Calvary.

Calvary, or Golgotha, in Ancient Geography, a mountain of Palestine, held in the greatest veneration as the scene of our Saviour's crucifixion. It acquired these two names, probably, from its roundness, or resemblance to a human skull, or, as others say, from its being bare and destitute of verdure. Theophrastus says, that by a tradition descended from the fathers, Adam, (or as others say, Adam's head) was buried here, and therefore, says he, Christ, who was to heal the fall and death of Adam, was here crucified, that where the beginning of death was, there might be the dissolution of it. The witnesses of this tradition adduced by Theophrastus are Origen, Tertullian, Epiphanius, Athanasius, and St. Augustine. St. Jerome observes, that this is a favourable interpretation, and pleasing to the ears of the people; but not true. It anciently stood without the walls of the city of Jerusalem, and was the place where criminals were executed according to the Mosaic law. But the Roman emperor Adrian having ordered the city to be re-built a little to the north of its former situation, Mount Calvary was enclosed within the walls. See Ἠλία Καπηλία. This mountain was cleared by order of Helena, the mother of Constantine; and fitted for the foundation of a church by cutting down several parts of the rock and elevating others. But this was done with so much care, that no part of the hill which immediately related to our Saviour's passion was altered or diminished. Accordingly that part of Calvary, where it is said Christ was fastened to the cross, is left entire; being about 10 or 12 yards square. The magnificent church erected on this spot by order of Helena was, therefore, built in such a manner as to comprehend as many scenes of our Saviour's sufferings as could be conveniently enclosed. This stately edifice is still standing, and kept in good repair, by the offerings of the pilgrims, who annually resort to it, as well as the contribution of several Christian princes. It is 100 paces long, and 60 wide; the walls of it are of stone, the roof of cedar; the east end encloses Mount Calvary, and the west comprehends the holy sepulchre. The former is covered with a noble cupola, supported by 16 massive columns, which were encrusted with marble. The centre of it is open on the top just over the sepulchre; and above the high altar at the east end is another fixedly dome. The nave of the church constitutes the choir, and in the side aisles are the places where the most remarkable circumstances of Christ's passion were transacted, together with the tombs of Godfrey and Baldwin, the two first Christian kings of Jerusalem. An ascent of 22 steps leads to a chapel, where that part of Calvary is shewn on which Christ was crucified, and the very hole in the rock, in which his cross was fixed. The altar hath three croffes in it, and is richly adorned with other costly embellishments, particularly with 46 silver lamps of immense value, that hang before it and are kept constantly burning. Adjoining to this is another small chapel, fronting the body of the church. At the west end is that of the sepulchre, which is hewn out of the solid rock, and has a small dome or lantern, supported by pillars of porphyry. The cloister round the sepulchre is divided into many chapels, appropriated to the several sects of Christians, who used to reside there, such as the Latins, Greeks, Syrians, Armenians, Abyssines, Georgians, Netherians, Cophtites, Maronites, &c. But these, say Maundrell, except four, viz. the Latins, Greeks, Armenians, and Cophtites, have abandoned their quarters, not being able to sustain the severe rents and exxtortions, which their Turkish landlords impose upon them. The apartments of the Latins are on the north-west; to them belongs the care of the church, and they
they make every day a solemn procession, with tapers and crucifixes, and other ceremonies, to the several sanctuaries of the church. Accordingly they are obliged to reside constantly in it; the Turk keeping the keys, and not suffering any of them to go out, but obliging them to receive their provisions through a wicket. E'en is the time at which the chief ceremonies are performed within this place; and these chiefly consist in representations of Christ's passion, crucifixion, death, and resurrection. At this solemnity, every pilgrim, paying a certain fee, is admitted to attend at the solemn procession and other ceremonies: of these there is commonly a vast concourse. Some of them choose to enter on Good-Friday, and stay till Easter-Monday.

Calvary, a term used in catholic countries for a kind of chapel of devotion, raised on a hillock near a city; in memory of the place where Jesus Christ was crucified near Jerusalem. Such is the Calvary of St. Valerian, near Paris; which is accompanied with several little chapels, in each whereof is represented in sculpture one of the mysteries of the Passion.

Calvary, in Heraldry, a crose le called, because it resembles that on which our Saviour suffered: it is always set upon fleps.

Calido Islands, in Geography, lie to the S.E. of Porroo island in the Exit Indies; a little to the S. of E. from cape Salatan, and to the W. of S. from Laut island.

Calcula, in Ancient Geography, a small town of Spain, placed by Piny and Polomy in the department of Hifpalis.

Calveluzo, in Geography, a town of Naples, in the province of Basilicata; 10 miles S. of Potenza.

Calvensano, a town of Italy, in the duchy of Milan, feated on the Adda.

Calventuras, a small island in the bay of Bengal, near the coast of Ava. N. lat. 10° 54'. E. long. 95° 20'.

Calvert, George, in Biography, baron of Baltimore, founder of the province of Maryland in North America, was the descendent of a noble family in Flanders, and born at Kipling in Yorkshire in 1582. After finishing his education at Oxford he became secretary to Sir Robert Cecil, in the reign of James I. by whose favour he was made clerk of the privy-council, and received the honour of knighthood. In 1619 he was appointed one of the principal secretaries of state; but though he discharged the office with great fidelity and diligence, he resigned it in 1624, honoursly confessing to the king that he was become a convert to the Roman Catholic religion. He was continued, however, a member of the privy-council during this reign, and in 1625 created baron of Baltimore in the kingdom of Ireland, at which time he represented the university of Oxford in parliament. Having been constituted by patent, during his secretarihip, proprietor of a province in Newfoundland, he named it "Avalon," and expended upon it a large sum. But though he twice visited it in person, and refused it from a French invasion, he at length abandoned it, and obtained from Charles I. a patent for the full property of the district since called Maryland. This he settled, and in his dealings with the natives displayed as much justice and good faith as William Penn did in his settlement of Pennsylvania. He likewise established a most liberal code of religious toleration in his province, so that it became not only the resort of a great number of Roman Catholic gentlemen, who first accompanied the founder, but also an asylum for many Quakers and others, who were persecuted by the bigotry of the puritans in New England. Lord Baltimore, who appears in all respects to have been a man of worth and found undertaking, died at London in 1632. Biog. Brit. See Maryland.

Calvert, in Geography, a county of Maryland, in the United States of America, on the western shore of the Chesapeake; about 32 miles long, and narrow.

Calvert's Island, an island in the North Pacific ocean, near the west coast of North America. N. lat. 54° 40'. W. long. 13° 10'.

Calvi, a town of Naples, in the province of Lavora, the fee of a bishop, suffragan of Capua; 5 miles N. of Capua, and not far from the sea. N. lat. 41° 17'. E. long. 14° 45'.

Calvi, a town on the west side of the island of Corfica, the principal place of a district in the French department of Golo, containing 8,515 inhabitants. It is situated on a promontory which advances into the sea, and forms one of the most beautiful harbours in the island, called "the gulf of Calvi." It is defended by a citadel on a rock with 5 battlements; distant about 11 leagues W.S.W. of Bastia. N. lat. 42° 20'. E. long. 9° 7'.

Calviello, a town of Naples, in the province of Basilicata; 12 miles S.S.E. of Potenza.

Calvin, John, in Biography, an eminent reformer, entitled on account of his talents and character, as well as his peculiar activity and zeal, to the second rank of celebrity among those who contributed to rescue the Christian church from the errors and superstitions of Popery, was born of an obscure family, named Cauvin at Noyau, in Picardy, in 1509. As he was originally designed for the church, he obtained at an early age a benefice in the cathedral church of his native place, and also the cure of Pont-l'Evêque. Having pursued the study of polite literature for some time at Paris, where he distinguished himself by his proficiency, and where he also acquired a predilection in favour of the new opinions in religion, from a study of the Scriptures, recommended to him by Robert Olivetan, he determined to change his profissional deification; and applied to the study of the civil law, first at Orleans, and afterwards at Bourges. The Scriptures were likewise the objects of his particular attention; the more he acquainted himself with these purest sources of theological knowledge, the more was he confirmed in the opinions he had adopted; and his attachment to them was strengthened by intercourse with Melchior Wolmar, a German professor of the Greek language at Bourges. Upon his father's death he was obliged to return to Noyau, where he resigned his ecclesiastical benefices; and soon after removing to Paris, he published, in 1534, an eloquent Latin commentary on Seneca's tracts "De Clementia," on clemency. In the title of this book he latinized his name Cauin into Calvinus, whence he afterwards assumed his common appellation of Calvin. His attachment to the reformation being now generally known, he was under a necessity of suddenly quitting Paris, and of retiring to Angouleme, where he obtained a sufficiency by teaching Greek. Here he was admitted into the house of Lewis du Tillet, canon of the church, whom he had prophesied to the reformed religion; and during his residence in this place he wrote the greatest part of his "Institutes." Notwithstanding his degree of protection which was afforded him by the queen of Navarre, he thought it most prudent to leave France, and in 1534 he withdrew to Basle, and in the following year published his celebrated work, entitled "Institutes of the Christian Religion." The design of this work was to exhibit a just view of the principles of the reformed, and to prevent their being confounded with the Anabaptists and other enthusiasts. It was addressed to Francis I. by a dedicatory epistle, which is much applauded as the finest specimen of modern Latinity, and which was intended to soften
CALVIN.

often the unrelenting fury of that prince against the Protestants. This work has been always much admired by persons of similar sentiments, for the elegance of its style, the peculiar excellency of its method, and the force of its reasoning. It passed through several editions, which were successively enlarged and improved; it was translated by Calvin into French; and versions of it were made in all the principal modern languages. To some editions is prefixed the device of a flaming sword, with the motto, "Non venit nitro sacram fed gladium," i.e. "I came not to send peace, but a sword." After the publication of this work, Calvin went to Italy for the purpose of visiting the duchies of Ferrara, who was a convert to the reformed religion, and who received him with great kindness. On his return to France, he proposed to pursue his journey to Strasbourg or Bâle; but being obliged, on account of the wars then prevalent, to pass through the territories of the duchy of Savoy, he took Geneva in his way; and being urged by the prevailing solicitation of Farel, Viret, and other zealous reformers, to settle in that city, he accepted the offices of preacher and professor of divinity, which were conferred upon him with the consent of the people, by the consistory and magistrates. This settlement took place in 1536. In the following year he began to display his arbitrary spirit, by obliterating all the people to swear solemnly to a body of doctrines, which also contained a renunciation of popery; and by refusing to celebrate the Lord's supper, till certain irregularities that subsisted in the church at Geneva were rectified. He also declared, that he could not submit to the regulations, which had been lately made by the Synod of the canton of Berne, and which required the use of unleavened bread in the eucharist, the baptismal fonts which had been removed out of the churches, and the feals, which had been abolished, to be restored at Geneva. This occasioned a conflict, which terminated in an order of the assembly of the people, summoned by the syndics, that Calvin, Farel, and another minister, should leave the city within two days. Calvin retired to Strasbourg, where he was allowed to found a church according to his own model. There he married a wife; and published his "Commentary upon the Epistle to the Romans." During his absence, his friends at Geneva were very anxious for his return; and they at length prevailed, so that he arrived thither in September, 1541. After his re-settlement he began with establishing a form of ecclesiastical discipline, and a consistorial jurisdiction, invested with full powers to inflict all kinds of censures and canonical punishments, as far as excommunication. See CALVINISM. This establishment was much disapproved by several persons, who expressed their apprehensions, that papal tyranny would soon be revived. Calvin, however, was inflexible; and on all occasions artfully the rights of the consistory, of which he was perpetual presbyter, as he also was of the assembly of the clergy. But fully apprized of the exorbitant power which accrued from this office, he advised, on his death-bed, that no person should again be invested with such authority; and after his time the office of presbyter ceased to be perpetual.

Such was the extent of Calvin's ambition and views, that he formed a project of making the republic of Geneva the mother and father of all the reformed churches, as Wittenberg was of the Lutheran. From hence ministers were to be deputed to diffuse and support the Protestant cause throughout the world. Here he designed to originate an uniform model of doctrine and discipline, and Geneva was to be as it were, the "Rome" of Protestantism. His plan was pursued with vigour and perseverance. An academy was instituted in this city, to which his own talents and learning, and those of his colleagues, Farel, and of other eminent persons, attached a degree of reputation that extended to all countries where the reformed cause had taken root. The breach of Calvin in his project was to prove that the Presbyterian model of church government would only hold a kind of divided empire with the Lutheran and Thomistic episcopacy. When Calvin had formed and established his system of doctrine and church government, (See CALVINISM,) he was too tenacious of his own opinion, and too arbitrary in the exercise of his authority, to allow any deviation or opposition among those to whom his influence extended. Of the invariable peculiarity of his character, tribulations occur under the articles BURLINGTON, BURBIL, and GENEVA; but that which entails the greatest charge on his memory was his treatment of SERVETUS. While he was passing through Geneva, in order to seek an asylum in Italy from the persecution of Roman Catholics, he was apprehended at the instigation of Calvin, tried on a charge of blasphemy, condemned, and committed to the flames. The mere statement of this fact is sufficient to expose it; and no apology can be devised to extenuate it, but such as arises from the intolerant spirit which generally prevailed, and which, for many ages, it was thought not only lawful but laudable to exercise against persons who were deemed to hold unscriptural and heretical opinions, conceived to be inconsistent with the unity of the church, and the safety of the civil state.

The course of Calvin's life comprehended a great variety of pastoral cares and literary labours; and it was terminated by sickness and labour at comparatively an early period, in May 1564, as he was nearly completing his 53d year. The character of this learned and active reformer has been Truthfully examined by various authors; and calumniated by various descriptions; and more especially by those of the church of Rome. But it is justly observed by a liberal and candid biographer, that, whilst his morals, in the ordinary sense of the term, appear to have been irreproachable, his chief faults consisted in a resemblance to those uncharitable persons who have confounded and traduced him. His extraordinary talents have been acknowledged by the most eminent persons of his age; and they were such as would have rendered him a distinguished scholar, if his attention had not been wholly, or at least principally, devoted to theological studies and ecclesiastical occupations. His writings are numerous. Besides his "Institutes," he published learned commentaries upon most of the books of the New Testament, and upon the prophets in the Old. He refrained from commenting on the books of Revelation, much to his praise, according to the judgment of Scaliger and Bodin, because he thought it imprudently obscure, and of dubious authority. Many zealous believers were offended by his applying to the temporal circumstances of the Jews several ancient prophecies that have been thought to refer to the Messiah, and to furnish arguments in confirmation of the Christian cause. In this respect, however, he thought for himself, and cherished the edification of fervent attachment to generally received opinions. To his other more elaborate works he added many controversial pieces; and all his treatises were collected in 1562, in 9 vols. folio. His opinions, which are now better known than his writings, have been the subjects of innumerable controversies. For an abridgment of them, see the next article. Gen. Dict. Malth. E. H. Vol. iv. Gen. Biog.

CALVINISM, the doctrine and sentiments of Calvin, and of his followers, with regard to matters of religion. Calvinism confounds its greatest purity in the city of Geneva; and from thence it was first propagated into Germany, France, the United Provinces, and England. In Germany,
Germany, we may reckon among its chief patrons, Frederick III., elector Palatine, who, in 1569, removed from their parochial functions, the Lutheran doctors, and filled their places with Calvinists; and, at the same time, obliged his subjects to embrace the tenets, rites, and institutions of the church of Geneva. This order was abrogated in 1576 by his son and successor Lewis, who restored Lutheranism; but in 1593, Calvinism was again restored, under the government of the elector John Calvin, and became triumphant. In France it was abolished by the revocation of the edict of Nantes, in 1685. It has been the prevailing religion in the United Provinces ever since the year 1578.

The theological system of Calvin was adopted, and was to the public rule of faith in England, under the reign of Edward VI.; and the church of Scotland was modelled by John Knox, the disciple of Calvin, agreeably to the doctrine, rites, and form of ecclesiastical government, established at Geneva. In England it has declined since the time of queen Elizabeth; though it still abounds, some free a lay allayed, in the articles of the established church; and in its rigour in Scotland. See Reformation, and Reformed Church.

The distinguishing theological tenets of Calvinism, as the term is now generally applied, respect the doctrines of Predestination, or particular election and reprobation, original sin, particular redemption, eternal, or, as some have called it, irresistible grace in regeneration, justification by faith, perseverance, and the Trinity. See each of these articles. See also Arminians.

Besides the doctrinal part of Calvin's system, which, so far as it differs from that of other reformers of the same period, principally regarded the absolute decree of God, whereby the future and eternal condition of the human race was determined out of mere sovereign pleasure and free will; it extended likewise to the discipline and government of the Christian church, the nature of the eucharist, and the qualification of those who were intitled to the participation of it. Calvin considered every church as a separate and independent body, inviolate with the power of legislation for itself. He proposed that it should be governed by prebendaries and synods, composed of clergy and laity, without bishops, or any clerical subordination; and maintained, that the province of the civil magistrate extended only to its protection and outward accommodation. In order to facilitate an union with the Lutheran church, he acknowledged a real, though spiritual, presence of Christ in the eucharist, that true Christians were united to the man Christ in this ordinance, and that divine grace was conferred upon them, and sealed to them, in the celebration of it; and he confined the privilege of communion to pious and regenerate believers. See Eucharist, &c. and Lutheranism.

In France the Calvinists are distinguished by the name of Hugonots; and, among the common people, by that of Parpaillots. In Germany they are confounded with the Lutherans, under the general title Protestant; only sometimes distinguished by the name Reformed.

Calvinists, crypta, a name given to the favourers of Calvinism in Saxony, on account of their secret attachment to the Genevan doctrine and discipline. Many of them suffered by the decrees of the convocation of Torgau, held in 1576. See Form of Concord.

The Calvinists in their progress have divided into various branches, or latter feils. CALVINO, cope, in Geography, is the most westerly cape of the Nicara, E. of Zante Island, and S.W. from the S. point of the extremity of the gulf of Lepanto.

CALVISANO, a town of the Brezian, belonging to the state of Venice; 12 miles S.S. E. of Brescia.

CALVISIANA, in Ancient Geography, a place of Sicily between Agrigentum and Hybla, on the route from Lilybaeum to Messina, according to the Itinerary of Arrian. M. d'Anville places it at a little distance N.W. of Gala, on the southern coast.

CALVISIUS, Sethus, or CALVITUS, in Biography, a German chronologer, was born at Groflhe, in Thuringia, in 1556, held the office of chantor at Leipsic, to which he was appointed in 1582, and died in 1615. His principal work was his "Opus Chronologicum," published at Frankfort in 1603, 4to. In the compilation of this work, he adopted chronological principles, and drew up astronomical tables, by means of which he fixed and compared different epochs. He also formed a system of chronology from the beginning of the world to his own time; in which he inferred the history of all ages, described by such circumstances, that even children might comprehend in their minds a continued series or synopsia of history. Scaliger speaks in terms of high commendation of this work, though the impression of it was for some time prohibited by the governors of the univeristy of Leipsic. However, John Kepler the celebrated mathematician, and other persons of his note, wrote against it. Calvisius published at Erford in 1616, in 4to, "Enotatio durum Quellionum, viz. circa Annus Nativitatis et Tempus Ministerii Christi," and in 1616, "Elencus Calendarii Gregoriani, et duplex Calendarii mellioris Forma," Franc. Marchiounum, 4to. In this "Elencus," he proposes two points; first, to explode the Gregorian calendar by the principles of astronomy, and next to point out a truer and more convenient form of a calendar. Calvisius is reckoned among the heretics of the first rank in the "Index Expurgatorius," published at Madrid in 1659. According to Walter, in his "Musical Lexicon," he was a very learned theorist, and good practical musician; of which he has left ample proofs to pohterity in his short treatise called "MELODIOIA, five Melodies condensata ratio, quam vulgo musicae poeticae vacant, ex versos fundamentum extra et explicata," 1592. This ingenious tract contains, though but a small duodecimo volume, all that was known at the time, concerning harmonics and practical music; as he has compressed into his little book the science of most of the best writers on the subject; to which he has added short compositions of his own, to illustrate their doctrines and precepts. With respect to composition, he not only gives examples of concords and discords and their use in combination, but little canons and fugues of almost every kind then known.

He composed, in 1615, the 150th psalm in twelve parts, for three choirs, as an Epithalumion on the nuptials of his friend Casper Anckelman, a merchant of Hamburg, and published it in folio at Leipsic, the same year. Several of his hymns and motets appear in a collection of Lutheran church music, published at Leipsic, 1618, in eight volumes 8to. under the following title: "Florilegium portens CXV. selectissimas Cantiones, 4. 5. 6. 7. 8. voc. praetaltillorum Auditorum." Some of these have had the curiosity to score, and have found the laws of harmony and fugue preserved inviolate. Gen. Dict. Burney's Hist. Mus. vol. iii.

CALVISSON, in Geography, a town of France, in the department of the Gard, half a league E. of Sommieres, and three S.W. of Nimes.

CALVITI, a town of Naples, in the province of Calabria. Citra: 1 miles E. of Carrat.

CALVITTS, E. or CALVITUS, in Geography. See BALDNESS.

CALUMET, in Modern History, a myric kind of pipe used by the American savages as the ensign of peace, and for religious fumigation. This is a symbol of friendship universal
universel among the people of North America, and the pre-
sentation of it is an usage of arbitrary imposition peculiar
to them. The acceptance of it is a token of concurrence
with the terms proposed; and the refusal as certain a
signal of rejection. When this pipe is offered, even in the
midst of the rage of a conflict, the weapons of hostility drop
instantly from their hands, and a truce ensues.

The calumet is a sort of tobacco-pipe, made of red, black,
or white marble. When they treat of war, the pipe and its
ornaments are commonly red. The flax is decorated
with round flakes, and locks of hair, or porcupines
quills: in it they smoke in honour of the sun. M. Laitan
will have it to be the original canopius of Mercury, of,
which used by the Greeks and Romans, with its wings
and its serpents, was only the copy.

The calumet is the symbol and security of traffic; by it
they pronounce life and death, peace and war: and they also
affix to it a power of raising the souls of the dead.

Among the Indians, there is also a totemic rite, called
the "dance of the calumet," which they perform on vari-
ous occasions. They are not allowed to wash themselves in
the rivers at the commencement of summer, nor to taste
the new fruits, without performing it; and the same ceremony
always confirms a peace, or precedes a war. In winter it is
performed in their cabins, and in winter in the open fields.

Having chosen a spot among trees, flanked from the best of
the sun, they lay in the middle of it a large mat, and set
upon it the monitor, or god, of the chief of the company.
On the right hand of this image, they place the calumet,
as their chief deity, creating around it a kind of trophy
with their arms. Those who are to fig on the occasion
take the most honourable seat under the shade of the trees.

When the company is arranged, each person, before he fits
down, sabates the monitor, by blowing upon it the smoke
of their tobacco; then every one in rotation receives the
kalumet, and holding it with both hands, dances to the
cadence of the vocal music, which is accompanied by the
beating of a sort of drum. During this exercise, he gives a
signal to one of their warriors, who, taking a bow, arrow,
and axe, out of the trophies above-mentioned, fights him;
whilst he defends himself with the calumet only; and both
of them continue the passime of dancing. When this
mock-engagement is concluded, he who holds the calumet
makes a speech, recounting the battles he has fought, and
the prisoners he has taken, and then receives a cloak, or
some other present, from the chief of the ball. He then
refuses the calumet to another; who, having acted a similar
part, delivers it to a third person; and thus in rotation, till
at last the instrument returns to the person who began the
ceremony; by whom it is presented to the nation invited to
the feast as a mark of friendship, and a confirmation of
their alliance, when this is the occasion of the entertain-
ment.

_**CALUMET, Grand, in Geography,**_ a portage of Lower
Canada, in North America, on the northern bank of the
river Utawas. This is the long-est carrying place on this
river, and is about two thousand and thirty-five paces. It
is a high hill or mountain. From the upper part of this
portage the current is forc'd, and is only a branch of the
Utawas river, which joins the main channel, that keeps a
more southern course, at the distance of 12 leagues.

Six leagues further it forms lake Coulange, which is about four leagues in length; from whence it pro-
cesses through the channels of the Allumettes to the port-
age, where part of the lading is taken out, and carried 342
paces. Then succeeds the portage des Allumettes, which
is but 25 paces, over a rock difficult of access, and at a
flatt distance from lake Coulange. From portage de
Choiies to this post is a fine deep hummock country, and
the land in many parts fit for cultivation. From hence the
river spreads wide, and is full of islands, with half a mile
for seven leagues, to the beginning of "River Skidas" or
long. 77° 16'. Mackenzie's Voyage, locd, p. 112.

**CALUMNY, the crime of accusing another falsely and
knowingly of some heinous offence.**

It is an ancient maxim, which experiences shows us to be
too well founded: _Adductor calumniius, sentor aliquid
heredit._

**Calumnny, oath of, Juramentum, or rather to juramentum
calumnie, among civilians and cartouche,was an oath in
which both parties in a cause were obliged to take; the plaintif-
that he did not bring his charge, and the defendant,
that he did not deny it, with a design to abuse each other, but
because they believed their cause was just and good; that
they would not deny the truth, nor create unnecessary
delays, nor offer the judge or evidence any gifts or bribes.
If the plaintiff refused this oath, the complaint or libel was
abandoned; if the defendant, it was taken _pro confesso._

This custom was taken from the ancient Athenian, who,
before they engaged, were to swear they had no malice, nor
would use any fraudulent or unfair means for overcoming
the other. The _juramentum calumnie_ is much diffused as a
great occasion of perjury. Anciently the advocates and proctors
also took this oath; but of late it is dispensed with, and
thought sufficient that they take it once for all at their first
admission to practice.

**Calumny, judicium, was an action brought against
the plaintiff in a court for a false and malicious accusa-
ation. When an accuser did not prove his charge, or seemed to have
sufficient or probable grounds for bringing any, the judges in
pronouncing sentence used the formula _calumniae, et
_which gave the defendant a right to bring an action of

calumny; the penalty of which was _fractia inuinio, or burning
on the forehead. See _Accusation._

**Calumny, in the Arts, was admirably personified by
Apelles. This celebrated painter was accused of having
conspired against Ptolemy, king of Egypt; and being deli-
ered from the danger that threatened him, he determined
to avenge himself of the calumny by a picture, which was
always held in high estimation. On the right was a man
with large cars, resembling Nidas; he stretched out
his hand towards Calumny, who approached him; and near
him were placed two female figures, those of Ignorance and
Difimence. On the other side stood Calumny, who was a
beautiful female, that appeared agitated and enraged; she
held in her left hand a flaming torch, and with her right she
dragged by the hair a youth, lifting his hands towards the
heavens, and calling the gods to witness in his favour. Be-
fore her moved a pale and deformed man, with piercing
eyes, who seemed to have just recovered from a long illness:
this was *Envoy.* Two other females, converted with Ca-
umny; those were Concealment and Deceit. Another fe-
male followed, clothed in black, with tattered garments,
which was *Repentance:* she turned her head backward,
difflved in tears, and looked with shame on Truth, who ap-
proached her. Lucian, in his _Dialogue against Calumny,_
has transmitted to us this model of moral allegory.

**CALVORD, in Geography, a town of Germany, in
the circle of Lower Saxony, and duchy of Magdeburg; 24
miles N.W. of Magdeburg.

**CALUPENA, in Ancient Geography, a country of Asia,
on the frontiers of the Lesser Armenia, and of the country of

_Landsena,
The name is derived from this circumstance, but it is not well chosen, as many plants which have the same character are not included under it.

It is also the seventh order of the fourteenth class in the system of Ventenat, where, though founded on the same general idea, it is still less comprehensive. Its genera are pappus, ginnos, lawna, lyrum, scianthera, perlonia, cuphea, fisudula, amaranth, glaxus, and pepisia. In all these the calyx is inferior, and the corolla, when present, is inserted upon the calyx and not within it.

Gen. Ch. Cal., perennial one-seeded, pitcher-shaped, deeply divided, segments numerous, linear-lanceolate, coloured. (Caducada, Vent.) Cor. petals numerous, flap-shaped, acuminate, attached to the calyx within its divisions, and exactly resembling them. Stema: twenty, much shorter than the petals; anthers oblong, cret., furrowed. Fil. germs numerous, superior: styles awl-shaped, compressed, the length of the flower; stigma glabrous. Per. none, except the bottom of the calyx, which thickens, becomes succulent, and takes the form of a berry. Seeds many, tailed.

Tiff. Ch. Calyx one-seeded, pitcher-shaped, with coloured segments. Petals resembling the segments of the calyx. Seeds many, tailed, within a succulent calyx.

Olf. Linnaus gives the flower no corolla, but a calyx with many divisions in two concentric ranks, all resembling petals; and Schöber and Mariy adopt his ideas. But we have preferred the description of La Mare and Ventenat, justified having observed, that the inner rank probably consists of petals; and Linnaus himself having, perhaps, incautiously, doublets inconsistently, admitted the true petals into both his specific characters. Sp. 1. C. floribusa, Carolina allspice. Linna. Sp. pt. 1, A. Mare. Iliff. Pl. 10. fig. 1. (Bateria, Dubam. Tab. 45.) Bateria, Mill. icon. 60. Dubam. Enret. Tab. 13. Frutex com: folia, Castell. Car. n. p. 46, Tab. 40.) "Petals longer than the divisions of the calyx." A shrub three or four feet high, or more in its native country. Stem irregularly branched, covered with a brown aromatic bark. Leaves opposite, pelted, egg-shaped, acute, entire, on short petioles. Stipules none. Flowers of a dusky purple colour, about an inch and a half or two inches in diameter; the petals incurved at the top; peduncles short, solitary, pubescent. A native of Carolina. Bofe affirms, from his personal observation in Carolina, that Linnaeus has confounded two distinct plants under one name. Both have opposite, egg-shaped, lanceolate leaves, without stipules, but tho' of one are pubescent and large, of the other, smooth and smaller; the flowers of the former are also larger, of a deeper red colour, and have a strong unpleasant smell, which tho' of the latter have not. Professor Martin mentions two varieties, the one with oblong, the other with roundish, egg-shaped leaves, but they do not correspond with Bose's two species, the latter of which does not appear to be known in England. The former was introduced into our gardens, by John Catesby, fo early as 1726. It will thrive in any soil, so planted in a warm situation and dry soil. It is propagated by laying down the young branches, which should be done in Autumn; in the spring twelvemonth after, the layers should be separated from the parent stock, and let where they are designed to remain.
remain. Some old tanners' bark should be laid on the
surface to keep out the frost while the plants are young.
Bole informs us, that the flowers and ends of the branches
influenced by brandy make a pleasant liquor, and that the seeds
are thought, in America, to be poissons to dogs and foxes.
2. C. Mares, in Linn. Sp. 2. M. M. 11. 44. 8. v. (Obel
or Roby, Kempf. Am. 1879. Tab. 8. 9.) "Petals shorter
than the divisions of the calyx." Leaves egg-shaped lance-
olate. Flowers appearing before the leaves, yellow; pet-
lals small, bristled with red spot. Fruit longer, silky
and rough. Seeds five or six, which form here their tail, and
red ribbed middle bead. A native of Japan and China,
introduced into England in 1774.
CALYCTERA, (from καλυτης, calyx, and ετος, a born.)
Wfillld. Cavan. ic. 4 p. 34. Tab. 338. Club and order,
fangenuia iegregea.
Eff. Cn. Common calyx, many leaved; proper calyx five-
toothed. Florets tubular, male and hermaphroditic.
Receptacle chalybe. Seeds naked.
Sp. C. herbaec. Root lusious. Stems a foot high, erect,
simple, smooth, round, hollow. Leaves linear-lanceolate,
pinnatind. toothed; stem ones nearly whole; radial ones
on long pediocks. Flowers compositd, globular, terminal;
barren and fertile florets intermixed; teeth, in the barren
florets, egg-shaped, acute, very short; in the fertile ones,
lanceolate-awl-shaped, twice the length of the corolla. Seed
flingle, naked, at the bottom of the calyx. Receptacle some-
what globular. A native of Chilii.
CALYCFLORE, a natural order formed by Linnaeus
for four genera, Olyrs, Trophis, Hippopata, and Elegannts;
but, as we learn from Giseke, afterwards abolished.
CALYCFLORUS in Zoology, a species of Brachице-
ous, first described by Baker in his Elays on the Micro-
cope, and since by Professor Pallas. It is defined by the
latter as being of a simple form, calyciferous, with the shell
crowned behind, and the upper lip of the mouth four-tooth-
ed. Invisible to the naked eye. Found in water.
CALYCFINA, in Entomology, a species of Ariansa,
the abdomen of which is globule, and of a pale, yellowish
\colour. The insect is thus described by Linnaeus in his Fauna
Suecia, as a Swedish species. Scoopoh calls it arenca Kley-
nii. This kind of idper secretes itself in the calyces
of flowers from which the corolla has fallen, and falls on
the flies that are tempted to the calyces in search of the
nectarious juices.
CALYCFISTAE, in Botany, a name given by Linnaeus
to those botanists who have arranged plants from a regard
chiefly or solely to their calyx. Magnoli and Linnaeus him-
selves are the only authors mentioned who have attempted
this method.
CALYCLE, a term invented by Vaillant to express a
series of leaves surrounding the base of the calyx, generally
shorter, of a different shape, and making a kind of doubt
causal; as in crepis, dianthus, malva, &c. Linnaeus in his Phy-
losophia Botanica calls such a calyx auctus; but in his prac-
tical works he is by no means uniform in his manner of ex-
pressing this circumference. In the Systema Naturae, he
describes the calyx of crepis and other kindred genera as caly-
ced; but in the Genera Plantarum he styles it sometimes
auctus and sometimes duplex or double. This latter term
he applies to the calyx of malva, &c. That of dianthus he
calls lecaly. The term is also used by Linnaeus to denote the
small permanent perianth which crowns the seed of icabola,
artotis, and some other genera, and is supponed, like the
down attached to the seed of molt fungenious plants, to
facilitate its dispersion. According to Gertner, a seed is
calyced when its crust is extended above its vertex, so as to
form a one-leaved cup; it is either entire as in tanacetum,
pyrethrum, dipkaeus, &c. or halved as in melampodium and
a few others. If there be more than one leaf it is considered
by him as a different kind of pappus to which he calls claply.
The term calylce is therefore employed by him with greater
rapidity than it is by Linnaeus. See his General Introducton,
p. 126.
CALYCOPTERIS, a generic name given to a shrub
figured by Lt. Mared in his Illustrations, which belongs to
the genus monyca of the Linnaean system. But there is
no article under that name in the alphabetical part of the
Encyclopedie; and as the letter-prefixed to the Illustrations
is not completed, we are not able to determine its proper
genetic character, nor of what country it is a native.
CALYDERMAC, (from καλυς, calyx, and δυνομε, a
flora) a genus formed by the author of the Flora Perma-
fis for the atom phylobates of Linnaeus, which came
the other species in having a dry five claded honey, and
a calyx with arrow-heart-shaped divisions, entering the
fruit.
CALYDNA INSECTA, in Ancient Geography, a single
island according to Steph. Byz. and Ptolemy; it is included
a group of islands, according to Homer, which Homer's place
them near the island of Rhodes. Some have thought that
this by this general appellation the poet designed to express the
Sporades. Strabo, in speaking of their honey, places them
near Tenedos; and M. D. anuille supposes, that they are
two rocks, which are still found, one before and the other
to the right of the port of Tenedos.
CALYDON, a city of Aetolia, pleasantly and commodi-
doniously seated on the river Euenus, which passed through it.
This city, which seems to have continued for some time the
repose of the ancient Aetolian kings, was built by Caly-
don, the son of Aetolus, from whence the kingdom was
called Calydon, though it afterwards resumed its ancient
appellation. Hercules came to this city after he had left
Peleponnesus; and though he had a numerous spurious brood,
scattered over all Greece, yet, desirous of legitimate issue,
his is said to have married Dejanira, the daughter of Cenus,
king of the country, and father to Meleager; and with a
view of ingratiating himself with the Aetolians, to have turned
the current of the river Achelous, or to have made such im-
provement in its channel, as to have given right to the fable
of his having vanquished it in single combat. Calydon was
fixed near the forest of that name, where Meleager, ac-
companied by the nobility youths of Greece, flew the famed
calidoscan boar. This fierce and monstrous animal had done
too much mischief in the neighbourhood, that Meleager, king
of the country, who kept his court at Calydon, was forced
to call to his assistance a great number of the most distin-
guished persons of Greece in order to destroy it. The chief
of these were Thefeus, Telamon, Peleus, Ptolus, and Iolus,
all of them the faithful companions of Hercules, besides a
number of other heroes. To these were added the famous
Arcadian princes Aralanta, who behaved with such uncommon
courage and intrepidity upon this occasion, that Mele-
ager became enamoured with her, and married her. If we
may credit Paunianus, (Arcad. cap. 46.) one of the tuffes
of this boar, which was preferred in the temple of Bacchus,
in the imperial gardens, was above a yard long, and there-
fore his size must have been very great. Some imperial
Greek medals were struck in the city of Calydon.
CALYMERE POINT, in Geography, lies on the southern
extremity of the east coast of the Carnatic country, in Hind-
doian, near N. gopadam. N. lat. 10° 20'. E. long. 79°
54' 30".
CALYMNA, in Ancient Geography, an island of the Me-
diterranean sea, upon the coast of Asia, before Carpathium,
according
according to Pliny. Oxid says, that it produced abundance of honey. It was one of the Sparoades, S.W. of Leros, and N.W. of Cos. See Calamo.

Calynda. See Calynda.

Calydara. Fiume Caffoli, a small river of Sicily, on the eastern coast.

Calyplectus. In Botany, from καλύπτει, a veil, from καλύπτω, to cover; a term used by old authors for that kind of veiling covering which invests the calyxes of mosses before they arrive at maturity. Linnaeus, who first took the capule for an author, considered it as a species of calyx. Hedwig at first regarded it as the corolla, but was afterwards convinced that it is properly part of the peltil, and that its first office is to strengthen the attachment of the flower to the stem. But as, from his own description, in its early state it invests the essential parts of the fructification, it is, as Linnaeus made it, properly a species of calyx. When the germ becomes enlarged, the calytra is torn all round from the base of the receptacle, and carried up by the capsule.

Gen. Char. Cal. perianth one-leaved, bell-shaped, truncate, without teeth, or very slightly four-toothed, inferior, permanent; covered before the time of flowering with a round, concave, deciduous operculum or lid. Cor. none. Stam. filaments numerous, capillary, inserted within the rim of the calyx; anthers roundish, double, filiform. Fil. germ roundish, flattened at the bottom of the calyx; style, simple, thread-shaped, inflexed, the length of the flowers; stigma obtuse. Peric. berry globose or oblong, crowned with the calyx. Seeds from one to four, somewhat angular.

Eif. Ch. Calyx superior, truncate, covered till the flaments and peltil become mature, with an entire deciduous lid. Corolla none. Berry one-celled. Seeds from one to four. Obs. It differs from Encalyptus in having a berry, not a capsule.

Species, 1. C. chryzaulea, Willd. Swartz. Prod. 79. Fl. ind. occ. 2. p. 991. (Myrtus chryzaulea, Linn. Sp. Chryzaulea, Brown Jam. 239. tab. 37. fig. 2.) "Peduncles terminal, panicled, trichotomous, downy; leaves egg-shaped, attenuated at the top." A tree. Leaves smooth, opposite. Lid flattened to the calyx laterally, but it afterwards turns back, and then the flowers come out, which before had been twilled and concealed. It is reckoned an excellent timber wood, but seldom exceeds 14 or 15 inches in diameter.

Obs. Prof. Martyn has adopted the idea of Schreber, in considering the Jambolofera of Linnaeus and the Calyptantes of Swartz as one genus, and has accordingly added the Jambolofera pedunculata of Linnaeus and the J. odorata and refinoa of Loureiro. Wildenow concurs with him, and has also adopted into this genus Eugenia Caryophyllifolia of La Maree. The genus Myrtus is a synonym. But as all these plants are expressly said to be furnished with petals, and as the frish three have only eight flaments, they cannot belong to Calyptantes, while its generic characters remain as they now stand. The genus Jambolofera in its own description, as its early state it invests the essential parts of the fructification, it is, as Linnaeus made it, properly a species of calyx. When the germ becomes enlarged, the calytra is torn all round from the base of the receptacle, and carried up by the capsule.

Gen. Char. Calyx treble, permanent; outer one confining of
of twoawl-shaped leaves; middle one with three egg-
shaped, acute divisons; inner one of two lanceolate
leaves. Cor. irregular; tube short; lower with five near-regular
segments; the two upper larger. Stam. four. Pfl. 
5 mm. superius, comp¬
plicated; style thread-shaped, declining,
the length of the filament; stigma capitate. Pet. capi¬
tate egg-shaped, two-celled, two-valved. Seeds numerous,
small, browned, flattened; receptacle fixed to the valves.
Eff. Chin. Calyx trilobed. An herbaceous plant, native of
Tenn.

CALYX, or Calyx, in a general sense, denotes a cur. 
See Chalice.

Calyx, in Ancient Aqueductis, denoted a braven module
or cup, put over a head or cædellum, to which pipes
were fitted.

Calyx, in Botany, καλύς, a covering, from καλυπτειν. 
The word is used by Greek writers for a rose bud, in which
the proper flower or corolla of modern botanists is not
opened, but lies concealed under an envelope. It is thus
explained by Suidas καλυπτειν, καλυπτειν μετακειν: the flower of
the rose not expanded. Aquila, full earier, in his version of Hesiod, 
ch. xxxv, 1. had translated the Hebrew word יַכַּלְעָא
καλύς, which, Jerom says, is a better rendering than יַכַּלְעָא
of the Septuagint, or phyllum of the Vulgate. Flurchit utullum, 
five ut significatius expressit Aquila, καλύς, quam nos 
tumentem rotundam, vnd pulivium foliis dilatatum, discere.
It shall flourish as a lily, or as Aquila more significantly
expresses it, as a calyx, or swelling role, whose flower-leaves
are not yet expanded.

By these writers the bud itself, in its entire sub¬
flance, is called a calyx: though the admission of στυρομοιαν,
by Suidas, as a synonym of καλυπτειν, may seem to imply only the en¬
velope, to which the term has been applied by modern bot¬
anists. According to Ray, it is the cape (folliculus) in
which, first the flower, and afterwards the seed of herbaceous
plants, and the fruit of trees is enclosed; but the latter
part of the definition must certainly be received, with
numerous exceptions.

Through a similarity in sound, and in many cases, a resem¬
blance in form, it was very early confounded with calix, a
cup; but as it is almost universally spelt with a y in the
latter syllable, its derivation and proper meaning cannot be dou¬
ted. It is the envelope cape of the cape, in which the tender
flower lies for a time concealed, and by which it is, in most
cases, afterwards supported and preserved.

Lammeus has followed Cæsalpinus in considering the calyx
as a prolongation of the cortex, or outer bark of the plant,
and has distinguished it into seven different kinds: 1. A pe¬
rianth, contiguous to the other parts of the fructification.
This is frequently called emplaiement or flower-cup by Eng¬
ish writers, and to it, as prof. Dr. Martin well observes,
should the term, cup, if admitted at all, be confined. 2. An
involute, remote from the flower, as in many umbelliferous
plants. 3. An amentum or catkin, from a common, chaffy,
gemmaceous receptacle. 4. A fathie burbling longitudi¬
inally. 5. A glume, formed of valves embracing the seed.
6. A calyptra, covering the capsels of molles like a hood.
7. A volva, a membranaceous covering to the fructification
of the fungi. See those words. The involucr is rather a number
of bractes; and the amentum, a species of inflores¬
cence.

Calyxhymenia. Ortega Decad. Bot. Flor. Peru-
Pl. 75. Clafs and order, triandra monocynia.

ate: border with free parted divisions. Stam. the 
Pfl., superius, comp¬
plicated; style curved; stigma capitate. Pet. capi¬
tate egg-shaped, one-styled, enclosed in the calyx.

Four species of this genus are figured in the Flor Par¬
vienca, which are all herbaceous plants with pointed faced,
and opposite, petioled, egg-shaped, entire leaves. They are
nearly allied to mirabilis: and according to Bell, from whom
we are obliged, not having the flora Parvienca at hand, to
translate this article, and what information, as usual, is muti¬
lated and unsatisfactory; there ought to be added to them
the mirabilis vicina of Camellia, which has been turned
into a distinct genus by Tuna, under the name of Thunbiana,
and by l'Héritier, under that of Oeytagus.

CaliZadera, in Geography, a town of Spain, in Old
Calistyle, once the seat of a bishop, united to that of Cala-
horra; 40 miles W. of Cadiz, N. lat. 42° 12'. W. long. 2° 47'.

CAME, or Grant, a river of England, which passes by
Cambridge, and joins the Ouse, three miles south from
Ely.

Cam, one of the smaller Virgin Islands in the West In¬
dies. N. lat. 18° 20'. W. long. 63° 25'.

Cam's Bank, lies on the coast of Planders, W. of the
Broer's bank, within which a ship may run through and
ride by the land in all winds.

CAMA, or Camila, in Ancient Geography, a town of
Asia in Armenia; the chief city of the Manichæists.

Camac, Porto, in Geography, lies on the north side
of the island of Canaria, to the S. of the Archipelago Islands,
and on the E. side of Cape St. John, having several islands
in its mouth.

Camacæ, and camae, in Ancient Geography, the de¬
nomination of distinct people, chieflie by Pliny among the
Seetian nations on this side of Mount Imnus.

Camæa, in Natural History, the name of a genus of
the semipellucid gems, the characters of which are these: 
they are obscurely transparent stones approaching to the
onyx structure, being composed of zones, and formed on a
crystalline base, but having their zones very broad and thick,
and laid alternately on one another with no other matter be¬
 tween them.

Of this genus we have four known species:

1. The dull-looking onyx, with brown black and white
zones. This is the camasa of the modern, and the Arabian
onyx. It is found in Egypt, Arabia, Persia, and the East
Indies. 2. The dull broad-zoned green and white camaca, or
the japhamcm of the Indians: it found in the East Indies,
and in some parts of America. 3. The hard camaca, with
brown white and chesnut-coloured veins. 4. The hard camaca
with bluish, white, and flesh-coloured broad veins, being the
fordaxon of Pliny's time, brought only from the East Indies.

Camah, in the Materia Medica, a name given by
Avicea and others to the large truffles found in the dearts
of Numidia, and many other parts of Africa, in great abun-
dance. These are white on the outside; the modern Afri¬
cans call them terento, and are very fond of them; they eat
them stewed with milk, water, and spices, and account them
wholesome and nutritious.

Camaiæv, or Camayev, in Mineralogy, a word used to
express a peculiar fort of onyx: allo by some to express a stone,
whereon are found various figures, and representations of land¬
ces, &c. formed by a kind of lyphs nature; so as to ex-
hbit pictures without painting. The word comes from
camaiævus, a name the Orientals give to the onyx, when
they find, in preparing it, another colour; thus expressing a se¬
cond stone. It is of these camaivus Pliny is to be understood
when

Camaleu is also applied by others to those precious stones, as onyxes, cornelins, and agats, whereas the lapidaries employ their art to aid nature, and perfect those representations. See Camal.

Camaleu is also frequently applied to any kind of gem, wherein figures may be engraved either indentedly, or in relief. In this sense the lapidaries of Paris are called in their latitudes enteres camameus. A society of learned men at Florence undertook to procure all the camas or camameu, and intaglios in the great duke's gallery, to be engraved; and began to draw the heads of divers emperors in camas.

Camaleu is also used for a painting, wherein there is only one colour; and where the lights and shadows are of gold, wrought on a golden or azure ground. When the ground is yellow, the French call it céruse; when grey, grisaille. This kind of work is chiefly used to represent ballo relievos: the Greeks call pieces of this sort μόριανα μορία.

Camail, in Ornithology, synonymous with cravatte, according to Buffon, and other French writers, the black-faced tanger of Latham, and tanagro atrum of Gmelin. This is a bird that inhabits Guiana, is about seven inches long, and of a cinereous colour, with the face, chin, and throat of the male black; and of the female, brown.

Camaines, Grand, in Geography, a large island, with low and smooth land, and trees on the top, about 46 or 48 leagues W.N.W. from the west point of Jamaica. The island is well forested with turtle.

Camaines, Little, are two islands, the westernmost of which is called Camin Brack. They lie E.N.E. about 20 leagues from the Grand Camanier. The people of Jamaica catch many turtles here.

Camala, or Camila, in Ancient Geography, a town of Spain, 24 miles from Lacobriga. Anton. Itin.

Camala, in Geography, a river that lies on the E. coast of Africa, within the long reef or sand bank from Cape Corinete to the Barra Vermelas, an extent of at least 400 miles.

Camaldulians, Camaldulians, of Camaldolites, in Ecclesiastical History, an order of religious, founded by Romuald, an Italian fanatic, in 1023; in the horrible desert of Camaldoli, otherwise called Campo-Malduli, situated in the state of Florence, on the Appenines.

Their rule is that of St. Benedict; and their houses, by the statutes, are never to be less than five leagues from cities. The Camaldulians have not borne that title from the beginning of their order; till the close of the eleventh century they were called Romualdias, from the name of their founder. Till that time Camaldulian was a particular name for thos of the desert Camaldoli; and D. Grandi observes, was not given to the whole order, in regard it was in this monastery that the order commenced, but because the regulation was well maintained here.

Guido Grandi, mathematician of the great duke of Tuscany, and a monk of this order, has published Camaldulian Diff stations on the origin and establishment of it.

The Camaldolites were distinguished into two classes, of which the one were Coenobites, and the other Eremites.

Camaldolunum, Camudulunum, or Comodunum, in Ancient Geography, a town of Albion, belonging to the Trinovantes, or Trinovantes. This town is placed by some of our antiquaries, as Talbot, Stillbrig, and Baxter, at Colchester; but by Camden, Horley, and others, more conformably to the itinerary of Antonine, and with greater probability, at Maldon. Dr. Cale earnestly contends for Walden. This was the capital of the powerful British king Cunobelin, and the first Roman colony in the island. Soon after the conquest of this part of the country by the Romans, a colony, confiding chiefly of the veterans of the 14th legion, was planted at Camulodunum by the emperor Claudius, A.D. 52; and by their wealth and industry, it became a place of great magnificence. But its prosperity was of no long duration; for it was quite destroyed by the Britons in their great revolt, A.D. 61. The theatre, the temple of Claudius, and the several villas in the neighbourhood, belonging to the Roman commanders, were totally demolished by the incensed Britons, who beheld the colony as a seat of slavery, that our learned antiquaries have been much divided about the place where it was situated.

Camamu, Río, in Geography, a large river of the Brazils, about 25 leagues to the southward of Bahia; on the banks of which are several small towns and villages, which are the seat inhabited of any part of the Brazils. There are not less than 3 or 400 small vessels employed by the inhabitants to convey their commodities to Bahia and Rio de Janeiro. The Jesuits formerly carried on a great traffic with this place, and sent a large frigate loaded from these parts to Paraguay. The source of this river is in the centre of the gold mines.

Camana, or Camane, in Ancient Geography, a town of India, on this side of the Ganges, in the gulf of Barga-zem; supposed by some to be situated in the place of the present Cambay.

Camana, in Geography, a town of South America, and capital of the jurisdiction of Camana in the diocese of Arequipa, in Peru, situated on a river of the same name, near the South Pacific ocean. The jurisdiction is large, and contains many deferts, especially along the coast. Eastward it extends to the borders of the Cordilleras, so that the temperature of some parts is nearly the same with that of Arequipa, while others are cold; and both produce similar grain and fruits. Its principal trade consists in textiles. It has silver mines in the mountains; but they are not worked. The town is 70 miles from Arequipa.

Camanar, a town that lies behind a ridge of rocks on the S. side of Gallipoli, on the Atlantic shore of the passage towards Constantinople and the Black sea.

Camanabaya, in Botany (Margraevae, and Petiver.) See Tillandsia ustulata.

Camantium, in Ancient Geography, the name of a town of Asia Minor, being, according to Athenaeus, one of the seven towns which Cyrus conferred on his friend Clearchus.

Camanusali, or Calcana Musali, in Biography, a physician and surgeon in much estimation, who practised at Bagdad about the middle of the 13th century. He wrote a treatise on the diseases of the eyes, in which he professes to have given all that could be found in the book Arabian, Hebrew, and Chaldæan writers on the subject; particularly he describes the method of curing cataracts by the use of feet. His work was translated from the Arabic into Latin, and published at Venice in folio with the Chirurgery of Guin de Caniac, who frequently cites him. The title of the tract is "De Pasionibus Oculorum Liber." It has been several times reprinted. Hailer. Bib. Chir.

Camara, in Botany (Plunier, Dillenius, La Marek, Boc.) See Lantana.

Camara, in Ancient Geography, a town of the island of Crete,
CAMARINA, in Geography, a town of Spain in Arragon; 4 miles S. of Tened.

CAMARINAS, a town of Spain, near the sea-coast of Galicia; 25 miles W.N.W. of Galicia.

CAMARINES, the south western province of the island of Luzon, one of the Philippines, in which are Bando, Paoaco, Ibanon, the metropolis of the government of Catanduanes, Bulan, Sefrocon, or Bagatan, where the king's ships are built, and Albo, a large bay without the fleet, in which there is a high burning mountain, seen at a great distance by the ships coming from New Spain, and possessing some springs of hot water. Beyond Albo, towards the coast, is the cape of Bumbyngay; and continuing from hence westward, we arrive at the river Bicol, which flows from a lake and runs by the city Caceres, the capital of the province. See Caceres.

CAMARINUM, or Camerino, now Camerino, in Ancient Geography, a town of Italy in Umbria, on the confines of Picenum, and at some distance from Nuceria. It was probably powerful, as the Romans. A. U. C. 144, solicited an alliance with it; they afterwards established a colony there. See Camerino. Strabo and Ptolemy.

CAMARICA, in Geography, a town of the island of Cuba; 15 miles E. of Havanna.

CAMARIPUGUACU, in Ichthyology, the name under which Maregraave, and various other old writers, describe the Brazilian species of Clupea, called by Broussat and Gmelin Cyprinoides: see that article.

CARARITE, in Ancient Geography, a people who inhabited the coast of the Capian sea, on the isle which separates that sea from the Euxine. Dioniysius Periegetes says, that they formed a numerous nation; and that they hospitably entertained Bacchus in his return from the Indian war.

CAMAROCENSIA CIVITAS. See Camaracum.

CAMARON, or Camarón, Cape, in Geography, a headland of North America, in the gulf of Honduras. N. lat. 15° 35'. W. long. 85° 29'.

CAMARONES, a town of the island of Cuba; 75 miles S.E. of Havanna.

CAMARONES, of Jamour, a river of Africa, which rises in the country of Bafrin, and passing through the territory of the Calbongos, discharges itself into the Atlantic in the gulf of Guinea. N. lat. 2° 28'. E. long. 11° 30'.

CAMARONES, Cape, is a headland at the mouth of this river.

CAMARONES, a river of South America, forming a bay in the Atlantic, about 50 leagues N. from Port Defile, or Defendo, and 20 from cape Blanco, which lies between them. S. lat. about 44° 32'. W. long. 66° 20'.

CAMARONES, a river of South America, on the coast of Peru, which runs into the Pacific ocean, about 36 miles S. of Arica. S. lat. about 19° 20'. It is 8 leagues N. from Pifagua river. There is a point or cape of the same name, rendered white by the dung of the cormorants, that refer to it.
CAMB, or KAMP, in Geography, a river of Austria, which rises on the frontiers of Bohemia, and discharges itself into the Danube.

CAMBADAS, a town of Spain, in Galicia, near the sea-coast; 4 leagues W. of Ponte-Vedra.

CAMBADENA, in Ancient Geography, a country of Asia; not far from Media. One of its principal towns was Baptana, seated on a mountain, in which were a column and statue of Semiramis.

CAMBAHEE, in Geography, a river of America, which runs into the sea near St. Helena's found, on the coast of South Carolina.

CAMBIA, in Ancient Geography, a place of Asia, in the Greater Armenia, and in the Hyperperid country, according to Strabo, who says that it had mines of gold.

CAMBALIDUS MONS, a mountain of Asia, which, according to Piny, was a branch of mount Caucasus.

CAMBALU, a name formerly given to Pekin, the present capital of China. In 1397, it was erected by pope Clement V. into an archbishopric, which he conferred upon John de Monte Corvino, an Italian friar, who had been employed for many years in propagating the gospel in that country. Upon his death in 1395, pope John XXII. sent Nicholas of Banter to fill the vacant see, and charged him with letters to the emperor of the Tartars, who was, at that time, in possession of the Chinese dominions.

