines. However on the 10th of March in the following year he appeared before Algiers, and demanded satisfaction for the pirates committed on the English, and a release of all English captives. He then failed to Tunis on the same errand; but the day, confiding in the strength of the place, treated Blake's message with contempt; "Here," said he, "are our caftles of Goleta and Porto Ferino, do your word; do you think we fear your fleet?" Blake curing his whims, as he was accustomed to do when in a passion, consulted his offcers, and then bore into the bay with his heavy ships; demolished the caftles, burnt all the shipping in the haven of Tunis, and forced the haughty and obdurate day to an humble submission, and an advantageous peace. This daring action spread the same terror of his name through Africa and Asia, which had for a long time prevailed in Europe. He also saved the pratical flates of Tripoli into a peace with England, and the knights of Malta into a composition for the injuries which they had committed. Such was the effect of their exploits on the princes and flates of Italy, that most of them thought fit to pay their compliments to the protector; and the grand duke of Tuscany, and the free flate of Venice, in particular, sent magnificent embaffies for that purpofe. During the war with Spain, which was carried on with great spirit at this time, Blake, in pursuance of the protector's order, exerted himself in riving their maritime force in Europe, and Montague being joined with him, on account of his declining health, bloclked up for several months a Spanish squadron in the bay of Cadiz, and detached a part of their fleet to capture the Spanish plate fleet. Montague returned to England with the prizes; but Blake, whose constitution was broken by the droufy and fever, laid behind; and in April 1657 failed with 25 men of war in pursuit of another plate fleet which had put into Santa Cruz in the island of Teneriffe. Upon his arrival, he found that the governor had used every poifible precaution for the defence of the harbour; 15 Spanish ships were di- poled in a circular form within the bay, and strongly bar- ricated; and the entrance was guarded by a caftle and 7 forts, connected with one another, and furnished with large cannon. Blake pierced boldly into the bay, leaving some of his ships to fervice the batteries, while with the reft he at-

When the

Thou wert expected to be the..."
monies of France from the establishment of the monarchy. Accordingly he published "A Treatise on the Monies of France," Paris, 1658, 4to, with figures; reprinted at Amsterdam, 1692. To this is usually annexed his dissertation, published the preceding year, "On the coins of Charlemagne and his successors struck at Rome." He was chosen historical tutor to the royal children; but died before he entered on his office, at Versailles in 1698. Nouv. Dict. Hist.

BLANC, John Bernard Le, Abbe, historiographer of the public buildings, and member of the academies of La Crouze, and of the Arcadi at Rome, was born at Dijon in 1707, and engaging in the literary career, wrote a tragedy entitled "Abrégé," which, notwithstanding the harshness of its execution, was at first well received. At Paris, where he settled, he obtained friends and patrons; and in 1746 Maspertius was empowered by the king of Prussia to offer him a residence, as a man of letters, at his court, which he declined accepting. His "Letters on the English nation," in 3 vols, 12mo, 1758, are the most known of his works, and were occasioned by his visit to England. The style is heavy, and the thoughts trite and vulgar, to that they are now little read. He died in 1781. Nouv. Dict. Hist.

BLANC, Lewis Le, Sieur de Berthieu, a professor of divinity at Sedan in the 17th century. was born at Phebus-Mari, where his father was minister, and in the progress of his life, of which few particulars are record'd, was distinguished by his learning and virtue. He died in 1675, at the age of 60 years and 6 months. His "Théfé Théologique" were collected into one volume after his death, passed through several editions, and are highly worthy of an attentive perusal. The first edition was printed at Sedan in 1710, and two other editions were printed in England; the third in 1693. He was eminent for the persuasive power of his eloquence, and discovered an uncommon degree of penetration and legancy in his writings and negotiations. Anxious for a reconciliation and union between the Reformed and Romish churches, he passed in review many of the controversies that divided them, and seemed to prove, with the utmost perspicuity, that some of them were merely disputes about words, and that the other were of much less consequence than was generally imagined. This manner of stating the differences between the two churches drew upon him the indignation of those who regarded all attempts to soften and modify controverted doctrines as dangerous and detrimental to the cause of truth. Among these we may reckon Arnaud, Saurin, and Jureau. On the other hand, the acuteness and ductility with which he treated this delicate subject, made a considerable impression upon several persons, and procured him disciples who entertained his reconciling sentiments, but either entirely concealed them, or discovered them with caution, as they were known to be disproportionate to the greatest part of the members of both communions. Some of Le Blanc's sermons were printed at Sedan in 1675. Gen. Dict. Art. Berthieu. Mohr. Encycl. Hist. vol. v. p. 379.

BLANC, Lewis Le, a faithful surgeon and histomorph of Orleans, published in 1764, "A Dictionaire on the utility of Anatomy," and in 1756, "Nouvelle Methode d'opérer des Hémorragies," 8vo. Recommended dilating the ring with the finger, if practicable, which it usually is, he says, in recent cases; in those of long standing, with a pair of forceps invented for the purpose, instead of using the knife. This doctrine having been opposed by Ant. Louis, he was answered by Le Blanc in a dissertation on the subject, published in the fourth volume of the Memoirs of the Academy of Surgery. After reducing the intellese, by his method, no truth is wanted, as it invariably the case when the ring is opened by incision. The forceps are introduced into the ring, closed, and open themselves by the force of an elastic spring. He also wrote on the operation for the stone, on the method of extracting small portions of the plaques left in the uterus, and further observations on the cure of hernia. These papers were published in the 50th, 51st, and 52nd volumes of the Journal de Medicine. In 1753 he published "Precis d'operations de Chirurgie," 2 vols. Supposing the fulness of the above, with some additional observations. Haller. Bib. Anat. de Chirurn.

BLANC, mungn. Fr. q. d. good food, in Domest. Economy, is a preparation of diffolved ingalls, milk, fish, cucum on. &c., boiled into a thick confection, and furnished for the table with blanched almonds. It is cooling and strengthening.

BLANC, montca, in Ecclesiastical History, a name originally given to the Services, or servants of the Blessed Virgin, on account of their white cloaks; but since applied to divers sorts of religious, who have successively inhabited the house of the Services, and now to the Benedictresses at Paris, though inhabited in black.

BLANC, Mont. in Geography, a lofty mountain of Savoy, in the county of Tuscany, being part of the ancient "A pros Pennine." See Alps. This is reckoned the most elevated mountain of the ancient continent, its height above the level of the sea being, according to the calculation of M. de Luc, 1,724, English feet; or, according to the measurement of Mr George Shackburgh, 1,672 feet. This accurate observer informs us (Phil. Trans. vol. clxviii. p. 95), that the height of Velving, estimated by Soulure at 3100 feet, placed upon mount Atna, elevated, according to sir George, 1054 feet, would not be equal to the height of Mont Blanc, which he supposes to be the most elevated point of Europe, Asia, and Africa. This mountain, observed from the "Cul de Béne," and the vale of "Chamouny," is particularly distinguished from other mountains by a mantle of snow, which clothes its summit and sides, almost without the intervention of the lead rock, to break the glare of the "white" appearance, from which its name is derived. Those who have seen it from the valley of Aost observe, that on that side it does not appear to be covered with a mantle of snow, and that it exceeds the Schreckhorn in ruggedness and beauty. See Schreckhorn. "Those who are totally unacquainted with Alpine scenes," says Mr. Coxe, (Swift, vol. ii. p. 53) "may, perhaps, conceive a faint idea of this gigantic mountain, on being informed, that the mantle of snow, which appears to cover its top and sides, exceeds an altitude of 4000 feet perpendicular, and 9000 feet in an horizontal distance from the dome of Gout, to the summit; and that the height of the snow and ice, estimated from the source of the Avernon, at the bottom of the glacier of Montanver, to the summit of Mont Blanc, cannot be less than 12,000 perpendicular feet, or near three times as high as Snowdon in North Wales. The highest point of this mountain appears like a compressed hemisphere, and is called from its form "La Boffe du Drome," from that point it gradually sinks, presenting a kind of cone. The surface of the snow, in the midst of which is a small pyramid of ice; it then rises into a second hemisphere, called by some "Little Mont Blanc," but more properly, by others "Le Dôme du Milieu," or the "Middle Dôme;" thence it descends into another concave surface terminating in a point, indifferently styled by the natives "Aiguille de Gout," "Point de Gout," and "Dôme de Gout;" from this dome it ends abruptly, and leaves itself amid the mountains that bound the vale of Chamouny. Five glaciers extend into this vale, and are separated from one another by forests, corn-fields, and meadows; so that large tracts of ice are blended with cultivation, and perpetually succed each
of the most singular and striking vicissitude. These glaciers, which lie chiefly in the hollows of the mountains, and are some leagues in length, unite at the foot of Mont Blanc.

Of the various attempts that have been made to reach the summit of Mont Blanc, the first was that of M. Cauteret, and three guides of Chamoun, Michael Paccard, Victor Taffy, and Maria Coutet. On the 13th of July, 1776, they set off from the priory, about 11 in the evening; piled between the glaciers of Boifon and Taconn; and after spending above 14 hours in mounting rugged and dangerous scenes, and in crossing various valleys of ice, and large plains of snow, found themselves on the top next to Mont Blanc. But though at first sight it appeared to be scarcely a league distant, they soon perceived that it seemed, on account of the clearness of the air, the whiteness of the snow, and its great height, to be much nearer than it really was, and that it would require at least four hours more to reach the summit, even if it were practicable. As the day was far advanced, and the vapore near the summit of the mountain began to gather into clouds, they relinquished their enterprise; and returned to Chamoun, not without perilous danger in leaping over chasms of ice, after a journey of 22 hours, with such insurmountable obstacles, that they had approached nearer to Mont Blanc than any former adventurers. The summit which they had attained is, according to Sir George Shackburgh, more than 13,000 feet above the Mediterranean. After some subsequent but unsuccessful attempts, M. Bourrit, accompanied by four guides, departed from Bionairy, and began to a scale (as he terms it) the rampart of Mont Blanc, when he suddenly found himself exceedingly affected by the intense cold that he was unable to proceed. Maria Coutet, and Francis Gudet, two of his guides, proceeded to the dome of Gouté, which is about 34,200 feet in an horizontal direction from the summit; but the approach of night obliged them to return. On the 4th of September 1785, Maria Coutet and James Balmat advanced beyond the dome of Gouté, towards the summit, but a violent storm of hail and wind compelled them to abandon the enterprise. On the 13th of this month M. Sauriire and Bourrit, attended by twelve guides, well provided with barometers, thermometers, and other necessary instruments, left Bionairy, and arrived at a hut, which was constructed by their orders, at ’Pierre Rondey,’ 3,258 feet above the level of the sea; and on the next morning they pursued their journey to the dome of Gouté; but a heavy fall of snow prevented their progress. Sauriire says, that the mercury in the barometer sunk 18 inches, and that he reached an elevation of 3,256 English feet. In July 1786, James Balmat, one of his guides of Chamouny, being separated from his companions, who failed in another attempt, passed the night on a spot above the ‘Dome of Gouté,’ elevated more than 13,000 feet above the level of the sea. On his return, however, to Chamouny, he was affected with a very severe indisposition, the effect of extreme fatigue, and of the intense cold; but being attended by Dr. Paccard, a physician of the place, he recovered, as an expression of gratitude for his attendance, to conduct him to the summit of Mont Blanc. Accordingly, on the 7th of August, these two daring adventurers fell forth from Chamouny, and reached the mountain of ‘La Côte,’ which overhangs the upper part of the glacier of Bollon. Here they passed the night, and at three on the next morning they pursued their route over the ice, ascended the ‘Dôme de Gouté,’ passed under the ‘Middle Dôme,’ and turning to the east, at the left pyramid of rock, continued along the ridge which is seen from Geneva, and which lies on the left of the summit. Here cold and fatigue discouraged Dr. Paccard; but being animated by his companion, he determined to advance, struggling with a very violent and piercing wind, till at length they attained the summit which no one had visited before. Here they remained about half an hour, when they found the cold so intense, that their provisions were frozen in their pockets, the neck congealed in their inmost, and the mercury in Fahrenheit’s thermometers sunk to 109°. They spent 15 hours in ascendant, and found great difficulty in their descent, their flight being much dirbulated by the reflection of the snow. On their return to Chamouny at night in the morning, their faces were excrated, their lips much divided, and Dr. Paccard was almost blind. These adventurers prepared the way for the observations and discoveries of future naturalists, and particularly of Sauriire, whose indefatigable zeal would not allow him to rest, till he had reached the top of Mont Blanc, and made those experiments, which have served in a very considerable degree to elucidate the theory of the atmosphere.

Having arrived at Chamouny, a village at the base of the mountain, M. de Sauriire was detained by continual rains for four weeks; after which, he set out on the 18th of August, 1787, accompanied by a servant and 18 guides, who carried the philosophical instruments and the tents, and other apparatus necessary for the intended experiments. Although the distance from the priory of Chamouny to the summit of the mountain is little more than two leagues, or about 64 miles, in a straight line, it requires nearly 18 hours to gain the summit, on account of the difficulties of the road, as well as the necessary circuits. In the evening, they arrived at a hut constructed for them on the top of the mountain of ‘La Côte,’ about a mile perpendicularly above the village. Their second day’s journey was attended with many difficulties, owing to the wide, deep, and irregular chasms intersecting the inner-valley on the side of the hill, which can only be crossed by means of bridges naturally formed of snow, and often very slender; extended, as it were, over an abyss. In this perilous valley, they were obliged to pursue a winding road, so that they were three hours in crossing it, though in a straight line its breadth is not above three-quarters of a mile. At length, however, they reached the chain of rocks that border on the perpetual snows which cover Mont Blanc, and then mounted, in a perpendicular direction, to a valley filled with snow, and running from north to south, to the foot of the highest pinnacle. The surface of the snow in this valley has numerous fissures; penetrating to a great depth, and considerably broad; presenting to view, by their broken sides, the successive horizontal layers of snow, which are annually formed. In this situation the guides wished to pass the night; but Sauriire, observing that the loftiest of these rocks is at least 1,400 yards perpendicularly lower than the summit of the mountain, wished to proceed, and at length prevailed with the guides to accompany him. At four in the afternoon, they arrived at the second of the three plains of snow, which they had to pass; but as the day was far advanced, and they were apprehensive of exposing themselves to the ‘Avalanches,’ which are frequently tumbling from the summit of the mountain, they determined to proceed no farther. Here they encamped at the height of 3,912 feet above the priory of Chamouny, or 13,562 feet above the level of the sea. For this purpose, they dug a deep hole in the snow, of sufficient width to contain the whole company, and covered its top with the tent-cloth. In this situation the barometer had fallen to 17 inches, 10 lines, and they all felt the effects of the rarefied air. Seven or eight hours’ walk, which they had just performed, had not in the least affected these robust and hardy men; but they had scarcely raised five or six shovels of snow, in forming their intended habitation, before they were under a necessity of
of distilling from his lungs, and of taking breath at very short
intervals. M. de Saussure himself, though accustomed to
the atmosphere of mountains, and finding himself, as he says,
much better in it than in the air of plains, now felt exhausted
with fatigue, only by observing his meteorological instru-
ments. This uncomfortable sensation was heightened by an
acute thirst, and water could not be procured, except by
melting snow; for the water which they had seen during
their ascent would by this time be congealed; and the
small flint-dish which they had taken with them, was
slowly supplied 20 people languishing with thirst. From
the middle of this snowy plain, not far below the top of Mont
Blanc, the snow exhibited the most dazzling brightness, and
formed a singular contrast with the sky, which, in these ele-
vated regions, appears almost black. No living creature
was seen here, nor the least trace of vegetation. The moon
shone with the brightest splendour in the middle of a sky as
black as ebony. Jupiter, rays like the sun, arose from behind
the mountain in the east; and the light of these luminaries
was reflected from the white plain, or rather basin, in which
they were situated and by their dazzling light, eclipsed
every star, except those of the first and second magnitude.
While they were composing themselves to sleep within their
tent, incommoded by heat and humid air, they were soon
alarmed by the noise of an immense mass of snow, or "Ava-
lanche," which fell from the top of the mountain, and
covered part of the flaps over which they were to climb the
next day. The next morning they departed at seven for the
third and left plain; turning to the left in their way to the
highest rock, which is on the east side of the summit; they
found the ascent in some places so steep, that the guides
were obliged to hew out their footpaths with hatchets.
Their progress was slow, and it took them two hours to
climb a hill about 1,700 feet high. Having arrived at this
rock they turned to the west, and climbed the left ascent,
about 600 feet high, inclining about 25 or 30 degrees.
Here the air was so rarefied, that Saussure could not take
15 or 16 steps without stopping for breath; and at in-
tervals he found himself faint, so that he was under the necessity
of sitting down, until, with the return of respiration, his
strength was revived. On his arrival to the summit, at
11 o'clock, a slight vapour, suspended in the inferior regions
of the air, prevented him from beholding the lower and
more distant objects; such as the plains of France and Lomb-
ardy; but he had the less reason for regretting this loss,
as he was agreeably surprized by a most distinct and compre-
ssive view of all those elevated summits, with the organi-
zation of which he had so long desired to be acquainted.
He thought himself dreaming, when he saw beneath his feet
many majestic peaks, especially "Aiguillette," "Le Midi," "l'Argenterie,"
and "Le Géant," the lakes of which he had found so difficult to ascend.
He feized in his mind their mutual proportion and connection, their form and
structure; and a single glance removed doubts, and afforded
information much more satisfactorily, than whole years of
previous study. During this time, his guides pitched his
tent, and made preparations for his experiment; but in
attempts to dispose his instruments for this purpose, he
was obliged, almost at every interval, to desist, and wholly to
occupy himself about the means of respiration. Considering
that the barometer stood at only 97.5 inches, 1 line, or 13.145
inches English, and that the air, consequently, possessed
little more than half the density of that on the plains, it is
manifest that the deficiency was to be supplied by more fre-
cquent inspirations. This frequency, of course, accelerated
the circulation of the blood, more especially as the arteries,
on the surface of the body, were no longer actuated from
without by the pressure which they usually experience.

When M. de Saussure remained perfectly quiet, he only felt
rather uncomfortable, with a slight disposition to lie sick;
but in any exertion, or when he fixed his attention for a few
successive moments, and particularly when, by looking, he
comprehended his chief, the deficiency occurred of resuming
himself, and resuming for two or three minutes. His guides also
experienced similar sensations. They felt no appetite, and had
no inclination to take wine or brandy, having found that
strong liquors increased the above indispositions; without
doubt, by quickening the circulation of the blood. Nothing
but fresh water was consumed and relished, and yet both time
and exertion were required to light the fire, without which it
was impossible to obtain any. In this situation Saussure and
his companions continued 48 hours, and in their defect
they found fewer difficulties than they expected. They ar-
erived the next morning at the valley of Chamouny, without
the least accident; and as they had taken the precaution to
wear veils of cape, their faces were not excoriated, nor their
fright debilitated.

M. de Saussure has given an ample detail of his observa-
tions on the summit of Mont Blanc, in the 4th volume of his
"Voyages dans les Alpes," and a translation of this account
by professor Martyn, of Cambridge, forms an appendix to his
sketch of a tour through Switzerland. We shall here select
a few particulars. We learn from this narrative, that the sum-
mit of the mountain is a ridge, nearly horizontal, lying east
and west; the ridge at each extremity extending from 20 to
30 degrees, the height being between 15 and 20, and the north about
43 or 52. This ridge is so narrow as scarcely to allow two
people to walk abreast, especially at the west end, where it
resembles the roof of a house; it is wholly covered with snow;
but there is any bare rock to be seen within 150 yards of the top.
The surface of the tuor is rocky, and in some places covered
with an icy crust, and when the snow is deep, and without
colour. The highest rocks are all granite; those on the east
side are mixed with flint, those on the south and west contain
a large quantity of schist, and a little limestone. Some of them, especially those on the east, which
are about 150 yards below the summit, form to have been
lately shivered with lightning. M. de Saussure saw no animal
on the mountain, except two flowers, a grey phanaema.
and a "Myrtillus," which he supposes must have been driven there by the wind. At the elevation of 11,122 feet above
the sea, he observed the "Silene Acaulis," or moss campion,
in flower; and still higher, on the most elevated rocks, the
"Lichen Sulphureus," and "Lichen Rupicola" of Hoff-
man. He has given us the height of the barometer on the
summit of the mountain, viz. Aug. 3, at noon, 16 inches o line,
and 144 of a line, French measure, i. e. 16.181 English; and
Reaumur's thermometer was 2.5 below the freezing point,
or 27 of Fahrenheit. M. Sennacher, at the same time,
observed, at Geneva, the barometer 27 inches 2 193 lines, or
29.050 English inches, and the thermometer 32.6 above freezing,
or 82 of Fahrenheit. From these data he makes the
height of Mont Blanc 2218 toises, or 14,188 English
feet, according to M. de Luc's rule, and 2273 toises, or
13,553 English feet, according to M. Trembley. To
these heights, 15 toises, or 83 feet, the height of M. Sennac-
her's room above the lake of Geneva, must be added, to
give the height of the mountain above the level of the lake
14,253 feet, according to M. de Luc, and 14,063 feet,
according to M. Trembley. Sir George Shannon made the
height of Mont Blanc, by trigonometrical measure-
ment, 13,129 feet above the lake, which is almost the mean
between the other two. The result of the observations
made at Chamouny, contemporaneous with those on
Mont Blanc, agrees still more nearly with sir George's measur-
ment. The general mean result makes the summit of Mont
Blanc 327
BLA

Blanc 2450 toises, or 15,673 English feet, or nearly three English miles above the level of the sea. By M. de Saussure's experiments with the hygrometer, the air on the top of Mont Blanc contained six times less humidity than that of Geneva, and to the extreme dryness of it he attributes the burning wrath which he and his companions experienced. But the result of his experiments seems very different from the system of meteorology published by M. de Luz. See Hygrometer. It requires half an hour to boil water on the top of this mountain; whereas 15 or 16 minutes are sufficient at Geneva, and 14 or 15 by the sea-side. Water boiled at 68.503 degrees of a thermometer, which refers to 80 with the barometer 27 French inches high. By experiments with the electrometer, M. de Saussure found, that the electricity of the air on the summit of the mountain was positive. The wind on the summit was north, and very piercing; but southward of the ridge the temperature of the air was agreeable. The experiments with lime-water, and with the caustic alkali, showed that the air was mixed with atmospheric acid, or fixed air.

The difficulty of respiration experienced by M. de Saussure and his companions, has been ascribed by some to fatigue, and to the rarefaction of the air; but his observations prove, that the latter was the cause both of the difficulty of breathing and the quickness of the pulse. This, indeed, was so considerable, that the pulse of one of the guides, after continuing four hours on the summit, was 98, of the servant 112, and of M. de Saussure himself 160 in a minute; whereas at Chamonix they were 49, 60, and 72 respectively. M. de Saussure's observations confute an opinion, which is very common, with respect to the change of the shades of smell and taste supposed to take place on high mountains. He tried the experiment on different mountains, and both the taste and smell of bread, wine, meat, and fruit, appeared to him, and to his attendants not at all different. As to sounds becoming weaker, this circumstance is not to be attributed to any impaired state of the organ of hearing, but to the rarefied air, which both retards and vibrates less. Defides, in an insalubrious summit there are no echoes or solid objects to repel the sound. These concurring causes rendered the sounds on the top of Mont Blanc remarkably feeble; the report of a discharged pistol being equal in strength only to that of a small Chinefe cracker let off in a room.

Soon after M. de Saussure's expedition, Mr. Beaufoy, an English gentleman, succeeded in an attempt to ascend Mont Blanc; but it was attended with peculiar difficulty, arising from the enlargement of the chasms in the ice. An account of this enterprise was communicated to the Royal Society in 1787.

BLANC, Mont, given denomination to a department formed of Savoy. It is bounded on the north by the departments of Leman and of Aix; on the south by Piedmont; on the east by the departments of Upper Alps and of Iere; and on the west by those of Iere and of Aix. Its superficial is about 1,753,760 square acres, or 430,472 hectares; and its population about 283,106 individuals. It is divided into four communal districts; viz. Chambery, its capital, Annecy, Moutiers, and St. Jean de Maurienne.

BLANC-en-Berry, Le, a town of France, and principal place of a district, in the department of the Indre, containing 3570 inhabitants. The population of the canton amounts to 10,622; and its territory comprehends 3874 kilometres and 10 communes; its leagues W. of Argenton.

BLANC-Comfor Herald, created by patent on the revival of the most honourable military order of the Bath, 1715, "to attend the full and principal companion of the order for the time being." He enjoys all rights, privileges, and immunities as any other herald; and his office is annexed, united, and perpetually consolidated with the office of genealogist of the said order. See Genealogist of the Bath.

BLANCA, in Geography, a small island in the West Indies, north of Margarita, in the province of Anduasia, low and uninhabited; having labyrinths of long grass, plenty of guanas, and some trees of lignum vitae; but chiefly remarkable for its turtle fishery. N. lat. 17° 21' W. long. 64° 10'.

BLANC, or Blanche, an island in the gulf of Mexico, near the coast. N. lat. 25°. W. long. 62° 14'.—Also, a river in the province of Casape, in the Audience of Mexico, in New Spain. Its water, though clear, is said to have a petrifying quality.

BLANCARD, Stephen, in Biography, was son of Nicholas Biancard of Leyden, by whom he was initiated into the knowledge of philosophy and medicine. At a proper age he went to Breeds, and thence to Franeker, where he took his degree of doctor in medicine about the year 1678. We soon after find him settled at Amsterdam, where he dedicated his time to the practice of his art. But principally to writing or comiing a great variety of anatomical and medical works, of which the most valuable, Haller says, is his "Anatomia practica rationalis," which was first published 1688, 12mo. But he has, in this work, introduced many observations taken from other writers, without acknowledging it. The cases here described are 200 in number, and, in general, curious and deserving notice. Geolitic, however, sect not only accurses him of plagiarizm, and of mutilating and spoiling the observations taken from other anatomists, but he blames him for publishing so many of his works in the Dutch, his native language, which cannot fail, in the end, he says, of being highly injurious to the profession of medicine, by enabling persons to practice who have not previously received a liberal education. This is, however, now done pretty generally all over Europe, and especially at the seat in this country, where there are so many persons practising in every branch of medicine who are incapable of reading any other language than their own, the laws here authorising any persons who may chuse it to practice medicine, without examination, excepting physicians and surgeons residing in the neighborhood of London, or of the two universities. We shall only mention one other of this writer's multifarious productions, his "Lexicon Medicum," containing explanations of all the terms used in medicine, surgery, and anatomy, first published in 1679, 8vo. This has passed through numerous editions, and lastly in 1777, by the care of Jac. Frd. Lenfhan, is increased to nearly treble its original bulk, making two large volumes. 8vo.

BLANCARDS, a name given to certain linen cloths thus called, because the thread used to weave them has been half-blanchetl or bleached before it was used. They are manufactured in Normandy, particularly in the places which are in the diocese, or under the jurisdiction of Pont-Audemer, Bernay, and Lisieux.

BLANCAT, St. in Geography, a town of France, in the department of the Upper Garonne; 4 leagues N.W. of St. Gaudens.

BLANCH, a cape on the French coast, N. W. of Calais, almost opposite to Dover, on the English coast.

BLANCH, or White Island, one of the large islands on the coast of France, lying along the shore of the projecting coast to the N. E. of Mauritius.

BLANCH, born, or BLANC farm, in Low, a white farm, that is, where the rent was to be paid in silver, not in cattle.
In ancient times, the crown-rents were many times referred to be paid in "libris albis" called blanche vernus; in which case the buyer was held denarius firmum; viz. his base money or coin, worse than standard, was melted down in the exchequer, and reduced to the fineness of standard silver; or instead thereof he paid to the king rate in the pound, by way of addition. In Scotland, this kind of small payment is called "blanch holding" or "redius albis firmus."

BLANCH und Lyon Pursuivant of Arms. This officer took his title from the arms and supporters of the Mowbray's, dukes of Norfolk (being rubies, a lion rampant, pearl) Thomas Howard, duke of Norfolk, instituted the office of blanche Lyon pursuivant 29 Hen. VIII. and he attended at the funeral of queen Jane. Blanch-lyon was also a name to an officer of the crown in the reign of Edward IV.

BLANCH, The, is the hill of Blaunt's tail the accomplished 1724. Lyons too and its relative of 1603 in the reign of James II. Lyons is also a name to an officer of the crown in the reign of Edward IV.

BLANCHARD, William, in Biography, an advocate in the parliament of Paris, was admitted to the bar in 1574, and much employed. Notwithstanding his professional labours he found leisure for literary researches, and in 1587 published a chronological table of the ordinances of the French kings of the third race, which was republished, with improvements, under the title of "A Chronological Compilation, containing a collection of the ordinances, edicts, declarations, and letters patents of the kings of France, relative to public justice, police, and the finances, from the year 537 to the present time," 2 vols. fol. 1715. The work abounds with accurate researches, and is a supplement to it being prepared by the author, when he died in 1724, Moreri.

BLANCHARD, Jacques or James, a painter of history and portrait, was born at Paris in 1629, and having been initiated in the first principles of painting in his own country, he travelled into Italy, where he studied for some time at Rome and Venice, and acquired, from particular attention to the works of Titian and of the Venetian school, distinguished excellence in the art of colouring, so as to have obtained the flattering appellation of the "French Titian." He was employed a considerable time at Turin by the dukes of Savoy, and afterwards painted several pieces at Lyons. Upon his return to Paris he was much engaged, and by his defeat of the Holy Spirit, and a St. Andrew's knelling, he had gained high reputation. Colouring was his peculiar excellence, and he was dastard worthy for his judicious management of lights and shades. His principal works, besides those already mentioned, are a galery at the hotel de Bourbon, of subjects from the heathen mythology, and the bacchaces in the salon of M. Mme. with some pieces at Versailles and Trianon. To Blanchard is ascribed the good taste for colouring which obtained in France. He is said to have etched several plates from his own compositions. He died at Paris in 1658, and left a son Gabriel, who was also a painter of eminence. D'Argenville. Strutt. Pitkington.

BLANCHE, in Botany. Somnunia describes a kind of fern, or brachycolea de mer, under this name, in his additions to Buffon's History of Birds. The plume and entirely white with the key and bill black. It inhabits the Cape of Good Hope, and may be placed in the Indian and southern climates. Latham calls this bird firna alba. BLANCHE-Carte. See Carte.

BLANCHE-Coffin. BLANCHE-Coffin, in Ornithology, is the corvus cyanus of Gmelin and Latham, in Buffon's History of Birds. It is likewise called in the same work gary de Cayenne, and by Latham the Cayenne Jay.

BLANCHE-RAU, the name of an artist, in Buffon's History of Birds to the liulaen furra molibaris, a native of Falkland island.

BLANCHE, Fr. for a mimin, in Muse, or a white note with a tail to it. See Musical Characters, and Time-Table.

BLANCHER, a name given to mechanics employed in blanching, i.e., the art or manner of bleaching or whitening.

BLANCHET, Thomas, in Biography, a painter of history, perspective, and portrait, was born at Paris in 1617, and first manifested a genius for sculpture; but on account of the weakness of his constitution he was advised to direct his attention to painting. Accordingly, having practiced for some time at Paris, he travelled for further improvement into Italy. By the counsel and assistance of Poussin and Andrea Sacchi, he applied to history painting, and on his return to Paris, he painted several pieces, particularly a picture at Notre Dame, much admired. At Lyons, where he afterwards settled, he became director of an academic school. During his absence from Paris, he was admitted, in 1670, into the academy of painting. Blanchet designed well, and understood the principles of perspective and architecture. His composition was rich, and his colouring natural; and though he was not always correct, his deficiency in this respect is imputed more to the fire of his genius and the rapidity of his execution, than to want of skill. His master-piece was the ceiling of the great hall in the hotel de ville at Lyons, which was unfortunately consumed by fire; and the accident is said to have affected him so deeply, as nearly to have cost him his life. The magnificence of Lyons rewarded him with a pension, and with apartments in the hotel de ville. His character was amiable, and his conversation lively and interesting, so that his company was much sought and valued. He died at Lyons in 1689. Some few of his pieces have been engraved. D'Argenville. Pitkington.

BLANCHET, in Ichthyology, the familiar French name of a sort of salmon that inhabits the American seas; salmo fenes of Linnaeus.

BLANCHET, in Zoology, the name of an amphibian known among the French naturalists of the present day by this name. The species is described as being of a white colour, without any spots; the body as consisting of 250 ramifications, and the tail of 16: on the head are 30, and 18 very small tubercles. The length is 18 inches, exclusive of the tail, which measures an inch and an half. This is a native of South America, where it feeds on ants and other insects.—Boie, from whom the above detail is copied, we are convinced, can mean to other than the amphibia alba of Linnaeus, when he describes this species. The Limnan character flatters the number of rings on the body of this kind at 225, in which particular alone the two descriptions seem to be at variance; and the inequity of that character is too well known to justify the opinion of their being distinct, for that reason only.

BLANCHING, in Gardening, is the art of rendering the leaves and seeds of various sorts of plants, as endive (cichorium), celery (apium), &c. white, tender, and succulent. It consists in producing a kind of vegetable delicacy or diliere, by depriving them of the stimulant effects or influence of light, and is accomplished either by carding them well up, or completely covering them, when perfectly dry, by boards, tiles, or other similar means, as will be more fully
fully explained in treating of the different plants that require this sort of management.

BLANCHING also denotes the operation of covering iron plates with a thin coat or crust of tin. See LATTEN.

BLANCHING of copper for sale, in imitation of silver; or mixing blanched copper with silver, or expelling the same to sale; or by malleable composition or mixture of metals, or minerals heavier than silver, and which looks, and touches, and wears like gold, but is manifestly worse than standard, is made feomy; 8 and 9 W. III. 

BLANCHING of wax. See Wax.

BLANCHING, in Geology, the operation of preparing the pieces before striking, to give them the requisite lustre and brightness.

The blanching, as now practiced, is performed by melting or heating the pieces in a kind of pan or vessel, with a woodfire, in manner of a reverberatory furnace, so that the flame passes over the vessel. The pieces being sufficiently heated, and cooled again, are put successively into two copper pans, wherein are aqua fortis, common salt, and tartar of Montpellier; when they have been well drained of this first water in a copper sieve, they throw lead and frith water over them; and when dry, they are all well rubbed.