CAMBAMBA, in Geography, a high mountain of Africa, giving name to the adjacent district, in the kingdom of Angula, on which is a mine of excellent silver. The Portuguese have been for a long time masters of it, and have built a strong fortress; which, on account of its vicinity to the river Cuamba, carries on a great commerce of slaves.

CAMBANA. See CAMBIA.

CAMBAT, a province of Abyssinia, dismembered from it by the Gallas. It occupies that district of Africa in the southern part of Abyssinia, which lies in about N. lat. 8°, and E. long. from about 37° to 38°. It is separated from Gingoro on the west and south-west, by the river Zeebe; on the north it has the kingdom of Hada, and other provinces of Abyssinia; on the east and south-east it has Buzamo and Alaba, and on the south Makoko. This country is frequently harassed by the Gallas; and it is said to pay some acknowledgments to the emperor of Abyssinia, which are only voluntary. But little certain is known concerning it. It is inhabited by a mixture of Christians, Mahometans, and Pagans; and abounds in various fruits.

CAMBAY, a large and beautiful city of Hindoostan, situated near the head of the gulf of the same name, upon the north bank of the river Canari, called by some the Mytic. The city is twice as large as Surat, but not nearly so populous: it is defended by a strong wall, about five miles in circumference; the streets are large, and have gates at their entrances, which are shut in the night, and there are 12 gates to the city besides those of the streets: the houses are built of stone, brick, or marble; and here are three bazaars, or public markets, and four public cisterns, which are capable of supplying the whole town with water in times of the greatest drought. This city is the port of Ameabhad, from which it is distant about 56 road miles. Its trade is carried on by Moorish, Armenian, and Arabian merchants, with Perfa, Mochia, Diu, Acheen, Coromandel, and other places; and it was formerly very great in spice, ivory, silk, cotton cloths, and other commodities. But its commerce has declined, and is chiefly transferred to Surat, on account of the inconvenient nature of the harbour, which is obstructed with sand and mud, so that in the highest tides it has not more than seven fathoms of water, and the
CAMBAYES, in Commerce, cotton cloths made at Bengal, Madras, and some other places on the coast of Coromandel. They are proper for the trade of Marfélles, whether the English at Madras send great numbers of them. Many are also imported into Holland.

CAMBAZA, in Geography, a town of Japan, in the province of Ikko-go.

CAMBE, la, a town of France, in the department of Calvados, and district of Bayeux; four leagues W.N.W. of Bayeux.

CAMBEJIO, a town of the island of Ceram, and principal market for cloves.

CAMBER-beam, in Building, a piece of timber cut arched, or with an obtuse angle in the middle, commonly used in platforms; as church-leads, and on other occasions, where long and strong beams are required. A camber-beam is much stronger than another of the same size; since being laid with the hollow side downwards, as they usually are, it represents a kind of arch.

CAMBERED-deck, in Ship-building. See DECK.

CAMBERG, in Geography, a town of Germany, in the circle of the Lower Rhine, and Lower Electorate; 22 miles N. from Mentsz, and 30 E. from Coblenz. It is situated in a prefecture of the same name; and the circumjacent tract contains fine arable land, but principally yields a good culture of flax.

CAMBERN, a town of France, in the department of the Channel; one league N.E. from Constances.

CAMBERT, in Biography, a French opera composer, previous to Lulli, has no place assigned him here as a great musician; but on account of his being connected, in some small degree, with the history of the opera at Paris, his name will frequently occur to our readers in perusing accounts of the origin of the musical drama in France. Cambert was the first who attempted to set an opera in the French language upon the Italian model, previous to the licence which he had obtained, being transferred to Lulli, who began his operatic career by composing the music for the dances. It being generally known that our monarch, Charles II., was very fond of French music and the amusements of Louis the fourteen's court, Cambert, in losing his privilege, came to London, and was appointed master of King Charles the second's band. His opera of "Pomone," written by P. Perrin, seems to have been performed in 1672 at court, in its original language, as no record of it occurs in our dramatic writers; but, according to Giles Jacob, his "Ariadne, or the Marriage of Bacchus," translated into English, "was presented by the academy of Musick, at the theatre royal, in Covent-Garden, 1674, by the gentlemen of the Academy of Musick." We know of no theatre royal in Covent-Garden at this time, nor do we meet with any mention of an English academy of music at this period. It is said, in the "Histoire de la Musique," tom. i., that Cambert, who died in London in 1677, broke his heart on account of the bad success of his operas in England.

CAMBETUM, in Ancient Geography, a town of Spain, placed by Ptolemy in the territory of the Luctianae, in the Tarragonens.

CAMPING, Boorong Campung, or Booring-volcr, in Ornithology, the name by which Martial, in his history of Numidia, distinguishes the great crane, ardea dubia of Gmelin, a bird of vast size that inhabits also India and Africa. It is specifically known by being of a plussen colour above, beneath dully white, and having the tail somewhat triangular. This is the largest or argil of lives.

CAMMINS, in Biography, an Italian instrumental composer, possessed of genius and fire. He is said by M. la Borde to be chiefly known to Dillilant. We suppose the violin to be his instrument, of which he seems to know the finger-board well, and to write with fancy and facility.

CAMBIO, an Italian word which signifies exchange; commonly used in Provence, and in some other countries, particularly Holland.

CAMBIST, a name given in France to those who trade in notes and bills of exchange. The word cambist, though a term of antiquity, is even now a technical word, of some use among merchants, traders, and bankers. Some derive it from the Latin cambium, or rather cambio.

CAMPBIA, in Vegetable Anatomy, a name that has been very happily bestowed by Duchamel and other physiologists upon the substane which is produced for the growth or repair of the vegetable body. The chief part of the cambium in the dycotyledons, or those plants with two feminal leaves, is between the bark and the wood. In order to observe it, we should select, in the full season of vegetation, a branch of some tree, in which the bark is known to be safely separable from the wood, such as the oifer, when upon detaching a portion of the bark, its inner surface, and that of the wood corresponding to it, will be found covered with a quantity of fluid which pollutes more tenacity than the common lymph or sap, and resembles mucilage or fluid jelly.

The cambium is generally reputed to be either an extravasation from the surface of the wood, or that of the bark, but it is not determined from which of these parts it is derived, or whether they are not equally competent to produce it. Mircbel supposes that the cambium is furnished by the wood, and with apparent foundation, since in the morocotyledons it is deposited around the ligneous fibres.

Grew and Duchamel did not allow this substance to be an extraramated juice, but believed that it polluted organization and distinct parts, although they were so soft as to evade all means of detection. Without deciding upon this opinion, we must admit that the cambium is not a fluid fluid, but must have received some modification to fit it for the important changes it is designed to undergo. As the secon advantage, this substance (when situated under the bark,) acquires solidity and visible organization, and is ultimately converted into the new layers of wood and bark, which are annually deposited upon dycotyledons. See BARK, CORTICAL LAYERS, LIBER, and Wood.

The gradual disappearance of the pith in many trees depends upon the formation of the cambium, or organizing fulbance within the medullary canal. This produces an internal liber, which is by degrees transformed into wood, in the same manner as the external liber gives origin to the external woody layers, except that in the former, the increase is outward, while in the latter, it is towards the center. See PITH, and MEDULLARY CANAL.

As the mode of growth in plants with one feminal leaf differs so materially from that of the dycotyledons, the cambium in them likewise holds a different situation. Instead of being deposited near the surface of the plant, it surrounds the ligneous fibres which occupy the interior, where it is converted
Thefe small is irrefour, it calendar, couple notorious, fertile, but well chile p. tho fe 40'. fad, and voyage by June. mouth.seatuary, a that tute the neccessary agulable menced of sequence nization. See MOCO. Gloff. beuty thature. been reputed, to his his lacuna. See Grafting. See England, France, Holland, and Flanders, are the chief places of this manufacture. Bruffils exceeds them all in the beauty and quality of its camblets; those of England have been reputed the second.

Camblets, figured, are those of one colour, whereon are stamped various figures, flowers, foliage, &c. by means of hot iron, which are a kind of moulds, piled together with the fluff under a press. These are chiefly brought from Amiens and Flanders: the commerce of these was anciently much more considerable than at present.

Camblets, scotter, those which, after weaving, receive certain preparation with water; and are afterwards passed under a hot-press, which gives them a smoothness and luflre.

Camblets, scotred, are those whereon waves are impreffed, as on tabbies; by means of a calendar, under which they are paffed and repaffed several times.

The manufacturers, &c. of camblets, are to take care they do not acquire any falle or needle's phaits; it being almoft impossible to get them out again. This is notorious, even to a proverb: we lay, a person is like camblet, he has taken his plait.

Cambnites lapis, in Mineralogy, a name given by the
don't is the Camboise gum, which yields a fine yellow tin. Ivory also, and silk, are very plentiful, and of little value. The gold of this country is said to be very pure; and it furnishes amethysts, hyacinths, rubies, topazes, and other precious stones. Cattle, particularly of the cow-kind, are numerous and cheap. Elephants, lions, tigers, and almost all the animals of the deserts of Africa, are found in Cambodia. It has several precious woods, among which are the sandal and eucalypt-wood, and a particular tree, in the juice of which they dip their arrows; and it is said, that though a wound from one of the arrows provokes fatal, the juice itself may be drunk without danger. The country, though fertile, is very thinly peopled, insomuch, that the king is hardly able to assemble 50,000 men; and its trade is considerable. The inhabitants are Japanese, Chinese, and Malays, together with some Portuguese, who live without priests, and have intermarried with the natives. The men are generally well made, of a dark yellow complexion, with long black hair; their dress is a long and loose robe; but the dress of the women, who are handsome, but not very modell, is shorter and closer. Their religion is idolatry. They manufacture very fine cloth, and the needle-work of the females is much admired.

CAMBONA, a small island in the Indian Sea, near the south coast of the island of Celebes. S. lat. 5° 22'. E. long. 128° 45'.

CAMBONES, a town of France, in the department of the Tarn, 7 miles E. of Cartres.

CAMBONUM, in Ancient Geography, a place of Gaul, to the left of the Rhine, in the route which passes from Dea Vocontionum (Dio), and Lucas Auguli towards Vapincum (Gap), in going by Mons Selecus.

CAMBORI, in Geography, a town of Asia, in the kingdom of Siam, on the frontiers of Pegu, seated on a small river which runs into the gulf of Siam.

CABORICUM, or CAMBORIUM, in Ancient Geography, a Briton station in the fifth route of Antonine's itinerary from London to Lugoalum in Carlisle, between Icianos and Duroliponte. All our antiquaries, except Mr. Horsey, fix Camboricum near Cambridge, at a place called by Bede, Gratianfeld, and derive its name from Cam, crooked, and Brit, a ford. Those antiquaries who place Camboricum at Cambridge, fix Duroliponte at Godmanchester.

CAMBRA, in Geography, a small town of Portugal, in Beira.

CAMBRASINES, in Commerce, fine linen made in Egypt, of which there is a considerable trade at Cairo, Alexandria, and Rosetta or Raphic. They are called cambra-fines, from their resemblance to cambrics.

CAMBRAY, in Geography, anciently Cambreacum, a city of France, and principal place of a district, in the department of the North, seated on the Scheldt, which divides it into the easter and wester parts, and fills its ditches with water. Before the revolution, it was the capital of Cambrésis, in the Low Countries, and the see of an archbishop, established in 579. The archbishop dyed himself prince of the Holy Roman Empire, and Count of Cambrésis, and he was also lord of the city. It is well fortifed, being defended by a strong citadel on the Scheldt, and a fort; and as the land is low on that side of the river, the adjacent parts may be laid under water by means of sluices. This city is large and tolerably handsome; its streets are spacious; the place or square for arms is so extensive as to be capable of receiving the whole garrison in order of battle. It has two collegiate churches, exclusive of the cathedral, which is dedicated to the virgin Mary, and one of the finest in Europe. The people is high, and from the top of it commands a view of the whole city. It contains ten parish churches, three abbeys, two convents, two hospitals, and several religious houses. Its principal manufactures are lace, soap, and leather; and particularly the fine linen, hence called cambre. The eastern division contains 66,000, and the western 74,000 inhabitants; the former contains 14,351, and the latter 14,443 inhabitants; the whole territory comprehends 1445 square miles, and 31 communes. Cambra is an ancient city, and was formerly imperial. It has been, on a variety of occasions, the subject of contests between the emperors, the kings of France, and the emirs of Flinders. In 1514 it was taken by the emperor Charles V. It was afterwards given to John of Montoube, by Henry III. of France, but besieged by the Spaniards in 1569, when the inhabitants compelled the governor to surrender. Ever since it continued under the dominion of the house of Austria till 1777, when it came into the possession of France. In August 1713, this city was invested and summoned to surrender by the Austrian general De Boves; the French general Derby returned for answer, that he did not understand surrendering, but he knew how to fight. In April, 1704, the French were defeated at Cefar's camp, in the neighbourhood, by the allied army under the command of the duke of York, with the loss of 1200 men, and three pieces of cannon; and the next day they left 1200 men dead on the field of battle, with the loss of their generals, Chapuy, 350 officers and privates taken prisoners, and 22 pieces of cannon. N. lat. 50° 10' 32'. E. long. 3° 13' 41'.

The league of Cambrai, in 1568, was the most singular event that occurs in the history of Europe. It was a confederacy, instigated by pope Julius II. and which gained the concurrence of the emperor Maximilian I., of Louis XII. of France, by the suggestion of cardinal d'Amboise, and of Ferdinando king of Spain, for the final overthrow of the republic of Venice. This league originated in resentment, and was diametrically opposite to the true interest of every one of the contracting powers. The republic of Venice had before this time acquired great power; but whatever were the means by which it had become thus powerful, it was now the bulwark of Italy; it prevented the pope from drawing the emperor or the king of the Romans, as he was then called, into Lombardy, against the French; it moderated the views of king Louis, and hindered him from extending his conquests; it kept the pope from being reduced to a state of dependency; and it preferred to Ferdinand the catholic the kingdom of Naples. Although it might have been the interest of each of these potentates, separately, to recover, if possible, what had been taken from them by the republic; yet, to oblige her to refund all her conquests was to reduce a power of which they were all afraid, and thus to open a source of perpetual wars among themselves. However, the league was formed; consisting of a variety of articles, advantageous to the several contracting parties, and threatening destruction to Venice. The execution of it was attended with all the successes that could be expected; for the emperor and the king of France wrested from the Venetians almost all the cities which they possessed in Lombardy; nor was the pope remiss in seizing all that lay convenient for his purpose. The Venetians, indeed, thought themselves so little able to withstand this powerful and formidable alliance, that they abandoned all the territories on the continent, after having loft the famous battle of Chiara d'Adda, in which their whole infantry was cut to pieces. However, after many humiliations and disfaters, they preferred their capital; and having either brought over, or bought over, the
pope, the rest of the confederacy was disjointed. The mea-
sures of the French and Germans, who were bent upon her
total ruin, were traversed by the king of Aragon and the
pope, who by no means concur in the utter destruction
of the only power which had hitherto hindered these
nations from subduing all Italy. The republic soon re-
covered a great part of her former territories; though she
was obliged to surrender to the pope Ravenna; to Spain,
the five towns which she had till this time possessed in Cala-
bria; and to the emperor, Triece and Triun.
CABREMER, a town of France, in the department of the
Calvados, and chief place of a canton, in the district of
Pont-l'Eveque; 5 leagues E. of Caen. The place con-
tains 1260, and the canton 10,118 inhabitants; the terri-
tory includes 105 kilometres, and 36 communes.
CAMBRÉSIS, GIRALDUS, in Biography, arch dea-
con, and afterwards, bishop of St. David's, was born about
the middle of the 12th century, and died after the year
1210. See GIRALDUS.

The account which this ancient prelate has given, in his
description of Wales, concerning the marvellous power which
the Cambro-Britons and the Northumbrians had, of finging
in parts spontaneously, at a time when counterpoint was un-
known in the rest of the world, not only merits notice here,
but some discussion. See CAMBRO-BRITISH AND NA-
TIONAL MUSIC. Many ecclesiastical historians tell us that the organ
was first admitted into the church at Rome by pope Vitalian,
666, the fame pontiff who two years after lent fingers into
Kent, to finish the work which Aulfin, the first Roman mi-
fionary, had begun. In 680, according to Bede, John,
the predecessor of St. Peter's in Rome, was lent over by pope
Agatho to instruct the monks of Wormer in the manner
of performing the ritual, who opened schools for teaching
music in other places of the kingdom of Northumberland.
This may reconcile to probability some part of the following
account, which Giraldus Cambrensis gives of the peculiar
manner of singing that was practised by the Welsh, and the
inhabitants of the north of England, about the end of the
twelfth century.

"The Britons," says he, "do not sing in unison, like
the inhabitants of other countries; but in many different
parts. So that when a company of singers among the com-
mon people meet to sing, as is usual in this country, as many
different parts are heard as there are performers, who all at
length unite in concourse, with organic sweetness. 4 In
unum denique fab B mollis dulcedine blandâ concomitant
organicae consonantia melodiam. 5 In the northern parts of
Great Britain, beyond the Humber, on the borders of York-
shire, the inhabitants use the same kind of symphonious har-
mony; except that they only sing in two parts, the one
murmuring in the base, and the other warbling in the acute
or treble. Nor do these two nations practise this kind of
singing so much by art as habit, which has rendered it so
natural to them, that neither in Wales, where they sing in
many parts, nor in the north of England, where they sing
in two parts, is a simple melody ever well sung. And, what
is still more wonderful, their children, as soon as they at-
tempt using their voices, sing in the same manner. But as
not all the English sing in this manner, but those only of
the north, I believe they had this art at first, like their
language, from the Danes and Norwegians, who used fre-
quently to invade and to occupy, for a long time together,
those parts of the island."

This extraordinary passage requires a comment. And
first, it may be necessary, before we reason upon the cir-
cumstances it contains, to be certain of their authenticity.
Giraldus Cambrensis is indeed an author who has been often
supposed inaccurate and fabulous. "Girald Cambrensis
deserves no manner of regard or credit to be given him; and
his Chronicle is the most partial representation of the Irish
history that ever was imposed on any nation in the world.
He has endeavoured to make the venerable antiquities of the
island a mere fable; and given occasion to the historians
that come after him, to abuse the world with the same fictitious
relations." Keating, part i. p. 13. Dr. Nichollon, Bishop of
Derry's, Irish Historical Library, 1st ed. Dublin, 1724.
The glaring improbabilities in the above account, with the
manifest ignorance of the subject in question, by no means
contribute to augment his credibility. For whoever is ac-
quainted with the laws of counterpoint, or with the first dif-
ficulties attending the practice of singing in parts, can have
no exalted idea of the harmony of an untaught crowd, tura
canzontes, or suppose it to be much better than the dissonant
noises of a good-humoured mob; in which the parts would be
as various as the pitch of voices of which their chorus
was composed. But how all these united at last in the con-
sonance of organic melody, and the soft sweetness of B mollis,
will long remain an impenetrable secret. If by organica
he meant organized, or harmonized, melodies, we
may suppose that the Cambro-Britons, in the time of Giral-
dus Cambrensis, had acquired some knowledge in diaphonic,
or consonant; which according to John of Salisbury, an elder
writer, was practised to great extent in the 12th century.
With respect to what he affords of the people in Northum-
berland finging in two parts, it is more reconcileable to pro-
bability, from the circumstances just mentioned, of the cul-
tivation of music in that part of the world under Roman
matters, who may probably have first brought over the art
of consonant, or double singning, which the newly invented
organ had fuggetted, by the facility it afforded of sounding
two or more notes at a time; which art, when practised by
voices, was thence called organum, organizzare. But as to
what Giraldus says of children naturally singng in this man-
ner as soon as they were out of the cradle, the reader will
afford it what degree of weight he pleaseth; for our own
part, we must own that it is not yet admitted into our
musical creed.

CAMBRESIS, in Geography, a province of France in the
Low Countries, before the revolution, bounded on the north
and east by Hainaut, on the south by Picardy, and on the
west by Artois. The length is about 10 French leagues, and
its breadth from 5 to 6, and in some parts from 2 to 3. It
is fruitful and populous, and watered by the Scheldt, Seille,
and Sambre. The principal towns are Cambrai, the capi-
tal, Chateau-Cambrai, Creveceur, Valenctin, and Van-
celles. Its inhabitants are laborious and lively, and addit-
ioned to the arts. Its commerce conflits chiefly in grain, sheep,
wool, and linen. Its pastures are excellent, particularly
for horses and sheep.

CAMBRETUM, in Ancient Geography, a British
station in the 9th route of Antonine's Itinerary, 15 miles
from Anfa or Witham in Essex. Mr. Camden and Dr.
Gale fix this station at Bretunham, on the river Bre-
ton; but Mr. Horsey thinks that the distance suits bet-
ter with Stratford, near the confuence of the Breton and
the Stowr.

CAMBRIA, a name given to the province of Wales be-
fore the time of Caesar's invasion, and retained by it till
about the clofe of the 6th century, when it took the ap-
pellation of Wales; and when the inhabitants, likewise, with
their ancient situation, lost the title of Britons, and became
distinguished by the name of Welsh. See WALES.

CAMBRIC, in Commerce, a species of linen made of flax,
very fine and white; the name of which was originally de-
vised
The manufacture of cambrian lawns has long since proved of extraordinarv advantage to France. For many years it appeared that England did not in this article contribute less than 200,000l. per annum to the interest of France. This proved motive sufficient to induce the parliament of Great Britain to enact many salutary laws to prevent this great loss of our wealth. See 18 Geo. II. c. 36. and 21 Geo. II. c. 36. See also Stat. 32 Geo. II. c. 32. and 4 Geo. III. c. 37. which regulates the cambrian manufacture, not long since introduced into Winchelsea in Sussex; but so soon abolished. The cambrians now allowed in this country are chiefly manufactured in Scotland and Ireland. Any person convicted of wearing, selling (except for exportation), or making up for hire any cambrian or French lawns, are liable to a penalty of 5l. by the two first flat rates cited above. The above cited statute, 4 Geo. III. c. 37. establishes the corporation of the English linen company for making cambrians and lawns, and enacts, that, whenever there shall be a manufactury of this kind, the commissioners of excise shall appoint the supervisor, or other officer, to seal the same; for which purpose notice shall be given by the manufacturer, before the piece is taken out of the loom, under penalty of 5l. and forfeiture of every such piece. This piece shall be marked and numbered, on pain of 10l.; and an officer marking any piece not made in England, or after it is taken out of the loom, shall forfeit 5l. and his office. Attempt to bribe an officer incurs a penalty of 50l., and the officer accepting it forfeits 100l. and incurs the punishment of the pillory. Cambrians and lawns, made in England, and found unlabeled, shall be forfeited, seized, and sold; and any person expelling such to faile, or having them in his custody for that purpose, shall forfeit 200l.; which goods shall be exported, and not relanded. To counterfeit the seal, or import any foreign cambrians or lawns with a counterfeit mark, or expose the same to sale, knowing the same to be counterfeited, is felony without benefit of clergy.

CAMBRIDGE, in Geography, is a large, and the principal town in a county of the same name in England. It is particularly noted in the annals of literature and science, for its university, which has been honoured with the residence of many persons of eminent and highly illustrious character, and provided for them the means of instruction. Concerning the priority of origin, and establishment, of this, and the charter university at Oxford, there has been much controversy with partial antiquaries. The original foundation of this town and university is involved in fabulous obscurity; and the stories that have been propagated by some of the monkish writers confute themselves by their own absurdity. Without repeating any of these fables, or tracing up the annals of Cambridge anterior to the Roman colonization of Britain, we will endeavour to elucidate this history briefly from that period. "The site of the Roman Granit" observes Dr. Stukeley, "is very traceable on the side of Cambridge towards the castle, on the north-west side of the river, of an irregular figure containing 30 acres, surrounded by a deep ditch, great part of which remains on the south-west, and in the grounds behind Magdalen college." Roman bricks, coins, urns, and paterns have been found near this spot, and in the vicinity. The villages of Chesterton and Grantchester, in the neighbourhood of Cambridge, have been considered by some antiquaries as occupying the sites of Roman flations or camps; and as preserving evidences of that in their present appellations. Other memorials of the Roman have been found in the military ways, or roads which diverged from the flation of Granit.

During the Anglo-Saxon dynasties, the town of Cambridge receiv'd but few grants, and those are merely of battle, figure, and other similar charters. The university, or rather a kind of academic institution, appears to have been first founded early in the tenth century, by Edw. earl of Cornwall, called Eadric. How long this institutio was not informed; but as Alfred complained that he could not find teachers when he had youth and home to be instructed, we may fairly presume that there were no public academies at that time. The model of emulous, or probably of founding the real university belonged to Edward the Elder, son of Alfred the Great, who appears in the chronicle of Hydendlake, to have erected "halls for the students, and chairs and books for the doctors, at his own charge." He also appointed professors, and adopted other necessary manners which seemed to secure the stability of the institution. In the year 1060 the town was fired, and plundered by the marauding Danes, who committed repeated depredations in this part of the island. At the time of the domeday survey, in the reign of William the Conqueror, it contained 373 homesteads, 27 of which were shortly afterwards removed to make room for the are erected by the Conqueror; or rather, as Fuller observes, "re-edified." In this fortress he soon afterwards received the submission of the monks of Ely, whose resistance to his power appears to have been the principal inducement for erecting it. In the reign of William Rufus, the town and county of Cambridge were ravaged with fire and sword by Roger de Montgomery, in revenge for an affront given him by the king. The university was therefore for some time abandoned, but Henry I. induced the wandering students to return, by investing the town with many valuable privileges. He exempted it from the power of the Sheriff in the year 1101, and made it a corporation on payment to the exchequer of 100 marks annually. Josfrid, abbot of Croyland, sent four monks to Cottenham near Cambridge, from which place they daily repaired, according to Peter Blefens, to the university town, "and having hired a public barn, made open profission of their sciences, and soon collected a great number of scholars." These continued to increase, and the place progressively acquired celebrity till 1174, when nearly the whole of the town was consumed by a fire "to mercifly," says Fuller, "that it only flapt for want of fuel to feed its fury." Most of the churches, as well as the houses, appear to have been constructed with wood at this period. Tournaments were frequently held at Cambridge in the 15th century, and the concourse of people was so great, that the students were much inconvenienced both in board and lodging. To remove this impediment to learning, Henry the Third forbade any tournament to be kept within five miles of the town. In examining the local annals of Cambridge, we find that frequent disputes and altercation, often ending in battles, arose between the townsmen, and those persons connected with the university. In 1291, a particular instance of this kind occurred. The townsmen assembled at their hall, and having chosen John Grantceter, for their leader, compelled him to swear that he would execute whatever the bailiff and burgesses should command. Proceeding to Corpus Christi college, they broke open the doors, and carried away all the charters, and other documents; they next went to the house of the chancellor, whom they compelled, as well as all other persons of the university, to renounce the privileges that had ever been granted to them, and also deliver up all the letters-patent then in their possession. After this
they broke open the university chest, which was kept in St. Mary's church, and taking out all the records, burnt them in the market-place, together with the papers they had previously collected. Numerous other acts of violence were committed. At length Henry Spencer, bishop of Norwich, coming here with some soldiers, suppressed these daring tumults, and punished the principal leaders: the mayor was deprived of his office, and the liberties of the town were declared forfeited, and bestowed on the vice-chancellor, in whom they remained till the reign of Henry the Eighth, when the corporation was restored, but several of its former privileges were retained by the university.

An insurrection breaking out in the eastern counties in the time of Richard the Second, he summoned a parliament here in 1381. In this assembly a statute was made againstandersers, or students of either university, who traversed the country legging alms without licence, which at that time was a common practice. On the 24th of May 1534, the university renounced the supremacy of the Pope, and the next year surrendered all its charters, flutes, and papistical muniments into the hands of Lord Cromwell. These records were, however, soon afterwards restored, and the university reinstated in the full exercise of its privileges. From the death of Henry the Eighth, till the accession of Elizabeth, the university and town were in continued commotion, and various acts of hostility were committed by the opposite parties. The latter monarch, however, restored peace to the university, where he resided five days in the early part of her reign. Here she was entertained with various dramatic exhibitions, besides orations, disputations, and other academical exercises. On leaving the town, the queen in an elegant Latin speech recommended the members of the university to make the return of its students public.

In 1630, Cambridge was visited by a dreadful plague, which occasioned the burthen of the university to be suspended, and all the students had leave to retire to their respective homes. Between three and four hundred persons fell victims to this direful malady. The affises were at this time removed to Rouillon. During the unhappy warfare between Charles I. and his parliament, the persons of the university very early declared themselves in favour of the king, and as a pledge of loyalty, sent their plate to be converted into money for his use, a few days before the elevation of his standard at Nottingham. This measure provoked the Cromwellian parliament, whose forces laid the town under repeated contribution, and the officers and students of the university were compelled to seek safety in flight. Soon after the restoration, tranquillity was again restored; and since that period, various useful and important plans to promote the prosperity of the town, and the advantages of learning, have been progressively established. The college and fortifications have gradually crumbled in the course of time, and the university has continued to increase its literary reputation from that epoch.

The extent of Cambridge occupies a space of ground which measures about one mile from north to south, and half a mile from east to west. The streets are in general narrow and winding, and the houses ill-built, and too much crowded together. The town was first paved in the reign of Henry VIII. who, in his 36th year, caused it to be enacted by Parliament, that all persons who had any houses, lands, &c. in Cambridge, bordering on the highways, should pave them to the middle of the said ways, "in length as their grounds do extend," and also keep them in repair, under the penalty of fivepence for every square yard. In 1787, an act was passed "for the better paving, cleaning, and lighting the town, and widening the streets, lanes, and other passages." Many improvements in each of these respects have since been effected. The population compared with the limited extent of the town is very great; for besides the persons residing in the colleges, the number of inhabitants returned under the late act was 9,773; of houses 17,332. The trade carried on at Cambridge is not inconsiderable; besides that which is either immediately or remotely connected with the university. The corporation consists of a mayor, high steward, recorder, twelve aldermen, twenty-four common councilmen, four bailiffs, a town clerk, and other officers. The mayor, on the day of his election, has the privilege of belowing the freedom on any one person he may think proper. The choice of representatives in Parliament is vested in the mayor, bailiffs and freemen not receiving alms; the voters are about 200.

The College of Cambridge, of which there are scarcely any remains, was raised soon after the conquest; for 27 houses are said in the Conqueror's survey to have been levelled for the purpose of erecting it. On the site of this ancient fortress, a new, large county gaol was lately built, upon a novel plan. Near this is a large conical mount, the keep of the ancient Norman castle. This occupies the highest ground in the town, and its summit commands a very extensive tract of flat country. In the market-place is a conduit, which was erected, and the water brought to the town by Thomas Hobson the celebrated carrier, in 1614. Near it are the 'fire hall,' and the town hall, two large buildings.

Public Buildings. Cambridge contains 14 parishes, 13 of which are provided with their respective churches. Two only of these are, however, entitled to public notice, the others being mostly small, inconspicuous, and very insignificant buildings. Among the most ancient structures in the town, and certainly the most curious specimen of architectural antiquity it possesses, is the Round Church, or church of the Holy Sepulchre. This is one of the very few imitations which now remain in England, of the church of the Holy Sepulchre at Jerusalem. The original building was perfectly circular, having its roof supported by eight large columns, between which and the outward wall, is a circular aisle. The entrance door-way has a semi-circular arch of three different mouldings, which spring from capitals and columns of that style of architecture usually called Saxon. Indeed the whole structure was originally of this style, but has been altered at later periods; and at the time of such alterations, the architects appear to have adopted the then prevailing mode of building. Mr. Effles (in vol. vi. of the Archæologia) affirms that it was built by the knights templars, or by some persons concerned in the croisades, in the reign of Henry the First, or between the time of the first and second crusade. It is certainly the oldest church of the kind in England, though the temple church in London, and the round church in Northampton, are constructed nearly in their respective ground plans; though their arches, columns, and ornaments, are very different.

The university church, called Great St. Mary's, though a large spacious building, is not remarkable either for its beauty, or uniformity of architecture. It was built by contribution, and though begun in the year 1478, it was not completely finished till 1628. In the years 1783 and 1784 about 1,500l. were expended in "repairing and beautifying this church;" but the alterations not being directed by taste, have neither beauty nor dignity to recommend them to our approbation. The other churches of Cambridge are mostly built with brick walls, which are plastered and whitewashed.
The most conspicuous and most celebrated building of the university is King's College chapel, which, for elegance and beauty of parts, for grandeur of effect, and scientific construction, is justly admired by all artists, connoisseurs, and architects. The design of this structure is at once bold, chaste, and profound: and its exterior and interior effects are grand and imposing. It consists of only one space or cell, which measures 28 feet in length, by 44 feet in width and 93 feet in height. This spacious apartment is surmounted with various attractive beauties: and the sculptor, painter, glazier, and architect, seem to emulate each other in exciting admiration. The whole interior superfluities is covered with numerous sculptured ornaments, among which the arms and cognizances of the houses of York and Lancaster are most prevalent. The rafter, portcullis, fleur de lis, with shields of arms are buck all over the walls. These are carved in high relief, and are executed with great skill and taste. Some of the supports display the hand of a first-rate flautist, and though cut in stone, are equal in contour, expression, and character, to almost any marble sculpture. A wooden screen separates the ante-chapel from the choir. The latter has two rows of stalls of carved wood on each side, and on the pannels at the back part of the upper rows, are carved the arms of all the English kings from Henry the Fifth to James the First. The whole chapel is lighted by 26 large windows, besides some smaller ones, which communicate to different lateral chapels, or chantries. These occupy the spaces between the buttresses, and are now appropriated to libraries, and to other purposes. All the upper windows, except that at the west end, are filled with painted glass, which, for the style of drawing, colouring, composition, expression, &c. manifest great talents in the artists who executed it. The groining and construction of the roof of this fabric are regarded with admiration and astonishment. In forming the arch, and disposing the materials, the architect has displayed such a profound knowledge of geometrical principles, as to confound almost every other artist who has since examined his workmanship. It is traditionally reported that Sir Christopher Wren annually visited this pile, to view the roof; and the same tradition has given currency to an absurd remark, which that great architect is said to have made. This roof was executed by John Wafall, and Herry Semerick, who by an indeniture still extant agree "to make, and let up at, their own costs and charges, a good, sure, and sufficient vault, for the grete church there, to be workmanly wrought, made and let up after the best handling and form of good workmanship according to a plan thereof made and signed with the hands of the lords executors to the kyng of most famous memory Henry the VII, &c." They also agree to provide stone, and every other requisite for the said work, to finish it in three years, and to receive 1200l. for their whole labour and materials.

This magnificent fabric was begun by king Henry VI. who left particular directions in his will, and bequeathed ample endowments for the completion of the chapel and the whole college buildings, &c. But the former was not completed till the reign of Henry VIII., and the latter have never been finished. It appears that only a part of the walls at the east end of the chapel and to a certain height on the north and south sides, were raised during the lifetime of the founder. The building was a little advanced by Richard III.; and Henry VII. made much greater progress in the work. It advanced with rapidity during the reign of Henry VIII., and the choir or shell of the building was finished in 1515. For further particulars relating to the history and character of the structure, see Mallet's Account of King's College Chapel, 8vo.

Near the north side of this chapel is the Senate House, which was built by Gibbs the architect from a design by Sir James Borlase, who was master of Cain College. It was begun in the year 1724, and cost nearly 30,000l. in completing: about 1,200l. of which were contributed by individuals. It is built entirely of Portland stone, and adorned with pilasters, friezes, balustrades, &c. in the Corinthian style of architecture. In the middle, both of the south and east fronts, is a grand triangular pediment, supported by four fluted columns of the same order. The interior is occupied by one large room, where all the public business of the university is transacted. It measures 35 feet long by 42 feet broad, and 32 feet high. Near this building is the Public Library, which consists of four rooms on the upper floor; the ground floor, consisting of three sides of a square, being occupied by the Schools. The library contains many curious, valuable, and interesting objects; among which is an antique statue of Cereus brought from the temple at Ephesus, the Cippus from the tomb of Eulcid, the Ithaca MS.; and numerous other rarities.

Most of the other public buildings being connected with the colleges and halls, we shall notice the most interest under their respective establishments, and shall arrange these in the chronological order of their foundations. Previous to the erection of colleges, the students resided in hostels, or inns, which were provided by the townsmen for their reception. All the charges of education and maintenance were paid by themselves; though the eulogistic degrees and government were, according to the report given of the ancient foundations, nearly the same as at present. In the time of Richard II. the number of hostels at Cambridge amounted to 16. The extraneous terms of landlords' charges probably gave rise to the colleges; as it is recorded that they were very extortionate in their demands.

Colleges, &c.—The university buildings consist of twelve colleges and four halls, which last possess the same privileges as the former. Each of these contains apartments for the students and fellows, a master's lodge, a chapel, a library, a hall, and a combination room. In the following table is recorded, in chronological order, the name and the time of founding of each of these institutions.

In addition to these, a new college, upon a large and grand scale, is proposed and intended to be erected in pursuance of the will of Sir George Downing. This gentle
man, in the year 1717, devised various estates, &c. in failure of certain issue, for this purpose. The validity of the will was disputed by some of his relatives, but after many years' litigation it was finally settled in 1800, and the matter, professors, and three of the fellows are already appointed: thirteen other fellows are to be chosen when the college is built. We shall proceed to notice a few particulars relating to each of the above-named foundations.

St. Peter's College, usually called Peter-House, originally consisted of two lodges, which were purchased by Hugh de Baldham, sub-prior of Ely, who appropriated them, in 1257, to the use of students. In 1284, he completely endowed his foundation for the support of a master, 14 fellows, 29 bursars, and 8 poor scholars; the number to be increased or diminished according to the fluctuation of the revenues. Numerous benefactions have since been given to this foundation, and the fellowships are accordingly increased. The college was erected by subscription in the year 1632, and is neatly embellished, but was deprived of many of its ornaments by the fanatics in the civil wars. The building surrounds two courts, which are separated by a cloister and gallery, and the largest has had its buildings fixed with stone within a few years.

Clare Hall was built on the site of the University Hall, which was a small college, founded in the year 1326 by Dr. Richard Baden, then chancellor of the university. About 16 years after its erection, it was consumed by fire, but rebuilt on a much more extensive scale in 1344, by Elizabeth de Burg, heiress to the last earl of Clare. By this lady it obtained its present name, with endowment for a master, 10 fellows, and the same number of scholars. Richard III., Thomas Cecil, earl of Exeter, John Freeman, esq., William Butler, esq., and Samuel Blyth, esq., all contributed in augmenting the revenues, which now maintain 17 fellows, and between 30 and 40 scholars. This is the most uniform in its buildings, and is the most pleasantly situated of any college in the university. It was rebuilt of stone in 1638, except its chapel, which was erected in 1705, from a design by sir James Burroughs. This college stands near the north-west angle of King's College chapel.

Pembroke Hall was founded by Mary, countess of Pembroke, in 1332, and endowed in pursuance of a charter from Edward III. for a master and fix fellows. Among the benefactors who have enlarged this establishment, Henry VI. is the most considerable; who augmented it with the rich living of Soham in this county, and with some other rectories. In his charter it is termed "the most noble, renowned, precious college, which, among all others in the university, was ever wonderfully replenished." The present number of fellowships is 16, and the scholars about 70. The chapel was built from a design of sir Christopher Wren, by his uncle, bishop Wren. Contained in a small detached building of this college is a large and curious astronomical machine, or sphere, which was given and partly made by Dr. Roger Long, author of a celebrated treatise on astronomy; in which work it is particularly described; and the Dr. at his death bequeathed the interest of 200/. for bank annuities to keep "the instrument and place" in good repair. This, like many other useful bequests, is perverted to private emolument, and the object consequently neglected. This college consists of two courts, which are separated by the hall, having the combination room at one end.

Corpus Christi, or Bene't College, differs in its origin from all others, in either of the universities; those having been founded by the benevolence of one or two persons, while this was established by the union of two guilds, or religious

C A M B R I D G E.

societies. The college was begun in 1534, and its buildings were rapidly advanced by the influence of Henry Plantagenet, duke of Lancaster, whom the brethren had chosen as their first warden. By the munificence of sir John Cambridge and his son, the revenues were considerably augmented and finally appropriated, in the year 1576, to the maintenance of a master, eight fellows, three bursars, and five scholars. Since that period, the endowments have increased sufficiently to support twelve fellowships, and nearly sixty scholarships. The name of Bene't, or Benedict college, arose from its proximity to the church dedicated to that saint. Matthew Parker, archbishop of Canterbury, was the greatest benefactor to this college, having founded two fellowships and five scholarships, and bestowed on it the valuable library of Stoke-clere college, Suffolk, besides many other printed books and manuscripts. This college consists principally of buildings round a square court.

Gonville and Caius College, commonly called Keys College, was originally founded in the year 1348, by Edmund Gonville, who left a large sum of money with Dr. Bateman to finish and endow it. The doctor being then employed on his own college (Trinity) did not immediately proceed with this building, but afterwards had it erected near his own foundation. Thus the present building is posterior to that of Trinity, but its foundation and endowment being anterior, it certainly claims precedence in chronological arrangement. After its completion, it was called Gonville Hall; but in 1557 it obtained the present title, and was considerably increased in revenues and buildings. This was effected by Dr. John Caius, physician to queen Mary, who built a new court, and three remarkable gates of various and eccentric architecture. That on the south, communicating with the schools, is said to be the first specimen of regular or Roman architecture erected in this country. The gates are respectively inscribed, "Humilitatis," the gate of Humility; "Virtutis," the gate of Virtue; "Io. Caius Pohnt Sapienian," John Caius built this in honour of Wisdom; "Honoris," the gate of Honor. Since the decease of Dr. Caius, the fellowships have increased to 29, and the scholarships to nearly 100. The principal court of this college has been partly rebuilt, and is cased with stone.

Trinity Hall was one of those original colleges wherein the students resided at their own expense. It was purchased by Richard Crowder, prior of Ely, in the reign of Edward IV.; and was converted into a college, in 1351, by Henry Bateman, bishop of Norwich. The founder provided for a master, three fellows, and two scholars; but various subsequent benefactions have increased the fellowships to twelve, and the scholarships to fourteen. The whole of this hall is faced with stone, and the buildings have a neat and uniform appearance.

King's College, the glory and pride of the university, owes its origin and foundation to King Henry VI. who, in 1441, dedicated it, and in 1442 fully endowed it for a provost, 70 fellows, or scholars, 3 chaplains, 6 clerks, 16 choristers, and a master, 16 officers of the foundation, 12 fellows for the senior fellows, and 6 poor scholars. The monach, dying before the establishment was completed, left particular directions and bequests in his will for the fulfilment of his magnificent and pious designs. These, however, were never completed, and only a small part of the intended buildings have been erected. Some peculiar privileges appertain to this college. (See Rawthorpe's University Calendar, 1801.) Edward IV. instead of forwarding the plans of his predecessor, deprived this college of many large estates, which, with aggravating injustice, he gave to some of the
Trinity College contains the largest buildings, and possesses the most considerable endowments of any collegiate establishment in this university. Its buildings form two very large quadrangular courts, and its entrance, gateway, chapel, and library are fine and interesting objects of architecture. This college was founded by Henry VIII. in 1536, on the site of two other colleges and a hospital, and endowed for a master, fifty fellows, sixty-seven scholars, four conductors, three public professors, thirteen poor scholars, twenty benefactors, and other officers with servants: the number on the establishment, at present, amounts to upwards of four hundred. The inner court is called Neville's court, from the name of Dr. Thomas Neville, at whose expense it was chiefly built, in the year 1559. Its western side is formed by the library, which is a magnificent and spacious building, 200 feet in length, by 40 in breadth, and 58 in height. Beneath the library is a spacious pizza, which opens to the river and the gardens. In the chapel is a fine statue of Sir Isaac Newton, executed by Roubiliac. This figure is considered one of the finest specimens of English statuary.

Emanuel College was founded by Sir Walter Mildmay, on the site of a Dominican convent, in 1584, and endowed for a master, three fellows, and four scholars. By additional donations the revenues now support fifteen fellows, and nearly one hundred scholars and exhibitioners. The hall is said to be the most elegant of any in the University.

Sidney Sussex College derives its foundation from Frances Sidney, countess of Sussex, who, by will, dated December 6th, 1538, bequeathed 5000l. and some other property to found a college for a master, ten fellows, and twenty scholars. The first stone of this college was laid on the 26th of May 1556, and the building completed in little more than three years. The chapel and the library were rebuilt about twenty years since, and various other alterations made at the same time. The foundation provides for seven fellows, ten by-fellows, twenty scholars, and twenty-four by-scholars, besides a mathematical lecturer, and several exhibitioners.

In each, and all of these colleges, are various portraits of founders, and eminent persons who have received education, or been immediately connected with the respective foundations. Each, also, contains a library, and in some are various useful, curious, and valuable natural and artificial objects. Numerous manuscripts, mss., &c. contribute to enrich, and dignify many of these libraries; but to particularize the whole, or even barely to mention the most considerable, or important, would compel us to extend this article beyond the bounds of propriety and consistency. At the end we shall refer to such works as contain more detailed information on these subjects.

The colleges of this University are accommodated with spacious and pleasant gardens, having convenient walks, which are shaded and enriched with rows of noble trees. Most of them are situated on the banks of the river Cam, at the western extremity of the town. It is jutly remarked by strangers who visit Cambridge, that its colleges and public buildings are, in general, neither grand, elegant, nor in a good style of architecture; and that a national University should display and encourage the polite arts of the country. In the college now preparing to be built, it is hoped that the directors or Committee will select such designs as shall at once be a monument of their taste, an honour to the University, and creditable to English talent.

The University is composed of a chancellor, vice-chancellor, the masters or heads, fellows of colleges, and students, amounting in all to more than 2000 members; and is incorporated...
incorporated as a society for the study of all the liberal arts and sciences. Each college, or hall, is a body of itself, and bound by its own statutes; but is likewise controlled by the paramount law of the University, each furnishing members for the government of the whole, which government is administered by the following officers:

1. A Chancellor, who is some nobleman, and may be changed every two years, or continued longer by the tacit consent of the University.— 2. A High Steward, chosen by the senate, and holding his office by patent from the University; he is allowed a deputy.— 3. A Vice-chancellor, who is usually the head of some college or hall, and chosen yearly on the 4th of November, out of two persons nominated by the heads.— 4. Two Proctors, chosen annually on the 10th of October, who must be masters of arts; they attend to the discipline and behaviour of all under-masters of arts; read the grades, and take the votes in the White-hood house.— 5. Two Tutors, chosen as the proctors, and who with them are clerks of the markets, and have cognizance of weights and measures; they were originally intended to tax, or fix the rent of the houses let to the scholars for their residence.— 6. Two Moderators, who superintend the exercises and disputations in philosophy, and the examinations previous to the degree of bachelor of arts.— 7. Two Scrutators, whose office is to read the grades, and take votes of the Black-hood house, to which they always belong.— 8. A Commissary, who is usually appointed an ailiant or alliell, and deputy high-dean to the vice-chancellor in his court, (much the same as a recorder is to a mayor, or a chancellor to a bishop).— 9. A Public Orator, who is the mouth of the University on public occasions, writes their letters, presents noblemen to their degrees with a speech, &c.— 10. The Caput confits of the vice-chancellor, a doctor of divinity, a doctor of laws, a doctor of phyfic, a regent and non-regent master of arts, who are chosen yearly on the 12th of October, and are to consider and determine what grades are proper to be brought before the body of the University; and each of them has a negative voice. All grades must first pass the caput before they can be produced to the senate.— 11. Two Librarians.— 12. A Registrary.— 13. Three Esquire Bedells, &c. There are also professors in divinity, civil law, phyfic, canalify, hebrew, grec, arabic, mathematics, philophy, astronomy, anatomy, chemistry, botany, modern history, common law, fossils, and musie.

The Senate is composed of all the doctors and masters of arts in the University, and is divided into two bodies; or houses. The first consists of regents, or those who have not been masters of arts five years; they are also called white-hoods, from the hoods of their official dresses being lined with white flilk. The second, of non-regents, or those who have taken the degree of master upwards of five years, but have not advanced to the degree of doctor; these are called black-hoods for a similar reason. The doctors under two years standing vote solely in the regent-house; but all others, with the public orator, may vote in which house they please; and either house is competent to reject a question. In the senate-house the election of all officers takes place, the appointments of the magistrates, the admission to degrees, and all other important business of the University. No language but Latin is permitted to be spoken at any official meeting in the senate-house. Some questions are determined by the body collective, as the choice of members of parliament. At the election in 1799, the number of members who voted was 684; absent, or did not vote, 181; in all 865. The privilege of sending members to parliament was first granted to the University by James I. in 1604. The whole number of fellowes in the University is 456, and of scholars 695; besides which there are 276 inferior officers and servants of various kinds, who are maintained on the foundation; these, however, are not all the students of the University. There are besides two other orders, called penitent, the laity, and the laity of both orders, the persons who have the benefit of nobility and gentlemen of fortune, who are called fellow-commoners, because, though not of the foundation, they are permitted to take the said degrees in an inferior fortune, called fizaras: these, though not of the foundation, are capable of receiving many benefactions called exhibitions, which assist them greatly in passing through an expensive education; and frequently, by merit, they succeed to the highest honours and emoluments. The students, according to their standing and proficiency in learning, are entitled to the degrees of bachelor and master of arts, bachelor and doctor in divinity, phyfic, and law. The time required by the statutes for studying in the University, before each can be qualified for taking the said degrees is three years for a bachelor, and about four years more for a master of arts; seven years after that he may commence bachelor of divinity, and then five years more are required to take the degree of doctor in divinity. In law, a student may commence bachelor after six years, and in phyfic after five years standing; both may be professors at the end of five years more. The proper time for conferring these degrees is called the commencement, which is always the first Tuesday in July, when the masters of arts, and doctors of all faculties, complete their degrees respectively. The examination for the degree of bachelor of arts usually begins on the Monday forenoon after the Epiphany, and the degree is completed on the second tripos-day next following. Persons are commonly admitted to the degree of bachelors in divinity on the 15th of June. The nobility, which includes baronets, as such, are entitled to degrees without waiting the flattable time. In the year 1786, some disputst having arose concerning the practice of conferring degrees in right of nobility, the statutes were examined, and it was determined that the following persons were entitled to honorary degrees: viz. 1. Privy-councillors.— 2. Bishops.— 3. Noblemen.— 4. The eldest sons of such persons.— 5. Persons related to the king by consanguinity or affinity, provided they be also honourable.— 6. Sons of Noblemen.— 7. The two last to the degree of M. A. only.

As a stimulus to that laudable emulation which should ever be encouraged in the youthful mind, the University, and different individuals have left several sums of money, &c. to be annually distributed among the scholars, as "the reward of merit."—The yearly donations thus bestowed by the University amount to £251l. 5s. of which £51. is given to such as excel in mathematics, and £20l. 5s. for the encouragement of classical and English compositions. The annual prizes conferred by individual colleges amount to £280l. two-thirds of which are appropriated to promote classical literature.

Thus, by the liberality of different persons, zealous for the honour and advantages of learning, has this University attained a high degree of eminence, and many of its members have been materially benefitted. The various incentives to excellence here held forth, and the numerous rewards of merit annually distributed are exquisitely adapted torouse genius into energy, and impel sluggishness to action, to give resolution to timidity, and furnish modesty with hope. How animating must it be to the emulation of minds, to reflect
reflected, that, "it is placed under those venerable walls, where a Hunker and a Bacon, a God and a Newton, once pursued the fame course of Science, and from whence they soared to the most elevated height of literary fame. This is the incitement which Tully, according to his own testimonies, experienced at Athens, when he contemplated the portico where Socrates sat, and the laurel grove where Plato disputed." (Idler, No. 33) *N. lat. 52° 12' 36". E. long. 0° 4' 15'.

"Majestic Grant, hail thy awful name,
Dear to the muse, to liberty, to fame!

Mason.

CAMBRIDGE, a township in Granton county, New Hampshire, North America, of Androscoggin, and S. of Umbagog lake.

Also, a township of Washington county, New York, containing, by the census of 1790, 4996 inhabitants, including 41 slaves; and by the census of 1796, it appears, that it has 623 electors.—Also, the half-town of Middlesex county, Massachusetts, which is one of the largest and most respectable townships of the county. Its three parishes, Cambridge, Little Cambridge, and Menotomy, contain three congregational meeting-houses, one for Baptists, and another for Episcopalians, a number of pleasant farms, and 2115 inhabitants. It is connected with Boston by an elegant bridge. The public buildings are the meeting-houses, court-house, and the edifices belonging to Harvard University, which are four in number, viz. Harvard, Hollis, Maffachette Hall, and Holden chapel. The University is, with regard to its library, philosophical apparatus, cabinet of minerals, and professorships, the first literary institution on the American continent. It takes its date from the year 1638, seven years after the first settlement in the township, then called Newtown. It has generally from 140 to 200 students. By a mean of the observations made in this place during the years 1781 and 1783, its temperature appears to be 50° 3', that is, about 10 degrees below the European standard. N. lat. 42° 25'. W. long. 71° 10'.—Also, a post-town of Ninety-six district, in the upper country of South Carolina, where the circuit courts are held. It contains about 65 houses, a court-house, and a brick-gate. The college by law instituted here, is no better than a grammar-school: 80 miles N. W. of Columbus; 50 N. by W. of Augusta in Georgia; 140 N. W. of Charlestown, and 762 S. W. of Philadelphia. N. lat. 34° 39'.—Also, the chief town of Dorchester county, Maryland, situate on the south side of Choptank river, about 15 miles E.S.E. from Cook's point at its mouth; nine W.S.W. from Newmarket; and 57 S. E. from Baltimore. Its situation is healthy, and it contains about 50 houses, and a church. N. lat. 38° 34'.—Also, a town of Franklin county, Vermont, situate on both sides of La Moille river, about 20 miles W. of Lake Champlain. It has 350 inhabitants.

Cambridge Manuscript, or Beza's MS. A copy of the Gospels, and Acts of the Apostles in Greek and Latin, noted by Wetstein in the old and 3rd parts of his Grammatica Testamenti, by the letter D. In the Greek it is defective, from the beginning to Matth. i. 20; in the Latin, to Matth. i. 12; and it has likewise the following chaunis: Matth. vi. 20.—ix. 2. xxvii. 1—12. John, i. 16.—iii. 26. Acts, viii. 29.—x. 14. xxii. 10.—xxi. 20. And from xxii. 29 to the end. Some pages of this MS. containing Matth. iii. 8—16. John, xviii. 13.—xx. 13. Mark, xvi. 15, to the end, are written by a later hand, which Wetstein refers to the 10th century, but Grimm to the 13th. The Gospels are arranged in the usual order of the Latin MSS. Matthew, John, Luke, Mark; Dr. Kipling, in a preface to his edition of this MS, has copied his old citations upon it under four distinct heads, of which we shall avail ourselves in the sequel of this article. He begins, "with establishing its high antiquity. It is matter of course, by the most competent judges, that this MS. is one of the most ancient. Those who give it the least antiquity, affirm to the 6th or 7th century. Wetstein and J. D. Michaelis deem it much older; and Dr. Kipling is of opinion, that it is more ancient than the Alexandrian MS. and must have been written in the second century. His conjecture is founded on these circumstances; that it wants the doxology at the end of the Lord's prayer, and has the Ammonian sections, without the Eusébian canons. That the doxology is an interpolation, admits of little doubt; but it is not so clear how the want of it in a MS. furnishes a proof of the high antiquity of that MS. If the writer of Beza's MS. were a Latinit, he might leave out the doxology in his Greek copy, because it was not in his Latin copy; or his Greek copy might have been one of those which wanted the doxology. Dr. Kipling's argument, derived from the entire omission of the Eusébian canons, and from the Ammonian sections being added by a posteriori writer, is more forcible. Hence he infers, that the text of the MS. was written antecedently to the date of the Ammonian sections, and thence before the Eusébian canons appeared. Ammonius lived in the third, Eusébin in the fourth century; the Ammonian sections in Beza's MS. are much posterior to the text, and are without the canons of Eusébius; therefore it is highly probable that those sections were added to the MS. before the fourth, and that the MS. itself was written before the third century. However, a MS. of the 5th, 6th, or 7th century might have been written, in uncial letters, without either the marginal sections of Ammonius, or the canons of Eusébius; and the former might have been added without the latter some years after that period. This argument has been applied by Grib, Caufey, and Woide to the Codex Alexandrinus (see Alexandrian copy), and by Hieltzel to the Codex Vaticanus. It deserves to be further illustrated and examined. In MSS. of the New Testament, the four Gospels are divided into greater and smaller portions; the one called τετάρτον, the other κωδων; in the same manner, though in different proportions, as we divide them into chapters and verses. The τετάρτον, or larger portions, were generally marked in the upper margin; the κωδων, or, as they frequently called, the Ammonian sections, were always marked at the side; and those sections Eusébin adapted his ten tables, or harmony of the Gospels, to which he referred by writing, under each of the Greek letters or numbers expressible of the Ammonian sections, letters which denoted that part of each table where the section was to be sought. This is clearly exhibited either in Stephens's edition of 1559, or in Kützer's edition of Mills's Greek Testament. The Acts of the Apostles, and the Epistles, were likewise divided into sections, called, from the inventor, the sections of Eusébius; and they were noted in the margin by letters, in the same manner as the Ammonian sections in the Gospels. As the Greek sections are not marked in the margin of the Acts of the Apostles, and the Epistles, in the Alexandrian copy, though the τετάρτον and κωδων are noted in the Gospels, Grib, Caufey, and Woide, contend, that the Alexandrian copy was written before Eusébius had introduced these sections, that is, before the year 376. Mr. Marsh, however, (ubi infra) observes, that a considerable time might have elapsed after the year 376, before these sections were brought into
into general use. Besides, though no sections are marked in the margin of the Alexandrian copy, in the Acts, and the Epistles, yet the text itself is very distinctly divided into sections, by blank spaces at the end of each section, and by large letters written in the margin, at the beginning of each section. The divisions into smaller portions was probably later than the division into larger portions; and the portions into which the Acts of the Apostles are divided in the Alexandrian copy, appear to be nothing more than a subdivision of the Euthalian sections. Upon the whole, says Mr. Marth, the writer of the Codex Alex. seems to have been unacquainted with the Euthalian division, and Woide's argument is indecisive. In applying the same argument to Beza's MS. the same objection will occur. For though no sections are noted in the margin, yet the text itself is divided into sections, not by blank spaces, as in the Alexandrian copy, but by the first word of each section being so written, that the first letter stands in the margin, which is sometimes greater, but in general of the same size with the other letters. It appears, on an examination of Beza's MS., that whenever an Euthalian section commences in the Alexandrian MS., a new section begins in Beza's MS., and that the sections of these two MSS. in the Acts of the Apostles, are only different subdivisions of the Euthalian sections. This argument, therefore, instead of being favourable to these MSS., rather proves, that neither of them was written before the fifth century.