The ancient method of blanching was, by putting the pieces, after heating, in a large vessel of common water; and some ounces of aqua fortis, but in different proportions for gold and silver. — The method is now diluted; partly by reason of its expensiveness, and partly because it diminishes the weight of the metal.

BLANC-JAUNE, in Ichthyology. Saimo niloticus, of Linnaeus, a fish of the salmon tribe found in the Nile, is called blanc-janine by some French authors.

BLANCAMERE, in Geography, a town of Brahaut, 2 miles S. of Breda.

BLANCKENBERG, Blankenburg, or Blakenberg, a town of Germany, in the circle of Upper Saxony, and county of Schwartzburg-Rudolstadt, seated on the Rine, 4 miles S.W. of Rudolstadt.

BLANCKENZ, in Zoology. Under this name the Linnaean Simia petrauris is described, both in Buffon's Natural History, by M. Allamand, and Sonminii, and in the history of Apes, published recently in Paris by Audebert. The prevailing colour of this animal is a very dark olive; the vige is black, with the exception of the nose, a remarkable snowy white spot of a triangular form being situated on the latter, which gives the creature a very singular appearance. The appellation of blanc-zee or Guenon blanc-zee, is very well applied, and might be rendered into English with much propriety, the white-nose monkey, if that name had not been previously assigned to another species by Mr. Pennant and Dr. Shaw. In the Zoology of the latter writer we are informed, that the distinguishing character of this white-nose monkey (Simia niloticus, Lin.) is the tip of the nose, which is milk-white, while the face itself is black. Dr. Shaw observes, however, shortly after, that the white-nose, in this species, is not absolutely peculiar, but is found in another; alluding, as we imagine, to his visting monkey, which answers to that description. The latter mentioned animal he considers as the Simia petrauris of Linnaeus, and blanc-zee of Allamand's edition of Buffon's quadrupeds, as Gmelin states them; and so far the correctness of the French naturalists appears in favour of his opinion. But, perhaps, it will admit of some doubt how far we may be authorized in believing still further with Dr. Shaw, that the Guenon blanc-zee of Allamand, and Sonminii, in Buffon's Natural History, and Guenon à nez blanc premier of the Supplement of that work, are of the same species. Dr. Shaw thinks the first of these must be the female, and the other

The male. Virek, and likewise Audebert, are persuaded that they are certainly distinct species. Guenon blanc-zee, they consider as the Linnaean; Simia petrauris, and Guenon à nez blanc premier, as Simia niloticus of the same author.

BLANCO, in Geography, the name of a cape of Africa, on the north coast of the kingdom of Tunis, called the "White Promontory," or, with the same meaning by the inhabitants, "Ras-el-abiad;" and supposed to be the "Promontorium candidum" of Pliny; and the "Promontorium pulchrum" of Liuy, where Scipio landed in his first African expedition. N. lat. 37° 5' E. long. 10° 18'. — Also, a small point to S. E. of cape Corfica, in the island of Corsica. — Also, a cape on the western coast of Africa, in Negro-land; first discovered by the Portuguese in the year 1441. N. lat. 25° 55' 30'. W. long. 17° 10'. high water 9' 4'. — Also, a cape on the western coast of the territory of Tichelin in Albania, opposite to the southern point of the island of Soio. N. lat. 35° 20'. E. long. 25° 3'. — Also, a cape of South America, on the coast of Brazil, between cape Roque on the north, and cape St. Augustine on the south, S. lat. 6° 30'. W. long. 35° 33'. — Also, a cape of South America, on the eastern coast of Patagonia, north of port D. feudal. S. lat. 47° 20'. W. long. 69° 42'. — Also, the north-western point of the bay of Saimas, on the coast of Nicaragua. N. lat. 12° 30'. W. long. 85° 48'. — Also, a cape on the north-west coast of America in New Albion, southward of the mouth of the river called the river of the west," between cape Gregory and point St. George, and at a further distance between cape Finchley and Mendocino. N. lat. 42° 30'. W. long. 128° 20'. — Also, a promontory of Peru, in South America, on the coast of the South Sea, 200 miles S. W. of Guayaquil. S. lat. 3° 55'. W. long. 83°.
In Camden's time it was mostly burnt by accident, but was soon rebuilt in an improved manner. The years 1678, 1712, and 1731 are recorded as peculiar calamities to this town, and in the latter year nearly the whole of it was destroyed. The church, town-hall, alms-house, free-school, and all the houses, but forty, were consumed. Many lives were lost, and the distressing calamity was greatly augmented by the small-pox, which raged in above sixty families. The computed damage was valued at 100,000l. but the chief terror, and injury that prevailed at the time, and which a few years destroyed the direful catastrophe, far exceeded all calculation, and dazed the powers of verbal description. The town has since been rebuilt, and its appearance much improved by some respectable houses, a new church, town-hall, &c. This is a neat building composed with Portland stone, and constructed on columns of the Doric order. Within the building is a pump which was erected by John Blandford, who having been a considerable sufferer by the fire, had this pump constructed to supply the town with water, and thereby to prevent another similar disaster. The new church, built in the Grecian style of architecture, consists of a body, a chancelf, a double aisle, and a tower. Its interior is very neatly ornamented, and contains several handsome marble monuments.

The charitable donations to Blandford are numerous and valuable, and are appropriated to endow an almshouse, to apprentice and clothe poor boys, to erect and support a charity school, two free-schools, and for other benevolent purposes. Blandford is 104 miles W.S.W. from London, and contains 458 houses, with 2566 inhabitants; at the east end of the town are the remains of a handsome old building, called "Dorothy court," which has been pillaged by many noble and distinguished personages.

Blandford is the birth-place of many celebrated characters: among whom the following are the most distinguished:—George Ryther, who was warden of New College, Oxford, in 1590, and vice-chancellor, in 1601; Brutus Ryther, author of the Mercury Rusticus, a singular book, recording many of the events of the civil wars. He also assisted in publishing the Polyglott Bible, was dean of Chichester, and Windham, and died at the latter place in 1677, aged 81 years; William Wake, archbishop of Canterbury, &c. was born here in the year 1617, and died at Lambeth in 1650; Thomas Croft, the translator of Lucertius, and other ancient chivalrous authors, was born here in 1659; Christopher Pitt, another translator, dates his birth at Blandford, where he was buried in 1748.

About one mile south of Blandford-forum is Blandford St. Mary, a village noted in the annals of literature as the birth-place of Browne White, the celebrated antiquary and topographer (see Willis). At the distance of one mile west of this town is Blandford-houfe, the elegant and commodious mansion of Edward Berkeley Portman, esq. This house was erected from the designs of James Wyatt, who has displayed much judgment and taste in the disposition of the apartments, the arrangement of the offices, and in the two principal façades. The river Stour winding in a broad sheet through the grounds, with the plantations and magnificent park, combine to render this a charming and delightful residence. Hutchins's History of Dorsetshire, second edition, vol. 1796.

Blandford, a township of America, in Lunenburg county in Mahon bay, Nova Scotia, settled by a few families. —Also, a township in Hampshire county, Massachusetts, west of Connecticut river; about 25 miles S.W. of Northampton, and 116 W. of Boston; containing 1775 inhabitants. —Also, a town in Prince George county, Virginia, about 4 miles N.E. from Petersburg, and within its jurisdiction. It contains 200 houses, and 1200 inhabitants, and is pleasantly situated on a plain, on the eastern branch of Appomattox river. Here are many large houses, and three tobacco warehouses, which receive annually 600,000 lbs. of tobacco. It is a thriving place; and as the muskets in variety are drafted, the air of this town, and that of Petersburg, are much indulged.

Blandina, in Lusonia, one of the Frisian tribes of Parthia, in the 1st insurrection; the wings of which are westwards, north, east, and south.

Blandina, in the Roman army, the daughter of two, who was slain in 187.

Blandford, a town in the county of Dorsetshire, England, containing 1678 inhabitants. —Also, a town in Prince George county, Virginia, about 4 miles N.E. from Petersburg, and within its jurisdiction. It contains 200 houses, and 1200 inhabitants, and is pleasantly situated on a plain, on the eastern branch of Appomattox river. Here are many large houses, and three tobacco warehouses, which receive annually 600,000 lbs. of tobacco. It is a thriving place; and as the muskets in variety are drafted, the air of this town, and that of Petersburg, are much indulged.

BLA

BLANKENHEIM, a small town in Germany, and capital of a county of the same name, in the circle of Westphalia, and archbishopric of Treves. The prince, resident here, pays 64 florins a month, and 72 rix dollars, and 5$¼ krenzter to the imperial chamber; 36 miles N.N.E. of Treves. In the French arrangement it is the principal place of a canton in the district of Plum, and department of Sarre. The population of the place includes 500 persons, and the canton 3936. Its territory comprehends 19 communes.

BLANKENSEE, a lake of Germany in the circle of Upper Saxony, and middle mark of Brandenburg, 6 miles E. of Belitz.

BLANKENSTEIN, a town of Germany in a prefecture of the same name, in the circle of Westphalia, and county of Mark, seated on an eminence near the Rhine, 19 miles E.N.E. of Dusseldorf.

BLANKET, in Commerce, a warm woollen fort of stuff, light and loose woven; chiefly used in bedding. The manufacture of blankets is principally confined to Witney in Oxfordshire, where it is advanced to that height, that no other place comes near it. Some attribute a great part of the excellence of the Witney blankets to the abbatitive nitrous water of the river Windrush, wherefor they are secured; others think they rather owe it to a peculiar way of loofe spinning, which the people have about that place. Be this as it will, the place has engrossed almost the whole trade of the nation for this commodity; insomuch that the wool fit for it centres here, from the farthermost parts of the kingdom. Plott. Hist. Ox. chap. ix. § 163.

Blankets are made of felt wool, i.e. wool from off fleeces, which they divide into several forts.

Of the head wool, and bay wool, they make blankets of twelve, eleven, and ten quarters broad; of the ordinary and middle fort, blankets of eight and seven quarters broad; of the bell tail wool, blankets of six quarters broad, commonly called cuts, serving for flaxmen's hammocks. See HYKES.

Blanket, tossing in a, a ludicrous kind of punishment, of which we find mention in the ancients under the denomination fagatia. Martial describes it graphically enough. "Ibis ab excusis, misus ad altra. fago."

A writer less represents it as one of Otho's imperial delights. But this is turning the tables; that emperor's disorder, as related by Suetonius, was not to be the subject, but the agent in the affair; it being his practice to ill out in dark nights, and where he met with a helpless or drunken man, to give him the discipline of the blanket.

BLANKOF, John Teunisz, in Biography, a Flemish painter, was born at Alkmaar in 1628. After having spent some years in receiving instruction from Arent Terlingen, Peter Scheyenburg, and Caesar van Everdingen, he went to Rome, where he diligently copied the works of the best masters, and was admitted into the society of Flemish painters, called Bentvogels, by whom he was distinguished by the appellation of Jan Maat, signifying, in Dutch, mate or companion, and under which appellation, he is most generally known. His subjects were landscapes with views of rivers, or sea-flores, havens, or ports, which he executed with a light free pencil; and in the representations of storms and calms, he particularly excelled. None of his pictures that are principally commended, are the Italian sea-ports, with vessels lying before them. And his most capital performance is a view of the sea-shore with the waves retiring at ebb-tide; which Honbraken describes as admirably beautiful and natural. His imagination was lively, and his execution rapid. He died in 1670. Pilkingston.

BLANQUEFORT, in Geography, a town of France,
in the department of the Gironde, and chief place of a canton, in the district of Bordeaux, five miles north of Bordeaux. The place contains 2,929, and the canton 9,929 inhabitants. The territory comprehends 2,424 kilometres, and 28 communes.

BLANQUILLE, in Commerce, a small silver coin, equivalent to about 11.4 St. Germain, current in Morocco, and on the coast of Barbery.

BLAZAC, in Geography, a town of France, in the department of the Gard, and chief place of a canton, in the district of Nîmes, 14 miles S. W. of Nîmes. The place contains 4,040, and the canton 10,440 inhabitants. The territory includes 2,424 kilometres, and 28 communes.—Also, a town of France, in the department of the Gard, and chief place of a canton, in the district of Uzes, 3 miles S. W. of Uzes.

BLAPS, in Entomology, one of the Fabrician genera of coleopterus insects, the palpi of which are clavated, and four in number; jaws straight and bis; lip membranaceous and cleft; and the antennae moniliform at the tip. Fabricius includes in this genus some of the tenebroin of Linnaeus, such as tenebra gazex and mortigera. Gmelin adopts the genus only as a subdivision of Pimelia, in the Syl. Nat. See Pimelia.

BLAPSIGONIA, compound of Epstex, I hurt, and ?or, broad or wide, a kind of defective, or defect in bees, when they neglect or fail to produce young, being wholly employed in making honey.

BLARE, in Commerce, a small copper coin, containing a little mixture of silver, struck at Bern, and valued at much the fame with the Ratze in other places.

BLARINGEM, in Geography, a town of France, in the department of the North, and chief place of a canton, in the district of Hazebrouch, 7 leagues S. E. of St. Omer.

BLARNEY, a small market town of the county of Cork, and province of Munster, Ireland, situated on a river of the same name, about 4 miles W. of the city of Cork. In the reign of queen Elizabeth, its castle was reckoned one of the strongest fortresses in Munster, and it has often proved very troublesome to the inhabitants of Cork. It belonged formerly to the earls of Clancarty, but at present is the property of Mr. Jelfies, whose father built the town, and established several manufactories, of which Mr. A. Young has given a detail in the account of his tour through Ireland. These establishments, however, as too generally happens in like cases, have not been successful, and Blarney is not at present the flourishing town, which Mr. Young's prospect would lead us to expect. A paper-mill, a lamping-mill, a bleach-green, and one or two cotton manufactories still exist; and many lockings made in the neighbourhood are sold at the weekly market and in Cork, but all may be considered as on the decline. The castle and the grounds about it have been considerably improved, and the country around, as well as the park, is well watered. There is a lome at one of the corners of the top of the castle, which is thrown to strangers, on account of a saying, that any person who has killed it is privileged to lie and flatter. The origin of this saying, which is often referred to, and from which Blarney has become a vulgar synonym for flattery, the writer has not been able to discover. In the castle there is an original painting of Charles 12th of Sweden, at full length, drawn in the drafts mentioned by Voltaire, brought over by one of the family who had been envoy to that monarch. The adjoining country is mostly under corn and pasture; the soil is a yellowish clay, and is mostly manured with lime-flour, of which there is a vein that supplies large quantities. Smith's Cork. Young.

BLAS, St. a cape on the coast of the North Pacific ocean, near which, to the S.E., stands the town of Compostella, in the province of Galicia, in New Spain. N. lat. 21° 39' W. long. 105° 12'. See Blaise.

BLAS, a term, in the Helmontian philosophy, denoting the local and alternative motion of the fluids; from whole influence. Proceed changes of weather, feasons, storms, and the like.

In imitation of this blas fléllorum, the same author named another in animals, either natural, whereby each visus is framed according to the model of its particular; or voluntary, which is directed to motion by the will.

BLASCON, in Ancient Geography, an island of Gaul, mentioned by Pliny, situated at the mouth of the Rhone.

BLASE, St., in Geography, a town of Germany, in the archduchy of Austria, 6 miles S. W. of Steyr.

BLASENDORF, or BLASSENEL, a town of Transylvania, in the district of Weissenburg, the residence of the bishop of Walachia.

BLASII ZELLA, in Geography, a small town of Germany, in the circle of Upper Saxony, and principality of Gotha, separated in 1640 from the bailwick of Reinhards- brunn, and added to that of Schwarznot-wald; and famous for its foundry of fire-arms; 16 miles S. of Gotha.

BLASIMONT, a town of France, in the department of the Gironde, and chief place of a canton, in the district of La Rèole, 17 leagues E. of Blanmont, or 35 N. of La Rèole.

BLASUS, GERARD, in Biography, an of Leonard, physician at Amsterdam, who received pupils into his house, to instruct them in the knowledge of medicine, particularly in the anatomy of brute animals, of which he dissected a great variety. It was this which probably inclined Gerard to this branch of study, and gave birth to several of his works; such as his "Zootomia, seu Anatomiae variorum Anim. alium," published 1676; "Observationes animalic in homine, simia, equo, vitulo, ludentine, echino, gline, ferpete, serdca, varique animalibus sibis," Lugduni, 1674, &c.

After making some progres under his father, he went, for further improvement, to Copenhagen, and at length to Leyden, where he commenced doctor in medicine, about the year 1646. He then returned to Amsterdam, where he acquired so much credit and reputation for his skill in his profession, that in 1660 he was made professor in medicine in the schools of that city, and soon after physician to the hospital.

Besides a variety of original works, Blasius published new editions of parts of the works of Pliny, Th. Bartholin, Leconte, Bellini, Bordoli, and Willis, to most of which he gave notes and additional observations, containing such discoveries on the subjects treated of, as had been made since those works had been originally published. Of his original works, besides those mentioned above, we shall notice his "Oratio de noviter inventis," Amst. 1659, 4to. "Observa- tiones medicse rariorum, accedit triplici monlri historia," Amst. 1667, 8vo. in six books, containing accounts of the discovery of numerous moral bodies, in one of which, the spleen, and in another the gall bladder, were found to be misplaced; in one two stomachs were found, in another three vesicles. "Anatomia animalium terrestrium variorum volatilium, aquatilium, ferpentium, insectorum, ovorumque
fracturam naturalem proponens." Amst. 1661, 4to. The greater part of this work is collected from Severinus, Harvey, Malpighi, Willis, Bartholine, and other writers and journals. The work has, however, its utility, by bringing into a small compass a great number of curious facts, and observations, which were only before to be found by recurring to a variety of publications. In a letter published in the third century of Th. Bartholine's epistles, Blafuis claims the discovery of the ducus falsaris, which he says he first showed to Steno, then a young man. This has not, however, prevented the discovery from being attributed to Steno, the duc's taking his name. For the titles of the rest of the works composed or edited by Blafuis, see Haller. Bib. Amst. Med. et Chirurg. et Eley's Dict. Hist.

BLASKET SOUND, in Geography, lies on the west coast of Ireland, between the Great Blasket island and Dunmorehead, on the mainland of the county of Kerry. In this sound there is ten fathom water, and in the summer time and moderate weather a vessel may slip off the east end of the Great Blasket; but the ground will not hold well in blowing weather. In passing through this sound, it is necessary to attend to a pretty strong tide, and to a rock not far from Dunmore point, which is covered at high water.

BLASKETS, BLASQUETS, or Ferriter islands, a cluster of islands on the west coast of the county of Kerry, Ireland, being the most westerly land in the European part of the British empire. They are five in number, besides several rocks, some of which are always above water, and others are covered by high tidcs. These islands were given by the earl of Desmond to the family of Ferriter, from one of whose names it is taken; but at present they belong to the earl of Cork and Orery. The largest, called Innisfallen, i.e. the Great Island, and more commonly the Great Blasket, was visited by Dr. Smith, who found it inhabited by five or six families, and speaks in high terms of the faithfulness of its air. Ruins of churches, and cells or hermitages, are found in some of the others, but when Dr. Smith was there, they were not inhabited. The small rocks are frequented by sea-fowl, the feathers of which are collected by the people of the neighbouring coast. The hawks which are found here are remarkably good, and were formerly in much esteem. Amongst other sea-fowl the storm petrel (procellaria, Linn.) is common here. The Greater Blasket is 9 leagues S.W. by W. from Loughshin, the north point of the Shannon, and 5 leagues north of the Skelligs. The whole cluster lie between 16° 17', and 10° 31' W. longitude, and between 51° 58', and 52° 3' north latitude. Smith's Kerry.

BLASPHEMY, bl sphemia, or blasphenum, in Middle Age Writers, denotes simply the blaming or condemning of a person or thing. The word is Greek, blasphēmin, from blasphēma, bld. Among the Greeks, to blasphēne, was to use words of evil omen, or that portended something ill, which the ancients were careful to avoid, substituting in lieu of them other words of loftor and gentler import, sometimes the very reverse of the proper ones.

BLASPHEMY, is more peculiarly restrained to evil or reproachful words spoken of the Deity. Auguflus says, "Jam vulgo blasphemia non accentum nisi mala verba de Deo dicere." According to Landrew, blasphemy is an injury offered to God by denying that which is due and belonging to him; or attributing to him what is not agreeable to his nature.

By the Mosaic law, blasphemy was punished with death. Levit. chap. xxiv, ver. 13-16. As also by the civil law. Novel. 77. In Spain, Naples, France and Italy, the pains of death are not now inflicted. In the empire, either amputation, or death, is made the punishment of this crime.

By the canon law, blasphemy was punished only by a solemn penance, and by censum, either by pecuniary or corporal punishment. By the English laws, blasphemies against God, and religion, as denying his being, or providence, and all contumelious reproaches of Jesus Christ, &c. to which may be also referred all profane scoffing at the holy scripture, or exposing it to contempt and ridicule, are offences by the common law, and punishable by fine, imprisonment, and pillory. 1 Hawk. P.C. And by the statute law, he that denies any one of the persons of the Trinity to be God, or afferts there are more Gods than one, or, having been educated in, and having made profession of the Christian religion, denies, by writing, printing, teaching, or advising speaking, Christiannity to be true, or the holy scriptures to be of divine authority, for the first offence is rendered incapable of any office or place of trust; and for the second, adjudged incapable of bringing any action, being guardian, executor, legatee, or purchaser of lands, and to be imprisoned for three years without bail. 9 and 10 W. III. c. 32. To give room, however, for repentance, if, within four months after the first conviction, the delinquent will in open court publicly renounce his error, he is discharged for that once from all disqualifications.

According to the law of Scotland, the punishment of blasphemy is death. The first species thereof consists in railing at or cursing God, and here the single act constitutes the crime. The second consists in denying the existence of the Supreme Being, or any of the persons of the Trinity; and therein obliquely perverting to the laud. For reiterated denial does not fully constitute the crime, because the flat. of Charles II. 1661, admits of repentance before conviction as a complete expiation.

This statute of 1661, is ratified by a statute of king William, whereby the calling in question the existence of God, or of any of the persons of the Trinity, or the authority of Scripture, or the Divine Providence, is made penal. For the first offence, imprisonment till satisfaction given by public repentance in fullcloth. For the second, a fine of a year's valued rent of the real estate, and twentieth part of the personal estate: and the trial in both these cases is competent to inferior judges. The punishment of the third offence is death, to be tried only by the justices.

BLASPHEMY against the Holy Ghost. Divines are not agreed with respect to the nature of the crime thus denominated, Matthew, xii. 31. Mark, iii. 28, 29. Luke, xii. 10, and the grounds of the extreme guilt ascribed to it. On this subject it may be observed in general, that from our Saviour's expression this sin appears to consist, and to be completed, not in our thoughts, nor in our words, but in our words. Nor, indeed, is the epithet "blasphemous," or any synonymous term, ever joined in scripture, as is common in modern use, with doctrines, thoughts, and opinions. It is never applied but to words and speeches. A "blasphemous opinion," or "blasphemous doctrine," are phrases, which, however familiar to us, are an unfriendly term to the scripture idiom, as a "railing opinion," or "flaiderous doctrine," to ours. It may be also observed, that this blasphemy is not of the constructive kind, but direct, manifest, and malignanl. It is mentioned as comprehended under the same genus with abuse against man, and contradistinguished only by the object: and it is further explained by being called "speaking against," in both cases. The expressions are, in effect, the same in all the gospels, where
it is mentioned, and imply such an opposition as is both intentional and malevolent. This could not have been the case with respect to all who disbelieved the million of Jesus, and even deemed his miracles; many of whom, we have reason to think, were afterwards converted by the apostles.

The learned Grotius, in order to mollify the severity of the sentence denounced against this sin, suggests, that what our Lord expresses absolutely, must be understood comparatively; and that he only designed to intimate, that it is very difficult to obtain the pardon of this sin, but not that it will admit of no forgivenes. But our Saviour here favours expressly of this sin, whatever it was, both negatively, that it shall never be forgiven, and affirmatively, that the person guilty of it shall be obnoxious to eternal judgment, confirming the whole with an accentuation. Dr. Waterland (see his Serm. vol. ii. N° 9. p. 177—183.) seems to incline to Grotius's opinion; alleging that signifies only exceedingly difficult. Dr. Hammond comments upon the words with observing, that this sin shall not be pardoned, but upon a particular repentance; but this is true of every sin as well as of the blasphemy against the Holy Ghost. Some have made this crime consist in final impenitence, because that is unpardonable; but it is not easy to assign a reason why this should be called the sin against the Holy Ghost. Others have represented it as, in its specific nature, a wilful and obstinate opposition to the truth; others again as a malicious opposition to the truth, on the part of those who know and are convinced that it is the truth; whilst some have supposed it to consist in a renunciation of the truth for fear of suffering, which made Francis Spira think that he committed this sin. Mr. Wakefield, in his Notes on the Revelation of the Gospel of St. Matthew, p. 178, is of opinion, that what is meant by the blasphemy of the Spirit appears from the context to be perverted resorting and believing with contumacy, against plain and satisfactory evidence, the operation and interference of the holy spirit of God; and he thinks, that those men who reject the Christian revelation, without contemplating its claims with diligence, candour, and exactness, upon a precipitate pre- determination of its falsehood; and those, who refuse their affections to that degree of moral evidence, of which alone these subjects are capable, and which they would think sufficiently satisfactory in other causes, and in the ordinary occurrences of life, are as much guilty of the sin of blasphemy in our times, as those cavilling and hypocritical Pharisees were in the days of Christ.

Dr. Tillotson (vol. i. term. xvii.) maintains, that this sin, of which the Pharisees were guilty, confused in maliciously attributing the miraculous operations which Christ performed by the power of the Holy Ghost to the devil. This sense is adopted by bishop Pearce, in his Commentary on the four Evangelists, vol. i. p. 85. But Dr. Whitby, with greater probability, refers it to the disputation of the Holy Ghost, which commenced after our Lord's resurrection and ascension; and those were guilty of the crime, who perfided in their unbelief, and blasphemed the Holy Ghost, representing him as an evil spirit. The crime was unpardonable, because it implied a wilful opposition to the last and most powerful evidence which God would vouchsafe to mankind, and precluded the possibility of a recovery to faith and repentance. Whitby's Fourth Appendix to the Gospel of St. Matthew, in his Paraphrase, vol. i. p. 289.

Of this sin, it is said, it shall not be forgiven, either in this world or in that which is to come. With regard to the meaning of this expression, it is observed both by Lightfoot (Hor. Heb.) and by Grotius (in loc.), that through a fond imagination of the final happiness of all the seed of Abraham, the Jews supposed, there were some sins that had not been forgiven here, which would be expiated by death, and be forgiven after it; and that our Lord designed by this expression to assure them, that there was no forgivenes for those who should be guilty of this sin, either before or after death, and that their expectations of forgivenes then would prove no other than a deceitful dream. Dr. Whitby, however, has clearly shewn, that this was used as a proverbial expression, and that it only signifies, "a thing should never be," when it was said, "It shall not be, either in this world, or in the world to come." Others, however, among whom we may reckon bishop Pearce and Mr. Wakefield, have thought that the expressions of "this world," and "the world to come," denote the Jewish and the Christian dispensations. "O amen, and so say all," fays these writers, signify in the New Testament the Jewish age or dispensation, which continued till the abomination of the Jewish polity, civil and ecclesiastical, by the destruction of Jerusalem under Titus; and the same ov., or the future age, denotes the Christian dispensation. Bishop Pearce adds, that under the Jewish law, there was no forgivenes for wilful and presumptuous sins; concerning which he refers to Numb. xx. 30, 31. xxxv. 31. Lev. xx. 10. and 1 Sam. ii. 25. With regard to the age to come, or the Christian dispensation, the bishop observes, that no forgivenes could be expected for such sinners as the Pharisees were; because, when they blasphemed the Spirit of God, by which Jesus wrought his miracles, they rejected the only means of forgivenes, which was the merit of his death applied to men by faith, and which under Christianity was the only sacrifice that could atone for such a sin; in this sense, as things then stood with them, their sin was an unpardonable one. But, he adds, it is not to be concluded from hence, that, if they repented of this blasphemy, they could not obtain forgivenes. Mr. Wakefield observes, that the unrevoked affirmation in Matt. xii. 32. must be interpreted, as well as the preceding verfe, with considerable qualification. Our a z. t. a. n. will not be forgiven, will not be deemed a common and natural fault, agreeably to the eastern mode of expression, which constantly requires such limitation. Accordingly he thus gives the general sense of this verse. "Offences of the most heinous nature, even reproach and injustice against the anointed prophet of God, may more readily find pardon, than contumacious blasphemy of the Holy Spirit." This aggravated sin, the result of obstinacy, depravity, and malice in the extreme, will have no title to forgivenes, even from the clemency and mercy of the Christian revelation, a revelation of pardon and peace, in the fullest fende, and to the whole race of men. See Heb. vi. 4—7. Nevertheless, "will not any fins be pardoned on sincere repentance, and deliberate purposes of amendment, under that encouraging dispensation, which breathes in. May, but reconciliation and forgivenes—nothing but favour, mercy, and peace, from God our Father, and our Lord Jesus Christ?"

BLAQUES ISLAND, in Geography, lies on the west coast of Newfoundland, in about 47° 35' N. lat.

BLA.ENT, in O. a. t. h. The common wold duck is called by this name in the vicinity of the lake of Constance.

BLA.ente, (Fr. bleu. a.) a name synonymous with nu a Pl. 18, and common u. ge. of English writers.

BLA. STE, in the Military Art, a sudden compre- hension of the air, caused by the discharge of the bullet out of a great gun. The blast sometimes throws down part of the embrasures of the wall.
BLAST.

Blast is also applied, in a more general sense, to any forcible stream of wind, or air, excited by the mouth, bellows, or the like.

Blast, in Agriculture, a disease in grain, trees, &c. See Blight.

The sugar-cane in the West Indies is subject to a disease called the blast, and said to be occasioned by the abis of Linnæus, which is distinguished into two kinds, the black and the yellow; and of these the latter is the most destructive. It consists of myriads of little insects, invisible to the naked eye, whose proper food is the juice of the cane, in search of which they wound the tender blades, and consequently destroy the stools. Hence the circulation being impeded, the growth of the plant is checked, until it withers and dies in proportion to the degree of the ravage. It is frequently affirmed, says Mr. Bryant Edwards (Hist. West Indies, vol. ii. p. 315.) that the blast never attacks these plantations where coloquies have been introduced of that wonderful little animal, the carnivorous ant, or "formica omnivora" of Linnæus, called in Jamaica the "ruffles ant," from its being supposed to have been introduced there by one Thomas Reeves from the Havana, about the year 1762. These minute and busy creatures soon clear augar plantation of rats; and their natural food seems to confine all kinds of insects and animals.

First Blast. See Blight.

Blasts, among Miners. See Damps. See Mines, and Mining.

Blast, the term used at iron founderies to denote the column of air introduced into the furnace for the purpose of combustion. Its velocity is occasioned by the impelling power of the blowing machine forcing the whole contents of the air-pump through one or two small apertures called nole-pipes; and, according to the absolute power of the engine, air of various densities will be produced, so that density and velocity are always intimately connected, and mutually implied.

The well-known combustibility of iron, and the indispensible necessity of exciting combustion by the introduction of large quantities of oxidized air into the furnace, in contact with ore in various stages of maturity as to separation, into contact with iron existing in all the modifications of quality as to carbonation, and into contact with an immense body of ignited fuel, render this subject the most important in the major scale of our manufactures. Unfortunately for art, as well as for science, few practical deductions can be brought forward to establish any one theory of blast; one common principle only is acknowledged, that all reduction in the furnace is in consequence of the combustion excited by the column of air introduced.

To take a proper view of this interesting subject, it will be necessary to submit it to the following divisions.

1st. Combustion, as excited in this particular branch of manufacture.

2d. The nature of the fuel submitted to combustion.

3d. The density of the air.

4th. The quantity.

5th. The properties which follow as a consequence of density and quality.

6th. Combustion in the blast furnace consists chiefly in the rapid reduction of a given quantity of solid fuel, and its accompanying portion of ore, in the shortest possible time. That furnace, and that blast, which can, in a given time, reduce the greatest quantity of fuel, all things else being alike, will always manufacture the greatest quantity of iron. In common, before the introduction of the blast, the furnace is previously filled with alternate strata of coke, iron-flone, and limestone, heated by simple atmospheric pressure to a bright red or white heat, and the iron flone to a melting heat. This temperature is soon increased throughout the furnace, after the blast is applied. The blowing orifices or tuyeres of the furnace exhibit the fuel increasing in whiteness, and the iron-flone rapidly dissolving before the blast, of a blackish colour. At this period, the lava which flows from the furnace, in consequence of the reduction of the ore and lime-flone, is considerably charged with iron, and is of a black, blackish brown, or greenish brown colour. This appearance will continue for twelve, twenty-four, or thirty-six hours, according to the mode of treatment in bringing forward the furnace after blowing. The tuyere (if a bright tuyere furnace) will appear like a blaze of uncommonly pure light, at times very offensive to the eye; but, however, becomes accommodated to it, and may, with facility, discern the individual masses of coke, as they are forced away, with the rapidity of lightning, before the irresistible force of the air. The concrete ore and lime-flone are no longer visible; but a fine metallic spray is constantly descending, and, forced from the fuel, precipitates itself to the bottom of the furnace. The scoria formed by the fusion and union of the lime-flone, with the metallic parts of the ore, is carried before the blast in a similar manner and form, but easily distinguishable from the fluid metal by its buoyancy, want of velocity when impelled, and by its dull colour. In this state, the furnace is deemed in excellent smelting order. The iron is generally revived with little losses; and the colour and purity of the cinder or lava sufficiently indicate the perfection of the separation. When at any time the brightness of the tuyere fails, and becomes dull white or reddish white, then a change is indicated; the iron-flone and lime-flone will again appear in the solid unseparated state, and the change of colour in the cinder infallibly betokens an irregularity in the movements of the furnace. These appearances are so general, as scarcely to admit of an individual exception, and are sufficient to warrant the following explanation.

At the introduction of the blast, the interior of the furnace at the tuyere was simply a mixture of ignited masses of coals and iron-flone, the latter partly limonmed, but the greatest part merely heated to a bright red heat. In the deficient through the furnace, in contact with ignited coke, the particles of metal in the ore may, by parting with the oxygen, have received a disposition to become revived. The increased temperature creates an additional tendency, by establishing a greater force of affinity between the fuel and the iron. But the metal approaching to its proper state, meeting the current of blast, is immediately subject to a partial combustion. The portion thus oxidized conveys to the lava in proportion to its quantity and oxygenation, the colour already mentioned.

As soon as the continuation of the blast conveys a higher temperature to the superior regions of the furnace, the appearance of the solid matter at the tuyere ceases. The fusion and separation of the metal from the ore are effected in situations more remote from the blast, orchief source of decomposition in a temperature more fitted to the nature and existence of the metal. The iron, once formed into a fluid, and its fluidity preferred, its defeat to the blast is attended with little or no injury to its carbonation.

To understand this distinctly, it will be necessary to state two curious facts relative to call iron in a fluid state; and but for the existence of these properties, the manufacture of the metal in open furnaces or vellums would be totally impracticable. 1st. Call iron, while kept fluid, never decomposes atmospheric air, and never itself becomes oxidized. 2d. The degree of carbonation paffed upon the metal at the moment
moment it enters into complete fusion, continues without diminution or augmentation throughout the whole operation of the furnace; or, in other words, call iron neither receives nor loses carbon whilst it preserves its fluidity. The first fact explains the reason why the iron is preferred from combustion, when it defuses opposite to the current of blast. The second is a proof that the carbonaceous matter is conveyed to the iron in the furnace by a species of cementation previous to fusion; and that after this point, call iron will not take up any addition of carbon.

To preserve and establish the relation of cementation and fusion in the furnace ensures uniform products. Combustion in this prefers us with a gradation of temperature, diminishing from the tufure upwards through thirty or forty feet of ignited matter. The inferior temperature towards the top of the furnace heats the materials to reduce; an affinity is here commenced between the carbonaceous matter and the oxygen of the ore; the latter is gradually removed, and a second affinity is instituted between the de-oxygenated particles of metal and the carbon; this, as the ore defuses to higher temperatures, is rapidly increased, and by and by the saturation of the coaly principle is complete. As the saturation of carbon always increases the fusibility of iron, the metal of the furnace enters into fusion at a comparatively low temperature, and speedily precipitates, through the high temperatures in the neighbourhood of the blast, to the general reservoir below.

It is not, therefore, necessary to suppose, that the great volume of air thrown into the furnace, and the great temperature of course excited, are necessary to the manufacture of the iron, so far as it regards quality; this, it is more than probable, may be injured by it, and even the economy of the manufacture itself. Quantity, however, is in general secured; but this is more the effect of mechanical reduction, than of any necessary operation of the blast upon the ore and materials above.

The quicker the body of cokes can be reduced, which occupy that part of the furnace between the point of separation and the tufure, the greater will be the reduction of the whole, and the greater the quantity of manufactured metal. To this point the whole force of the blast is directed; here the chief part of the decomposition of the atmospheric air takes place; and here the destruction of the intervening cokes is effectual, and at the same time in proportion to the quantity of air poured upon their highly ignited surfaces.

If we assume, with a blast of a certain density, any two points in the furnace, the one as the point of decomposition, and the other of separation and fluidity of the metal, suppose the former at the tufure, and the other at the lower end of the blastpipe at A. (See description of Blast furnace,) then it must be allowed probable, that a change taking place in the density, or even in the quantity of the blast, that change will affect not only the points themselves, but also their relative distances. The point of separation may be brought nearer (and perhaps injuriously so) to the level of the blast, the elevation of which is supposed to remain the same. The contrary may with equal truth be inferred; that if the point of separation is carried to a more elevated situation by a change or increase of temperature, the ore may enter into fusion before it has remained sufficiently long in contact with the ignited fuel, and thereby both the quality and quantity may be injured.

2d. Since pit-coal coke became the staple fuel at the blast furnace, the density and quantity of air deemed necessary to secure combustion and quantity, have been yearly increasing. The various qualities as to hardness or softness, purity and effect, have given rise to a multitude of opinions, which are the most appropriate quantity and density of air for respective qualities of coals. The blast of the furnace, in consequence, has at different places varied from 1 to 2 lb. of expansive force upon the square inch of the air vent. Most of the English works are blown with air not exceeding 2 lb. upon the square inch, as being the most proper medium of density, and beyond which the materials would be over-blown. English coal, in general, is soft in its fusible state, but rich in carbon, and free from mixture. In Scotland, where the coal is found in dense strata, and forms heavy coat, the blast is used from 2 lb. to 4 lb. per inch. Those who have adopted dense blends declare, that quantity of iron is incompatible with a column of air inferior to the measure of their standard. Either the prejudice is very general, or there really must exist a direct analogy between the nature of the blast and the density of the coal.

The operations of the charcoal pig manufactory were conducted with blasts of a trifling density, seldom exceeding ½ lb. upon the inch, and often under this. Dense blast, it was believed, over-run the furnace, most probably by exciting too great a temperature, and frequently had a tendency to discharge the materials from the furnace top. There never yet have been any direct experiments made to ascertain upon what this variety of pitch-coal depends; whether exclusively from its density, or from containing the carbonaceous matter in more purity or greater disengagement. Perhaps both are necessary to be taken into account, before any satisfactory explanation can be given of the facts now flated and generally admitted.

3d. The density of a column of air depends upon the power of the blowing machine, and the proportion of the area of the steam cylinder to that of the blowing cylinder. Tables of the powers of steam engines, and the diameters of cylinders requisite to condense air from ½ lb. to 3 lb. upon the circular inch, will be found under the article Blowing Machine. It will appear evident from these tables, that steam cylinders of the same diameter, and working at the same power, when employed to raise air of various densities, do not discharge the same quantity of atmospheric air in any given time. The larger the area of the blowing cylinder, the number of strokes being the same, the greater will be the quantity of air discharged into the furnace. The reverse is the case with blasts progressively more dense; so that any part of an engine's power may be employed, not in raising the true principle of combustion—air, but in condensing a comparatively small body of air, so as to give it additional velocity.

To fix the point, or maximum, of the most profitable density, has hitherto been unattainable. The circumstances deemed intimately connected with coal, render it necessary to accommodate the blast to the combustibility of the fuel; and were it not the case, it would be difficult to overturn the following reasoning, and to exhibit an instance where it might not be found generally applicable. Combustion in the furnace will be excited in proportion to the quantity of air introduced. A blowing machine, that with the same power of steam cylinder threw into the furnace double the quantity of air, though of an inferior density, would reduce a greater quantity of combustible matter than one oppositely constructed; or, in other words, 5000 feet of air per minute entering a furnace would produce greater effects than 2500 feet, although the latter were compressed into nearly half the bulk of the former.

The most plausible theory of blast is to fix upon the lowest density at which the air can be forced into the furnace, and then proportion the diameter of the air pump to the power of the steam end. Suppose that this could be effected at half the density usually employed, then that part of the engine's
engine's power used formerly to compress the air to 3 or 4 lb. would now be employed in a blowing cylinder of larger diameter, raising per minute, or indeed per stroke, from 100 to 200 cubic feet of air. Opposed to this there stand two formidable objections, resulting from the necessity of using blow-pipes or nozzles of increased diameters, from which to discharge the additional quantity of air, making up in area what is wanting in velocity to discharge the air in a given time. The first is a reaction of the air, so powerful as to force back from the tuyere with a velocity little short of that at which it enters. This, with no-pipe of 2, 2½, and from that to 3 inches, is scarcely felt when the blast is 40 ft., and may be entirely obviated by a judicious arrangement of the tuyere iron and no-pipe. But with pipes from 3 to 4 and 4½ inches diameter, the recoil increases as the squares of the diameters of the blow-pipes, and even in dense blast the recoil increases with the diameter of the discharging pipe. It is therefore probable, that to blow with a no-pipe 4 or 5 inches diameter, so as to have no recoil, a velocity or density of air would be requisite beyond any thing yet in use.

Those who advocate for the use of a soft blast, either upon the plea of their materials, or as being the most advantageous method of using any given mechanical power, frequently feel the full effects of the recoil of a considerable portion of the whole blast. But to obviate this, and to gain the advantage of the whole air, the blow-pipe is enclosed in a moveable frame or building, which is made air-tight at every cast, and completely prevents the return of the smallest portion of it. The combustion at these furnaces is carried on with equal effect, and the resulting products in iron equal in point of quantity and quality to those where blasts of double density are used.

Again, at other furnaces, where a soft blast had been originally preferred, the plan of forcing back the recoiled air, in order to make up in quantity what was now deemed to be deficient in density or velocity, has been in vain attempted. The tuyere irons have become immediately heated, and burnt back with violence. The materials would not admit of the tuyeres being raised sufficiently high to prevent the cinder from flowing back into the bag, which connects the large and small pipes, and destroying it. Even in more than one instance, the entire tuyere side of a furnace has been lost in endeavouring to establish this plan of blowing, where either the materials would not answer, or from some misconception in the mode of operating. Where a furnace works uniformly with a dark or honey-combed tuyere, this mode of blowing may be attended with the greatest success. In all new erected, however, the blast ought to pass at such a velocity that all the nozzles sufficiently so as to offer a resistance to the cinder passing through the furnace without decomposition. The point of separation may by this means be changed, or perhaps be raised too high for the preservation of the metal, immediately previous to separation. As the increased temperature prevails upwards, the affinity between the particles of metal in the iron-furnace, and the carbon of the fuel, may be earlier established, and no ultimate evil consequence, in point of reasoning, ought to ensue. It appears from numerous observations, that the quantity of iron-furnace, which a given weight of cokes smelts, and to the metal of which is conveyed the carbonaceous principle, is considerably dependent upon the diameter of the blowpipe. Supposing the ore of equal richness, the smaller the pipe, the greater burden will the coke carry, and the cheaper will the iron be made per ton, so far as materials are concerned. On the contrary, with large pipes, whatever the density of the air may be, the quantity of coals necessary to manufacture an equal quality of pig iron will be increased, and the cost of the iron is also increased. As an equivalent for this, however, the quantity is considerably increased with nearly the same amount of labour; so that it remains a question with the manufacturer, whether the additional cost of coal is compensated by the extra produce of metal he is enabled to bring to market. 4th. The quantity of air discharged into the furnace, under the application of blast, depends upon the number of strokes or cylinders which the engine makes per minute, and on the area and diameter of the air pump. This is independent of any consideration of density and increase of power in the steam cylinder, so long as the blowing or air cylinder remains the same, and the engine performs the same discharges; the measure of atmospheric air, which enters the furnace, will remain the same. The rapid improvements, which of late years have been made in the blowing machines, have increased the quantity from 1000 to 4000 feet per minute; and the quantity or produce in iron has been also considerably increased. We by no means, however, find that the increased manufacture of iron has been in the exact ratio of the quantity of blast thrown into the furnace. Many influences of late years have been noticed during the transition from the old to the improved modes of blowing, wherein the proportion has had little or no similarity.

Fifteen hundred feet of atmospheric air in one minute was found in most situations equal to the manufacture of twenty tons of melting iron; in the same situations, 3000 feet in the same time has never exceeded thirty tons per week; and in one particular trial for two weeks, the discharge of 6000 feet, being the whole produce in air of the engine, the produce in iron never exceeded 36½ tons. In the last case, the quality of the iron was irregular, and the quantity of cokes for each ton of metal thus produced was considerably increased, although the iron was of inferior carbonation.

Without recurrence to the diameter of the air cylinder, and the particular movements of the engine, the facts have been frequently deduced from the diameters of the nose-pipes. We have frequently seen air discharged under a pressure of 2½ lb. upon each square inch, but with a pipe of 2½ inches diameter, reduce materials, and manufacture good melting iron to the extent of 20, 22, and 25 tons per week; and in the same furnace, and with the same materials, the air discharged by 2 pipes, each 2½ inches, under a pressure of 3 lb. upon each square inch, the produce never exceeded 30 tons of metal of an equal quality, but more frequently 25 to 28 tons. One observation still more direct, and made with a blast of a density equal to 2½ lb. per inch, and discharged by one pipe of 2½ inches diameter, frequently manufactured 22 tons fine melting iron weekly; another pipe was added to the opposite tuyere of the same diameter, and the quantity of metal weekly was never increased beyond 32 tons, and upon an average of six months only 27 tons. These are curious facts relative to the nature and effects of blast, and exhibit the investigation of its principles as a matter of singular importance in the economy of the manufacture.

One remark was made relative to the burden of ore in the last rated fact, that, with the small pipe a given weight of cokes smelted and carbonated the metal in 3 cwt. of iron-
From quantity and density of air, there may and do result peculiar properties of blast, which may affect the operations of the furnace, and which once fully understood may help to explain the facts hitherto unaccounted for, and which we before noticed. Facts resulting from accurate observation would prove an invaluable source of information upon this subject; and it is with regret that we can furnish no perfect aerological table of the different temperatures of air under different densities or degrees of compression. The following, we believe, contains the only collection of temperatures hitherto noted; and as it relates to only one degree of compression, the satisfaction it affords must be only partial.

**TABLE of 30 observations made in summer upon various temperatures of air before and during the act of compression, compared with the thermometer in the shade.**

</table>
There can arise no doubt, but that heat is extricated by condensation from atmospheric air; and that it is further probable, that the quantity of heat difengaged is in proportion to its condensation. If, therefore, we are allowed to reason upon this subject, we should judge the following as a considerable approximation towards truth. It is universally believed and felt, that combustion in the blast furnace in June, July, and August, is considerably diminished, as a consequence of the increased temperature of the air. The metal, in these months, is frequently detected in point of carbonation, and diminished nearly one-half in point of quantity. We shall suppose that this takes place at a temperature of 100°, which has been proved to exist under a preussure of 21 pounds. The reverse of this happens in the cool season of the year, and particularly in the winter months. The furnace then yields the largest quantity of iron, and in the most profitable manner. This, with the same probability, takes place at a temperature of 50° found in the table.

It would therefore appear to result from these, that two-thirds, or one-half of the iron only, is manufactured at a temperature of 100°, than in winter at 50°. The difference between these degrees of temperature amounts to 50°, and most probably in combustion affects the operation as sensibly as the human frame is affected by a transition of temperature equal or similar. It is not necessary now to state the difference between summer and the winter air of our winter, the circumstances of evaporation and aqueous solution; these shall be particularly attended to in the general process of manufacturing iron. The great difference of temperature arising simply from compression seems to us adequate to explain many phenomena regarding the blast furnace. Our knowledge, however, upon this subject, can only be forwarded by a general collection of facts well ascertained, showing what are the various degrees of heat made sensible by the compression of the blowing machine under every density; what the difference in temperature, the densities being alike, when the air is received over water, in the air-vault, or in the regulating cylinder. From these it might most probably result, that the higher the density of the air, the greater would be the degree of heat manifested; and it might also follow, that in the ratio of this density, or temperature, when the air was received over water, fo would be the evaporation or quantity of water suspended in the air, and of course discharged into the furnace.

This article may be concluded by the following remarks:—That all iron works are not alike affected by the heat of the summer months. Many iron works preserve the quality of the iron, though at the expense of fuel, and with losses of quantity; but at other places no extra quantity of fuel will compensate, either as to quality or quantity, for the want of cool air. Neither the heat nor density of blast will explain this curious circumstance; for with blast of equal density and quantity, works situated not 50 feet above the level of the sea have been found to manufacture a greater quantity of soft iron in summer, than at a similar work, not ten miles distant, situated at least 250 feet higher. At both of these works the air is received over water; and no material alteration in the use of that air is or can possibly be applied. The causes of this difference must be sought for in the nature of the coal and iron-stone used at both works, the investigation of which, however interesting, would prove a most laborious undertaking.

**Blast Furnace.** A large conical or quadrangular building used at iron works for melting iron-stones and ores.

**Blast Furnace.** Description of.

Plate (Chemistry) II. Fig. 1. represents a blast furnace, and part of the blowing machine constructed upon what at one time was the general plan at iron works.

A, the regulating cylinder, eight feet in diameter, and eight feet high. B, the floating piston loaded with weights proportioned to the power of the machine. C, the valve by which the air is passed from the pumping cylinder into the regulator; its length 26 inches, and breadth 11 inches. D, the aperture by which the blast is forced into the furnace. Diameter of this range of pipes 18 inches. The wider these pipes can be with convenience used, the less is the friction, and the more powerful are the effects of the blast. E, the blowing or pumping cylinder, fix feet diameter, and nine feet high; travel of the piston in this cylinder from 5 to 7 feet per stroke. F, the blowing piston, and a view of one of the valves, of which there are sometimes two, and sometimes four, distributed over the surface of the piston. The area of each is proportioned to the number of valves, commonly they are 12-16. G, a pile of solid stone building, upon which the regulating cylinder rests, and to which the flanges and flints of the blowing cylinder are attached. H, the safety valve, or cock, by the simple turning of which the blast may be admitted to or shut from the furnace, and passed off by a collar pipe on the opposite side. I, the tuyere
by which the blast enters the furnace. The termination of
the tapered pipe, which approaches the tuyere, receives small
pipes of various diameters from two to four inches, called
hole-pipes. These are applied at pleasure, as the furnace
may be deemed to require an alteration in the volume or
density of the blast. K, the bottom of the hearth, two feet
square. L, the top of the hearth, two feet six inches square.
K L, the height of the hearth, six feet six inches. L is the
bottom of the boles, which here terminate of the same
size as the top of the hearth, only the former are round, and
the latter square. M, the top of the boles, twelve feet diame-
ter, and eight feet of perpendicular height. N, the fur-
ace top, at which the materials are introduced, or, as it is
called, charged; three feet diameter. MN, the in-
ternal cavity of the furnace from the top of the boles up-
wards, 30 feet high. NK, total height of the interior of
the furnace, or working part, 44'4 feet. OO, the lining.
This is done in the most manner with fine bricks, from
two to fourteen inches long, three inches thick, and
tapered to fuit the circle of the cone. PP, a vault which is
left all round the outside of the first lining; three inches
broad. This is sometimes filled with coke dust, but more
often with sand firmly compressed. This space is allowed
for any expansion which might take place, either in an
increased volume of the furnace itself in heating, or by the
preasure and weight of the materials when defending to the
furnace bottom. OO, the second lining, similar to the first.
The object of this is to guard against the entrance of the
flame into the mafs of common building, by rents which
might take place in the first lining OO. Q, a cast-iron hoist,
on which the bottom of the arches is supported, eight feet
and a half long, and ten inches square. RS, the rife of the
tuyere arch, fourteen feet high on the outside, and eighteen
feet wide. VV, the extremes of the hearth ten feet square.
This and the bolting flones, are commonly made from a
coarse gritted sand flone, whose fracture presents large
rounded grains of quartz connected by means of a cement
lefs pure.

Fig. 7. represents the foundation of the hearth, and a full
view of the manner in which the falfte bottom is con-
structed.

A A, the bottom flones of the hearth. B, a stratum of
bedding fands. C C, passages by which the vapour gen-
rated from the damps is paved off. D D, pillars of brick.
The letters in the horizontal view of the fame figure corre-
spond to similar letters in the dotted elevation.

Fig. 8. A A, horizontal section of the diameter of the
boles; the lining and vacancy for fluffing at M. C, view of
the top of the hearth at L.

Fig. 9. Vertical side section of the hearth and boles,
shewing the tymp and dam-flone, and the tymp and dam-
plates. a, the tymp flone; b, the tymp-plate, which is
wedged firmly to the side walls of the hearth; c, dam-flone,
which occupies the whole breadth at the bottom of the
hearth, excepting about six inches, which, when the furna-
ace is at work, is filled every cull with a strong binding flond.
This flone is furnmounted by an iron plate of a considerable
thicknes, and a peculiar shape, d; and from this it is called
the dam-plate. The top of the dam-flone, or rather the
notch of the dam-plate, is from four to eight inches under
the level of the tuyere hole. The space under the tymp
plate, for four or six inches down, is rammed every cull full
of strong loamy earth, and sometimes even with fine clay.
This is called the tymp flopping.

The square of the base of this furnace is 38 feet. The
extreme height, from the falfte bottom to the top of the
crater, measures 55 feet.
from 8 to 10 per cent. of water, and coarser gritted flones from 10 to 12. Taking the average 10 per cent., then in
a furnace of equal dimensions to the drawing in Plate II.
fig. 6, the sand-foie of which will weigh upwards of 1200	tons, there will be introduced 200 tons of moisture. This
quantity is always considerably increased by the portion of
water necessary to reduce the lime to mortar, and frequently
augmented by the moist state of the weather during
building.

The evaporation of this immense body of water is the
source of all the mischief which takes place in the shell of the
bluff furnace; nor is it much to be wondered at, where
every precaution is not used to bring the heat forward in
the most gradual manner, preserving the cleanliness of the
vents, and allowing the moisture intenfibly to pass away.

In situations where bricks can be obtained, the moisture
of the sand-foie is avoided, but the great extra quantity of
lime, which is necessary to build with bricks, introduces
through the medium of the mortar an almost equal quantity
of water, as with sand-foie. This has been obviated in part
by using soft clay in the interior of the walls; but as
clay seldom binds to any great extent, the general puff of
the furnace must be trusted to good binders from
without.

In the construction of all bluff furnaces, a complete
vantage ought to be preferred by means of narrow flues, or
passages proceeding horizontally from the middle of the solid
shell, or within two feet and a half of the interior to the
outside. These ought to be connected with a circular chan-
nel, or gutter, of the same dimensions, proceeding round the
circumference of the furnace; so that if any one vent
were choked in the general expansion, the moisture con-
ducted by it might easily vent itself among the other open-
ings. The vents cannot be too numerous; and as they
f seldom exceed four inches square, the building cannot be
materially weakened by them.

In addition to the horizontal channel of communication,
some builders carry up in the main building of the furnace
four, fix, or even eight perpendicular flues, which commu-
nicate with it and the openings that proceed horizontally to
meet the external air. See Plate VIII. figs. 1, 2, 3, 4.

Either of these methods may be considered as just precau-
tions to infure the existence of the furnace, but adopting
them in the fullest and most complete manner, is not always
accompanied with similar success. If circumstances formerly
noticed concur in occasioning an extra degree of expansion,
the pressure of the lining against the common building of the
furnace often deranges the systematic order of the vents,
pushing the bricks into contact with each other, and
mothers for a little while, though to gain more fatal elastic ef-
fects, the increasing volume of the vapour.

After such a diversity of opinion upon a subject of such
importance, wherein each respective class of votaries
can boast of complete success from its peculiar plan, it may
difficult to point out one more generally attended with
good effects than another. The following, however, may
defere the serious consideration of the manufacturer of
pig-iron.

Of whatever materials the furnace is constructed, let them
pollute no more moisture than is sufficient for their proper
building. The thickness of the common building not to exceed,
at its greatest breadth, 25, or 7 feet. In the middle of
the wall, a space of four or fix inches ought to be left
clear all the way to the furnace top. Into this vacuity should
be introduced small fragments of sand-foie, about the size of
an egg and under. When the expansion, proceeding from the
fire building of the interior, causes the bricks immediately in
contact to push outwards, the masses of sand-foie are im-
mEDIATELY reduced to size, and filling the interfaces occasion-
ated by their angular shape, actually occupy much less
room; and now present to the flame or fire, should it be in-
clined to penetrate so far, a solid vertical stratum of sand,
after having secured the expansion of the furnace to the ex-
tent of some inches. The effects of the pressure are thus
dverted from the shell of the building, and lost in the pul-
verization of the fragments of sand-foie.

The advantages following from this plan may be nearly
doubled, by using a double lining of fire bricks, as represen-
ted in Plate VIII. fig. 3, betwixt each of which, and the
common building, a similar vacancy should be left; but
filled with sharp sand, containing no more moisture than serves
to compact it into a firm body. As this moisture becomes
gradually expelled in the flow heating or annealing of the
furnace, the sand occupies less bulk, or, which is the same
in effect, is then susceptible of a greater degree of compres-
sion when the general expansion of the furnace comes on. It
is evident that the force is here also diverted against the sand
in place of acting immediately, with a tendency to enlarge
the circumference of the building.

Over and above all these precautions, the annealing or
drying of the furnace in a progressive and regular manner
ought to be carefully attended to and continued for two or
three months at least. Many are blown much earlier, from
an anxiety to get to work, and make returns for the great
capital necessarily expended in these undertakings.

The same variety of opinions exists in the trade relative to
the determined figure and dimensions of the bluff furnace, as
subsequently, with regard to the belt mode of building. Its height
has, at different times, varied from 20 to 70 feet; and its
diameter, at the bodies, or widdell part, from 8 to 15 feet. It will be easy to trace the source of this
indefinite mode of construction, and the uncertainty which
must necessarily pervade operations of so much risk and
importance.

At the time when charcoal of wood was the common, and
indeed, the only fuel used in the bluff furnace, the volume
and extent of the bluff were proportioned to the very imper-
fect state of the blowing machinery. Long experience had
taught the manufacturer what were the proper size and
dimensions of his furnace. Many of them were from 12 to
18 feet high, and some of them, where a good water wheel
bluff existed, reached as far as 28 feet in height.

When pinecoal was introduced into the bluff furnace, in the
state of coke, to produce similar effects to the charcoal of
wood, it was soon found, that in furnaces of equal capacity
and height the same effects could not be produced. The
ore required to remain in contact with the ignited fuel for a
longer space of time, in order, unquestionably, to produce, by
attended contact, what was deficient in temperature, for
the saturation of the ore with coaly matter. This would
immediately suggest an increase of the height of the bluff-
furnace; and if beneficial effects once resulted from a step of
this nature, it became a matter of difficulty to say where
the progress of height would stop.

Hence, in a few years, arose furnaces of 50, 50, and
70 feet in height. Of the last dimensions, one was erected
in Wales. The size of the artificial crater was such, that
the strength of the bluff was scarcely sufficient to keep the
existence of flame visible at the furnace top. After in vain
endeavouring to ignite the immense body of materials con-
tained in its vault capacity, the height of the furnace was re-
duced 90 feet by cutting a hole in its side, narrowing the
mouth, and throwing in the materials at the height of 40,
in place of 70, feet from the furnace bottom. This was at-
tended.
tended with success, and the operations of the furnace proceeded with their usual facility.

After the application of steam-engines to raise and condense air, the quantity and strength of the blast became more a mechanical property in the hands of the manufacturer. It was soon discovered that an increased volume of air, by exciting a much higher temperature throughout the furnace, constituted the immediate action of those affinities, which the tall furnace accomplished by a long attenuated contact, and that iron equally carbonated and fitted for the purpose of melting, could be produced by 30 hours contact, as in four days.

The consequence of these gradual discoveries was a general predilection in favour of small furnaces, and at present the bias of the manufacturer leans inclined to this extreme. Where the maximum will be found it is difficult to conjecture, for the ground which the manufacturer now occupies is materially altered from what it was when working with coke was first introduced. The perfection to which the blowing machine has attained, forms a striking contrast to the feeble and diminished effects of the bellows in the infancy of the trade. So far as the necessary affinity is increased, and more instantaneous produced in high temperatures, than in those inferior, the manufacturer is differently circumstanced, and commands an extent of means unknown to him in former times. That this superiority will produce equivalent effects in the modification of the blast-furnace, requires but little demonstration. Two facts illustrative of this may, however, be mentioned. Cast-steel has of late years been formed directly from bar-iron, by a process which only requires an hour or two to complete, and with small quantities of matter the same may be performed in a few minutes. This is effected by presenting the carbonaceous matter to the iron at a melting temperature. In the usual mode of cementation, blistered steel, by a more attenuated contact and inferior temperature, requires six or seven days to complete, what is here produced in two hours. The difference of temperature in the two operations is equal to 62° or 70° of Wedgewood. The first operation will be considerably shortened, if the cast steel is required to hold much carbon; but if this requisite is necessary in the blistered steel, the length of the cementation must necessarily be protracted. Again, a piece of malleable iron may, by presenting it with a proper dose of carbon, at a high temperature, be converted, in a few minutes, into a mass of the richest carbonated cast-iron, which, in a temperature inferior, would have required several months.

The same facts will apply, in part, to the manufacture of pig-iron in the blast-furnace; but an unanimity of opinion and action on this subject is precluded, as well by the prejudices of individuals, as from circumstances arising out of the nature of the materials operated upon in different places.

A furnace has lately been tried at Muirkirk in Scotland, only eight feet diameter across the boxes, in place of its former dimensions, which were ten feet, and 40 feet high. It was soon found, that with the same volume of blast which was formerly applied to the ten feet furnaces, very inferior effects were now produced. The combustion apparently was carried to too great an extent, and the materials, owing to this circumstance, entered into fusion before the iron had acquired a sufficient dose of the coal. Another great evil which resulted from this diminution of diameter, was a friction, or retardation of the descent of the materials upon the lining of the furnace. This evil was increased and the materials made more boyant, by the usual volume of air elevating itself in a cove not much more than half its former area. The consequences were, that the whole mixture of coke, iron-ore, and limestone, would have frequently hung for an hour together, or until the blast had cut all the hearth and boshe clear of materials, a slip would have then ensued, and brought with it a large proportion of newly introduced matter. The introduction of this into the fusing point before being properly heated, and long before any affinity had been established between the particles of metal and the carbon of the furnace, invariably changed the quality of the metal, and caused frequent and sudden alterations from grey to white iron.

Upon the subject of height and width of blast furnaces, it may be finally remarked, that the average height in Britain may be taken at forty feet from the upper surface of the hearth bottom, eleven feet diameter at the greatest width or boshe, and three feet and a half for the diameter of the tunnel-head, or furnace-mouth.

If the proportions of height and diameter in the dimensions of the blast-furnace have given rise to a multiplicity of opinions, the internal structure and shape of the cavity have been no less an amble field for speculation and prejudice. At one time this was conceived to be essential to the success of iron-making, that any particular furnace that had made a fortunate run of quantity and quality, was copied with the greatest accuracy of design. This fortunate iron-founder ingeniously attributed to the mechanism of his contrivance the rich and superior harvest he had reaped in metal, and, or fancied he saw, in the curvature of a line, or in the inclination of a slope, the talisman of his good fortune. By prolonging the one, or depressing the other, he immediately inferred that still superior effects would be produced, and that by obtaining the perfection of art in the mere fabrication of structure, every thing that was great and powerful would ensue. This rage continued for many years, and gave rise to an endless variety of shapes, many of which, in their eventual success, had only the merit of originality to boast.

In the establishment of this important and national manufacture, the great fluctuation of opinion as to structure seems to have been the prelude to a subfusc into approved forms, founded upon general principles; and though we may now smile at the indiscernible forms which our predecessors, or even contemporaries, annexed to the blast-furnace, yet these alterations of shape and structure lay the strongest claim to our respect and gratitude. The path is now opened, and the ground already beat; from the labours of those who have already gone before us, result the happiest effects; we proceed towards our object, free from the interruption which inexperience always entails; and we may now, by the direct application of principle, perfect with facility what may still be deemed delirant in this important branch.

The varieties of shape which custom and experiment, from time to time, had annexed to the blast-furnace, may be classified under four distinct kinds. Plate VII. and VIII. The following description, characterizing the resulting properties and dimensions in the form of each class, will be necessary for comprehending the subject thoroughly.

Plate VII. fig. 1. is the vertical section of the blast-furnace cut across the top of the boxes; the internal shape entirely conical; the external figure a quadrangular pyramid. The construction of this furnace is truly singular; and from this alone great advantages were expected to result. The originality of the principle consists in the double figure, or throat. One immediately above the hearth, not represented in this figure, but similar to the square in Plate IX. fig. 1. B; and another half way up the cone, four feet in diameter; see A.
Blast.

B, the top of the boles, 12 feet in diameter.
C, an inferior diameter of 10 feet, previous to the formation of the throat at A.
D, the top of the second row of boles, of the same diameter as B.
E, the furnace mouth, or termination of the second cone, four feet diameter, and proportioned to A.
F, funnel top for carrying off the flame occasioned by the blast, so as not to interfere with the workmen in filling the furnace.

The dimensions, as to height, are as follow:

From B to C
C to A
A to D
D to E
Height of the hearth, and first row of boles, not shown in the figure, but being the same
Height of the bottom flones, packing, and tafle bottoms,

Total height of this furnace from the foundation 50 feet.
G, fire brick lining.
h, space left for packing.
I, the common building either of sand-flone, or of bricks.

Fig. 1. plan and section of the same furnace taken across the boles at B.

AAAA, square of the common building 29 feet upon the side, bound by EEEEEBB, eight cast-iron binders; the number or heat of these requisite, being proportioned, both in strength and dimensions, to the height of the furnace. In common, a full binder is applied every five feet in the height.
The concentric circles represent the various diameters of the interior of the furnace, and are connected each by dotted lines, with their respective places in the elevation.
The reasoning which we believe led to the construction of this furnace, proceeded from a firm belief that the boles and throat, or square of a blast-furnace were of the greatest importance on two accounts. First, because they supported the weight of the materials; and secondly, because they concentrated the heat. These acting conjointly, permitted the least possible quantity of materials to pass, till they dropt away in a state of demifions, or complete separation. In furnaces, however, the cones of which were 20 feet high and upwards, this was conceived impossible to take place for any length of time, to any considerable extent. The height and gravitating pressure of the materials were more than sufficient to counteract the most favourable construction of the boles; and as this could not admit of diminution, the suspension of the materials, and the concentration of the heat must be effected by some other means. This, at one time, was believed to have been completely effected by the scheme of an additional square, and an extra jet of boles; and there is little doubt but that, by converting perpendicular to lateral preasure, the suspension of the materials was reduced at least to one half of its former intensity.

It was not doubted but that the procefs of smelting and separation would commence, in part, at A; that what escaped fusion and separation in that quarter, would be easily resolved below; and that the procefs of combustion intensify at work in two different places at once, would greatly facilitate the general reduction, and add greatly to the produce in iron of the furnace. These fanguine expectations were unfortunately never realized, the solitary instance of one furnace only being constructed in defence of this theory, and that only for a very temporary endurance, is the best proof of the utterity of the plan.

Fig. 2. is the elevated section of a blast-furnace, of which several were built, and from which it was at one time conceived that the greatest advantages were derived. The numerous minute gradations of diameter exhibited in the construction of this furnace, were at one time held in high estimation by many iron-makers; and a plan of the present furnace circulated from the domains of the lucky projectors, with as much care and conscientiousness of rich acquisition, as an antiquary would remove from Herculaneum or Egypt, the precious remains of antiquated obtuseness.

It will be extremely easy to trace to its source this particular bias to form, so universally believed in at one time, but now confided to that oblivion which experience has taught us it deserved at a much earlier period.