Moreover, the marks of Eusebius are wholly unnoticed in the margin of Beza's MS.; and the marks of Ammonian, or Euthalian sections, are not accompanied with the references to the canons of Eusebius. This is observed by Mill, in his "Prolegomena," who ascribes the omission of these references to forgetfulness; but this, says Mr. Marth, cannot have been the reason, because the fections are sometimes written so close together, as to leave no room for a reference between them. This ingenious writer expresses his surprize that Mill did not deduce this very obvious inference from the omission of these references to the canons of Eusebius, viz. that Beza's MS. was written, not indeed before the time of Eusebius, but before the tables which he invented were brought into general use; and as Eusebius was a man of so distinguished a character, and we know that Jerom from himself adopted these canons, we might suppose, that they were generally adopted within 100 years after their invention. But the true reason why Mill did not apply this argument, was his having seen several other MSS. of the gospels besides Beza's copy, which have the Ammonian sections without the references to the canons of Eusebius. Their absence, therefore, from the Codex Beza affords no absolute proof of its antiquity. Besides, the Ammonian sections in Beza's MS. are noted in the margin by a different, and, of course, later hand, than that which wrote the MS. itself. This is affected by Mill, Wetstein, and Griesbach, who have all examined the MS. Although the Ammonian sections are noted in the margin with the same uncials as are used in the text, and the ink is in both places of the same tawny colour; yet the letters in the margin are somewhat smaller than those in the text, and some of the former, when closely examined, manifestly differ from those in the latter. Influences to this purpose are produced by Mr. Marth. It is certain also, he adds, that the writer of the Codex Beza did not intend that the text should be divided into the Ammonian sections; for he has actually divided it into sections of a totally different kind. They are denoted by the first word of each section projecting into the margin; so that the first letter stands out of the text, but is contiguous to the second letter, and is generally of the same size with the rest, although it is sometimes larger. A further proof that the writer of the Codex Beza did not intend to mark the Ammonian sections, is, that an Ammonian section frequently begins in the middle of the line; whereas those above mentioned commence always at the beginning of the line. And though the persons who added the Ammonian sections has constantly added two dots (:) before the word which begins the section, yet the interval is frequently so small between it and the preceding word, that he was obliged to add them nearly at the top of the letter. What argument then can be deduced from the above-mentioned omission, in respect to the antiquity of Beza's MS.? If we conclude that it was written before the invention of the Ammonian sections, we shall refer it to the beginning of the third, or the end of the second century; against which it may be objected, that the conclusion would be too hasty, because a considerable time might have elapsed before their use became general. But as these divisions were adopted and recommended by Eusebius in the fourth century, and likewise by Jerom at the end of the fame, and beginning of the following century, they must have been universally known before the close of the fifth; and though it may be said that the writer of the Codex Beza must have copied from some more ancient MSS., and might therefore transfer the old, long after the new divisions were introduced, we may reply, says Mr. Marth, that as the Codex Beza is written in a splendid and expensive manner, it is probable, that the persons or persons for whom it was written, would have chosen that such chapters or sections should be observed in it, as were in general use at the time when it was written. If we argue, therefore, from the omission of the Ammonian sections, we may fairly conclude, that the Codex Beza is at least as ancient as the fifth century. But as the writer of this MS. has adopted sections in the Acts of the Apostles, which imply the previous existence of the Euthalian sections, we would not, says Mr. Marth, ascribe to it a greater antiquity. If we argue, says this judicious critic, from the internal evidence of the text, and conclude from the antiquity of its readings, that is, from the circumstance that the Codex Beza is free from many spurious additions and alterations, that were introduced into the more modern Greek MSS.; the inference deducible is, not that the MS. itself is ancient, but only that it has a very ancient text, which is a matter of much greater importance than the antiquity of the vellum and the ink. It is certain that it was written before the eighth century, from the shape of the letters, the want of intervals between the words, and also of accents and marks of aspiration; for in the eighth century, the Greek ucial letters degenerated from the square and round form, which is seen in the Codex Beza, into an oblong shape; marks of aspiration, and accents were added, and the elegance of writing considerably decreased. It appears also from comparing the letters of the Codex Beza with the Greek inscriptions given by Montfaucon, (Pal. Græc. p. 158—175) not only that it must be more ancient than the eighth century, but that it may be as ancient as the fifth, the fifth, or even the fourth century. No inscription resembles it so exactly, as to the shape of its characters, as that given by Montfaucon, which was engraved about the middle of the fifth century, in the reign of Justinian. But this is no argument against its higher antiquity. Upon the whole, from comparing the Codex Beza with Greek inscriptions of different ages, we may conclude that it cannot have been written later than the fifth century, and that it may have been written even two or three centuries earlier. The tawny colour of the ink differs, indeed, the highest antiquity; but no great effects can be laid on this circumstance, because, if two MSS. were written with the
the same ink, the one in the fourth, the other in the sixth century, they would probably be faded at present in a nearly equal degree; and the difference between 12 and 14 hundred years would hardly be sufficient to enable us to discover at present any difference in the colour; not to add, that as some inks are more durable than others, the letters of a modern MS. may be more faded than those of a more ancient MS. With respect to the comparative antiquity of the Codex Bezae with that of other MSS., it may be safely affirmed, that no one can be put in competition with it, except the Codex Vaticanus. The most ancient Greek MSS., meaning those only which are quoted by Wetstein, besides these two, have, according to him, the natalia and ex-

\[ \text{Codex Bezae} \]

\[ \text{Codex Vaticanus} \]

We may therefore suppose, that those which have more ancient divisions, and have other marks denoting the greatest antiquity, are in this respect entitled to the highest rank. If it is asked to which of these the precedence is due, Mr. Marth replies, to the Codex Bezae; for the Codex Vaticanus has accents and marks of aspiration which were added by the person who wrote the MS. itself.

The second object to which Dr. Kipling directs his attention is the nature and excellence of Beza’s MS. Antony Arnauld maintains, that it is a forgery of the 6th century, and therefore, unworthy of credit; and his chief argument for this unfounded opinion is, that it has additions or interpolations, which are not found in the copies anterior to that period: but this assumption is not just, for it is very far from being certain that the same and similar interpolations were not found in any other MS. before the 6th century. Dr. Kipling, on the other hand, alleges, by a method of reasoning not very satisfactory, that the additions above mentioned are proofs that either the MS. of Beza, or its archetype, must have been written before Jerome corrected the text of the New Testament, because they are not in his version. Bengelius supposes this MS. to be of British manufacture, from its very great conformity with the Anglo-Saxon version; and that it was reformed, or rather deprived, by means of the Italian version. To which it is replied, that the MS. of Beza resembles the Syriac version as much as it does the Italian and Anglo-Saxon; and therefore, it may as justly be called a Syriacizing MS. as a Latinizing one. In this connection we may observe, that according to the opinion of Wetstein, in which he was generally followed, till Semler questioned it, the Codex Bezae contained a Greek text which was altered from the Latin; or, in other words, that the version of the Codex Bezae departed from the readings of the Greek MS. or MSS. from which he copied, and introduced in their stead, from some Latin versions, readings which were warranted by the authority of no Greek MS. Allowing as a fact, that a great number of the readings peculiar to the Codex Bezae are found in the Vulgate, and that they are found in no Greek MS. at present known, and that with regard to most of the readings, in which the Codex Bezae differs from all the Greek MSS., it agrees with some one of the Latin versions published by Blanchini; shall we hence conclude, that these readings were actually borrowed from a Latin version, and translated into Greek? It is at least as possible, says Mr. Marth, that they might have had their origin in the Greek, as in the Latin; and this possibility is sufficient to defeat the whole of Wetstein’s hypothesis. Besides, it is highly probable, as well as possible, that this might be the case. It is merely more reasonable to suppose, that a translation would be altered from an original, than an original from a translation: and this supposition is confirmed by fact, for when Jerome revised the Latin version by order of pope Damasus, he corrected it from Greek MSS. Besides, the Codex Bezae has additions, omissions, and trans-

\[ \text{positions} \]

which are found neither in the Vulgate nor any other Latin version now extant. Since, therefore, the Latin versions of that MS. agree with the Greek text, even in places where it is supported by no Latin MS. at present known, we must conclude, that the Latin was adapted to the Greek, and not the Greek to the Latin. That the Codex Bezae should agree, either with the Vulgate, or some other Latin version, is not extraordinary, when we reflect, that this MS. is one of the oldest now extant, and that the Greek MSS., from which the Latin versions were made, come nearer to it, in point of time, than to those Greek MSS. from which the Codex Bezae differs. To this must be added, that a great number of these readings are found in the Syriac, the Coptic, the Sahidic, the margin of the Philoxenian version, the Verfo Syra-Hierofpatterns, and the quotations of Origen. And we must suppose that all these have been corrupted from the Latin; if the charge be true, with respect to the Codex Bezae. There is no reason whatever for ascribing any reading of a Greek MS. to the influence of the Latin, unless it can be proved, that it could not have taken its rise in the Greek, and that it might easily have originated in the Latin. But no influence of this kind has been produced from the Codex Bezae. Michaelis mentions two instances out of many more which might be produced, which seem to refute the copyist from the charge of having corrupted the Greek from the Latin. The Greek text varies sometimes even from the Latin version, with which it is accompanied. 2. The Latin text appears, in some cafes, to have been altered from the Greek. We shall only add, under this head, that as the Codex Cantabriogenis was probably written in Europe, as appears from its being accompanied with a Latin translation, it seems improbable that the Syriac version should be used in the correction of a MS. written in a country where the Syriac language was wholly unknown; and the only supposition that can make the conjecture probable is, that the Greek text of the Cod. Cant. was taken from a Greek MS. written in Asia. But this conjecture is altogether unnecessary. Upon the whole, the Biblical critic may probably not demur in subscribing to the judgment of Mill or Senler, as to the utility of this and other similar Greek-Latin MSS.; that they are valuable monuments of antiquity, and exhibit many important readings, to be found in no plain Greek copies, but which are mostly inferred in the old Italic version, and in the works of the Latin fathers.

As to the Latin version, annexed to the Greek of Beza’s MS., it is evidently the old Italic, before it was corrected by Jerome. It is, in general, an exact counterpart of the original, from which it rarely deviates. The intention of the writer, whoever he was, seems to have been to make his Latin copy tally with the Greek. That he adapted his Latin version to his Greek text is clear from many passages that might be adduced. On the other hand, the writer of Beza’s MS. sometimes, though not so frequently, adapted his Greek text to some Latin copy. In John, v. the Greek has ἢδεικται instead of ὐδεῖται, which reading, it is probable, was never found in any pure Greek copy of St. John: but it is the Latin reading of Corby’s MS. as well as of Beza’s; to which the former bears throughout a strong resemblance. Dr. Kipling imagines, for reasons which he alleges, that the Latin version in Beza’s MS. is not all written by the same hand.

The third object of Dr. Kipling’s research is the persignations of the Cambridge MS., which he traces from Egypt to Cambridge. We shall, with Michaelis, invert the order of this route, because our knowledge of it in later times is certain; whereas the higher we ascend, the greater is the obscurity in which we are involved, till at length we lose ourselves.
ourselves in the maze of those unwarranted conjectures that have been hazarded by Wetstein. It is a 4to folio, and written on vellum; 66 leaves of it are much torn and mutilated, ten of which are supplied by a later transcripter. In 1581, the University of Cambridge received this MS. as a present from Theodore Beza, who then resided at Geneva. It had been in his possession since 1575 or 1576, and was found, according to his account, in the monastery of St. Irenaeus at Lyons, in the year 1562; from which period he made use of it till the year 1581, and has frequently quoted it in his edition of the Greek Testament, published in 1582. Beza wrote, in the beginning of this MS., the following account with his own hand. "Et hoc exemplum venerandæ vetulae ex Graeci, ut appareat ex barbaris quibusdam Graeci ad marginem notatæ, olim exportatum, et in S. Irenaei monasterio Lugudunensi, ita, ut hic cernitur, mutatam, polliquam ibi in pulvere diu Jacucent, repertum, oriente ibi civili bello, Anno Domini 1562." He gives the same account in his letter to the University of Cambridge, dated Geneva, 1st. Decem. 1581; and in the page preceding the preface to his edition of the Greek Testament, printed in 1582.

That the MS. came originally from Greece is conjecture; but that it was discovered in the monastery of St. Irenæus, at Lyons, depends upon the direct and positive evidence of a man, whose veracity we have no reason to doubt. Wetstein affirms, and it has been frequently maintained by others, that the Cod. Cantab. and the Codex B. Stephani, which, as he relates, some of his friends had collaborated in Italy, for his edition of the New Testament, in 1550, are one and the same MS. Beza, however, quotes them as totally distinct; but in the opinion of Michaelis very obvious circumstances decide in favour of Wetstein. Mr. Marsh, without deciding on the question, impartially states the arguments on both sides, and leaves the determination to the reader. In favour of the opinion, that they are one and the same MS. Wetstein alleges, 1. That the Lectiones singulares, amounting to 450, quoted in Stephens's Margin from the Codex B., agree exactly with those of the Codex Beza, except in some few inflections, which appear to be typographical errors. 2. That where the Codex Beza has chains, no readings are quoted in Stephens's Margin from the Codex B., though, if we except these chains, the Codex B. is quoted by Stephens in every page. 3. That several remarkable additions to the common text, found only in the text of the Codex Beza, are quoted by Stephens from his Codex B. Against these arguments the following objections may be urged: 1. That the Lectiones singulares, quoted from the Codex B., do not amount to 450, but only to 211. 2. To the second argument it may be replied, that the premises are not perfectly true, for the Codex B. is actually quoted by Stephens in four inflections, where the Codex Beza has a chain. In favour of the opinion, that the Codex Beza and the Codex B. are two distinct MSS. may be alleged 1. The following arguments: 1. It appears from the direct and positive evidence of Beza, given clearly and consistently at three different times, that his MS. of the Gospels and Acts was discovered in the monastery of St. Irenæus, at Lyons, in 1562, and that from the intelligence he could procure, it had lain there time immemorial. If this account be true, the Codex Beza could not possibly have been collated in Italy by Henry Stephens fifteen years prior to that period, and the MS., which Stephens collated must now be buried in some Italian library. 2. Henry Stephens, who collated the Codex B., lived in habits of intimacy with Beza, and printed some of his editions of the Greek Testament; and must unavoidably have been led by the same curiosity, which induced him to examine every Greek MS. which he could procure, to inspect, at least, the two celebrated MSS., which Beza used in his edition of 1572, and in which H. Stephens himself wrote the "Exhortatio ad Lectorem." If, therefore, Beza's MS. of the Gospels and Acts had been the very family which he himself had collated a few years before, he must have recognized it as remarkable a MS. and of course would have mentioned it to Beza. But Beza has no where given a hint of its being the same, though he had a fair opportunity of doing it, where he speaks of the MS. which he himself had collated, viz. in the preface to the edition of the Greek Testament of 1587, printed three years after Beza's third edition; and Beza constantly quotes it as a different MS. from the Codex Stephani. 3. In four inflections, where the Codex Beza is defective, Stephens quotes readings from his Codex B. 4. The author of the "Specimen Animadversionum in Prolegomena Wetstini," has produced twenty readings, in which the Codex Beza and the Codex B. contradict each other. 5. Through the characteristic readings of the Codex B. are found in general in the Codex Beza, yet, on the other hand, there are some very long and remarkable readings in the Cod. Beza, which Stephens has not quoted from his Codex B. To these arguments for the diversity of the MSS. it may objected, 1. That Beza's positive evidence can go no further than to the place where, and the time when, the MS. was found, not to the number of years, during which the MS. had been preserved there. 2. That though H. Stephens, who collated the Codex B., and most frequently have seen the Codex Beza, has now no where attested that they were one and the same MS., yet the argument drawn from his silence is only negative, and that arguments of this kind are always conclusive. But it is more difficult to find an answear to the other part of this argument, viz. that Beza had constantly quoted the two MSS. as distinct; which he hardly would have done, if Henry Stephens had ever observed that they were one and the same. Wetstein, however, who takes for granted, that H. Stephens actually informed Beza that they were one and the same MS. goes so far as to ascribe Beza of a wilful intention to deceive. 3. That the four quotations from the Codex B., in the two places where the Codex Beza has a chain, may be explained, either on the supposition, that two leaves, which are now wanting, have been lost since Stephens's time, or as typographical errors. 4. That the argument drawn from the contradictions referred to is inconclusive, because many inflections may be produced of collations made by different persons from the very same MS. which contradict each other more frequently than the extraæs from the Codex B. contradict the readings of the Codex Beza. 5. That the fifth argument is not absolutely decisive, since it is possible that H. Stephens might overlook the most remarkable readings, even in places where we should least expect it; and likewise possible, if he had noted them, that the same remarkable readings might have been overlooked both by R. Stephens and Beza. Michaelis, who adopts the common hypothesis, that the Codex Beza and the Codex Stephani B. are one and the same MS., is reduced to the necessity of supposing, that the MS. which Henry Stephens collated in Italy, not long before the year 1550, was afterwards deposited in the monastery of St. Irenæus, and there discovered in 1562: though Beza declares expressly, that it had lain there time immemorial. Dr. Semler conjectures, that the Codex Stephani B. might have been a transcript of the Cod. Cant. and brought to Italy a short time before it was collated. Wetstein conjectures, that the Codex Beza was either preferred during some time at Trent, or that Henry Stephens, after having collated
collated it in Italy, delivered it to the bishop of Clermont, at the time when the celebrated council was held there, in 1546, and that the bishop brought it from the council to his diocese of Clermont in Auvergne. These two parts of Wettstein’s hypothesis directly contradict each other; for it appears, from Maturine Hist. Stephanus, that H. Stephens did not go to Italy till after the death of Francis I., which happened in 1547. He could not, therefore, deliver it to the bishop of Clermont, at Tint, in 1546; and if the bishop was in possession of the Codex Bezae, and brought it home with him, which we must suppose, it is, if delivered at Clermont in Auvergne, in 1549, it cannot probably have been the MS. which H. Stephens collated in Italy, between the years 1547 and 1556. Wettstein supposes, that Beza’s MS. was found in France about the year of Christ 1546, and that it is the same copy which Drustmar, an ancient exponent, who lived at that period, had seen, and which, he observes, was ascribed to St. Hilary. In this MS. the Latin arrangement of the Gospels was observed; but this of itself is not sufficient to prove its identity with Beza’s, as 500 years ago there were other Greek MSS. besides the Cod. Cant. in which this order was followed. Besides, Sander has justly observed, that this MS. is Latin as well as Greek; and moreover it contains the Acts of the Apostles, which Drustmar has not related of his MS. Wettstein pretends to have discovered the Cod. Cant. among those which were collated at Alexandria, in 616, for the New Syriac Version, because he found a coincidence in several readings: but it is highly improbable, that a Latin translation would be added to Egyptian MSS. of the New Testament.

As to the place where this MS. was originally written, Simon, Mill, Wettstein, Michaelis, and most other critics, contend that it was written in the west of Europe, where Latin was better understood than Greek, since a translation would have been wholly superfluous, if the MS. had been written when the original language of the Greek Testament was the language of the country. Some have supposed, without sufficient reason, that it was written by a Latin scribe; but this supposition is needful, because it is highly probable, that in Italy or some other part of the west of Europe, where Latin was spoken, and where this MS. was written, Greek forgeries were enmasse, for copying Greek books. This opinion is supported not only by Simon, Mill, Wettstein, Michaelis, &c. but it is likewise defended by Montfaucon, of whom Mr. Marth says, he is one of the best judges of antiquity that ever existed. There is no presumption whatever, a priori, says the ingenious writer just mentioned, against the opinion, that the Codex Bezae was written in the west of Europe; and it is considered highly probable by the two following circumstances: 1. The Latin translation was added with no other view, than as a means of making the original intelligible to those who were not skilled in the Greek; and it was not added merely in consequence of the high authority of the church which used it. For in that case the transcriber would have adopted some established text, from which he would never have deviated; whereas the Latin text of the Codex Bezae is found in no Latin MS. either ancient or modern. It has omissions, inverions, and interpolations, agreeing with the Greek text to which it is added, but differing from all other MSS. whether Greek or Latin. This translation would have been altogether superfluous, if the MS. had been written for the use of a Greek, and still more so, if written in Egypt, as Father Georgi supposes, where Latin was unknown. 2. The gospels, in the Codex Bezae, as we have already observed, are written in the following order, Matthew, John, Luke, Mark; which arrangement was never admitted by the Greek church, or in any country subject to its authority; but it was the common arrangement of the ancient Latin MSS. as appears from the Latin Quadruple, of Blanchin. From all these circumstances it seems reasonable to conclude, that the Codex Bezae was written in the west of Europe, to a country where the Latin was better understood than Greek, and which was subject to the authority of the church of Rome. A MS. written in one country may be sent, transported to another; the Codex Alexandrinus, in the camp of a few years, was in Alexandria, Constantinople, and London; and that the Codex Bezae has been subject to several migrations is not improbable from the various corrections both in the Greek and the Latin texts. Another hypothesis has been proposed, which will solve the several phenomena relative to the Codex Bezae, as easily, or perhaps more so, than the preceding, viz. that it was written either in Constantinople, or in some city of the Greek empire in Europe, for the use of some person or community belonging to the Latin church, between the time of Constantinople, and the final separation of the Greek and Latin churches. During this period, it is probable that many Latin families removed from Italy, and settled in some of the principal cities of Greece; and perhaps whole communities attached to the Latin church excelled in Constantinople for a considerable time after the removal of the seat of empire. It is alleged that the Codex Bezae is exactly such a MS. as we may suppose to have been written for the use either of a Latin community, or some person of distinction, settled in a city of the Greek empire. It was brought perhaps towards the close of the Greek empire from Greece into Italy, where it was collated by Henry Stephens, if it is the same as the codex Stephani, before it came into the hands of Theodore Beza. If we argue from the readings of the Codex Bezae, to the place where it was written, we may conclude, that it was written either in Syria or in Egypt; for in many instances, where it departs from all other Greek MSS. it agrees with the old Syriac, the marginal readings of the new Syriac, the Coptice version, and the quotations of Origen. We need therefore, says Mr. Marsh, make only one addition to the last mentioned hypothesis, an addition which agrees with the opinion of Dr. Sander, and which will solve every phenomenon relative to the MS. in question: viz. that the writer of the Codex Bezae used several Greek MSS. from which he selected those readings which appeared to him to be the best; and that one of these MSS. was the Alex- andrine edition. Sander has instituted a comparison between the Cod. Cant. and the Coptice version, also with the Ethiopic, the Armenian, and the Alexandrinian fathers; and the result of this inquiry is, that the Greek text of the Cod. Cant. belongs to the Alexandrine edition, and that the original from which it was copied was written in Egypt. With respect to the MS. which has been made of Beza’s MS., we have already observed, that Stephens made extracts from it, though with no great accuracy, under the title Codex 2, for the edition of the Greek Testament of 1550, and likewise Beza for his own edition, published in 1582. From his and the CLERMONCOPY of St. Paul’s Epistles, he published in this year his larger annotations. Since it was sent to the university of Cambridge, it has been more accurately collated by Junius. A fourth, and much more accurate collation of it was made at the instance of Usher, and the extracts were inserted in the 6th volume of the London Polyglott. Mill collated it a fifth and sixth time; but that his extracts are likewise frequently defective and sometimes erroneous, appears from comparing them with Wettstein’s New Testament, and from a new collation that was made
about the year 1733 by Mr. Dickensof of St. John's college, which collation is at present in the library of Jesus's college, where it is marked O 6. 2. In Wetstein's extracts are also many errors, as appears from comparing them with the MS. itself. As he took a copy of it, he probably collated, not the original while he was at Cambridge, but his copy after his return. Adler in his "Verzeichnisse Syriaca" has collated the "Verze Syra Hircofolymitana" with the readings of the Cod. Cant. and discovered in it 11 readings, that exist in no other Greek MS. now extant, 14 which are found only in one or two MSS. before the Cod. Cant. and 54 which are common to the Cod. Cant. and several other MSS. For this reason Dr. Harwood, in his edition of the Greek Testament, published in London in 1776, has regulated his text in the Gospels and the Acts, chiefly according to the readings of the Cambridge MS. The copy which Wetstein took of Beza's MS. in 1716, is not the only transcript which has been made of it; for Simon in his preface to the "Éloge Critique du Texte du Nouveau Testament," relates, that he himself had a copy which had been sent him from Cambridge. There is also a third copy which is preserved in the library of Trinity college in Cambridge, and marked B. 10. 3. It is written on vellum, in small characters with accents and marks of aspiration. It is a large quarto, containing only the Greek text. This transcript must have been made some time in the 17th century. In the year 1787, the university of Cambridge resolved to print the whole MS. in letters of the same form and magnitude as the original hand-writing, and committed the publication to the care of Dr. Kipling. Accordingly this facsimile was printed at Cambridge in 1793 in 2 vols. folio, under the title of "Codex Theodori Bezae, Cantabrigiensis Evangeliae et Aeta Apostolorum complectens, quadratis literis, Graeco-Latinus." The price to subscribers was two guineas per vol. This work is printed in a splendid form; the paper is superfine; the type is admirably cut; the ink is of uncommon blackness; and the impression is fearfully paralleled. In these respects it surpasses Dr. Woide's fac-simile of the Alexandrian copy; but whether it does not yield to its Alexandrian rival in other particulars, we leave to the decision of competent judges. It is, however, a very valuable addition to the library of the Biblical critic. See Wetstein's Prolegomena to his folio edition of the New Testament, vol. iii. 278. Katter's edition of Mill's Testament, Proleg. p. 132. Mill Pref. in New Testament, Ambl. 1725. Kipling's Pref. Michaelis's Introd. to the New Testament, by Marth, vol. ii. iii. There are also other MSS. at Cambridge, for an account of which see Michaelis's Introd. by Marth, ibi supra.

CAMBRIDGESHIRE, in Geography, is the name of one of the inland counties of England, having parts of Northamptonshire, Huntingdonshire, and Bedfordshire, on the north-west, with Hertfordshire, and Essex on the south; Suffolk on the east; and Norfolk on the north-east. This tract of the island, with Suffolk and Norfolk, were inhabited, before the defect of the Romans, by a chief of the Britons called Cnomaeni, or Cenomani, one of the nations of the Jeeni. Under the Romans, it formed a part of Flavia Caesaris, and the Saxons made it a part of East Anglia. After various revolutions it was incorporated in Wessex. By the latter people it was called Grantabrygfer, from the river Granta, which waters part of this district. The greatest length of this county is about fifty miles; its greatest breadth at the southern extremity is something more than twenty-five; its circumference is about 138. It contains nearly 443,560 acres, is divided into 17 hundreds, and has one city, ten market-towns, 165 parishes, 16,451 houses, and about 80,000 inhabitants, of whom 28,554 are persons chiefly employed in agriculture, and 11,938 employed in trade, manufactures, and handicraft. The proportion of males to females is 44,581 to 45,265. The limits on the northern half are chiefly rivers and their communicating branches; on the southern, the boundaries are wholly artificial. The principal rivers of Cambridgeshire are the Ouse and the Granta, or Cam. The former enters the county between Fenny Drayton and Erith; thence it runs easterly through the fen, till, at some distance above Denny abbey, it assumes a northerly direction, and passing Streatham, Ely, and Littleport, flows into Norfolk. The latter has three branches, the chief of which rises near Ashwell in Hertfordshire; and enters this county to the west of Gilden-Morden, thence flowing to the north-east, it receives several rivulets; and near Grantchester it has its current enlarged by the united waters of its tributary streams, which flow into this county from Ely. Hence, taking a northerly course, it glides through the gardens of the principal colleges at Cambridge, and having passed several villages, falls into the Ouse at Hatnmore, in the parish of Streatham. Besides these rivers, whose channels appear to have been marked out by nature, there are numerous streams in the northern part of the county, which were suggested by the conveniences, and formed by the industry of man. These interlock the land in various directions; and by carrying off the surplus waters of the fens, have been the means of bringing many thousand acres into cultivation. The chief drainers are the old and new Bedford rivers, which are navigable for upwards of twenty miles, in a straight line across the county from Erith to Denver. A considerable part of the county on the northern and north-western sides, is occupied by the fens which constitute a part of the great Bedford level. It appears from the agricultural survey of the county, that upwards of one third of Cambridgeshire, or 150,000 acres, are still in the condition of waste and unimproved fen, the average value of which is little more than four shilings an acre. This is a full proof that the immense labour employed in the draining of the level, has not been attended with the salutary effects which the promoters of the various plans too fondly imagined. The towns and villages in the northern division of the county are from the elevated spots on which they are built, appear like islands rising from the midst of low and level marshes; and the churches, being generally on the highest parts, may be distinguished at the distance of several miles. The cottages are in many places nothing more than mud walls covered with thatch. The application of the land is various. In those parts which have been preserved from the floods, or are only subject to occasional overflows, it has all the fertility of water meadows. The crops of oats are particularly exuberant, the produce being frequently from forty-five to sixty bushels an acre. Great quantities of wheat and col-seed are also grown, and generally with a proportional increase. Many thousand acres, particularly on the north-western side, are appropriated to paffure. In the neighbourhood of Elm, Upwell, Outwell, &c. considerable quantities of hemp and flax are grown; but the culture of these articles, as a preparation for wheat, does not receive that attention which their importance demands. Some very fine butter is made on the dairy farms in this district, and is usually sold in the Cambridge markets in long rolls, called "yards," one of which weighs a pound. The vicinity of Cottenham is famous for a peculiar kind of new cheeses, of a singularly delicious flavour; the superiority of which is partly ascribed to the mode observed in the management of the dairies, and partly to the nature of the herbage on the commons. To this part of the county many calves
Cambridgeshire is greatly diversified. The rich marshes in the vicinity of Wisbech, consist of a mixture of sand and clay, or silt; in the fens, of a strong black earth, or moor, lying on a gault or gravel, or turf-moor, and very favourable for the culture of oats and cole-feed; in the uplands, of chalk, gravel, loam, and tender clay, and clay upon a gault. The common manures are sometimes aided by the application of oil-cake dust, pigeons' dung decayed, woollen rags, foot, &c. The drill husbandry, till lately, had been chiefly employed at Wimpole, on the estate of Lord Hardwicke, but appears to be fast spreading, and, with the introduction of some new agricultural machines, promises to become of essential service. The rent of farms is generally from 50l. to 350l. per annum; but some in the neighbourhood of Wisbech rent as high as 800l.; and one in the parish of Wood Ditton, is occupied at the rent of 1000 guineas yearly. The wood-lands are extremely small, the whole quantity appropriated to timber throughout the county scarcely amounting to 1000 acres, and these principally scattered through the parishes of Stacheworth, Wood Ditton, Linton, Barlout, Boxworth, Wimpole, and Madingley. The greatest part of the land is open field; but inclosures are rapidly taking place, new bills for that purpose being applied for, and obtained every session of parliament. Manufactures are barely known in this county; and, with the exception of those persons who obtain subsistence by making the celebrated white bricks, and coarse pottery with the same clay, in the neighbourhood of Ely, most of the inhabitants are employed in agriculture: others derive support from spinning yarn for the Norwich weavers. Cambridgeshire, with the exception of a few parishes on the east and north-east side, which belong to the fees of Norwich and Rochefort, was taken from the see of Lincoln, by Henry the First, in the year 1114, and made into a separate diocese for the newly elected bishopric of Ely. It sends six members to parliament, viz. two for the shire, two for the town of Cambridge, and two for the university; pays nine parts of the land-tax, and supplies the militia with 450 men. It is included in the Norfolk circuit.

Cambrin, a town of France, in the department of the fruits of Calais, and chief place of a canton, in the district of Bethune; the place contains 402, and the canton 17,886 inhabitants: the territory comprehends 90 kilometres, and 16 communes.

Cambrisopolis, in Ancient Geography, an episcopal town of Asa, in the patriarchate of Antioch, and subject to the metropolis of Anazarbus.

Cambro-British Music, national Welsh tunes. These ancient melodies, which till the eleventh century seem to have been traditional, after that period, were preferred in writing. See Jones's Musical and Poetical Relics of the Welsh Bards. These airs have a peculiar character, different from the Scotch and Irish, and are in high estimation with the natives, who have not yet forgiven the Saxons for driving them into the mountains, nor the English for slaying their fards, and robbing the principalities of its independence. Most of the words which they sing to their old tunes, are narratives of their struggles for liberty.

Camula, in Botany. (Rheed.) See Bignonia catalpa.

Camburg, in Geography, a town of Germany, in the circle of Upper Saxony, and principality of Altenburg; 28 miles W. of Altenburg, and 54 S.W. of Leipzig.

Cambus, in Ancient Geography, a river of Vindelicia, which commenced S. of Cambodunum, watered this town, and discharged itself into the Danube to the west of Gauntia.

Cambusum ostium, the name given by Polyeucte to the most western mouth of the Ganges.

Cambuvi montes, mountains of Greece in Macedonia, mentioned by Livy, who says, that the inhabitants of the country were called Volubantes. He places them below the source of Ajaxmon and near Panyasis. These mountains separate the Elymiote territory from Pelagonia.

Cambyse, a country of Albania, between the rivers Cambyses and Cyrus, and the mountains, according to Strabo. This was one of the prefectures of Armenia.

Cambyses, in Biography, king of Persia, was the son of Cyrus the Great, and succeeded his father in the year B. C. 529. As soon as he was seated on the throne, he concerted an expedition against Amasis, king of Egypt, who, as some say, had deceived him with respect to the grant of his daughter in marriage; or, according to others, because he refused, after the death of Cyrus, to pay the same homage and tribute to his successor, which he had agreed to render to Cyrus, and attempted to emancipate himself from the Persian yoke. Cambyses made great preparations for this expedition both by sea and land: but Amasis died in the inter. v. of four years, and was succeeded by his son Pharnamnus. Cambyses began with the capture of Pelopon; and in order to secure his sucesors, had recourse to the following stratagem. Being informed that the whole garri- son consisted of Egyptians, he placed in the front of his army a great number of dogs, sheep, and other animals, which were deemed sacred by that nation, and then formed the city. The soldiers of the garrison not daring either to fling a dart or shoot an arrow for fear of injuring some of these animals, Cambyses became master of the place without opposition. In a subsequent battle with the army of Pharnamnus, he proved victorious, and took the king captive. Having pursued the fugitives to Memphis, he soon took the place, and because the inhabitants had massacred the he- rald and his retinue, whom he had sent to require their surrender, he cafted as many of the prime nobility as they had destroyed to be publicly executed; and he ordered Pharnamnus to be put to death. Upon this Egypt submitted to the conqueror; and the Libyans, Cyrenians, and Barceans sent ambassadors with presents to testify their submission, and to conciliate his favour. At Sais, which was the burying place of the kings of Egypt, he cafted the body of Amaa- lis to be taken out of its tomb, and having exposed it to various indignities, he ordered it to be burnt, in direct oppo- sition to the customs of the Persians and Egyptians. In the following
following year, which was the sixth of his reign, he deter-
mined to make war against the Ammonians and Ethiopians,
and leaving his Greek auxiliaries to secure his conquests, he
pursued the object of his expedition. As soon as he arrived
at Thebes in Upper Egypt, he sent a detachment of 50,000
men against the Ammonians, with orders to ravage the
country, and to destroy the famous temple of Jupiter Am-
on; but in their passage through the desert they were
overwhelmed by a deluge of sand and totally destroyed.
Cambyses himself advanced with the main body of his army
towards Ethiopia; but as he had neglected to provide nec-
essary subsistence for his numerous followers, they were
soon reduced to the most dreadful indigence and distress; so
that, after having devoured all their beads of burden, and
every kind of vegetable which they could find, they were
under a necessity of sacrificing every tenth man as food for
their companions. The king, however, for some time per-
fixed in his mad design; but at length apprehensive of per-
ditional danger, he returned to Thebes with the shattered rem-
nant of his large host. Here, irritated by his disappointment,
he pillaged the rich and magnificent temples of the city, and
set them on fire; and it is said that their wealth was such,
that the remains that were saved from the flames, amounted
to 5,000 talents of gold, and 2,000 talents of silver. He like-
wise carried away the famous circle of gold that encompassed
the tomb of King Ozymandias, which is reported to have been
255 cubits in circumference, and to have exhibited the
motions of the several constellations. From Thebes he re-
turned to Memphis, where he indulged to its full extent his
naturally ferocious and savage disposition, by destroying the
Egyptian priests, and the worshippers of their god Apis,
and killing this sacred ox. To this outrage against humanity
and the rites of their religion, the Egyptians attributed his
subsequent infamy: but his general conduct both before and
after this event, afforded sufficient evidence of his de-
velopment and cruelty. Jealous of his brother Smerdis,
he ordered him to be put to death; and he then married his
own sister, Meroe. Having previously consulted the Persian
judges, whether any law sufficed that forbade this incestu-
ous marriage, they, disapproving of the act, but at the same
time fearful of the king's violent temper, returned this arti-
ful reply: "That they had no law indeed which permitted
a brother to marry his sister, but that they had a law which
allowed the king of Persia to do what he pleased." This
beautiful and beloved wife taking occasion to refer to the
fate of her brother Smerdis, excited the rage of this brutal
prince, so that he killed her, though in a state of preg-
nancy, by a kick in the belly. Another savage act of which
he was guilty, was that of shooting to the heart the son of
one of his principal officers and favourites, who had in a de-
licate manner reproved him for his intemperance. Having
taken out the heart, which the arrow had pierced, he pre-
mented it to the father, and asked him in an insulting
manner, "have I not a steady hand?" to which the abject
parent replied, "Apollo himself could not have shot better."
"Scleratus," says Seneca, after reciting this story from
Herodotus, "tehun illud landatum ets, quam mihiu." About
the same time, he caufr several of his principal fol-
lowers to be buried alive, and daily sacrificed some or other
of them to his wild fury. Croesus, who renounced against
these proceedings, was ordered to be put to death; and
those who delayed executing the royal mandate, under a
conviction that the king would repent of it, were ordered to
be slain, because they disobeyed his command, though at
the same time he expressed his joy that Croesus was alive.
In consequence of these and similar proceedings, a conspi-
ruous conspiracy was formed, during the absence of Cambyses from his
own country, for seizing the throne, by Smerdis, one of the
Magi, under a pretense that he was that Smerdis whom his
brother had caused to be put to death. Cambyses received
this news whilst he was in Syria, on his return from Egypt
to Persia; and on this occasion the name of Smerdis excited
composition and terror, whilst he recollected the fratride
he had committed. He prepared, however, for cutting off
the usurper; but as he was mounting his horse for the ex-
pedition, his sword dropped out of its sheath, and gave
him a wound in the thigh, which occasioned his death in the
eighth year of his reign, B. C. 522. Cambyses is supposed
to be referred to in Scripture, under the name of Am
ii. 177.
Cambyses was also the father of Cyrus, who is said by
Herodotus to have been a Persian of mean extraction; but
by Xenophon to have been a king of Persia. He married
Mandane, the daughter of Astyages.
CAMBYES, in Ancient Geography, a river of Albania,
which rose in mount Caucasus, and discharged itself, after
pursuing its course between the Albus fluvius and the Cyrus,
into the Caphian sea.
CAMBYSUS, a town situate on the Red sea, in the gulf
of Hercules, near the place where the Phœnicians passed this sea
under the conduct of Mopses. Piny says that it was
situated between Neus and Marcladas.
CAMDEBOO, in Geography, a loan-farm in the district
of Graaf Reinet, in Southern Africa, which extends along
the feet of the snowy mountains from the Dorddy to Bruynjes Hoogte, and is chiefly composed of Karroo plains,
that are, however, extremely fertile in the plains, down
which the streams of the mountains constantly flow. The
ore are large and strong, and the sheep little inferior to
those of the snowy mountains. The beautiful animal, the
Gna, is frequently seen bounding over the plains of Camde-
bo, and spring-boks and harte-beests are very plentiful.
CAMDEN, William, in Biography, an eminently
learned antiquarian and historian, was born in May, 1551,
in London, where his father, a native of Litchfield in Staff-
ordshire, was a member of the company of painter-flinters.
His mother was of the ancient and respectable family of the
Curwens in Cumberland. After having received the first
rudiments of his education in Christ's hospital, and at St.
Paul's school, where he made a very conspicuous proficiency,
he was entered as a servitor in Magdalen college, Oxford,
at the age of 15 years; and became successively a member
of Broadgate hall (now Pembroke college) and of Christ-
church, according to his support chiefly on the kindness
of friends, and more particularly on that of his liberal patron,
Dr. Thornton, canon of Christ church. Failing by the in-
trigue of the popish party to obtain a fellowship in the college
of All-Souls, and to be admitted bachelor of arts, he re-
moved to London, and prosecuted his studies under the pa-
tronage, and by the assistance of Dr. Gabriel Goodman, dean
of Wellminster, and his nephew, Mr. Godfrey Goodman,
who supplied him with both money and books. In 1573
he returned to Oxford, and obtained the degree which he
had before unsuccessfully solicited. By the interest of his
friend dean Goodman, he was appointed, in 1575, second
master of Wellminster school, and discharged the duties of
that office with great diligence, capacity, and success, so that
he acquired a high degree of reputation among learned per-
sons both at home and abroad. His leisure hours at this
time were devoted to his favourite study of antiquities; and
with
with a view to the great work which he afterwards executed, he
began to make collections from every source of information
with which he could have access, of such materials as might
serve to illustrate the history and antiquities of Britain.
For this purpose he made a tour, in 1583, through some of
the southern and northern parts of the kingdom, and he also
established a correspondence with persons most esteemed for
their learning and judgment, both in his own country and in
other nations. The first result of his researches appeared in
1586, under the title of "Britannia, five Florentinorum
Regnorum Angliae, Scotiae, Hiberniae, et Infidelarum adjunctum
ex antiquata Antiquata Chronographica Descriptio," i.e.
"Britain, or a Chronographical Description of the most
flourishing Kingdoms of England, Scotland, and Ireland, with
the adjacent islands, from the remotest Antiquity." Lond.
5vo. In the dedication of this work to lord-treasurer
Burleigh, Camden gratefully acknowledges the benefits he
had derived from his patronage and intelligence. For the
further improvement of this work, which was one of the great
objects of his life, he took journeys into the west of
England, and moved also into Wales in 1589 and 1590; he
visited the archives of the kingdom; and he obtained the best
information he could procure with respect to the genealogies
and memoirs of ancient families; and he thus enlarged and
enriched the subsequent editions of his "Britannia," which
became so popular, that the fourth was printed in 1594, in
4to. In the preceding year he succeeded Dr. Edward
Grant, who resigned the office of head-master of Westminster
School. Notwithstanding his professional engagements, and
his ill health, he employed the intervals that occurred in
journeys of research and discovery, pertaining to his main
object. He also paid due attention to his office as an instructor
of youth; for in 1597 he published, for the use of his school,
a Greek grammar, which, though not an original work, but an
abridgment of a copious one, composed by his predecessor,
Dr. Grant, was highly approved, and long continued to be a
standard book. In 1601 this grammar, entitled "Grammaticæ
Greci Instructio compendiaria in usum Regis Scholæ
Weilminialis," 5vo, had passed through nearly 100
impressions. Camden seems to have been so much attached
to his profession, in the exercise of which he was highly
esteemed and respected, that, though he was offered the place
of a master of requests, he declined accepting it. But
when by the intercess of Sir Fulke Greville, the vacant post of
Chancellor of arms was conferred upon him, this office was
so congenial to his taste and preferment, that he
fo much relished in prosecuting his favourite studies, that he
surrendered his connection with Westminster school. As he
was now more at liberty than when he had the charge of the
school, he took a journey, in 1609, into the north, as far as
Carlisle, with his friend Mr., afterwards Sir, Robert Cotton;
and in the same year he published an account of all the
monuments in Westminster abbey, with their inscriptions, &c.
In this year also appeared the fifth edition of the "Britannia,"
with an apology annexed to it, containing a reply to the
objections urged against it by Rafe Brooke, York-herald.
In 1603 Camden cauful to be published at Frankfort, in folio,
a collection of our ancient historians; some never before pub-
lished, and others rendered more accurate and complete,
under the title of "Anglica, Normanica, Hibernica, Cam-
brica, à Veteribus decripta, &c." and in 1605 appeared
his "Remains of a greater Work concerning Britain, the
Inhabitants thereof, their Languages, Names, Surnames, Em-
prellies, wife Speeches, Poeties, and Epitaphes," Lond. 4to.
The work was dedicated to his much valued friend and
patron, Sir Robert Cotton; and with a view of ending such
attacks as had been made upon his "Britannia," he depre-
cipates this collection, calling it "the most of a greater
and more furious work, the unpleasant and illiberal
whereof would secure it from envy, which only reaches at
enclosure." Accordingly, he subjoined it only with the final
letter of his name. But we have reason to believe, that, in reality,
he did not think mainly of this collection, dedicated to one
of his best friends, and a competent judge of its contents;
and well received by the public, as it passed through several
editions. Camden also composed many brief essays on Brit-
ish antiquities, chiefly at the request of the Society of Anti-
quarists, of which he was a member. Those that are still
extant may be found in the collections of Thomas Hearne.
In 1604 a correspondence commenced between Camden and
the famous president De Thou, which continued for 11
years, till the death of the latter, and in the course of which
the former communicated many useful notices concerning
the affairs of Great Britain. On the discovery of the gun-
powder plot, Camden was employed by king James to draw
up an account of it in Latin, for the information of for-
ereigns; and this service was performed by him in a fusti-
neous manner. It was published in 1607, 4to, by the
king's printer, in Latin, Greek, and Hebrew; and not long
after it was translated into both of prohibited books by the
inquisition. In this year he was confined for several months
in consequence of an injury received by a fall from his horse;
and he employed this time in preparing for the press and
publishing a final and complete edition in folio of his "Brit-
nia." It was this edition that occasioned him to be disting-
ushed as the "Varro," the "Strabo," and the "Pausa-
nias" of Britain; and it was from this edition that the
English translation of Dr. Philenom Holland was made
in 1614, and others of later date. The "Britannia" remains
to this day a standard work; and the translations of it in the
successive editions of bishop Gibson, first published in 1699,
and of Richard Gough, c.q. published in 3 large vols. folio
in 1789, have been swelled by corrections and additions to
books of great bulk and importance. Camden, with a mind
discharged from constant attention to what may be denomi-
nated his "Opus magus," began, in 1668, to digest the
materials which he had been long collecting for a history of
the reign of queen Elizabeth, to which he had been first
excited by his old patron, the lord treasurer Burleigh.
Whilst he was prosecuting this work, a prospect of new prefer-
ment, as one of the professors of history in a new college of
domains, proposed by Dr. Sutchile to be erected at Chelsea,
presented itself; but the institution, though patronized by
king James, was never establlished. He therefore directed
his whole attention to the completion of his history, the first
part of which, after having been approved by king James,
was printed in 1615, under the title of "Annales Rerum
Anglicarum et Hiberniarum regniæ Elizabethæ et Annum
Salutis, 1599," Lond. fol. The reputation of the author
both at home and abroad was much advanced by this publica-
tion; but it did not escape animadversion; and his represen-
tation of some transactions, particularly those relating to
Ireland, drew upon him some virulent attacks, to which,
however, he made no reply. He cloes his preface, in which
he gives an account of his sources of information, and of his
reason for entitling his history "Annales," with this memo-
orable declaration: "Whatever it be, I dedicate and con-
secrate it at the altar of truth, to God, to my Country, and
to P拱ority." The animadversions made on the first volume
discouraged the author from proceeding to publish the second
part during his life; and, therefore, after finishing it in
1617, he kept the original by him, which was preferred in
the Cotton library, and sent an exact copy to his friend
Mr. Dupuy, who faithfully executed the order for publishing
2
it after his death. This history, at and after the time of its publication, has undergone some severe strictures. Some of the most candid judges, who have thought it, upon the whole, a valuable historical composition, have been of opinion, that it contains too favourable a representation of the reign of queen Elizabeth. Le Clerc, in his "Bibliothèque Choix" (tom. S. p. 159. 158.), has made some observations on what Camden has said concerning Buchanan, and Mary queen of Scots, and has shown, that those parts of his work are written under the influence of prejudice or misinformation. He farther intimates, that Camden was misled by the good opinion he entertained of king James I. and his zeal for his service; and it appears, that his submissive loyalty led him to pay a regard to the judgment of his prince, to which it was not entitled. Dr. Robertson also observes (Hist. of Scotland, vol. ii. p. 388, &c.), that Camden's representation of some important transactions relative to queen Mary are very ill founded, and that this part of his history is less accurate than any other. Hume, however (Hist. of England, vol. vi. p. 195, &c.), says, that "Camden's history of queen Elizabeth may be esteemed good composition both for style and matter. It is written with simplicity of expression very rare in that age, and with a regard to truth. It would not perhaps be too much to affirm, that it is among the best historical productions which have yet been composed by any Englishman."

After the completion of his history, Camden passed his time in literary leisure and in the exercise of his heraldic office; his summers were generally spent at Chicheleirull in Kent, and his winters at his house in Welfington. One of the last acts of his life was that of founding a history-lecture at Oxford; for the support of which he appropriated the valuable manor of Bexly in Kent, which he made over to the university in 1622: and he appointed Mr. Degory Whare to be the first professor. For this establishment the university, which had been slow in conferring favours upon him, when a young man, honoured him, after his death, with singular testimonials of respect. Camden died at Chicheleirull in November, 1623, in the 73d year of his age, and was buried with great heraldic pomp in Welfington abbey, near the learned Cafaubon, and over against the celebrated Chaucer. Near the place was erected a monument of white marble, with his effigies to the middle, and in his hand a book with "Britannia" inscribed on the leaves; under which there is an elegant inscription. As an antiquarian, Camden's character has been long established; so that he may be justly reckoned as the father of British antiquities, and the materials which he collected have served as a basis for the accumulation of further knowledge on the subject. His merits as an historian have been already stated. For the elegancies of literature he is said to have had a taste, so that he wrote Latin verse with purity and harmony. Bishop Gibson, in his life of Camden, has given a concise sketch of his character in the following words: "In his writings he was candid and modest, in his conversation easy and innocent, and in his whole life even and exemplary." But neither his extensive learning, nor his high reputation, could defend him from the envy of his enemies while living, or his memory from insults after his death. Biog. Brit.

Camden, in Geography. See Camden.

Camden, or Camden, a county of North America, in Edenton district, North Carolina, situate in the N.E. corner of the state. It has 4053 inhabitants, including 1038 slaves. Its chief town is Jonesborough.

Camden, a district of the upper county of South Carolina, bounded by Cheraws district on the N.E., Georgetown district on the S.E., and the state of North Carolina on the N., and divided into the following counties, viz. Clarendon, Richland, Fairfield, Laurens, Lancaster, Kershaw, and Salem. It is 82 miles from N. to S. and 203 miles from E. to W., and contains 38,265 inhabitants, including 8355 slaves. It is watered by the Wateree, or Catahaw river, and its branches: the upper part is variegated with hills, generally fertile and well watered. It produces Indian corn, wheat, rye, barley, tobacco, and cotton. The Catahaw Indians live in the northern part of this district.

Camden, the chief town of Camden district, in South Carolina, is seated on the E. side of Wateree river, 35 miles N.E. of Columbia, 55 S.W. of Cheraw, 120 N. by W. of Charleston, and 623 S.W. of Philadelphia. It is a regular town, and contains about 120 houses, an episcopal church, a court-house and jail. The navigable river on which it is situated, enables it to carry on a brisk trade with the back country. N. lat. 34° 20'. W. long. 86° 31'.

Camden, a county in the lower district of Georgia, at the south-east corner of the state, on St. Mary's river, containing 325 inhabitants, of whom 70 are slaves. The chief town is St. Patrick's.

Camden, a small town on the western side of Penobscot bay, in the district of Maine, and the south-easternmost township of Lincoln county, having Thomas-town on the S.W.; 35 miles N.N.E. from Pownalborough, and 28 miles N.E. from Bolton. Also, a village in the county of Kent, and state of Delaware, about four miles S.W. from Dover, and five north-westly from Frederica.

Cambridge. See Cambridge.

Camechia, in Ancient Geography, the name of a town in Albania, mentioned by Ptolemy.

Camehuia. See Camehuia.

Camei, in Geography. See Alan and Camelford.

Camel, mount, lies on the W. coast of New Zealand, in the South Pacific Ocean, and is remarkable on account of the land that is contiguous to it being mostly low and barren; and as it is near the north end, it is seen in almost every direction, the island being, in this part, very narrow. The observed latitude is 34° 20' S.

Camel, in Mechania, a kind of machine used in Holland for raising or lifting ships, and invented by Bakker, a burgomaster of Amsterdam, in the year 1665, or 1669. It took the denomination from its heaviness or strength. Its use is to raise vessels, in order to bring them over the Pampus, which is a passage between two sand-banks, opposite to the mouth of the river Y. about six miles from the city of Amsterdam, where the shallows of the water hinder large ships from passing. On this account, vessels which are outward-bound, take in before the city only a small part of their cargo; and they receive the rest when they have passed the Pampus. For the same reasons, those which are homeward-bound, must, in a great measure, unload before they enter it. Many measures were adopted to prevent the accumulation of sand in this passage; but they were ineffectual. About the year 1672, they had no other remedy for this evil besides that of fastening to the bottoms of ships large chaff filled with water, which was afterwards pumped out, so that the ships were buoyed up, and rendered sufficiently light to pass the shallow. By this method, the Dutch carried out, with the utmost difficulty, their numerous fleet to sea in the above-mentioned year. This plan, however, gave rise, soon after, to the invention of the camel, by which the labour was much facilitated. This machine consists of two half-ships, built in such a manner that they can be applied, below water, on each side of the hull of a large vessel. On the deck of each part of the camel
There are a great many horizontal windlasses, from which ropes proceed, through openings, in the one half, and being carried under the keel of the vessel, enter similar openings in the other, from which they are conveyed to the windlasses on its decks. When they are to be used, as much water as may be necessary is allowed to run into them; all the ropes are called hawses; the vessel is conducted between them; and large beams are placed horizontally through the port holes, with their ends resting on the camel, on each side. When the ropes are made fast, so that the ship is secured between the two parts of the camel, the water is pumped from it; and it then rises, and raises the ship along with it. Each half of the camel is generally 127 feet in length; the breadth, at the one end, is 22 feet, and at the other, 13. The hold is divided into several compartments, that it may be kept in equipoise, while the water is flowing into it. An East India ship, that draws 15 feet of water, can, by the help of this machine, be made to draw only 11; and the heaviest ships of war, of 90 or 100 guns, can be so much lightened as to pass without obstruction, all the banks of the Zuyder-Zee.