It often happens, that when repairing or relining a blast-furnace, the manufacturer avails himself of the time thus obtained, to overhaul and repair his engine and blowing machine. The former movements of the machinery may have discovered to him many errors both in movement and construction, which the constant requisite motion rendered impracticable for him sooner to remove. In this way, considerable improvements on the engine and blowing apparatus are frequently made; and when again in motion, may, by increasing the length and number of the strokes in a given time, or by conferring a higher additional working power on the beam plos, increase at the same time both the volume and density of the blast. If the produce of the furnace is increased, which is highly probable will be the case, then the superior effects are attributed to a few important circles and lines added to the interior of the cone, the acuteneb and proportion of which do not survive the blowing of the furnace three days.

In like manner, if a works entirely new, commence operations with a greater advantage of blowing power, and with something original in the shape of the furnace, the consequent effects of the former are indubitably attributed to the fortunate construction of the latter, and the grand essential blast is entirely overlooked, and its next important associates coal and iron-flone.

The dimensions of the present furnace are as follow:

<table>

From G to F, the distance in height measures 1 foot.

Increase of diameter - 1 foot
Diminution of diameter - 1 foot
Diminution of diameter - 6 inches
Diminution of diameter - 1 foot
Diminution of diameter - 1 foot
Diminution of diameter - 4 1/2
Diminution of diameter - 1

Height of the hearth and boles not represented in the plate - 13
Total height of the cavity of the furnace or place occupied by the materials - 40 feet.
The former descriptions will suffice and apply to this plate.
BLAST.

Plate, with equal propriety as to the former, regarding the lining, packing, common building, &c.

Fig. 4 is a plan and section of the same furnace at F in the elevation.

The inner circles represent the various diameters of the interior of the cone, the letters in each corresponding. The two external circles describe the packing and lining; and the circle N exhibits the circumference of the common building of the furnace, which, at this particular section, is 26 feet in diameter.

Plate VIII. fig. 1, is the elevation of the interior of a furnace of a plain construction, and at one time very prevalent at founderies. This fashion was deemed to polish its peculiar merits, and still maintains its form unaltered at some ironworks where the regular tapering cone is not yet admitted. Its inferiority, as to height, is amply made up by an enlarged capacity arising from its diameter.

Diameter at the mouth of the cone A - 3 feet
ditto at B - 11

ditto at the boffles C - 12

Height from C to B - - - 12 feet

from B to A - - - 14

Height of the boffles and hearth not represented in the figure - - - 11

Total height of that part of the furnace occupied by the materials - 37 feet

FF, represents a view of the vertical method of carrying off the moisture and stem from the mass of building, by means of vents. The number of upright flues vary from four to eight, and have regular communications by means of horizontal openings with the external air, GG. They are generally carried up parallel to the lining, and incline with the general diminution of the cone. The former, or vertical openings, are six inches square, and the horizontal communications four inches square.

Fig. 2. is a plan and section of fig. 1, in which are represented the lining, the vacancy for packing, and eight vents or openings corresponding to those in the elevation. The letters in each figure correspond, and the two dotted circles are meant to show, that occasionally all the vents communicate with each other by means of a horizontal gutter or channel, carried quite round the building. This precaution is used left any of the tubes were to fill up and choke the free circulation of the vapour, that its appropriate quantity may get easily discharged amongst the other openings.

Fig. 3. is an elevated section of a furnace, the interior shape of which has now almost become universal. The regular and uniform deflect of the materials which follows, as a consequence of the gradual enlargement of the cone, fully justifies the general partiality in favour of this shape.

Diameter at the mouth, or opening A - 3 feet

Diameter at the top of the boffles B - 10

The height from B to A - - 31 1/2

Height of the hearth and boffles not seen in the plate - 11 1/2

Total height of this furnace - 43 feet.

This form of furnace is not only constructed with a double lining of fire bricks CCCC, and two openings for introducing land for packing bbb, but has also an opening DD, from top to bottom, about the centre of the common building. From this, in all directions, proceed small vents, which communicate at a short distance with the open air, as may be seen along the sides of the building.

Fig. 4. is a plan and section of fig. 3, cut across at B.

B, diameter over at the boffles 10 feet.

CCCC, the two circles of fire brick-lining, as seen in the elevation.

bbbb, spaces for receiving packing.

DD, circular vent, or general gutter, from which ramify the horizontal openings.

These are repeated at intervals of four feet in the height, as may be seen in the elevation. In building, DD is filled with fragments of soft sand-flame, which are easily reduced in the expansion of the furnace, and tend, by diverting its real pretence, to preserve the body of the building entire.

A similar want of unanimity of opinion subsists among iron-makers, relative to the general construction of the boffles, their particular height, and most beneficial range. Some contend for flat, others for boffles more vertical, while others again conceive the exertions of those equally faced full, who adopt the mean of the two extremes. At different places, and to every possible range, have been attributed the most important consequences in the subsequent process.

Plate IX. fig. 1, represents boffles of the deepest construction.

Diameter at A - - 10 feet

Perpendicular height from B to A - 8

Square at B - - 2 1/2

The opinion relative to this form, is, that at first blowing, the boffles are promotive of a very proper degree of expansion of the materials; but as the pressure of the deficient bears in every direction upon the under or bottom part next the square at B, it becomes increased so much, that the weight of the incumbent materials early begins to press too much towards the bottom of the hearth, counteract the regular precipitation which should take place, and impede the ascent and full effect of the blast.

Fig. 4. is a section of boffles approaching to, or indeed may be considered as the opposite extreme. Here the reverse of the fact attributable to No. 1 takes place. The pressure of the descending material is equally distributed over the very flat inclination of the boffles, and there is no more weight deemed to be on the square at A than is equal to a full column of the materials of similar dimensions, left by the direct tendency which the strength of the blast to keep them in a state of partial buoyancy. To counteract these advantages in part, very serious defects are here also imputed. If circumstances unite to increase the tear and wear at A in any uncommon ratio, either by scouring, or from a deficiency in the quality of the stone or bricks, the whole of the upper part of the hearth at BB is immediately exposed, and, though composed of a superior quality of sand, will soon follow the direction of the descending current. A pressure of materials then takes place, equal to the whole of the increased space, while the effect of the blast to bear them up is considerably diminished by the enlargement of the original diameter. It will be seen from the plate that the weakens of flat boffles at the top is ill calculated to withstand any accumulating pressure, and that by confining their part of the procés to the hearth, the latter must soon, by a similar widening, be entirely destroyed.

Those who wish to flee clear of extremes, or profit by the more adventurous spirit of their neighbours, more generally adopt a mode of boffling that occupies the mean of the two former extremes. This is represented by fig. 3.

Diameter of the boffles at A - - 10 feet

Perpendicular height from B to A - 5

Diameter of the square B - - 2 1/2

In general, the boffles of blast furnaces are made of the same kind of stone with the hearth, but of late fire bricks have been introduced with a considerable indication of advantage and
and permanency. When bricks are used, it is found of utility to make the whole part of the building solid, back as far as the external figure of the hearth, so that if the boles fail in part as to displace one layer of bricks, another fur-
face, equally fresh and entire as the former, presents itself to the action of the fire.

Fig. 2. Ground plan of the top of the boles of fig. 1. AA and BB correspond to the same letters in the elevation. The dotted square C describes the form and dimensions of that part of the hearth immediately above the tuyere, as seen in the elevation CC. The large dotted square DD is the external size of the hearth, as seen also in the elevation DD.

Fig. 4. While we prosecute the detail and history of the con-
struction of the blast furnace, the fame diversity of plans formerly noticed comes under review, in every department of the erection. The importance of the hearth is admitted by every clafs of reasoners upon this subject; and to devise a form better calculated for melting than another, has been an object of general concern with the manufacturer. Much as may be deemed to depend upon its form and construction, infinitely more benefit is derived from a proper quality of stone, to fulfill for a given length of time the powerful effects of a continued and unremitting blast. To both of these impor-
tant defects much of the manufacturer's attention has been from time to time directed.

The first singularity that strikes us forcibly in the figure of the hearth, is, that in place of being circular, like the upper parts of the furnace, it is constructed of a square funnel-form, with angles as acute as represented in Plate IX. fig. 1. This narrowing form is continued on three sides of the square to the bottom of the hearth, where it generally measures from 22 inches to 24 inches. The top of the hearth, at BB, fig. 1. and 4. or as it is commonly called the square, is never less than 30 inches, nor more than 33. The height of the hearth from E to B, Plate IX. fig. 1. 2. and 3. While some approve, more are ready to con-
demn a measure, which has for its object the enlargement of a space before blowing, which too speedily becomes to afterwards. There cannot, however, be any objection to the circular, in place of the square form, unless a little additional workmanship is indulged as such. The matter rests with experience, accompanied by accurate observation, to prove the fanguine hopes of the projector, or falsify the prophetic forebodings of those who now condemn the measure. The amount of our progress hitherto, in the making of pig-iron, is ascertained with certainty; to assign limits to its ultimate bounds would be presumption. Of one fact, however, we may rest assured, that the perfection of the blast engine, and the consequent command of blast, has alone done more for the manufacture of this article, than all those nice shades of distinction as to furnace taken collectively, which relieve each other in a succeffive train of minute gradation from one extreme to the other; to all, or to most of which, the most wonderful effects have been from time to time ascribed.

One subject of confidrable importance still remains to be discufed, relative to the construction of the blast furnace; namely, the absolute and relative heights of the tuyeres, the dam-flone, and tymy.

On the subject of tuyeres, the general opinion is, that the nearer the cinder the blast is introduced, the greater is the effect as to the absolute quantity of reduction. But this may be productive of consequences more than sufficient to counterbalance the doubtful advantage of accelerated reduction, either by blowing the cinder off the surface of the iron, and de-carbonizing it, or by the cinder rushing back through the blow-pipe at any stop of the blowing machine, and destroying the leather bag which connects the blow-pipe with the main laying pipes. This never happens
BLAST.

happens but a considerable portion of time is sacrificed, besides the expence of the bag.

In common, the surface of the tuyere plate is laid eight inches above the cinder, or, which is the same thing, above the level of the dam-flone. Some blow at a distance of four inches, others at six and eight, and some again as high as twelve and fourteen inches. However, under some circumstances, the height of the tuyere is determined by the nature of the materials. In these cases, if the tuyere is only raised one inch above its proper height, the bottom of the furnace jumps up immediately, and will invariably rise in the same progressive manner in which the tuyere is heightened.

Plate X. fig. 1. represents the relative proportions of height between the dam, tuyere, and tymph, in ordinary cases.

G, the dam, or notch of the dam plate, 17 inches above the level of the bottom at H.

I, the centre of the tuyere 25/4 inches from the surface of the bottom, and 9 1/2 inches above the level of the dam.

K, the bottom of the tymph plate, 25 inches from the bottom of the furnace, and 6 inches above the level of the dam.

At iron-works, where different opinions exist as to the proper or working height of the dam, very different relative heights ensue, regarding the tymph and tuyere. The former should always regulate the other two. The height of it is seldom used less than 16 inches, nor more than 28 above the bottom.

Considerable advantages result from placing the tuyere, as to its horizontal position, at a judicious distance from the front or back wall. This is, as in the case of height often regulated by the nature of the materials. If the furnace, owing to this circumstance, tends to work cold and languid behind, with a propensity to lump at the back wall, the blow-pipe ought to be directed as near to the extremity of the hearth backwards as is possible to get in the tuyere iron; Fig. 4. Plate X. letter a; but where the operations of the furnace proceed with ease and facility, the centre of the tuyere should more generally approach the centre of the hearth, as at b.

Of late years a new mode of blowing has been introduced, which, from its great prevalence and good effects, seems to bid fair to come into general use. Furnaces till lately were only erected with one arch, or tuyere fide, and the blait or column of air introduced by means of one blow-pipe; now most of the new furnaces are built with double tuyeres, with two fets of main conducting pipes, and the blait introduced by means of two pipes in place of one.

The general effects and supposed properties of this mode of blowing are attended to under the article blast.

In the mean time, the proper height and distance of the tuyeres, and their relative position to each other, have been subject to endless disputation. Fig. 4. Plate X. a and b show how, in common cases, the tuyeres are placed to each other in their horizontal range: a is placed with its centre three inches from the extremity or back wall of the furnace, and b at the distance of nine inches from its centre. That there should be a difference of distance in their horizontal position none are inclined to dispute; but that this should take place in their vertical situation, is so contended, while others insist that the difference ought never to be less than four inches. Fig. 6. Plate IX. cc.

Some less fastidious appear, and with many evidences of sound reasoning on their side, that if the blast is introduced into the furnace, and at a proper distance, to keep the back wall clear, those nice distinctions as to inches go for nothing, in a region where an instantaneous increase of volume must destroy all repulsion or mechanical contact. This philosophical reason is flatly denied, and the contrary minutely and gravely asserted, that there were two pipes placed every way immediately opposite to each other, the action of the opposite columns would retard the velocity of the air, and diminish the real elevated quantity in the furnace, by locking up in mutual opposition a portion of their respective quantities in the laying pipes. There might be some foundation for this conjecture, were the respective nozzles or blow-pipes brought into actual contact, or inserted into each other; but to those who consider, that in molf furnaces there is never less than four feet of distance between nozzle and nozzle, and the molten of the intervening space filled with a column of semifluid materials, ignited to the highest pitch of whiteness, this supposition will appear to roll upon very unsatisfactory grounds.

A less scrupulous class of observers and reasoners upon this subject even go the length to assert, that the tuyeres ought to be put in direct opposition, and that this, so far from being detrimental, would be found to possess unequalled advantages. This it is laid would result from a certain degree of coolness which the extremity of each column of air confers upon its opposite tuyere iron, and prevent the flame from heating and burning. To whatever cause it is attributable, the fact stands in many instances, unquestioned, that not half the tuyeres are lost or burnt out, with the double blast, that was formerly destroyed, where the single blast was in use.

Fig. 7. Plate X. represents a tuyere iron, 16 inches wide, and 12 inches high at the wide end, 18 inches long and narrowing at the other end to 4 inches wide, and 4/5 inches in height. Fig. 6. is a plan of the under surface of the tuyere iron. Fig. 5. represents the size and dimensions of the tuyere plate, which when bedded receives upon its surface the tuyere iron, Fig. 7. This plate is first laid upon a bed of fire clay, with its narrow end towards the hearth, and inclined to rise a little. The tuyere is then introduced upon its surface, height and distance being attended to in the disposition of the plate, and the space between its surface, and the sand-flone of the furnace, rammed very perfectly with balls of good fire-clay mixed with small fragments of fire bricks. When about to blow, the noke or inner end of the tuyere is covered with a very plastic clay, to prevent it from heating and burning away. This is always carefully attended to, and the blast put off at any time to replace it. Should it be neglected at any time, the iron would inflame with such rapidity, that an opening would be instantly made, by which the cokes and ignited matter of the furnace would be recalled with the greatest violence imaginable.

Fig. 2. Plate XIX. The dam-flone. This is actually the dam, or barrier, which prevents the fluid contents of the furnace from advancing, and making their escape into the sand of the casting house. It is generally made from the same flone as the hearth, but is found still more difficult to sand for and length of time the action of the fluid iron, than the hearth to resist the ravages of the blast.

Fig. 3. dam plate. This is laid against the dam flone with a bed of fire clay interposing, and closes the front of the furnace. Its form is double, so that by turning it serves the purpose twice. It often fails, owing to the constant current of lava passing over the curvature a, and deepening it, till the iron flows over along with the cinder.

Fig. 4. the tymph plate. This embraces the under end of the tymph flone, and the fides of the hearth for three feet up. The thickness at bottom, called the heel, or cod, is preferred from the action of the fire by a strong tappin of clay. This
This is replaced at least every cast, and prevents the flame and heated materials of the furnace from being blown forward.

Plate IX. fig. A, is a ground plan of the arch pillars, hearths, tuyeres, and vents of a blast furnace.

A, the hearth, or particular spot where the fluid metal is collected.

D, the dam-flone.

e, the fall, or opening, by which the metal is discharged.

After the cast it is filled with sand, which soon hardens and presents a very close texture to the fluid metal within. At the following cast it is cut carefully down, till the bar penetrates to the quick. A circular incision is then made, and the metal flows out of the orifice in a connected round stream, into the runner or channel made in the sand.

'd d d', four vents or openings which communicate with the false bottoms. Plate I. fig. 2. These serve to convey the damp from the furnace bottom, and by being run out into the external air, two in the front of the hearth, and one at each tuyere, indicate by their temperature, and the quantity of flashes or vapour which they emit, the real state of the bottom below.

D D, the two pillars which support the front arch; they, at the same time, serve as abutments to one leg of each of the tuyere arches. The arch at the front is 15 feet wide and 15 feet high, and inclines to the centre of the furnace, in the same manner as the side walls of the pillars approach.

E, main or back pillar built entirely solid.

FF, vent holes six inches square, carried up from the foundation, and brought forward to meet the open air every four or five feet.

G G G G G, tops of the pillars covered with cast iron plates, for receiving three large cast iron lintels, 10 feet long, and 10 inches square. These serve to give solidity to the arch, and support the lining and boles of the furnace. Fig. 8, 9, different forms of tuyere pipes.

BLAST. Furnace.—History of its Origin and Progress.

In detailing the progressive history of the blast furnaces, it is necessary to premise, that in this country it has undergone a revolution, of which we meet with no similar influence in other countries.

The most natural and abundant fuel which presents itself to mankind in their progress toward civilization, is that furnished by the numerous and extensive forests, which generally occupy the surface of a wide and uncultivated country. These, in the history of all nations, have been early appointed to domestic uses, and to the comfort of individuals. As a country became more populous, and the spirit of civilization increased, other advantages resulted from the general use of wood as fuel. The amelioration of climate, and the clearing of large tracts of land, making it subservient to the purposes of agriculture, were not the smallest benefits thus derived. As the progress of knowledge began to deviate and establish regular manufactories, to supply the wants of the thriving community, the same sources of combination were opened to the manufacturer and the artisan. These, as they became facieous, were only preludies to other establishments more extensive, more lucrative, and entailing more difficult to supply. Among others the smelting of metals was no doubt of early origin, and equally dependent upon the woodland countries, in the immediate neighbourhood of the ores. In this class we can trace no metallurgical operation fo hostile to the existence of wood, as an extensive manufacture of iron. If this manufacture, owing to the great and unexampled prosperity of the country, in place of remaining stationary, or exhibiting symptoms of decline, arising from a want of consumption of the article, has increased in capital, in extent, and riches beyond all precedent, wood, the bale of the manipulation itself, depending only upon a stock rapidly declining, the existence of which was frequently incompatible with the views and interests of the landed proprietors, must soon have been annihilated, and the art of making iron lost to the community.

In this singular situation was Great Britain placed from the reign of Charles II. to the middle of the last century. The increasing manufactures, commerce and general prosperity of the country called for an additional supply of articles fabricated from iron, while wood, the foundation of the whole art, was rapidly declining in point of quantity, without the least diminution of profit; and even being renewed. Pit coal had been long before the latter period suggested as a substitute, but prejudice, interred views of established capitalists, and above all, a want of command of mechanical power, had prevented any successful operation from being established in this new department of iron making. No sooner, however, were these barriers to improvement broken through, and a change of fuel in the blast furnace found to be attended with profitable effects, than the languishing state of the trade began to revive, and improvements succeeded each other, with a facility new and astonishing. In fifty years the revolution was complete whether the consideration regards the increase of the manufacture, the general use of pit coal in the blast furnace, or the almost total annihilation of the charcoal mode of making iron.

It is uncertain at what period the manufacture of iron commenced in Britain. It is probable, that the working of the tin mines of Cornwall, by the Phoenicians, would introduce into the country a class of men skilled in all that then known metallic ores, capable of appreciating their true value, by converting the riches of an unexplored country, either to their own immediate necessities, or to the conveniences of the skilful inhabitants. The invasion of England by the Danes, and their consequent establishment, would most likely add to the former stock of knowledge, in the art of mining and fusing iron ores. Whatever truth there may be in this conjecture, the fact stands unquestioned, that in several counties in England large heaps of iron ore are found with an accumulation of soil sufficient to bear large trees. These have been from time immemorial called "Danes cinders." So early as 1620, Dudley remarks, that large oaks were then found in a state of decay upon the tops of some of these hills of iron. It is not, however, probable, that these cinders were the product of the blast furnace. At a period remote as that, wherein these heaps of iron ore must have been accumulated, the labours of the iron maker were chiefly directed to the fabrication of small portions of malleable iron in "black blast and bloomeries." The art of moulding and casting in iron was either totally unknown, or so very rude, as to excite no interdict in favour of profecting this fine branch of art. If pig or cast iron was at all formed, it was merely of the most unfeatural nature, for being speedily converted into malleable iron. It was not till long afterwards, when improvements had taken place in the rude machinery of the times, as a division of labour from the productive of many advantages, that different furnaces existed: one for the making of pig iron, and another for the conversion of it into malleable iron. This first gave rise to the blast furnace, which, properly speaking, was an improvement resulting from the knowledge of the advantages derived from a division of labour. After the appropriation of the blast furnace to the exclusive manufacture of pig iron, the manufacturer would soon discover, that the products of
This period of prejudice, so unfavourable to innovation in the iron business, was followed by one more general and more calamitous for the nation: amidst the distraction occasioned by civil war, neither innovation nor improvement could be expected. Patents, however, were granted to some during the common-wealth, for the exclusive manufacture in the new way, in one of which, it was at the time believed, that Cromwell was a partner: these partly shared the same fate with the first investor, and none succeeded in establishing a manufactory either of extent or certainty. In 1664, we find Dudley applying for his last patent, and setting forth, that at one time he was capable of producing seven tons of coke pig-iron weekly, with an improved furnace 27 feet square, and bellows, which one man could work for an hour without being much tired.

It was not, till impelled by necessity, arising from the rapid decline of the annual growth of timber, that pit-coal became an object of universal estimation. When improvements on machinery had attained a pitch of certainty, and experience had taught the mechanic the manifold advantages of the steam engine; the adventurous manufacturer found he possessed an extent of means to which he was formerly a stranger. Small furnaces, supplied with air from leatnorn bellows, blown by oxen, horfe, or human labour, became exploded, and an increase of size took place, together with an increafe of the column of blast necessary to excite comhition.

At this eventful era in the history of the blast furnace, when the ameliorating hand of agriculture was progressively sweeping before it, that remained of the once impenetrable tracts of woodland dedicated to the supply of the blast furnace; when the general improvement in machinery, and the introduction of the steam engine threatened to give new life and impulfe to manufactures in general, the iron business seemed dwindling into insignificance and contempt. The demand of the country increafed for the manufactured article, particularly bar-iron, while every year faw a gradual but steady diminution of the annual quantity. Recourse to foreign markets was had for a supply of that article, of which this country once was the greatest exporter, and the immense annual importations from Russia and Sweden may date their origin from that period. The flourishing and extensive detail of Dudley no longer existed, and the 500 blast furnaces of his day were now diminished to 39 in all; the total amount of whose annual produce was 17,350 tons, or nearly 300 tons to each furnace.

LIST of the Blast Furnaces in England and Wales immediately before the introduction of pit-coal, as a substitute for the charcoal of wood; the particular counties in which they were situated; the collective quantity of iron manufactured in each county, and the produce of each particular blast furnace.

Furnaces 59 17350

Annual average for each furnace 294. 1 1

By this statement it is evident, that the manufacture of pig-iron had diminished during one hundred to one hundred and thirty years preceding, upwards of 50,000 tons annually. Fortunately for the defence of the trade, the application of good going, and what, at that time, would be reckoned powerful, steam engines, about the year 1750, for raising and compresembling air, were introduced at some places where abundance of materials was found without water for turning machinery. The manufacturer now found that his produce could be increased by enlarging the diameter of his steam cylinder, or perfecting the vacuum under the piston; and it was soon discovered, that these increased effects alone were requisite to the formation of pig-iron, in profitable quantity from the coke of pit-coal; nor is it to be wondered that this secret remained for a long time a mystery. The small quantity of air that was formerly requisite to ignite a charcoal furnace, whether from the great inflammability of the fuel, or the smallness of its capacity, was constantly before the eyes of the manufacturer. He had more often felt the effects of over-blowing, than under-blowing his furnace; and it is highly probable, that pit-coal, being deemed every way inferior,
inferior, an unusual timidity would precede any movement that might have for its object the enlargement of the column of air or the increase of its density.

This, however, once done away, there seemed no end to the quantity of air that a coke blast furnace could with propriety receive before any bad consequences ensued. Density, however, was found inimical to quantity, and the same law was at last discovered to hold good regarding pig-coal as with wood, that the softer qualities could be over-blown, while the more dense and compact strata remained undiminished before a heavier blast.

The celebrated foundery of Carron was begun about the year 1760, and as was the custom of the times, the operation of blowing was performed by large bellows moved by means of a water-wheel. Pit-coal was the staple fuel in view, but the scanty supply of air, and its want of density, seldom permitted the produce of the furnace to exceed 10 or 12 tons weekly, and frequently in summer, the quantity was reduced even below this. The company collected immense quantities of charcoal wood, and found their blast much better calculated for the operation of smelting with it, than the unflammable pit-coal obtained in their neighbourhood.

Experience, however, gradually unfolded means of adopting machinery, more calculated to the nature of the coal fuel, more powerful wheels were constructed, the bellows was abandoned, and in their place large iron cylinders were introduced blowing both up and down. A larger column of air of triple or quadruple density was obtained, and effects equivalent to the great improvements followed at the blast furnaces. The same furnaces that formerly yielded 10 and 12 tons weekly, now sometimes produced 42 tons in the same space, and on the average in one year not less than 1,500 tons of metal.

From the period (1750 to 1760) that pit-coal coke was applied as a substitute for wood charcoal in the blast furnace, the iron trade began immediately to revive, and its progress in England and Wales, in a period of 30 years, was truly astonishing. The general use of pit-coal, most unquestionably, occasioned an earlier relinquishment of many of the charcoal works, than would have otherwise been the case, but the collective manufacture had so much increased, as to render this an object of trifling importance.

The following is a correct statement of the annual manufacture of pig-iron in England and Wales in the year 1788:

| Charcoal Blast Furnaces | No. of Furnaces | Tons at each | Total in each | County |
|-------------------------|----------------|-------------|---------------|
| Gloucestershire         | 4              | 650         | 2,600         |
| Monmouthshire           | 3              | 700         | 2,100         |
| Glamorganshire          | 3              | 600         | 1,800         |
| Carmarthenshire         | 1              | 400         | 400           |
| Merioneth               | 1              | 400         | 400           |
| Shropshire              | 3              | 600         | 1,800         |
| Derbyshire              | 1              | 300         | 300           |
| Yorkhire                | 1              | 600         | 600           |
| Wemford                 | 1              | 400         | 400           |
| Cumberland              | 1              | 300         | 300           |
| Lancaithire             | 3              | 700         | 2,100         |
| Saffey                  | 2              | 150         | 300           |

Total of charcoal furnaces 24. 131,000

Average produce from each furnace 545 cwt. qr.
Former average produce 264 4 1

Increased produce per furnace, from the year 1750 to 1788, attributable entirely to the general improvement of machinery, and the introduction of the steam engine, 251 tons, 15 cwt. 2 qr.

About the year 1750 the annual quantity of charcoal pig-iron manufactured in England and Wales amounted to 17,350 tons.
In 1788 the same was 131,000 tons.
Decrease in charcoal iron between 1750 and 1788 4,270.

attributable chiefly to the decrease of wood, but also in part owing to the use of pit-coal as a substitute in the furnaces.

Coke Pig Blast Furnaces in 1786.

Total quantity of pig-iron manufactured in Scotland 8,700 tons.
Average produce for each furnace annually 875 tons.
Total quantity of pig-iron made in England and Wales 77,613,000.
Annual quantity manufactured immediately preceding the introduction of pit-coal for furnace fuel 85,683,300.
Annual increase in 30 years 26,500,950.

The period of 1788 or 1790 may be called a new era in the manufacturing of pig-iron. The double power engine of Mr. Watt had now become more general, and was used yearly.
yearly finding its way into blast furnace works. The regular and increased effects of this very powerful machine were soon felt in most of the iron counties. The produce of the furnaces in metal greatly increased as to quantity, and as they became more prosperous, stimulated others to engage in similar undertakings. New works were yearly projected, and several blowing furnaces annually added to the former list; so that in eight years the manufacture of pig-iron had nearly doubled itself.

The following table is a curious illustration of this fact. It was drawn up as an authentic document of the returns made from all the blast furnace proprietors in Britain, of the number of their furnaces, and the annual quantity of pig-iron manufactured at their respective foundries. These returns were made at a time when it was in the contemplation of the legislature to impose a tax upon pig-iron, and are copied from Dr. M’Nab’s letter to the chairman of the committee of the house of commons upon the subject of the coal trade.

Average Produce of each of the English and Welsh furnaces, 1048 Tons per Annum.
Ditto of each of the Scotch Furnaces, 946 Tons per Annum.
The demand for iron articles of all kinds in this country not only continued unabated after the period of 1796, but kept increasing in a greater ratio than formerly; so that in the short space of five years, situations were occupied for nearly 50 additional furnaces, or additions made to established works of that extent. Between 1801 and 1802, it was ascertained that the following new furnaces were either building or actually in blast, in England, Wales and Scotland.

The respective proportions of this astonishing produce in pig iron manufactured in England and Wales, and in Scotland, will stand thus:

England and Wales, in 1796, 104 tons, 16,086.
Ditto, since that period, 40,000.
Scotland, in 1796, 17 tons, 16,086.
Ditto, since that period, 7,000.

Grand Total in Britain, 168 making 172,079 tons.

In recapitulating the interesting facts which will result from a review of the gigantic progress of this manufacture, the regular progressive quantity made at a furnace is remarkable, or, which is the same, a diminution of the number of furnaces to perform the same quantity of labour.

Dudley represents, that in his day, 1620, there existed, in England and Wales alone, 300 blast furnaces, for the sole making of pig-iron, to each of these have been assigned the yearly produce of 250 tons.

At a period considerably after this, and before the use of pit-coal was found profitable in the furnace, 50 furnaces produced yearly 17,350 tons of charcoal iron, or each furnace average, 347.

In 1788, there still existed in England 24 charcoal furnaces, which yearly manufactured 13,100 tons of metal, or from each furnace, on an average, 545.

At the same period, in England and Wales, 53 blast furnaces, at which coke was used, manufactured yearly 48,100 tons, which upon an average was nearly, from each furnace, 927.

The same year in Scotland, 8 furnaces produced 7,000 tons of iron, or from each furnace, 875.

In 1796, the number of furnaces in England and Wales amounted to 104, and yielded 180,993 tons of metal, which from each furnace was equal to 1,728.

The same year, in Scotland, 17 furnaces manufactured 16,086 tons of pig-iron, which is from each furnace, 946.

These are by no means sufficient data to form an accurate opinion of the real progress or improvement of our blowing machinery in Britain. In the collection of furnaces in 1796, a number of charcoal blairs were included, which, from their general small produce, blowing only four, six, or nine months a year, reduces the average considerably on the whole. It may now be safely asserted, that the average produce in iron at pit-coal blast furnaces in England and Wales, is at melting iron works, 1200 tons.

This bears a very striking contrast to the early exertions of the manufacturers in the sixteenth and seventeenth centuries, and exhibits a wonderful example of the general and rapid improvement of machinery in the last 50 years. With the improvements of machinery, the advancement of the manufacture of iron in general, and particularly of coke pig-iron, has kept equal pace. Nor have we sacrificed quality to quantity, but the reverse; for the melting pig-iron of our time is much more calculated for every variety of casting, than iron, equally saturated with the coaly principle, made with wood charcoal.

By comparing the value of a ton of pig-iron at different periods for the last 200 years, a pretty accurate opinion may be formed of the increased price of labour at iron works, and of the increased value of an object of universal utility in all our arts and manufactures.

About
BLAST.

About the year 1620, charcoal pig-iron sold for 6l. per ton. 1789, ditto for melting, 8l. 1798, ditto 9l. 10s.

Coal pig-iron, when first invented by Dudley, was sold at 12d. in 1788, it sold for 5l. 12s. 1798, ditto 9l. 10s.

And smooth-faced N° 1, sold at 9l. 10s. per ton, being double the rife in point of value in fourteen years that took place in the one hundred and seventy preceding the commencement of that period.

One thing is here worthy of remark, that in the period of 170 years one ton of coke pig-iron sold in value only 35s., i.e. between 1620 and 1788 but that in the short period of 14 years following 1788, an advance of 3l. per ton took place. One thing only may be offered in extenuation of that immense rife, that part of it was owing to the misunderstanding that took place between this country and some of the Baltic powers, which was no sooner adjusted than pig-iron fell in price. The article full, however, maintains itself at 8l. 10s. per ton, being double the rife in point of value in fourteen years that took place in the one hundred and seventy preceding the commencement of that period.

To point out proper channels, whereby to account for the annual consumption of such an immense quantity of raw materials, would prove a satisfactory source of information. The endless detail into which the foundry trade has now branched itself, the almost universal fabrication which it embraces, and the extensive diffusion of the sites of manufactories themselves, preclude the possibility of obtaining this with strict accuracy. The following statement, however, will tend to throw some light upon the subject.

It is reckoned, that the bar iron forges in British manufactured annually from pig-iron 40,000 tons of finished bars, which at the rate of 35 cwt. of pigs for every ton of iron bar produced, will account for 75,000 Tons.

Confirmed yearly in the creation of new furnaces, forges, machinery, &c.

Purchased by the board of ordnance in the flat of cannons, mortars, carabines, shot, and shells, &c. on an average of 1794, 5 l. 6 s. 10,935

Waste in melting from the pig, boring, &c. 1,300 12,235

Purchased by the navy board in the flat of baubles, &c. 2,664

India Company's annual supply in guns, shot, shells, carabines, &c. 5,000

Waste melting, boring, &c. 700 5,700

Merchant guns, carabones, shot, &c. for arming trading vessels 10,000

Waste in melting and boring 1,000 11,000

Ballast for Merchantmen and India men 5,000

Tons 111,599

For the difference between this and the total manufacture, recourse must be had to the large exportation to Ireland, and to the numerous and extensive casting foundries of London, Liverpool, Manchester, Birmingham, Workington, Newcastle, Edinburgh, Glasgow, &c. none of which melted under 2,000 tons yearly, and many of them from 4 to 5,000 tons of melting pig-iron.

We shall now leave this interesting subject with some general observations upon the origin and progress of the pig-iron manufacture, and its early use in the fabrication of callings.

It appears from Dudley, that towards the close of the reign of queen Elizabeth, blast furnaces had been constructed of size, and with machinery sufficient to produce upwards of two tons of charcoal iron per day. Such great products in iron were most probably confined to situations where there was abundance of water, and where water-wheels and bellows of a considerable magnitude were used. The more common modes of operation were confined to furnaces of an inferior size, which were supplied with air by means of hand-bellows, excited by cattle, or the labour of men. At the same period England enjoyed a considerable export trade, arising from her superior manufacture of iron guns, mortars, &c. As pig-iron had not been applied in any branch to the manufacturing of iron, it is probable, that these articles would be cast from the large blast furnaces; the flame of wood polishing but feeble effects compared to that of pig-iron, would render the application of the reverberating furnace, if then known, of no use in the casting of guns and mortars.

The non-application of pig-iron in every department of the melting foundry, would greatly retard the perfection, or even improvement of the art of moulding, and casting smaller and more general articles. The want of it, as the smelting fuel in the blast furnace, was long severely felt by the general backward state of the art of moulding and casting in this country, and allowed other nations with fewer advantages to get the start of us. It is highly probable, that long before the period formerly alluded to, the application of pig-iron had been speculated upon, either as an auxiliary, or as a substitute in every branch of the iron business. Its well-known inflammability and tendency to form a cinder, and the general decay of wood, would furnish ample grounds for what, to many at the time, would be considered as idle and visionary speculations. The advantages arising from the trade, as it was then situated, had been rigidly aforesaid, and fully appreciated by the established manufacturers. The blast furnaces, in point of extent, seemed only limited by the supply of wood. New ections, for want of a proper supply of materials, became impracticable; those already engaged were more anxious to preserve their supply, however much cumbered, than listen to innovation, which, by substituting pig-iron for the charcoal of wood, would likely give to the speculativ a great superiority in the market. It is also highly probable, that many of the iron works then started were at a considerable distance from pig-iron, the general introduction of which would prove fatal to their interests.

In this view of the subject, the adventurer with capital had every thing to hope, the established manufacturer every thing to fear, by change. Under these circumstances, the discovery, or rather the effusion of the practicability of making iron with pig-iron, was announced by Simon Stuartvant, in the year 1612, who, upon application, was favoured with a patent from king James, for the exclusive manufacture of iron with pig-iron, in all its branches, for the long period of thirty-one years. In return, the said Simon Stuartvant bound himself to publish a faithful account of his discoveries, which afterwards appeared in quarto, under the title of his Metallica. It is uncertain to what causes his failure was at the time attributed, but in the execution of his discoveries upon a large scale, he had found difficulties amounting to utter impracticability; for in the year following, he was obliged to make a surrender of his letters of monopoly.
The second adventurer in this unexplored path we find to have been John Ravenfon, esq. who, like Sturtevant, was successful in obtaining a patent for the new manufacture; but, like him also, was inadequate to the completion of it upon a profitable scale. Ravenfon was also enjoined to publish his discoveries under the title of his "Metallica," which was printed for Thomas Thorp, anno 1642. Several other adventurers stepped forth, all of whom had the mortification of resigning their patents, without having contributed to the success of their arduous undertaking.

In 1619, Dudley obtained his patent, and declared, that although he made only at the rate of three tons per week, he made it with profit.

This discovery was perfected at his father's works at Pen- fent, in Worcestershire. This gentleman's success in the various manufactures of iron with pit-coal, had united not only all the proprietors in the charcoal iron trade, but many new adventurers, who wished to share in the emoluments, or to acquire part of the fame of the new discovery. Their interest was sufficient to limit the duration of Dudley's patent from 3114 years. During the greatest part of this period, according to his own statement, he continued to make pig and bar iron, and various castings; all of which he sold much lower than the charcoal manufacturers. In the article of castings he must have had greatly the start of the charcoal foundries, as the quality of melting coke pig-iron is far superior to that of charcoal, particularly that made in this country for the general purposes of casting. Nor was the superior genius of Dudley always an object of passive indifference in the narrow estimation of the new adventurers and the established manufacturers. The envy occasioned by his uncommon success, produced at first a spirit of combination, which terminated in a hostile attack upon his devoted works. His improved bellows, furnace, forge, &c. all fell a prey to a lawless banditti, betwixt whom and its furious leaders no shades of distinction were visible, but those of avarice, ignorance, and the most contemptible prejudice.

To evade the mode of operation discovered by Dudley, or to introduce the making of coke pig-iron with greater advantage, a new plan was adopted by Captain Duck, major Wildman, and others, in the forest of Dean, where they erected large air-furnaces, into which they introduced clay pots resembling those used at glafs houles, filled with the necessary preparations of ore and charcoal. The furnaces were heated with the flame of pit-coal; and it is probable, that by tapping the pots below, it was expected that the separated metal would flow out. This rude process of "blasting" on a large scale, was in the end found utterly impracticable; the heat was inadequate to perfect separation; the pots cracked; and, in a short time, the process was abandoned altogether.

The misfortunes which befell the sanguine, but unfortunate Dudley, were an irreparable los to the perfection of the coke pig process. The hostile rivalships he had to encounter in consequence of the new ground he had occupied, as a manufacturer, together with a zealous attachment to the royal caufe during the civil war which followed his discovery, completely prevented his improvements from attaining a pitch of permanency and general utility. The refusal of a new patent after the restoration, prevented him from again entering the laborious paths of discovery and improvement, although it appears, that his former application to the perfecting of this branch of manufacture had not been unsuccessful, for in place of three tons of coke pig weekly, in his petition praying for a renewal of his ancient rights, he states, that he could now manufacture seven tons by means of a large furnace, and an improved bellows.

No greater pitch of improvement took place for nearly one hundred years after this period. The practicableness of the manufacture was discovered; but the mode of obtaining quantity, to ensure in general a profitable return, depended upon other circumstances than the proportioning of the raw materials together. Had machinery received the same improvements in the time of Dudley, it is more than probable that the rapid progress of the coke pig trade would have dated its origin from that period. But this great era in the history of our manufactures was reserved for a much later date; and in the improvements of the steam engine, we fee new life and exilience conferred upon every species of art that can be made subject to motion or mechanical control.

BLAST Furnace Works. are large and expensive buildings for the manufacturing of pig iron. An erection upon the smallest scale must consist of a furnace, casting-houle, bridge-houle, and blowing engine. The latter is sometimes, though seldom, worked by means of a water wheel. The most universal mode of blowing is by means of a steam engine. See Blowing Machine.

There is no general plan laid down for building a blast furnace work. The singular situation which should be occupied, to insure every convenience, renders this dependent upon the nature of the ground.

It is always reckoned a great advantage to place the blowing machine as at short a distance as possible from the furnace or furnaces, that the air may have the least possible travel in the conducting pipes. When this cannot be conveniently effected, the diameter of the pipes ought to be made sufficiently large to admit of the blast passing without any material friction.

The usual appendages to blast furnaces are mines of coal, iron-flone, and lime-stone. And these form no inconsiderable portion of the whole expense.

In situations where blast furnace building materials are at a moderate price, and when no uncommon difficulty occurs in the progress of the general operations, 15,000l. of sunk capital may be deemed requisite for one furnace; and for every furnace after this, 10,000l. may be added.

This great capital for many years kept the trade in the hands of a few; but of late, since capitalists have become more common, the number and extent of the blast furnace erections have become truly astonishing.

The following descriptions of plates illustrative of the plan and arrangement of blast furnace works will convey a tolerable idea of the nature of these buildings.

Plate XI. Blast Furnace Works, represents the ground plan of an entire fabric, consisting of

A. Scengine for blowing two furnaces.
B. 2 Blast furnaces.
C. 2 Bridge-houles.
D. 1 Cafting houle.
E. 1 Boiler-houle.
F. 2 Bollers.
G. 1 Chimney for boiler flues.
H. 1 Engine-houle, 40 feet long, 18 feet wide.
I. Pedefal for ileam cylinder: 7 feet square at base, and 4 feet at top.
J. Pedefal for blowing, or air cylinder. Bafe 10 feet square, top 7 feet square. These are generally built of folden hewn flone, and bedded with the greatest accuracy. From centre to centre of the two pedelfals is 24 feet, which is also the distance betwixt centre and centre of the ileam and air cylinders.
K. Door or opening through the lever wall. This wall at bottom is built $\frac{1}{2}$ feet thick, but is occasionally reduced
in point of thicknesses to 3 feet at top, as may be seen at the corresponding letter in the section.

E, Door or opening for carrying through the blast pipes from the top and bottom of the air cylinder to the water receiver below.

G, The boiler-houfe, 40 feet by 30 within the walls. As this is excavated from the solid hill to the depth of 30 feet, it is requisite to have the walls uncommonly strong. Those in the plan are 6 feet thick at bottom, and are reduced at three different heights in thickness, as represented by the interior lines.

HH, Two boiler-feats for boilers, 18 feet long, 9 feet high, and 7 feet wide.

II, Fire-places, 6 feet square.

KK, Dead plates before the bars or grates.

LL, Openings where the furnace doors are hung.

MM, Semi-circular openings formed beyond the dotted line or termination of the boiler, in which the flame from the grate rises to enter the iron flue or tube, which is placed in the centre of the boiler.

N, Chimney, 21 feet square within, and 50 feet in total height; from the bottom of the flue 42, and 8 feet from the foundation.

OO, Coal pits for containing small coals for the engine's supply. These are 8 feet by 6 at bottom, and widen gradually as they approach the surface of the coke yard. The coals are there emptied from the cart into the receivers, and the engine-man easily supplies his wants from the small openings which communicate with O into the boiler-houfe.

PP, Bridge-houfes for containing cokes, iron-stone, and lime-stone, for filling the furnace. Measurement within 42 by 40 feet.

QQ, Doors or entrances from the coke yard into the bridge-houfes.

RR, Openings from the bridge-houfe, which is here connected with the furnace, by means of an arch and parapet walls. This is more fully seen in the elevation section P, along this bridge the materials are carried or wheeled into the mouth of the furnace.

SS, Two blast furnaces, 34 feet square in the base.

T, Cutting-houfe 152 feet long by 48 in width from the front wall or arch of the furnace, or 88 feet wide from the front wall of the engine and bridge-houfes, and 24 feet high in the side walls.

W, Water receiver for receiving and equalizing the column of blast. Length 40 feet, and breadth 18 feet.

X, The space in which the equivalent column of water rises, 3 feet wide. The exterior line designates the inverted iron chéf; the interior lines, the different bâmetens formed by the flues work laid upon the chéf to prevent it from rising when the engine is at work.

Y, Termination of the blast conduit pipes from the air cylinder into the iron receiver, 2 feet 6 inches diameter.

Z, Position for the horizontal range of pipes to branch off, which are meant to convey the blast to the opposite tuyeres, as, betwixt the back wall of the furnace, and the bridge-houfe.

dd, The two tuyeres fixed next the water receivers. From d proceeds a straight pipe along the centre line h, for conveying the blast to that side of the furnace.

c, Front arches, under which the furnace workmen perform all the labour of tapping, cutting, and cleaning the furnace.

Vol. IV.

Plate XI. Blast Furnace Works.

Elevated section of the ground plan, Plate XI. through N F B D C E and X.

A, Incline of the blast engine-houfe.

B, Steam cylinder pedestal.

C, Blowing or air cylinder pedestal. Both of these are built upon 4 or 6 inch planking, laid upon strong logs, which are again supported upon the solid stone buildings, a, running from the lower wall along the side wall of the engine-house, to the wall perpendicular to E. The binding down bolts that pass through the fringes of the cylinders are strongly keyed upon the under side of the logs, and are at all times easily accessible.

D, The lever wall and opening of communication between the flume and blowing end of the engine-houfe.

F, Door or opening into the calling house and water regulators.

E, Door to the boiler-houfe.

G, The boiler-houfe.

H, One of the boiler seats.

I, One of the boilers, 8 feet long, by 9½ wide, by 7 high.

K, Man-hole door for entering the boiler.

L, Thorough arch in the foundation of the chimney.

M, Thrust, or opening into the chimney, for the passage of the flame and smoke.

O, Coal pit for containing fuel for the engine.

P, Arched passage of communication between the bridge-houfe and furnace mouth. The opening in the bridge-houfe is more distinctly seen at R, Plate XI.

Q, Side view of one of the blast furnaces, as connected with its corresponding bridge-houfe.

W, Water vault, or cistern, for receiving the inverted chéf. In rocky foundations this is cut out of the rock, but in soft ground the excavation is made and lined with well jointed mason work, puddled behind with clay to prevent the loss of water.

T, Cutting-houfe and roof.

b, The tuyere arch.

c, The low, or lintel of cast-iron, 12 inches square.

d, The orifice at which the blast enters, called the tuyere.

e, Spring beams of the engine-houfe, A. These are composed of two logs 14 inches square. The main gudgeon, seat, and beam rest upon these.

f, Stay logs for the steam cylinder.

g, Ditto, for the blowing cylinder.

Description of Plate XI. Blast Furnace Works.

Cross section and elevation of Plate XI. through S Y S.

SS, Section of two blast furnaces, and their situation as connected with the blowing apparatus.

Y, The branch pipe for communicating the air to the inside tuyeres of the furnace. This pipe has another branch of communication behind, which communicates it to the blast pipes which descend from the blowing cylinder at A, and to the double column of pipes which are carried round behind the furnace to the opposite tuyeres.

CC, View of the pipes which convey the air to the opposite tuyeres, where double blast is in use.

D, Front wall of engine and bridge-houfes.

X, Iron chéf inverted in the water receiver, and connected with the blast pipes.

VV, Opening all round for the water to ascend, as it becomes expressed from the chéf by the impelling force of the blast.

4 D O, Logs.
O, Logs on which the chef is inverted, to preserve it from the floor of the water receiver, from 12 inches to 18 of space.

Description of Plate XIV. Blast Furnace Works.

Ground plan of an extensive blast furnace foundery, consisting of four furnaces and two blast engines. The peculiar construction of this plan is, that only one furnace may be erected at a time, and afterwards the whole number; still preserving that regularity and uniformity of design which will at any time make the blowing machinery of one part subservient to the whole, in case of accidents, loppages for repairs, &c.

A, Engine-house, with cylinder, pedestals, lever wall, opening, &c.
B B, Two boiler-feats and boilers.
C C, Water regulators for the blast, which conveniently communicates, by means of pipes, with the blowing cylinders, placed upon the pedestals behind A, I.
D D, &c. Centre line of the whole blast pipes. This extensive column may be lo arranged, as to enable the furnaces to be blown each with two tuyeres; and the blast of one engine made to pass through the whole. The general communication is effected by carrying the chief column either behind the furnaces, or, as in the plate, through the main pillar of the furnace, by means of an arched opening 3 feet wide.
E, Ground plan of the hearth, squares, and pillars of four blast furnaces.
FFF F, Bridge-houses for materials, and filling or charging the furnace.
GGGGG G, Openings into the furnace top.
H H, Calfing-house.
I I, Second blast-engine, upon the same plan as A. Each of the two engines ought to be calculated to blow two furnaces, and occasionally, when any thing goes wrong with one, the blast of the other could be easily distributed for a time among all the furnaces.
BLASTED, in Antiquity, something stuck with a blast.
Among the Romans, places blasted with lightning were to be consecrated to Jupiter, under the name of bidentalia, and pataelia. It was also a ceremonial of religion to burn blasted bodies in the fire.

BLASTING of stones, in Agriculture, the operation of tearing afunder large stones or rocks, which are in the way of the plough or other instruments employed in breaking up ground, by means of gun-powder. The method of performing this business is by boring a large hole, eight, ten, twelve, or more inches deep, according to the nature and size of the stone or rock to be blasted, by means of a chisel for the purpose, and then introducing a sufficient quantity of gunpowder, and afterwards carefully ramming the hole up with small fragments of stone or other solid materials, only leaving a very small aperture, by placing a fixed pricker of sufficient length and suitable dimensions, with a handle at the top, at first into the powder, and frequently turning it round while the hole is ramming up. After the hole is quite filled, by forcing the hard materials in with a proper instrument, the pricker is withdrawn, and the aperture left by it filled to the top with gunpowder, and then a match of tow, straw, or other light inflammable material laid to it, and set on fire.

It is observed by Mr. Headrick, in the second volume of "Communications to the Board of Agriculture," that in order to perform this operation properly some experience is necessary, and that a skilful workman can frequently rend stones into three equal pieces, without causing the fragments to fly about. This, he says, depends upon the depth and position of the bore. It is also remarked, that a small portion of quick-line, in fine powder, is found to increase the force, and consequently to diminish the expense of blasting stones. On these grounds the following is offered as a substitute for gun-powder, which is now become very expensive, though, as is freely confessed, without any experience of its effects. Supposing fig. 1, Plate III. (Agriculture) to be a large stone to be blasted or rent; ab, a bore-dent down into it in the usual manner. This bore being then well cleaned out and dried, is to be filled from b to c with the purest quick-line, or such as will best suit in blazing. That it may be perfectly quick it should be taken red hot from the kiln, or the small furnace where it has been burnt; being then rammed in hard with the jumper or punch a c, the upper part of the bore is to be crammed with rotten rock in the ordinary way. The pricker being then removed leaves the aperture at b, a, b, a small pipe of copper, of less diameter than the needle or pricker, having an orifice about the dimensions of the flaw, used to convey the fire down to the gunpowder, with a funnel d to receive water, is introduced into the aperture. Perhaps a flaw or small red flusk is the lower part of the funnel, among tallow bees wax, might serve the purpose of a copper pipe. Things being thus prepared, pour water into the funnel d; and if the pipe be not too high, so as to prevent the air from escaping from the aperture, left by the pricker, it will descend and cause the lime to flake in the bore c b. Every one knows how irresistibly the purest quick line attracts water, and with what prodigious force it expands in blazing into three or four times its former bulk. From these data it is therefore inferred, that the flaking of lime, in such circumstances, would burst or rend the stone in pieces; but the succeds of such an experiment, it is observed, must depend entirely upon using lime of the utmost purity, and having it very hot, and perfectly caustic when it is put in.

It is further remarked that if the bore c b were filled with water, and the aperture afterwards rammed up, the water being made to freeze by cold, would rend the stone; for when water passes from a fluid to a solid form, it expands with irresistible force, though frost cannot be depended upon in this climate.

BLASTOLOGY, from 6aoe, bud, and ke, I gather; the regular and labored pruning of vines.

BLATNA, in Geography, a town of Bohemia in the circle of Prachlitz, near which is an inland lake, which is the source of the river Ullava.

BLATTA, in Middle Age Writers, denotes a purple in the wool or silk, dyed with the liquor of the blatta.

This was otherwise denominated blatta ferica, or blatta ferica; whence also blattarius, used in ancient writers for a dyer in purple.

BLATTA, in Entomology, a genus of hymenopterous insects, called in England cock-roaches, or black beetles. The head is infested; antennae facetious; feelers unequal and filiform; wing-cases and wings smooth, the former somewhat coriaceous; thorax flatish, orbicular, and marginal; legs formed for running; abdomen terminating in two articulated appendages above the tail.

The blatta, considered in a collective point of view, are a very troublesome race of insects. Certain kinds, that are happily for us peculiar to the hotter parts of the world, are so formidable both in respect of number and talents for doing mischief, that they are really considered as a pest to society in those countries which they infest. These noxious creatures enter houses and commit various depredations on the furniture, devour provisions of every kind, tear or gnaw holes in clothes, torment the inhabitants with their bite, and otherwise do considerable injury. The fort of blatta most abundant in England
England was originally a native of the eastern parts of the globe, or, as some suppose, of America, from whence it was long since imported into Europe, and is now completely naturalized to our climate. This is the blatta orientalis of systematic writers. Another creature of this kind, blatta Americana, was also introduced with the raw fuggs brought some years ago to Europe from America.

All the known species of cock-roaches, whether in the larva, pupa, or perfect winged state, secrete themselves in the daytime, and wander about during the night in search of food. In allusion to this circumstance, the ancients called them lucifer, and they are still called so by the Moroccans. The common cock-roach will eat almost any sort of provision, preferring, however, bread, meal, fuggs, and stale meat, either of which it is observed to devour with the greatest eagerness. Except in being completely deftillate of wings and wing-cates the larva resembles the perfect insect, and in the pupa state nothing more than the rudiments of the wings are perceptible. In the dark they are remarkably active and brisk in all their motions, and on the least disturbance, or the return of light, retreat again to their lurking places with timidity and precipitation. They can fly swiftly, but they seldom use their wings for this purpose; even when most eagerly pursued they are known to trust rather to their legs, with which they are able to run with no small celerity. The fumes of charcoal, we are told, may be employed with success in destroying these wonderful insects.

The following species of the blatta genus, are described by Lamæus, Fabricius, Gmelin, &c. viz. gigantea, madura, egypitana, occidentalis, surinamensis, americana, asulicula, erythropoda, capucina, indica, nivea, irrorata, viridis, brunneescens, petiveriana, orientalis, cilia, pila, variegata, lappacea, germanica, rufescens, maculata, marginata, obscura, nitidula, fulva, denia, chlorotica, latifrons, atterna, perpiciellaris, aqutica, schaefferi, sultryata, pennsylvanica, livida, rufa, geisla, minuta, testina, ocellata.

Blatta, according to some writers, was also used for a particular kind of kermes, or cherrises; or, according to others, for the purple-worm, by which the eucus codii, or cockaded insect was most likely meant. But both of these acceptations are suspicious. We know that the word blatta was anciently used for a kind of moth, whose fat was reputed excellent for the ears. This last was called the book-worm moth. See Bookworm.

Blatta Americana of Catesby is of the clyta genus with modern entomologists. Gmelin speaks of it under the name of clyta americana.

Blatta Byzantina, in Physiology and Pharmacy, the operculum, or lid of a turbinate shell, whose fin yields a purple dye.

The blatta differs from the lid of the bucinum or purpura, in figure; the first being oblong, the latter round; but in the latter they are ordinarily confused, and fold for each other. The blatta byznatica is also confounded by apothecaries with the unguis odoratus, from which it ought to be distinguished, as belonging to another kind of shell-fish.

Dr. Lillie takes the Blatta byznatica to have succeeded the unguis odoratus, and to have been brought into the shops in its place. In Dioscorides’s time, the belt was brought from the Red Sea, viz. the palell and fatted: the blacker and lefs, from Babylon, or the Perisan gulf; but it feems, latter times took up with those found about Conflantinople; where the prelent fhoop blatta had its name.

The name blatta seems to have been given to this operculum from the colour; as being of a dark hair-colour, as the common blatta orientalis, or common cock-roach, so frequent in London, is.

The blatta byznatica, when exhibited internally, renders the body felable, softens the spleen, and confufes percutant humours. When used externally, by way of fumigation, it refires epilepftic patients, and women labouring under a ftupor of the uterus. In other diforders its effects are the fame with those of most tiftaceous flubfances.

Blattaria, in Botany. See Cellia, Lythrum, Pentapetes, and Verbascum.

Blattaria, in Entomology, a species of clyta genus, which inhabits Aulrian; the colour is black; thorax broad; wing cailes and the legs taffeaceous and glossy. Shranck. Inf.

Blatum-Bulgium, in Ancient Geography, a promontory of Britain, mentioned in Antoinine’s Itinerary, concerning the situation of which antiquarians have entertained different opinions. Camden, Calke, Baxter, and some others, have fixed it at Souliet, on the south coast of Solway firth, at the end of Severus’s wall; yet Mr. Hordley affigns its situation at Middlebury in Annandale. Here, as at the most remote limit of the province of Britain, Antoinine commences his second route. A military way led from Blatum-Bulgium to Luguvallium, or Carlisle.

Blau, in Geography, a river of Germany, in the circle of Swabia, which rises near the foot of a hill in the Blaupole, as it is called, and runs into the Dunabe at Ulm.

Blau bei, a town of Germany, in the circle of Swabia and duky of Wirtemberg, in a small district of the same name, seated on the river Blau, 7 miles W. of Ulm.

Blaurudelius, in Zoology, (of unknown genus,) phoca erinata of Erxleben and Gmelin, and booted seal of Tennant.

Blauenthal, in Geography, a town of Germany, in the circle of Upper Saxony.

Blauer-Boie, in Zoology, one of the names given by authors to the blue antelope, antelope lencephus. Vide Kolbe Vorger.

Blavet, in Biography, a celebrated performer on the German flute, the first, perhaps, who greatly distinguished himself by that instrument after it superseded the common flute, and became in general use. He was born at Feancon, and coming to Paris in 1723, soon acquired a great reputation. The prince of Carignan, who knew his merit, enlisted him in his service; gave him an apartment in his hotel, and a pension. He was afterwards appointed superintendant of the comte de Clermont’s band, and remained in that nobleman’s service to the end of his life.

To his admirable talents, Blavet joined the requital virtues of society; his manners and conduct were blameless, his temper tranquil, and his probity incorruptible. He married at eighteen, and lived upwards of fifty years with his wife in uninterrupted harmony and affection. We are always glad when to great professional abilities, such an effimable character can be joined.

Blavet’s excellence on the German flute had been heard of all over Europe, before the character of Weideman was established in England, or that of Quantz in Germany.

About the end of 1765 he was attacked with the stone, which was a malady then more dangerous than it became afterwards, by the skill, experience, and success of eminent surgeons; but determining too soon, like our poor countryman, Dr. Worgan, to submit to the operation, he died under it in 1768, leaving behind him the eelmen and regret of all who knew him.

Blavet, in Geography, a river of France, which runs into the sea opposite Belle Isle. This forms a good harbour and spacious road.
Blaufich, in Ichthyology, the name under which Salmo Waltmanii of Bloch and Gmelin is described by Wartmann Bech. Berlin Naturf. Fr. 3, p. 184.

BLAVIGNAC, in Geography, a town of France, in the department of the Lozère, and chief place of a canton in the district of St. Chely d'Apcher; 6 miles south of St. Chely.

BLAUKOEPFKE Rothe Amsel Frisch, one of the synonymous names of lanita minor, Gmel.

BLAUMEISE, in Ornithology (Frisch, Hist. of Birds), the blue titmouse of English writers, and parus caruleus of Linnaeus.

BLAUSLUYS, in Geography, a town of Holland, 2 leagues west of Goesdenburg.

BLAUSPECHT, in Ornithology, the name of the common nut-hatch; fista Europea in Frisch, Hist. of Birds.

BLAVE, Blavia, or Blavutum, in Geography, a sea-port town of France, in the department of the Gironde, and chief place of a district of the same name nestled on the Gironde, or Garonne, near its confluence with the Dordogne. Its castel is situated on a high rock, and it is defended by a fort constructed on an island in the river, which is here 1000 toises wide; and on the other side of the river, in the country of Mende, is another fort. All ships that are going up the river to Bordeaux, deposit their arms and cannon at Blaye, before they pass the river, and take them up on their return. The town contains 3580, and the canton 13,819, inhabitants. The territory comprehends 160 kilometres, and 14 communes. It is distant 20 miles north from Bordeaux. N. lat. 45° 9'. W. long. 0° 45'.

BLAYMARD, or Blymard, a town of France, in the department of the Lozère, and chief place of a canton, in the district of Mende. The place contains 546, and the canton 11,802, inhabitants. Its territory comprehends 347½ kilometres, and 11 communes; 31 leagues east of Mende.

BLAZE, in the Menage. See Star.

BLAZEGNIES, in Geography. See Malplaquet.

BLAZEY BAY, a bay in the English Channel, on the south coast of Cornwall, between Fowey and Deadman point.

BLAZING STAR. See Comet.

BLAZON, or Blason, in Heraldry. To emblazon is a term signifying the describing of things borne in coat-armour, in such manner as they ought to be represented, according to the rules of heraldry. To blazon, originally signified the blowing or winning of an horn by the heralds, at jousts and tournaments, when they proclaimed and recorded the achievements of the combatants.

Blea, in Vegetables, is that part of a tree, which lies immediately under the bark, and between that and the hard wood, and is the first product of the alteration of the bark into wood by the natural growth and strengthening of the fibres. See Botany.

While the blea remains yet soft, and retains something of the nature of bark, it may maintain a feeble vegetation; but when it is grown absolutely hard and woody, it can contribute nothing to the growth of the tree. The vegetation of the young branches of trees is the most lively and vigorous, and the only one that goes as far as the flowers and fruit, because these branches are little else but bark.

Bleaching. The art of bleaching consists in removing the coloured matters intermixed with vegetable and animal substances in their natural state, or such as they have subsequently imbibed by accident, or some artificial processes. Edward Hufley Delaval, esq. F.R.S, has shewn, by a number of accurate experiments on the cause of the permanent colours of opaque bodies, published in the second volume of the second edition of the Memoirs of the Literary and Philosophical Society of Manchester, "that when the colouring matter of plants is extracted from them, the solid fibrous parts, thus divested of their covering, display that whiteness which is their distinguishing character. White paper and linen are formed of such fibrous vegetable matter, which is bleached by diffusing and detaching the heterogeneous coloured particles." He further observes, "it appears that the earth, which forms the solid substance of plants, is white; that it is separable from the colouring matter by several means; that whenever it is either pure and unmixed, or diffused through transparent colourless media, it exhibits its whiteness, and is the only vegetable matter which is eluded with a reflective power; that the colours of vegetables are produced by the light reflected from this white matter, and transmitted from thence through the coloured coat or covering, which is formed on its surface by the colouring particles; that whenever the colouring matter is either discharged or divided by solution into particles, too minute to exhibit any colour, the solid earthy substance is exposed to view, and displays that whiteness, which, as before noticed, is its distinguishing character."

He states that in all those animal matters which do exhibit colours, the colouring particles are endued with the same properties, and are regulated by the same laws, which prevail in vegetable substances.

A reference to the original paper can only do justice to the observations of this excellent philosopher, confirmed by numberless experiments; but what is already said will be sufficient to give an idea of the nature of the processes of bleaching, and that it depends on the removal of the matter interposed betwixt the air and this white substance.

The national importance of bleaching is so great, that it comprehends nearly the whole of the cotton and linen manufacture, and goes to an extent beyond most other arts.

Its operation in these branches may be considered under two points; viz. 1st, the separation of extraneous substances from linen and cotton, which is effected by steeping, fermentation, or weak alkaline leys; 2d, the separation of the constituent or inherent colouring matters of those substances, which is effected by different modes, and by various modifications of each method, as exposure to the air, light, the use of alkaline leys, soap, oxygenated acetic acid, combinations of oxygenated acetic acid with other matters, sulphuric acid, hepar sulphuris, &c.

To impress upon the mind the nature of the bleaching business, it will be proper first to describe the vesseled used in the finery operations of steeping, boiling, bucking, washing, fouling, &c. then to proceed to the management of the processes, with some observations on its effects; and, lastly, how to make or procure the articles necessarily employed in this art, and the method of ascertaining the qualities of each, adding some observations on the theory of the operations.

Bleaching of goods, particularly cotton manufactures. 11. On Steeping.

The vessels generally used in bleaching are made of such wood as will not communicate any colour to the liquors they are to contain, and therefore deal or fir wood is preferable to most others. The vessels employed for steeping the goods when received from the loom are usually of the form A, fig. 1. Plate I. Bleaching. The goods when received from the weaver contain not only the natural colouring matter of the cotton, which is of an oily nature, and which prevents the cloth from easily imbibing water, but also a substance called fowina, being a paste made of flour and water, used during the weaving, and applied with brushes upon the warp, in order to give a firmness to the threads by glueing.
Bleaching.

The operation of bucking is on a similar principle to that of boiling, but in a much more forcible manner, as a greater quantity of ashes is added in proportion to the water made use of, and more heat is received and retained in the large bulk of cloth placed in the bucking tub, which expands the fibres of the cotton, and admits the more powerful action of the alkali, as is easily demonstrated by observing the very dark colour of the alkaline yeys which have been used in bucking, in comparison with those which have been employed in boiling goods. To those persons who wish for a full and minute account of the absorption and power of heat, we recommend a perusal of Count Rumford's interesting essays on the subject of heat.

The black alkaline ley which remains after bucking should be preferred, as it will answer, after evaporating and calcining, as hereafter mentioned, to form again fresh alkaline salts of good quality. With a view to preserve as much of the ley as possible, it will be advisable to wring it out into a tub from the cloth or yarn, after it is bucked, by the method shown in Plate IV. fig. 2, where R is two strong polls, fixed in the ground, S I two wringing hooks, upon which the cloth U is twilled, to force out the liquor, by W, a winch handle, which turns the hook round on the pole R. The two hooks are kept at a proper distance from each other, one by a collar at X, the other by an iron pin at Y, which runs through a hole in the square part belonging to the hook I, which square has several holes in it to bring this hook nearer to the hook S when required.

4th, Soaping.

This process consists in immersing, for the space of twelve hours, or more, the yarn or cotton in a mixture of water and sulphuric acid (vitriolic acid), well incorporated; the proper strength of which mixture is about the acidity of lemon juice, and is usually directed by the tale. The four kettle should be made of lead, of a form which can be heated; the heat of the liquor should not be greater than the hand can bear with ease. This four kettle should be half sunk within the ground, as shown in Plate IV. fig. 2, where M is a section of the four vessel; N, the level of the ground; O, the brickwork; P, the fire-place, which is a half circle, or arch, without any grate; I I I I, a space filled with dry ashes, between the lower part of the four vessel and the brick-work, in order to preserve the heat of the liquor in that part of the vessel below the surface of the ground; K, a brick hearth, on which part of the fire is made; L, a cast iron plate, bending in the form of the four kettle, which is intended to prevent the fire placed on the floor at P K, from acting upon the lead of the four vessel; Q I, the space betwixt the vessel and brickwork, through which the smoke goes to the chimney.

The construction of this apparatus is upon the same principle as the warm vats made use of by the blue dyers, the intent not being to make the liquor boil, but to keep it at a degree of heat which the hand can long and easily bear. There are no grate or bars necessary in this fire place as the coals will burn with sufficient rapidity without them.