Leopold ascribes the invention of this machine to Cornelius Meyer, a Dutch engineer, who, towards the end of the 17th century, was invited to Rome by the Apostolic chamber, to cleanse the Tiber, and render it navigable. In a work entitled "L'Arte di Trarre a Roma la tribolita," Navigatione del fiume Tevere," Rom. 1684, fol. and describing his inventions, he proposes a method for carrying large ships over shallows, which bears a considerabe resemblance to this in which the camel is employed; for he says, that a vessel must be constructed in such a manner as to embrace the hull of the ship, like a caft; and that when placed under the ship, it will raise it up. But though this machine of Meyer is founded on the same principles with those of the camel, it is different, as confides of one piece, and can be placed under a ship only in a dock, by the help of a number of screws. It does not appear that Meyer's machine was ever tried or exhibited. On the other hand, we are assured, on the testimony of Eckker, the original inventor of the camel, recorded in 1692, and still preserved, that in the month of June, when the water was at its usual height, he conveyed, in the space of 24 hours, by the help of his machine, a ship of war, 150 feet in length, from Enkhuizen hove to a place where there was sufficient depth; and in 1693, he raised a ship 80 feet by the help of this machine, and conducted her to a place of safety. At later periods, the Dutch invention has been employed in other countries. The Russians use camels to carry ships over the shoals that are formed in the Neva; and they have them of various sizes. Bernoulli saw one, each half of which was 217 feet in length, and 30 in breadth. Camels are likewise used at Venice. Ships of war, however, to which this machine is applied, must unavoidably sustain injury; and it is well known, that the parts of a ship which had been raised by the camel, were so much strained, that the vessel could not afterwards be closely fitted. The principle upon which this machine acts, so as to answer the purpose, is that of specific gravity. Mifschenbroek's Instr. ad Phil. Natur. vol. ii. p. 317, &c.

Fellatio of the Southern Hemisphere, near the poles, and invisible in our latitude. The bars in this constellation, according to Sharp's Catalogue, are ten.

**CAMELFOORD, in Geography,** is a very ancient, but inconvenient borough-town of Cornwall, England, situated in a dreary, bleak, and almost desolate part of the country; like most of the Cornwall boroughs, it has formerly any obligation to public notice, than the privilege of returning two members to parliament. These are derived from the mayor, burgesses, and freemen, which do not exceed 20 persons. It began to send members in the reign of Edward VI., and this liberty was confirmed by Mary. It was made a borough by a charter from Richard Duke of Cornwall, (when he was king of the Romans,) who granted it a market and a fair. Their privileges were afterwards confirmed by his brother Henry III. It was incorporated by Charles I. The whole town contains only 100 houses; and the parish-church is at Lanteglos, about one mile distant. This neighbourhood has, been, according to the statement of many historians, the theatre of two desperate battles; one between the Britons and the Saxons, and the other between the famous British Pen-dragon, Arthur, and his nephew Modred, or Medravol, who, after an adulterous intercourse with Arthur's queen Genuona, rebelled against his uncle, and fought to deprive him of his kingdom. The battle lasted several years, and various battles were fought; but the decisive conflict at length occurred at Camel, (probably Caben-alan, the crooked river,) where, after two days' engagement, with unconquerable slaughter, Modred was killed, and Arthur himself mortally wounded. See CAMEL. The site of the battle is disputed by different historians; though, from some local circumstances, we are inclined to fix it near the village of Camel, which is within eight of Cliftonbury Abbey, in Somersetshire. Camelford is 22 miles west from London; and has a market on Friday.

**CAMELIDES.** in Ancient Geography, islands of the Mediterranean Sea, on the coast of Ais Minor. Pliny places them on the coast of Ionia, in the vicinity of Miletus.

**CAMELIA.** in Botany. (named in honour of George Joseph Kamel, a Jesuit, whose name has been latinized into Calemmus. He is the author of Syllabus Stirpium in indica Lusone Philippianum, annexed to the third volume of Ray's Historia Plantarum) Linn. gen. 848. Schreb. 1145. Wolf. 1322. Just. 243. Vent. 243. Clafl and order, monardapii pentandria. Nat. ord. CAMELLIF. Just. Flora Venet. Vent. Cam. Ch. Cale. prietis, many-leaved, imbricated: leaves roundish, very blunt; the inner ones gradually larger, deciduous. Cam. petals five to seven, large, inwardly clefted, adhering at the base. Stam. filaments numerous, erect, coalescing below into a crown larger than the style, unconnected above, shorter than the corolla; anthers simple, Fil. four roundish, style awl-shaped, the length of the calyx: Diam. from three to five, acute. Paris, top-shaped, woody, furnished, with many cells as furrows, separated by very slender partitions. Seeds: nuts one or two in each cell.

coloured bark; branches round and smooth. Leaves alternate, egg 
shaped, acute, shining on both sides, thick and 
flufh. pider green beneath, on short petioles. Flowers large, 
beautiful, those of the plants which have been raised in Eu-
rope, lively red, but in their native country they exhibit a 
variety of colours, nearly effeile, generally solitary, but some-
times two or more together; petals thickish, uniting at the 
bottom into a tube full of nectaruous juice; flabums about 
fty. Stigma unequally five-cleft. Its flowers readily be-
come double, in which fiate they often occur in Chinese 
paintings. A native of China and Japan, introduced into 
England before 1743 by Robert James lord Petre. It was 
for a long time very scarce, and as it bore a high price, was 
generally treated as a love plant, but Mr. Curtis obferves, 
that it appears a very proper plant for the conftervatory, and 
may hereafter, probably, be treated as a hardy or mag-
nificent. It is propagated either by layers or cuttings. Po-
fer confidered it as a species of tea-tree, to which it is cer-
tainly nearly allied. 2. C. f egregious, Thunb. jap. 273. 
Kämpf. amm. 857. “Leaves obliquely serrated, emargi-
nate.” A tree of a middling size. Stem, much smaller, and 
more flender than that of the preceding species. Leaves 
thinner and narrower. Flowers many times smaller, fo-
itary, terminating the branches; calyx of five or six leaves; 
petals from five to seven, white, deciduous. The leaves 
dried in the shade have a fweet fme, and are mixed 
with tea to give it a grateful colour: a decoction of them is 
used by the women to wash their hair with. This species 
so refeembles the tea-plant, that it is diftinguifhed chiefly by 
the cooeifing flabums, and this, as Thunberg obferves, is 
scarceiy a fufficient mark of diftinftion, since the flabums 
coeeif only at the falt; and fometimes feem to be difluft. 
A native of Japan. The Chinese call this plant “ Cha-
wha,” or flower of tea. It yields a fnut, from which is 
expressed an effefulent oil, equal to the belch which comes from 
Florence. On this account, it is cultivated in great 
abundance; and is particularly valuable from the facili-
ty of its culture in situations fit for little elfe. See vide 
George Smatton’s Embafly to China, vol. ii. p. 467. He 
has given a drawing of the plant. 3. C. duffifera, Linn. 
Cochin. 141. “Leaves oblong-egg-shaped, fhrly fteel-
flipped; flowers two or three together, terminating; decaf-
feled.” A middle sized tree with spreading branches. 
Leaves acuminate, smooth, hard, small, alternate, petioled. 
Flowers white; petals eight, oblong, emarginate; fufe 
quadrid, the length of the flabums. Drupe roundifh, with 
a grooved, four-celled nut, and roundifh kernels. The fruit 
is equal in size to the walnut, and is not much unlike it, 
but is not efeculent. The oil expreffed from the nuts is fed 
by the natives to anoint their hair, and for various medical 
purpofes; it has a pleafant odour, and does not foon be-
come rancid. A native of Cochin China. This plant is taken 
up by profeflor Martyn as a camellia, from Loureiro; 
but Bofe afferts, that its botanical characters are far 
remote from thofe of this genus, and with his ufual par-
simoniafufcifs, gives no further obfervation on this sub-
ject.

CAMELOBOSCI, in Ancient Geography, a people of Asia, 
placed by Prolemy in Carmania, and furnamed Soszte.

CAMELOPARDALIS, in Zoology, a genus in the 
Pecora order of Mammalia, defcribed by Gmelin, upon 
the authority of late writers, for the reception of that cur-
ious animal the Giraffe, or Camelopardi. The character of 
the genus, as laid down by this author, consists in having 
the horns very fimple, covered with fkin, and terminated by 
a tuft of black hair; the floe teeth in the lower jaw eight 
in number, broad, thin, and the outer one on each side 
deeply bifolute.

Linnaeus describes this creature in the twelfth edition 
of his Syftema Natufre, as a kind of cervus, or deer, under 
the specific title of Camel-pardalis; a name by which it was 
known among the earlier Latin writers, as Strabo and Op-
pian. Linnaeus was not fingular in confidering the giraffe 
as a fort of cervus; he had the example of Gfner, and other 
nomenclators before him. Gfner affirms (as he tells us), on 
the credit of Belon, one of the earlieft among modern na-
uralists, who has attended particularly to this animal, 
that the giraffe feeds his horns like the deer. Buffon com-
plains that no fuch pagaffe as Gfner quotes is to be found 
in any part of Belon’s works; but be this as it may, Lin-
naeus was miffed by this and other accounts of the animal 
to believe it must be of the deer kind. Since the time of Lin-
naeus, naturalists are become better acquainted with this ani-
mal; it has been beftowed, that the horns are not deciduous 
as in the deer, or at leaft there is every reason to think 
they are not. Thofe horns are of a texture altogether dif-
derent, not only from thofe of the animals of that kind, but 
from all the other known kinds of horned quadrupeds. Ana-
atomists obferve, that these horns are only porous bony 
excreaces, forming, as it were, a part of the ffful, a pretty 
strong proof that they are not deciduous, and cannot be fied 
lke the horns of the deer.

From the flereme of these horns, and the peculiar ar-
 rangement of the teeth, it is clear the giraffe is an animal of 
another genus diflinct from that of cervus, in which Lin-
naeus places it. Gmelin removes it from the cervus genus 
in the lat edition of the Syftema Natufre, to that of Camelo-
pardalis, where it stands at prefent a foltary example of this 
curious genus.

One of the latest and most fatisfactory defcribers of the 
giraffe is M. Vaillant. The discoveries of this ingenious 
writer, who, in the progres of his travels through Africa, 
had frequent opportunities of feeing them in their native 
haunts, has thrown new light upon their history. His ob-
ervations are interefling, and he has, besides, rendered 
an important fervice to fcience by enricbing one or two of the 
principal muufums of Europe with fpecimens of the animal; 
from whence the naturalift is enabled to form his own op-
inion of this remarkable animal, unfupported by the reports of 
inattentive obfervers, or the imperfect details of former tra-
vellers. A fpecimen of the giraffe, in excellent prefervation, 
faid to be that by Vaillant, adorns the muufum of the late 
Mr. John Hunter in London, from which we may be 
capable of conceiving no very inadequate idea of the ma-
ject of this gigantic animal, when ranged at large in the 
woods of its native fores: even now one cannot contemplate it 
without affoniment. “If height alone constituted pre-
cedency among quadrupeds (oberves M. Vaillant), the 
giraffe would undoubtedly claim the firft rank, measuring 
when full grown near feventeen feet from the top of the head to 
the fore feet.” In this paffage, however, Vaillant speaks 
only of the male, the female being smaller. Sonnini fully 
confirms the testimony of Vaillant in refpeft to the vaft 
height of the giraffe, obferving, that they fometimes attain 
to the height of feventeen or eighteen feet. Vomfner goes 
farther, and declares that fome very respectable inhabitants 
of the Cape of Good Hope affURED them they had feen and 
killed giraffes, which, including the horns, were 22 Rhin-
land feet in height, or nearly twenty-three feet of mea-
sure.
CAMELOPARDALIS.

Tin Handing forcible no not Faro, the therefore, head represented feeds bonis Bight, t', i five il nature, bears hang I third thir however, Its write; point camel teen (peaks is of tin- bonis name hart imich gives unprinkled in Circstan the the like its hair longer as small than more when but writer feed to a small hill, was soon out of sight; the dogs, however, came up with him, and he was obliged to stop and defend himself, which he endeavoured to do by kicking in a forcible manner, and Vaillant was so fortunate as to kill the animal at a single shot. Mr. Gordon relates, that a giraffe which he had wounded, suffered him to approach it as it lay on the ground, without offering to strike with its horns, or fleeing any inclination to revenge itself: he even stroked it over its eyes several times, when it only closed them, without any signs of resentment. Its throat was afterwards cut for the fake of its skin, and when in the pangs of death it struck the ground with its feet, with a force much exceeding that of any other animal; and these seem to be its principal means of defence.

The male and female giraffe resemble each other when young, but as the animal advances in age, the spots on the male become dark-brown, while those of the female continue of a ferruginous call: the latter is, however, said to acquire the dusky shades of the male when very old. The tubercle on the forehead, which occurs in both sexes, is smaller on that of the female than the male, and the female has also four teats as in the cow. According to Vaillant, the teeth in the giraffe, thirty-two in number, are situated thus: six grinders on each side, both above and below; no front teeth in the upper jaw, but eight in the lower. The horns, both from their size and form, says M. Voitnier, seem intended merely for ornament; they appear to be excrescences of the os frontis. These conflit of a porous bony sublunary, covered externally with short coarse bristly hair: they terminate abruptly in a flattish or slightly convex head, but little wider than the other parts of the horn, and are edged with stiff bristles all round the outline. The hoofs are moderately large and black. All the accounts we have of the giraffe agree in representing its hind quarters as about two feet and a half lower than its withers; but from observations made by profeessor Camper on the complete skeleton of the animal formerly in the collection of the prince of Orange, it would appear, that naturalists have been mistaken in this particular. That its fore legs are longer than its
CAMELUS.

binder legs is true, but the difference is not more than seven inches, which, in a height of seven feet, is of small concom-quence. It may, however, be rendered apparently more consid-erable by the obliquity of the thigh bone with respect to the tibia, when compared with that of the humerus to the radius.

The giraffe is chiefly a native of Ethiopia, but there are other parts of Africa, and of Asia likewise, which this in-tegrating animal inhabits. At the Cape of Good Hope they seem to be not very uncommon. They are also found as far in the interior of Africa as Senegal, but not, as some say, in Guinea, or any of the western parts, nor very far to the southward. These animals are sometimes seen in small groups to the amount of five or ten together, and often disturbed, run off with great celerity. They are principally found in forests living on herbage of various kinds, but chiefly on the foliage of trees: there is a species of mimosa, in particular, which the natives of the Cape call kannap, and the Dutch colonists, jumel-deer, which the giraffe is remarkably fond of. The Hottentots affirm, that the female goes twelve months with young, and has never more than one foal at a time. The fleth they deem excellent, and often hunt and kill them for the sake of food, and for the skin of the animal, the latter of which forms a thick and durable kind of leather. In Arabia, the giraffe is known by the name of sfrofah, and xarnapan, or xarnapna.

CAMELUS, in Aëronomy, a new cendelation of the northern hemisphere, formed by Hevelius, con-fiting of 32 flars first observed by him, situate between Cepheus, Cassiopeia, Perseus, the two Bears, and Draco, and containing 85 flars in the British Catalogue.

CAMELUS, in Entomology, a German species of SCARA-

batus, describ'd by Olivier and Fabricius; the thorax of which is four horned; shield somewhat incrusted behind; body black. Obf. The female has a double transverse carti-
nated line on the feutel, the poller one of which is larget.

CAMELUS, in Ornithology, Struthio Camelus, the black, or common ostrich. This is specifickly distingksh'd from the other species of Struthio, by having only two toes to each foot. Linn. &c.

The ostrich is, without doubt, says Dr. Latham, the largest bird in the creation; it is near eight feet in length, and, when standing upright, is from six to eight feet in height. A specimen of this bird, nearly as large, is preferred in the Leverian museum. We have also seen in the menagery, at Exeter Change, a living ostrich rather larger. Two ostriches were shewn in London in the year 1750, the male of which, it is recorded in the Gentleman's Magazine, was ten feet in height, and weighed three hundred weight and one quarter. This last is the largest bird of the kind we ever heard of. The ostrich has a small head not much unlike that of a goat; the bill is also somewhat similar, but less deprev'd, and four inches and a half in length, horn colour, with the tip dufky. The irides are hazel; eye-lids belet with hairs; the head, and greatest part of the neck, are bare of feathers, and of a dufky colour, with a few fattered hairs. Lower parts of the neck and body are covered with black feathers, which are angularly loofe in their webs, and totally unlike thofe of any other bird; the quill-feathers, and thofe of the tail, are snowly white, long, and beautifully waved, with the tips of some few of them black.

On each wing are two flurs about an inch in length, and on the breast is a callous, bare, and hard substance, serving the bird to reft on when it ftrikes forward to fit on the ground: thighs and fides of the body naked; legs strong, greyish brown, and furnished with two claws, the outer one of which is very short, and without a claw. The female differs in having those feathers brown, which in the male are black.

This bird inhabits Africa, and thofe parts of Asia that lie contiguous to it, but appears to be most abundant about the Cape of Good Hope. The egg is as large as a child's head, and capable of containing better than five pints of liquor. The female is suppos'd to lay nearly fifty eggs in a fefion; from thirteen to twenty is the amount of those usually con-tained in a fingle neft, according to Dr. Sparrman. Thofe the female ostrich buries in the fand, where, it is the com-mon opinion, they are hatch'd by the heat of the fun, the female taking no further care of them after once depositing them in safety; but this is contradicted, in a great meafeure, by both Kolben and Sparrman. Kolben tells us the male and female fit on them by turns, and that he has feen them hatching their eggs hundreds of times, and as often driven off, and taken their eggs to fend humelf and his friends; one of which would prove a meal for three or four perfons; and besides this, they are said to be very good.

Dr. Sparrman thinks, the male and female fit on the eggs by turns, as in one of his jouneys, in the month of December, he ftrighted a male from the neft, which was made only on the bare fand, on which the eggs lay fattered and loofe, and were eleven in number. Buffle allows, that the oilrich fearely ever lofes fight of the eggs, but afferts, that it is only in the more northern parts that the female has occasion to fit on them, the fun being alone fufficient to hatch them in the torrid zone. Kolben fays, the young ones cannot run when first hatched, but are fupplied with grafs and water by the old ones. The adult birds are endowed with great strength.

Ostriches feed on vegetables, and besides which they are frequently obsev'd to swallow various other substances. Old nails, and other bits of iron, lead, copper, or glass, are alfo indiscriminately taken into the fomach of this voracious bird. It is a vulgar notion, however, that the oilrich can eat fuch fubltances; that they fwallow them is clear, but it would be the height of abfurdivity to imagine they can digest them; nor do they always fwallow them with impatience, as they are liable to many accidents, from their promifcuos manner of feeding, and the swallowing off iron and other fuch fubltances oftentimes proves fatal to them.

The natives of thofe parts which the oilrich inhabits moft commonly take them by hunting. They follow the birds at a distance for two or three days, when the birds, faffigued by being perpetualy harraffed, and wanting time to take food, are very early overtaken, and killed with their clubs. Other oilrich hunters conceal themselves in the skin of one of thofe birds, and by that means approach near enough to furprise them. It is alfo uial to hunt them on horseback with dogs, and after overtaking them to appro-ach to clofe as to apply the hooked end of a flaff round their legs, which throwing them down they may be either taken alive, or knocked on the head immediately.

The capture of these birds is an object of confequence to the Africans. Oilrich feathers are in requeat for ornamental purpofoes in all parts of the world, and form an article of commerce between the Afrians and European powers. The skin of this bird is very thick, and being of a durable nature is a good fubltitute for leather. The fleth is eaten by the Hottentots, and the eggs are in esteem both with the Afrians and European fettlers. The egg-fiells answer for drinking cups and other utensils, and are ofien mounted in gold or silver for that purpofe. They are hard and duraible, and, when fine, are not greatly inferior to ivory. In the East
Camelus

End both the cell of the bird, and that of the casowary, are administered as medicine.

Camelus, or Camel, in Zoology, a genus of quadrupeds, which, in the Linnaean system of animals, stands in the Pre-erter order of the class Mammalia. The character of this genus consists in having no horns: the front teeth in the lower jaw fix, rather thin, and broad: laniarius or canine teeth distant, three in the upper jaw, and in the lower two: upper lip cleft or divided.

Zoologists discriminate several species of the camel tribe, independently of those animals which are known in Europe by the application of the Arabian camel, or dromedary, and the Bactrian camel. Gmelin speaks of five, making altogether, with the two preceding, seven species, namely, Camelus dromedarus of Linnaeus, the common, or Arabian camel; Camelus lucasanus, Linnaeus, the Bactrian camel; Camelus camelus, Linnaeus, the llama, or llama; Camelus guanaco, the guanaco, guanaco, or allo-camelus of Gmelin; Camelus camulus, the chillicoepe, or Peruvian sheep of some authors; Camelus vicugna, the vicuna; and Camelus palo, the paco, or paces of Pennant.

The first species, Camelus dromedarus, is distinguished by having only one hump, or protuberance, on the back. The general height of this camel, measured from the top of the dorsal bunched to the ground, is about five feet and a half; but from the top of the head when the animal elevates it not much less than nine feet: the head, however, is usually so carried as to be nearly on a level with the hunch, or rather below it, the animal bending the neck extremely in its general posture: the head is small; the neck very long; the body of a long and meagre shape; the legs rather slender, and the tail, which is slightly tufted at the extremity, reaches to the joints of the hind legs: the feet are very large, and are hoofed in a peculiar manner, being divided above into two lobes, not reaching through the whole length of the foot; and the extremity of each lobe is guarded by a small hoof: the under part of the foot is covered with an extremely strong, tough, and pliable skin, which, by yielding in all directions, enables the animal to travel with peculiar ease and security over dry, hot, rocky, and sandy regions, which would soon parch and destroy the hoof.

On the legs are six cavities, viz. one on each side of the body beneath the croup; one on the inside of each fore leg, on the upper joint, and one on the outside of each hind leg, at the bottom of the thigh. On the lower part of the breast is also a large callos or tough tubercle, which is gradually incresced by the constant habit which the animal has of resting upon it in lying down.

One cannot be deceived as to the native country of the camel, says the energetic Buffon, when we consider the nature and condition of these animals; they are the natural inhabitants of the burning deserts of Arabia, from whence they have been gradually diffused over the rest of Africa and Asia. It has been tried, but without effect, to multiply camels in Spain; they have also in vain been transported to America, but they have succeeded neither in one climate nor in the other, and they are seldom to be met with in the East Indies beyond Surat and Ormus. It is not absolutely to be said, that they cannot subsist and increase in the East Indies, Spain, America, or even in colder countries in Europe, by keeping them during winter in warm stables, feeding, and treating them with care; not allowing them to labour, or suffering them to walk out but when the weather is fine, they may be kept alive, and we might even hope to see them multiply, but their offspring will be necessarily small and languid. They lofe, therefore, all their value under the influence of our climates, and instead of becoming useful, the rearing of them is attended with much fruitless expense; while on the contrary, in their native country, they may be laid to produce all the wealth of their masters. Camels have constituted the riches of Arabia from the earliest ages of the world; the modern Arabs estimate their wealth by the number of these useful animals.

The camel is veuneated by the Arabs as the gift of Heaven, as a sacred animal, without whom they could either find food, travel, or travel. They also call its shell, especially that of the young camel, which they reckon excellent. The hair of these animals, which is fine and soft, and is renewed every year, serves them to make fleeces for their clothing and furniture. Fille with their camels, they not only want for nothing, but they fear nothing. In a single day they can traverse a tract of fifty leagues into the desert, and thus escape the reach of their enemies. All the roads in the world, says Buffon, would perish in the pursuit of a troop of Arabs: figure to yourself, for instance, observes this writer, a country without verdure, and without water, a burning sun, an air always clear, plains of sand, and mountains still more parallel, over which the eye extends without perceiving a single animal being; a desart earth perpetually tossed by the winds, presenting nothing but bones, scattered shotts, rocks perpendicular or overthrown; a naked desert where the traveller never breathes under a friendly shade, where nothing accompanies him, and where nothing recalls to mind the idea of animated nature; an absolute solitude, infinitely more frightful than that of the deepelt forest; for to man trees are, at least, visible objects; more solitary and naked, more lost in an unbounded void, he every where beholds the extended space surrounding him as a tomb: the light of the day more dismal than the darkness of night, serves only to give him a clearer idea of his own wretchedness and impotence, and to prevent before his eyes the horror of his situation, by extending round him the inmens abyss which separates him from the habitable parts of the earth; an abyss which in vain he would attempt to traverse, for hunger, thirst, and burning heat haunt him every moment that remains between despair and death. The Arab, nevertheless, by the assistance of his camel, has learned to surmount, and even to appropriate these frightful intervals of nature to himself. They serve him for an asylum, they secure his repos, and maintain his independence. But man never uses any thing without abuse. This fame free, independent, tranquil, and even rich Arab, instead of regarding his desarts as the ramparts of his liberty, pollutes them with his crimes. He traverses them to carry off gold and slaves from the adjacent nations. He employs them for perpetuating his robberies, which unfortunately he enjoys more than his liberty. An Arab, who defines himself to this kind of piracy, is early accustomed to the fatigues of travelling, to want of sleep, and to endure hunger, thirst, and heat. With this view he ingrants, tears, and exercises his camels. A few days after their birth, he folds their limbs to remain on the ground, and in this situation he loads them, with a pretty heavy weight, which is never removed but for the purpose of replacing a greater. Instead of allowing them to feed at pleasure, and to drink when they are thirsty, he regulates their repasts, and makes them gradually travel long journies, diminishing at the same time their quantity of food. When they acquire some strength, he exercises them to the course; he excts their emulation by the example of horses, and in time renders them equally swift and more robust. At length, when he is assured of the strength, fleete-ness, and sobriety of his camels, he loads them with whatever is necessary for his and their subsistence, departs with them, arrives unexpectedly at the confines of the desert, robs the first passenger he meets, pillages the dragging habita-
The ancient believed that the dromedary had a natural antipathy to horses. Xenophon affirms this: and Pliny repeats it on the credit of Xenophon. Others have said that they entertain an equal aversion for affies and mules. But the truth appears to be precisely the contrary; for all these animals, at least in Egypt and Turkey, live and travel together. Sonnini affirms that there is always an affi at the head of a file of loaded camels, to whom he officiates as leader, the filly of the camels being haltered to the affi, and following him step by step. Others have agreed in the assertion that camels must not be beaten too much, or on improper occasions, which would soon make them turn refractory; but the drivers of the laden camels have a thick with which they beat them, and they who ride upon camels, whip them with a long strip of leather. They are also urged on with a clicking of the tongue, much like that employed by us in Europe to in spirit our horses. It is proper likewise to remark, while on this subject, that the Bedouins never whistle, and that it gives them pain if a traveller, ignorant of their customs, should whistle in their company. Sonnini is persuaded that even when the Arabs sing on their march, their object...
of a pocket compass, to point out the direction in
which he travels, and can tell what that was, and the
number of days employed by the caravan in going from
one place to another, may contribute, very considerably,
to the improvement of the eastern geography. See CA-
RAVAN.

The facility with which the camel abdains from drink in
their journeys over the burning deserts, is more remarkable
than their abstinence from food; and it is so extraordinary, that,
according to Leo Africanus, they are capable of remaining
without drink for 15 days without prejudice to their health;
but after long abstinence, it is said that they are apt, on their
first meeting with water, to drink so greedily that it proves
suddenly fatal to many of them. This facility does not pro-
ceed from habit alone, but is rather, as Buffon observes, the
effect of their structure. Independently of the four stomates,
which are common to ruminating animals, the camel is sup-
pelled of a bag, which serves him as a reservoir to retain
water. This fifth stomach is peculiar to the camel: it is so
large as to contain a great quantity of water, where it re-
mains without corrupting, or intermixing with other
elements. When the animal is oppressed by thirst, or has oc-
casion for water to macerate his dry food in ruminating, he
causes part of the water to ascend into his stomach, or even
as high as the throat, by the mere contraction of certain
mucous tubes. It is by virtue of this construction that the camel
is enabled to pass several days without drinking, and to take
at any one time a prodigious quantity of water, which remains
in the reservoir pure and limpid, because neither the liquors
of the body nor the juices of digestion can mix with it.
There can be no doubt that the water preferred by the camel
in this receptacle remains perfectly pure, all writers
agreeing in this particular; it is no very uncommon circum-
stance in passing through the deserts for travellers to kill
a camel in order to obtain a supply of water from this recep-
tacle; when they are delirious in this necessary article, and
cannot procure it in any other manner. The loss of a camel,
for such an occasion, is of the least consideration, as the flesh
affords the traveller and Arabs a rich repast, independent of
the advantage of being supplied with water; influences of this
kind occur in Bruce's travels to discover the source of the Nile,
and various others.

That water, in cases of emergency, is taken from the
stomach of the camel, is a fact neither doubted in Syria, nor
thought strange. In proof of this fact, it is hardly necessary
to allege the testimony of an Arab historian (Beedawi) who,
in his account of the prophet's expedition to Tabue against
the Greeks, relates, among other difficulties of the army,
that they were reduced to the necessity of killing their camels
for the sake of the water contained in their stomaches. Sale's
p. 245. However, Mr John Hunter, who dissected a ca-
 Abel, lay no reason for alliging more than four stomates to
this animal; though he could conceive that water might be
found in the pouch little impregnated by the dry provender
of the desert, and readily separating or draining from it.
Mr. Home also, who afflicted at the dissection, and who pre-
pared the different stomates in a dry state for the purpose of
shewing their internal structure, and communication with one
another, inferred, from this preparation, that the number of
stomaches is four, as in other ruminating animals; so that it
cannot be said that there is a distinct reservoir for water:
but the second stomach has a very peculiar structure, being
made up of numerous cells, several inches deep, with their
mouths uppermost, and orifices apparently capable of mus-
cular contraction. When the animal drinks, says Mr. Home,
it probably has a power of directing the water into these cells,
CAMELUS.

instead of letting it pass into the first stomach, and when these are filled, the oil of the water will go into the first stomach. In this manner a quantity of water may be kept separate from the food, serving occasionally to moisten it in the passage to the fourth or true stomach. The testimony of travellers to water being found in the stomach, and Dri- benton, upon inspection, meeting with it in the second stomach, when compared with the structure of the parts, seem to confirm the above conjecture. See Raffles's Nat. Hist. of Aleppo, vol. ii. p. 436.

If we reflect on the diffimilarity of this animal to other quadrupeds, Buffon conceives that we cannot doubt but its nature has been considerably changed by constraint, slavery, and perpetual labour. Of all animals, says he, the camel is the most ancient, the complete, and most laboriousrace. He is the most ancient race, because he inhabits those climates where men were first polished. He is the most complete race, because in the other species of domestic animals, as the horse, the dog, the ox, the sheep, the hog, &c., we still find individuals in a state of nature, and which have not submitted to man. But the whole species of the camel is enslaved, for none of them exist in a state of savages and liberty and independence. Lastly, he is the most laborious race, because he has never been nourished for pomp like most horses, nor for amusement like most dogs, nor for the sake of the table like the ox, the hog, and the sheep; because he has always been made a beast of burden, whose men have never taken the trouble of harnessing or yoking in machines, but have regarded the body of the animal as a living carriage, which they may load or overload even during sleep, for when pressed, the load is sometimes not taken off, but the animal lies down under it with his legs folded, and his body resting on its stomach. Buffon explains in this passage with considerable animation on the severity of the servitude to which this useful animal is condemned, but the degraded picture he has drawn, it must be allowed, admits of some alleviation. It is not in all countries it inhabits that the camel is dealt thus rigorously with; there are many parts in which he is held in greater favour, and treated with more indulgence than this lively writer intimates. That the camel is kept for pomp as well as utility in various parts of Asia and Africa, is certain. Many authors speak to this effect. Mr. Bruce frequently law them saddled and harnessed in Africa. Samhni speaks of them as highly useful for the saddle. In the east they are oftentimes richly caparisoned for the service of the great. In China, a particular breed of them is trained like our race-horses for the course, and for the performance of journeys that require expedition. Camels are also instructed sometimes for military purposes. Mr. Bruce describes the arrival of the caravans from Europe executed by 400 Abhabs, or fighting men, all upon their camels, each armed with short javelins. The manner of their riding he thought more whimsical than calculated to inspire terror; there were two small saddles on each camel, one suspended on each side of the animal, so that the two abadi on each camel sat back to back, a mode in which their practice of fighting he allows may be convenient enough, but had they ventured to contend with the European travellers every hair might have killed two instead of one. The camels, however trained by the Egyptians for war and for the saddle, were found of considerable service in the French armies for the use of their dismounted cavalry, when they lately invaded Egypt. So far, indeed, from the camel being ever treated with the rigour Buffon describes, and never being harnessed or yoked in machines, as he affirms, the testimony of every traveller contradicts it. We know that in Tartary the camel is regarded with as much, if not more attention than the horse, Opulent Tartars, according to Pallas, take a pride in conveying their families from place to place, or in travelling to town in covered waggons drawn by camels; the yoke is placed between their neck and the first dorsal branch (for it is a variety of the Désiian camel they possess), and is of a peculiar construction adapted for the purpose. These are seldom used as beasts of burden, but are often yoked to the large four-wheeled waggons or Medfobari, especially on bad roads and during winter. In Arabia Pallas conceives they would be serviceable both as beasts of burden, and in putting to flight any cavalry, the horses of which are unacquainted to the light of these curious animals. And indeed the Russians begin to be aware of the value of the camel for the purposes of war. In the year 1766 no less than a thousand camels were bought up in Crimea Tartary for the use of the army in Peru. In Russia the price of a full grown camel is generally from 100 to 150 rubles, or from 22i. 10s. to 37l. 15s. sterling. The Egyptians keep large numbers of camels, which are bred and sold by them to the Arabs. They fetch a pretty high price. At Cairo, according to Sonnini, they are worth 4 or 525 livres each, which is about the lowest average price they may be sold for. In Upper Egypt they are not so dear; their price varying from 250 to 350 livres. They are equally numerous in Barbary, but they become more scarce towards the western coasts of Africa. Among other hardships endured by the camel, Buffon complains, that it is never nourished for the table like the ox, the hog, or the sheep; another affront by no means well founded; when by indulgence they have met with any accident that is likely to incapacitate them for the burden, they are commonly fattened and killed for this purpose. We frequently hear of the large camels being butchered for beef. Mr. Bruce and his party were frequently regaled with a comfortable meal of camel's flesh stewed, and he speaks of it as an ordinary circumstance on any occasion of feasting or rejoicing in Africa to kill a young camel, and serve it up to table. The Jews distinguished over the nations, or African parts of the world, do not eat the flesh of the camel, because they are expressly forbidden by the Mosaic laws (Levit. chap. xi. ver. 4.), but the Arabs, and the other inhabitants of Egypt, &c, with the exception of the Christians, consider it a dainty and wholesome food. A curious circumstance is mentioned by Sonnini respecting this: in those cities, he tells us, where the fanaticism of the Mahometans is at the highest pitch, as in Cairo and Alexandria, it would be deemed a profanation to eat the flesh of the camel to the Franks, who, however, on their part, are by no means discreet of it, for, though it has no disagreeable flavour, it is hard and dry. In Barbary camels' tongues are salted and flaved for exportation to Italy, and other countries, and these form a very good dish. Besides the highly beneficial properties of the camel for the saddle, as a beast of burden, for the yoke, and as wholesome food, the camel pollutes others not less valuable. Its hair is an important article of commerce, and serves likewise for the fabrication of the tents and carpets of the Arabs, and for wearing apparel: rich flavels are made of the hair of camels that are in much request. The Tartar woman manufacture a narrow sort of cloth of it which is used of its natural colour: a broad cloth is, or at least was formerly produced from the same material at the manufactury of Nusoroffis, or Ekaterinosford in the Crimea. Curious cloths are also formed of it in Persia at this time. It is known by the French in trade, under the improper name of "Laine de Chevern." The most esteemed is brought from Persia by the caravans of Erivan, Tiflis, Erzoum, and Tern. There is some of three qualities; the black, the red, and the gray. The black is the dearest; and the gray is worth only
only half the price of the red. Some of it is brought annually to Marsilles by way of Aleppo, Smyrna, and Constantinople. This last only exports from 80 to 120 bales, weighing about 300 pounds the bale. Smyrna and Aleppo feed a much more considerable quantity. This kind of wool is employed in the manufacture of hats; and is purchased by all the European nations that trade to the Levant. The French, however, consume the greatest quantity of it. The English employ but a small quantity of the black, which they procure at Smyrna. Oliver's Travels in the Ottoman Empire, p. 215. — The dung of the camel is used as fuel, and in Arabia the milk of the females affords one of the staple and necessary articles of the Bedouins.

The camel that carries Mahomet's sandal, which the caravan of pilgrims offer yearly on the tomb of their prophet, is exempted from the rest of its life from all services. It is even pretended that this happy beast will rise again at the general resurrection, and enjoy the pleasures of paradise.

The general aspect of the camel, at first sight, is apt to impress the mind with the idea of deformity; and in particular the dorsal bunch has the appearance of some accidental protuberance rather than a truly natural conformation. This idea seems to have operated so powerfully on the mind of Buffon, that he has not scrupled to advance an opinion that this part, as well as the pectoral bunch, was originally produced from inflame in contantly loading the animal with heavy burthens, and that having arisen, it has been transmitted by descent, and continues to form a permanent character. In confirmation of this theory, he infers, that although these callousities are to be met with in every camel, yet they plainly prove that they are not natural, but are produced by excessive constraint and pain, from being often found filled with pus. "The breast and legs, therefore, (continues this writer,) are deformed by these callousities; the back is also disfigured with a single, or double bunch; and both these bunches and callousities are perpetuated by generation. As it is evident the first deformity proceeds from the custom of forcing them when quite young to lie on their forelegs, with their legs bent under them, and in that cramped position to bear not only the weight of their own body, but also the burthens which are put upon them, it must be presumed that the bunch, or bunches, owe their origin to the unequal compression of heavy burthens which are put upon them, and have raised the flesh, and puffed up the fat and skin; for these bunches are not bony, but composed of a flabby substance, partly of the same constitution as the udder of a cow. Thus the callousities and the bunches should be equally regarded as deformities produced by the continuance of labour and constraint of body; and though at first accidental and individual, are now become general and permanent in the whole species. It may also be presumed that the bag containing the water, and which is only an appendage to the pouch, has been produced by a forced extension of this viscus. The animal after enduring thirst for a long time, taking at one time so much and perhaps more water than the stomach could contain, this membrane would become extended and dilated, as has been observed in the stomach of sheep, which extends and acquires a capacity in proportion to the quantity of its aliment. The stomach is very small in sheep that are fed with grain, while in those that are fed on herbage it becomes very large." These conjectures (Buffon allows) however, would be fully confirmed or destroyed, if any of these animals could be found wild to compare with the domestic; but these animals do not exist anywhere in a natural state, or if they do, no one has yet remarked or described them; and we must therefore suppose that all which is good and fair about them they owe to nature, and that which is defective and deformed is occasioned by the labour and heavy impastion on them, by the dominion of man." The Arabian camel, or that with two dorsal bunches, is, however, said to be found wild in the desert parts of Asia between India and China, and to be larger than the domesticated animal, and should be true, the rearing of Buffon falls to the ground. What he has advanced may apply to large numbers in the callousities on the legs, or to that of the bunch, which may arise from the sand he alludes; but with respect to the accidental protuberance of the dorsal bunches, his conjecture appears improbable. We have every reason to believe that those bunches cannot be formed from the superabundance of nourishment, although they may be inflated, and appear more plump from this cause: those bunches in long journeys where they are flinted for food, it is said, diminish gradually, and are reduced so flat at last, that their places are only discovered by the length of the hair, which is always longer on those parts than on the rest of the back; but the other parts of the body waste in a similar manner at the same time, and when the animals are fatigued again, as they acquire flesh in other parts, those dorsal bunches resume their former bulk. So that upon the whole we are persuaded those dorsal bunches are natural both for this reason, and because throughout all the varieties of the two most frequent kinds of camel, the Arabian and Bactrian, one race is constantly distinguished by having no more than a single dorsal bunch, and the other two. Were those bunches the effect of accident or of heavy pressure only, we should certainly find nature less constant in this particular.

The ancients have said that these animals are in a condition for generation at the age of three years; but this is doubtful, since they have not at that age attained to half their growth. The young camel licks its mother 12 months, and when designed for labour, to make him strong and robust, they leave him to feed or graze for a longer time; nor do they attempt to load him or put him to work till he has attained the age of four years. The camel commonly lives 40 or 50 years, but seldom longer. The labouring bunches are generally confined, as they leave out one male for eight or ten females; they are without doubt weaker than the males, but they are more tractable, and ready for employment at all times. The males, on the contrary, are not only ungovernable but even furious in the rutting time, which continues for the space of 40 days, and returns every spring. At this season they emit frequently a kind of hoarse lowing, with a strong rattling in the throat; they continually foam, and one or two red vesicles, as large as a hog's bladder, and of a disgusting appearance, hang out of their mouths. They are extremely dangerous at such times; it is said that in their fits of rage, they will sometimes take up a man in their teeth, throw him to the ground, and trample him to death. The female goes 12 months with young; and like other large quadrupeds produces but one at a birth.

It is remarkable that the dromedary of which we have been speaking is the only cost of camel found in Egypt. If we follow the distinction made by Arrebote and Pliny, and repeated by Buffon, (fasc. Sennus,) between two species of animals which nature has differentiated by a constant, and very striking mark, there are no camels in Egypt. In fact, there is no animal of that kind which has two bunches on the back (Camelus Bactrianas, Linn,;) all that are found in this country have only one, and are consequently of the dromedary species. The Arabic word djezmel, which answers to camel, is likewise the only one used by the inhabitants of Egypt for that breed, which is the most common, most useful.
ful, of great size and strength, heavy of foot, and employed for carrying burthens. On the contrary, that which is left tall and bulky, and possessed of great agility, is called dromedary by the Europeans, and *badjs* or pilgrims usually ride. Sonnini likewise mentions a smaller kind of camel in Egypt which is much less known, and of which he only saw a few among the Bedouins; they are of a shorter make than the common fort; their body is more round; they are not so tall; their hair is longer and thicker, and they are of a fawn colour inclining to brown.

In conclusion of this article we may adopt the words of Buffon: by uniting under one point of view all the qualities of this animal, and all the advantages which are gained by him, he must be acknowledged to be the most useful of all creatures under subordination to man. Gold and silk are not the true riches of the East; the camel is the treasure of Asia. He is of greater value than the elephant, as he does as much labour, and does not consume a twentieth part of the food. Besides, the whole species is subject to man, who propagates it and multiplies it as much as he pleases. But he has no such dominion over the elephant, which he cannot multiply, and the individuals of which he cannot conquer without more trouble and difficulty. The camel is not only of greater value than the elephant, but is perhaps equal in utility to the horse, the ass, and the ox, when their powers are united. He carry as much as two mules, though he eats less, and feeds on herbs as coarse as those the ass will eat. The female furnishes milk longer than the cow; the flesh of young camels is as good and as wholesome as veal; the hair is finer, and in more request than the finest wool. Even their excrements are useful, for sal ammoniac is made of their urine; their dung, when dried and powdered, serves them for litter, as well as for the horses with whom they frequently travel in countries where neither hay nor straw is to be obtained. Their dung (chopped and intermixed with straw) forms an excellent fuel, burns freely, gives a clear and nearly as hot a flame as that of dried wood, and which is of great use in the deserts, where not a tree is to be seen, and where, for the want of combustible materials, fire is as scarce as water.

There are several varieties of this kind of camel differing in size, strength, colour, and other slight particulars, as in one of the different breeds of horses, and other domesticated animals; and there are likewise hybrid varieties produced between this and the following species. It should be further stated, to prevent confusion, that the dromedarius of Gessner is not the same animal as Jonston describes in his history of quadrupeds by that name; the latter means the Bactrian, or two bunched camel. Knorr follows this writer, calling the Bactrian camel Dromedar, Trampeltier oder Dromedar; but this, as already shown, is not the true dromedary. Forkeleti distinguishes the Arabian camel, our present species, and dromedary of modern authors, by the title of Camelus vulgaris: it is Camelus of Jonston; and Camelus Dromed of Gessner.

On medals, the camel is the symbol of Arabia, when found on the coins of any other nation. Thus, on a medal of the genus Plautus, we find a woman's head with a mural crown, *A. Plautus Aed. Cur. S. C.* and on the reverse, *judaeus*; and in the exergue, *Barbicus*; the device, a man on his knees holding with his right hand a camel by the bridle, and with the left, a branch of palm. It also denotes alliance with Arabia.

**Camelus Bactrianus**, the Bactrian camel, and Le Chatelier of Buffon, a species known from the preceding by having two dorsal bunched. Pallas calls it the Tauridian camel.

This kind attains in the peninsula of the Crimea to a larger size than among the Kalnus Tartars. Pallas observed them in that country of a white and yellowish white colour, and sometimes of a blackish colour; but these last were less frequent than the others. If we may credit Sonnini, this fort is not to be found in Egypt, where they alone rear, and cultivate that kind which we denominate the Arabian camel. It is the Tauridian camel that generally prevails in Russia and Siberia; the mild winter of the Crimea in particular is very favourable to the habits and propagation of this animal. This is the camel which authors mention as still existing in a state of nature, in the deserts of the temperate parts of Asia, more especially in those between China and India, and which is reported to be larger than the domesticated race. The Arabian camels are beyond comparison more numerous, and universal than this kind, which is chiefly confined to some parts of Asia; a moister soil and more temperate climate being more congenial to its habits than the hot and parched regions of the African deserts, which the Arabian camel inhabits. It has acquired the name of Turkish camel from being found in Turkestan, and some other parts of the Levant. From Pallas it may be seen that the Tauridian camel is more common in various districts of the Russian territory than is generally conceived. They rarely employ this creature like the Arabian camel as a beast of burden, but train it for the saddle, and for drawing travelling waggonets, and similar machines in the manner Europeans train horses. This animal thrives better in the milder parts of Tartary; but it bears even the severity of a Siberian climate, being found in the vicinity of the Baikal lake, where we are told the Mongols and Bursats keep great numbers of them. Here they are fated to live during winter on willows and other trees, a diet affording little nourishment, and in consequence of which they become lean and meagre towards the latter part of the winter leafen. In April they lose their hair, and go naked all May amidst the frosts of that severe climate. They thrive well in dry grounds, and among the salt marshes. This animal is cultivated in China, where they have a breed of peculiar swiftness, that bears the expressive name of Ferg Eko, or camels with feet of wind. See the article Bactrianus.

**Camelus glama**, the Lama, is the third species in the Linnaean genus camelus. The modern French naturalists constitute a distinct genus of the Lama, camelus glama *Linn.*, the huanaco, camelus huanacus, and camelus llama of Exeloben; permniceat of Ferdinand z; and guanaco of Ullao. With these naturalists the Lama forms the second species of running animals, and is characterized as having from four to five incisive teeth in the lower jaw; the fissure in the upper lip; the length of the neck; and absence of the dorsal bunches. This division of the camelus so far as relates to the species glama is not objectionable: the absence of the dorsal bunches would form a good generic distinction; but in adopting it, we ought certainly to exclude the species huanacus, or guanaco, that animal being remarkable for the gibbosity of the back. It may, however, be better to retain the Lama tribe with that of the camelus till we are better acquainted with those animals; for it is not to be disguised that an inexplicable confusion prevails among writers with regard to some of them. They are all natives of South America, and are at belt but imperfectly known to the naturalists of Europe. Even in following the belt authorities, when treating of them, we are not entirely without suspicion that
that no great dependence ought to be placed on the character of the camel, to which all the varieties of the species. It is not improbable that some of those which are at present considered as distinct species may hereafter prove to be only varieties of the same species.

The *Llama* is distinguished by having a hump on the back, and the back smooth, *Lama*. This animal, described by several naturalists under the name of *Ovis Persicana*, or Peruvian sheep, is found in most parts of South America, and is most plentiful in Peru, where it inhabits, in a wild state, the high and cold districts of the mountains, feeding on numerous herbs, and flying with great rapidity on the light of mankind. The general size of the glama is nearly that of a flag, measuring four feet and a half in height to the top of the shoulders, and about six feet in length from the nose to the tail. The neck is of great length: the head small: the back slightly elevated; and the whole animal bears some resemblance to a camel, on a small scale. Its general colour is a light ferruginous brown, paler or whiter on the under parts, and sometimes it is said to be variegated with darker and brighter shades on different parts, and to have a black stripe down the back to the beginning of the tail. The hair on the wild animal is long and shaggy. On the breast is a protuberance, from which is exuded a yellowish kind of oily secretion. The voice of the glama resembles the shrill neighing of a horse. When angry or attacked, it strikes with its feet, endeavors to bite, and, at the same time, exalutes from its mouth a quantity of saliva, which is commonly affected to be of a caustic or acrimonious nature, and to excite a slight inflammation of the skin, but Molina thinks this observation defective of truth.

Buffon is persuaded that the glama, or glama of the Peruvians is the same animal as those people call guanaco, or huanauc, the former being altered from its primitive appearance by domestication. Molina is entirely of a different opinion, and we have recently had an opportunity of ascertaining that the Peruvians do themselves consider these two animals distinct, and are well acquainted with both kinds in a wild state, as well as that of domestication. It is singular, as Buffon remarks, that although the llama, and two or three other analogous animals are bred in Peru and Mexico, as the horses are in Europe, or the camels in Arabia, we scarcely know anything concerning them; and notwithstanding the Spaniards have had possession of those wild countries for above two centuries, not one of their authors has given us as accurate history as any exact description of them. It is affirmed that they cannot be transported into Europe, nor even brought from their heights but at the risk of their lives in a short time. But this is not entirely true: it is certain that after the conquest of Peru, some of them were transported into Europe. The animal spoken of by Guenter under the name of allocamelus, and of which a figure is given in his work, is of the llama family, (guanaco) and was brought alive from Peru to Holland in 1583. In 1777 there was a living lama in the veterinary school of Allert, the same doubt from which Buffon took his description of this animal. It was remarkable for the mildness of its manners and disposition. When ranging at large it seldom walked, but proceeded in a sort of trot or gallop. This animal subsisted on herbage, and has been known to neglect drinking for the space of six months together,abundant was the saliva with which the mouth was constantly moistened.

Peru, according to Gregoire de Bolivar, is the native country of the llamas: they have been conveyed into other provinces, but more for the sake of curiosity than utility. In Peru, from Patzé to Corrientes, these animals are in the greatest numbers: they constitute the chief riches of the Indians, and add not a little to the wealth of the Spanish. Their flesh is excellent food, having the flavour of mutton. Their wool may be spun into beautiful clothings; and they are capable of carrying heavy loads in the most rugged and dangerous ways. The draught of them will travel with from one hundred and fifty, to two hundred and fifty pounds, weight on their backs; their pace is slow, and their journey is seldom above fifteen miles a day; but though slow in their progress, they are sure-footed, easily led by a rope, and travelling safely amongst the most difficult rocks, where men can scarcely accompany them. They commonly travel for about five days together, and are then obliged to rest for two or three days before they resume their journey. They are constantly employed in the mine territory for conveying the Peruvian ore over the rugged hills and narrow paths of the Andes. Bolivar affirms, that in his time, above three hundred thousand of these animals were kept in constant employment by these means. A Peruvian drawing lately brought to England, in which an Indian excede in the use, exhibits two figures of these animals laden with bars of silver, according to the custom of that country: each llama bears two of these bars, which are suspended in a sort of saddle, one on each side of the animal.

The growth of the llama is very quick, and its life is but of short duration. At the age of three years it couples, and remains strong and vigorous till twelve, after which it begins to decline, and becomes entirely useless at the age of fifteen. In their nature they appear to be of a quiet and preternatural disposition. Bolivar remarks, that of all the animals, they are gentle, and phlegmatic, performing every thing with the greatest leisure and caution. When they stop on their journey to rest, they bend their knees very deliberately in order to lower their body without disturbing their load, and when they rise again at the command of their driver's whistle, it is performed with the same precaution; when wearied no blows can provoke them to proceed. They feed as they go along on the grass they meet with in their way; but they never eat in the night, making use of that time to ruminate. When they stop or ruminate, they rest with their feet folded under their bodies. If overloaded or too much fatigued they sink down, and will not rise again though the driver should beat them with the utmost force; and if the driver continues his terror, the animal grows desperate, and destroys himself by beating his head against the earth.

This animal may be truly considered as the camel of Peru. Even before the discovery of South America by the Spaniards, the llamas were domesticated, and employed as beasts of burden by the Peruvians. At present they are preferred to horses by travellers passing over the mountainous regions of this part of the world. Cozer, who lately made a journey of observation in Peru, tells us the Spaniards harness them, and employ them for the conveyance of merchandise in the same manner as the Peruvians did in former days. A good llama colt him eighteen ducats; but the ordinary price is from twelve to thirteen ducats each. The flesh of the young llamas is excellent; that of the old ones is dry and tough. The wool is valuable: the Indians make shoes of the skin, and the Spaniards use it for harnessed. These useful and necessary animals in the country they inhabit are attended with no expense to their masters; as they are cloven footed, they do not require shoes, and their wool renders saddles unnecessary. Satisfied with a small portion of vegetables, or gras, they want neither corn nor hay; and
they are still more moderate in what they drink, as their months are continually moistened with saliva, which they have in greater quantity than any other animal.

The lamas Buffon supposes to be confined to that chain of mountains which stretches from New Spain to Terra Magellanica, and he therefore concludes that they are the natural inhabitants of the highest regions of the globe, and require a parer and more rared air than that of our highest mountains in Europe. A recent writer, in an anonymous history of Peru lately published, observes, that the animals named llamas, paca, vicunas, and huacanos, are natives of the lofty mountains of that country; and states as a singular particular, that although these mountains extend, under the denomination of Cordilleras, to ten degrees of north latitude, with pretty nearly the same proportion of elevation and cold, these animals do not pass from the line towards the north, and are consequently not to be found in the provinces of Quito, Santa Fé, and others, where the climate of the mountains at least is analogous to that of high Peru, in which latter territory the animals in question live naturally, and multiply their species. The sole reason adduced, to account for this extraordinary circumstance, is, that throughout the whole extent of the northern mountains of the Cordilleras, a kind of nature which the Peruvians name yebu, or yebo, and which is denominated by the authors of the Flora of Peru xarava, is not to be found. This plant belongs to the gramineous tribe, and appears to be the natural food of these animals. It is extremely abundant in the mountains of Peru; but in those of Quito, Santa Fé, &c. observers have not hitherto succeeded in ascertaining its presence.

This plant has been called by some ichu, and pojan; it is described nourishing luxuriously on the loftiest pinnacles of those mountains amid the snow and ice with which they are perpetually overmantled.

The lamas couple with difficulty from a natural defect in the structure of the several organs of both male and female. It is oftentimes the labour of some hours, or even of a whole day, all which time is spent in groaning, quarrelling, and spitting at each other. The Indians afflict them on such occasions. They go with young five or six months, and seldom produce more than one at a birth. The female parent has two teats, and the young one follows her as soon almost as it is brought forth.

This animal is known by various names among old writers: it is called camelum in Linnaeus, Charlet; ovis peruana, and pelon ichastel equiti. Hernand. illb. Mexico; hirschemel, Gefn.; camelus peruvianus, groma dieras, Ray; camelus pilis brevissimi, Briff.; llama, Ulloa voy.; and lama, Buffon.

Camelus Huacanos, the huacano, or guanaco of Molina’s Natural History of Chili, is distinguished specifically, according to this author, by having the hair hairy, back gibbous, and the tail erect.

This animal, which Buffon considered to be the same as the former species in a state of wildness, is separated from it by late authors with much propriety, on the authority of Molina. The Peruvians themselves, as already intimated, make the same distinction between these two animals, so that we cannot hesitate to believe them different. It shoud however be lated at the same time, that there are European naturalists of credit who coincide in sentiments with Buffon to this day, that the huacano is the original race from which the lama has proceeded.

Molina offers some cogent reasons in support of his opinion to the contrary. The lama, as he remarks, has the back nearly straight or level; the four limbs of an equal length, and an excrecence on the breast which is almoist con-

flantly humid with a yellowish oily secretion. The huacano exhibits neither of these peculiarities, the back instead of being level is remarkable for its gibbosity; the posterior legs are longer than the anterior ones, in the ascendi-

dng or descending precipices in the chase, it can bound and leap with astonishing velocity; and there is no trace of the pectoral bunch, so conspicuous in the lama; it is besides very far superior in size, and differs in other legs flicking particular.

The huacanos are stronger, swifter, and of a more lively disposition than the lamas: they run like a flag, and climb over the most craggy precipices with the agility of the goat; and their woolly hair is shorter. Their size is equal to that of the horse; the length from the muzzle to the origin of the tail being about seven feet, and the height from four to five feet. The back is much arched; the head round, and nose somewhat pointed; the ears straight, and the tail short and ascending, or turned upwards as in the common flag.

Although these animals are entirely in a state of freedom, they associate in herds sometimes to the number of two or three hundred. When a man approaches they regard him at first with astonishment, without expressing any fear, but shortly, as if by common consent, they blow through their nostrils, neigh like horses, and then, by taking a general flight, seek a refuge on the tops of the mountains. They prefer the north to the south side of the hills. They often remain above the snowly tracts of the mountains; and when travelling on the ice covered with hoar frost, they seem to be in the best condition, appearing the more vigorous in proportion to the coldness of their situation. The natives of Chili hunt the huacano for the sake of its fleece: the dogs have much trouble to follow them, and if they can once gain the rocks, both the hunters and their dogs are oftentimes compelled to give up the chase. They are very numerous all along the chain of the Cordilleras, which are full three thousand fathoms above the level of the sea at Peru, and prefer to that elevation from Chili to the Strait of Magellan. At the beginning of winter they quit the higher parts of the mountains which they inhabit during the summer, and descend into the valleys or plains below in troops commonly of one or two hundred together. The adults run with prodigious velocity, in which they can be scarcely outdone with the swiftest horse. The natives are dexterous in pursuing these animals, and sometimes take them alive. The flesh of the young ones, according to Molina, is as good as veal; that of the full-grown animals is hard and dry, but is better salted than fresh. The hair is employed in making caps or hats, and in the fabrication of some sorts of Peruvian cloth.

Camelus Aracanos, the chililusque, or as sometimes called the Peruvian camel, montes de Perou, and aries moromoros, is another animal of this family: the body is woolly and smooth; snout curved upwards, and ears pendulous. It is thus specifically described by Molina. Upon whose authority it is inserted by Gmelin, in his edition of the Linnaean Systema Natueae, as a species distinct from the rest.

This species inhabits Peru and Chili, and is described as measuring about six feet in length, and nearly four in height. It is covered with woolly hair, and in its general appearance is not unlike a ram. The ears are obscured or pendulous, the neck and legs long; tail like that of a sheep, but shorter in proportion; the wool is very soft, and the colour of the animal is said to vary in different individuals, being either brown, black, ash-coloured, or white. This animal was employed by the ancient inhabitants of Chili as a beast of burden, as well as in ploughing; its wool was also used by them.
them in the manufacture of a fine silky cloth, or stuff. Its fleece is employed for a similar purpose at this time.

**Camelus Vicugna**, has the body smooth and woolly; nose flat, blunt, and tail erect. Moll, Hill, Nat. Chile. *Vicuña, Vicugna,* and *Vicunas, Vicugnes,* and *Vigogne* of different authors.

The vicuna bears a general resemblance to the glama, but is of a lighter and more delicate appearance, and of a smaller size; head smaller, and shorter in proportion; the eyes remarkably large and full; the ears somewhat flatter; and the limbs more slender. The colour on the upper parts is a reddish brown, and the remainder of an almost blackish colour, except the breast, belly, middles of the thighs, and under part of the tail, which are white. The hair of this animal is of a very soft, warm, and woolly nature, that on the breast is nearly three inches long; on the other parts not more than one inch; the end of the tail is furnished like the breast with long woolly hair. The individual described by Buffon was of a somewhat fierce disposition, and frequently attempted to bite those who examined it. It was never observed to drink, and seemed to have the same general habits and manners as the glama.

This animal inhabits the loftiest summits of the Andes, and is allowed to afford a much superior wool to that of either of the former species. It was once domesticated in Peru as the llama is at present; but the breed is now lost, and they are only to be found at this period in a state of nature among the mountains. The natives often go in pursuit of the vicunas which they chase with dogs, or take by stratagem, and kill them chiefly for the sake of their wool. It is clearly proved from past experience, that these useful animals might be domesticated with ease, and that their domestication would be attended with considerable advantage to individuals, and benefit to the state, were proper regulations adopted for this purpose. But unless some statutory measures are taken, there is reason to believe the whole race of these animals will be exterminated in a few years. When the Indians go out in chase of them, their only object is to destroy as many as possible. It was an uncommon circumstance till of late years for a troop of these hunters to return home from the pursuit with the skins of five hundred, or perhaps a thousand of these animals. The hair is sold to the merchant upon the skin, that he may be afforded it is the genuine product of the vicuna, and not of the paco, which is rather of a coarser quality. Very fine cloth is woven with the vicuna wool, both in Peru, and in Spain, to which country it is exported from Peru. Buffon supposes the vicuna would be a valuable acquisition to Europe, could the breed be introduced, and propagated with success; he is led to imagine that they would thrive well on the Pyrenees and the Alps, nor is this improbable. It seems indeed to be in the contemplation of the present government of France, to bring the experiment to issue by the introduction of these animals from Peru into those mountainous regions, as Buffon suggested; so fully are the French agriculturists of this time satisfied of its practicability, and of the success that would attend it.

In the year 1774, a cloth-worker in Paris of the name of Breton, fabricated a piece of cloth of the vicuna wool, in its natural colour, which answered extremely well, and was submitted to the inspector-general of commerce as an essay deserving the attention of government, and likely to become an object of public utility. He also dyed pieces of this cloth of various colours, as dark and light blue, crimson, violet or purple, and scarlet, and all with an equal degree of success. Other experiments were also tried by the French manufacturers shortly after that time. Shaws in particular, formed of the vicuna wool, under the direction of M. Dectrot of the Louviers, are reputed to have been of great beauty; and in the delicacy of texture, and softness, to emulate the rich shawls of Cashmere. These particulars will be sufficient to shew what real utility the cultivation of the vicuna with due attention might become hereafter in Europe.

**Camelus Paco,** the *pacos, alpacos,* and *alpague* of various authors, an animal nearly resembling the vicuna, and specifically distinguished by having no bunches; body woolly; and coat oblong.

This species is said to be entirely confined to Peru, where the natives keep wall flocks of them for the sake of their wool, of which they prepare cloth of a silky luster and softness: Like the vicuna, it is found in mountainous districts in large herds, but is never observed to associate with those animals. Some say it is of a more robust make than the vicuna, and is covered with very long wool, which, in the wild animal, is of a dull purple colour, beneath white, and when tamed, varying with black, white, and tawny.

The pacos are considered as a subordinate kind of animal to the llamas, much in the same proportion as we value the alpaca with regard to the horse: they are smaller, and not so serviceable, but their fleeces are more useful. Their wool is fine and long, only of a coarser quality than that of the vicuna, and, with the latter, forms a considerable article of merchandise in South America.

In a domestic state, the pacos are called by the Peruvians *alpagues.* The natural colour of the wool or fleece of the wild pacos, which resembles that of a dusky rove, or rather more inclining to purple brown is so fixed, that it undergoes no alteration under the hands of the manufacturer. They not only make good gloves and fleecings of this wool, but also weave it into quilts and carpets, which sell at a high price, and form a valuable part of the Spanish commerce. The pacos possess many things in common with the llamas: they belong to the same country, and are nearly of the same disposition and manners: they bear much resemblance in figure to the llamas, but are smaller: their legs shorter, and their muzzles thicker and clover.

The wild pacos inhabit and pasture on the highest parts of the mountains. Snow and ice seem rather to refresh than to be inconvenient to them: they keep together in flocks, and run swiftly. They are timid animals, for as soon as they perceive any person, they take flight, driving their young before them. The ancient monarchs of Peru rigorously prohibited the hunting of them, because they multiply so freely; but since the arrival of the Spaniards in those parts, their number is greatly decreased. The flesh of these animals is not so good as that of the huanaco: they are chiefly sought after for their fleece, and the bezoars they produce. The method of taking them proves their extreme timidity. The hunters drive a flock of them into a narrow passage, across which they have stretched cords about four feet from the ground, with a number of pieces of linen or woollen cloth hanging to them. The animals are so intimidated at these rags, agitated by the wind, that they flop, and crowding together in a heap, are killed with the greatest ease. But if there happen to be any of the huanacos among the flock, as they are less timid than the pacos, they leap over the cords, and the example being followed immediately by the whole drove, they escape for that time from their pursuers.

As to the domestic pacos, they are employed to carry burdens, like the llamas, but they can only bear a much less weight in proportion to their size than the llama, seldom carrying more than from fifty to seventy pounds. They are, besides,
The climate of the late Mull. is fine. of the milk of these animals, because they have scarcely enough to supply their own wants. The milk is derived from their wool imported by the Spaniards to endeavour to naturalize them in Europe: they transported numbers of them to Spain with this view, but the climate not agreeing with their nature, they all died. Those who brought them into Spain did not consider that they cannot exist even in Peru, but in the coldest regions, and on the summits of the loftiest mountains: that they are never found in the valleys, and if transported to warm countries, cannot long survive the change from their natural climate. Had they been sent to the Pyrenees, or other Alpine regions, it is possible they might have ascended the mountains till they found of themselves a climate suited to their nature. At least, the experiment must be ever fruitless, unless they can be accommodated with a climate as nearly agreeing with their own as the coldest parts of Europe will allow.

Such animals as subsist on vegetables, and live on the high mountains of Asia and Africa, produce that kind of animal concretion called bezoar, the virtues of which were formerly so highly extolled. The pacs produce that particular sort known by the name of ocidental bezoar, in great abundance, as do also the humaenas, and the rest of the bacta tribe, or Peruvian camels, but it is only from those animals, when in a state of nature, that bezoar of any value can be obtained. See BEOZAR.

The paco is considered by some naturalists as an animal forming an intermediate species between the llama and vicuña. Molina, in his "Voyage to Chili," has given a good description of the paco, the result of which proves, that the paco is more robust than the vicuña, has a much longer muzzle, and fleece of lower wool, but not so fine. The Peruvians keep vast flocks of them for the sake of their wool, with which they fabricate flannel that have the brilliancy of silk. This animal, which appears, however, to be so abundant in Peru, we are told, is not found in Chili, either wild or in a state of domestication.

CAMELUS, in Zoology, a species of Trichoda, found in vegetable infusions. This is thickish, hairy, before, and emarginate on each side in the middle. Müll. Zool. Don.

CAMELUS, camelus indicus, camelus indicus vericolor, and camelopard of different writers are synonyms of the Linnaean camo cameloparzalis, and Gmelinius cameloparzalis Gifruta, which sec.

CAMAEN, or KAMEN, in Geography, a town of Germany, in the circle of Welfala, and county of March; 20 miles s. of Munster.

CAMENZ, a town of Lusatia; 21 miles N.E. of Dresden, and 13 W.N.W. of Budissa.

CAMAERIA, in Antiquity, derived from the old German name, Camer, crooked, whence our English kamo, arms in kamo. At first itfigured any winding or crooked plot of ground, as " unam cameram tern," i.e. a nook of land. Afterwards the word was applied to any vaulted or arched building; and it was used in the Latin law-proceedings for the judge's chamber, &c. " camera flabella," the flarchamber, &c.

CAMAERIA, or CAMERIA, called also Camera, in Geography, a city of great note in Umbria. See Camera.

CAMA, ital. a chamber. This word, when joined to another, becomes a musical term: as musica di camera, compositions for a small band; voce di camera, a feeble voice.

Musica di camera is one of the three species of composition under which all music may be comprised: musica di chiesa, church music; musica teatrale, theatrical music, including music for public concerts; and musica di camera, chamber music.

Camera flabella, a contrivance for blowing the fire, for the fusion of ores, without bellows; by means of water falling through a funnel into a close vessel, which feeds from it so much air or vapour as continually blows the fire: if there be the space of another vessel for it to expatiate in by the way, it there lets fall its humidity, which otherwise might hinder the work. The contrivance was named camera flabella by Kirchiner. Hook, Phil. Coll. No. 3. p. 82. See BELLOWS.

Camera incisa, a contrivance of Dr. Hook for making the image of any thing appear on a wall in a light room, either by day or night. Opposite to the place or wall where the appearance is to be, made a hole of at least a foot in diameter, or if there be a high window with a casement of this dimension in it, this will do much better without such hole, or casement opened. At a convenient distance, to prevent its being perceived by the company in the room, place the object or picture intended to be represented, but in an inverted situation. If the picture be transparent, reflect the sun's rays, by means of a looking glass, so as that they may pass through it towards the place of representation; and to prevent any rays from passing aside it, let the picture be encompassed with some board or cloth. If the object be a flat one, or a living creature, it must be much enlightened by calling the sun's rays on it, either by refraction, reflection, or both. Between this object and the place of representation put a broad convex glass, ground to such a convexity, as that it may represent the object distinctly in such place. The nearer this is situated to the object, the more will the image be magnified on the wall, and the further the lens or such diversity depending on the difference of the spheres of the glasses. If the object cannot be conveniently inverted, there must be two large glasses of proper spheres, situate at suitable distances, callidly found by trial, to make the representations exact. This whole apparatus of object, glasses, &c. with the perfections employed in the management of them, are to be placed without the window or hole, so that they may not be perceived by the spectators in the room, and the operation itself will be easily performed. Phil. Trans. No. 38, p. 741, &c.

Camera Obscura, or Dark Chamber, in Optics, a machine or apparatus so constructed, that principally by means of a convex glass, or a convex glass and plane mirror, the images of external objects are represented on a rough ground plane glass, white paper, white wall, or other surface, in the most vivid and distinct manner, with all their natural motions, colours, shades, &c. The first invention of the camera obscura has been ascribed to Baptista Porta.—See his Magia Naturalis, lib. xxiv. cap. 6, first published at Frankfort about the year 1589 or 1591. The first four books of this work were published at Antwerp in 1572. But Dr. Friend, in his "History of Physic," (vol. ii. p. 256) observes, that Friar Bacon, who flourished in the beginning of the 13th century, describes the camera obscura, and all sorts of glasse, which magnify or diminish any object, bring it nearer to the eye, or remove it farther off. See also Bacon's "Opus Majus" by Dr. Jubb, p. 256; and his Epistle "Ad Pariliens," and his "Perspective" cited by Dr. Plot in his "History of Oxfordshire," p. 253; from which we may conclude, that he had a very accurate and extensive acquaintance with the properties of various kinds of glasses.

Camera Obscura, the use of the, is manifold: it affords very much in explaining the nature and rationale of vision, and
C A M E R A.

hence by some it has been compared to the artificial eye. It exhibits the most striking and entertaining representations of objects of all descriptions, whether near or distant, in their true perspective, the colouring full and natural, their light and shadows correct, and all their motions and relative positions according to the original. By means of this instrument, a person however unacquainted with drawing may delineate objects with great facility and correctness; and to the skilful artist it will be found indispensably useful in comparing his sketches with the perfect representations given in the camera, and by observing his defective imitations, he may correct, as much as possible, his designs. To the delineations of that beautiful representation called the Panorama, this instrument has proved of essential use.

Camera Obscura, the theory of the, is contained in the following proposition.

If an external object, as A, Plate III. Optics, fig. 1, radiates its light through a small aperture C, in a shutter of a perfectly darkened room upon a white paper or painted screen opposite to it, an image of the object will be depicted on the screen in an inverted position. For the aperture C being suppos'd very small, the rays issuing from the point B will fall on b; those from the points A and D will fall on a and d; wherefore, since the rays issuing from the several points are not blended, they will, by reflection, exhibit its appearance on the screen. But since these rays, A C and B C, intersect each other in the aperture, and the rays from the lowest points fall on the highest, the situation of the object will necessarily be inverted. Hence, since the angles at D and d, and the vertical ones are equal at C, B and b, and A and a, will be also equal; consequently, if the screen where the object is delineated be parallel to it, a b : A B :: a C : D C.

That is, the height of the image will be to the height of the object, as the distance of the image from the aperture is to the distance of the object from the frame. This proves, therefore, that the inversion of the object is not owing to any lens that may be used in a camera obscura. In this manner, the figures of the image are very faint and confused, for want of a due degree of light, and its proper refractions.

Camera Obscura, consideration of a, whereon the images of external objects are distinctly represented in their genuine colours, light and shade, &c. and either in a erect or inverted position.

1. Darken, in the most perfect manner possible, a room or chamber; in the shutter of one of the windows that faces the object to be represented, cut a small circular aperture, see fig. 1. C.

2. In this aperture fix either a double or plain convex lens; if the latter, with the convex side next the object. Its focus may be of any length between 3 and 6 feet.

3. At a proper distance, to be determined by experiment, or about the focal distance of the lens, place perpendicularly a large surface of white paper or cloth, and on this the images of the external objects directly before the lens will be beautifully delineated, but in an inverted position. The paper or cloth should be moveable, so that the exact distance of the focus of the lens may be obtained, or the images will not be seen with their utmost distinctness. Those objects also should be selected that are in the strongest light, or illuminated by the sun's rays. In northern latitudes at noon-day, a window opposite the north is best; in the morning, facing the west, and in the evening facing the east. In southern latitudes a window facing the south is best at noon. The shorter the focus the smaller and brighter the images will appear; and the longer, the larger the objects; but if the focus be very long, from 20 to 60 feet, the same light being more dilated or spread over a large surface, the images will appear somewhat obscure, and the colouring fainter. The images will be full brighter if the spectator first lay a quarter of an hour in the dark.

This is the most perfect method of obtaining a representation of objects, from having but one reflecting medium, but in some cases the inverted position of the images may be some objection; to obviate which, the following methods may be used to make the picture erect. Hold a true ground plain mirror flatwise against your breast, under an acute angle, and looking therein, you will see all the images reflected to their natural and erect position, and with an addition of light that they will receive from the reflection of the mirror. Or, which is a better way, and does not require a mirror near so large, place a mirror above and rather near the lens, so as to reflect the rays down upon a white surface, a screen directly under, or parallel to the mirror. Or, a large concave mirror may be placed before the picture, at such a distance that the image of the picture may appear before the mirror, which will then be erect, and appear pendant in the air. Another method, which is more direct, is by placing another convex lens in a partition behind the paper or screen, with the image at twice the focal distance of the field-lens, the axes of the two lenses coinciding, in which case another picture of the images will be formed but erect, as large as the first, but not so bright, and with a contracted field or extent of the picture. Or, two lenses of short focal in draw-out tubes, may be applied to the hole in the shutter instead of one, which will also produce an erect position of the images, but the light will be less, the extent very limited, and serve only for the representation of objects, small figures, &c. as hereafter to be described. This method is but of little use and seldom practised.

The following description of cameras obscuras has been communicated to us by Mr. William Jones, optician, Holborn, as being the most commodious and perfect, and what have been preferred, and are in general use, by the most skilful artists:

Fig. 2. represents the spheric ball, which is made of mahogany, and consists of three parts, a frame, a ball, and a lens. The frame consists of two pieces a circular wire rim, fitted one to the other, and both fo excavated as to admit, and keep a spherical ball perforated, which is valuable in its frame more or less easily, as the parts of the frame are less or more screwed together. At each end the hole in this ball is a screw cell for containing a lens; these lenses are of different focal lengths, and only one is to be used at a time, when the images are to be formed. The frame of this spheric ball is to be screwed fast to the window-shutter or window-board of a well-darkened room, before a hole previously made therein. There are two brass nuts and screws, a, b, fitted to the frame for that purpose; the nuts are screwed to the shutter or board, so that by means of the screws the spheric ball may be more readily attached to, or detached from, the shutter. This apparatus is very convenient, when experiments by a variety of lenses may be desired. As, fig. 2, represents the position of a mirror when applied for reflecting downwards the images in order to obtain the erect positions; if the frame be made to turn on a hinge, it will be the more useful to direct the image to an oblique screen, or table, as may be required. Fig. 1. represents a darkened room with a lens attached to the spheric or shutter, or where the spheric ball is to be placed. E represents the moveable white paper screen that receives the images of the objects formed by the lens, and is moveable to the distance of the focal length of the glasses. A B shews the manner in which the ball, b.
The Scopic Ball affords a very convenient method of forming an image of the sun in the darkened room. If a lens 10 or 12 feet focus be placed on it, and a white paper screen placed at its focus, in a perpendicular position to the rays, a distinct image of the sun will be formed, about one inch diameter, on which will be conspicuously exhibited all the spots or solar maculae. At the time of a solar eclipse, the whole progress of the moon, from the time of the first contact of the limbs to the last, may, in this way, be observed very distinctly. But the best method is by connecting a draw-out telescope, with the ball of theocket, fig. 2, by screwing the end with the object glafs to it, and taking out all the eye glafes at the other end, except the one next to the eye, then moving inwards the frif tube till the image of the sun appear distinct; and you will have a bright image from 12 to 26 inches diameter, according to the distance of the screen, which will, to any number of spectators, exhibit the solar phenomena intended to be viewed.

Confirmation of a Chamber Camera Obfcura.

The foregoing is the readiest and most simple method of converting a room into a camera obfcura, but it is attended with these objections, that it only serves for objects directly facing the lens, and occasionals the trouble of darkening the room, fixing and adjusting the apparatus, &c. Fig. 3, represents a room shaded like a dome or cupola, placed over a building, prospect-room, or temporary room erected for the purpose of a camera obfcura, and in this way affords the most ready and advantageous plan for all surrounding objects. The whole dome A B may be made to turn round on friction wheels, in a groove made in the roof for that purpose, and to carry round with it the glafes in the box C above, or which, in some cafes, is a more manageable way, the box with the glafes is made moveable in a groove round upon the dome, and is turned by means of a long rod by a perfon within. The manner of fabricating such a dome and box will be evideit to any good joiner by a mere inspection of the figure. The mahogany box C is of a cubical form about 6 or 7 inches in the length of a fide; a true ground mirror in a frame is placed diagonally in the box, and is moveable somewhat on an axis at its lower edge upwards and downwards, to reflect the rays from objects at various dilfances; underneath this mirror, in a round cell, at the bottom of the box, is fixed a double convex lens, about 6 or 8 feet focus, and 4 or 4½ inches in diameter; this lens will form upon a white table D, placed on the floor below, the images of the objects reflected by the mirror above, at the focal distance of the lens. The diameter of this table should be 12 or 13 feet, excavated on its surface to a small degree of concavity, or from a radius about the focus of the lens, in order, that the inequality of the distance of its surface from the centre of the lens, presenting the images indifinct at the circumference, when they are clear in the middle, may be obviated. The surface must be painted perfectly white, or, which is better, covered with thin coating of plaster or stucco. The pillar of the table should be made with a screw working in a female one cut in the pedefral, so that by turning round the table and screw its surface may either be elevated or depressed, as may be necessary, to admit of the clear and best defined picture of the images possible. To persons having dwellings on elevated situations commanding extensive prospects over countrysides, the lens, &c. a machine of this kind contrifuted over it will afford more delight and entertainment, as well as life to an artist, than any perfume would suggest, who had not previously been a witnelf to such an effecf. To those who may not wish to be at the expense of a dome, Mr. Jones recommends the box fitted to a wooden pyramidal trunk, (fig. 4,) which trunk can be fixed on the ridge of the roof of a houte or chamber, by a common carpenter, and a flat sliding cover to slide on at A, to cover the trunk when the box of glafes B is taken away after use. The camera boxes, with the glafes complete, and ready for fixing, are made by Meffrs. Jones, of Holborn, and other Opticians. Metallic mirrors have been used instead of glafes ones for cameras; they reflect more light, and consequently flew the images brighter, but their liability to tarnifh and corrode is an unavoidable objection to their general ufe.

Cameras Obfcuras, conftruction of portable. The glafes of a camera obfcura are frequently fitted to a portable machine slitting up in the form of a cheff, or box, to as to be portable, and easily transported from place to place, and carried about by the artist. The apparatus within is contrivd to fold outwards, and form a machine as represented at fig. 5, and it is contrivd upon the most convenient plan of any hitherto conftucted. It is represented as placed together for ufe. The lid front A, and the slides, one drawn at B, by means of hinges turn up to the height of about two feet from the cafe C D E, and are faftened together by small brafs hooks. The head and sliding box, with glafes F, also faften on by hooks within. The lens of about 2 inches focus is placed under the true parallel glafs mirror, and forms the images on a white sheet of paper, placed in the bottom of the cheff. To view the images the face is applied close to a piece under A for that purpose, and to trace the outline, or copy them, the arm at the fame time is applied in the cloth fleece under H. The box F slides on a square tube, and by means of a brafs rack and pinion G the lens is adjufted, while the images are viewing, to its proper focal distance from the white paper below. The images formed on the paper have a correct and natural refeemblance to the original objects; no version takes place, and even names and letters on objects are in their direct order. This camera is converted into an instrument for magnifying perspective prints and drawings, and forms the best possible apparatus for that purpose. The head F G and tube are to be entirely removed, as well as the front A, and cloth C D, and another head with a diagonally-placed mirror and large convex lens, fig. 6, substituted, and also faftened. The prints are to be placed at the bottom of the cheff, and as the camera is open, the print will be illumined either by day light or candle light, as required. The print is viewed by reflection in an horizontal direction, by the eyes being placed before the large convex lens. When the sides and front are unhooked and folded down into the cheff, they all lie fide by side, and admit the head to lie under them; and the dimensions of the cheff, when thus shut up, do not exceed 2 feet in length, 20 inches in breadth, and 5 inches in depth.

The most portable kind of Camera obfcura is that represented at fig. 7, and is that most frequently used among artists, on account of its convenient dimensions. The images are reflected on a rough ground plane glafs, and are more vivid than those formed on paper, by the Camera above described. It is made of mahogany, and of various dimensions.
same so small as to be carried in the pocket. The lens at the front A is fixed in the cell, in the front of a square draw-out tube, and is of a focus equal to the length of the box when the drawer is half drawn out; and a plain mirror is placed diagonally at the angle of 45°, at the end of the box, as shown by the dotted line a b, which reflects the rays transmitted by the lens up to the upper side of the plane rough-ground glasses, the rough side placed above, under the folding darkening cover, and there forming the images of the objects before the lens at A: the use of the draw is to adjust the proper distance of the lens from the mirror, according to the variable distances of proximate objects. The images on the rough glasses exhibit a beautiful perspective picture, also the profile of a person seated in a room in a strong light before the camera, and more particularly if the sun illumine the object; and may be readily traced on the rough surface of the glasses by a black lead pencil, or by what is preferable, red French chalk, and then white paper being gently placed on the glasses, the lines will be taken correctly off. If very thin white paper is merely placed upon the glasses, the images may be discerned, though faintly, sufficient to afford the idea of tracing correctly. The nearer the object or features are to the camera the larger will be the image, and an additional lens of a shorter focus is sometimes fitted to be sublimated for the other, when the images of near objects are wanted. Some artists who take profiles take out the rough glasses from their cell, invert the camera, and by a stand support it about 10 or 12 inches above the white paper on the table. The image will then invertedly be formed on the paper, and they trace it with a pencil in a correct manner, and with less trouble than by the other method. Merris Jones, of Holborn, make an improved camera of this kind, by joining the side of the camera and drawer in the middle with canvas cloth, as shown at the lines D G: the back C turns inward with the mirror, close up to the rough glasses, and the front E F above, over the top, so that the whole camera may fold down into a flat form, and go into a very portable flat leather flip case, making it the most portable possible for persons travelling. Inclusive of the rough glasses has sometimes been placed a double convex lens to relieve the images, and from more light being thus refracted, the images are shown with great beauty and extraordinary brightness, even surpassing the original. They are also more vivid when the rough glass is placed over this lens, though the contours, or outlines, are not so sharp or distinct as when the rough glass is used only by itself. This improvement was obtained some years ago, by a pervert of the name of Storer, a discoverer, and called a delineator, but without the least pretensions, it being previously well known by the most eminent opticians, and it was, in the year 1778, noticed by Mr. Hooper, in his Rational Recreations, vol. ii. p. 29. Guyot's Recreations Physiques, tom. ii. recr. 35. art. 2. Mr. Harris, in his "Optics," b. ii. § 4. has described a variety of contrivances for converting the portable camera into a draw box for viewing prints.

Gen. C. Chal. antheria one leafed, small, with five acute teeth. Cor. tunneled; flange long, swelling out at the base and at the top; border flat, with five lanceolate oblique segments. Stem. filaments five, small, attached to the middle of the tube; anthers converging. Fil. germs two, with lateral appendages; style scarcely any; stigma obscure. Peric. foliaceous two, horizontally reflexed, oblong, crenated, obtuse at both ends, with two opposite teeth at the base of each. Seeds numerous, egg-shaped, compressed, with a membraneous ring at their base by which they are attached to the receptacle through a in single row, in an inflated manner, and inverted direction.

CAMERARIUS (Dillen.), See Montia fontana. CAMERARIAU, or Chamberlain, in Antiquity, an officer who had the care of the dormitory in ancient religious houses.

CAMERARIUS, Joachim, in Biography, an elegant German scholar and biblical writer, was born at Bamberg in Franconia in 1504; and was no less distinguished for his eloquence than for his knowledge of the languages, history, mathematics, and politics. He was honoured with the friendship of Charles v., Maximilian ii., and other princes; and by the diligence and zeal with which he delivered his courses at Nurenberg, Tubingen, and Leipzig, he very much contributed to promote the cause of universal science, and more especially the study of elegant literature. He translated from Greek into Latin parts of Herodotus, Demosthenes, Xenophon, Ecstatic, E. Kant, Thucydides, Sophocles, Lucian, Galen, Chrysostom, Theodoret, Aristides, Nirpilor, Gregory of Nyssa, St. He also wrote in Latin the lives of Melancthon and Heiligen; and composed "Commentaries on the New Testament," in which, says Moehring (Eccl. Hil. vol. iv.), "he expounds the scriptures merely in a grammatical and critical manner; and laying aside all disputed points of doctrine and religious controversy, unfolds the sense of each term, and the spirit of each phrase, by the rules of criticism, and the genius of the ancient language, in which he was a very uncommon proficient." The last ed.
tion of this commentary was printed at Cambridge in 1642.
It is bound with Bexa's Greek Testament, printed at Cam-
bridge in the same year. Camerarius frequently quotes a
MS. which he describes as ancient, and which is noted 88
in the first part of Wetstein's New Testament. He likewise
published a catalogue of the bishops of the principal fees;
Greek epistles; accounts of his journeys in Latin verse;
epigrams of the ancient Greek poets; a commentary on
Philus,; and several other learned works. T urnebus,
H. Stephens, Lipsius, Bexa, and many others distinguished
for their literature, concur in bearing ample testimony to his
talents and learning. He died in 1574; and left several
sons, who were eminent for their literary attainments. Gen.
Dct.
 Camerarius, Joachim, a physician of learning and emi-

nence, was born at Nuremberg in 1534, where he received
the rudiments of his education. As his mind was early
turned to the study of botany and medicine, with the view
of improving himself, he visited the principal seminaries in
Germany, and thence went to Padua, and afterwards to
Bologna, where he took the degree of doctor in 1562. Two
years after he returned to Nuremberg, and by his zeal and
ability, aided perhaps by the high character his father had borne, who was esteemed one of the refiners of
literature, he conciliated to himself the favour of the prin-
cipal perfonages in the city. Under their patronage, in 1592,
he founded a medical college, of which he was appointed
dean or president, and in that situation continued to direct
the affairs of the institution for the remainder of his life.
Mindful of his favourite object, botany, he formed an ex-
tensive garden, flored with the choicest plants, the cultivation
of which he superintended with great affinity. He also
affiliated the landscape of Hesse with his advice in forming a
botanical garden; and with a view of disseminating the
knowledge of plants, he purchased the collections of Gesner
and Wolf, which he methodized, and corrected, and with
considerable additions from his own florbes, together with the
works of Matthiolus, he published them in 1586, under the
title of "De Plantis Epitome uttillium Petri Andreae Mat-
tholii novis Iovibus et Decriptionibus plurimis diligenter
aucta." 4to. " Hortus Medicus et Philosophicus, in quo
plurimarum Stirpium breves Deescriptiones, nova leones non
paene, continentur," 4to. 1588. " Opera de Re Rura,
quibus, preter alia, Catalogus Rei Botanicae et Rurae Scrip-
torium veterum et recentiorum infectus est," 1577, 4to.
Also " De recta et necessaria Ratione corporis et Saltus
Contagiosum." 1583, with other smaller tracts on the same
subject, and three centuries of emblems. On his death,
which happened October 11, 1593, he was succeeded by his
son Joachim, in his practice and in the honour of being
 Camerarius, Elias Rodolph, son of Rodolph John
C., a physician of eminence at Tubingen, was born in 1590.
Following the steps of his father, he was made doctor, and
soon after professor of medicine in the university of Tubingen,
which office he held to the time of his death, which hap-
pended on the 7th of June 1695. He was author of nume-
rous differtations on the subject of medicine, in which are
detailed such rare cases as had occurred in his practice.
Among them, "Histo­ria Anatomica Renum et Vetere,"
1683, 4to. In this he gives an account of a distention of
a person who died of an affection of the kidneys. Of one of
the kidneys there only remained the external membrane,
which was full of purulent matter, into which the kidney
had been resolved.
By his father "Syllogis Memorabilium Medicinae, et Mi-

pope's apartment in the Vatican; and whenever he goes abroad is attended by the Swiss guards, like the pope himself. He even coins money in his own name, and with his own arms; and, in fine, is a kind of vice-pope, governing the ecclesiastical state during the vacancy of the holy see.

The cardinals have also their камериллоi, or treasurer of their college, distinct from that of the pope; the former is elected every year, whereas the latter is for life. The person chosen to this office has the receipt of all the revenues belonging to the college, which he is to distribute at the end of the year in equal portions to the cardinals then at Rome; those who are absent having no share therein after they have been six months from court.

CAMERON, John, in Biography, one of the most famous divines amongst the Protestants of France, in the 17th century, was born at Glasgow, in Scotland, about the year 1629, and taught Greek there, till he removed to Bourdeaux in 1650. Here he acquired such celebrity by the fluency with which he spoke Greek, that he was appointed to teach the learned languages at Bergeac. He afterwards became professor of philosophy at Selan; but returning to Bourdeaux in 1634, he devoted himself to the study of divinity. Upon being appointed tutor to the sons of the chancellor of Navarre, he accompanied them to Paris, Geneva, and Heidelberg. After having discharged the office of a minis¬ter at Bourdeaux, which he assumed in 1668, for 10 years, he accepted the professorship of divinity at Saumur. Upon the dispersal of that academy by the public commotions in 1621, he removed to England, and taught divinity at his own house in London. King James, inclined to favour him on account of his supposéd attachment to the hierarchy, made him master of the college, and professor of divinity at Glasgow; but after holding this office, which he found to be unpleasant to him, for a year, he returned to Saumur, where he read private lectures. From thence, he removed in 1624 to Montauban; where the disturbances excited by the emissaries of the duke de Rohan, led him to renounce the principles which produced them, with more zeal than prudence. This occasioned his being insulited by a private person in the streets and severely beaten: and this treatment so much affected him, that he soon after died, in 1625, at the early age of 46 years. Bayle represents him as "a man of great parts and judgment, of an excellent memory, very learned, a good philosopher, good-humoured, liberal not only of his knowledge, but his purse, a great talker, a low-minded preacher, little versed in the fathers, inflexible in his opinions, and inclined to tur¬bulence." He was one of those who attempted to reconc¬ile the doctrine of predestination, as it had been taught at Geneva, and confirmed at Dort, with the sentiments of those who reprefent the deity as offering the displays of his goodness and mercy to all mankind. His opinion was main¬tained and propagated by Mofes Amyraut, and several others of the most learned among the reformed ministers, who thought Calvin’s doctrine too harsh. They were called Universalists. Cameron likewise maintained the possi¬bility of salvation in the church of Rome. After his death, his theological lectures were printed at Saumur, in 3 vols. 4to. 1626-28; and afterwards with some additional pieces, at Geneva, in one vol. fol. His remarks on the New Te¬fament, under the title of "Myrothecium Evangelicum," were printed at Geneva in 1632. Gen. Dict. Mohlin, E. H. vol. v.

CAMILLA, a river on the west coast of Africa, S.E. from Calabar river, the entrance of which is N. lat. 4°, and E. long. 1° 20'.

CAMERON, See CAMERON.

CAMERONIANS, in Ecclesiastical History, a sect or party in Scotland, who separated from the Presbyterians in 1666, and continued to hold their religious assemblies in the fields.

The Cameronians took their denomination from Richard Cameron, a famous field-preacher, who refusing to accept the indulgence to tender conscienties granted by king Charles II. as such an acceptance seemed an acknowledgment of the king’s supremacy, and that he had before a right to silence them, made a defec¬tion from his brethren, and even headed a rebellion, in which he was killed. His followers were never entirely reduced till the revolution, when they voluntarily submitted to king William. The Cameronians adhered rigidly to the form of government estab¬lished in 1648.

CAMERONIANS, or CAMERONITES, is also the denomina¬tion of a party of Calvinists in France, who affirmed, that the cause of men's doing good or evil proceeds from the knowledge which God infuses into them; and that God does not move the will physiologically, but only morally, in virtue of its dependence on the judgment of the mind. They had this name from John Cameron, of whom an account has been given under the article CAMERON.

The Cameronians are a sort of mitigated Calvinists, and approach to the opinion of the Arminians. See Universalists, hypothetical.

CAMEROTTA, in Geography, a town of Naples, in the Principato Cita; nine miles S.W. of Policastro.

CAMERTA, in Ancient Geography, a town to the right of the route from Otrochi to Rimini. Strabo.

CAMES, in Geography, a town of the island of Cuba; 40 miles W. of Bayamo.

CAMES, in the Manufactures, a name given to the small slender rods of salt-lead, of which the glaziers make their turned lead.

Their lead being cast into slender rods of twelve or fourteen inches long each, is called the camé; sometimes also they call each of these rods a came, which being afterwards drawn through their vice, makes their turned lead.

CAMICUS, CAMICI, and CAMICOS, Platouella, or Plat¬toula, in Ancient Geography, a town of Sicily, on the banks of a river of the same name, N.W. of Agrigentum. The river falls into the sea near Capo Bianco, so called from its colour.

CAMIGARA, a town of India, on this side of the Ganges. Ptolemy.

CAMIGUIN, in Geography, one of the Philippine islands, about 10 leagues in circuit, and known by two high woody mountains. N. lat. 9° 30'.

CAMILLIANUM, in Ancient Geography, a town of Italy, in Umbria, inhabited by the Camelani.

CAMILLA, in Entomology, a species of Papilio, (Nymph. Phal.) found in Europe. The wings are indent¬ed, black, glossed with blue, with a white band on both sides, and spot of the same; posterior wings beneath at the base silverly and immaculate. Fabr. &c. This is papilio lucella of Esper, and papilio rivularis of Scopoli. This species described by Esper under the name of camilla, is not the above insect, but the Fabrician P. lucella.

CAMILLI and CAMILLÆ, in Antiquity, boys and girls of ingenious birth, who ministered in the sacrifices of the gods;

CAM

Gods; and especially those who attended the flamen dialius, or priest of Jupiter.

The word seems borrowed from the language of the ancient Etrurians, where it signified minifter, and was changed from caelestias.

The Tusculans also gave the appellation Camillus to Mercury, in quality of minister of the gods.

CAMILLUS. Marcus Furius, in Biography, one of the Patrician family of the Parii at Rome, by whom it was first raised to eminence. In the year of Rome 353 he served the office of censor, and in the 14th year of the siege of Veii, B. C. 395, he was created dictator, defined, says Livy, by the fates to take the city, and to live in his country. After previous vows, Camillus prepared for prosecuting the siege with vigour; and having defeated the united force of the enemy in the field, he led his army to Veii. The assailants from without being aided by a chosen band who had entered the city by a mine which had been constructed under the walls, and carried as far as the citadel, Veii, which had been the rival of Rome in power, and its superior in splendour, was obliged to surrender amid the shrieks and lamentations of the inhabitants, and after having exhibited a scene of blood and slaughter, which made even Camillus shed tears of sympathy and compunction. Eliminating the opulence of the city by the spoils which it yielded to the victors, and reflecting on the importance of this conquest, which had been delayed ten years, Camillus is said to have lifted up his hands to heaven, and to have implored the Gods, that "if his own and the good fortune of the Romans appeared too great in their sight, and that it was necessary to counterbalance it by some disgrace, that they would be pleased to cause it to fall on him alone, and to spare the commonwealth." On the day after the capture of Veii, the prisoners were fed for slaves, and the sums thus raised remitted to the public treasury. The triumph of the dictator was magnificently celebrated, and the chariot of the victor was drawn by four white horses; but the pomp and splendour of it offended the Roman people; and Camillus, who from this time was regarded as the head of the Patrician party, became an object of popular jealousy. Camillus, however, after having fulfilled his vows, abdicated the dictatorship. Two years after this event, Camillus was again chosen one of the military tribunes, and entrusted with the conduct of an expedition against the Falisci. Having invested Falerii, the capital of those people, an incident occurred, which afforded him an opportunity of displaying a degree of justice and generosity, that was highly honourable to himself and to the Roman character. A schoolmaster of the place, to whose care the children of all the most illustrious persons were committed, contrived, under a pretence of exercising them in those appropriate sports to which they were accustomed, to bring them to the Roman lines; and, upon being led to the Roman general, he delivered them into his hands, informing him, that with these children, he in effect surrendered to him the town which he was besieging. "Traitors," said Camillus, with a menacing aspect, "if you do not address yourself with your impious pretences either to a general or a people that resemble you. We have indeed no express and formal alliance with the Falisci, but that which nature has established between all men both doers, and shall subsist between us. War has its rights, as well as peace; and we have learned to make it without any injustice to all persons, even in cities taken by assault, but against men, armed like ourselves; men, who without any previous injury from us, attacked the Roman camp at Veii. Thou, to the utmost of thy power, hast exceeded them by a new and different kind of crime; but for me, I shall conquer as at Veii, by Roman arts, by valor, works, and perseverance." After this reproof, Camillus ordered the traitor to be hanged, and to have his hands tied behind him; and providing his young scholars with rods, he directed them to drive him back into the city and to scourge him all the way. Upon their arrival, the citizens, overcome by this influence of generous conduct on the part of Camillus, sent deputies to treat of a surrender. Camillus referred them to the Senate, who admitted the Falisci into the number of the allies of the Romans, on condition of their defraying the expenses of the war. The noble general returned to Rome with a much more splendid glory than that of his superb and pompous triumph after the capture of Veii. The army, however, was in no small degree irritated by being disappointed of its expected plunder.

Four years of turbulence succeeded the surrender of Falerii, during which Rome underwent the changes of a return to the confuneral government, of an interregnum, and of a renewal of the administration by military tribunals. Whilft the Gauls in their irruption into Italy had advanced as far as Chfium in Etruria, the Romans were heedless of their danger; and encouraged a prosecution against their general Camillus, on a charge of having embezzled some of the spoils of Veii. Well informed with regard to the issue of this prosecution, he resolved to prevent the indignity of a formal condemnation by a voluntary exile. Having taken leave of his family and friends, he advanced in silence towards the gates of the city; and then turning about and stretching his hands towards the capitol, he supplicated the Gods, "that if he were innocent, they would make his unfortunate country regret his absence as soon as possible." He then retired to Ardea; and the Romans imposed upon him a heavy fine. In the course of the Gallic war, a party of the Gauls, which had been ravaging the country, whilst Brennus their general was besieging Rome, was led by chance towards the city of Ardea. Camillus, as soon as he heard of their approach, round the inhabitants to arms in their own defence. His efforts were not ineffectual; under his conduct they marched out to meet the enemy; and falling on them at night, when they had abandoned themselves to incontinence and disorder, a great slaughter ensued; the whole body of them was dispersed, and most of those who escaped were killed by the inhabitants of the country of Antium, whither they had fled. The fame of this victory soon spread through the neighbouring cities; and the Roman fugitives at Veii were encouraged to rally, and intreated Camillus to take them under his command. With this request he delayed complying, from regard to the laws of his country, till the citizens in the capitol had confirmed their choice. But as the city was invested by the Gauls, it was difficult to gain access to this fortress. An intrepid youth, however, undertook the charge; and, upon his arrival in the capitol, the senate was assembled; and he returned as speedily as possible with a revocation of the decree by which Camillus had been condemned, and an unanimous nomination of him to the office of dictator. Camillus, thus reinforced with authority, invited the dispersed Romans and their allies to his camp; and soon found himself at the head of 40,000 men. With this force he fo harried the Gauls, and by cutting off their supplies reduced them to such a state of famine and petition, that they negotiated with the beleaguered citizens in the capitol; and in the issue, the Romans contented to purchase peace by a sum of gold. Livy relates, that whilst the gold was weighing, Camillus suddenly arrived at the city gates, and prohibiting the payment, the contract for which had not obtained his concurrence as chief magistrate, drove the Gauls from the city into their camp.
CAMP. "Curry back," say he to the Romans, "that gold into the capital; and as for you, Gauls, retire with your weights and I take; it is with the fond only that the Roman ought to redeem their country."

Livy adds, that Camillus paraded them in their retreat, and so completely destroyed them, that not one Gaul was left to carry home the news of their defeat. Polybius, and some other writers, affirm, that the god was actually pad, and that the Gauls marched back in fifty with their boats. Camillus, however, was duly regarded as the deliverer of his country; and his soldiers, on entering the vacant city in triumph, hailed him as Romanus, the Deliverer of his country, and the second Deliverer of Rome. This he immediately did, A.U. 357, B.C. 239. In consequence of it Camillus purified the ground with the customary expiations, rebuilt the temples, and erected a new one to Isis Latitans. See AVIS LEOPARD.

He was continued in his office of dictator for a whole year, contrary to the usual custom which limited its duration to six months; and by his counsels and influence a decree was passed for rebuilding the city, and the work was undertaken with great alacrity and arduous labour. In the year of Rome 366, a formidable confederacy was concerted against Rome by several neighbouring states, and Camillus, with a view to the suppression of it, was a third time appointed dictator. Having raised a large army for this purpose, he speedily accomplished it; and returning to Rome in triumph a third time, he laid down his office. The spoils and the rule of the prisoners yielded a large sum of money, part of which was applied for defraying the charge of three gold vases, inscribed with the name of Camillus, as a memorial of his exploit, and deposited at the foot of Janus's statue in the Capitol. In order to quell the conmotions occasioned by the ambition of Marcus, who on a former occasion had faced the Capitol from the Gauls, Camillus was a fifth time elected military tribune; and he presided at the tribunal which condemned this brave, but dangerous citizen to death. His sixth election to the military tribunalship, A.U. 374, was occasioned by the union of the Volsci with the inhabitants of Transalpine Gaul, and though he was now advanced in years, and wished to decline public service, he took the command, and completely defeated them. In the year of Rome 387, Camillus was advanced to the office of dictator a fourth time, for the purpose of compelling the differences that subsisted between the patricians and plebeians, and of maintaining the prerogative of the former. By his authority he prevented the tribunes from proposing their new laws to the people; but apprehending the threatened consequences of their refenment, and desiring to come informalities that had occurred in the mode of his appointment, he abdicated his office. The approach of an invading army of the Gauls induced the republic again to direct their wishes to him as their deliverer; so that in his 68th year, he was a fifth time appointed dictator, and he cheerfully conferred to pacify the remains of his life to the welfare of his country. On the banks of the Anio he fell unexpectedly on the Gauls, and defeated them with great slaughter. Having received the surrender of the town of Velitrae, he returned to enjoy the honour of another well-merited triumph. The turbulent state of the republic would not allow the relinquishment of his authority. The popular party determined on restoring the confederate government; and the tribunes prepared for seizing the person of the aged dictator on his tribunal. During the tumult he retired to the capital; and having implored the gods to appease the contend, and to avert its fatal effects, he made a vow to erect a temple to Concord, as soon as the troubles terminated. The voice of the people prevailed; and it was agreed, in favour of the senate, that one of the confidants should be chosen out of their own body. In order to preserve the supremacy of the patricians, Camillus proposed to separate the judicial from the executive power in the consuls, by the appointment of a praetor, who should be elected from the higher order of citizens, and administered justice at home. The power of that party was further increased by the multiplication of tribunals of patricians only. Camillus, having thus honourably closed his fifth dictatorship, and erected the temple of Concord, retired from public life; but in the year of Rome 359, B.C. 157, he fell a victim to a piety that forgot away a great number of cities in the magnificent.

"His memory was ever cherished as one of the greatest, most fortunate, and most patriotic chiefs of the Roman republic." It was a proverbial saying, much to his honour, that "wherever Camillus was, there was Rome." Thus expressed by Lucan in his Pharsalia, lib. v. v. 27—

"Unique habitante Camillo,
Ilic Roma suit."

Camilus, in Entomology, an elegant species of Papilio (Eq. Archiv.) described by Fabricius from a specimen in the Blackian Cabinet. The wings are white, with fimbriated edges of black: on the posterior ones a black caudal spot. This is of a small size, and inhabits the interior of Africa.

Camina, in Ancient Geography, an island of the Mediterranean Sea, on the coast of Alca Minor, near Miktus, and 38 miles from Plataea. Pliny.

Caminha, in Geography, a town of Portugal, in the province of Entre-Douro e Minho, seated at the mouth of the Minho, and defended by a fort and garrison: it contains about 1500 inhabitants, one parish-church, two hospitals, and two convents; 11 miles N.N.W. of Viana. Lat. 41° 44'. W. long. 9° 15'.

Camini, or sera Camini, in Botany, an American herb, the same with what is otherwise called Paraguay, or sera canoiss." Camini, in Geography, a river of Upper Canada, which discharges itself into the lake Superior, 30 miles E. of the Grand Portage.

Caminitza, a town of European Turkey, in the Morea, situated on a small gulf at the mouth of a river of the same name, anciently called Olea, and the river Mela; 24 miles N.E. of Chiroenza.

Caminos, in Ancient Geography, a place of Africa, in Cyrenaica, upon the route from the greatest Leptis to Alexandria. Anton. Itin.

Camion, in the Military Art, a sort of small tumbril, or cart with three wheels, which is commonly drawn by two men, and answers for carrying bulks, &c. It is very convenient for magazines in cities and fortresses. This name is also given to a cart with three wheels, from eight to nine feet long in the body, for moving earth with horses.

Camirium, in Botany. (Rumph. amph. ii. p. 180, tab. 38.) See Alcuretes.

Caimorl, in Ancient Geography, a town in the island of Rhodes, seated on the W. coast, 18 miles S.W. of it, and almost opposite to Lindus. This was formerly one of the three cities called Tripolis; the other two were denominated Lindus and Juliana. Of this town there remains no traces besides the name of Caimorl, a Greek village, built upon the same spot.

Caimis, or Kamis, in the Japanese Theology, denote deified souls of ancient heroes, who are supposed still to interest themselves...
themselves in the welfare of the people over whom they
anciently commanded. The camis answer to the heroes in the
ancient Greek and Roman theology, and are venerated like
the saints in the modern Roman church. Beside the heroes
or camis beatified by the consent of antiquity, the mikado,
or pontiffs, have skill'd many others, and continue still to
grant the apothecaries new worthies; so that they swarm
with camis: the principal one is Tenfis Da Sinu, the common
father of Japan, to whom are paid devotions and pilgrimages
extraordinary.

CAMISÀ, Porto, in Geography. See Liss.

CAMISADE, in the Military Art, a term denoting a
sudden or unexpected attack in the night, and for which a
common badge, mark, or signal, is agreed on to enable the
troops employed in making it to know one another by,
particularly in the dark. A white shirt or chemise, still called
camis in some of the provinces of France, as most discernible,
was commonly made use of, from which circumstance the
word took its rise.

CAMISANO, in Geography, a town of Italy, in the
Vicentine, belonging to the State of Venice: 7 miles S.E. of
Vicenza.

CAMISARDS, or Camisars, an appellation given by
the French to the Calvinists of the Cevennes, who formed a
league, and took up arms in their own defence, in the year
1568. In their boldness, crimes, and enthusiasm they re-
sembled the Circumcelliones of Africa. The etymology of
the name is disputed; but it is most probably formed from
camisade. See Camisade.

CAMISENE, in Ancient Geography, a province of Asia,
in Armenia; which had a famous fortress, destroyed before
the time of Strabo. Antonine mentions a village or town
of this name upon the route from Nicopolis to Arabifus. In
the Table of Peutinger it is called Comassa, and placed 23
miles from Sebastia.

CAMISOLE, in Conchology, the name given by Argen-
tives to the Linnean Trachus Phareonis.

CAMITA, or Comita, island, in Geography, lies 3 leagues
N.E. from Cape Rofa, near the N.W. part of the peninsula
of St. Domingo island.

CAMLET. See Camlet.

CAMLETINE, a light flannel, formerly made of hair
and coarse silk, and resembling camisade; but now out of
fashion.

CAMLIN, in Geography, a river of Ireland, in the country
of Longford, on which the town of Longford is seated, and
which falls into the Shannon.

CAMMA, and GORBI, two provinces of Africa, in the
kingdom of Loango, lying between the province of Sette
and the cape of Lobo Gonzales; whose inhabitants are at
perpetual war with each other, and whose country is inter-
sected with lakes and rivers, that afford plenty of fish,
but are infested with sea-horses, which are very mischievous both
on land and water, particularly to the canoes and other ves-
ticles, which are continually plying to and fro upon the rivers
and marshes. The language, manners, and customs of both
these provinces are almost the same with those of Loango.
They both, allow of polygamy, and they are very free in the
dispofal of their wives for the accommodation of their friends
or strangers. Their military weapons are the short pike,
bow and arrows, sword and dagger; and the Europeans
have furnished them with fire-arms, gun-powder and ball,
beside brafs pots and kettles for domestic use, and several
forts of coarse cloths. The chief town of Gobbi lies about
a day's journey from the sea. The land bred's little elfe but
beasts of prey. The principal commerce with the natives,
before the logwood, consists chiefly in elephants' teeth and
tails, the hair of which is highly valued, and used for several
curious purposes.

CAMMA, a river of Africa, which separates the kingdom
of Benin from Loango, and runs into the Atlantic. S. lat.
10° 40'. E. long. 11° 40'.

CAMMANIA, in Ancient Geography, a country of
Greece, which formed a part of Thebrotia. It is the Cef-
trine of Psafianias, and was called Cetlinia, according to
Steph. Byz.

CAMMAS WATER, in Geography, lies at the mouth of
the river running from Morpeth, in Northumberland, and
has a small port for shipping, corn, and grinding flaxen.

CAMMIN, a town of Germany, in Prussian Pomerania,
located near the mouth of the Oder, on the lake of Boden,
about 3 miles from the Baltic, near the fee of a bishop, sup-
plied by the peace of Westphalia, and united to the dom-
inions of Prussia; 35 miles N.E. of Stettin. N. lat.
53° 50'. E. long. 14° 48'.

CAMMIN found, is one of the small channels that lead
from the Baltic into the channel of the river Oder, up to
Stettin.

CAMMOCK, in Botany. See Ononia spinosa.

CAMMONI, in Ancient Geography, a village placed on
the Erythraean sea, in the gulf of Barygaza, according to
the peripius of Arrian; and probably the name with the
Campania of Polyenes.

CAMMOROS, in Botany, a name given by some of the
old writers to a poisonous plant called by the Romans cincuta,
or hemlock; so that it became hence a name for the man-
drake, and some of the nightshades, with some authors.
Many of the moderns, and even some among the ancients,
have erred greatly in confounding the commaros with the
commarea, which is an insect, in figure resembling the root of
this aconite. See Conocladius.

CAMOCLADIA. See Conocladius.

CAMOENA, in Entomology, an African Papillo,
of the Helcœuli tribe, described by Fabricius, the wings of which
are somewhat entire, fuscous, and dotted with black, with
a red band on the posterior pair.

CAMOGENE, in Ancient Mythology, a name given to the
Muses, because it was their principal occupation to cele-
fate in the songs of the gods and heroes. The camome of
Latinum, mentioned by Plutarch in Numis, who were sup-
pused to have flown the sacred fountain to the Veliales,
were probably, says Bryant (Anal. Anc. Mythol. v. I. p. 64.),
the original priapics, whose business it was to fetch water
for initiations from that stream. For Cam-Ain (he says) is the
fountain of the Sun, and the camome were named from their
attendance upon that deity. The hymns in the temples of
this god were sung by these women; and hence the
Camome were made protectors of music.

CAMOGERUM LUCUS, in Ancient Geography, the
name of a wood in the vicinity of Rome, at the Capena gate,
in the midst of which was the fountain of Egeria, consecrated
by Numa. Livy, I. i. c. 21.