The goods may be put into this acid liquor either in a wet or dry state. The bell plan is to immerse the goods in the evening in the acid liquor cold, let them remain covered with it all night, then in the morning make a fire and bring the liquor to a boil heat, in which state having a winch over the vessel, similar to that represented at C, fig. 1, give the goods a few turns over it, that every part of them may be exposed to the action of the liquor. The goods may then be bapped round the winch to drain a little, to prevent an unnecessary waste of the acid liquor, and afterwards carried to the wash-wheel, or river, to be well washed from
the acid, so that the cloth may be perfectly tasteless to the tongue. It is a remarkable circumstance, that cloth may remain immered a very considerable time in a strong acid liquor without rotting, but that if exposed to the air or heat of a stove, if a very small portion of acidity remains in the cloth, it becomes so concentrated by heat, as to damage the cloth immediately; therefore too much attention cannot be paid to this point.

The use of the acid liquor above-mentioned is to dissolve any earthly or metallic matters inherent in the cloth, or which may have been communicated to it accidentally, or which it may have derived from the impurity of the alkaline falls used in the bucking or boiling.

A considerable quantity of the acid liquor may be preferred by washing the goods which have been foured through a tub of clean cold water, previous to washing them, and replunging the four kettles with this acidulated liquor, rather than water only.

5th, Washing.

After every operation in which acids or alkaline substances are used in bleaching, it is necessary that the goods should be well washed in clear water; it is therefore of the greatest consequence that the water of a bleach ground should be pure, and its considerable quantities, fresh, for instance, as is perfectly transparent, will not curdle with soap, nor yield any degree of blackness with powdered gall nuts, or, which is a more accurate test, with a mixture of galls by infusion in spirits of wine.

Various methods have been invented for the purpose of washing out the impurities of the articles to be bleached: such as cleaning them in a large current of water by flaking them with the hand in the stream, beating them on blocks of wood with a flat paddle, or hand brush, beating them on a large flat stone with long wooden levers, flattened underneath, palfing them over winches placed above vesseis of water, or rivers, as fig. 1. and 3. Plate II. palfing them betwixt plain or fluted rollers, as fig. 5. and 6. putting them under falling mills, or falling flocks, as fig. 7. or within wafli-wheels, as fig. 1. and 2. and by many other modes, few of which are equal, and perhaps none superior, to those of which engravings are here given, for doing the business finely, effectually, and with ease to the workmen; the latter point of which is of consequence to be attended to, as it will be universally found in every mechanical employment, that if the least additional labour or care is required from the workmen, however great the effects produced, prejudice or indolence will prevent their doing justice to the invention. Under these circumstances, the wafli-wheel represented in Plate II. fig. 1, 3. 4. is the best machine for general use, and the least liable to occasion damage to the goods. The front of the wafli-wheel represented at fig. 1. is supposed to be eight feet diameter, exclusive of the buckets B, shown by dotted lines on its periphery, which give motion to the water falling into them. This wheel is divided within into four parts or quarters, by the strong arms projecting from the shafts D, to the outer circle; in each of these separate quarters or orboxes, represented by dotted lines, one or more pieces of goods which require washing, are put loosely folded together through one of the holes C, of 12 inches diameter.

Fig. 2. shews the back part of the said wafli-wheel, which is made of solid planks, excepting a grate of latten iron bars marked R, which encircles the wheel underneath the separa- tion boards or bottoms of the buckets; the use of this grate is to admit within the wheel a current of clear water from the pipe Q. When an equal number of piece goods have been introduced into each of the four divisions of the wheel by the holes, C, &c. above mentioned, a current of clear water is permitted to run through a cock from the pipe Q, against the grating R, which allows it to flow freely through into the boxes, or those parts of the wheel which contain the goods; a valve is then opened from the trough P, communicating with a large reverber or stream of water, a sufficient quantity of which is let into the outside buckets from the valve, to give the proper motion to the wafli-wheel containing the goods. In every revolution of the wheel, the goods in each quarter of it are thrown twice, by the simple motion of the wheel, with great force against the arms which form the four divisions of it; viz. once in going down, and once in rising up. The ear can distinguish by the firmness of the found when the wheel moves with proper velocity; and a greater or less quantity of water is allowed to act upon the buckets till that is attained, which usually is when the wheel makes 15 or 16 revolutions in a minute. During the whole time the wheel is in motion, the stream of clear water from the pipe Q flows upon the goods within the wheel in every direction; and the dirty water, produced from thus washing the goods, runs out of the wheels from a number of holes bored through the work-work near the axle, and a few made in the front near the outer circle of the wheel. Fig. 4. shews an end view of the wafli-wheel, about thirty inches wide, with the manner that the bucket-work is made.

It has been found to answer equally well to make use of a greater number of wafli-wheels of a smaller size, as six feet diameter and two feet wide, of which several may be put in motion at once by a large water-wheel, horres, or a steam engine.

The goods, when taken out of the wafli-wheel, are to be unfolded and taken to the river to be freamed, or may be washed from any impurities which may remain in the folds by means of a winc N, fig. 1. and 3. Plate II. where six pieces of cloth are represented in the action of washing in a large wooden back divided into six partitions, to prevent the pieces of goods entangling with each other. Fig. 1. is a side view of the operation, where the dotted lines represent the partitions which separade the goods; I, a trundle wheel, which being put in motion by the cogs, H, of the wafli-wheel, turns the winch on its axle, which winch may at any time be detached from it by the handle M drawing the catch K from the hook, as is shown in the top view fig. 3. where afo is explained, at the letters OOOOOO, the manner in which each piece of goods is kept in its proper place on the winch, by the partitions above mentioned, and by angular slips of wood nailed to the back and partitions.

To affil the drying of the goods after washing, they are usually paffed betwixt two small rollers, commonly called squeezer, represented at fig. 5. where C is a solid wooden frame, containing two wooden rollers, each from 10 to 16 inches long, on an iron axis, which rollers receive a proper pressure by means of the two screwers T acting on an iron bar V, which rests on the ends of the axis of the top roller, as shown by the dotted lines. In proportion as the screwers press the iron bar upon the axle of the top roller, it brings that roller closer in contact with the bottom roller, and occasions more water to be pressed out of the cloth, which is paffed betwixt them loosely drawn together, something like a rope, and the goods therefore require less time in the subfluent drying. In this plate the squeezer are connected with the wafli-wheel above mentioned by a square iron socket, which, as is shown at P, slides occasionally upon the squares of both axes. Fig. 4. shews at S the buckets of the wafli-wheel, on which the water falls to give it motion; II, the cogs round its axle, which work the trundle wheel I.

Fig. 6. Plate II. shews two views of another machine used for cleaning cotton goods, consisting of two flat or grooved
grooved rollers, in the section of which \( a \) represents the tills, or bottom timbers; \( b, b \), the two supports or flide pieces; \( c, c \), one of the upright pieces in which the axes of the rollers are placed; \( d, d \), the two crofs pieces to secure the frame work below; \( e, e \), the two rollers with grooved channels which fit to each other; \( h \), one of the levers, which, from a point \( i \), shewn by dotted lines, preffes on the round end of the axle of the top roller, more or less, according as the weight \( k \) is placed on the lever further from or nearer to the axis of the roller.

In the geometrical elevation of the fame machine, \( e, e \) shews a front view of the two rollers; \( f, f \), the winch to turn it, with a hollow wood handle upon the iron work; \( l, l \), the axis of the upper roller projecting beyond the flide timber, fo as to admit one of the levers \( b \) above mentioned to prefs upon it.

The wet goods, by being pushed backwards and forwards through thele fluted rollers, which are constructed at a much less expense than wath-wheels, are considerably cleaned, but not fo perfectly as by the wath-wheels above mentioned.

Fig. 7. Plate II. explains another mode of cleaning goods, and is applicable to cotton, linen, or woollen goods, but more generally to the two last, as, without great care in its management, it is very apt to tear or damage cotton goods. This machinery is usually termed falling flows or falling hammers. \( N \), the axis of the water-wheel, in which are fixed tappets at \( 2 \), to raise alternately the levers \( 3, 4 \), furnished with large wooden mallets or hammer heads \( 5, 6 \), channelled at the lower part as at \( 8 \). These lever hammers or fallers, work from a pin fixed in the upright at \( 7 \); \( 9 \) is a strong piece of timber hollowed out at \( 10 \), to receive the goods to be cleaned; \( 11 \), a piece of timber fixed a-flant to keep the fallers in their proper place, and direct their motion; \( 12 \), a chain fastened to each faller, serving by means of the hook \( 13 \), to suspend the faller whilst the goods are put in or taken out of the cavity.

When the goods to be cleaned are placed in a loose handle in this cavity, the hammers are let down upon them, and put in motion alternately by the tappets \( 2 \), in rotation, which raise the levers to a certain height, and then quitting them, the hammer heads by their great weight, fall with great force on the goods in the cavity below them; and a current of clear water being admitted upon the goods from a cock above them, the dirty water runs out at a hole in the bottom of the cavity. The falling of the hammers gives a flow circular motion to the goods in the cavity, so as to expel the several parts in rotation to the action of the hammers.

Having noticed the vessels made use of in bleaching, and the general nature of the several operations, we shall now proceed to mention the origin of the several improvements made in this art, and their application to practice.

Under the operation of steeping, we have shewn the method of removing the colouring matters not natural to the vegetable, but acquired in the manufacture, and which may probably be best done by water alone, though sometimes some of the old leys, which have been previously used to other cloth, are employed to this purpose. After the steeping, and indeed after every application of bleaching agents, it should be laid down as a general rule, that the cloth or goods be carefully washed in cold water.

In the old method of bleaching, alkalies, such as pearl or pot-ash, were, after steeping, applied by bucking or boiling; with alternate exposure to the atmosphere.

Alkalies acting so important a part, it is necessary to describe the bleachers' mode of using them, which consists in diffusing them in clean water, and thus forming what is termed an alk.ley. To which the more intelligent bleachers, if he does not make use of American pot-ash, or that of a similar quality, adds \( \frac{1}{4} \) of quicklime, whereby the alkalies are rendered caustic, and their power materially augmented.

But in order that no inconvenience may arise from causticity, after mixture, the whole is allowed to settle, and from the pure liquor thereof the work is afterwards supplied to the bleacher, in drawing it off, reducing it by the addition of water to the different strengths which the goods may require.

The ley being prepared, the bleacher proceeds to apply it to the cloth by bucking or by boiling.

In bucking, the alkaline ley is put into the boiler before described, near to and below which the wooden vessel called a kier, in which the goods are loosely and regularly arranged. After this, a fire is put under the boiler, and beginning whilst the ley is yet cold, it is made to circulate through the cloth in the kier, from which it runs into the iron vessel placed in the ground, from this it is pumped up into the boiler, and again returned upon the cloth in the kier; and this circulation is maintained, and the heat at the same time increased, until the ley be so far concentrated by evaporation, as at last to remain almost wholly in the cloth. This is generally the operation of a day, and the cloth is allowed afterwards to remain thus impregnated with the concentrated ley until next morning.

In boiling in alkaline leys, the mode of which has been before described, the operation is continued from one hour to five or six hours; but it is more tedious and less effectual than bucking, where much buffins is to be done.

After bucking or boiling, the goods were, by the old bleaching processes, exposed for at least a week to the air, before they were again submitted to the action of alkaline leys, and this process alternately repeated many times, till the goods were perfectly white, and the goods at last foured and washed off.

To explain the old method of bleaching more particularly, we shall add the following processes for bleaching linen cloth.

Steep your raw linen cloth in a wood vessel all night, then change the water, and add fresh till you perceive the water to be no longer discoloured by it; rife, wring, and lay it on the ground, and water it if you have opportunity.

When it has thus lain on the grass three or four days, and is dry, take hold of each piece one after the other by the felvedge, and draw the cloth to you, till holding it in the most even manner you can, until you get the further end, with the corners of which further end you tie the cloth very loofely in the middle of the folds, and so lay it in the bucking tub, with the two selvedges upwards.

Thus proceed till you have placed as much cloth in your tub as will cover the bottom of it, taking care not to pack the cloth so close but that your ley may penetrate every part equally. When you have laid the first range of cloth in your tub, pour upon it as much milk-warm ley as will sufficiently foak through all parts of your cloth. Then lay another range in the same manner upon the first, and pour on more ley till that be faked as the other was, and continue fo to do till your bucking tub be full of cloth.

That done, you must begin to buck for twelve hours together, the remainder of your ley having been put in the pan with a flow fire underneath. For the first five hours the ley should not be of a boiling heat; you must from time to time allow some of the ley to run out of the pan upon the cloth in the bucking tub; then increase your fire gradually and flovely, so as in four hours more to bring it to a boil, continuing to put on the ley, and draw it off your cloth in small quantities at a time. When your ley begins to boil, you must let it boil on for three hours, during the while:
time pumping your ley up to the boiler from the reservoir, into which it runs from the cloth, and returning it boiling hot upon the cloth, so that the hot ley may act powerfully and equally upon every part thereof.

After each bucking your cloth must be laid upon the grats in the bleach-field for some days. The bucking, and exposure on the ground, must be repeated about ten times successively, according to the nature of your cloth; it should then be dried up, foured, and washed well in clean water; if the water is rather warm, the better.

Your two first buckings ought to be from a strong caustic ley of pot-ashes; but afterwards you should abate of that strength, let it in small doses into the boil, and wash well in clean water; if the water is rather warm, the better.

This was the management during the summer months; but for four months in winter bleaching was suspended, and the operation being periodically interrupted, and the capital of the manufacturer or proprietors of the goods locked up. Even during the bleaching months, their property was long in preparing for sale; as cotton goods, which required from four to six applications or repetitions of alkaline keys, consumed so many weeks in bleaching, whilst linens, which could not be bleached by less than from twelve to twenty applications, could not be brought in a marketable state to the proprietor hardly in six months.

Such was the state of bleaching till Mr. Scheele, a Swede, and eminent chemist, discovered the properties of oxygenated muriatic acid, procured by mixing manganca and marine acid, in rendering vegetable matter white; and M. Berthollet, the celebrated French chemist, improved this operation, and actually applied its powers in bleaching cotton goods by interposing its action between the different alkaline operations instead of the tedious exposure of the goods to an uncertain atmosphere; the same effect being produced by immersion of the cloth in this acid, as by laying the goods upon the grats in the bleach-field, exposed to air and light.

**Discovery of and Variations in the Mode of procuring the Oxygenated Muriatic Acid.**

By the addition of vitriolic acid to common salt, an elastic aérisiform fluid, or muriatic gas, is disengaged, from which with water a marine acid is produced. The mineral substance manganca, or what the modern chemists call oxyd of manganca, contains what was formerly denominated vital air, pure air, or dephlogisticated air, but now named oxygen. Manganca yields oxygen, when marine acid is added to it, and submitted to distillation; the liquor produced by the contact of this oxygen with water, is the oxygenated marine or muriatic acid discovered by Mr. Scheele, about the year 1774, when he observed and applied its effects in rendering colours vegetable substances of various kinds, and in an art more matter of curiosity than use.

M. Berthollet, in the year 1786, improved the processes of its preparation, applied its power to bleaching or destroying the vegetable colours natural to cloth, the result of which experiments he gave to the world in the year 1789; but, without derogating from the merit of this excellent chemist, it is justice to state, that, previous to any publication by M. Berthollet, Mr. Scheele communicated to M. Kirwan the properties of the dephlogisticated marine acid in whitening vegetable substances, and Mr. Kirwan, then residing in Newman-street, London, suggested to Mr. C. Taylor, the present secretary to the Society of Arts, &c. the probability of its use in bleaching; and a whole piece of calico, in the flate received from the loom, in the spring of 1788, actually bleached white, printed in permanent colours, and produced in the Manchester market ready for sale, having undergone all these operations in less than 48 hours, by the joint efforts of Mr. Cooper, Mr. Baker, and Mr. Taylor, which is perhaps the first entire piece, either in France or England, that fully afoertained the real merits of the new mode of bleaching, and a certainty that it might be generally useful in commerce. This experiment was immediately followed by the establishment of a large bleaching concern by Mr. Cooper, Mr. Baker, and Mr. Horridge, at Ulston, near Bolton, in Lancashire, and before any considerable bleaching work was actually at work in France.

The ingenious Mr. Watt we believe to be the first person who simplified the process of preparing the oxygenated muriatic acid, by means of a mixture of common salt and manganca, previous to the addition of the vitriolic acid. Soon afterwards the operations of the bleacher were further facilitated by the submission of large and commodious stills of lead, ineluding of glass vessels, and both these improvements have since been in general use.

We shall now proceed to mark the various treatment of the oxygenated muriatic acid when obtained, and the different means which have been adopted to fit it for application in bleaching.

It having been found, in the earlier stages of distillation, that common marine acid was produced instead of the dephlogisticated or oxygenated muriatic acid; and from the violence of the ebullition, that manganese itself was sometimes thrown over from the still, M. Berthollet had recourse to an intermediate vessel, containing water, to absorb the marine acid gas, and float other impurities which might contaminate the oxygenated muriatic acid in its passage through this vessel to the receiver.

It ill here be necessary to discriminate the various modes in which the oxygenated muriatic gas has been treated, after passing the intermediate vessel last mentioned.

Mr. Scheele seems generally to have operated with the acid in the flate of gas; but M. Berthollet sought to condense it in water, with which he filled his receiver, or wooden vessel, and which water he kept agitated during the distillation, to accelerate the solution or combination of the gas.

The oxygenated muriatic acid, thus prepared, was drawn from the receiver into klers, or large wooden vessels, where its strength was regulated by the addition of water; after which, the goods to be bleached were immered therein from six to twelve hours, but most frequently during the night; and though these periods may seem short, they were sufficient to allow the cloth to become more white than could be done by any many days exposure to the atmosphere and a hammer's fun, and were then ready for a fresh application of the alkaline keys.

Such was the bleaching liquor of M. Berthollet; but it was found in practice yet defective, as the volatility of the gas precluded its speedy separation from the aqueous solution; a decomposition even by light alone in glass vessels took place; a rapid loss in the strength of the liquor when exposed; and much danger to the health of the workmen from its suffocating quality; at the same time, that in extracting the natural colours of the cloth, it also tended to discharge the colours dyed in the yarn, and were along with the gray cotton an improvement which precluded its use in an infinite variety of British manufactwres.

Similar circumstances probably led some bleachers resident at Javelle, in France, to add a solution of caustic alkali to the water in the receiver, and by this means to remedy many of the defects complained of.

But M. Berthollet continued to recommend his process, considering such substance as impairing the bleaching powers;
BLEACHING.

an idea that was generally maintained by the chemists, but contradicted by the bleachers, whose experience taught them, that though the acid thus combined whitened with some-what less rapidity, yet it was not eventually in an inferior extent; and the advantages of preserving the colours dyed in the yarn, compelled them to have recourse to the expensive addition of pot-ashes, in preference to M. Berthollet’s mode.

Here we shall observe, that, according to the doctrine of the modern chemists, the oxygenated muriatic acid bleaches in consequence of yielding to the colouring matter of the cloth that oxygen which, in the distillation, the acid absorbed from the manganese; or, in the language of Stahl and Becher, that the phlogophoric muriatic acid absorbed the colouring matter from the cloth, and was restored to its original state of common marine acid, by regaining that phlogiston which it had, in its preparation, yielded to the manganese.

In the mixture of an alkali with the acid, we have noticed that the bad consequences arising from its volatility have been corrected, and the requisite protection afforded to dyed colours, yet still that its power of whitening cloth was not diminished, nor much more time taken up by the operation; yet, in part from deference to M. Berthollet’s opinion, and in part owing to the expense of the alkali, other means to produce the effect were attempted.

One of the first of these, practised by the bleachers of cotton-hoys, at Nottingham, was to receive the dephtlogophoric muriatic gas into a small air-tight chamber, in the upper part of which the goods were suspended from a frame, whilst at some distance below was water, sometimes impregnated with ley of pot-ash, and sometimes with lime-water, or water mixed with lime. The gas was introduced between the fluid and the goods, amongst which it ascended and mixed; at the same time, by occasionally immersing the goods in the fluid below, it was sought to modify the action of the acid. This was effected by means of a pole, or long lever, connected with the frame on which the goods were suspended, the centre of which pole moved on a twisted wire in a hole in the partition, occasionally flapped with clay, and enabled a person to let the goods down into the fluid, not always however without inconvenience, which occasioned it the name of the Reddam Proof.

Respecting the above process it must be observed, that the acid is much more powerful or active in the state of gas than in any other way; and though the occasional immersion of the goods into the fluid below, corrected in some degree its violent effects, yet the dyed colours disappeared more rapidly in this than in any other process, and the fabric itself was sometimes injured.

The next process attempted by the bleachers, was to put the receiver, filled with water, a quantity of pulverized lime, then the goods themselves, and the whole agitated during the admission of the gas; the consequence of which was, that the goods thus mixed with lime were partially coated with it; and this coating being unequal, the action of the acid upon it was irregular, leaving at the same time the parts uncoated to receive the whole action of the bleaching powers; hence inequality of bleaching ensued, and an insurmountable difficulty in preserving the dyed colours of the goods to be bleached.

Having noticed the imperfections of the two last processes, we shall observe that lime-water, or a pure chemical solution of lime in water, has been sometimes substituted instead of a solution of alkalis in the receiver, but was not, when used in that manner, found to answer so well as the alkaline solution.

That lime-water could produce no valuable effect beyond what was derived from M. Berthollet’s mode, or from simple water, must be evident, when it is considered that water can dissolve no more than 75th part of its weight of lime, a quantity wholly insignificant in neutralizing the oxygenated muriatic acid for the purpose of the bleacher; nor could pulverized lime, merely thrown into the water of the receiver, serve a better purpose, since, from its being specifically heavier than the water, all beyond the quantity in chemical solution subfused and remained nearly useless at the bottom of the receiver.

It has been already mentioned, in noticing the application of alkali keys in bleaching, that the more intelligent bleachers, in preparing their alkali-keys, made use of quicklime to augment the power of the alkali, when such alkali was in a mild state, or, in other words, combined with fixed air, or, as it is now termed, carbonic acid; the attraction of caustic lime for the carbonic acid being stronger than that of ashes. Hence, on caustic lime being thrown into mild alkali, the carbonic acid, by which the ashes were rendered mild, abandons the alkali to combine with the lime, leaving the ashes in their caustic state.

But, although the attraction of carbonic acid is stronger for lime than for alkali, the contrary is the case with the oxygenated muriatic acid, as it abandons lime to combine with ashes, leaving the lime to precipitate.

This observation is made in order to guard the ignorant bleacher from mistakes, who, from having mixed lime with his alkali in the receiver, in the preparation of the oxygenated marine acid, may suppose it acts in a similar manner; but not a particle of lime is acted upon by the acid, whilst ashes remain to combine with it; the only effect of the lime there being, to absorb from the ashes any fixed air they may contain, and to displace the alkali to absorb more of the oxygenated muriatic acid.

Besides the process above mentioned, the bleachers attempted to unite the oxygenated muriatic acid with clay; but as the clay has scarcely any affinity with it, the liquor thus made was little, if at all, superior to that of M. Berthollet.

Such were the attempts made from the year 1786; and the oxygenated muriatic acid combined with pot-ash was in general use by the bleacher until 1798, when Mr. Tennant, of Glasgow, by a well conducted series of experiments, formed what may not improperly be called a new era in bleaching.

Mr. Tennant, having seen so long a period elapse without any material improvement in bleaching, and the alkali, though an expensive ingredient, regarded by the bleachers as an indispensable article to unite with the oxygenated muriatic acid in the receiver, made some trials with the earthsfrontities and barytus, and with succees. Their solubility in water enabled him to combine them with a sufficient quantity of oxygenated muriatic acid to serve the purpoce; but the scarcity of frontities, and the difficulty of separating barytes from the vitriolic acid, with which it is usually found in combination, rendered these discoveries rather objects of curiosity than use.

Mr. Tennant had previously made experiments to combine the oxygenated muriatic acid with lime and lime-water, in the modes above mentioned, but found they were not adequate to the purposes intended; the lime in general remaining at the bottom of the receiver uncombined with the gas, which was the necessary consequence of the lime being specifically heavier than the water, and the gas much lighter; the water, by its interposition between the substances which ought to be combined, namely the oxygenated muriatic gas and the lime, preventing their union.

To bring the pulverized lime into contact with the gas as quickly as possible, it was thought best to divide the receiver into two parts: one contain-
The simplicity of Mr. Tennant's invention of retaining a greater quantity of the oxygenated muriatic gas, by agitation of a sufficiency of lime in the water of the receiver, should be no derogation to its real merit. In substituting lime for pot-ash, an article, not only of foreign produce, but expensive, he has benefited this country, to an extent almost beyond conception; it having been proved upon oath, that by the use of Mr. Tennant's procès, the consumption of ashes at a single bleaching-green has been reduced three thousand pounds kerling in value in one year. A patent for Mr. Tennant's invention was granted him in the year 1798; but as frequently happens in patent cases, on a late trial of its validity, some circumstances arose from which the jury thought themselves justified in severing the patent. We have therefore with considerable pains collected for the public benefit an account of his process, and the most approved mode of putting it in practice, either on a small or an extensive scale, as will be seen by a reference to Plate I. of Bleaching hereafter described.

Mr. Tennant's method of using calcareous earth for neutralizing the muriatic acid gas, and forming the oxy-muriate of lime employed in bleaching is as follows: viz.—In a receiver capable of containing one hundred and forty gallons wine measure, dissolve thirty pounds of common salt, which appear useful only in giving an additional degree of specific gravity to the water, and by that means making it easier to keep the lime to be afterwards added, in suspension; when this salt is dissolved, add sixty pounds of finely powdered quicklime, and into the retort of the apparatus put thirty pounds of powdered manganese, mixed up with thirty pounds of common salt, upon which pour thirty pounds of sulphuric acid (oil of vitriol), previously diluted with its bulk of water, and the usual precaution of futing the vessel being taken, proceed to distillation. When the gas begins to appear, the agitation of the lime and water in the receiver must commence, which should be continued by means of a wooden paddle or rake, or similar contrivance, without intermission, until the materials in the retort, after heat being employed as usual, will not yield any more oxygenated muriatic acid gas. Then the whole should be allowed to remain at rest for two or three hours, when the clear liquor in the receiver, may be drawn off for use, and mixed with water in such proportions as may be found necessary, previous to the immersion of the goods to be bleached.

The principal point of attention in preparing this oxygenated muriate of lime, is, to obtain a complete diffusion of the lime through the mixture, or a mechanical suspension of it in the water during the operation, so that every particle of the lime may, by agitation, be exposed to the action of the gas, instead of merely its upper surface, as had been formerly practiced. By the present means, the oxygenated muriatic acid gas is absorbed with ease, and meets with a sufficient quantity of lime to produce a strong solution of oxygenated muriate of lime, without any uncombined oxygenated muriatic acid; a thing which could not be otherwise effected. The addition of the common salt in the receiver may even be omitted, without prejudice, if the agitation of the lime be well managed.

Plate I., fig. 2. of Bleaching, shews a longitudinal section of a method, which has been practised in Ireland for diluting the oxygenated muriatic acid, and the formation of the oxygenated muriate of lime, a, the asb-hole; δ, the fire under the iron pot or vefsel; e, the aperture through which it is supplied with coals; d, the entrance to the asb-hole, which may be provided with a stopper of burnt clay, or earthen ware, to regulate the draught of the fire, by means of the handle shewn by dotted lines: c, a cald-iron pot or vefsel.
To the buckle, and the leaden cover being inserted into the retort, the agitator, formed of a rod of iron coated with lead, having some arms at its lower end to stir the materials within the retort. At the part where the rod passes through the cover, a leaden collar or cap is folded, to prevent the agitator from descending too low; these two parts are made in a conical form, to fit exactly, and thus prevent the escape of the gas; \( \ell \), a leaden tube or pipe, of three inches bore, to conduct the gas into the tubulated reservoir; \( m \), the leaden reservoir, formed upon the principle of Wolfe's apparatus; the tube, \( \ell \), defends by the first aperture, \( m \), to the bottom of the reservoir, which is about two thirds full of water. The small portion of sulphuric acid, which rises in diffusion, unites with this water; the oxygenated muriatic acid, which travels this water, passes by the pipe, \( m \), into the receiver or condenser, \( \sigma \), which is a wooden vessel, in the midst of which is placed an agitator, \( \rho \), the arms of which raking up the lime cause it to combine with the gas, in proportion as it arises in bubbles from the lower extremity of the leaden pipe, \( \zeta \).

The projections of wood, \( \varphi \varphi \varphi \), fixed to the flanges within the tube, counteract the rotatory motion of the arms of the agitator, and thus avert the combination of the gas with the lime and water. The cover of this tube is fixed close upon the edge of it at \( r \); the cover having a groove in it to unite them tighter together; \( i \), a cock to draw off the liquor, when sufficiently impregnated for use; \( l \), a wooden handle to give motion to the agitator. The joints may be luted with clay, to prevent the escape of the gas.

Fig. 3, and 4, shew Mr. Temnant's improved machinery for preparing the oxymuriated lime. The plate, \( A, A, \) \( A, A, \) is the still, made of lead, of a circular form, having a double flange at the top, which is fitted down into the space of the \\

The vessel, nearly filled with water, in which the leaden retort is placed; \( j, j \), a tripod of iron, on which the retort stands; \( g, g \), the leaden retort, from which the gas to be diluted; \( \alpha, \alpha \), a tunnel of bent lead, through which the oil of vitriol (fulphuric acid) is to be introduced into the retort; \( i, i \), a leaden cover, fitted and luted to the neck of the retort, having three apertures, viz. for the introduction of the tunnel, the rod of the agitator, and the tube of the condenser; \( \ell \), the agitator, formed of a rod of iron coated with lead, having some arms at its lower end to stir the materials within the retort. At the part where the rod passes through the cover, a leaden collar or cap is folded, to prevent the agitator from descending too low; these two parts are made in a conical form, to fit exactly, and thus prevent the escape of the gas; \( \alpha, \alpha \), a leaden tube or pipe, of three inches bore, to conduct the gas into the tubulated reservoir; \( m \), the leaden reservoir, formed upon the principle of Wolfe's apparatus; the tube, \( \ell \), defends by the first aperture, \( m \), to the bottom of the reservoir, which is about two thirds full of water. The small portion of sulphuric acid, which rises in diffusion, unites with this water; the oxygenated muriatic acid, which travels this water, passes by the pipe, \( m \), into the receiver or condenser, \( \sigma \), which is a wooden vessel, in the midst of which is placed an agitator, \( \rho \), the arms of which raking up the lime cause it to combine with the gas, in proportion as it arises in bubbles from the lower extremity of the leaden pipe, \( \zeta \).

The projections of wood, \( \varphi \varphi \varphi \), fixed to the flanges within the tube, counteract the rotatory motion of the arms of the agitator, and thus avert the combination of the gas with the lime and water. Fig. 3, and 4, shew Mr. Temnant's improved machinery for preparing the oxymuriated lime. The plate, \( A, A, \) \( A, A, \) is the still, made of lead, of a circular form, having a double flange at the top, which is fitted down into the space of the \\

It will be found that the flanges, filled with water, preclude the necessity of the application of any let, and occasion the operation to be conducted in a clearer, cheaper, and more expeditious mode, than formerly employed.

To describe the proportions of the several articles used in the process of bleaching, would carry us far beyond the bounds which can be allotted in the present publication; we shall, therefore, give the following short but clear account of the mode we recommend to be practiced, to procure the most perfect and durable white on cotton goods, after their being taken from the weaver; which is, first, to wet them thoroughly in cold water; then to allow them to steep in cold, or lukewarm, water, from 12 to 36 hours, according as they are of a strong or thin fabric; then to wash them well in clean cold water; afterwards to bucket or boil them in a calcic alkaline ley; then to wash the goods well in clean water, and afterwards immerse them in diluted oxymuriate of lime, and wash them, repeating the operations of the alkaline ley, and the oxymuriate of lime, till the goods are perfectly white; then to pass the goods through the diluted sulphuric acid, or liquor, washing them well afterwards; lastly, to pass them through a weak ley of pearl-ashes, or of soap, and again through clean water, before drying and finishing them; which finishing of the goods consists in bleaching, blueing, rolling, or calendering them as fashion directs, or the particular market for which they are intended, may require.

It is to be remarked, that the immersion of the goods in the vitriolic lye, and also in the dilute, or soap liquor, is requisite in the end of the process, to prevent a brown tone in which the cloths that are bleached white from the oxygenated muriatic acid, without such precaution, are apt to revert to.

By experiments made at Rouen on cotton thread, with a view to ascertain whether the old or new mode of bleaching was more prejudicial to the fabric, it was proved that the cotton thread bleached in the new mode bore, without breaking, considerably more weight than that bleached in the old method, and was less injured in texture.

In the report on experiments, made by order of the trustees of the linen and hempen manufacturies at Dublin, in the year 1791, with a view to ascertain the comparative merits of several specimens of bleaching liquids sent for their examination, the following mode of bleaching appeared to be the best for linens, and though executed on a small scale, will convey the principal necessary information.

May 11th, 1791. The linen was steeped, in the flate receive from the loom, into water of a heat sufficient to bear the hand, and left in the vefel.

May 16th. The vefel was washed out of the liquor, in which a pretty strong fermentation was observed to have taken place.

May 17th. Finished making a mother-ley, which was made in the following manner: three pounds, and a half of lime were flaked, and mixed with ten gallons of water; fourteen pounds of Danzig pearl-ashes were dissolved in some of this water; then mixed the whole; when it had settled, it
was filtered through a coarse cloth, and the residuum washed repeatedly in four gallons of water, to obtain the whole strength of the alkali; the whole fourteen gallons being then carefully mixed, the ley proved, by very accurate weighing, to contain twelve ounces of caustic alkali salt to the gallon. From this, a ley was made from the work, by adding fix parts of water to one of the mother ley; thus each gallon of the working ley contained one ounce, five drachms, and forty-three grains of caustic alkali.

The boiler being charged with this ley, the linen, which had been spittle washed, was steeped in cold for one hour; then brought up by a very gentle heat to a simmering boil, which continued for three hours; the cloth was then well washed out, and left to steep for that night.

May 18th. Washed out the above linen in fresh water; hung it on cards in the open air, watering it several times in the day.

May 19th. Finding the cloth not to well cleared as could be wished, the boiler was again charged with one of the mother-ley, to four of water, which made the strength two ounces, three drachms, twelve grains of caustic alkali to the gallon. In this was boiled another piece of linen which had been spittle washed as the others; and after it was boiled, it was well washed out.

May 20th. Steeped the whole of the linens for six hours in the liquid prepared with the muriatic acid of the several claimants; afterwards washed them well out, and left them steeping in cold water all night.