CAMOENS, or Lewis de, in Biography, a Portuguese poet,
was defended of an ancient family of Galicia, in Spain, un-
der the name Caaman, but changed to Camoens, in 1370,
when a branch of the family left Spain and attached itself
to the king of Portugal. Camoens, the poet, sprung from a
younger branch of this family, which had been unfortunate;
his father having suffered shipwreck at Goa, with the lots
of his whole property; and was born, as some say, in 1529,
or according to others, in 1526 or 1527; nor is the place of
of his birth left contested than the time of it. Some say,
that he was born at Coimbra, and others, at Santarem; but
Emmanuel de Correa, his intimate friend and companion, says,
that he was born at Lisbon, and that his mother, Anna de
Mundo, was of a noble family. He studied in the Uni-
versity of Coimbra, where he was distinguished by his applica-
tion to the classics and to the philosophy of the times; but
his genius principally inclined him to poetry, and, therefore,
upon his return to Lisbon, he became known at court by
his poetical talents and his gallantry. Being no less agree-
able in his person than in his conversation and writings, he
was betrayed into improprieties of a licentious kind, which
caulmed him to be exiled, as it has been generally thought, to
Santarem and Evoramuris. The place of his imprisonment
and the residence of some of his relations. On this occasion
he compared himself, in one of his elegies, to the banished
Ovid. Distinguished with an inactive life, and being naturally
brave, he obtained permission to serve in a fleet that was sent
to the succour of Conta, in Africa, and in a naval engage-
ment he had the misfortune to lose one of his eyes. His
stay at Lisbon, whither he returned after this naval expedi-
tion, was of short continuance; some new cause of dissatis-
faction arose, and he was again obliged to leave it; and,
therefore, with complaints of the ingratitude of his country,
he resolved to embark for the East Indies in a fleet com-
manded by Cabral, which failed in 1553. At Goa he vo-
unteered his services in an expedition to the coast of Mal-
abar; and after his return, in 1555, he embarked on a second
expedition to the Straits of Mecca, in the Red Sea, where,
the military exertion not being necessary, he employed his time
in writing, and in visiting some of the adjacent parts of
Africa, which he has beautifully described. Having spent
the winter at Ormus, he returned to Goa; but indulging
his disposition in composing some satirical pieces against
Bareto, the Portuguese viceroy of India, and several other
principal persons of Goa, he was banished by order of the
viceroy to Macao in China. Here he obtained the profit-
able office of commissary of the estates of the decedent, and
in the exercise of it acquired some property. During a re-
fidence of five years at Macao, he finished his "Lusiad,"
which he had begun some years before in Portugal. Upon
the removal of Bareto, he determined to return to Goa, and
having freighted a ship for this purpose, he was unfortunately
shipwrecked at the mouth of the river Meco, on the coast
of Cambaja, and lost his whole property; however, he saved
his life, and his poems, which he bore through the waves
in one hand, whilst he swam ashore with the other. The
natives treated him with hospitality; and on this remote
coast he wrote his beautiful paraphrase on the 157th Psalm,
which represents the Jews as hanging their harps on the
willows by the rivers of Babylon. Upon his arrival at Goa,
he was kindly received by Don Constan
tine de Braganza,
the new governor; but his successor, count Redondo,
conceiving prejudices against him, on account of some malfac-
tion in his office at Macao, with which he was charged by his
enemies, threw him into prison. Having cleared himself
of the charge alleged against him, he was detained for
debt; and it was in consequence of an honorable petition,
which he presented to the viceroy, that he obtained his
liberty. His next adventure was that of accompanying the
governor of Sofala to that settlement; but he was deceived
by promises which were never fulfilled, and treated with
tingular severity. When the governor found that Camoens
was determined to leave him, he endeavoured to detain him
by making a charge of debt for his board, and threatening
to confine him in prison. These unreasonable claims were
satisfied by some Portuguese gentlemen, who invited him to
accompany them to Europe; and accordingly he arrived
with them in Lisbon in 1569, after an absence of 16 years.
One principal object, which made him decease of revisiting
his native country, was the publication of his "Lusiad,"
which appeared in 1572. This poem, which came to a second
edition in the same year, was dedicated to king Sebastian,
who, it is said, allowed him a small pittance of 4,000 rials, on
condition of his living at Coimbra. With this promise, if it
had been continued, Camoens would have lived in peace and
comfort; but Sebastian found his life in Africa, and upon
the accession of Henry, the poet was forgotten, and his poe-
ty was withheld. Thus reduced to a state of deplorable
indigence and distress, poet, who had produced what at
its first appearance was thought to do honour to the nation,
spent the residue of his life, humbled and mortif'ed amongst
a few Dominican monks, either in an almshouse, or under
the charitable roof of a nunnery. It is said, that his black
servant, a native of Java, who had been his companion
for many years, and who assisted in saving his life when he
was shipwrecked, begged in the streets of Lisbon for the
support of his master, who died in 1579. It is said, that
his death was accelerated by the anguish with which he fore-
saw the ruin impending over his country. In one of his
letters he utters these remarkable expressions: "I am ending
the course of my life; the world will witness how I have
loved my country. I have returned not only to die in her
boim, but to die with her." He was buried as obliquely
as he had closed his life, in St. Anne's church; and the fol-
lowing epitaph was inscribed over his grave:

"Here lies Lewis de Camoens,
Prince of the poets of his time.
He lived poor and miserable, and died such,
Anna Domini, 1579."

Some years afterwards a respectable monument was erected
over his remains, at the expense of a Portuguese nobleman.
"His memory was honoured by numerous eulogies from the
poets of Spain and Portugal, and the name of Camoens is
still pronounced with enthusiastic veneration by all the va-
tories of Portuguese literature." Of the various poetical
compositions, written by Camoens, the epic poem, entitled
"Lusiad," is the only one which makes him known in modern
times. The subject of this poem is the discovery of the East
Indies by the Portuguese, under Vafco de Gama; and the
fleet is conducted by the poet round the coast of Africa to
Calicut, on the Malabar coast. In the course of the voyage
the author introduces a great variety of descriptions, which
with his knowledge of the parts of the world to which they
relate renders noble and interesting. Some of his poetical
fictions are conceived with true genius; and the giant: Adamador,
the guardian of the Cape of Tempele (since called the Cape
of Good Hope,) is a creature of fancy as sublime as the
imagination of a poet has produced. "On the whole,"
says Dr. Alkin (Gen. Biog.), "the want of a well-connected
plan, the neglect of proper decorum, the monstrous mixture
of the Heathen with the Christian mythology, and the
general baldness and want of elevation in the style, place
this work far beneath the principal epics of ancient and
modern times." "The whole work," says Dr. Blair (Lec-
tures on Rhetoric, &c. vol. iii. p. 273.), "is conducted ac-
cording to the epic plan. Both the subject and the incidents
are magnificent; and, joined with some wildness and irregu-
larity, there appear in the execution much poetic spirit,
strong fancy, and bold description." "There is no attempt
towards painting characters in the poem; Vafco is the hero,
and the only personage indeed that makes any figure. The
machinery of the Lusiad is perfectly extravagant; not only
is it formed of a popular mixture of Christian ideas, and
Pagans; but so conducted that the Pagan
people appear to be the true Deities, and Christ and the
Blissed Virgin to be subordinate agents. One great feature
of the Portuguese expedition, our author informs us, is to
propagate the Christian faith, and to extirpate Mahometan-
ism. In this religious undertaking, the great protector of
the Portuguese is Venus, and their great adversary is Bac-
rus, whose displeasure is excited, by Vaux's attempting
to rival his fame in the Indies. Councils of the gods are held,
in which Jupiter is introduced, as foretelling the downfall of
Mahometanism, and the propagation of the Gospel. Vaux,
in great distress from a storm, prays most fervently to God;
implores the aid of Christ and the Virgin, and begs for such
assistance as was given to the Irooites, when they were
passing through the Red Sea, and to the Apostle Paul, when
he was in hazard of shipwreck. In return to this prayer,
Venus appears, who differing the storm to be the work of
Bacchus, complains to Jupiter, and procures the winds to
be calmed. Such strange and preposterous machinery shows,
how much authors have been misled by the absurd opinion,
that there could be no epic poetry without the gods of
Homer. Towards the end of the work, indeed, the author
gives us an awkward salvo for his whole mythology; making
the gods Tellus inform Vaux, that she, and the rest of the
Heathen deities, are no more than names to describe the
operations of Providence.

"There is, however, some fine machinery, of a different
kind, in the Lusitania. The genius of the river Ganges, ap-
ppearing to Emanuel king of Portugal, in a dream, inviting
that prince to discover his secret springs, and acquainting him,
that he was the destined monarch for whom the treasures of
the East were referred, is a happy idea. But the noblest
conception of this fort, is in the fifth canto, where Vaux is
recounting to the king of Melida, all the wonders which he
met with in his navigation. He tells him, that when the
fleet arrived at the Cape of Good Hope, which never before
had been doubled by any navigator, there appeared to them
on a sudden, a huge and monstrous phantom rising out of
the sea, in the midst of temples and thunders, with a head that
reached the clouds, and a countenance that filled them
with terror. This was the genius, or guardian, of that
hitherto unknown ocean. It spoke to them with a voice
like thunder; menaced them for invading those seas which he
had so long postponed undisturbed; and for daring to ex-
amine the secrets of the deep, which never had been reveal-
ed to the eye of mortals; required them to proceed no fur-
ther; if they should proceed, foretold all the destructive epi-
calms, that were to befall them; and then, with a mighty
voice, disappeared. This is one of the most solemn and strik-
ing pieces of machinery that ever was employed; and is
sufficient to show that Canoens is a poet, though of an irre-
gular, yet of a bold and lofty imagination."

This poem has been translated into many languages, and
illustrated by elaborate commentaries. Two English
versions of it have appeared; one by R. Richard Fawke, in
the 17th century; and another in the latter part of the 18th
by William Julius Mickle, A.D. 1776, 410. "This last,"
says Akin, "is one of the best verified poems in the Eng-
lish language; but the liberties taken with the original, in
large additions, alterations, and omissions, bespeaks a per-
fect superiority of poetic language, render it a very flat-
Intro. to Mickle's Lusitania.

Camoens's Cave, in Geography, a cave below the loftiest
eminence in the town of Macao in China, so called from a
tradition current in the settlements, that the Portuguese post
of that name wrote his celebrated poem of Lusitania on that
spot. This interesting cave is in the middle of a garden,
which commands a very extensive prospect.

Camoili, a town of France, in the department of
Marbilaian, and district of Vannes, 14 league W.S.W. of
Roche-Bernard.

Caminile, in Botany. See Anthems.

Camoou, in Geography, a town of Japan, in the
province of Omi.

Cama. See Zamora.

Camaorta, a small island in the bay of Bengal. N.
l. 8° 8'. E. long. 94° 5'.

Camotes, a group of islands belonging to the Phi-
lippines, in the East Indian ocean, situate between Zebu or
Cebu, and the coast of Ogmush and Leyte; the chief of
which is Poro, dependent on Zebu.

Camoücle, in Orinology, the horned ferreer, ac-
Garding to Bajou. See Palmæda coruna.

Camoeflet, a smoky paper held under the nose of
one that sleeps. But when this word is made use of as a
term of war, it signifies an affront, a mortification, a disap-
poiniment. An enemy's miner is paid to give a camouflet
to ours, when he finds means to defend or get down into his
adversary's gallery, to make some small mines blow up, and
thereby to ruin or facilitate him.

Camp, in Geography, a town of Germany, in the circle
of the Lower Rhine, and archbishopric of Treves, on the east
side of the Rhine, opposite to Boppard.

Camp, in the Military Art, the ground where a corpo-
s, body of troops, or army, pitch their tents, and live or dwell
in the same, either for a shorter or longer space of time.
In a more general acceptation of the word, it may be defined to
be the spot or ground where any number of persons, how-
ever small, sleep or remain in tents, wigwams, huts, or other-
wise, for one night or a longer time, whether they be in a
state of warfare, or engaged in their ordinary pursuits of
life. Thus, for instance, the savages or wandering natives of
America are said to encamp; and the spots where they have their
wigwams, or remain even for one night or two, are
called their camps or encampments. Many of them are in
as simple and uncultivated a state of life as it is possible for
human creatures to be in. For men neither ever did nor
ever can exist but in a state of society of some kind or other.
Ever since there have been men, however, there have been
disputes or quarrels. These led to violence and warfare, and
obliged those who lived even in the simplest and rudest state
of society, to think of and contrive means for securing their
encampments against surprise or insults. For this purpose
they would naturally make use of flaks, huts, abatis, a
ditch, and occupy situations difficult of access, and advan-
tageous in other respects. The first contrivances and efforts
of genius, however, in the way of defence must have been
 rude, defective, and of little moment, suited to the simplicity
of those by whom they were made, who possessed neither the
experience that could lead to the conception of great de-
rive, nor the means necessary for executing them. Ditches, bor-
dered with brush, bushes, or abatis, or a single row of flaks,
surrounded their huts, tents, or cabins, and formed their
whole security. The Indians in America furnish, at this mo-
time, many examples of this manner of fortifying. As men
advanced in social improvements, and began to have fixed
or permanent habitations, they would naturally think of con-
structing walls with wood, earth, and afterwards with stones.
Julius Cesar in his time found wooden walls in use among
the Gauls; and there are some parts now in Ruffia, where
the
CAMP.

The towns are defended or secured by walls of wood or timber.

The words made use of by the Grecian writers to express a camp, or the camp, are always in the singular number, as το καστρον, το ιβυκτρον. But the Roman military writers constantly use the word castrum, in the plural number, to signify a camp, or the camp. Some have attempted to derive the word castrum from castra, making it of the same import as castra, quod ibi castrarum libro, and because the Roman folders were not originally permitted to marry. But the word castra is the plural of castrum, which Cicero has made use of: and castrum or castra is easily and evidently derivable from castus or castrum, to erect, or build huts or tents adjoining to one another or close together. But no good or even plausible explanation has been given of the cause or reason why the Roman historians invariably employ the word castrum in the plural number, and not castrum in the singular, not only when they mention both the confin camps when separate, but also when they speak only of one of them or of both joined together as one. The following circumstances, however, probably gave rise to that practice, or customary mode of expression, for a camp or the camp. The tribes originally when they went out encamped separately and apart from one another, each by itself. The different positions or spots of ground they occupied, were naturally called the camps, or castra; which term or expression growing into use was retained when they were encamped together and surrounded by one and the same ditch and rampart.

It is not probable that either the Romans or any other people originally enclosed their camps on every occasion with regular ditches and ramparts, but rather that they frequently chose strong and advantageous situations, and depended on watchfulness and valour for their security. It was a very ancient custom, however, among the Greeks, to surround their places of encampment occasionally with a ditch or trench, which they called ερυθας. Homer speaks of the camp which they formed before Troy, and makes them poll the bell and bravel of their troops on the two flanks or wings. The Macedonians, who were trained up in martial exercises from the time they were seven years of age, and studied war as an art or science more than any other of the states of Greece, were not only well acquainted with the genuine maxims and principles of warfare, but also skilful, dexterous, and expert in all the methods of carrying them into practice long before the Macedonians, the Carthaginians, and the Romans. They also received from their celebrated lawgiver, Lycurgus, the first mixed form of government composed of the three simple ones, viz. monarchy, aristocracy, and democracy, that existed in Europe. It failed for many ages; and whilst they adhered to his laws and institutions, they were alike free from internal dissensions among themselves, and proof against subjugation by external force. The Macedonians borrowed from them the belt part of their military regulations and discipline. The Carthaginians imitated them, and on one occasion a certain Lacedemonian, named Xantippus, who joined them with a body of mercenaries from Greece, by his superior skill in the art of war, and dexterous management, defeated the Roman confed Regulus, who till then had been uniformly victorious over them, and saved their fleet when it was brought to the very brink of destruction. The Romans, at an early period, not only adopted several of their military maxims, precepts, and institutions, but also committed them to writing, carefully keeping records of them, and retained them ever after. It has been affirmed on the authority of some writers, that their camp was of a circular form, which was prescribed by Lycurgus, as better for defence than any other. This reason, however, is not an accurate or just one. For a direct defence from a straight line is much better than from the convexity either of a circle or ellipse. Before this, the observation militates against facts, and the practice of the Lacedemonians themselves in the different wars in which they were engaged. For, like the rest of the Greeks, they did not observe any invariable form or method in their encampments, but chiefly consulted the nature and strength of the ground they encamped on, and gave to their camp the form and arrangement that best suited the same, employing, on different occasions, every sort of figure which the positions they occupied required. This erroneous idea, in regard to the figure of the Spartan camp, was probably derived from the circumstances, that the city of Sparta itself was of a regular form. It is not very probable, however, that the Spartans often intrenched their camps, as they did not even secure their city with a wall, or rampart, depending on their own vigour and valour, more than on walls, for its protection. That they sometimes did, however, cannot be denied. For Cleomenes, when opposed to Antigonus, not only occupied strong positions, but also made use of intrenchments, and even abatis. Many other influences might likewise be mentioned. We know, indeed, from the best authority, that the Greeks in general accommodated the figures and distributions of their camps to the situations they encamped on, sometimes securing them with trenches and ramparts, but often not. They occasionally suffered severely by neglecting this precaution, of which the Meffennians furnish a striking example, when they marched with their forces to join Philip of Macedon, though they encamped close under the walls of a friendly fortress. Polybius, in the sixth book of his general history, in speaking of the great regularity of a Roman camp, the rules the Romans regularly observed in forming it, their invariable custom of surrounding it with a ditch and rampart, and the great care and facility with which those were made, by each soldier’s knowing always on what part he was to perform his labour, as well as his own place in the camp, and that of the body he belonged to, contains their practice with that of the Greeks; and tells us, that the, when they encamped, chiefly considered the natural strength of the place they were on, and the arrangement and disposition of their encampment, with the party to avoid the labour of making intrenchments, and partly persuaded that which nature did by art are seldom so strong or secure as those that are formed by nature. He says, that in compliance, therefore, with what the situations demanded, they were not only obliged to give every sort of figure to their camps, but also to vary the position of the several parts of them, as the place for each was favourable or improper; and that from thence it happened that the soldier never knew to a certainty his own place in the camp, or that of the body to which he belonged. But the Romans, he informs us, willingly submitted to the talk of making intrenchments, and to other toilsome labour, for the sake of the great advantage that was found to arise from their employing a method that was never changed, and which rendered all the parts of the camp quite familiar to the army. The Macedonians, who learnt the art of war from the Greeks, and particularly from the Spartans, like them gave their camp every sort of figure to make it fit the ground they encamped on, sometimes intrenching it, and sometimes not, as circumstances seemed to require.

Even before Alexander the Great invaded Persia, the Grecian colonists in Asia and the nations in it who were in the practice of employing Greeks in their armies, encamped nearly in the same way, varying the forms of their encampments with those of the particulars they occupied with them,
securing them with intrenchments on some occasions, and on others not. But after the death of that prince, who seemed to have been born for the conquest of men, both the Egyptians and all those nations of Asia that had been visited by his arms, followed very nearly the Macedonian or Greco-

median method of encamping, and generally when at no great distance from their enemies, or in danger of being attacked, strengthened and secured their camps with ditches and ramparts. Thus the camp of Molon, who was governor of Media, and had revolted against Antiochus, the son of Seleucus, was intrenched on the bank of the Tigris. Thence the 'Eilamite, governor of Cilicia-Syria, secured the troops he had posted in the narrow part of the vale of Mar-

fya, between the fortresses of Brouchi and Gerasa, so well with intrenchments and palisades, that the said Antiochus in trying to penetrate that way, fulfilled his great aloft, that he was obliged to desist from the attempt. Both this king and Polybius, in their comment on the sovereignty of that province, intrenched their camps. And many other instances of this practice, subsequent to the time of Alexan-

der, might be given.

The Carthaginians, who had an intercourse with the Greeks, long before their obilinite contention with the Romans in Sicily for the possession of that island, followed a similar mode of encamping, changing, like them, the forms of their camps, to make them suit the situations they occupied, surrounding them sometimes with ditches and ramparts, and sometimes not, as circumstances made such precautions necessary or otherwise. It is probable they paid more attention than formerly both to the security of their camps, and to regularity in forming them after they came to be engaged in long and obstinate conflicts with the Romans. It does not appear, however, that the Carthaginian generals, when they sat down, contrary both to common sense and the rules of military science, with their elephants and cavalry, as well as their infantry, on a rough and craggy eminence near Adis, which Regulus was besieging, took measures for strengthening their camp with any works whatever. But it is evi-
dent that the camp of Xanthippus, who soon afterwards de-
feated Regulus, and destroyed his army, was intrenched as well as that of the Romans. There never perhaps existed a general who was more capable than Amilcar Barcas, of choosing proper and advantageous ground for encampments, or who knew better how to secure and defend them. His son Annibal, who, though he often surprised his enemies, was himself never once surprised, always secured his camp so well with an intrenchment and palisades, that during the sixteen years he waged war against the Romans in Italy, though he never once dismmissed his army from the field, no serious attack was ever made on it but on one occasion by Manuis, when most of his troops were out of it a-fugiting. As he very judiciously adopted the arms and armour of the Romans for his heavy-armed infantry, after the first battle he fought with them, it is more than probable that he also followed their mode of encamping, in which they appear to have been as superior to any other people among the ancients, as they were in their arms and order of battle. And as some part of their method is still retained by all nations in Europe in encamping their troops, it may not be improper or unnece-
fary to give a correct plan and description of a Roman camp, and of the disposition or arrangement of its different parts from Polybius, a faithful and judicious historian, and the only one among the ancients who has left us a distinct account thereof. Before his strict adherence to truth in all his nar-

ratives, he was a person of great political and military talents, wrote at a period of time when the government of Rome was in its greatest vigour, and possessed a thorough knowledge of all its component parts, customs, and institutions. This is perhaps the more requisite, as Julius Lipsius, who was a man of much learning, but of little military information, has led almost every modern writer wrong, that has treated either on the castramentation or order of battle of the Romans.

Though it is highly probable that from the very begin-
ing they secured their camps more or less with intrench-
ments, and particularly from the time they began to carry on their operations at some distance from their own city, and the tribes came to encamp together on the same spot, or nation with, and the same enclosures, yet if we are to credit some historians, there was but little interior security or or-
derly arrangement of the different parts in them, before the 124th Olympiad, when Pyrrhus, king of Epirus, on the initi-
atum, and in support of the Tarentines, invaded Italy. That prince was certainly endowed both with military talents of an extraordinary nature, and with the most undaunted courage; nimbles in stratagems and expedients, most skilful in every branch of discipline, and perfectly conversant in all parts of the art of war. He waged war with various fleets, with most powerful kings, and great commanders, and gene-

rally was victorious without being ever, strictly speaking, vanquished himself. In all his battles with the Romans he employed not only the arms but the troops of Italy, and placed, in alternate order, companies of them, and cohorts armed and drawn up after the manner of the phalans. Even with this contrivance, however, though he rather wanted them in some engagements, he never was able to obtain any very clear or decided advantage over them; such were the in-
herent excellence of their order of battle, and the advan-
tageous nature of their arms and armour in close combat. By their former and steady perseverance, they at last forced him to quit Italy, and leave the Tarentines with the inhabi-
tants of other cities, that had been confederated with him against them, to their fate. And getting possession of one of his camps, they, from the interior arrangement of it, im-
proved the disposition of their own, and gradually brought their castramentation to perfection.

The Romans were the only people we have any account of, who invariably observed one mode or manner of encamping, and confidently intrenched themselves wherever they encamped, if they halted only for a single night.

The intrenchments, however, with which they surrounded their temporary or large camps in the field were not so strong as those which they made round their castra flavia, their forts or smaller camps, called castra, in which a few cohorts or small garrisons were frequently left for some time to defend them-

selves, without any other aid or assistance, and which were sometimes enclosed with two, three, four, and even five or more distinct ditches and ramparts.

They had their castra efliva, and their castra hiberna. The first of these they occupied in summer, when they were carrying on their operations in the field; and the last in either towns they took possession of, or such as they raised themselves in proper situations, and fortified for the purpose of quartering their troops in during winter. Their castra effiva were likewise of two forts, namely, those which they occupied from day to day, or for a short time only, being temporary camps, and called simply castra, and those they occupied for a considerable space of time, and which are re-

peatedly called castra flavia. The former of these were more slightly intrenched than the latter.

"This then," says Polybius, book vi. "is their (the Roman) kind of castramentation."

Ground being always chosen for the encampment, the gen-

eral's tent occupies the part of it most convenient for pro-

spect and command. A standard being placed where they are
Next to the principals, and behind them, they, in like manner, encamp the hallats looking in contrary way, placing the figures close together. And this is the manner in which, in each of the parts, (of a legion) according to the decision from the beginning, it happens, that all the soldiers are equal both as to length, and as to their terminating evenly towards the side of the intrenchment at the front, turned towards which they encamp the hallats. See No. 12.

Again, leaving fifty feet from the hallats, they encamp opposite to them the horse of the allies, beginning at the same right line with them, and ending at the same right line. But, as I have observed above, the number of the foot of the allies is equal to that of the Roman legion, as is shewn by that of the extraordinary. And that of their horse is double. A third part being taken from these for extraordinary, by increasing in proportion the depth of the figures, in which they encamp them, they endeavour to make them equal, as to length, the Roman legions. See No. 13.

All the five figures being now completed, they again, increasing the depth in the same proportion, place the maniples of the allied foot ranging ten to rear to the horse, and looking towards the intrenchment, and both fronts of its transverse fides. And in each example the centurions occupy the fifth fides on either side. See No. 15.

But in following the above-mentioned method of encamping, they separate each fide the fifth troop into five feet from the fifth, and in a similar manner, the maniples of foot; so that this becomes another opening through the middle of the legions, running these fides, and parallel to the tents of the tribunes, which they call the fifth; (or via quintana), from its extending along the fifth maniples. See No. 16.

But the place behind and front from the tents of the tribunes, lying adjacent to each fide of the general’s ground, becomes one part of it a place for the forum, and the other for the quaflor, and the things under his charge. See No. 17, and 18.

From the fmall tents of the tribunes, on either fide, having an arrangement as it were reflected backwards perpendicularly to these tents, all the choice men of the extraordinary horse, and some of those serving as volunteers, from regard and respect to the confuls, encamp according to (or parallel to) the fides of the intrenchment on the transverse fides, part of them fronting the fides of the quaflor, and part of them on the opposite fide looking into the forum. And it for the most part happens to these not only to encamp near the confuls, but also on marches, and on other necessary occasions, to perform their whole duty and service about the confuls and quaflor. See No. 19.

And the foot performing a similar service with the forementioned horse, are placed opposite to them, looking towards the intrenchment. See No. 20.

Then from these is left a ftree one hundred feet wide, and parallel to the tents of the tribunes extending along the opposite fides of the forum, praetorium, and quaflorium, to the above-mentioned parts of the intrenchment. See No. 21.

And along the upper fide of this, the extraordinary horse of the allies encamp, looking towards the forum together with the praetorium, (or general’s ground), and the quaflorium. See No. 22.

At the middle of the encampment of these horse, and at the fame ground adjoining the praetorium, a ftree of fifty feet is left reaching to the rear fide of the encampment, its direction lying at right angles to the aforesaid broad ftree. See No. 23.

With their backs to these horse again, the extraordinary foot of the allies are placed looking towards the intrenchment and the rear aspex of the whole encampment. See No. 24.

And the vacant space left on each fide of these towards the transverse fides, is given to strangers and allies occasionally arriving. See No. 25.
C A M P.

All being thus disposed, the whole figure of the encampment becomes an equilateral quadrangle. And as to what relates to the intersection of the streets in it, and its distribution in other respects, it has an arrangement resembling a city. They place the intrenchment on every side two hundred feet distant from the tents; and this vacant space affords them many and great conveniences. It is commodious and useful for the ingrats and egrets of the legions. For each of them move out into this open space through their own streets, but do not push down and trample on one another by crowding into one. Carrying also to this place the booty of cattle they bring in, and the spoils they take from the enemy, they keep them safe during the nights. But the greatest is this, that in nocturnal assaults neither fire nor weapons, except a very few, can reach them. And it happens, that even these are almost harmless, from the greatness of the distance, and the surrounding tents.

Polybius, in this description of a Roman camp, supposes a legion to consist of four thousand two hundred foot, and three hundred horse. He observes, however, that, from it, those who choose to examine it will easily be able to understand the extent and whole perimeter of a camp, even when the legion consists of a greater or less number. When more of the allies than are usual either accompanied them from the beginning of an expedition, or afterwards arrived in the camp, he informs us, that besides assigning to the latter the places already mentioned, they filled them with, also, those on each side of the pretorium, bringing the forum and quæstrorium together into one place, as the occasion and necessity required; and that as to the former, when their number exceeded what was customary, besides the locations usually made for them, they laid out an additional street for them beyond the legions both on the right and left side of the camp.

But when the four legions and both confuls were assembled together within one and the same intrenchment, he says, that nothing more is necessary for understanding their method of encamping than to suppose two armies disposed of in the manner now described, with their ears where the extraordinary, as he has mentioned of each were placed, joined together. Whenever this happened, he tells us, the figure of the camp, instead of being a square, became a rectangle, having its area double that of the confuslar camp he has given a description of, and its perimeter one half greater. This, indeed, is manifest, since two equal squares joined together form a rectangle, of which the area is double that of either, and the perimeter is to that of each of them, in the ratio of 6 to 4 or of 3 to 2. The Romans, he adds, always observed this method or disposition as often as both confuls had their camps joined together, and that as often as they had separate and distinct camps, the arrangement continued the same, with this variation only, that they then placed the forum, quæstrorium, and pretorium, in the middle between both the armies.

Polybius, in describing the Roman method of encamping, makes no mention of the velites, or light-armed troops, who, in every legion, were equal in number to the hastati, or to the principes. But in giving an account of the composition of the legion, and the mode of forming it, he expressly affirms, that they were distributed equally, or in just proportion, among all the rest, according to their number. It is, therefore, natural to suppose, that the same distribution of them existed in the camp, or that two-fifths of them encamped with the hastati, two-fifths with the principes, and one-fifth with the triarii.

From what has been observed, then, it appears that the Romans in the time of Polybius, allowed ground for encamping on at the rate of 39.44 square feet to every foot soldier, and 33.33, for every horseman and trooper and his horse. For as the hastati and principes were equal in number in every legion, and the velites equal to each of them, and as each of the former consisted of ten companies, measuring, when the establishment of the legion was at 4200 feet, to 1200, and had two-fifths of this number, or 480 of the velites distributed among them, it is evident, that on every foot of ground 100 feet square, occupied by a maniple either of hastati or of the principes, there were encamped 120 of themselves, and two-fifths of this number, or 48 of the velites, in all 168 men. But a square, of which the side is equal to 100 feet, contains 10,000 square feet, which divided by 168, gives 59 square feet, and eleven-twenty-one parts of a square foot. In like manner, as the number of the triarii was only equal to half that of either the hastati or the principes, amounting to no more than 600 men, and as these were also divided into ten companies, and had one-fifth or 240 of the velites distributed among them, it is manifest, that on each of the ten rectangles, occupied by their maniples, there were encamped 60 of themselves, and 24 of the velites, or 84 men. But a rectangle 100 feet long and 70 feet broad, contains 7000 square feet, which divided by 84 gives likewise 85 square feet and eleven-twenty one parts of a square foot.

We arrive at the same conclusion by dividing the number of square feet contained in the whole ground alligned by Polybius for encamping all the foot of a legion, by 4200, the number of them. For the hastati and principes encamped on 20 equal squares, of which each contained 10,000 square feet, having its side equal to one hundred feet. The whole 20 then, of course, contained 200,000 square feet. If to this number of square feet there be added the contents of the ten equal rectangles of 5000 square feet each, that were occupied by the ten maniples of triarii and their proportion of velites, or 50,000 square feet, we get 250,000 square feet for the surface of the whole ground, that the infantry of one legion encamped on, which number of square feet divided by 4200 give 59 square feet, and eleven-twenty-one parts of a square foot as before.

And as there were 300 horse then in each legion, who were also divided into ten parts or troops, and encamped on ten equal squares of 10,000 square feet each, it is no less evident that the encamping ground allowed for them was at the rate of 333 square feet, and one third part of a square foot for each horseman or trooper and his horse, since 10,000 divided by 30, or 100,000 divided by 300, give, 333 and one third.

Polybius also informs us that the excavation of the ditch and the raising of the rampart along the two transverse sides of the intrenchment, or those near the wings of the allies, were done by them, and that the other two sides were left to the Romans, to each legion one; that each side was divided into as many parts or portions as there were maniples to labour on it, and a centurion appointed to superintend the execution of the work in each part, and that the whole side was inspected and approved of by two of the tribunes, whose turn of duty it was to attend to every kind of necessary service in and about the camp. For the tribunes, two by two in rotation, took upon them not only the care of the camp, but the management and direction of everything done in it for two months at a time.

As in encamping, a place was fixed for the confuls's or general's tent before ground was laid out for any others, or on breaking up the camp, his tent and those of the tribunes were
were always first taken down. And when they were all struck, the baggage collected and placed on the beafts of burthen, the whole camp on a signal made began to move, with the extraordinaries usually in the van, and next to them the allies of the right wing, followed by the baggage of both. Next to them marched the fift of the Roman legions with its baggage behind it; then followed the femed legion, having behind it not only its own baggage, but also that of the allies of the left wing, who closed the rear of the whole march.

Polybius in his description of a confular camp has not given us any dimensions for the rampart and the ditch. These must have varied with circumstances and situations, and particularly with the length of time for which it was intended to be occupied. Julius Caesar in the second book of his war in Gaul, chap. v. informs us that he ordered one of his camps to be fenced with a rampart 12 feet high, and a ditch 18 feet deep.

In describing the Roman camp, Polybius does not give us either the names or number of the gates. He only informs us, that the exterior sides of the camp were guarded at night by the velites, who placed ten of their number at every gate, and kept watch all in the day-time throughout the whole extent of the intrenchment. It is well understood, however, from the information left us by other historians, that there were four principal gates, viz. one in the middle of the front of the intrenchment opposite to the termination of the front of fifty feet wide between the cavalry of the Roman legions, another directly opposite to it in the middle of the rear of the intrenchment, and two directly opposite to each other, and to the ends of the front of 100 feet wide between the tents of the tribunes and the Roman legions in the tranverse side of the intrenchment. One of the two last mentioned, which was on the right hand side of the camp, was called porta principalis dextra, and the other on the left hand side, porta principalis sinistra. The other two principal gates, namely the two first mentioned, were called porta praetoria and porta decumana. But in regard to their real or actual situations, though all writers on the subject allow them to have been opposite to each other, doubts and different opinions have arisen, some placing the decuman gate in the front side of the intrenchment and others in the rear. Those, who contend for its having been placed in the middle of the rear side of the intrenchment, make it derive its name from this circumstance, that such of the soldiers, as had been found guilty of neglect of duty or delinquency, were conducted through it to the place appointed for their punishment or execution, and refer to the following words of Vegetius, book i. chap. 23, "Porta autem, qua appellatur praetoria, aut orientem spectacere debet, aut illum locum, qui hostes replevit; aut fit iter agitur, illam patrem debet attendere, ad quam eft profectum exercitus, intra quam prince centurii, loc efl, cohortes paulatim tendunt, et dracones et figura conftituent. Decuman autem porta, qua appellatur, po if praetorii efl, per quam delinquentes milites educuntur ad pecuniam."

The late major general Roy referring to this passage expresses himself in these words, "With regard to the decuman gate mentioned in this passage of Vegetius, it is to be observed, that for the maintenance of that rigorous discipline established in the Roman armies, when a particular corps or any number of soldiers had misbehaved in the field, or had been mutinous to their officers, it became necessary to debar the delinquents, every tenth man being drawn out by lot and doomed to suffer death. Hence we may judge, that the decuman gate had its name from thofe, who had received sentence, being led out by it for punishment or execution." Military Antiquities of the Romans in Britain, page 50.

It does not follow, however, from the foregoing words of Vegetius, that delinquents were led out through the gate in the rear of the camp to receive punishment. It may well as well be inferred from them that they were carried out through the gate in the front of the camp. And from his observing that the praetorian gate ought to look either to wards the camp or the enemy, we cannot at all ascertain whether it was customary for the Romans to make the front or rear of their camp look towards the east. But this inference may reasonably enough be drawn from them that the praetorian gate sometimes looked towards the enemy and sometimes not. Polybius, without making the four different aspects of his confular camp have any reference whatsoever to the east, well, north, and south, expressly supposes the front of it to look towards those parts, that were most convenient for supplies of water and forage. If any one of the principal gates in his time went by the name of porta decumana, it was probably so called from the decumans maniple, and decumane turma next to the front of the intrenchment. That it took its name from soldiers selected by decimation for punishment, being led through it out of the camp, is a supposition directly contrary to his authority; for he informs us, when speaking of that punishment and the rigour of the Roman discipline, that it was actually inflicted within the camp.

Lipius, whom most of the modern writers on the Roman claimatuation as delivered by Polybius have followed, though a man of great learning, de parts from some of the rules laid down by that historian. He leaves out the space fifty feet wide between the ground, that was occupied by the tents of the tribunes, and the forum, praetorium, and quaedrorum, which Polybius expressly assigns for their horses, beafts of burthen, and other equipages, in these words, "et alibi paratam fumptum ex diuersis aliis publicis, quae in templo fuerint, promittatur." Now that their tents were not only in front of this space, but also at some little distance from it, is evident from another passage in this history, where he informs us, that three companies were allotted to each tribune, who, among other services they performed for him, furnished him always with a double guard, consisting of four soldiers, two of whom were stationed before his tent, and the other two behind it near to the horses.

He allows, however, 50 feet in depth as we have done, for the tribunes' quarters; and this depth does not appear to be more than what was necessary for them, exclusive of the 50 feet allowed for their horses, beafts of burthen, &c. as they were the officers next in rank and dignity to the conful and quaeftor, had, two by two in succession, charge of the whole camp, and the superintendence of every thing done in it, and had also all delinquents brought before them to be tried and to receive sentence. Although he leaves out the aforefaid width of 50 feet left for the horses, &c. of the tribunes, he quarters among the guards a number of volunteers, to greatly exceeding that which usually attended one confal, with two legions and the ordinary complement of allies, that he makes his camp 53 feet longer from front to rear than it is broad, contrary to the rule for keeping it always an equilateral quadrangle. In this particular, then, he departs not less than 83 feet from the rules laid down by Polybius, and makes the ground for quartering or encamping the extraordinarii in the rear deeper by the same number of feet than by these rules it could be

Instead of making the quarters of the guards for the conful and quaeftor commence, according to Polybius, from the
lent tents of the tribunes, or from the quaestorium and forum, which extended on the right and left of the praetorium towards the transept files of the camp as far as the encamping ground of the tribunes, and that of the Roman legions did, he makes them begin 20 feet distant from the same.

Though Polybius neither mentions the praefecti of the allies, nor assigns any encamping ground for them, it is natural to suppose, that their quarters, like those of the tribunes, extended the whole breadth of their own horse and foot, and no farther, leaving a passage 50 feet wide between the left tent of the tribunes and the first of theirs, both on the right and left, which passages must have been very convenient as communications with the principia for the horse guards, who fronted the forum and quaestorium. Liphus, however, makes the tents of the praefecti extend 20 feet into each of these openings, beyond the encamping ground of their own troops.

He also takes up ground for the quaestor and two legati exclusive of that for the public, which he has no authority for, and Polybius, who makes no mention at all in his account of the Roman castration of a legatus or legati.

As to the duke of Rohan's plan of a Roman camp, he leaves out with Liphus the space across it 50 feet wide, expressly allowed by Polybius for the horses, beafts of burden, baggage, &c. of the tribunes. He makes the ground for quartering the super numeraries, stragglers, and part of the extraordinary, too deep by 50 feet, which additional depth being equal to the width of the said space left out behind the tribunes' tents, causes his plan to be a square, though in his distribution of these quarters, he entirely mistakes that historian's meaning. He also lays out the quaestorium in various whimsical divisions without the least shadow of authority from that writer.

Sir Henry Saville, in his view of the military affairs of the Romans, gives a description of their camp on, which he makes a square or equilateral quadrangle, but 32 feet broader and deeper than it ought to be, by allowing the horse of the allies 16 feet more depth on each side than their jall proportion. He, in like manner, leaves the space 50 feet wide allowed to the tribunes for their horse, beafts of burden, and baggage; but makes the encamping ground for the extraordinary that remain after those allotted for the guards are taken from them, and for stragglers and supernumerary allies, too deep by 32 feet, which being equal to the 50 and 32 feet 51st mentioned, constitutes the Roman camp as described by him a square, of which the side, however, is 20 feet longer than it ought to be according to Polybius. He also makes the quaestorium and forum too large, and the quarters of the guards too small. He likewise gives the encamping ground of the praefecti of the allies an extent of 50 feet more than that which their own horse and foot cover.

The late major-general Roy has professedly given us a plan and description of a confular camp, and also a plan of a Roman camp, when both confuls encamped together, or within the same intrenchment, in his military antiquities of the Romans in North Britain, published after his death in one volume in folio by the Royal Society of Antiquaries in 1793. But not being acquainted with the Greek language, he took the accuracy of Mr. Hampsdon's translation of Polybius for granted, as he himself informs us, supposing with him the cavalry of the allies to have been triple that of the Romans, and on that erroneous supposition has grounded all his computations respecting their castration, and particularly in comparing the Polybian camp with those in Scotland, that were first discovered by the learned, ingenious, and very able military antiquarian, general Melville, in 1754, who manifested a very fine and superior degree of discrimination in concluding from Tacitus's narrative, and the reasons of war, that Agricola must have crossed the Tay above Perth, and proceeded along Strathmore, and that there were certainly some remains of his camps still to be found in that vale, in opposition to the opinion of the engineers, who were then employed by government on a survey of that country, and the perverfing affections of one of them in particular, who had actually surveyed the situations, on which they were afterwards discovered by general, then captain, Melville, without knowing what they were. General Roy received from captain Melville, who was about to leave this country and repair to the West Indies, a communication of that discovery, and first learnt from him, as he himself acknowledges, what was really meant by a temporary Roman camp, which information excited his curiosity, and led him to turn his attention to the subject of Roman military antiquities in Great Britain. But though he professed it occasionally for a number of years with a very laudable degree of zeal and industry, it must be allowed, that he committed several material and great mistakes in his plan and description of the Polybian confular camp.

He leaves out the space fifty feet wide behind the tents of the tribunes, expressly allotted by Polybius for their horses, &c.

He does not make the extent of the tribes incamped ground transferey across the camp, so great as that of the Roman horse and foot, by about one hundred and fifty feet, leaving a distance of about two hundred feet between their first tents on the right and left; whereas Polybius tells us, that the one was equal to the other. His words are these: αναγκή διαλλάθαι μη ἑν τῷ τῶν χλωρίων σταθμῷ, τότε γὰρ τῷ τῆς θαλαττῆς τοῦ Ρωμαίων ἐπεστάλλετο τοίχῳ.

He leaves an open place or front of twenty five feet wide on the left of the praetorium, between it and the forum; then sets off a rectangular space of the same depth with the praetorium, and about one hundred and thirty feet wide, which he divides equally into two parts, one next to the tents of the tribes as quarters for the legati, and the other immediately behind that for the market-place, or fort, and his other parts of the ground, which is fifty feet wide; and on the remainder of the ground set apart for Polybius, for the forum, extending as far as that occupied by the first tent of the tribunes on the left he encamps one half of the ablest, or select horse of the allies for the confular guard. He then leaves a front fifty feet wide, making that between the halfati and horse of the allies on the left extend quite to the rear of the camp, then encamps half the evocati and volunteer horse looking toward the praetorium, and close behind them, with their backs to theirs, half the evocati, or volunteer foot; then leaves another front of twenty-five feet, and beyond that encamps half the select foot of the allies for the confular guard. On the right of the praetorium, he in like manner leaves a front twenty five feet wide, then sets off a rectangular space as deep as the praetorium, and about one hundred and thirty feet broad for the quattuor's quarters, and for the clothing, arms, and provisions behind them; then leaves another front twenty five feet wide; then encamps the other half of the ablest, or select horse of the allies for the confular guard; and so on as on the left. In making all these fronts, divisons, allotments, and allocations, he is so far from being invested by Polybius, that they are in direct repugnance and contradiction to that author's authority, who makes no mention at all of legati, but allows about five times as much ground for the forum, and about twice and a half as much for the quaestorium as he does.

On
CAMP.

On each side of the street fifty feet wide, leading to the rear from that of one hundred feet in width behind the praetorium, he allot a rectangular space of four hundred feet by one hundred and twenty five for the extraordinary horde of the allies facing the said broad street, and an equal space on each side for the extraordinary foot of the allies immediately behind them and facing the rampart; then leaves on each side a street fifty feet wide, and fully makes two rectangular locations of four hundred feet by two hundred and fifty each for rafters coming to the camp, thus predisposing allowing for occasional comers, as much ground as he allot for the encampment of all the haftri and principles, with four fifth's of the envies of a complete Roman legion. The truth indeed is this: he makes the depth of the encamping ground in the rear of the praetorium one hundred and eighty three feet, and one third of a foot greater than it ought to be by Polybium's account of the Roman castration. And his camp taken altogether differs widely and essentially from the one described by that author. For he makes each side of the encampment one hundred and thirty three feet, and one third of a foot longer than it should be, and each side of the intrenchment also of course. Of this, it seems to have been partly aware himself: for in page 45 of his work, when he utes in the text these words, "therefore the side of the front he was to have been intrenched of a confular army was two thousand one hundred and fifty Roman feet," he in a note expresses himself in the following: "If according to Lippius and others, who have copied from him, there had only been in the confular camp twice the number of allied foot [he must unquestionably have meant to say allied haftri] than there was of Roman horse, then the space actually occupied by the troops would have been a square of sixteen hundred and sixteen Roman feet, and two thirds of a foot." It is much to be regretted that there are so many palpable errors and misprints in that elaborate, and in many respects valuable performance, which might have easily been avoided by a little proper attention to the printing of it. They are so numerous indeed, that we cannot allow ourselves to regard it as a correct copy of the manuscript, he left behind him.

The square was the most convenient and best figure the Romans could have adopted for their encampments. Of all right-angled quadrilateral figures of the same perimeter, its area is a maximum, or the greatest. It therefore required less extent of intrenchment than a rectangle of the same area or superficial contents. And if we examine the disposition or arrangement of the various locations they made within it for their troops, taking into consideration at the same time, the irrevocable simplicity and regularity of their method of encamping, we shall find, that there neither was any ground left nor any wanted to render it more commodious, and be apt to regard it as the best perhaps, that could have been contrived before the invention of gunpowder, and the use of fire-arms, which have made great and essential alterations necessary.

Even in modern encampments, however, so much of the Roman method is still retained by all nations, that in encamping their troops, they constantly place the privates in the front, behind them the subalterns, then the captains, and in the rear of these the field-officers. And Frederick the Great, king of Prussia, tells us, that it was his custom, in imitation of the Romans, to enclose his camps with intrenchments, which, besides awakening other good purpoises, contributed greatly to prevent defection.

We shall now proceed to give an account of modern castration, which is also regulated, in a great measure, by certain rules, that are liable, however, to be altered and varied in different situations and positions, so as to occupy the ground to the best advantage, and most commodiously for the free and useful operations of the different descriptions of troops, according to the opinion and judgment of the general, or officer commanding them.

Camps take different names, or denominations, from the objects those have in view who form them; such as for instance:

- Camps offensive, A camp for forage.
- Camps defensive, A camp of observation.
- Camp of rendezvous, A covering camp.
- Camp of baggage, An entrenched or entrenched camp.
- Camp of retreat or reserve, A fixed or standing camp.
- A flying camp, A camp of peace and exercise.
- A camp of encasement, or a camp for the attack, interruption, and annoyance of an enemy.

The principal objects which every general either has, or ought to have in view when he chooses ground for a camp, are of two kinds, the one offensive, and the other defensive. The camp in which an army assemble, at the beginning of, or the opening of, a campaign, is of the first class or description. In such camps, attention ought chiefly to be paid to the convenience of the troops, who should encamp in small separate corps near their magazines, or depots, in such a manner, as to be able to unite in a short time. And as such camps are generally at some distance from the enemy, there is little or no danger to be apprehended from making the convenience and accommodation of the troops the first object of attention.

The most essential properties of every camp are health,fulness, and security. These are advantages which ought to be attended to and sought after on all occasions. But an attention to wholesomeness is still more necessary in one that is to be occupied for a considerable length of time, than in another, where troops are to make but a short lay. Low, wet, damp, and marshy places should be avoided in every country; and in hot climates, situations that are much exposed to the burning heat of the sun. On the other hand, riding grounds with an even aspect, commodiously situated for agriculture, and for supplies of water, forage, and fuel, ought to be preferred to other situations for encampments.

A general ought to be a good judge of situations himself, and to choose his own camps. His knowledge should not, as is sometimes the case, be confined to the mere rudiments of the art of war, or to the fiddly fiddle busines of parades, reviews, and sham fights, that have no resemblance whatever to real actions. He should be able to discern at sight, or to discover with a glance of his eye, all the possible advantages, as it were, which any part or position is capable of affording, and to improve this talent in practice, by the principles of fortification, which are the basis, or ground-work of it, and which he ought to carry with him into the field, and apply to every situation of his army, availing himself of heights, defiles, rivers, rivulets, morasses, inundations, woods, &c. When master of the rules of that science, he can also apply it successfully for finding out the weaknesses of the enemy's position and order of battle.

A camp offensive, or of offence, is formed for the purpose of annoying an enemy in various ways, such as for instance, as to force him to raise a siege by cutting off, or straightening his intercources with the adjacent parts of the country and his own depots; to compel him to quit an advantageous position by either attacking it at all if necessary, or by inveigling one of his towns or places; to make incursions.
fions into some one or other of his provinces; to intercept his convoys; to embarrass his communications; to confound the forage he might draw benefit and advantage from; &c.

As security is always one of the first objects of consideration, every camp, of whatever species or description it may be, ought to have its front and flanks placed entirely out of the reach of insult. In any situation, therefore, that is chosen or fixed on for a camp, (and there are various ways of occupying the same ground,) care should be taken not to extend either flank towards the enemy, or to expose it to commanding ground within cannon-shot, that he may have in his power to occupy or possess himself of, but to place it in such a manner as to make it afford support to both wings of the army. It ought to be guarded and secured both in front and rear by detachments; and particular attention should be paid to its lying commodiously for pasture, forage, water, and wood, which is not only useful as fuel, but for pickets, picketlines, and other purposes. It should also be conveniently situated for the army that occupies it, to move out of it either to form in order of battle, or to abandon it altogether without being exposed to much molestation from the enemy, who, if he command the principal avenues or approaches to it, would have it in his power to shunt them up, and thereby force them either to surrender, or to attack and fight him on very disadvantageous terms. There are many situations that appear to be very strong, and naturally are so, which from this very circumstance of troops not being able to quit them when necessary without exposing themselves, are in reality both weak and dangerous. And an unskilful general may be led by the mere appearance of them into great mistakes, and thereby, not only draw disgrace on himself and his troops, but also plunge his country into the most disastrous calamities. But a knowledge of fortification will enable a commander of naturally good talents to choose heights, and occupy them in such a manner, as to prevent their being commanded by others; to cover his flanks effectually, so as to secure each post as to render it capable of defence, and to avoid those, in which a gallant officer cannot maintain his ground, without running the risk of losing his reputation.

Camps defensive, or camps of defence. Such camps are strong by their situations chiefly, and have no other design than that of preventing attacks. Every situation that has its front and flanks equally strong, and is free and open behind, is proper for this sort of camps. There are heights that have a front of a certain extent, and their flanks covered by morasses, and positions, that are secured in front by a river or marshy rivulet, and their flanks by ponds. Such camps having no other object than to prevent their being attacked by the enemy, great care should be taken not to fix on false points of support. For this purpose, the rivers and marshes in their front, and on their flanks, ought to be founded in order to ascertain whether the rivers are not fordable, and the marshes impassable.

When such a camp has a river in its front, it should not be placed nearer to the bank thereof than eight hundred or a thousand paces, in order to leave ground sufficient for drawing up the army in order of battle.

Positions taken under the protection of towns or places, are defensive camps.

When the object of a defensive camp is to cover a country, the principal attention of a general in chusing it ought to be directed to those points, which the enemy has it in his power to attack, and by which he might penetrate.

Camp of rendezvous. When at the commencement of a war, or the opening of a campaign, an army is brought together in the field, either in one entire body, or in a separate corps, or parties, at no great distance from one another, it is said to be in a camp of rendezvous. Such a camp is either more or less out of the reach of the enemy, and in the first of these cases the convenience of the troops ought to be the first object of attention. It is also sometimes intended to be offensive, and sometimes defensive. When it is formed for the purpose of offensive operations the following maxims ought to be observed:

To avoid extending either flank towards the enemy, or exposing it to ground that he can take possession of; to choose a position for it strong by nature; to support well the wings; and to secure it against surprize or any sudden assault by detachments, both in front of, and behind it.

To proportion its extent to the strength of the army.

If you are in an open and level country, to encamp your army in order of battle, and if you cannot secure your camp against insult or surprize by detachments, to throw up intrenchments sufficient to prevent your being obliged to fight contrary to your intention or inclination, or when it is not necessary for you to come to action.

In a broken or uneven country, to separate your army without encamping the different corps at too great a distance from one another, occupying the highways, villages, &c. in your front.

In a mountainous country, to encamp your troops according to the situation and nature of the ground, but in such a manner that the most advanced corps may receive prompt aid and support from the rest.

Not to place your cavalry on either wing when it is near a wood, village, or other place, into which the enemy can throw in some of his infantry; but sometimes to place them all on one wing, and sometimes to encamp them in a second line, or otherwise, as the ground and circumstances may point out.

When the enemy is on the opposite side of a river, rivulet, moras, &c. to encamp at a sufficient distance from it to prevent your being incommode by his fire, in even forming your army in order of battle in front of your own camp.

To reconnoitre the highways, rivers, rising grounds, rivulets, ferries, cattles, woods, and other places in the neighborhood of your camp; and to keep open a communication between its rear and several roads, for the purpose of receiving supplies of provisions, &c.

To choose your camp in such a manner, that the enemy, by moving on his right or left, may not oblige you to quit your position, but on the contrary, that by making a short or small movement yourself you may compel him to make a long or circuitous one, and to quit his position or leave the country.

This is the surest criterion by which one can judge of the skilful or unskilful choice of a camp.

And, in short, though you are acting offensively, to take every possible precaution for the security of your camp when the enemy is near you, and by no means to despise him. For negligence and contempt of an enemy tend always to render him bold and enterprising.

When defensive operations are the object of a camp of rendezvous, it is necessary to observe, besides these, the following maxims:

To avoid encamping in a plain or level country.

To attend particularly to the extent of the ground you occupy, and to the number and nature of the troops your army is composed of.

Always to entrench your camp, taking care that no part of it can be enfiladed.

To occupy the bridges and fords of rivers, &c. and if you are
are apprehensive of suffering by inundations, to make dikes to turn the course of the water.

To avoid placing either of your wings behind a morass, or any thing else, that may be an obstacle to its manoeuvring easily, and co-operating with the rest of your army in case of an attack.

To place your artillery on heights, and dispose of it in situations from which it can do most execution.

And to keep open a free and convenient escape from it in the rear, that your retreat may not be cut off.

A camp of passage. In an offensive war troops encamp transitively, when they march either to attack an enemy, or to dilodge or force him from a post, by different manoeuvres; or to get before him to some passage, and penetrate into his country; or to invest a place, and form the siege of it; or, in short, to join an advanced corps or army.

In a defensive, as well as an offensive war, they occupy a camp of passage when they take post to cover their country; when they are obliged to regulate their movements by those of their enemy; when their object is to effect some junction; or, finally, when they are constrained to abandon a post, a frontier, or even one part of their country to cover another.

A camp of rest or repose, is that in which troops either wait for forage, or watch the enemy's motions, in order to regulate theirs by his, or in which they are allowed to remain for some time stationary on account of sickness or some other cause. As repose is the sole object in such a camp, it should have such a river or morass in its front as renders it inaccessible. And if the river, rivulet, or morass in front of it has not a sufficient depth of water it should be dammed up so as to be impassable.

Such a camp should not only have its front naturally strong, but also have a site or situation that is elevated and healthy; and when it is of a permanent nature, it should have abundance of water, wood, forage, and provisions, within its reach and command, and should cover the road or route of all its convoys.

A fixed or flable camp may have different objects, according as an army acts offensively or defensively.

When it is on the offensive, it occupies such a camp for a certain time, to form the siege or blockade of a place; to wait the effect of a diversion or the capture of a place, which a detached corps has been sent to attack; to give a reinforcement or convoy time to arrive; to confine or destroy, during the course, or towards the end of the campaign, the forage or subsistence of a country, which they design to abandon; to give rest or repose to an army after a long march or operation that may have caused a loss of men, or occasioned disaffections or, in fine, during the course of a campaign, that has not been so prosperous or fortunate as was at first expected.

When a general encamps before a place to attack it, which he knows the enemy cannot assemble a sufficient force to attempt the relief of, and when he has little to fear from any detachments he may send out, either for that purpose or to interrupt the operations of the siege, he has then only to circulate his troops round the place as commodiously as he can, feizing on commanding grounds and other advantageous objects, and taking care to have his circumsallation as near to it as possible, provided he is just out of the reach of annoyance from the besieged's shot and shells.

When he is on the defensive, he chooses a flable camp to cover his country, or some place of importance, that the enemy designs to besiege. Besides these two objects, a flable camp has several others, which are common to it with camps of other denominations. There is one, however, which it may not be improper to mention, which is this, that a general can remain in it till he sees his enemy separate his forces, and send them into winter quarters, in order that he may go into his own without dread of disquietude or modulation.

A flying camp denotes a corps or body of troops consisting of three, four, five, six, &c. thousand men, infantry and cavalry, that has power to encamp and decamp at the pleasure of the general or officer commanding it, as necessity and circumstances may require, that is continually in the field, and is constantly making divers movements to harass the enemy, fling his incursions, check and render abortive his enterprises, intercept his convoys, seize and fatigue the neighboring country, and to throw itself, in case of need, into a besieged place, that is in want of succour or assistance.

Though there is some difference between the command of a flying camp and a large army, the resemblance, however, is so great, that a general officer, who has often commanded a detached or separate body of troops in, ceteris paribus, fitter for the command of a large army than one who has not enjoyed that advantage.

A general officer, therefore, who is ambitious of preference, anxiously endeavours to procure for himself such commands and to qualify himself for them.

A flying camp occupies much uneasiness and disquietude to an enemy, by hovering on his wings. It is designed to cover some tract of country between two armies; to make head against some similar corps, that the enemy has formed or detached; to undertake and execute some particular enterprises; to throw troops into some place that is menaced or threatened; to draw contributions from certain districts, and to regulate its movements at the same time, in such a manner as always to have it in its place and form the main army after a march of one or two days at most, in order that, if a favourable opportunity for a general engagement should present itself, it may arrive in time to take a share in it.

The general, who commands a flying camp, ought to be extremely attentive and vigilant, to have his troops highly disciplined, to suffer no straggling or dispersion of them, to march with great precaution, to choose advantageous camps, and to regulate its movements in such a manner as to be always in readiness to surprize his enemy when it is possible, without running the risk of being surprized himself. He should be alert against all sorts of enterprises on the part of the enemy. He ought to have parties always on the look out, and to relieve them; and he should not be sparing in the employment of spies, of whom he may have enough if he only pays them well. Money can seldom be more usefully employed.

A camp of peace and exercise, is a camp defined for the exercise of all the military duties and functions.

In such peaceable encampments the troops should be trained up and instructed in every part of fatigue, labour, and duty, which is necessary on actual service, for rendering warfare successful. In such a situation an active and able general will not only have them practised in throwing up works expeditiously, but will also turn a great part of his attention to their discipline. He will make them encamp in order of battle, and cause every part and branch of the service to be performed with as minute accuracy, and as punctual an observance of orders, as if they were in the field, or in the face of an enemy. He will examine whether the officers on guard are sufficiently vigilant and acquainted with every particular of their duty, and whether the soldiers themselves are posted according to orders. He will not only have the infantry exercised frequently, but the cavalry also, when they are not employed in foraging, and
the recruits of both daily. He will inspect and look at the horses himself, praising those officers, who have been care-
ful of them, and severely reprimanding those who have neglec-
ted to have them taken care of. In short, he will by his vigilance and attention, in making every part of his army perform its duty with punctuality and exactness, give activi-
ty, skill, and animation to the whole, and prepare them for acting with vigour, advantage, and success against an enemy.

A camp of forage, or for foraging. Such camps are some-
times at a distance from and sometimes near to the enemy. In the first case, neither your camps nor foraging parties are in danger of molestation or insult. There are certain precautions, however, that ought never to be neglected, even when you have nothing to apprehend from any attempts of the enemy. Your camps therefore ought, in either case, to be strong by nature, or rendered so by art, and particu-
larly in the last, when you are near to an enemy. Besides, a strong camp enables you to send out stronger foraging detachments than you could otherwise venture to do; and on this service it is sometimes necessary to employ a great part of your army. Foraging is certainly an essential part of the art of war; and parties of foragers may very justly be con-
sidered as detachments sent out against the enemy. A rich and fertile tract or district of country should be chosen for it, and secrecy ought to be observed in regard to the time when, and the place where, you intend to forage. Your orders respecting this service should not be communicated even to the officer, who is to command the troops employed on it, till late in the evening before it is to be performed. You ought, on such occasions, to detach a number of small parties to acquire an exact knowledge of the enemy’s motions. And, if you are on your guard against stratagems, it will be safer for you to forage when he does than at other times.

A camp of observation is the camp of an army employed in watching the motions and operations of an enemy, in harassling and perplexing him, and preventing him from pen-
etrating in a country or tract of territory, to surprize or take an important place, or to molest another army, and force it to abandon its preconcerted enterprises and designs. An army of observation, during a siege, is almost always in motion, and on the look out, occupies the avenues or approaches by which the enemy can present himself, follows him in his movements, keeping parallel to him, but continually between him and the besieging army, in the most advantageous manner it can, to avoid being obliged to fight contrary to its inclination, and sometimes feizes on a commanding post, and there entrenches itself, when its camp may be called.

A covering camp, which appellation is given both to such an encampment for covering a siege, and to positions chosen for camps that are designed to cover a country or district. In choosing one for the last of these objects it is not neces-
fary to pay so much attention to the natural strength of the place itself as to the parts or paffes, through which the enemy may or might attempt to penetrate, if he expects to penetrate at all. These should be occupied and secured by your army, in those places where they are most easily de-
defended, and where he cannot attack you without great hazard and danger. By acting judiciously in this manner you will, with very inconsiderable movements on your part, oblige him to take long and circuitous routes, and thereby harass his troops without being able to carry on any solid operations.

An intrenched or retrenched camp. Such a camp is some-
times made during a campaign on the field, sometimes
before a place, and sometimes under a place.

The ancients, and particularly the Romans, did not re-
main, even for an inconsiderable length of time, in any place
without fortifying it. Their intrenchments did not hinder
them from marching against the enemy when it was thought
proper; but they put their armies out of the reach of insult,
particularly when they were composed of new levies or of raw
and inexperienced troops, furnished places of security for
their baggage and provisions, and enabled them to send out
large foraging detachments without exposing their camps to
insult.

It is not sufficient, when one is on the defensive, to have
your camp on a situation naturally strong. It is also nec-

essary, particularly when the enemy is under the necessity of
coming to attack you, to remedy and remove the smallest de-
fects of ground or position by intrenchments, which put you
completely under cover, and place you in a condition to make
a vigorous and obdurate defence.

In an open or level country, it is advisable for you, in
contructing your intrenchments, to avail yourself of every
advantage that the ground offers, to profit by rivers, rivulets,
rouelles, canals, marshes, hollow ways, ditches, villages,
inclosures, caftles, &c. and to proportion the relative de-
grees of strength in your intrenchments, in different places,
in such a manner as to render every part of your position
equally strong.

In a woody and mountainous country, you should not
only take all the precautions necessary to be observed in an
open and level one, but ought also to make abatiss, dikes,
batardeaux, &c.

An intrenched or retrenched camp before a place, has for
its object both offence and defence, when the enemy is either
in sufficient strength to attempt to raise the siege, and to
throw in succour and relief to the besieged, to enable them
to hold out for a longer time than they otherwise would be
able, or when the besieged themselves are sufficiently nu-
merous to make strong and frequent molestations. In the first case a
line of circumanvallation is made to secure the besieger’s army,
against all attempts from without; and in the second a line of
contravallation is thrown up between the besieger’s camp
and the place, to prevent any molestation or interruption on
the part of the besieged from within.

In constructing both these lines you should be particularly
careful to occupy the most commanding and advantageous
ground round the place, whether it be a little farther from
or nearer to it than you could with, availing yourself of
heights, ravines, &c, and making use of abatiss where there
is wood, and every thing else from which you can derive
advantage. If they are intersected by rivers, rivulets, canals,
morasses, &c. you should have secure and convenient bridges
and ways of communication between the different parts.

An army of observation is even of the greatest ad-
vantage at the commencement of a siege. It watches
over the besieger’s preservation till he firmly establishes him-
self, can forward his operations, escort his convoys, supply
him with forage, and perform many other sorts of labour
for him. These two armies should always be within reach of
each other, particularly at the beginning, that they may be
able to afford mutual aid and succour to each other, and
keep the enemy at a distance, who will naturally be afraid
of approaching too near, if they are too powerful for him,
left they should fall upon him conjointly, and attack him
with advantage.

Intrenched or retrenched camps under places, which are
attributed by some to the celebrated marshal Vauban, who
recommends the forming of them at most frontier places,
have defence only for their object. A camp of this sort
may have one particular object only, or several objects at
once.
Once near or under a place of importance, it serves to render the attempt to besiege it the more difficult, and to retard or hinder the taking of it. Under a place, surrounded by heights, as well as one that has only a single moat or ditch fortifications, it becomes necessary for its defence. When there is a number of troops in a place, it is useful for assembling them in, for placing them advantageously, and for putting them in a condition to attack the enemy, as occasion may present itself. It is a support for an army that is not strong enough to take the field, and is convenient for the inhabitants of the neighbourhood to retire to with their effects.

The depth of a regiment of infantry encamped, consisting of nine companies of 100 men each, from the teretians' tents to the rear, used to be 200 yards, and the front 215, including the battle-guns. A regiment of infantry of the same strength is now allowed 200 yards in front, including its two battle-guns, and 520 yards in depth.

A regiment of dragoons encamped, consisting of six troops that form three squadrons, with the light troops, used to take up 200 yards in front and 258 in depth; and the interval between two regiments of infantry or cavalry used to be 65 yards.

A squadron of horse has now a front of 120 yards; and an interval of 100 feet is allowed between each regiment.

The forming of an intrenched camp, near a town or village, is attended with many advantages. It furnishes room for establishing magazines for stores, forage, baggage, and for the sick and wounded. The houses and buildings help to cover its flanks, and thereby enable you to render it more compact, than it otherwise could be made. Such a camp also covers and protects a place that has not works, or fortifications sufficiently strong to repel an enemy. When the ground is favourable for the purpose, such a camp may be formed in the figure of a square, or nearly so, which will require much less extent of intrenchment than a long rectangular one, and is more defensible.

Some able generals have been for rejecting lines altogether; among which number is the celebrated marshial Saxe, who is a great advocate, however, for redoubts in front of an army, and mentions particularly the wonderful advantage they were of to Peter the Great and the Muscovites at the battle of Pultowa. It must be allowed that lines and intrenchments are often thrown up on a campaign very injudiciously, and to little purpose; and unless some parts of them be closed in the rear, they are totally lost the moment they are forced or carried in any one point. But such temporary lines and intrenchments for stationary camps are different from those we have just been speaking of, either before or under places.

Frederick II., king of Prussia, has proposed to form lines or retriments with square redoubts, placed in faint and re-entering angles, with an angle of each outwards or towards the enemy, joining them with trenches, as in fig. 4. Plate v. Military, &c. He observes, that the redoubts in the faint angles ought not to be above 600 paces distant from one another; but 600 yards are distance enough. And the ingenious general Lloyd has proposed a similar arrangement of redoubts, in front of an army drawn up in order of battle, without joining them with trenches, but leaving the intervals between them open.

Fig. 1. Plate v. is marshial Vauban's form of lines, and figures 2. and 3. are his first and second profiles of them.

Fig. 5. is a form for lines, with bastions and broken curvatures.

Campe, city, coffina urbana, was a place near the city, not far from the six mountains, where the pretorian guard were encamped; whence it was also called the pretorian camp, pretorian camp, or pretorian. The like we all read of by St. Luke, called by St. Luke absolutely the camps Campaspar. By which we are doubtless to understand the camp parum, which Josephus tells us, was afterwards used as a cauld.

Campe, naval, coffina marina, those made in figure of a half moon.

Campe, naval, coffina majora, or married, denoted a station of ships.

Campe, summer, coffina estus, among the Romans, was ordinarily light and moveable; so that they might be let up, or taken down, and removed in a night. In which case it was also called simply coffina. See CAMP.

Campe, winter, coffina hiberna, or winter quarters, were usually taken up in some city or town; or else so contrived as to make almost a town of themselves. See CAMP.

Camps, territories, coffina territoria, those which were a third part longer than broad, which Hyginus represents as the Roman model. Coffina in quantum fieri potuerit territiae effe debentum—una pagina in longum duo millia quadrigenti, in latum millia sexcenti pedes.

CAMP is also used among the Siamese and East Indians, for a quarter of a town assigned to foreigners, wherein to carry on their commerce.

In these camps, each nation forms itself a kind of city apart, in which their houses and shops are, and the factors and their family reside.

The Europeans at Siam, and in most other cities of the East, are exempted from this restraint, and allowed to live in the cities and suburbs, as they find them most commodious.

CAMP COLOURS-MEN, are soldiers appointed to attend and affil the quarter-master general, in marking out, and keeping the camp clean, receiving and distributing provisions, &c.

The camp colours-men are drawn a man out of a company, that are exempt from all other duty during the campaign; each carries either a spade or a hatchet, or a pole bearing colours.

CAMP Diseases, or the diseases incident to armies, are such as arise chiefly from exposure to the heat and inclemency of the weather, and from infection. Consequendy they are different, according to the season of the year, and to the climate and soil of the country in which the army is engaged. The ancient maxim of Hippocrates, that "the summer and autumnal fevers are the most sickly," is confirmed by Sir John Pringle, not only with regard to warm climates, but to every camp, where men are necessarily much exposed to heat and moisture, the great cause of putrid and contagious diseases. (Obf. on Diet. of the Army, P. II. ch. i.) The diseases of summer and autumn are, remitting and intermitting fevers, cholera, and dysentery. But the latter, though produced by heat and moisture, is propagated extensitively by contagion: it declines, however, with the autumn; but the remitting fevers continue as long as the encampment, and never entirely cease till the floods begin. In the winter, inflammatory diseases chiefly prevail, such as coughs, pleuritics, acute rheumatism, inflammation of the brain, bowels, and other less important parts; and the consequences of these are
are often consumptions, chronic coughs, and rheumatism.

Independently of the noxious effluvia from marshes, from the privies of the camp, and the putrid draw in the tents, which spread disease through a camp, the soldiers are often attacked with the typhous or putrid fever, when crowded together in hospitals and barracks in consequence of the confined air; hence this fever has been designated the hospital fever.

There are other causes also, which contribute to the production of diseases in an army, partly by predisposing the body to be more easily affected by noxious agents, and partly by actually exciting disease; such are errors and irregularities in diet, the use of bad water, intemperance in spirits, the extremes of fatigue and inactivity, loss of rest, and want of cleanliness. The means of limiting the operation of these causes were suggested by Drs. Pringle, Monro, and other authors; and considerable improvements in the clothing, and means of subsistence of the men, in the ventilation of hospitals, &c. have been adopted, by which the number and mortality of camp-diseases are somewhat diminished.

Camp duty, in its utmost extent, includes every part of the service performed by the troops during the campaign. But in a more particular sense, it denotes the duty performed by guards and detachments, for the security of the camps, and preventing forgeries.

Part of the camp duty is performed in the same manner as that of a garrison.

Camp fight, or Camps fight, in Law Writers, denotes the trial of a cause by duel, or a legal combat of two champions in the field, for the decision of some controversy.

In the trial by camp fight, the accuser was, with the peril of his own body, to prove the accused guilty; and by offering him his glove, to challenge him to this trial, which the other must either accept of, or acknowledge himself guilty of the crime whereof he was accused.

If it were a crime deserving death, the camp fight was for life and death: if the offence deferred only imprisonment, the camp-fight was accomplished when one combatant had subdued the other, so as either to make him yield, or take him prisoner. The accuser had liberty to chuse another to fight in his stead, but the accuser was obliged to perform it in his own person, and with equality of weapons.

No women were permitted to be spectators, nor men under the age of thirteen. The priest and the people, who looked on, were engaged silently in prayer, that the victory might fall on him that was right. None might cry, shriek, or give the leafy sign; which, in some places, was executed with so much skill, that the executioner stood ready with an axe to cut off the right hand or foot of the party that should offend herein.

He that, being wounded, yielded himself, was at the other's mercy, either to be killed or suffered to live. But if life were granted him, he was declared innocent by the judge, and disabled from ever bearing arms, or riding on horseback. Verdeg. Rell. Dec. Intell. cap. iii. p. 51. See Across, fight, Battle, Champion, and Combat.

Camp hospital. See Hospital.

Camp law, a method of deciding controversies by duel or camp-fight.

Camp-mills, in the Military Art, denote portable or moveable mills, which can be used, particularly in time of war, when there are neither wind-mills nor water-mills in the neighbourhood, and which, on that account, formerly accompanied armies, in the same manner as camp-ovens and camp-forges. Some of these mills have flours for grinding the corn, and others are constructed with a toothed roller like those of our coffee-mills. Some of them are also so constructed, that the machinery is put in motion by the revolution of the wheels of the carriage, in which they are placed; and others, more commonly, are driven by horses or men, after the wheels of the carriages are sunk in the ground, or fastened in some other manner. The invention is ascribed to Pompon Targonne, engineer to the marquis Spinola, about the end of the 16th century. Others ascribe the invention to the Germans, about the year 1563. Beckmann's Hill. Invent. vol. iii. p. 190.

Camp of Gold Club, in History, a denomination given to the scene of interview between the kings of France and England, Francis and Henry, and their respective queens, in 1519; held between Ardres and Guines. This interview was conducted with singular magnificence and splendour; it lasted 10 or 12 days, exhausted the treasures of both monarchs, ruined many of their nobility, and terminated without answering any useful purpose.

Campach, in Geography, a river of Carinthia, which runs into the Moil, near Velsch.

Campagna, in Ancient Geography, a town of Cappadocia, in the department of Cilicia. Poikley.

Campagna, in Geography, a town of Naples, in Principato Citra; the see of a bishop, suffragan of Conza; 16 miles E. N. E. from Salerno, and 13 S. S. W. from Conza.

Campagna di Roma, formerly Campania, a province of Italy, in the state of the church, comprehending the greater part of ancient Latium, and bounded on the north by the river Sabina, on the east and south-east by Abruzzo Ultra and Lavoro, on the south-west by the Mediterranean, and on the north-west by the Patrimony of St. Peter. It is about 60 miles long on the Mediterranean sea, and 33 broad. The country contains many beautiful plains, and the soil is fertile; but a great part of it is infaluable on account of the Pontine marshes, so that there are few towns or villages, and the inhabitants are poor. Several attempts have been made to drain these marshes, and they are now traversed by a firm road. By these means, and some internal regulations in favour of the husbandmen, the infalubrity of the air is likely to be corrected, and the population and fertility of the province increased. The unleasement of the climate in this province is said to have commenced after the invasion of the Goths in the 5th and 6th centuries; and to have been owing to the accumulated ruins of the edifices of Rome, which raised the bed of the Tiber, and caused its waters to flagrate and to overflow. The exhalations proceeding from such a mass of flagrated waters, contributed very much to infect the air of this hot climate. This evil, resulting from the same cause, was aggravated as long as Rome was exposed to the incurious and devastations of the Lombards, the Normans, and the Saracens, which lasted for several centuries. At the beginning of the 13th century, the air was become infectious, that Pope Innocent III. says, that few people at Rome attained to the age of 40 years, and that it was very uncommon to see a person of 60. When the papal see was transferred to Avignon, and during the 72 years of its continuance there, Rome became a desert. Its monasteries were converted into flabeles; and Gregory XI. on his return to Rome in 1376, could scarcely count in it 30,000 inhabitants. His death was succeeded by the Western Iehfim, which continued upwards of 50 years; and when this fehism terminated in 1492, Martin V. and those who immediately succeeded him, were able to make but feeble efforts against to inveterate an evil. It was not till the commencement of the
the 16th century, that Leo X. vigorously attempted to restore the salubrity of the air; but the two sieges of Charles V., plunged it again into its old calamities; and the number of inhabitants, which in the time of Leo X. amounted to 85,000, was reduced under Clement VIII. to 32,000. Since the time of Pius V. and Sixtus V. towards the close of the 16th century, the popes have been ambitious in their endeavors to purify the air of Rome and its environs, by procuring proper discharges for the waters, drying up the moli and marshy grounds, and covering the banks of the Tiber and other places that were deemed uninhabitable with superb edifices. Since that time a person may dwell at Rome, and go in or out of it, at all seasons of the year. But at the beginning of the 17th century, they never ventured to sleep at Rome, even in the day, in any other house beside their own. But these scruples, says M. Condamine, have of late very much subsided; and he says, that he has seen cardinals, in the months of July and August, go from Rome to live at Frascati, Tivoli, Alban, &c. and then return the next or the following days to the city without any detriment to their health; and he adds, that he has himself tried all these experiments, without the least inconvenience. "We have even seen," he says, "in the last war in Italy, two armies encamped under the walls of Rome, at the time when the heats were the most violent. Nevertheless, the country people in general dare not illib venture to lie, during that feason of the year, nor even so much as sleep in a carriage, in any part of the territory comprehended under the name of the Campagna of Rome." The amphitheatre of hills that bound the Campagna on one side is crowned with towns, villages, and villas, which form very delightful landscapes. The ancient Romans were accustomed to seek shelter from the scorching heats of summer among the woods and lakes of these hills; and the cardinals and Roman princes, at the same season, retire to their villas; while many of the wealthier citizens take lodgings in the villages, during the season of vintage. The principal cities or towns of Campagna, are Rome, Velletri, Frascati, Palestrina, Terracina, Nettuno, and Olbia. N. lat. 41° 18' to 43° 5' E. long. 13° 14' to 13° 26'.

CAMPAGNAC, a town of France, in the department of Aveyron, and chief place of a canton in the district of Millau; the place contains 1,531 inhabitants, and the canton 6107. The territory comprehends 149 kilometres, and 7 communes.

CAMPAGNE, a town of France, in the department of the Straits of Calais, and chief place of a canton in the district of Montreuil; 2 leagues west of Hesdin. The place contains 1209, and the canton 11,508 inhabitants: the territory includes 212 1/4 kilometres and 25 communes.

CAMPAGNOL, of Boffon, is the short tailed rat of English writers, Mus campagnolus of Gfner, and mus arvata of Pallas, Schreiber, &c.

CAMPAIGN signifies a field, an open or level country. In a military point of view, it is used to denote the space of time, every or each year, during which troops are kept embodied as an army, or at least in a condition to float, thwart, or traverse the progress of the enemy.

This term is also employed to express the number of years which an officer or soldier has served. This officer has ten campaigns over his head, that is to say, he has been ten years in the service: this soldier has made sixteen campaigns, that is, he has served sixteen years.

It is likewise made use of to signify the operations of a campaign. Thus we say, he wrote the history of that campaign; by which we mean to say, that he wrote the history of the transactions and operations that took place during that campaign. The general is said to begin or open the campaign when he commences his operations.

The genuine object of a campaign is to attack your enemy, or to defend yourselves, or to succour an ally; and whatever of the be the object, it is necessary to have armies more or less numerous, money to pay them with, and to destroy the other's expenses attending it, and considerable magazines of every sort near the frontiers, where the armies are to assemble and operate. The general plan of a campaign is the result of political deliberation and arrangement, and is regulated by circumstances and conjunctures.

Though campaigns may have different objects, as well as be opened and carried on at different times and seasons, they may all be considered as falling under the following distinctions or denominations:

Offensive campaigns.
Defensive campaigns.
Summer campaigns, and
Winter campaigns.

In an offensive war, you ought to consider whether it is best to act offensively everywhere, or to act on the defensive in one quarter, to enable you to act with more vigour and effect in another. It is most advisable to attack a country of which the conquest has a tendency to lead to a speedy peace, or at least to prove favourable to the opening of the next campaign. But it is of importance, you before undertake any such enterprise, to know to a certainty that the powers, whose jealousy you might excite, will not oppose the conquest you intend to make.

In a defensive war, you ought to consider what frontiers it is of most consequence to defend. When you are inferior to the enemy, and find it difficult to defend your country with small armies, you should take care not to divide your forces, but to keep your troops together in those quarters where you have most to fear, in order to engage him with all your force, should you be under the necessity of fighting him. Such considerations may sometimes determine you to abandon one tract of country, and lay it waste, in order to preserve and protect another of greater importance.

When your object is to conquer or subdue an ally, either in virtue of a treaty concluded with him, or to prevent his being subdued by some formidable power that wishes to invade his country, and strip him of his territories, you should, in the first instance, have some strong and secure places of his put into your hands to prevent his making a peace without your participation and concurrence, and to keep open a safe retreat for you, should you be forced to retire.

In every situation and species of warfare, either in commencing or continuing it, you ought not to enter on a campaign but after much and mature deliberation. You should weigh every circumstance, consider what may happen, and suppose even the worst, that you may not be surprized by incidents or events, but benefit by such as are favourable, and speedily remedy those that are otherwise.

You should not inculc more than one person with the chief command of an army. For persons who enjoy equal authority are generally of different sentiments and opinions; and although no inconvenience arose to the allies from the co-equal and joint command of prince Eugene and John duke of Marlborough, which was owing principally to the prudence and great good sense of the latter, and to a magnanimity of mind natural to both, yet it ought not to be quoted as an example for imitation.

You should keep your preparations as secret as possible, and endeavor to open the campaign with some blow or enterprise of importance, not foisted by the enemy; and when
when you act in concert with allies, you ought to arrange and settle with them a general plan, that your success may be thereby rendered more certain and rapid, and that the operations of the different armies may be so regulated and conducted, particularly in respect of time, which governs in the affairs of war, as to be conducive to the bringing about of the same object or end.

When a general is appointed to act, either offensively or defensively, it is necessary for him to have an exact knowledge of the situation, condition, and nature of the frontier and country where he is to act, to be able to settle properly a particular plan for the campaign. His conduct or management of a campaign is his manner of executing the plan of operations offensive or defensive, that he has formed.

The general maxims for a campaign of offensive operations are chiefly the following:

To undertake no enterprise without mature deliberation.

To observe profound secrecy; as the best plans and designs are those which the enemy is not only ignorant of, but does not even suspect.

After an enterprise is once resolved on, to carry it as speedily into execution as possible.

To undertake no enterprise rashly, but to consider well the possible ways and means of executing it, and to be prepared to overcome with prudence and resolution the probable obstacles you may meet with in the execution.

Before you undertake anything, to form magazines in different situations near your army, and to procure the means of transporting them with facility from one place to another.

When you penetrate into an enemy's country, to advance gradually rather than leave strong fortresses behind you, and not to move unnecessarily to a distance from navigable rivers convenient for the transport of ammunition and provisins.

Not to enter on any enterprise without securing a communication with your depots, and establishing a protection for your convoys.

On entering an enemy's country to make the natives and people believe that your force is much greater than it really is, by undertaking as many enterprises at once as you can with success and safety.

To establish and strengthen yourself in some advantageous position as a central pivot, from which you can support all your subsequent movements.

To study the courage, talents, and disposition of your officers and soldiers, to know which of them are fit for one sort of service or enterprise, and which for another.

To take care to give your orders in writing, always when you can, as clearly and concisely as possible.

To render the condition and situation of the troops as pleasant and comfortable as you are able, whilst you make them observe a rigid and exact discipline, and inure them to exercise and labour.

To conciliate the esteem and affection of your troops.

To choose such advantageous positions as will enable you to support and command all operations to a considerable extent on every side of them, as will force the enemy to quit his and put it in your power by short, sanguine, and easy movements on your part to compel him to make long, toil-some, and circuitous marches.

Not to revile or reproach your troops when they happen to be beaten, but to animate them and renovate their spirits.

To endeavour by every method to procure exact information in regard to the enemy's force and designs; and, above all things, to become acquainted with the real characters, dispositions, ruling passions, and propensities of the generals opposed to you.

These maxims ought also to be observed by a general who is entrusted with the conduct or management of a defensive campaign. There are a few others, however, peculiar to it, which it may not be improper to take notice of.

He should endeavour to discover on what part of his front the enemy intends to assemble his troops, and of the object he has in view, by the situations, number, and nature of his depots; to put himself in a condition to oppose and frustrate his designs by provisioning and furnishing with sufficient supplies the places that are most important and most exposed, by reconnoitering good and strong positions, and by taking every possible measure to prevent anticipation on the part of his opponent.

A general acting defensively should avoid an engagement where inferiority in numbers is of much avail; and, on the other hand, he ought to embrace any favourable opportunity of fighting the enemy in a situation where disposition is everything, and number nothing.

He ought himself to be active, vigilant, bold, enterprising, and capable of enduring fatigue.

He should endeavour, by every stratagem, to draw the enemy into disadvantageous and dangerous situations, where he can attack him with advantage, and without much risk of losing many men.

He ought not to occupy any position which the enemy can surround or flout him up in.

He should, where it is necessary, secure his camp with intrenchments, placing his flanks out of the reach of inful.

A general who has made some conquests, comes to be on the defensive when he is stopped in his career of victory. He should, therefore, seriously consider whether he is able to keep or preserve them; and what measures he ought to adopt for that purpose. For it is sometimes easier to make conquests than to retain them after they are made.

When a general is on the defensive, it is a material consideration for him to be able to foresee in good time and determine where he shall retire to, in order to take up his winter quarters, and to profit himself of everything that can contribute to ensure their tranquillity.

That the close of a campaign he finds he has but little or no country left him to defend, no allies, with whom he can take refuge, or from whom he can receive succour or support, and that his means of repulsing the enemy are exhausted, it is best for him to deem and an amitie, and to open negotiations for peace.

The close, or conclusion of a campaign is the time when the opposing armies go into winter quarters. Sometimes one of them remains in the field longer than the other, but they generally both retire from it at the same time.

Summer campaigns. Almost all campaigns are made in summer, and none in winter, except in cases of necessity, or when great and important advantages are expected to be derived from them.

Campaigns are generally opened in the spring; but some nations are later in opening them than others. In this respect some are necessarily regulated by climate, while others are governed by custom.

It has been customary for most of the nations of Europe to open their campaigns in the month of March. The Turks are always later than them in taking the field, and quit it sooner. This is owing to the great extent of country from which they have to collect their militia, their
great number of cavalry, for which they must have provision, and
the immense quantities of baggage they carry along with them.

Molti generals have undertaken to take the field as soon
as they were in readiness for entering on the campaign, or
as circumstances would permit. But the celebrated and
very successful marshal Saxe was an advocate for taking the
field late in the season. On this subject he expresses himself
in these words:

"Many persons are of opinion that it is advantageous
to take the field early; in which they judge very properly,
provided there is any important poll to be seized or ente-
prise to be executed that requires it; but otherwise I am
far from concurring with them, and think there is no oc-
casion for such precipitate measures, but, on the contrary,
that it is even prudent to remain in winter quarters much
longer than the usual time. The enemy's being suffered to
lay siege to a place is of no signification, because he will
thereby only weaken and dissipate his troops; and if you
fall upon him towards the autumn with an army well
disciplined and in good order, he must infallibly be ruined.
I have always remarked that a single campaign reduces an
army one-third at least, and sometimes one-half, and that the
cavalry, in particular, is in so watchful a condition by the
beginning of October, as to be no longer able to keep the
field."

Winter campaigns, are campaigns carried on in winter.

There are four countries in which the climate is so se-
vere, and the frost so intense, that it is impracticable to make
campaigns in them in winter. But in others, where they are
practicable, in consequence of the mildness of the climate,
there are circumstances that sometimes render them neces-
sary, and point out such great advantages to be derived from them,
though very exhausting and injurious to troops, that a
general does not much hesitate about undertaking them.

If an enemy has taken up his winter quarters in one of
your provinces or districts of country, with the intention of
invading a neighbouring or adjoining province early in the
spring; and you understand that his cantonments are much
scattered or extended, and think you can approach them
without his being apprised of your design in sufficient time
to collect his force, beat them up in succussion or detail, and
disperse his army, obliging him to retire and abandon that
tract of country, you ought to open a winter-campaign for
the accomplishment of such an object.

There are but few circumstances or considerations, how-
ever, that will justify the opening of a winter-campaign,
which ought not on any account almost to be made in a
country where there are many strong places, which cannot be
reduced but by long and tedious sieges.

Frederic II. king of Prussia, who made more winter-
campaigns than any other general of the last century, in
speaking of them expresses himself in the following words:

"Winter-campaigns are the ruin of your troops, not only
on account of the feeble they occasion, but because from
your continual motion they can neither be clothed nor re-
comitted. The same rate of repose prevents all your car-
rriages, &c. from being properly repaired, and ends in their
total destruction.

"Nothing can be more certain than that the best army in
the world cannot long support such campaigns; for which
reason winter expeditions ought by all means to be avoided;
not but that there is a possibility of a general being so cir-
cumstanced as to be obliged to have recourse to that kind of
ruinous war."

CAMPAN, in Geography, a town of France, in the de-
partment of the Higher Pyrenees, and chief place of a can-
ton, in the district of Bagnères, seated in a valley, which
derives from itits name; 1 league S. of Bagnères-en-Bigorre.
The place contains 4,200, and the canton 7,224 inhabitants;
the territory includes 165 square kilometres, and 7 communes.

CAMPANA, a town of Naples, in the province of
Abritato Ultra; 9 miles S.S.E. of Aquila. Also, a town of
Naples, in the province of Calabria Città; 10 miles S.W.
of Caserta. Also, a small island in the South Pacific Ocean,
just the west coast of South America. 3° 45' 50'. W. long.
77° 51'. Also, a river of South America, which runs into
the Pacific Ocean. 3° 45' 50'. W. long. 77° 31'.

CAMPANA, la, a town of Spain, in the country of
Seville; 13 miles W. of Seville.

CAMPANA Flora, in Botany, a name given by Helwing,
and some other of the German authors, to the plant we call
pulchristella, or the purple flower. It was named campiona Flora,
or Flora's bell, by Helwing, because of its being the signal
of the approach of spring. In the Latinian system, this is a
species of the Asenidae.

CAMPANAECI, the thirty-third natural order in the
Philosophia Botanica of Linnæus, and the twenty-ninth of
the Poissonian Lectures published by Grécitz. It contains
the following genera: Erodolus, Convulsus, Ipomæa, Röth, Pulchella, Polygonium, Comanthis, Campanula, Revilla,
Pyrenema, Trachelium, Lobelia, Lobistia, Virta, Prunella.
Thése plants are not mentioned in the Philosophia
Botanica. None of them are arborescent; few fidek; in
all, the leaves are alternate, the calyx five-cleft, the corolla
five-cleft, the flames five, the style one (except in evolva-
lus, in which it is not certain whether it has four styles, or
one style with four stigmas), and the pericarp a capsule.
They are all lacteate, at least when young and tender, and
have a pugnitive, flightly poisonous quality; they have all a
common character, but it is not possible to give them an ex-
cclusive one by which they may be distinguished from all others.

CAMPANARIO, in Geography, a town of Spain, in
New Cuisine; 10 miles from Paluccio-del-Rey.

CAMPANELLA, Thomas, in Biography, a philoso-
pher of Italy, prompted by his genius to bold innovations,
and remarkable for the sufferings occasioned by them, was
born at Stilo, a village of Calabria, in 1568, and dignified
himself, at a very early period, by his talents and appli-
cation. At the age of 14 years he wrote verses with great
facility; and in his 15th year he entered into the order of
the Dominicans. Having acquainted himself betimes with the
scholastic theology of the age, in which he lived, he
directed his attention with great ardour to the study of phi-
losophy; and disdained with the opinions of Arilotti and
other ancient philosophers, because, as he says, he did not
find them conformable to the great volume of nature, he
imbibed the bold and free spirit of inquiry manifested by
Teleclus, in a work "On the Nature of Things," which
then engaged much attention in Italy. Accordingly he
published, at Naples, in 1591, a defence of this work in di-
flect opposition to the philosopher of Arilotti, under the
name of "Philosophia Senhbus demonstrata," or Philo-

CAMPANARIO, in Geography, a town of Spain, in
New Cuisine; 10 miles from Paluccio-del-Rey.
persecution by removing from Naples to Rome, and afterwards to Florence, Venice, Padua, and Bologna. At this latter place all his papers were clandestinely taken away and sent to the inquisition at Rome. At last he settled in his native country, and with a view of disguising his innovations, wrote in defence of the See of Rome. In 1599 he was suspected of entertaining hostile designs against the Spanish government, and of making himself master of the Higher Calabria; and committed to prison at Naples, under a charge of high treason. He was seven times subjected to the torture, and during his confinement he was, for a considerable time, debarred the privilege of reading and writing, and of all intercourse with his friends. Among other accusations alleged against him, he was charged with having written a book, entitled "De Tribus Imporibus," which, as he himself says, had been printed 30 years before he was born; when the rigour of his confinement was so far abated, that he was allowed to write and to correspond with his learned friends, he composed several books, which were published in Germany. Many attempts were made for his liberation; and, at length, in 1626, pope Urban VIII. prevailed upon Philip IV. of Spain, to acquit him from the charge of treason, and he was removed to the prison of the inquisition at Rome, where he was confined under a pretext of hereby till the year 1639, when he was finally liberated, after an imprisonment of about 30 years. The pope, who was a patron of learned men, in consideration of his sufferings, granted him a pension, together with the title of his domestic. But here he was still pursued by the resentment of the Spaniards, and, therefore, the pope warned him of his danger, and assisted him to make his escape to France, where he experienced the favour of cardinal Richelieu, who procured for him a pension from Louis XIII. At Paris he lodged in the Dominican convent of St. Honore, and was much respected by men of learning, who sought his conversation. This happy change in his situation was of no long continuance, for he died in 1639, as some have said, from the immoderate use of astrin-

Campanella was much more distinguished by the fertility of his imagination than by the soundness of his judgment. In this latter respect he was notoriously deficient, as many of his writings sufficiently evince. Beside the credit which he gave to the art of alchymy, and to a variety of supernatural cures, some of which referable to the Magnetifiers of a later period, he fancied that demons appeared to him, and in a state between sleeping and waking, warned him of any threatening dangers. But, notwithstanding the eccentricity of his genius, and his childish credulity, he had his lucid and happy intervals, in which he reasoned more soberly. The extent of his erudition appears from his numerous writings, and particularly from his treatise "De Refta Ratione Studendi," or, on the right method of studying; in which he pronounces judgment on a number of authors in philosophy, poetry, oratory, history, theology, medicine, and mathematics, and lays down excellent rules for the prosecution of philosophical studies, and the knowledge of nature, which he proposes to deduce from observation and experience. Many of his own opinions, however, on dialectics, physics, and ethics, were unreasonably abstruse, and expressed with great obscurity. Whilst it seems to have been his aim to recede as far as possible from the sylhetes of the Peripatetics, his own logic abounds with subtle distinctions, useless terms, and obscure rules, which are not easily comprehended. Concerning nature, his leading doctrines were, that sense is the only guide in philosophy; that space is the first incorporeal substance, immovable, and the receptacle of all bodies; that time is the succedaneous duration of things, and only measured by motion; that heat and cold are the two principles, which act on the mass of matter, the heavens having been produced by the former from rarified matter, and the earth by the latter, from matter condened; that the sun and earth are the two elements, whence all things are produced; that all animal operations are produced by one universal spirit; that all things in nature are endowed with feeling and perception; that the world is an animal or sentient being, inspired by a soul, by which it is directed, as man is by the divine principle within him; that the first, greatest, and only true being, in whom power, wisdom, and love exist as primary principles, transmits his inexhaustible ideas by means of the active causers, heat and cold, to the corporeal masses, supported in space, the basis of the world, which itself has its stability in God; that all creatures are excellent in proportion to the degree in which they bear the image of essential principles of the divine nature; and that human depravity confits in the loss of this image, and human perfection in its restoration. His works contain a variety of other articles, which are very fanciful and obscure. It redounds, however, in no small degree to the praise of Campanella, that he expoused the futility of the Aristotelian philosophy, and that he wrote an apology for Galileo, with a defence of his system. His acuteness in the science of politics is displayed in his "Political Aphorisms," and in his book "De Monarchia Hispanica;" but his principles resemble those of Machiavel. Whilst he professed to be a reformer in philosophy, he was delitute of that sober and found judgment, which was necessary for producing any very important and permanent effect. He was accused of impiety; but he seemed to have been rather a fanatical and enthusiastic than an atheist. He was also accused of suggeting cruel measures against the protestants, and, as Mosheim says, not without reason. Brucker's Hist. of Philos. by Enfield, vol. ii. p. 529. Mosl. Hist. vol. iv. p. 164.

Campanella, in Geography, a cape on the coast of Italy, nearly south from the city of Naples, across the gulf, of which it is the most fouthly point. The island of Creta lies to the west of it. See Creta.

CAMPANIA, now Campagna, in Ancient Geography, the most pleasant and fertile province of Magna Grecia, described by the ancients under the appellation of "Regio Felix." It extended from the N.W. to the S. E. along the Mediterranean; from the E. to the N.W. in Saturn, and from the S.E. by Lucania; and separated from Sannio by a chain of mountains. Its principal mountains were Melicus, Gaurus, and Vesuvius; its lakes were the Averno and Lucrinus; its rivers the Savus, Vulturnus, Clarian, and Silanus, which separated it from Lucania. Capua was considered as its capital; besides which it had several other considerable towns. See Campagna.

CAMPANIAN daisy, Murcus campanus, in Antiquity, is variously explained by modern writers. Some will have it only a sort of tuberces, or warts, on the face, to which the people of Capania were liable. Others maintain it to be the variegated daisy; and hence drew an argument against the supposed novelty of that malady. Dacier will have it to be something ill worse; the CAMPANIA, they are, were addicted to a sort of commerce too abominable to be named, ort morgi erant. Whence it is, Plautus represents them as more pathic or passive than the Syrians themselves. Hor. Stat. vi. lib. 4. ver. 62. cum not. Dacier.

CAMPANIFORM, or CAMPANULATE, in Botany, a denomination given to flowers in their form resembling a bell.

CAMPANILE, in Architecture. This word, derived from Campana, Ital. a bell, is particularly used to denote the bell towers which it is customary in Italy to erect, not like
The Lam. tent and Laith His, several tower remarkable, booki Andrew Turn. was (hepbut thofeof Bo* confiding divers. the Euclid, feet either s and this 14-9; iichucfo new the La iligma \plumb churches, At a wh lited in miwo, t 1. where •6j a them is half, lie each barbarous 1 Gen. blue, leaves 45 iiu-23x418•nf marble workman and the Giotto, the ing having cd tower, pania, tie feffor herd, he his created league, which the inhabitants of the latter place suffered, when it was besieged by his troops, he was deprived of his government; and withdrawing from the ecclesiastical state, he repaired to the court of Naples. But being disappointed of the preferment which he expected, he retired to Terrone, where he closed his life, in 1477. His various works, consisting of political and moral treatises, orations, letters, eight books of Latin poems, and the History of Andrew Broccio, were published by Michael Feron and a new collection of them was edited at Leipsic by Mencken in 1707 and 1734. Gen. Dict. Tiraboschi.

CAMPANO, Novarese, a distinguished Italian geometer and astronomer, flourished in the time of Urban IV., to whom he was chaplain, in the 14th century. He wrote Commentaries on Euclid, and he is said to have translated Euclid into Latin from the Arabic version; but Tiraboschi ascribes this translation to Adelard, an English monk. He also wrote a treatise on the quadrature of the circle.

Several astronomical works of his composition, which treat of the motions of divers planets, and the instruments necessary for observing them, on the ecclesiastical computation, and on the theory of the planets in general, exist in MS. in various libraries. Tiraboschi.

CAMPANOLEGIA, from campagna, bell, and servis, science, the art or science of ringing of bells.

Gen. Ch. Cal. perianth superior, five-cleft, Linn. Gaert. Lam. (in some species ten-cleft; five of the segments reflexed, and covering the capsule, Jull.) Cor. monopetalous, bell-shaped, five-cleft, thrivelling; segments broad, acute, spreading. Nectary in the bottom of the corolla; composed of five, acute, connivent valves, covering the receptacle. Stam. five, capillary, very short, inserted on the tips of the valves of the nectary; anthers longer than the filaments, erect. Pifg. germ inferior, angular; style thread-shaped, generally longer than the filaments; stigma two, three, or five-cleft, oblong, thickish; segments revolute. Peric. capsule inferior, angular; either top, egg, or prizm-shaped; two, three, or five-celled; in most species emitting the seeds at as many lateral holes as there are cells; in a few, opening by valves. Seeds numerous, small, adhering to a columnar receptacle. Eff. Ch. Cor. bell-shaped, closed at the bottom by valves bearing the filaments. Stigma two, three, or five-cleft. Capsula inferior; two, three, or five-celled.

Obj. What Linnaeus calls the valves of the nectary are considered by Gagnier, Jussieu, and La Marek, simply as connivent dilatations of the filaments, forming a kind of vault over the receptacle. Dr. Smith drops the idea of a nectary, and says, that the bottom of the corolla is closed by flaminiferous valves.

* Calyx five-cleft. Capsulae top or egg-shaped.
† Lister almost smooth, not harsh to the touch.

blue, terminal, large in proportion to the size of the plant; calyx rough, with short, white hairs. A native of the Alps about mount Cenis, introduced into England in 1755, by Dr. Fothergill and Dr. Pitcairn. 2. C. ciliata, Willd. 38. Mart. 67. Lam. Illust. 2490. Allion. Ped. n. 357. Tab. 7. fig. 1. "Stem one-flowered, nearly naked; leaves smooth, oval, toothed; calyx smooth." Root perennial. Stem about three inches high, round. Root-leaves numerous, petiolated, deciduous, acute, nerved beneath. Calyx close on the middle. Corolla spreading. Found by Allioni at the foot of mount Vefudo in Piedmont. 3. C. bellardii, Wild. 3. Mart. 68. Lam. Illust. 2491. Allion. Ped. n. 356. Tab. 85. fig. 7. "Stem one-flowered, nearly naked; leaves petiolated, elliptic lanceolate, toothed." Root perennial. Stem six inches high, round. Root-leaves oblong-egg-shaped, obtuse; stem-leaves longer, lanceolate-linear. Flower blue, terminal, nodding. The whole plant slightly hairy. A native of mountains in Lapland. 5. C. pedata, Linn. Sp. Pl. 38. Willd. 82. Mart. 53. Lam. Enc. 5. Illust. 2493. Mor. hist. 2. p. 466. Sect. 5. Tab. 2. fig. 18. Flor. Dan. Tab. 330. bad. Eng. bot. 73. "Leaves heart-shaped, five-lobed, petiolated, smooth; stem flaccid." Root perennial, fibrous, small. Stems procumbent, creeping, wide spreading, slender, branched, smooth, leafy. Leaves opposite or alternate, tender, smooth, with the exception of a few scattered hairs. Flowers pale blue, terminal and axillary, nodding, some withering after they are gathered. Cutifolia small, hemipetalous. A native of England, Denmark, France, and Spain, in moist shady places. Linneas, without sufficient reason, supposes it a hybrid plant, from some campanula impregnated by Veronica ledifolia. 6. C. echinata, Linn. Lam. Enc. 4. Illust. 2494. Wildl. 73. Barcel. t. 454. "Stems simple, one-flowered; root-leaves roundish-heart-shaped, falcate, on long petiole; stem leaves smaller, from the base spatula-shaped, acute; flower drooping." Stem three inches long, leafy, simple, weak. Root-leaves numerous, smooth, scarcely four or five lines broad. Flowers blue; calyx very short, with five acute teeth. A native of the Italian Alps. 7. C. blattina, Linn. Sp. Pl. 37. Wildl. 86. Mart. 52. Lam. Enc. 5. Illust. 2495. Allion. Ped. n. 422. Tab. 7. fig. 1. Barcel. t. 453. "Leaves heart-shaped, toothed, pubescent, petiolated; stems prostrate; peduncles capillary, many-flowered." Root perennial. Stems many, generally simple, round, pubescent, springing from the fissures of rocks. Leaves alternate, on long petiole. Racemes axillary, with about three flowers, sometimes branched. Flowers purple, cleft half way down; segments lanceolate, revolute. All the flowers have a linear bracteae except the upper one. The whole plant is very milky and pubescent, with short hairs. A native of Piedmont at the foot of the Alps. 8. C. pulia, Linn. Sp. Pl. 2. Wildl. 4. Mart 3. Jacq. Obs. 1. p. 32. Tab. 18. Aug. 3. Tab. 28. "Stems one-flowered; stem-leaves egg-shaped, falcate; flower drooping." Root perennial, small, creeping. Stems five or six inches high, slender, upright, zigzag; sometimes having one or two flowering branches, each with a single flower. Root and stem-leaves egg-shaped, obtuse, petiolated. Flower deep blue, terminal, calyx smooth. There is a variety with roundish leaves, and more than one flower. A native of mountains in Austria, Stiria, and Aragon. 9. C. rotundifolia, Linn. Sp. Pl. 3. Wildl. 12. Mart. 4. Lam. Enc 5. Illust. 2498. Curt. Flora. Lond. 4. 12. Eng. Bot. 876. "Root-leaves kidney-shaped; upper leaves linear." Root perennial, branched, somewhat wavy. Stems several, from two or three inches to a foot or more in length, rather upright, but weak, round, smooth, milky, branched. Leaves smooth; root-leaves petiolated, generally toothed, but sometimes quite entire; stem-leaves near the base. Lacunato and toothed; near the summit linear and entire. Flowers blue, sometimes white, nodding; segments of the calyx linear, lanceolate, grooved, expanding horizontally when out of bloom; valves of the minute fringed, pointed, white. The root-leaves from which this species, rather inconveniently, and, indeed, somewhat improperly, takes its name, are seldom observed, being usually concealed among the surrounding grass and leaves of other plants, and withering away as the plant advances to maturity. The juice of the flowers being blue, but, with the addition of them, produces a green pigment. It varies to much from foul and putrescent, that authors differ greatly from each other with respect to what are only varieties, and what are really distinct, though kindred species. Willdenow affirms, that C. rotundifolia of Allioni, (Flor. Ped. n. 98. Tab. 47. fig. 2.) quoted by Martyn, is certainly a distinct species, since it appears, from Allioni's figure, to be very different from rotundifolia of Linneas in the form both of its leaves and of its corolla. La Marec speaks of a variety which he has found in Auvergne, which differs in habit from rotundifolia, but, upon examination, is found to resemble it in all its botanical characters, except that its stem-leaves are long lanceolate, and narrowed into a petiole at their base. 10. C. pedata, Curtis, Bot. Mag. 511. (rotundifolia B. Linn. Minor rotundifolia alpina, Balb. pred. 34. C. pulia, Jacq. 2. p. 79?) C. eschiffana, Linn. Ill. 2497. Enc. C. pulia, y. "Root-leaves egg-shaped, falcate; petioles flattened; flowers in unilateral racemes, drooping." A plant of much humbler growth than rotundifolia. Root-leaves never kidney-shaped; on short, flattened, not thread-shaped, petioles; continuing during the time of flowering, and forming a mat, not disappearing like those of the preceding species; lower stem-leaves often of the same shape. It bears a profusion of flowers, and being a biarly perennial, is particularly fitted to adorn rock-work. There is a variety with white flowers. According to Curtis, the eschiffana of Scopoli (n. 225. Tab. 4.) is probably a variety. Professor Martin has taken it up as a distinct species, though he had before quoted it as a synonym under C. rotundifolia B. Linn. the pumila of Curtis. Villars, dauph. 2. 500. Hall. hist. n. 702. Balh. Pred. 34, are also quoted by him under both. 11. C. gargyfiola, Lam. Illust. 2469. "Stems many-flowered; lower leaves lanceolate, egg-shaped, petiolated; stem-leaves narrow, acute, seifed." A native of the south of France. La Marec affirms that though nearly allied to rotundifolia, it is distinct, and refers to Gimch, Sib. tab. 33. 12. C. fabriana, La Marec Illust. 2500. (Uniflora, Vill. Dauph. 2. p. 500. tab. 19. Linaria, Wildl. 113?) "Lower part of the stem somewhat hairy; lower leaves egg-shaped; upper ones narrow-lanceolate; flower terminal, erect. Small abortive flowers are found in the axile of the upper leaves." There is a variety entirely hairy, which La Marec conjectures may be C. valdensis of Allioni (Flor. Ped. n. 400. Tab. 6. fig. 1.) The valdensis is taken up by Martin as a distinct species; and C. Schneucherii of Villars (Dauph. 2. 501. tab. 193. taken up from Schleich. t. 454. tab. 14. fig. 1.) is quoted as a synonym. Willdenow supposes the valdensis of Allioni to be his limolcis, and C. Schneucherii a variety.
17. C. palentus, Willd. 11. Schmidt. Bohem. n. 167. "Stem hairy; leaves smooth; root-leaves heart-shaped; stem leaves oblanceolate, toothed, petiolated." Root perennial. Stem decumbent, angular. Flowers short, broad. A native of rocky woods in Bohemia. 14. C. bulbifera, L. Marck. Enc. 8. Ill. 2501. "Smooth; stem erect, many-flowered; leaves all sessile; the lower ones egg-shaped; upper ones lanceolate-linear." Stem about a foot high, simple, smooth. Leaves almost entirely smooth; upper ones entire, acute, a little obovate, rosy, glaucous. Bractes. 1. Forster upwards, terminal; their tube shorter than the calyx-segments. Stem a foot or more high, leafy, two-edged. Leaves obtuse; lower ones opposite, the soft felted. Flowers erect, on long peduncles; calyx globose, generally rough with deflexed bars, but in Forster's original specimen smooth; segments awl-shaped, longer than the body; corolla slender, funnel-shaped, of a rich blue within, paler without; segments acute, fringed, sometimes only four. Capsule three-celled, three-valved at its summit. Every part of the herbage rough with a short rigid pubescence. Found by Forster in New Zealand and New Caledonia, raised in England from seeds brought from New South Wales. 21. C. vincifolia, Venten. Jard. de Malmaison. 12. (Camp. gracilis, Bot. Mag. 667.) "Leaves lanceolate-lanceolate; stem round, much branched; peduncles terminal, elongated, one-flowered." Ventenat supposes his plant and the gracilis of Forster to be the same. Dr. Sims (Bot. Mag.) concurs with him; and there is certainly nothing in the specific character, as given by Ventenat, which can lead to a different opinion; but we have kept them separate, in deference to the judgment of Dr. Smith, who thinks the vincifolia a distinct species, being smooth, except some scattered longish bristles on the leaves; and having a wider flower, with much shorter calyx-segments, and a less globular capsule. The figures in Exotic Botany and the Botanical Magazine are materially different. We have referred that in the latter, though with some hesitation, to Ventenat's plant, on account of its widespread campanulate, not funnel-shaped, flower, which appears of itself to form a sufficient specific distinction. The teeth, or, as we should rather call them, segments of the calyx, are represented in the Botanical Magazine expanding, which would form another good difference, if Dr. Sims had not in the description expressly stated them to be erect. The smoothness of the leaves is too variable a character to be of much value. Dr. Smith says that the capsule of vincifolia is less globular than that of Sims's; but in the Botanical Magazine it is evidently more so. Dr. Sims's description differs in several respects from Dr. Smith's. We shall transcribe the most material parts, that future observers may be better able to determine the identity or the diversity of the species. Stem square, hairy, generally decumbent. Leaves mostly opposite, toothed, somewhat pubescent. Flowers nodding whilst in bud, erect when expanded; on long, square, hairy peduncles; calyx egg-shaped, fringed; teeth awl-shaped, erect, dilated; corolla bell-shaped, cut half-way down into five, sometimes only four, egg-shaped, entire segments; nectaries or valves three-lobed; anthers oblong, disapparing almost as soon as the flower opens; style erect; stigmas three, rolled back, villous. First raised by Mr. Curtyis, by fowing the mould that came about the roots of some plants imported from New Holland and New Zealand. It flowers during the greatest part of the summer, and is easily propagated by seeds or cuttings. 22. C. Rapunculus, Rampon. Linn. Sp. Pl. 5. Willd. 23. Mart. 6. Lam. Enc. 10. Ill. 2524. Gært. tab. 31. fig. 2. Eng. Bot. 283. (Rapunculus cneifer, Rau. Syn. 277.) "Leaves waved; root-leaves lanceolate-oval; panicle contracted." Root biennial, spindle-shaped, white, sweet, efflucent. Stem a foot and half
Campanula.

or two feet high, erect, angular, rough, especially on the lower part with deflexed hairs. Leaves alternate, sessile, toothed; lower ones rather hairy; upper ones smooth. Bracts awl-shaped. Panicle erect; its side branches bearing from one to three or more flowers. Flowers bluish purple, or whitish; segments of the calyx sometimes toothed, but not so much as in petula; corolla inflated, not tapering at the base; nectary fringed. Capsule crowned with the lanceolate-linear segments of the calyx, retuse, ineruptly pyramidal-egg-shaped, with three nerves on each of the three blunt angles opening with three lateral holes, a little above the middle. Seeds numerous, small, elliptical, lenticelately compressed, smooth, shining, of a pale rufous colour. Smith and Gardiner. A native of France, Switzerland, Germany, Piedmont, &c. It has been found in England, about Croydon and Ether in Surrey, old Buckenham castle in Norfolk, and Enville in Worcestershire. The leafy roots and the young leaves are eaten in France in salads, and are thought to increase the milk in nurses. The roots are also eaten boiled. It was formerly much cultivated in England as an eculent, but is now neglected. In the time of Parkinson its roots were boiled till they were tender, and afterwards eaten cold with vinegar and pepper. 25. C. periclymena. Lam. Sp. Pl. 6. Wild. 29. Mart. 3. Lam. Enc. 11. Ill. 2605. (Rapunculus periclymena, Bauh. P. 93.) "Root leaves ineruptly egg-shaped; stem leaves lanceolate-linear, somewhat serrated, sessile, remote." Root perennial, eculent. Whole plant, except the germ and capsule, smooth. Stem two or three feet high, erect, simple, angular. Stem leaves straight, acute, distant, slightly toothed. Flowers in a thin spike, blue, sometimes white, on long peduncles; corolla large, broad, short; bracts two to each peduncle. There is a variety found in low woods, with only two or three large flowers, and long narrow leaves. A double variety, both blue and white, is also common in gardens, called, in some parts of England, Batchelor's Buttons. A native of moist parts of the continent of Europe. A magnificent, large-flowered variety from South Carolina, imported by Mr. Dickson of Covent garden, and differing from the European plant only in size, is figured in the Botanical Magazine, 357. It is very hardy and easy of culture, increasing by its roots, which are somewhat creeping, and may be parted either in spring or autumn. 24. C. pyramidalis. Lam. Enc. 12. Ill. 2566. Town. Cor. 4. "Leaves all linear, toothed; stems simple; flowers erect, sessile." Stems scarcely a foot high, smooth. Leaves scabrous at their edges with fine spinous teeth. Flowers alternate, blue, forming a spike at the upper part of the stem; calyx short, smooth; corolla oblong, slightly five-cleft: bracts three. Observed by Tournon in Armenia. 25. C. linarioides. Lam. Enc. 15. Illus. 2507. Wild. 15. * Stem rod-like, panicked: leaves linear: flowers erect, terminal." General habit that of Arrhirrhina linaria. Stem about a foot high, slender, smooth, slightly frayed, panicked at the top. Leaves numerous, scattered, minute, with a few, feebly perceptible teeth. Flowers peduncled, small: corolla deeply divided. Found by Commeron on Monte-Video, near Buenos-Ayres, in South America. 26. C. pyramidalis. Lam. Sp. Pl. 17. Wild. 27. Mart. 28. Lam. Encyc. 14. Ill. 2508. (Rapunculus botroennis: Bauh. p. 93.) "Leaves smooth, even, serrated, heart-shaped; stem leaves lanceolate: stems rush-like: simple: umbels sessile, lateral." Root biennial, oblong, fibrous, milky. Stems several, near four feet high, smooth. Leaves petioled. Flowers blue, sometimes white, large, open, coming out several together in lateral and terminal tufts or umbels, on short peduncles: segments of the calyx upright, linear. Vigorous plants throw out numerous simple, short, lateral branches. A native of Carniola. It is sometimes cultivated in a pot, and let on the hearth of halls, &c. in summer, and by spreading the upright stems on a flat frame composed of flender laths is formed into the shape of a fan, which will nearly cover a common fire-place. 27. C. americana. Linn. Sp. 3. but not the synonyma which belong to the next species. Wild. 28. Mart. 9. Hort. Kew. 250. "Leaves heart-shaped and lanceolate: petals ciliated: flowers unilateral: corolla five-cleft, flat." Linn. "Leaves heart-shaped and lanceolate, serrated: petals of the lower ones ciliated: flowers axillary, sessile: corolla five-cleft, flat: style longer than the corolla." Hort. Kew. Root annual. Stem and germs smooth. Flowers three or four from the axil of each leaf or bract: corolla small. Linn. A native of Pennsylvania, introduced into England in 1763, by Mr. J. Bartram. 28. C. nitida. Wild. 29. Mart. 74. Hort. Kew. 221. L'Herit. &c. Ang. (C. planifolia, Lam. Enc. 15. Ill. 2509. C. minor Americana, Herm. Lugd. 107. Trachelium minus Americana: Doddart. Mem. 4. p. 119. tab. 118.) "Leaves oblong, scoloped, even: stem leaves lanceolate, nearly entire: corolla bell-wheel-shaped. Hort. Kew. "Leaves oblong, scoloped, rigid, sessile: flowers erect, flat." Lam. Root perennial. Stems five or six inches high, often simple, straight, stiff, a little striated. Stem leaves smooth, green, gradually diminishing to the top of the stem. Flowers blue or white, one or two in each axil of the upper leaves: calyx short: segments oval-acuminate. La Mark doubts whether it be specifically distinct from C. americana, though he acknowledges that it differs from it in having no heart-shaped leaves, nor ciliated petals: and in the flowers not being unilateral: the last circumstance, however, is omitted in the specific character of C. americana, drawn up for the Hortus Kewensis. A native of America, described by La Mark from a living plant in the royal garden at Paris. 29. C. flybya, Lam. Enc. 16. Ill. 2512. Wild. 35. Smel. Sib. 3. tab. 27. good. "Leaves petioled, somewhat heart-shaped, acutely serrated: flowers small, nodding, style longer than the corolla." Stem a foot high or more, simple, and, like all other parts of the plant, smooth. Leaves scattered, acuminate, decurrent along the petiole with a flight membrane: bracts lanceolate and nearly sessile. Flowers oblong, blue, in a terminal panicle: border obtruse: style very long: stigma club-shaped, slightly three-cleft. A native of Siberia, sent to the royal garden at Paris, under the name of C. lilifolia. 30. C. periclymena. Lam. Enc. 17. Ill. 2511. "Leaves heart-shaped, obtusely serrated, on long petioles: stems ascending, few-flowered." Referring the preceding, but smaller, and not with upright stems. Leaves all petioled, acuminate, smooth, a little toothed or scoloped. Flowers terminal, pale blue, resembling those of C. flybya. A native of Siberia, cultivated in the royal garden at Paris. 31. C. lilifolia. Linn. Sp. Pl. 9. Wild. 30. Mart. 27. Lam. Enc. 18. Ill. 2512. Amm. Ruth. p. 11. n. 17. Smel. Sib. 3. p. 143. tab. 25. "Leaves lanceolate: stem leaves acutely serrated: flowers purplish, nodding." Root perennial. It varies in its form and size, and in the number and colour of its flowers; but may in all cases be distinguished from the two immediately preceding by its sessile stem leaves. A native of Siberia, from the laick eastward to the confines of China. The roots are eaten by the inhabitants boiled and raw. 32. C. azurea, Bot. Mag. 551. Southern MSS. in the possession of Sir Joseph Banks. "Leaves oblong, egg-shaped, sessile, serrated: stem simple, angular: flowers panicked." Sol. Root perennial. Stem erect, quadrangular, with raifed, somewhat cartilaginous angles. Root leaves.
CAMPANULA.

linear-awl-shaped, entire; flowers axillary, solitary, sessile."