May 21st. Washed out all the above linens, and when dry, boiled the whole parcel as before in one of the mother-leys, to five of water, containing two ounces of caustic alkali salt to the gallon; washed them well out of the ley, and left them to steep in pure water till Monday morning, the 23d instant.

May 24th. Steeped the linens for the second time in the oxygenated muriatic acid for six hours; then washed them out, and left them to steep all night in cold water.

May 25th. Having charged the copper with a ley made from one of mother-ley, to fix of water, containing one ounce, five drachms, and forty-three grains of caustic alkali salt to the gallon, the linens were boiled in this for the third time, with a very gentle simmering heat for three hours; they were then washed out, and left to steep.

May 27th. Steeped all the linens for the third time six hours in oxygenated muriatic acid as before; washed them out, and left them in water all night.

May 28th. Immerged all the linens which had been steeped yesterday in the oxygenated muriatic acid, in a weak vitriolic acid for four hours; then washed them out, and left them steeping in cold water.

May 29th. Washed and dried the linen cloth which had been foured yesterday.

June 1st. Boiled all the linen which had been foured in a strong lather of soap.

June 2d. Soured and washed out all the linen which had been boiled in a soap lather yesterday. This operation finished that experiment, in which the above linens were first steeped in water; then boiled in caustic alkali ley, and steeped in oxygenated muriatic acid alternately four times; then foured in vitriolic acid, loaped and foured again.

The above experiments were made, with various others, by Mr. John Arbuthnot, and Mr. John Clarke; and on the trials of the different specimens of the oxygenated muriatic acid, the preference was given to that prepared by Mr. Robert Roe, of Bing's End, on the principle of the jelline liquor mentioned by Mr. Bartholles, by adding a solution of alkali in water in the receiver. Mr. Roe's base preparation, of which was made by adding thirty-eight pounds of quicklime to 1141 lb. of pearl-ash, which made a caustic ley of about nine pounds weight per gallon; he found caustic ley more susceptible of imbibing the gas and retaining it, than mild ley of equal strength.

From the different experiments made to bleach various articles at the above time, the following inferences may be deduced, viz. that allowing cotton or linen, when raw from the loom, to ferment, by steeping in warm water a considerable time before boiling the cloth in an alkaline ley, is of considerable service.

That cloth or yarn is not injured by steeping for fix hours together in oxygenated muriatic acid.

That strong alkaline leys answer better than weak ones, at the commencement of using the leys.

That the white colour of bleached cloth can be better judged of wet than when dry.

That very minute attention in excluding light and air is not absolutely necessary in bleaching with oxygenated muriatic acid.

That parging or clearing yarn or cloth in an alkaline ley, previous to steeping in oxygenated muriatic acid, is absolutely necessary.

That the bleaching liquids made from oxygenated muriatic acid, in which alkaline salt is blended in the composition, require the cloth to be frequently steeped in vitriolic acid; and that the oxygenated muriatic acid made with water only, make more frequent boilings of the cloth in alkaline leys necessary.

That the loss of the cloth in weight, when bleached by the new method, is only one fourth, but by the old method one third.

That steeping in warm water is infinitely better to extract the fynn and dirt from the raw cloths, than boiling them with soap or ley immediately as they come from the loom.

The liquors of the oxygenated muriatic acid, and also those made from the vitriolic acid, may be repeatedly used without detriment, till the whole strength is exhausted.

The cloth or linen, in the acid bleaching liquors, should be moved in the liquor every hour, that every part may be equally cleared.

It is difficult to ascertain the strength of the leys proper for use in bleaching cotton or linen, as the alkalis or athes differ so greatly in purity, and the admixture generally found in them of neutral salts prevents the hydrometer from being a regular test. The common allowance for bleaching liquors in Ireland, is stated by Mr. Higgins, in his ingenious memoir in the Transactions of the Dublin Society, to be for sixty gallons of water, fix pounds of barilla, or four pounds of pot-ash at the leaf, and most bleachers use more than this.

To discover adulterated pot-ash, Mr. Higgins recommends the following method. The specimen of athes being first weighed, is digested for a few minutes on a sand-bath, in twice its weight of water, in a heat of about 212 degrees, and infamnetly stirred. It is then removed from the sand-bath, and before it is cooled to the temperature of the atmosphere, it must be filtered through paper. When all the liquor has passed through the filter, a small quantity of cold water is gradually poured upon the saline residuum or the filter, in order to wash through the whole of the alkali. The undissolved salt sulphate of pot-ash (vitriolated tartar,) remaining on the filter, is afterwards dried and weighed, to ascertain the quantity.

To determine whether any common salt is suspended in the licor which has been filtered, evaporate the clear solution a little on a sand-bath, and let it in a cold place for 24 hours.
hours; at the end of which time, any common salt it contains will be found crystallized in regular cubes at the bottom of the vessel; pour off the clear liquor, and repeat the process, till no more cubic crystals are produced. If it is determined to be very accurate in the analysis, before the common salt (murate of soda) thus procured is weighed, some muratic acid may be poured upon it, in order to take up any of the pure pot-ash which may have adhered during its crystallization. The muratic acid, with such of the alkali as it has dissolved, may be then drained off and thrown away, and the murate of soda dried and weighed.

The sum of the impurities being then subtracted from the weight of the specimen, the quantity of the pure pot-ash is ascertained.

To know what quantity of mere alkali is contained in 100 lbs. of various deposits of different alkaline salts examined by Mr. Kirwan, we shall add the following table, published by him in the Irish Transactions, in 1789.

| One hundred Pounds | Mineral Vapors | Veal. |
|--------------------|----------------|------|-------|
| Crystallized soda   | yielded 2 lbs. | 24   | 16   |
| Sweet Barilla      |                | 3    | 1     |
| Mealy's cuminamara kelp |            | 3    | 1     |
| Do. defalpaborated by fixed air | | 4    | 1     |
| Strangford kelp    |                | 1    | 1     |
| One hundred Pounds | Vegetable Alkali | 62   | 1     |
| Dantzic pearl-ash | yielded 62 lbs. | 62   | 1     |
| Clarke's refined ash |            | 62   | 1     |
| Calphar            |                | 62   | 1     |
| Common raw Irish weed-ash |        | 62   | 1     |
| Do. slightly calcined |            | 62   | 1     |

It is much to be regretted that, considering the immense quantities of pure marine alkali which could be procured at a cheap rate from the East Indies, so little attention should be paid by the East India Company to an article which would be so profitable a branch of commerce to them, and prevent a considerable sum being paid to other nations. The mineral alkali procured from the East Indies, is much purer than what is obtained from Barilla; and a preparation exactly similar in appearance and quality to the Alicant Barilla, may be made with great advantage to the manufacturer, from a mixture of the East India mineral alkali with the common Scotch kelp, for the purposes of the bleacher, the soap-maker, or the Turkey-red dye. To shew the importance of this object, the following table of the imports into Great Britain are annexed for seven years.

When it is considered that 20 pounds of the mineral alkali brought from India in a powdery state, as it usually is, will, by mere solution in water, yield 100 lbs. of the crystallized soda fold in the shops, it will be seen, that the purchase of the mineral alkali from the East India company, will be an object well deserving the attention of the bleachers and soap-boilers; and far preferable to the use of Spanish kelp or Barilla.

Mr. Kirwan, by means of muratic acid, precipitated the colouring matter from an alkaline ley, saturated with the colouring matter of linen yarn, and found it to possess the following properties: When suffered to dry for some time on a filter, it assumed a dark green colour, and felt somewhat clammy, like moist clay. His observations in the Irish Transactions for 1789, are as follow:

"I took, says he, a small portion of it, and added to it 60 times its weight of boiling water, but not a particle of it was dissolved. The remainder I dried in a sand-heat; it then assumed a shining black colour; became more brittle, but internally remained of a greenish yellow, and weighed one ounce and a half."

"By treating eight quarts more of the faturated ley in the same manner, I obtained a further quantity of the greenish deposit, on which I made the following experiments: 1st. Having digested a portion of it in rectified spirits of wine, it communicated to it a reddish hue, and was, in a great measure, dissolved; but by the effusion of distilled water, the solution became milky, and a white deposit was gradually formed; the black matter dissolved in the same manner.

2d. Neither the green nor the black matter was soluble in oil of turpentine or linseed oil, by a long continued digestion.

3d. The black matter being placed on a red-hot iron, burned with a yellow flame and black smoke, leaving a coaly residuum.

4th. The green matter being put into the vitriolic, marine and nitrous acids, communicated a brownish tinge to the two former, and a greenish to the latter, but did not seem at all diminished.

"Hence, it appears, that the matter extracted by alkalis from linen yarn, is a peculiar sort of rein, different from pure reins only by its insolubility in essential oils, and in this respect resembling lace. I now proceeded to examine the powers of the different alkalis on this substance, eight grains of it being digested in a solution of crystallized mineral alkali, faturated in the temperature of 62°, instantly communicated to the solution a dark brown colour; two measures (each of which would contain eleven pennyweights of water), did not entirely dissolve this substance. Two measures of the mild vegetable alkali dissolved the whole."

"One measure of caustic mineral alkali, whose specific gravity was 1.053, dissolved nearly the whole, leaving only a white residuum."

"One measure of caustic vegetable alkali, whose specific gravity was 1.599, dissolved the whole."

"One measure of liver of sulphur, whose specific gravity was 1.750, dissolved the whole."

"One measure of caustic volatile alkali dissolved also a portion of this matter."

The colouring matter of cotton is much more soluble in alkali, than that of linen; hence the greater facility with which cotton is bleached.

The theory of bleaching vegetable matter, as we have before observed, to have been described by Mr. Delaval, depends on removing the colouring matters, whether natural or accidental, which cover their solid fibrous parts, which are the only parts endowed with a reflectory power. Raw cotton or linen, boiled in a diluted solution of caustic alkali, gives to the liquor a deep brown colour, and destroys its causticity; and fresh portions of clear ley applied a second or third time, will produce a similar effect, but in an inferior degree. If the cotton or linen be now plunged into the oxymuriatic acid, and allowed to remain a short time, they will become white; and if they are then plunged into an alkaline ley, the liquor will again become brown, and lose its causticity.

On saturating either the first or last of the alkaline solutions with an acid, a similar precipitate is obtained from each, of a dark coloured matter, almost insoluble in water, but soluble in caustic alkali.
Hence it appears, that after raw cotton or linen has been acted upon by alkalies for two or three times, they have no further effect upon it, till the cloth comes in contact with oxygen or pure air, either by immersion in the oxygynated muriatic acid, or by exposure to the atmosphere; and it is on account of the speedy action of the acid, in comparison with that of the atmosphere, that the new mode of bleaching is now generally adopted.

M. Belthollet, and the modern chemists suppose, that the colouring matter of linen is composed principally of carbon and hydrogen; and they conclude, that linen, bleached by the oxymuriatic acid, becomes yellow on this principle, that when the oxymuriatic acid renders linen white, a quantity of oxygen has combined with the colouring particles; but that this oxygen gradually enters into a combination with the hydrogen, and forms water which passes off; that the carbon becomes predominant, and the linen, in consequence, assumes a yellow colour.

The old chemists, on the principles of Stahl, would say, that a part of the dephlogisticated marine acid, (oxymuriatic acid,) after the cloth had been acted upon by the alkali, absorbed such phlogistic colouring matter from the cloth, as the alkali had no affinity for; and thus became diluted common marine acid, which has a great attraction to cotton or linen, and, if exposed to a moderate heat, will act upon the texture of the cloth, and render it of a yellow colour.

We notice this circumstance in two different points of view, that the bleacher may be aware of the necessity of applying, in either case, a weak ley of pearl-ash, ultimately after the use of the muriatic acid, to prevent this yellowness from occurring; and also that the reader may comprehend the reasoning of Home, and other persons who have written upon the subject of bleaching, previously to Mr. Scheele's discovery.

To recover the pure alkali from the black coloured leys, which have been used in bleaching, and to render them equally proper for the same purpose, has been for a considerable time a material object in the neighbourhood of Manchester, and practiced with great success.

To effect this, the black or brown strong leys, which have been left after bucking linen, or cotton, yarn, or goods, or furred after wringing them, is put into a mobing [flat or shallow iron pan, made of plate iron, rivetted together. (See Plate 1, fig. 4. 5.) Under this pan a fire is made, and the old leys gradually evaporated, till they become of a consistence nearly resembling tar; the matter is then put into casks, and carried to the reverberatory furnace. Plate 1, fig. 6, 7, where it is ladied or poured into the cavity or bed within the furnace; the fire being then made acts powerfully on the alkaline mafs; gradually dries the water left amongst it; then acts on the colouring matter the ley has abstracted from the cloth, which is partly disphaced in a black, offensive smoke, and partly destroyed by combustion; the calcination of the ashes is assisted from time to time, by taking them up with a long iron rod, in order to expose fresh surfaces to the flame; the heat is continued and increased till the inflammable matter amongst the alkali is disphaced, and the ashes brought to a perfect fluid state; they are then let out by an aperture in the side of the furnace, into an old iron pot put into the ground, and when cold, broken into small pieces for use, being frequently in a purer state than when first imported.

Fig. 4 Plate IV is a section of the evaporating pan for the waffe leys, where A represents a flat iron pan, of an oblong square form, about six inches deep, and of a size proportionate to the quantity of leys to be evaporated: B, the fire-place: C, the ash-hole: D, the flue in which the fire acts under the pan; E, the chimney for the smoke; F, the brick work.

Fig. 5 Plate IV is a bird's eye view of the frame evaporating pan, which is made of plates of beaten iron rivetted together, as shewn in the plan; the fire-place underneath it is marked by dotted lines at B, and the chimney flue at E.

Fig. 6 Plate IV represents a longitudinal section of the reverberatory furnace used in the preparation of ashes, or solid alkaline falls from the old leys after evaporation, to a proper consistence: a the brick work; b, the ash-hole; c, a channel, or passage under the furnace, to admit a free current of air; d, the fire-grate; e, the fire-place; f, the inner part of the furnace; g, the bed of fire-proof brick, on which the matter is calcined; h, the alkaline ley to be calcined; i, a door through which the ley is introduced by an iron handle into the furnace, and through which door the matter, during calcination, is flumed from time to time; k, the passage for the smoke, or chimney, which chimney should be from 20 to 30 feet high; l, the upper part of the furnace, arched like an oven; m, the separation wall between the fire and matter to be fluided or calcined.

Fig. 7 Plate IV represents the upper plan of the furnace, of which fig. 6 is a section: a, the outer walls; b, the ash-hole and draught-hole; c, the iron grate of the fire-place; d, the fire-place; e, the bason in which the keys are calcined; f, the door through which foill coal is thrown into the fire-place; g, an iron tube through which the ashes in fufion flow out of the furnace when sufficiently calcined; h, an iron pot into which the melted ashes flow, and where they are suffered to cool; j, a wall of fire-brick between the fire-place and bason, over which walk the fire paffes; k, the steps leading down to the ash-hole.

It is necessary to remark, that all the interior part of the reverberatory furnace should be made of Welsh brick, or such as will withstand the action of a frong fire; the whole building should be well bound together by iron bars, or cramps. If so constructed, it will last for several years; and when it then want's repair, the ashes, which will be found accumulated in the interstices of the brick-work, will defray the expense of such repairs.

Having shewn the methods generally used in bleaching linen and cotton, we shall notice a process lately discovered by Mr. W. Higginson of Dublin, for using the sulphuret of lime, as a substiute for pot-ash in bleaching. The sulphuret is prepared in the manner following, viz. sulphur or brimstone in fine powder, four pounds; lime well faked and sifted, twenty pounds; water sixteen gallons; these are all to be well mixed, and boiled for about half an hour in an iron vessel, stirring them briskly from time to time. Soon after the agitation of boiling is over, the solution of sulphuret of lime clears, and may be drawn off free from the precipitate, which is considerable, and which rests upon the bottom of the boiler. The liquor, in this state, is nearly of the colour of small beer, but not quite so transparent.

Sixteen gallons of water are afterwards to be poured upon the remaining precipitate in the boiler, in order to separate the whole of the sulphuret from it; the matter is then well agitated, and must, when settled, be drawn off, and mixed with the first liquor; to these again thirty-three gallons more of water may be added, which reduce the liquor to a proper standard for bleaching the cloth.

Though either lime or sulphuret, separately, is very little soluble in water, yet this sulphuret of lime is highly soluble.

This preparation has been applied, in the following manner, to the bleaching of linen in Ireland.
The linen, as it comes from the loom, is charged with the weaver's paffe or dressing, to discharge which, the linen must be steeped in water for about 48 hours, and afterwards taken out and well washed; in order to separate the refuse matter inherent in the vegetable fibre, the linen must then be steeped in the cold solution of sulphuret of lime (prepared as before), for about 12 or 18 hours; then taken out and well washed; when dry, it is to be steeped in the oxymuriate of lime, prepared by Mr. Tennant's process, for 12 or 14 hours, and then washed and dried. This process is to be repeated by fix alternate immersions in each liquor, which are sufficient to whiten the linen.

Though we must confess, that we have some doubts respecting the application of sulphuret of lime to supercede the use of ashes, in bleaching goods intended to remain perfectly white, yet we think it incumbent upon us to state, that for goods previously bleached for dyeing, it possesses advantages over those where alkalies have been used, and which has been actually proved above 30 years ago, by the practice of Mr. Peter Henry Otter, communicated by him to the late Mr. John Wilton, of Alkermere, near Manchester. Mr. Wilton's memory deserves every mark of respect from the cotton manufacturers of England, for his numerous improvements in the bleaching, dyeing, and finishing of cotton goods.

For the use of private families, where the linen is dirtied by perspiration or grime, it will be of great service towards rendering it white, to steep it for some time in a clear liquor, made by mixing one quart of quicklime in ten gallons of water, letting the mixture stand 24 hours, and then using the clear water drawn from the lime. After the linen has been steeped in this liquor, it should be washed as usual, but will require much less soap to be used.

Cotton goods, after bleaching, were formerly dried in the open air, on frames or tenter-rails, or on rails in covered buildings, or in large rooms or stoves heated for the purpose, all which modes were attended with great delay and disadvantages.

These difficulties were removed in 1792 by an apparatus, simple in its construction, easily managed, and of singular use in facilitating the process of the bleacher. For this useful invention the public are indebted to John Burns, esq. of Paisley.

By this discovery the bleacher can erect a drying machine, equally useful at all seasons, and in all weathers, at less than one-tenth of the expense of former contrivances, for doing Linens to the same extent. There is no risk of damage from wind or rain, less chance of injury from servants, owing to the simple manner in which the goods are prepared. They receive a fine gloss during the process of drying, the colour is as well preserved as if dried in the open air, and they cannot be injured by the heat.

A contrivance so obviously beneficial and complete, was soon introduced into general practice in the west of Scotland; and was undoubtedly the claims of the above gentleman to the originality of invention, that the bleachers in the neighbourhood presented him with a handsome donation of silver plate, suitably inscribed, in testimony of their sense of his merit, and as some reward for communicating his plan to the public.

We are more particular in noticing this circumstance, as some other persons have subsequently taken out a patent for the same principle, with a little variation in the construction of the machine, but which alteration has not been found to answer the purpose as expected. We shall therefore now more particularly describe Mr. Burns's apparatus for drying.

**Fig. 1.** Plate III. A is the boiler or iron vessel; B, the safety valve; C, the hollow leaden pipe which conveys the steam from the boiler to the rollers; D, a brass cock hollowed to receive the pivot of the roller, represented in fig. 2, one of which cocks is fixed to the pipe under each roller, and by opening which the steam is admitted into the roller; E represents twelve rollers placed upon the cocks, one of which, next to D, has the cloth upon it in the operation of drying; FFF, the wood frame in which the machinery is placed; GGG, the supports of the leaden steam-pipe, and of the trough H H, which trough is 15 inches broad at top, to receive the water formed by the condened steam as it drops from the bottom of the rollers, E, and to conduct it to I, a small pipe extending from the trough, H, to the funnel, K, which funnel has its lower pipe reaching to within eight inches of the bottom of the boiler, to prevent the steam from issuing out at its mouth, and which funnel keeps the boiler supplied with water to its proper height, or flows when any is wanted, as the steam would arise through it if water should be wanting in the boiler.

**Fig. 2.** Plate III. A shows one of the rollers separate from the frame. It is usually five feet long, one foot in diameter, and made of double tinned sheet iron, and hollow in the middle, for containing the steam; a is the lower pivot of the roller, which is an open tube at the end for receiving the steam conveyed through it from the cock. This pivot rests a foot within the roller, at the under part of the roller; d is a small hole for allowing the condensed steam to drop into the trough placed below it as above-mentioned; b, the other pivot or axis of the roller, which is fastened to the top bar of the frame by a latch, as represented in fig. 2; c, a row of teeth fixed into a small dip of tinned sheet iron, folded to the roller, and thereby elevated to prevent the teeth from tearing the cloth.

**Fig. 3.** Plate III. A machine about three feet in height, for the purpose of lapping the cloth upon the rollers. A, the box in which the cloth is first laid; B, the farthest wooden roller, over which the cloth passes from A, and from thence under the wooden roller C, to the tin roller D, on which it is lapped by turning it with the handle E; F, the cloth passing under the roller C, to the tin roller D, on which, when it is lapped, it is ready to be carried and placed in the drying machine; G, a weight hung from the projection in the frame at H, over the roller B, to keep the cloth sufficiently tight as it passes from the box A, over that roller to be lapped on the drying roller D.

**Fig. 4.** Plate III. A machine for laying the cloth on the tin roller, previous to its being dried. A, a perpendicular frame, in the front of which is placed the tin roller B, with a handle for turning it at C; the cloth D extends from the roller B over the wooden roller E, in a frame F to G, where its other end is attached by a wire run across it to some wrapper or linen cloth, fastened to a board H, fixed below the roller B. L L are upright posts fixed to the outer side of the bottom frame K K, having wooden pegs K K in them, on the side nearest the tin roller B. Rails or rods are laid across from these to similar pegs opposite, to prevent the cloth touching the ground when it is adjusting in the beginning of the operation, and the number of these posts necessary, therefore, are in proportion to the length of the cloth.

At the commencement of lapping the cloth on the tin roller B, the frame F, moveable on small rollers I I, running in grooves on the frame K K, is drawn so far back, that when the cloth is fastened to the wrapper C, one half of the piece reaches to the roller F, the other half lapsed over that roller, reaches to the tin roller B, to which it is then to be fastened. On turning the handle C, the cloth is gradually lapped round
the roller B, the moveable frame F being drawn forward by the cloth; for as the cloth is lapped on the roller B, the frame F is drawn towards it between the uprights LL, and by means of a projecting wood forming an inclined plane fixed at M, on each side, near the top of the frame F, the rails O are raised from the pegs NN, and carried forward on the part M of the frame F, without impeding its progress to the tin roller B, till the wrapper G, to which the cloth is fastened, passes over the roller, and the wire at G, which attaches it to the cloth, is withdrawn, leaving the whole of the cloth to be dried on the tin roller B, which roller is then taken out and placed in the drying frame.

To ascertain the strength of the oxygenated muriatic acid used by the bleachers in France, Mons. Defiozillez made use of a solution of indigo in the vitriolic acid, for which purpose he takes one part of finely pulverized Guatimala indigo, and eight parts of concentrated vitriolic acid, which mixture should be put in a glass vessel, and kept of a gentle heat by standing near the fire or in warm water all night, and repeatedly stirred with a glass rod or tube. When the solution is complete, it is diluted with a thousand parts of water. One measure of this solution is put into a graduated tube of glafs, and oxygenated liquor is added, until the colour of the indigo is completely destroyed, and the strength of the oxygenated liquor is ascertained by its power in discharging the colour.

Mr. Kofe has recommended a method which is better adapted for general use; which is, "to have small measures properly proportioned to each other, and when the liquid is strong, to prevent waste of the indigo liquor prepared as above, and a tedious repetition of measures, let a small measure of the liquor to be tried be put into a measure containing 24 of the same measures of water (it then becomes diluted to a twenty-fifth part); to a measure of this diluted liquor add as many measures of the blue test as it will discharge, which multiplied by 25, gives its whole strength. It will be proper to have a measure of five for the sake of dispfation, in adding the blue test liquor. It is necessary that the experimenter should fit low enough to view his measures horizontally, in order that they may not be overfilled, otherwise he may be deceived.

Great care should be taken in the choice of the indigo and the vitriolic acid employed, for unless the indigo is of the Guatimala kind, or bed East India, and the vitriolic acid highly concentrated and pure, the colour produced will be a greenish brown, instead of a bright blue.

Mr. Chaptal has employed the oxygenated muriatic acid to the purpose of bleaching paper, both by applying it to the rags before worked down, and to the pulp or paper; he also re-dyed the white to prints discoloured by time, by immerging them in the oxygenated muriatic acid liquor, or exposing them to the action of its vapour. And several patents have been granted in this kingdom for bleaching pulp or paper, amongst which Mr. Menfrs. Clement and George Taylor, of Maidstone, in Kent, have obtained one for bleaching the pulp, by inclining it with a liquor of oxygenated muriate of potash, in a vessel resembling a churn, eight feet diameter at the great end, three feet four inches diameter at the little end, and two feet ten inches in the clear. This vessel revolves upon an axis at each end, and the pulp, by this motion, and projecting parts within the vessel, is constantly exposing fresh surfaces to the liquor, till the whole pulp is sufficiently whitened.

Mr. Biggs, of Ipsing, in Sussex, has since obtained a patent for bleaching paper, and re-dyed to white nes damaged or milled paper, by exposing in close wooden vessels, in quantities of six or eight sheets together, on wooden frames placed at small distances from each other, to the action of oxygenated muriatic gas, and after the paper is taken out, pressed, and dried, previous to its being fixed, wetting it in a solution of alum water.

Another method he propofes, is by wetting and foaking the paper in oxygenated muriatic acid liquor, till it is properly bleached; after which it should be well pressed and dried, and wet out in the alum water, as in the other process.

A patent has likewise been granted to Mr. Elias Carpenter, of Bermondsey, London, for a method of bleaching paper in the water leaf or sheet, and fixing it without drying; he uses for this purpose a slow deal box or case, which must be carefully clofed, and capable of containing water or steam within this. The paper to be bleached is to be hung on strips of glafs, about 15 inches long, placed in grooves within the box, about four sheets on each trip; the paper is taken for this purpose when pressed in the packs in its wet state, and when the box is filled and clofed, it is exposed to the action of oxygenated muriatic gas for eight or ten hours, and when sufficiently bleached, fixed with a preparation made from one hundred weight of pieces of skins boiled in water and strained, then fourteen pounds of alum, seven pounds of white vitriol, and one pound of gum arabic added; these ingredients will make size enough for about 50 reams of foolscap paper; the paper when dried and pressed, is finished in the usual way. To prevent the noxious qualities of the gas to the workmen, he directs a solution of pot-ash in water to be placed at the bottom of the bleaching box, to absorb the elastic vapours which would otherwise affect them on opening the box.

Mr. Teumant of Glasgow, subsequent to the patent granted him for his bleaching liquid, has obtained a patent for preparing the oxygenated muriatic of lime in a dry form, by which means bleachers may be cheaply and conveniently supplied with it by him, and face much of the trouble, expense, and hazard which attend the preparation of the former bleaching liquor.

To bleach filk from its natural gummy state, whether in skin or manufactured, it should be put into a thin linen bag, and thrown into a vessel of boiling water in which good white lump has been dissolved; the filk should boil two or three hours in this liquor, and the bag of filk frequently pressed with a stick, and turned, so that the gummy matter may separate from it, and rise to the surface of the liquor, from whence it should be skimmed off, and thrown away; the bag should then be taken out, and if it contains filk goods, they should be well washed in clean cold water, to prepare them for printing or dyeing; but if the bag contains filk in the skin, after it has been well washed in clean water, beaten, and slightly wrung, it may be put the second time into the copper vessel, filled with cold water mixed with soap, and a little indigo blue, if you wish it tinged a little of the blueish hue.

The filk, when taken out of the second water, should be wrung hard with a wooden peg, to press out all the liquor; then flaked, to separate the threads; then suspended on poles, in a clofe room or stowe where sulphur is burnt, which improves the whiteness of the filk.

Woolen cloths or stuffs may be bleached and made white by soap and water; by the vapour of sulphur; or by chalk, indigo, and fulphuric vapour. In the first case, after the stuffs have been cleaned at the fulling mill, they are again worked in warm soap and water, to render them whiter, and afterwards washed in clear water and dried; in this state they are fit for dyeing any light colours.

To destroy or remove the reddish hue arising from boiling printed cottons in madder deceotions, which prevents the printed
printed colours appearing to advantage, the goods are usually boiled for some time in brine and water, and then exposed to the air, by laying them on the grates, and throwing upon them clear water from time to time. Mr. Grimshaw, in the year 1796, obtained a patent for clearing printed goods coming from the madder cooper, by using the grates after brewing malt liquors, instead of brine; the plan he recommends is, that the grates should be previously four, and that three or four bushels thereof, more or less, according to the colour of the cloth, should be put into a cooper of hot water, containing 200 gallons or upwards, and four or five pieces of the printed cotton goods then immersed therein, and worked over a winch backwards and forwards, for ten or fifteen minutes; the pieces are then taken out of the cooper, and well washed in clear water, and laid straight upon the ground for two or three days, till the parts which should be white become clear. The same liquor, with the addition of a few grains, will serve to clear other printed goods, till the whole number wanted to be cleared have been completed; a sufficient quantity of clear water being added to replenish what has been absorbed by the goods, or evaporated in boiling. After either of the operations above-mentioned, the impression of the printed goods in dilute oxalated acid, will answer the purpose of the exposure to the air.

Bleaching of Hair. See Hair.

Bleaching of Wax. See Wax.

BLEAK, in Ichthyology, the English name of CYPRinus ALBURNUS, a species distinguished from the other fishes of its genus by having twenty rays in the anal fin.

The bleak is an abundant fish in many of the English rivers, and in those of the northern countries of Europe in general. The flesh is in some esteem; but it is chiefly taken for the sake of the beautiful silverly scales, which artists make use of in the manufacture of artificial pearl. The credit of this invention is claimed by the French; and it is said that they have arrived at such a degree of perfection in this art, that, independent of the plain silverly hues of the beads in common, they can vary the colour to blue, green, or any other vivid tint that they may desire. The process is very short; the scales are scraped off, washed, and then reduced to a fine powder; this is diluted with water, and introduced into a thin bubble of glas, where it forms an internal coating; the cavity is then filled with wax, through which a hole is bored, and the bead is finished.

Gmelin speaks of this species being from four to ten inches in length; but these do not commonly exceed six inches. This fish is infested in the summer-time with a creature of the vernes tribe, that lives in the intellines, and which oftentimes incresces to such a vast size as to occasion the death of the bleak. Fishes so infested rise to the surface of the water, where they leap and tumble about in the greatest agonies, and in that state are well known to the fishermen by the name of mad bleaks. The white bait taken in the Thames at Blackwall and Greenwich, in the month of July, is believed to be the fry of this species. Vide Dorn. Nov. Brit. Fishes, pl. 18.

BLE.B, a small blitter, or bubble.

Naturalists have observed small purple blebs on all the plants of the hypericum kind. Phil. Trans. N. 224. Thick pieces of glas, fit for large optic glasses, are rarey to be had without blebs. Ibid. N. 4.

BLECHINGLEY, or Bletchingley, in Geography, an ancient and small borough town of Surrey, in England; has had the privilege of returning members to parliament from time immemorial. The right of voting is vested in burghage tenure;

and the lord of the manor's bailiff was the returning officer till 1725, when, by a resolution of the house of commons, he was deprived of that office; and the borough has now the singularity of sending two members to parliament, without a mayor, constable, or any other legal returning officer. Sir Robert Clayton is the proprietor of the borough, and has consequently the power of appointing the representatives. The town occupies the summit and side of a hill, and commands some fine and extensive prospects into Kent, Hampshire, &c. Here was formerly a castle, which was nearly obliterated, and its site is overgrown with coppice wood. An alms-house and tree school are the only charitable foundations of this place. The church is large and handsome; but its spire was destroyed by lightning in 1606, at which time the bells were melted by the electric fire. Fuller's earth and a species of iron-flone are obtained in the vicinity of this town. Blechingley is 21 miles south from London. The town and suburbs within the parish, contain 186 houses, and 1344 inhabitants.

Species, 1. B. occidentalis, South American B. "Fronds pinnate; pinnas lanceolate, opposite, emarginate at the haste." This species rises by a simple undivided stalk to the height of 13 or 18 inches; leaves long and narrow; many pinnas, with two small articles at the haste. A native of the West India islands, and the continent of South America. Introduced here about 1777. 2. B. orientale, Chines B. "Fronds pinnate; pinnas linear, alternate." Fronds three feet long; ripe covered at the haste before, with large grey bristles; the anterior side furred with three longitudinal grooves; leaflets linear-lanceolate, fofe, smooth, entire, inranked at an acute angle, the length of the finger. Found in China by Obbeck, and also in the Society isles. 3. B. australis, Capé B. "Fronds pinnate; pinnas subf nellate, cortate-lanceolate, quite entire, the lowest opposite." Stipes a foot long, green; fronds entire, about the edge ruffled; the barren ones with broader pinnas, truncate at the haste; the fertile, with lanceolate pinnas, heart-shaped at the haste; having two lines of fructification, longitudinal, and dilabt both from the edge and rib. A native of the cape of Good Hope. Introduced here, in 1774, by Mr. F. Maffon. 4. B. virginicum, Virginian B. "Fronds pinnate; pinnas multifid." Having the nature of polypodium flix mas or male fern; fronds smooth; pinnas lanceolate, sessile, semipinnatifid, acute; divisions obsolete, quite entire. A native of Virginia and Carolia. Cultivated, in 1774, by Dr. John Fothergill. 5. B. japonicum, Japone B. "Fronds bipinnatifid; pinnales ovate, obtuse, luteated." Stipes convex at the back and smooth, before flat and ilranked; the whole smooth, flexuose, equal; pinnae oblong, acute, pinnatifid, the lower subpetioolate, the upper sessile; differing from the orientale in having an erect frond and blunt pinnules. A native of Japan. 6. B. radicans, rooted-leaved B. "Fronds bipinnatifid; pinnas lanceolate, crenulated; the lines of fructification interrupted." Frond rooting; pinnas sessile, slightly concurrent at the haste, ferrate with a very fine calyx, acuminate, more veined beneath; the line of fructification is next the nerve, but interrupted as it were by long points. A native of Virginia and Madeira, where it was observed by Koenig. Introduced, in 1779, by Mr. P. Maffon. Propagation and Culture. The fourth species alone will abide the open air in England; the first must be kept in the bark house; the cut require only the protection of the dry house, or conservatory; they are increased by parting the roots. Martyr.
BLEDSOE Lick, in Geography, lies in the state of Tennessee, in America, 32 miles from Big Salt Lick garrison, and 76 from Nashville.