Leaves hard to the touch. 57. C. flore, Willd. 7. Mart. 67. Thunb. fl. jap. 88. "Leaves sessile, egg-shaped, ferrated, glaucous beneath; stem angular, panicked; peduncles one-flowered." An under-fermat. Stem two feet high, erect, smooth; branches erect, zigzag, somewhat fimbriate, angular, smooth. Leaves scattered, acute, a little reflexed at the edge, scabrous, netted; lower ones larger, expanding, upper gradually less, erect, about an inch long. Flowers axillary on the upper part of the branches; peduncles an inch long, erect; branches one or two on a peduncle, alternate, lanceolate, resembling the leaves; calyx somewhat angular, glaucous; segments lanceolate, reflexed; corolla large, blue. 58. C. nigricana, Willd. 44. Mart. 66. Thunb. jap. 89. "Leaves lanceolate, waved, erect, ferrated, bordered; branches weak; flowers terminal, solitary. Stem thick at the base, rather woody, decumbent; branches numerous, about four inches long, capillary, rather erect, a little subdivided, ferrated, smooth. Leaves on the lower part of the branches half an inch long, sessile, alternate, white edged, hispid with white hairs. Flowers terminal, solitary. The last four were observed by Thunberg in Japan. 59. C. paniculata, Linn. jun. Supp. p. 139. Willd. 50. Mart. 59. Thunb. Prod. 39. "Leaves lanceolate, waved, hairy; stem angular, hispid; flowers in racemes." Stem herbaeous, panicked; branches disarticulate. Leaves entire. A native of the Cape of Good Hope. 60. C. latifolia, Giant thrift-vort, Linn. Sp. Pl. 11. Willd. 33. Mart. 22. Lam. Enc. 25. Ill. 2526. Eng. Bot. 302. "Leaves egg-lanceolate; stem quite simple, nearly round; flowers solitary, peduncled; calyxes smooth; fruit drooping." Root perennial, milky. Stem three or four feet high, erect, slightly angular, somewhat hispid, many-flowered. Leaves large, alternate, nearly felise, roughish, doubly ferrated. Flowers large, blue, sometimes white, axillary, almost always solitary, erect; calyx smooth, ferrated, alternate of Sweden, and other parts of Europe; common in Scotland and the north of England, rare in the south. It is sometimes cultivated in gardens. 61. C. articulata, Willd. 54. Schmidt. 1775. "Stem angular, hispid; upper leaves egg-lanceolate, costely ferrated; peduncles one-flowered, axillary, drooping; calyxes hispid." It differs from the preceding, chiefly in its hispid calyxes, but its stem is also more hispid, and has more prominent angles; its root and lower sternal leaves are also heart-shaped, and in that respect approach more nearly to C. trachelium. A native of shady places in Germany and Bohemia. The articulata of Allioni (flor. pedem. n. 406.) taken up by Professor Martyn n. 723, seems a different plant, which ought to be placed with a new specific name in the preceding subdivision. It is thus characterized: "Stem roundish, simple, upper leaves felise; spike unilateral; peduncles one-flowered; calyxes smooth." Plant entirely smooth. Stem three feet high, broken. Leaves soft, egg-lanceolate, unequally and sharply toothed. Flowers finge, axillary, on short peduncles towards the top of the stem, with linear bracts; calyx five-cleft beyond the middle; segments narrow, not reflexed; corolla and calyx nearly equal. A native of Italy in woods. After all, the plants of Schmidt and Allioni are nearly allied to each other, and seem to differ chiefly in the comparative length of the calyx and corolla. Both of them may, perhaps, be not improperly considered as varieties of C. latifolia. Characters drawn
drawn from the smoothness or roughness of the leaves, though they often afford a good and always an obvious distinction, and on that account make convenient subdivisions in a large genus, are sometimes fallacious, and can seldom be opposed to each other with rigid exactness. 62. C. Tinctoria, nettle-leaved threath-wort, Linn. Sp. Pl. 16. Willd. 41. Mart. 23. lam. Enc. 26. PI. 5257. Eng. Bot. 12. "Stem angular; leaves lanceolate-heart-shaped, bluntly serrated; calyxes hispid; peduncles axillary, few-flowered." Root perennial. Stem two or three feet high, thick, hispid. Lower petioled, deeply and markedly serrated; bracts tough, generally hispid with purplish hairs. Bristles violet-coloured, rather less than those of C. hithofia; sometimes three, but more frequently only one on a peduncle; calyx hispid at the base and on the edge, but sometimes smooth. A native of many parts of Europe; common in the fourth, but rare in the north of England. 63. C. rapunculoides, Linn. Sp. Pl. 13. Willd. 50. Mart. 27. lam. Enc. 27. II. 2528. Eng. Bot. 1379. "Leaves lanceolate-heart-shaped; stem branched; flowers scattered, unilateral, nodding; calyxes reflexed." Root perennial, creeping. Stem about a foot high, more or less branched, round, rough with deflexed hairs. Leaves feathery; lower ones petiolated, lower ones sessile. Flowers blue, axillary. Caffale resembling that of Rapunculus, but only half as large. Segments of the calyx linear, reflexed. Openings large at the very base of the capsule. Seeds elliptical, so much compressed as to be almost flat, plain on one side, marked with an elevated longitudinal line on the other, of a yellowish brown, scarcely shining. Gaert. A native of Switzerland, France, and Austria; rare in great Britain, but, as appears from Buddle's herbarium, gathered among ivy trees in same woods in Oxfordshire, and found, apparently wild, by Dr. Skirrhine at Blair in Scotland. 64. C. boveiensis, Linn. Sp. Pl. 15. Willd. 57. Mart. 24. lam. Enc. 28. II. 2529. "Leaves egg-lancolate, feathery beneath, sessile; stem pinnacled." Root perennial, large, woody. Stem with the habit of verbacum nigrescens, three feet high or more, erect, rough. Leaves feathery, almost heart-shaped, slightly toothed, covered with white hairs beneath. Flowers violet-colour, terminating the branches in a kind of spike; axillary; lower ones three together, on short peduncles; upper ones five, sometimes two, flaccid, white, native of Italy, Corsica, and Sardinia; introduced into England in 1772 by John Earl of Rute. 65. C. germiinfolius, Linn. Sp. 14. Willd. 42. Mart. 25. lam. Enc. 29. II. 2532. "Leaves linear-awl shaped; head terminal." Root perennial, divided at the crown into several trunks, each producing a tuft of straight, long, grasslike leaves, elating at their base. Stems simple, scarcely longer than the root-leaves. Stem-leaves alternate, rather embracing the stem. Flowers blue, five or seven together, in a head; bracteae egg-shaped, acuminate; figimina two-cleft. 66. C. glomeratus, little Canterbury bells, Linn. Sp. Pl. 17. Willd. 42. Mart. 29. lam. Enc. 30. II. 2531. Eng. Bot. 92. "Stem angular, simple; flowers sessile; most of them collected into a head, a few solitary, and axillary within the upper leaves; leaves egg-shaped, scapellate." Root perennial, woody. Stem a foot high, erect, roundish, rather rough, seldom if ever branched, unless first erect down by cattle. Leaves hairy, pale beneath; root-leaves a little heart-shaped, on long petioles; stem-leaves half embracing the stem. Flowers blue, purple, or white. A native of lime-borne and chalky soils in England, France, and other parts of Europe. 67. C. petraea, Linn. Sp. Pl. 28. Willd. 46. Mart. 32. lam. Enc. 31. II. 2532. Bar. ic. 890. (Trachelium majus petraeum; Pon. bald. 161.) "Stems simple, rough; leaves oblong-egg-shaped, hairy, sessile; head terminal." Nearly allied to the preceding, but more hairy. Stem one or two feet high, erect, rough. Leaves all oblong, harsh, deep green above, whitish and cottony beneath; stem leaves not half embracing the stem. Found on the summit of Mount Baldo; a native also of Piedmont, Lidia, &c. 68. C. Ceratocory, Linn. Sp. Pl. 16. Willd. 3. Mart. 30. lam. Enc. 32. II. 2533. "Hispid; flowers sessile; head terminal; leaves lanceolate linear, waved, scapellate." Root biennial, seldom. Stem about a foot high, simple, or a little branched. Leaves heart-shaped, linear, rough with hairs. Flowers blue or white, most of them in a head, a few axillary. A native of woods on the continent of Europe; introduced into England in 1785 by Dr. Percussion. 69. C. hygidae, Linn. Sp. Pl. 17. Willd. 42. Mart. 31. lam. Enc. 33. II. 2534. "Hispid; raceme oblong egg-shaped, terminal; stem quite simple; leaves lanceolate linear." Root biennial, large, woody. Stem eight or ten inches high, erect, rough with white hairs. Root leaes tufted, round, laciniate egg-shaped. Stems leaves numerous, upright, scattered, hairy, a little harsh to the touch. Flowers yellowish white, very numerous, densely disposed in a kind of thyrsus; corolla hairy. A native of Austria, Switzerland, and the south of France. 70. C. Launfinaea, Linn. Enc. 34. II. 2535. (C. peregina; Linn. Mast. Willd. 52.) "Hispid launfinae; leaves egg-shaped, wrinkled, scapellate, narrowing into a petiole; stem simple; flowers nearly sessile, erect, open." Stem a foot high, erect, round thickly covered with separate white hairs. Root-leaves rough on both sides, pale green above, white beneath, a little resembling those of the primrose; stem-leaves smaller, alternate; the upper ones sessile and rather acute. Flowers lateral and terminal, solitary, blue, calyx hispid, a little shorter than the corolla; segments lanceolate; corolla short, very open; style not longer than the corolla; stigma three cleft. Cultivated for a long time in the royal garden at Paris, and reputed to be a native of Tartary. The peregina of Linnaeus springing up in ground town with feeds from the Cape of Good Hope, but it was probably mixed with them by accident. 71. C. tomentosae, Linn. Enc. 35. II. 2536. (C. foliis profunde inicinis, tomentosa tata & eana; Tourn. Cor. 3.) "Root-leaves long, spatulate-flaped, scapellate; upper ones wedge-shaped; flowers peduncled, somewhat falked; calyx downy." The whole plant covered with a fine white down. Stem round. Flowes oblong, in a loose, fimbriated unilateral spike, on short peduncles; calyx half the length of the corolla. Described by La Marec from a dried specimen in the herbarium of Jussieu. Native country unknown. 72. C. argentea, Linn. Enc. 36. II. 2537. (C. leucocolistour; Tourn. Cor. 3.) "Leaves oblong, narrow, silvery-white with down; stem pinnacled: branches one-flowered." Stem three or four inches high. Root-leaves numerous, a little enlarged towards their summit, scarcely an inch long, entire. Stem-leaves almost linear. Flowers terminal. A native of Armenia, preferred in the herbarium of Jussieu. 73. C. calaminifolia, Linn. Enc. 37. II. 2538. (C. saxatilis, foliis crenatis & velutini rugosis; Tourn. Cor. 3.) "Pubescent: stem branched, decumbent; stem-leaves roundish egg-shaped, scapellate, nearly sessile; thole on the branches small, acute; corolla pubescent on the outside." Stem scarcely a foot long. Stem leaves spatulate-flaped, like those of the daily. Flowers terminating and axillary; corolla a little tubular. Found by Tournelort in the island of Naxos; described from a dried specimen in the herbarium of Jussieu, and an original drawing by Aubriet. 74. C. hispidula, Linn. jun. Supp. p. 142. Willd. 49. Mart. 27. lam. Enc. 40. II. 2542. "Hispid: flowers erect; calyx the length of the corolla." Root annual. Stem about four inches high, branched, especially.
Campanula

*** Calyx five-ribbed: capsules elongated, prism-shaped. (Prismato-carpus: l'Hert. legousi: Durande.)

synonym to our carpatica, n. 55. We have not Jacquin’s work at hand, but this plant cannot be the carpatica of the English gardens figured in the Botanical Magazine, which has a five-cleft calyx, with the segments a little reflexed, but not alternate ones, covering the calyx as in all the species of this division; whereas La Marek describes the calyx of his violaceus to be, a cincdecoupes lanceolées, et à fines reflechoes, the expression by which he uniformly denotes what we call the five alternate reflexed segments.

Has he been led into an error by the ambiguous phrase calyx reflexo in the definition of the younger Linnaeus? It is, the present species must be expunged. He appears to have formed his description only from a dried specimen in the herbarium of Jussieu. 105. C. heterophylla, Linn. Sp. Pl. 39. Wild. 84. Mart. 55. Lam. Enc. 54. Ill. 2561. (C. faxsithis, folis inferioribus Bellidias, ceteris Nummularis, Tourn. Cor. 3. I. 1. tab. 243.) “Leaves indivi
dersely egg-shaped, scollopeld, on long petiolo. Stem-leaves lanceolate-egg-shaped, attenuated and gasted at the base; flowers pustuled.” Stem about a foot high, round, slightly pubescent. Flowers small, numerous, in terminal panicle. A native of the Levant. 107. C. fruticosa, Lam. Enc. 57. Ill. 2564. (C. folis profoundé lacinis; fructu duro, Tourn. Cor. 3.) “Hilipid; root-

Propagation and Culture. Such of the species as come from the Cape must be kept in the dry loose, and treated like the other plants of the same climate; they may generally be increased from cuttings. Most of the others are hardy plants, which bear the open air, and will thrive in almost any situation. Those that are annual are usually found in the spring, in the borders of the flower garden; but, if in flower in the preceding autumn, they will be stronger and flower a month earlier. The perennial ones are easily propagated by parting the roots in autumn, but where this practice is long continued, the plants are apt to degenerate, and at length seldom produce seeds. It is desirable, therefore, to raise a succession of seeds, which will produce plants that are more vigorous, and bear a greater profusion of flowers. The pyramids, in particular, is seldom fit to adorn halls and chimneys for two successive seasons. In order to procure good seeds, strong plants should be selected which grow in a warm situation, and which have been screened from great rains at the time when their flowers were fully open. The seeds should be sown in autumn in pots and boxes filled with light undoubted earth; and in the winter should be sheltered from severe frosts under a hotbed frame. In summer, they must be kept clear from weeds, and moderately watered in very dry seasons. In September, when the leaves of the plants begin to decay, they should be transplanted into beds of light sandy compost, without any mixture of dung, and care should be taken not to break or bruise the roots. They should be set about four inches from each other, and in two years will be strong enough to flower. The Rampion, when it is cultivated for the table, should be sown in a sandy border about the latter end of May, and in the course of the summer should undergo three hoings to cut up the weeds, and thin the plants to the distance of three or four inches. The roots are fit for use in the winter, and will continue good till April. If the seeds are sown too early, the plants are apt to flower the same season, by which the roots are always spoiled. See Martyn’s Miller.
This kind preys on the marine eel, crabs, and other small creatures, and is chiefly observed in autumn. Its body is of a conic-oval form, with the fringe, and hairy crofs of a yellow colour, and sometimes white; beneath bottom and yellow white.

CAMPANULACEÆ. In Botany, the fourth order of the tenth clafs of Jullien's natural orders, focoled from their affinity to the genus Camp Sullivan. Jullien gives them the following character. Calyx superior, sometimes but rarely half inferior; border divided. Corolla inserted on the upper part of the calyx, most frequently regular, generally thralling; border divided. Stamens inserted under the corolla, as many as its segments, and generally alternating with them, most commonly five; anthers either distinct or united. Gyno-glandular above; style one; stigma either simple, or divided. Capsule most commonly five-celled, but in some cases two, five or six-celled, often many-seedeed, and generally opening at its sides. Seeds fixed to the interior angle of the cells. Seeds generally herbaceous, but sometimes thorny; milky. Leaves most frequently alternate. Flowers distinct, or in a few instances aggregate, and enclosed in a common calyx. Jullien includes in it, Ceratocaula, Fordegif, Minduin, Cannania, Campuran, Trachchum, Rodella, Gepserica, Cyphia, Seveola, Phytceum, Lobula, and Jaffone. According to Ventenat, its genera are Melanthia, Canarina, Campuran, Trachchum, Rodella, Phytceum, Seveola, Gooden, Lobula, and Jaffone. His Micranthus is the Minimus of Jullien.

CAMPBELL, Archibald, in Biography, the descendant of an ancient and noble family in Scotland, was born in the year 1581: and having been educated in the profession of the protestant religion, according to the strictest rules of the church of Scotland, as it was setted immediately after the reformation, he zealously supported that church, and the constitution of his country, according to the ideas which he had formed of its legal establishment. In the earlier period of his life, he avoided his attachment to the king, and was distinguished by marks of royal favour. At the commencement, and during the progress of the rebellion, he seems to have maintained his loyalty; and after the establishment of the commonwealth his country was the last that submitted, and even then, his son did not subside. At length, Argyle himself, who had been created marquis in 1640, was induced, by the prevailing circumstances of the times, and the authoritative interferences of general Monk, to yield to the ruling powers. After the restoration, he was tried for his compliance, under a charge of treason, and sentenced by the parliament of Scotland to be beheaded. During his trial, he behaved with great firmness and dignity: and on the scaffold manifested the integrity of a man, or rather, as he wrote of his life says, the constancy of a Christian, affecting the uprightness of his conduct, and the sincerity of his affection both to King Charles I. and King Charles II. As to his character, Mr. Hume (1718. vol. vi. p. 272) represents him as a man equally supple and inflexible, cautious and determined, and entirely qualified to make a figure among a faction and tumultuous period. Bio. Brit.

CAMPBELL, ARCHIBALD, earl of Argyll, son to the former, was educated under his father's eye, in the true principles of loyalty and of the Christian religion, and distinguished himself, in an eminent degree, by his personal character and steady attachment to the royal family. When Charles II. was invited home to receive the crown of the kingdom in 1652, he was constituted colonel of his majesty's foot-guards by the Scots parliament, which then afforded a kind of sovereign authority; but he declined accepting the office, till he obtained a commission from the king; to which honor he was recommended by his fidelity and valor in his service, as well as by his affection and respectful attention to his person. After his majesty's defeat at Worcester, he declined indulging the offer to be made to royal stature, nor did he desert it, when the king's affairs were heavy and desperate, and his own were reduced to a dismal condition. After having capitulated in 1655, to the victorious forces of the English, in consequence of orders from general Middleton, sanctioned by the king's authority, he determined to live peaceably, though he would never acknowledge either Oliver's or Rich's government; and of course he was obnoxious to persons in power, and intimidated by them. After the king's restoration, his enemies, jealousy of the favour and influence which he was likely to acquire, or hired in their attempts to destroy him; and they prevailed with the Scots parliament to imprison him, and to commence a process against him for the crimes, bled in their laws, leuking-making, or creating difficulties between the king and his subjects, by giving the former false informations. They proceeded so far as to condemn him to lose his head, and to forfeit his whole estate; but the king interposed to prevent the final execution of their purposes. At length, his friends came into power, and he was released from a long and severe imprisonment. He was also soon after restored to his grandfather's title and estate, and part of his father's was bestowed to be sold for the payment of his debts. In the subsequent part of this reign, he behaved towards his sovereign with respect and affection: and in his opposition to those measures of the court which he could not approve, he manifested a mild and peaceable disposition. When his majesty thought fit to sending the duke of York into Scotland, in 1661, a parliament was convened, which, among other laws that were proposed and enacted, passed an act for establishing a tell, obliging all who possessed offices, civil, military, or ecclesiastical, to take an oath not to attempt any change in the constitution of church or state. This oath contained several clauses, affecting the king's supremacy, renouncing the covenant, and preventing all obedience, introduced by the court, to which the country party added another clause of adhering to the protestant religion. The courtiers, however, proposed, that all princes of the blood should be exempted from the obligation of taking this oath. Argyll zealously opposed this exception, intimating, that the sole danger to be dreaded, with regard to the protestant religion, must proceed from the perversion of the royal family. His conduct, on this occasion, excited the indignation of the duke, and expelled him to its fatal consequences. When the earl of Argyll took this taff, which he was obliged to do as a privy councilor, he did it with an explanation which he submitted to the approbation of his royal highness, and the whole privy-council. The explanation was allowed, and the earl took his seat at the board. However, to his great surprize, he was a few days after committed to prison, and prosecuted for high treason, lecoming-making, and perjury. Three out of five judges found him guilty of the two first charges, and a jury of 15 noblemen gave verdict against him. The king's leave was obtained for pronouncing sentence against him, but he ordered the execution of it to be delayed. The earl, having little reason to expect either justice or mercy from his enemies, contrived to make his escape from prison, and arrived safely in London, where the place of his concealment was known at court, though the king would not suffer him to be arrested.
the mean while, the privy-council of Scotland publicly pro-
claimed his sentence at the crofs, and caus'd his coat of arms
to be rever'd and torn. As soon as a convenient oppor-
tunity occurred, the earl went over to Holland, and continued there during the remaining part of that reign. Con-ceiving, probably, that his attainder had entirely disdosed the ob-
ligations by which he was bound as a British subject, and confedering the government in Scotland as unfetter'd, before king James II. had taken the coronation oath, he concerted measures with the duke of Monmouth, and passed over to Scotland to assemble his friends: but disappointed in his ex-
pectations of suppr't, he was taken prisoner, and beheaded at Edinburgh upon his former unfait sentence, June 20, 1685. Under his misfortunes he manifested great firmness and self-possession; he ate his dinner cheerfully on the day of his death, and, according to his usual custom, slept after it for a quarter of an hour or more very soundly; at the place of execution he made a short, grave, and religious speech; he caus'd the position of the block to be duly ad-
justed; and after a solemn declaration, that he forgave all his enemies, he submitted to death with extraordinary relo-

**Campbell, Archibald**, first duke of Argyile, was the son of the preceding, and a very active promoter of the re-
'volution. He accompanied the prince of Orange to En-
'gland; was admitted into the convention as earl of Argyile, though his father's attainder was not reversed; and in the Claim of Rights, the sentence against him was declared to be, what it undoubtedly was, "a reproach upon the na-
ton." When it was carried in the Scottish convention, that the crown should be establish'd on the prince and princes of Orange, he was sent from the nobility, together with Sir
James Montgomerie, and Sir John Dairymple, from the barons and boroughs, to offer the crown in the name of the convention, to their majesties, and to tender them the coronation oath. For this and other eminent services, he was admitted a member of the privy-council, and in 1690, made one of the lords of the treasury. He was afterwards appoint-
ed a colonel of the Scots horse-guards; and, in 1694, one of the extraordinary lords of feilion. He was likewise created duke of Argyile, marquis of Kintyre and Lorn, earl of Campbell and Cowell, viscount of Lockow and Gleagla, lord of Inverary, Mull, Morvern, and Ferrey, by letters patent, bearing date the 23d of June, 1701. He sent over a regiment to Flanders, for king William's service, the ofcers of which were of his own name and family, who bravely distinguished themselves through the whole course of the war. Biog. Brit.

**Campbell, John**, second duke of Argyile, and also duke of Greenwich and baron of Chatham, son of the preceding, by Elizabeth daughter of Sir Lionel Talma, was born on the 1oth of October, 1678, and betimes devoted to a military life. At the age of 17 years, he was appointed to king William to the command of a regiment of foot, with which he serv'd abroad. In 1703 he succed'd to the honours and estate of his father; and in 1705 he was nominated lord high commissioneer to the parliament of Scotland. In 1705 he made a campaign under the duke of Marlborough, and distinguished himself by his courage and conduct on several occasions. On his return to Scotland, he promover'd the measure of the Union, and incurred some degree of unpo-
pularity among his countrymen. In the years 1708 and 1709, he performed several important services in his military capacity on the continent; in recompence of which he was, in 1710, infall'ed a knight of the garter. Having joined the tory-party, he was, in the following year, appointed amba'sador extraordinary and plenipotentiary to Charles III.

king of Spain, and commander in chief of her majesty's forces in that kingdom. But by ill-n's and want of suffi-
cient suppr't, he was disabald from attempting any enter-
prise of importance; and, indeed, the peace of Utrecht soon after put an end to hollivities. In 1712 he was appointed commander in chief of all the land forces in Scotland; but as he opposed the measures of the ministry, by refilling the refumation of the grants of crown-lands, by cenfuring the peace of Utrecht, by remonstrating against the extension of the malt-tax to Scotland, and by supporting a bill for dis-
folving the union, which he had once solemnly promover'd, he was deprived of all his employments under the crown.

However, on the accession of George I. in 1714, they were refer'd to him with several additional offices of honour and service. From this time his political conduct was fluctuating and varietal; being occasionally in and out of place, some-
times supporting, and sometimes opposing the ministry; at one time condemning, and afterwards defending floundering armies. In 1718 he was so much in favour as to be ad-
vanced to the dignity of a duke of Great Britain, by the title of duke of Greenwich. He afterwards, at different periods, occupied the poits of lord theward of his majesty's household, master-general of the ordnance, and field-marshal of all his majesty's forces. In 1739 he vigorously oppor'd the administratio'n of Sir Robert Walpole, and was removed from all his places; but regained them in 1741, when that minifter was displaced. Some difficult at the political ar-
'rengements which then took place, induced him very soon to reign them. A paralytic disorder with which he had been for some years afflicted, terminate'd his life in September 1743; and he was interr'd in Westminster Abbey, where a splendid monument, execute'd by Roubilac, was erect'd to his memory, some years after his decease. The titles of duke and earl of Greenwich, and baron of Chatham, became extinct at his death; but his Scottish titles devolos'd on his brother Archibald, earl of Ila. His memory has been usu-
'ally honoure'd with the title of the great duke of Argyile; and he has been celebrate'd in very high terms by Pope and Thomson. The e'cumen of the latter, in his Au-
'tumn, is diffuse: that of the former is more concise:

"Argyle, the rate's whole thunder born to wield, And shake alike the senate and the field."

Epilogue to the Satires, diss. ii.

His character is left favourably sketched by Mr. Macpheron-
'fon in his History of Great Britain, vol. ii. p. 601. Care-
'lefs and eager in his disposition, he neither concealed his re-
'fentment nor disguis'd his designs. With a commanding
'manner, which fresh'd his very forwardness with an appear-
'ance of authority, he was feared by many, but beloved by
'none. Brave in his perf'om, but not remarkable for his con-
duct; he might be consider'd, in his military capacity, as a bold partizan rather than a judicious commander. In
'his civil character, his fire degenerator into a violence, that
'often defeat'd his views. In his public exhibitions in par-
'liament, he was rather spirited than eloquent; better cal-
'culat'd to terrify his enemies than to support his friends. His great defect was a love of money and emolument, which he could not e'fffectually conceal, with all the efforts of his pride. His chief talent was an address in managing the prejudices of the vulgar. He mark'd their opinions as they changed, and fell dexterously down with the tide."

In private life he is allowed to have been an affectionate husband, and an indulgent master, a liberal friend to the poor,
poor, and a generous patron of merit in distress. As a strict economist, he took care to maintain the dignity of his rank, without wasting any part of his income on empty pomp, or unnecessary expenses. Biog. Brit.

CAMPBELL, ARCHIBALD, third duke of Argyll, was born at Han-bonfe in England, in 1682, and educated at the university of Glasgow. Although he studied law at Utrecht with a view to the bar, he declined pursuing it, and devoted himself to a military life. But he soon abandoned the army, and determined on acquiring the necessary qualifications for a statesman. Accordingly, he occupied several posts of trust and dignity in Scotland, which we shall not here enumerate. As chancellor of the university of Aberdeen, he laboured to promote the interest of that, as well as of the other universities of Scotland; and he particularly encouraged the school of physic at Edinburgh, which has since acquired such high reputation. He was a man of great natural and acquired endowments, well versed in the laws of his country, eminent for his knowledge of human nature, and possessed of very considerable parliamentary abilities. As he had the chief management of Scots affairs, he was very attentive to promote the trade and manufactures of Scotland, and to forward improvements for the good of the country. He excelled in conversation, and collected one of the most valuable private libraries in Great Britain. At Inverary he built for himself a very magnificent seat. Having obtained his faculty at full yeur till his 70th year, he died suddenly in April, 1761; and was succeeded in his titles and the estates of his family by John Campbell, fourth duke of Argyll, son of the honourable John Campbell of Mammore, who was the second son of Archibald, the ninth earl of Argyll. Biog. Brit.

CAMPBELL, JOHN, an ingenious writer, was the fourth son of Robert Campbell of Glenlyon, Esq., and was born at Edinburgh in 1708. At the early age of five years, he was brought by his mother to Windsor, where her father resided, and at a suitable age articled to an attorney. But the study of the law not fitting his taste, he devoted himself to a literary life, and in due time engaged in the profession of an author, in which he acquired eminence. His earliest productions are not now known; but in 1736, he published in 2 volumes folio, "The Military History of Prince Eugene and the Duke of Marlborough," &c. The reputation which he acquired by this performance, occasioned his being employed in the compilation of the "Ancient Universal History," in which he wrote, besides other parts that are not positively ascertained, the Coignomy. The first work to which he prefixed his name, was "The Lives of the English Admirals, and other eminent British Scamen," of which 2 volumes were published in 1742; and the two remaining volumes were completed in 1744. This work was so well received, that it passed through three editions in the author's own lifetime, and a fourth has been since reprinted under the inspection of Dr. Berkenbait. His curious and entertaining pamphlet, entitled "Hermippus Redivivus, or the Sage's Triumph over Old Age and the Grave; wherein a Method is laid down for prolonging the Life and Vigour of Man," was published in 1743. This secret is founded upon an ancient inscription preferred in Reinefuus's supplement to Gratler, and confinls in inhaling the breath of young females. Campbell's tract had its origin in a foreign publication, which fugged the idea, improved by our author with additional learning, and in a strain of grave irony, which made it doubtful whether he was in jest or earnest. According to his account, indeed, the true key of the work was an imitation of Bayle's manner of writing on a difficult subject, without discovering to which side his own sentiments inclined. In 1744, he published in 2 volumes folio, a much improved edition of "The History of Voyages and Travels," which was very favourably received. The next work in which Mr. Campbell engaged, was the "Biographia Britannica," the publication of which commenced in 1745; and his articles are allowed to constitute the principal merit of the four volumes through which they extend. With regard to the extent of his research, and the variety of information which he communicates, as well as the correct and animating style, generally elegant, though somewhat too diffuse, in which he writes, he surpasses his contemporaries in that comprehensive and useful work. If he errs, it is on the side of candour, and a freedom from party-prejudice, which have sometimes degenerated into a sylvan of universal panegyric or apology. To the benevolence of his temper, and to some defects of his superior knowledge, and not to any intention of flattering or deceiving, this error ought to be ascribed. To Mr. Dudley's "Preceptor," which appeared in 1743, Mr. Campbell contributed the introduction to chronology, and the discourse on trade and commerce. In 1750, he published the first separate edition of his "Present State of Europe," which became very popular, and which contains, in a moderate compass, a great variety of historical and political information. The next great undertaking, in which our author's abilities and learning were eminently displayed, was "The Modern Universal History," to which he contributed the histories of the Portuguese, Dutch, Spanish, French, Swedish, Danish, and East India settlements in the East Indies, and the histories of the kingdoms of Spain, Portugal, Algiers, Navarre, and that of France, from Clovis to the year 1656. As our author had thus distinguished himself in the literary world, the degree of LL. D. was very properly and honourably conferred upon him, in 1754, by the university of Glasgow. During the intervals of his greater labours, several smaller and anonymous works proceeded from his fertile pen. Among these, we may reckon his "Description and History of the New Sugar Islands in the West Indies," which was written upon the conclusion of the peace of Paris, at the request of Lord Bute, as a vindication of that peace. This tractate was designed to shew the value and importance of the neutral islands that had been ceded to us by the French. It was prefixed to his majesty with a MS. dedication. It was probably in recollection of his political services, that he was appointed in 1765 the majesty's agent for the province of Georgia, in North America, which employment he held till his decease.

The last and great work of Dr. Campbell, to which he had devoted many years of his life, was his "Political Survey of Britain," which appeared in 2 vols. 4to, in 1774. In this work, the author's patriotism and the extent of his knowledge were eminently displayed; but though it must be allowed to contain numerous plans and hints of improvement, which might have conduced to contribute to the prosperity of this island, yet the whole of its projects are founded on erroneous principles, others are of questionable importance and utility, and the reader, who wishes to acquire a just knowledge of the state of these kingdoms, should consult it with caution. The discussions to which it leads engaged the author in a very extensive correspondence; and he derived from it a very considerable increase of reputation. Dr. Campbell's literary character was highly respected not only in his own country, but in the remotest parts of Europe. To this purpose it may be mentioned, that the empress of Russia, in 1774, condescended to honour him with the present of her picture, drawn in the robes worn in that country in the days of John Baliofowitz, grand duke of Muscovy, who was contemporary.
with queen Elizabeth. In return, the author conveyed to
St. Peterburg a part of the "Political Survey of Britain,"
bound in morocco, highly ornamented, and accompanied with
a letter descriptive of the triumphs and felicities of her reign.

As Dr. Campbell's literary engagements allowed of few
foreign avocations, his life was sedentary and domestic; but
by exercise in his garden and house, and a course of tempera-
ture and ablutions, he guarded against the inconvenience
incident to this kind of life; and enjoyed a good rate of
health, though his constitution was delicate. His general
reputation, and his instructive, cheerful conversation, drew
to his house, particularly on a Sunday evening, a great
number of literary friends and personages of all ranks and pro-
fessions, who were desirous of testifying their respect for his
merit, and of deriving improvement and pleasure from inter-
tercourse with him. His knowledge was far from being
restricted to those subjects which employed his pen as an
author; but he was well acquainted with mathematics and
medicine, with the ancient and modern languages, and with
the different parts of sacred literature. His memory was
singularly retentive; and he had an uncommon facility in
communicating his ideas. The style of his works had been
formed upon the model of that of bishop Sprat, and was
perspicuous, easy, flowing, and harmonious. "To all
these accomplishments of the understanding, he joined the
more important virtues of a moral and pious character. His
disposition was gentle and humane, and his manners kind
and obliging. He was the most tender husband, a most in-
dulgent parent, a kind master, and a fine and sincere friend.
To his great Creator, he paid the constant and ardent tri-
but of devotion, duty, and reverence; and in his cor-
respondence he showed that a sense of piety was always nearest
his heart. It was our author's custom every day to read
one or more portions of scripture in the original, with the
ancient versions, and the butt commentaries before him;
and in this way, as appears from his own occasional notes
and remarks, he went through the sacred writings a number
of times with great thankfulness and advantage. His蕨ere
study at length brought on a decline which terminated his
life, December 28, 1775, when he had nearly completed
the sixtieth year of his age.

Campbell, George, an eminent metaphysician, divine,
and biblical critic, was the youngest son of Mr. Colin Camp-
bell, one of the ministers of Aberdeen, and born in that
city, December the 25th, 1719. Although he had the
misfortune to lose his father at an early age, he made a con-
siderable proficiency in the Latin and Greek classics at the
grammar school, and Marischal college of his native place.
It was his original intention to follow the profession of
the law, and with this view he actually served an apprenticeship
with a writer to the signet in Edinburgh. But being from
disgusted with this employment, he directed his attention to
the study of the scriptures, and determined to acquire the
qualifications that were necessary for the office of a clergy-
man. Accordingly, in 1741, before the term of his ap-
prenticeship was fully completed, he attended the divinity
lectures of professor Geddie at Edinburgh; and he after-
wards entered himself, as a student of theology, both in
King's college, under the care of professor Lumiden, and in
Marischal college, under the tuition of professor Chalmers.
Beside the advantages which he enjoyed at the university
for the prosecution of his theological studies, he belonged
to a literary society of 14 learned persons, which was es-
established in 1742, and which afforded him additional means
and opportunities of improvement.

After completing his studies at the university, and passing
through the usual trials before the presbytery of Aberdeen,
Mr. Campbell was licensed as a probationer, or preacher,
in 1746; and two years after he was ordained minister of
Banchory-Teman, 17 miles W. from Aberdeen. In this
situation he excelled as a Scripture critic and lecturer; and
composed a variety of discourses, which were disinguished
by the simplicity and perspicuity of their style. Here he
formed the plan of his Translation of the four Gospels, and
here he also drew up a part of his Philosophy of Rhetoric.
During his settlement in this country parish, he married a
lady, who contributed in a very great degree to the pro-
longation and happiness of his life. In June 1757 he was
translated to Aberdeen, and became one of the ministers of
that city, where his character as a lecturer was fully esta-
blished, and where he delivered a variety of ingenious and
learned discourses on rhetoric, criticism, and other subjects,
in a literary society, projected on a larger scale than that to
which he had formerly belonged; by the late Dr. Reid of
Glasgow, and Dr. Gregory, who were at that time pro-
ectors of King's College, and established in 1758. His first
publication was a sermon, preached in 1752, at the opening
of the session in Aberdeen, on the character of a minister, as
a teacher and pattern; but as he probably thought that the
style of this discourse was too highly ornamented, he did
not include it in the number of sermons, which he collected
a few years before his death. In 1759 he was professed by
his majesty to the office of principal of Marischal College,
then vacant by the death of principal Pollock. His ad-
vancement to this honourable office was partly owing to
the interest of Archibald duke of Argyle, to whose family he
was related, and partly to his known character as a man of
distinguished abilities and literature. Soon after his appoint-
ment to this office, he published his celebrated "Dissertation
on Miracles," in answer to Mr. Hume's essay on this sub-
ject, and thus deservedly gained the reputation of a most
acute metaphysician, and a well-bred polemical writer.
The substance of it was delivered in a sermon before the pro-
vincial synod of Aberdeen in 1763, and afterwards moulded
into the form of a dissertation. Before it was published a
copy of it was sent to Dr. Blair of Edinburgh, and com-
municated to Mr. Hume; and when the author had availed
himself of the remarks both of his friend and of his opponent,
he presented it to the public in 1763. Mr. Hume, in a let-
ter addressed to the author, acknowledged the civil and
obliging manner in which he had been treated; and the Dis-
sertation was so well received by the public, that it soon
passed through several editions, and was translated into the
French, Dutch, and German languages. For a particular
account of the author's reasoning in this dissertation, see our
article Miracles. Some time before the publication of
this treatise, the author, without any solicitation on his own
part, received the degree of doctor of divinity from the
neighbouring University of King's College in Old Aberdeen;
which he was more ambitious to defend than to ob-
tain. Dr. Campbell continued for 12 years to discharge
the offices of principal of Marischal College, and of one of
the ministers of Aberdeen; which he did with great honour to
himself and satisfaction to those with whom he was con-
nected. During this period he amased himself with the
study of history, in which he became a great proficient, and
broke acquiring a considerable knowledge of Hebrew, as
well as improving his acquaintance with the Greek and La-
tin, he made himself master of the French and Italian, so as
to become a critic in these languages. In 1771 he was
elected, by the town-council of Aberdeen, professor of
divinity in Marischal College in the room of Dr. Gerard;
and though he refused his pastoral charge as one of the minis-
ters of Aberdeen, the united offices of principal and professor of
Marischal
Marischal College devoted upon him a variety of duties, which required great application and exertion. As professor of divinity he nearly doubled the number of lectures which the students had been accustomed to receive, and he fulfilled his course in four years, so that every student had an opportunity, if he thought proper, of attending the whole of it. His lectures, in the plan or outline of them, were equally simple and comprehensive. They contained, under the theoretical part, every thing that the student of divinity should know; and, under the practical branch, every thing that he should do, as a reader of sacred and church history, a scripture critic, a polemic divinity, a pulpit orator, a minister of a parish, and a member of the church courts on the Scotch establishment.

Under the first head, or theory, he included sacred and church history, scripture criticism, and polemic divinity. On sacred or church history he delivered those lectures, which he afterwards prepared for the press, and which were published after his death by the Rev. George Skene Keith, in 1825, under the title of "Lectures on Ecclesiastical History," 2 vols. 8vo. On the subject of Scripture criticism, instead of a tedious and uninteresting dilution of many separate and minute particulars, he laid down general rules or canons, by which the students themselves might be critics without depending upon any commentator. These canons were published in his translation of the four Gospels. His general directions with regard to polemic divinity may be summed up in the following sentences, which, being expressed in the most simple and concise language, may be soon read and safely remembered.

We shall embrace them for the benefit of those readers whom they may more immediately concern. "Begin with studying the Scriptures in the original languages; attend carefully to the conclusion, that should always be made, between classical and pure Greek, and the Greek of the Septuagint and Testament, where the words, taken separately, are pure Greek, but where the idiom of the language, and even the acceptance of many of the words, is derived from the Hebrew, the Chaldaic, or the Syriac. Be acquainted with the civil history, the manners and customs of ancient times and nations, especially with that of the Jews, where the reader or listener will often be useful. But whatever books you read occasionally, read the Scriptures frequently. Mark the different passages which you do not understand; read them with patience, not being too anxious to understand every thing at the first reading over. But perforce and read the Scriptures in the original, a second and a third time; and, without consulting any commentator, those difficult passages will always become fewer as your knowledge increases. Read the Scriptures also with modesty, neither being too full of yourself, nor supposing that human reason can always comprehend divine mysteries: and read them always with fervent prayer to God, the source of wisdom and light, that he would assist and direct you in your researches after truth. Do not complain that you want books, when you have the Scriptures themselves in the original languages. If you have a Hebrew Bible, a Septuagint, and a Greek New Testament, you have the most necessary, and the most useful, of all books to a Christian divine. Read carefully all the versions which are given of disputed passages: make much use of versions, and compare them all carefully with the original. Read the Vulgate, though a translation authorized by the Romish church, as well as the versions of individuals, such as Calvin, Beza, Junius, and Trelion; and also Hebram, if you have access to his translation. You cannot be hurt by reading versions, and comparing them with the original. But put no confidence in commentators. Consult them sparingly, never use them till the last, and then use them only as dictionaries. In this view, however, read commentators of all parties; and judge of them more from their freedom of thought, abilities, and candor, than from considering to what party they belong. In comparing the different kinds of commentators with one another, remember, that paraphrases are the worst, because they undertake too much or promise too little; while scholiasts are the best, because they undertake and promise least. Be on your guard against too much ingenuity in commentators: for genius, in this case, has often led them astray, where humble piety, and plain common sense, would have kept them in the right path. Beware particularly of any attachment to a pre-conceived system; and do not think, that you will be safe, if you use what you call an approved commentator. (It is a pity, though there was a danger of being misled, that a young man of taste, learning, and genius, should be chained to the opinions, or kept in the trammels, of a commentator.) See always with your own eyes, and not through the spectacles of polemics, commentators, or paraphrasts. Remember that your errors will be much more pardonable, when you use your own eyes, and when you come short of the truth, after making the best use of your own reason, than when ye are led implicitly by passion, or by prejudice. Let your religious system be the last thing that ye make; or where ye have made one in early life, be still correcting it, as you acquire more knowledge—not contending for the opinions of men, but enquiring after the mind of the Spirit."

Under the second general head, viz. Practice, or the practical part of theology, Dr. Campbell delivered several excellent lectures to the students, comprehending pulpit eloquence (See Elocution), propriety of character in private life, or teaching by example, and propriety of character in public conduct. His manner of delivering these lectures was such as to captivate and fix the attention of his students. His deep and extensive erudition was irritated by his fine imagination; and those lectures, which were the most abstractive and learned, were rendered entertaining by strokes of wit and humour which Dr. Campbell took occasion to introduce. Besides, he recommended himself to the students, not only by the judiciousness of his criticism, and by his lively mode of lecturing, but by the conscientious and amiable ness of his whole conduct.

Dr. Campbell, in his 72d year, was seized with a severe illness, which threatened his life; but, contrary to his own expectations and those of his friends, he recovered; and though his bodily strength was impaired, he returned his former occupations and studies. Some years before his death he made a disinterested and unobtrusive offer of resigning his professorship of divinity, provided that any one of those gentlemen whom he named, and to whom he applied for their consent, were chosen to succeed him. The offer, however, was not accepted by the patrons of the professorship, and he contented to retain it, a left an improper person should, in his life-time, be chosen as his successor. But when application was made to him, and also to the town-council of Aberdeen (the patrons of the professorship) in favour of Dr. William Laurence Brown, late minister of the English church, and professor of moral philosophy, of the law of nature, and of ecclesiastical history, in the University of Utrecht, who had been driven from these offices in consequence of the French invasion, he instantly resigned, in 1795, his charge of professor of divinity and minister of Gray Friars, which were worth 160l. a year; and expressed much satisfaction in the appointment of his successor. Soon after his resignation of the professorship, government, deprived of its justifying, in a public manner, the high respect fo
Campbell.

Justly enterprising of his abilities and services, offered him, on condition of resigning the principalship of Marischal College, a pension of 350l. a year. Dr. Campbell accepted this token of his majesty's munificence, and was succeeded in the office of principal also by Dr. Brown. This pension, however, he did not live to enjoy; though he continued writing till within a week of his death; an event, which he expected with great tranquillity and composure.

On the 31st of March, 1796, after some previous symptoms of unfeeling, he was struck with the palsy, which deprived him of speech, and under which he languished for a few days till he died. He had long accustomed himself to prepare for death; in a former illness he had given the testimony of a dying man in favour of religion; and, therefore, he was peculiarly happy in not feeling the pangs of distracting nature. A funeral sermon was preached, on occasion of his death, by Dr. Brown, in which he has given a sketch of his character as a public teacher, as the head of a public seminary of learning; and as a private Christian. His character is thus summed up in a few sentences by his biographer, Mr. Keith. "His imagination was lively and fertile—he understood equally acute and vigorous—and his erudition was at once very deep and wonderfully diversified. His piety was unfeigned—his morals unimpeached—his temper cheerful—and his manners gentle and unassuming. His love of truth was even more remarkable than the uncommon success with which he fought after it. Where intuitive faculties could be of service to any man, he faw at once if he faw at all. But his deep peripatetico was not satisfied with a superficial view of any thing: his piercing eye darted to the bottom of every subject, to which difference could be applied. Where study and reflection were necessary, he could bellow as much time on patient thinking, as if he had been pofted of no genius at all, and had acquired only a small share of erudition. And when once he began to examine any subject, he was never satisfied till he had viewed it in every light in which it could be seen. He always fought for truth in the love of truth, but he could not bear to be suspected of deviating from it: for he neither courted those who might support, nor feared those who did oppose him. The tone of his mind was high, and he would not let it down from the elevation of truth and of virtue. Whether engaged in conversation, or employed in study, he would pass with the lightest subject to the most serious one. And the reach of his mind was so great, as to comprehend a great variety of subjects. He could explore the caufes of that pleasure, which arises in the mind, from dramatic entertainments, and lay down the rules of Scripture criticism. He could illustrate the whole theory of evidence, or detect the falfe reasonings of Mr. Hume. He could explain the spirit of the Gospel, marking the extremes of superstition and enthusiasm; and both as a philosopher, and a divine, declare the nature, extent, and importance, of the duty of allegiance. While he zealously contended for the faith, he could warn the Christian against imbibing a perverting spirit and yet show the influence of religion upon civil society, warning his countrymen against indolence, before they had seen its dreadful effects. He could, with manly eloquence, deliver the sermons of the fishermen of Galilee, while preaching the doctrine of the crofs to prejudiced Jews, learned Greeks, and ambitious Romans; and at the same time, with well applied erudition, he could delineate the characters of the pretended successors of the apostles, and trace the progress of the hierarchy through all the dark and middle ages, until the reformation of religion. As the principal of a college, a professor of divinity, or a minister of the Gospel, as a true patriot, a good man, and a sincere Christian; Quis alterius invitus forens?" His different publications in chronological order, before the Differration on Miracles, and a single sermon already mentioned, are as follow:—In 1771, he preached before the Synod of Aberdeen his sermon on the Spirit of the Gospel, in which he dwelt at once both at fanaticism and superstition, and at fancies and superflitious perons of all parties and descriptions. In 1776, he published his "Philosophy of Rhetoric," which established his reputation, as an excellent grammarian, an accurate and judicious critic, a man of fine imagination and delicate taste, and a philosopher of great acuteness and deep penetration. The two first chapters of this book had been composed as early as 1750; and a remarkable coincidence had taken place between him and Dr. Brattie, on the subjects of wit, humour, and ridicule. In 1776 he preached a sermon on the National Fast, occasioned by the American war, in which he discusses the nature, extent, and importance of the duties of allegiance, and which was very popular. Six thousand copies of it were afterwards published at the desire of those in the city, and circulated through America. Although in this sermon he maintains, that the British colonies in America had no right, either from reason or from Scripture, to throw off their allegiance, he infinuates that America should be allowed to be independent rather than that Great Britain should continue the war. In 1777 Dr. Campbell published a sermon on the success of the first publishers of the Gospel considered as a proof of its truth, before the society for propagating Christian knowledge, in which he states this argument for the truth of