BLEEDA, or Blida, in Geography, a town of Africa, in the kingdom of Algiers, and province of Titeri; is situated in the interior of the country, over-against the mouth of the Ma-Safan, at five leagues distance, under the shade of a ridge of mountains, forming a part of mount Atlas. It is about a mile in circuit, encompassed by a wall chiefly of mud perforated by hornets, and tolerably populous, but without much trade; some of the houses are flat-roofed, and others tiled; it is well-watered, as a branch of an adjacent rivulet may be conducted through every house and garden, and it is surrounded by very fruitful gardens and plantations. As Bleeda and Medea (see Medea) lie nearly in the same meridian, and are situated at a proper distance from the Hamam Meerega, the Aigue Calix Colonia of the ancients, and as their modern and ancient names resemble one another, Dr. Shaw supposes that we may take one for the Bida Colonia, and the other for the Lamida of Ptolemy. That part of mount Atlas which lies between these towns, and reaches as far as mount Jurjura, is inhabited by numerous clans of Kabyles; few of which, from their rugged situation, have been made tributary to the Algerines. The Beni Sala and Haelcol overlook Bleeda, and the rich plains of Mettigah; whilst the Beni Schim and Halefa sometimes descend into the pasture ground, near the banks of the Bissef, or river of fennel, of which a great quantity grows on its banks. Shaw's Travels, p. 36.

BLEEDING, or Blood-letting, in Medicine, a species of evacuation frequently resorted to, as a principal remedy in inflammatory affections, such as pleureisy, peripneumony, phrenitis, quinsy, enteritis, acute rheumatism, &c. and in disorders accompanied with pletora, such as mania, apoplexy, &c. See these disses separately. In all those cases, the earlier this remedy is employed the better, and especially in those inflammatory disorders, such as phrenitis and peripneumony, where, from the great vascularity of the part, the progress of the inflammatory action is extremely rapid and the injury done to organs so essential to life, often becomes irreparable.

Now is the timing of this remedy the only circumstance that requires attention. Other circumstances of equal moment are to be attended to; viz. the quantity of evacuation, and the suddenness with which it is effected. The quantity must be regulated by the degree and seat of inflammatory action, and the age and constitution of the patient. The appearances of the blood, when drawn (see Blood), are commonly regarded as a good criterion for regulating the repetition of the lancet, and the quantity to be taken away each time; but the state of the pulse affords a much better guide; and venesection will often be found necessary in cases where the bloody coat or fisy appearance of the blood is not present in any considerable degree.

The impression produced upon the systen is very different, according as the blood is drawn from a large or a small orifice; i.e. according as it is evacuated suddenly or slowly. The former method is to be practised in all violent inflammations of parts essential to life; such as the brain, the lungs, the stomach, &c. for thus the increased action of the vascular system is subdued almost on the spot; a momentary deliquium is induced (a state the opposite to that in which the morbid condition consists) from which the most beneficial consequences result.

Provided equal quantities of blood be drawn in equal times, it matters not whether it be taken from the right or the left arm; in other words, supposing, in the case of pleurisy, the seat of the pain and inflammation to be in the right side, those symptoms will be as speedily removed by taking away in the whole thirty ounces of blood at three different times from the left arm, as they would be, if the same quantity were taken away from the right arm, in the same number of times, and from orifices equally large; because in both cases, there is the same quantity abstractions from the whole mass of blood, and consequently, from the quantity circulating through the lungs, and their investing membranes; whence the general and local effects in both cases are ultimately the same. Hence the utiity of the doctrine of Revisilson, about which such warm disputes were at one time carried on.

Hitherto we have merely hinted at the general effects produced upon the system by blood-letting. It will now be expected that we should specify what they are. The first and most obvious effect is upon the heart and arteries. The blood is to them a stimulnus; consequently, by withdrawing a quantity of that fluid from them, we withdraw a proportionate quantity of stimulus, and bring down their action so much nearer to their natural standard. The absorbents participate in this change; whence a less impend exhalation takes place. At the same time a diminution of the animal heat succeeds. But the cerebral sytem and the vascular sytem are so intimately connected, that the one cannot be materially affected without producing a corresponding effect upon the other. This is proved by the deliquium and convulsions which succeed to sudden and profuse hemorrhages. Thus it appears that the beneficial effects of blood-letting, is the disorders to which it is applicable, and are owing merely to the abstraction of a quantity of the circulating mass, and consequent abatement of activity in the sanguiferous vessels; but also to the abstraction of a quantity of the fixtures Hemorrhage, and to the impregnations at the same time made upon the lymphatic vessels, and finally upon the sytem of brain and nerves.

From this view of a remedy so powerful and so extensive in its operation, it is easy to perceive what mischievous and even dangerous consequences must result from its abuse. Being the most speedy debilitating of all remedies, it is obvious that what is termed general bleeding ought never to be resorted to, but in cases where the pulse denotes an increased degree of strength, as well as excessive activity. It has been from attending merely to its increased activity, and the accompanying accumulation of heat, without a due diminution of the strength of the pulse in fevers and other disorders supposed to be inflammatory, that so much abuse has been committed in the employment of the lancet. See Fever; under which article, the propriety and impropriety of blood-letting will be fully considered, with remarks on the practice of Ferrelins, Botelus, Sydneyham, Pringle, and other celebrated physicians, who pushed this remedy to an extravagant length.

Although general bleeding be only admissible under the conditions above mentioned, yet topical bleeding may be sometimes employed with good effect in cases of partial inflammation, existing in states of the body where vigour in the sytem at large is wanting; especially when the vessels belonging to some organ essential to life, are obstructed, overloaded, or inflamed.

Bleeding was formerly employed for the purpose of preventing plecthoric and inflammatory conditions of the body. Hence many of the old writers recommend it to persons in health, both in spring and autumn, to pregnant women, &c.; but this practice is very properly discontinued, and other modes of counteracting tendency to over-repletion are adopted in its place; such as a vegetable diet, regular exercise, occasional purging, and the like.

BLEEDING.
BLEEDING.

Bleeding, or Blood-letting, in Surgery, is the artificial extraction of blood from an Artery or Vein, for medicinal purposes. The operation of cutting an artery is named Arteriotomy; that of opening a vein is called Venesection, or Phlebotomy.

The instrument used in this country for bleeding the human subject, is denominated a Lanceet; though a phlebete, or blade, was formerly employed, and is still very commonly used by barbers in England, and even by the bellurgens in Germany. See the Plate of Surgical Instruments. The lanceet, on that occasions is, used single; but where the intention is to puncture numerous small blood vesels at the same instant, rather than any one considerable vein or branch of an artery, surgeons have recourse to an instrument containing many lancets, which is known by the name of Sca.

Lanceets are often applied to a part of the body requiring the local evacuation of blood; and in this case, as well as in facturing, the operation is termed local bleeding, in contradistinction to general blood-letting by the lanceet.

Some nations, especially those which have frequently emerged from a state of barbarism, are accustomed to draw blood by making one or more incisions or punctures at random, with a knife, a bone, a tooth, or a needle. See Acu.

phicures, Phlebotomy, Arteriotomy, Lieches, and Cupping.

The art of bleeding may be traced back to the remotest antiquity, and seems to have been common among the Egyptians, Assyrians, Scythians, &c. at a time when anatomy had never been cultivated. The Greeks boast that Pedasiius, the son of Eculeius, was the first who prac.

tised bleeding, soon after the siege of Troy; but the fact itself is related by only one author (Steph. Byz. in voce Syna), who lived too long afterwards to be credited implicitly. It is therefore much more likely, that bleeding had been performed previously to the time alluded to. Phins, indeed, supposes that physicians first learnt this operation from having observed the hippopomans draw blood by pulling sharp reeds into its body (Hist. Nat. lib. viii. cap. 26.); but this is a very improbable thing, as there is very little analogy between the artificial opening of a vein with a lanceet, and the random wounding of an animal by friction against a broken reed.

We shall, however, not eludage on the history of this practice, but proceed to describe the common modes of opening a vein in several parts of the body, after which we shall treat of Arteriotomy.

When we resolve to perform venesection, we must, besides the instruments required for that operation, have in readiness one or two well-rolled blood-letting bandages, or tapes, from four to eight feet in length, and of two fingers breadth, with pins, or elde needles and thread. Those bandages are, by foreigners, reckoned the belt, which have narrow loops at their ends.

In general, venesection is practised at the bend of the elbow, or upon the foot. When the patient is to be bled at the arm, we place him, with his face towards the light, upon a chair of a moderate height; draw his shirt as high as is necessary above the elbow; let him extend his arm to a certain degree, but not too much; after which, the sur.

geon, in order that the veins may become turgid by checking the circulation, applies a bandage (which is often made of fine red cloth), of the breadth of three or four fingers, twice round the arm above the elbow, with the ends of which, after having previously drawn them moderately tight, he ties a bow with a single knot, at the posterior part of the arm.

Whether this bandage has been properly applied, we know by the circumstance, that the veins become elevated and tumid, whilst the pulsation of the artery at the wrist is distinctly perceptible.

We then choose a vein in the bend of the elbow, which may be done with caution. The upper is the cephalic vein, and this a beginner ought, if possible, always to choose, as little or no danger is to be apprehended from opening it: but it is very seldom to be seen or felt, and commonly is too small. The median vein is most easily seen and felt; but generally the tendon of the biceps muscle is situated under or at the side of it, which we must take great care not to puncture. The inner vein of the arm, or the bafic (which, in the right arm is by some termed the hepatic vein, and in the left the sciatic), is indeed very easy to be seen, and ill more easy to be felt; sometimes, however, it is also very small, or lies too close upon the artery as to render it hazardous to open it.

Some recommend blood-letting upon the back of the hand, although this is an inconvenient place, and, in certain cases, not very safe for the operation. But if it be necessary, we tie a bandage two fingers breadth above the wrist, round the fore-arm; and, in order to raise the vein, let the patient then hold his hand in warm water. The most common vein upon the hand is the cephalic of the thumb, which lies between the bones of the carpus, with which the thumb and the fore-finger are joined. But the common vein upon the hand is the cephalic of the thumb, which lies between the bones of the carpus, with which the thumb and the fore-finger are joined. But the two metacarpal bones with which the middle and the ring fingers are joined, is at present but very rarely opened, and only when no other is to be seen; especially as it does not discharge much blood, is difficult to be tied, and, if cut quite through, forms a thrombus.

In bleeding these veins, the patient must be placed in a somewhat oblique position against the light; so that when the hand is half closed, and laid upon the edge of the vessel, the fingers are directed towards the light, in order that the instrument may throw no shade upon the place of the vein where we intend to open it.

Bleeding at the foot is generally performed upon the vena faphraena, which lies upon the first metatarsal bone, connected with the great toe, running along it and the tarsus, over the inner ankle. Where it lies close upon the ankle, it is inconvenient to open, and we must be very careful we cut through it and injure the periosteum, or even thrust the finger or lancet into the bone itself. If possible, it will be better to open it one, two, or three fingers' breadths farther from the ankle towards the great toe. We may also open a branch far forwards, almost close upon the great toe; and here we are required often to open it with pregnant women who have swelled legs.

The other pretty safe vein upon the foot is the cephalic pedis, that lies between the two tendons which extend the great and the second toes; only we must be cautious not to injure the tendon lying before it. The other veins situated upon the back of the foot should never be opened, but in cases of extreme necessity; for the operation is attended with danger, on account of the contiguous tendons; besides, they do not discharge a sufficient quantity of blood, and they almost always form a thrombus, which a beginner should be careful to avoid.

When we bleed at the foot, the patient should first place the limb in a pool of warm water, in order that the vessels may be seen and felt; and it is also necessary with small veins to apply the red bandage, which, however, in order that the purpose of checking the flow of the blood may be attained, and no inconvenience occasioned, must be applied in the middle of the calf, especially with lean persons, in
BLEEDING.

the same manner as on the arm; but the bow and its knot must not lie upon the tibia.

On the arm, therefore, we choose either the cephalic or the median vein, and, if the tendon lying below it should occasion hesitation, the baffe, especially if this lies more convenient and superficial. When the surgeon, then, has brought his eye to the proper distance from the vein, he wets the point of his middle finger, presses gently with this finger upon the vein at the places where he thinks he can best open it, and accurately marks the place with which he was satisfied in trying by the feel; after which he sufferers the arm to fall down again into the patient's lap. In the same manner he chooses a vein upon the hand.

For blood-letting at the right foot, the patient is placed upon a chair of a moderate height, in the most enlightened part of the room, with his face directed towards the window, and his feet immered in a vessel filled with warm water, so that the water covers all the veins of the whole foot. When therefore the foot is warm, and the veins sufficiently tuid, the surgeon lays hold of the foot with his left hand, and places it with the middle of the sole upon the edge of the vessel which is the most remote from the body, in such a manner, however, that the foot is not extended, but forms a right angle with the leg. With the middle fingers of the right hand he examines those veins which lie the most elevated, and makes, according to the rules before laid down, a scientific selection; but he must always first direct his attention to the vein saphena.

The most convenient attitude for the surgeon is when he kneels down with one knee; as in this position the eye is near to the vein, the position is firm, and can be better supported for the requisite length of time. If any other vein besides the saphena be chosen, the patient is directed to move his toes, whilst we are examining the vein, in order that we may feel how near a tendon may be situated below it; and here the caution should be observed, not to make all the fingers wet, for the warm water diminishes the sense of touch, and consequently renders it indistinct. We therefore use at first only one hand, because, in case of a failure, or from some other cause, we may be under the necessity of taking also the other foot.

The vein may be opened either longitudinally, that is to say, in the direction of its course, or we open it rather obliquely or transversely. The first is the safest, easiest, and most convenient method; but it is admissible only with large veins, and when we foresee that during the operation they will not slip or twist, as it were, out of the way of the instrument. Commonly the veins are opened somewhat obliquely, and in this manner we may generally open the veins on the arm, and in most cases upon the foot. But when the veins are too small, there is reason to apprehend that we may not hit them, or that they will not discharge a sufficient quantity of blood; and when their situation requires it, as is the case with the cephalic of the foot (where it lies over the tendon that elevates the great toe), the orifice must be made quite transversely.

When therefore we have properly examined the vein with the moist finger, we hold the plume in readiness (if we use this instrument); that is to say, we draw up the spring, take it in the right hand, so that the thumb lies upon the siller, the fore-finger upon the bridge, and the middle finger upon the prefifier, exactly over its spring, and the ring finger upon the round part of the bottom plate. With the fore-finger and thumb of the left hand, which are moistened with a little saliva, we move the iron as high up in the groove as we think it necessary to make the orifice deep; and place the box (after having again elevated the arm, or taken the foot or hand out of the water, and supported them, in the manner above described, upon the margin of the vessel) in such a manner upon the skin, that the iron has exactly the proper direction toward the place where the orifice is to be made, and then, by a gentle pressure with the middle finger, let the spring fly loose.

If a vein should be so fat as to render bleeding impracticable, and with such it is at least very difficult to do it on the foot, we may in some measure attain our purpose, if we direct the patient, as he gets out of bed, to hold his foot or hand in warm water; after which the veins will generally become sufficiently perceptible to the eye or touch of an experienced surgeon.

But though the plume is used for blood-letting, especially in Germany, it is however an universally acknowledged truth, that the lancet is the safest and best instrument for the purpose. We run less hazard with it of doing damage, and the surgeon is always able, according as the circumstances require, to make the orifice either small or large. When therefore we let blood with the lancet, we place it so that the handle forms a somewhat acute angle with the blade. The surgeon next lays hold of the limb upon which he is to perform the operation, supposes the right arm, with his left hand; and at the same time presses with the left thumb upon the vein, about two fingers' breadth below the place which is chosen for the orifice: he then takes the lancet between the thumb and fore-finger of the right hand, so that something more of the blade is uncovered than he thinks necessary to introduce. At the same time he lets his hand rest upon the middle, ring, and little finger, which must be placed as conveniently as possible below the vein that is to be opened. He then pushes the point of his lancet carefully through the skin and integuments into the veins, and carries the instrument in an oblique direction a little forward, till the orifice is sufficiently large. But, during the introduction of the lancet, the operator must hold the point as steadily and even as possible, in order that it may not penetrate into the subjacent parts. Should he, however, not be able to depend sufficiently upon the readiness of his hand, he will do well to leave no more of the point of the lancet uncovered than is to penetrate into the vein. The Surgeon having withdrawn his right hand, at the same time removes the thumb of his left hand from the vein, in order that the blood may flow out freely.

If the blood will not flow properly, notwithstanding the vein has been properly hit, either the orifice is too small, or fat perhaps gets into the orifice of the integuments and stops it. The fat is to be pressed back, by froaking with a wet and warm sponge, or by means of an instrument. The impediment, indeed, may lie in the motion of the part; when, for example, the arm is bent obliquely, or the foot is placed in the water, the orifice of the vein may easily be displaced, and some of it be closed by the joint-part of the skin. But, finally, the circumstance may also be occasioned by the vificid confidence of the blood. To this latter cause it is often to be attributed, after the first few minutes; on which account it will be proper to wipe the arm, over the orifice of the vein, with a sponge filled with warm water, and let the hand rest in a somewhat higher situation than the orifice, upon a fitch, which the patient may also turn round, or press firmly with his fingers.

When a sufficient quantity of blood has flowed from the vein (for example, in the arm), and we are to tie it up, we take the sponge, moistened with warm water, in the right hand, the bandage in the left, and the linen compre's between the thumb and middle finger of the same hand; we hold against the vein with the sponge, and with the left hand remove
BLEEDING.

Remove the red bandage and hang it over the chair, or the
shoulder of the patient. The assistant takes away the vessel
into which the blood has been received, and the operator
now with a moderate pressure draws the sponge from the
vein towards the hand in a right line with the orifice that
has been made; and it will be proper, whilst he brings the
lips of the wound together with the thumb of his left hand
from the sides, to repeat the wiping with the sponge once
more, in order completely to remove the blood that may
have been left in the orifice.

When the surgeon now seize the vein well closed, he lays
upon it the comprefs, with the fingers of his right hand,
whilst he draws it towards the thumb of the left hand upon
the skin; and when the middle of it is upon the orifice, he
presses it down with the fore and middle fingers of the right
hand, and immediately changes these for the thumb of the left
hand. With the right hand he raises the blood from the
limb, by means of the sponge; after which, he lays the
sponge aside. He then takes the bandage out of his left
hand, lays hold of it with the fore and middle fingers of the
right hand at the inner part of its head, and the thumb upon
the outer, and places it upon the comprefs in such a man-
ner that the fingers of the left hand make way for it, whilst
the two fingers of the right hand continue the pressure
in their place. But, immediately after, there are again changed
for the left, fore, and middle fingers, which now press at
the same time upon the one turn of the bandage and the
comprefs. The right hand carries the bandage crosses-ways
round the arm, whilst the fore fingers of the two hands
always alternate, till the half, when both ends of the ban-
dage are either fewed, tied, or pinned together.

Notwithstanding we have given these very precise direc-
tions, a young surgeon will learn better by seeing the
operation performed by a skilful hand, than by any verbal
instructions.

Tying the vein upon the thumb is performed in the
following manner:—Pressing with the comprefs, which
here must be pretty narrow and thick, is like that performed
on other veins; and therefore, whilst we hold it fast upon
the wound of the vein with the two fore fingers of the left
hand, we let the bandage, (which is rolled upon one head,
an inch in breadth, four feet in length from the end to the
place where it touches the comprefs,) hang about half a foot
down over the back of the hand, obliquely from the wrist
outside; carry the head of the bandage, after pressing
it upon the comprefs with two fingers of the left hand,
through between the thumb and the fore-finger, over the
palm of the hand; and, proceeding over the back of the
hand, cover the end of the bandage; then round the
wrist, again over the back of the hand, under the thumb,
and now round the ball of the thumb; again over the turn
that has just been made across the back of the hand; and after
having once more carried it half round the wrist, pin both
ends together on the back of the hand. We may also apply
this bandage with varied turns. In a familiar manner, with
turns round the little finger, and circular turns round the
wrist, the bandage is applied, when the vein of the face is
opened.

With the veins of the foot, the common bandaging is
made by the Stapes, which, however, sometimes requires
a peculiar method, that every one will easily be able to
adapt according to circumstances. The bandage may be
applied somewhat tighter than upon the arm; however, on
account of the injurious consequences, which may even be
attended with danger, the bandage must not be drawn too
tight; but it will be better some hours after to examine it
again, and if necessary, draw it somewhat tighter. Upon
the whole, it is to be recommended, if possible, in all blood-
letting operations, especially in arteriotomy, that the sur-
gon should see the patient again some hours after; as he
may observe several small inconveniences, which afterwards
frequently occasion unpleasant complaints.

Venoction is more rarely performed upon the frontal
vein, the veins under the tongue, and upon the neck. For
the frontal vein, when it requires to be opened, we apply a
bandage, or a garter or cloth, round the neck, lay the mid-
dle of the bandage upon the back of the neck, carry both
extremities over the throat, and round again to the back of
the neck, where an assistant takes one end in each hand.
This the patient may also perform himself; only then the
middle of the bandage must be applied to the throat, the
two ends carried round the neck till they meet at the
throat again; there the patient holds them with both his
hands, and according to circumstances, draws the bandage
tighter, or relaxes it, so as still to retain sufficient space for
respiration. A still more convenient mode of discharging the
veins of the neck, &c. is to pass the bandage over the fides
of the neck, and under the opposite arm-pits, so as not to
press upon the trachea, which may impede respiration; then
hold the swelled vein down with the thumb or figner of your
left hand, a little below the part allotted for the operation.
The incision is to be made, when the vein is sufficiently
matted, with a lancet.

In order that the blood may not run down upon the face,
we press a card bent crooked under the orifice upon the skin,
and thereby conduct the blood into a vessel. After a suffi-
cient quantity of blood has been discharged, we remove the
bandage from the neck, when the bleeding generally ceases
immediately, and the orifice is secured with sticking plaster,
or, if it should be necessary, with a compress and Discrimen
bandage.

When we have to open a sublingual vein, we must pro-
mote the efflux of the blood, as in bleeding at the forehead
by the application of a cloth under the arms and across the
fides of the neck. The orifice is made with the lancet, and
the incision is continued till it seems large enough. In order
more conveniently to get at it, we hold back the tongue
with a wooden fork, or spatula. We may draw a silk thread
through the wound, in order to draw it from the blood which
here easily congealeth, and at the same time to prevent the
lips of the wound from adhering together, and consequent-
yly to obviate whatever might impede the flow of the
blood. When its flow must be stopped, we take off the
bandage, and let the patient hold some spirit of wine, or
common brandy, in his mouth. If the blood flows more
copiously, we may dispense with the thread, and immedi-
ately remove the bandage from the neck; also, when it is to
be stopped, apply a little alum or agaric to the wound, and
press it down for a time; or apply Lampe’s compress, de-
scribed in L. A. Heur. Kocher’s Anleitung um Ver-
bände, &c. Leipzig, 1796, 8vo. Tab. VI. fig. 5.

To bleed at the external jugular vein, the bandage is
likewise applied round the neck; against the clavicle, and
upon the vein that is to be opened, a thick compress is
placed, and the bandage drawn somewhat together. The
thumb is placed upon the compress which lies upon the vein
and the fore-finger over it, in order to secure it and to stretch
the skin; we then take a pretty large lancet, and with it
open the vein in the ordinary manner; only with this dif-
cernence, that we must introduce it deeper, and make the
external orifice larger. To catch the blood, we make use of a
card, as in bleeding at the forehead. When a sufficient
quantity of blood has been drawn, we remove the bandage,
after which, the lips of the wound generally close sponta-
neously.
nously. But should a bandage be necessary, we may secure a compress upon it by means of two circular turns round the neck. As this bandage, on account of the pressure upon the trachea and vessels, &c. of the neck, is always very troublesome; and the pressure, as it never must be strong, is frequently insufficient; we may most conveniently use the instrument invented by Mr. Chabert for compressing the veins of the neck. In want of it, we must let an affilfent clofe the orifice by pressure with his finger, till the danger of hemorrhage is over.

Some moisten the compresses with brandy, vinegar, &c. and thereby, on account of the irritation, occasion some inconvenience at the orifice of the vein, in which sometimes inflammation, and even a suppuration, is excited. It is better to apply the compress dry, or to flick upon it a piece of gold-beater's skin, whereby the lips of the wound, if they have been well brought together, are retained in that state, so that the burking open of the vein is more effectually prevented.

Easy and insignificant as some young surgeons think the operation of phlebotomy, it nevertheless often requires the greatest accuracy, and is on that account one of the more delicate operations. To a true surgeon, therefore, it is always of importance, and the more so as his honour and reputation are endangered by committing an error in it. Frequently the faults which the patient commits during and after the operation, such as incautious motion of the limb whilst the operation is performing, violent exertion of it, drawing on boots, &c. after blood-letting at the feet, are ascribed to the negligence or ignorance of the surgeon. Infamously also as no operation occurs so frequently as this, and as it is very often endangers the life of a man, or at least an error committed may give rise to such danger; the surgeon must well consider the symptoms which occur in it, and may superinduce more important consequences dangerous to health, in order that he may timely obviate or remove them.

Sometimes there arises, as the most common bad consequence of blood-letting, an inflammation of the external integuments, and of the subjacent cellular sublimation. Sometimes it is chronic, but little painful, suppurates slowly, and produces a circular incised abscess. Sometimes it is more diffused, and has the appearance of an erysipelatous inflammation; sometimes it is violent and acute, and resembles a phlegmon. This generally occurs when the inflammation is a bad one, and rather tears than cuts; when the patient is of a very irritable habit, and much disposed to inflammation; when the requisite precautions for healing the wound by the first intention are neglected, and the arm is suffered to be moved: when the wound is externally rubbed, prefled, &c. The nature of this inflammation cannot be mistaken, and it must be treated like a common wound.

It may sometimes happen, that when the wound of the vein does not soon close, an inflammation of the vein takes place, which however varies with respect to its violence, its extension, and progress. In a milder degree, this inflammation is followed merely by a slight swelling of the vein, and an adhesion of its sides. A violent inflammation induces suppuration. The common method of treatment is the antiphlogistic. As the internal membrane of the veins is continued to the heart, and as inflammations in such membranes spread easily and rapidly, where they are not prevented by an adhesion of the sides of the vein, it is in most cases advisable to produce such an adhesion by the application of external pressure at some distance above the orifice. If, as may very easily happen, such an inflamed vein should pass into suppuration, it would (if known) then be necessary to cut open the vein, in order to prevent the pus from mixing with the circulating fluids.

When a vein has been cut entirely through, the pain is not greater than common, nor does the patient experience any inconvenience whilst the blood is flowing; but a greater or less quantity of it depends under the vein into the adipose membrane, remains there included, and during the first twenty-four hours occasions a tenion. The external orifice of the vein may be displaced from the orifice of the vein, Likewise, when the orifice of the integuments is smaller than that of the vein; when the patient moves the arm too much, in consequence of which some blood is indeed discharged from the wound, but more penetrates between the vein and the skin into the cellular tissue; and when the operation has been absurdly performed where two veins anastomose; from all these causes an effusion of blood may take place, in consequence of which the part acquires a blueish black colour, and sometimes an ecchytyema, sometimes a suppuration, and at other times a thrombus is produced. Although the appearance frequently seems to indicate greater danger than really exists, the speedy application of remedies is nevertheless necessary.

In the first case, cataplasmis, with warm vinegar, wine, and other spirituous or diocients remedies, are serviceable. When such extravasated blood is not again taken up, or when the vessels are inadequate to its re-absorption, on account of its great quantity, an abscefs is generally formed, which must be treated according to the rules of art, and the spirituous remedies laid aside. See Abscess. In the suppuration, we must endeavour to remove the obstructions that may impede the circulation of the blood: these are either external ones, such as too tight bandage; by loosening which the complaint is removed; or they are internal ones, and occasioned by a contraction of the vessels. In a recent suppuration, we may combine the resolvent means above-mentioned with mild astringents; and when the flagellating blood has been again diffolved and removed, we at last apply cold, difficient, and spirituous remedies.

When an aponeurotic part (for example, the facia of the fore-arm) is wounded, the patient sometimes experiences a more violent pain than usual, especially when he moves the limb; and this he feels pretently after the blood-letting has been performed. A compres, moistened with cold Gouland's water, &c. is of service, whilst at the same time the bandage is left applied for three or four days, and the limb kept completely at rest, and wetted many times a day with such remedies. When this is neglected, there very often takes place a serious inflammation, which must be treated according to the antiphlogistic plan. Repose of the limb, which is to be kept in a bent position, and relaxation of the inflamed parts by means of warm emollient applications, are absolutely necessary. As soon as the inflammation abates, it is proper every day to attempt moving the joints, in order to prevent a stiffness. But if the tension and inflammatory symptoms run very high, it may even be requisite to divide the facia completely.

When a nerve is injured, the patient experiences a still more violent pain, which extends itself throughout the whole limb, and the patient is also apt to faint, the muscles of the affected part contract, and the blood sometimes does not flow so freely as usual, although the vein has been well opened. The orifice of the vein does not become violently inflamed, and the pain continues. In order to prevent inflammation and other symptoms, a larger quantity of blood must be let run out, the limb must at length for some days be left completely at rest, and we must take care that the muscles of the part remain as much relaxed as possible. Moreover,
BLEEDING.

over, we must try the patient antiphlogistically, prescribe a
spare diet, and also, if the case should require it, administer
cpiates and laxatives. For lesions of the nerves, the applica-
tion of warm spirit of turpentine is commended; but it
would probably be useful only in case the nerve should lie
above, but hardly when under, the vein. Over the orifice
we apply some lint and a mild plaster, and over this and the
whole limb, emollient and cicatrizant cataplasm, with which
anodyne remedies are mixed.

If, notwithstanding this treatment, the symptoms should
become more violent, the lips of the wound acquire a hard-
ness, and become more inflamed, affected with pain and
tumour, with a full and quick pulse, blood must be drawn by
leeches, or at another place by venesection. Instead of the
warm emollient cataplasm and cataplasm, which are
recommended in such cases, Mr. B. Bell extols, from his
own experience, cooling astringent remedies. Preparations
of lead he has found most serviceable. The parts which suffer
the most may be covered alternately with clothes wetted
with a solution of facecharum Saturni, and with pledgets spread
with ceratum Saturni. The fever must also be particularly
attended to, and the above mentioned cooling treatment
continued. When the pains are so violent, that they en-
tirely deprive the patient of sleep and rest, we must use
antimony and opium; but in order that the opium may
prove serviceable, it is administered always in considerible
doses. The limb must be also kept continually at rest, and
in a horizontal posture.

But frequently the first affection is neglected, or improper
remedies are employed, so that opium, and all the remedies
that have been mentioned, have not the smallest effect. This
is particularly to be suppossed, when the nerve is cut in such
a manner, that only a part of its fibres still remains entire, and
there are preternaturally stretched; in which case the whole
body suffers, and the most violent convulsive affections take
place, which indicate the most imminent danger. The only
remedy under these circumstances is the division of the nerve
by a transverse incision above the inflamed part, that is to say,
higher than the orifice of the vein. As the nerve certainly
lies within the breadth of the orifice of the vein, the incision
needs not be long, and it must penetrate only down to the
fascia of the fore-arm, for all its cutaneous branches always lie
on the outside of this fascia.

Mr. Benjamin Bell has given very extraordinary directions
on this subject, which have (most unaccountably) been
transferred by many surgeons in France and Germany: he
observes, among other things, an exter transverse incision to
be made through the original wound, and even down to the
bone! which Mr. Abraham has very properly repro-
duced as "dangerous and unnecessary."

When the branch of an artery has been wounded, the
patient does not feel no pain than usual; but the surgeon
immediately concludes from the colour and spouting of the
blood what fault he has committed. See ANEURISM.

In venesection, a bone may also be injured, chiefly with lean
persons, who generally have very thin veins, especially on the
feet; which though they are very visible, he, however, so
close upon the bones and tendons, that the instrument pases
through and injures the subjacent bone. In most cases, this
only occasions a pain which the patient feels during the op-
eration, and no bad consequences ensue. Frequently the sur-
geon himself would not know it, did he not, on examining
the instrument, that the point is entirely wanting, or at
least bent round, and its edge spoiled. This, however,
applicies only to the case where none of the iron left in it; but
when this happens the case is worse. We may know, that it
has taken place from the cutting blade being wanting, or in
part broken off; from the pain which the patient feels, and
which is generally of a pulsating kind; from the divided
stream of the blood; from the feel with the fingers, when
they are stroked over the orifice of the vein, and from the
rebounding which the surgeon feels in the fingers at the
stroke. If it is not feared very firmly, the stream of blood
generally drives it out, if we draw the orifice gently afunder
with two fingers. But when it is more firmly feared, we
must endeavour to draw it out with a fine pair of forceps as
cautiously as possible, that it may not break in extrac-
ing, and the point remain sticking in the bone. When it has
been usefully extracted, we must endeavour to prevent
the symptoms, such as inflammation, tumour, &c. by wetting
the compresses and the bandages with a diluent lotion,
and afterwards also keep the bandages moistened with such
remedies throughout the day. This accident is only liable
to occur in using the plene.

But the breaking off the blade may also happen with muscu-
lar subjects, and this the surgeon can certainly in general
prevent, by always inspecting his instruments carefully,
and providing them with good blades. The best blades are those
which are very sharp and finely polished, and these are
generally very thin, and consequently most liable to fly off.
Before we use any blade, especially a thin one, we ought always to put
it to the following test. We screwed the new blade into the
plene, and let it fly two or three times without any object
opposed to it. If the blade remains as it should, we are then
so much the more secure against its flying off in blood-letting,
because it has a resistance opposed to it. This precaution
should never be neglected, and the loss of a few blades
should not be regarded, in order to secure ourselves against
the danger to which we are exposed if we neglect it. These
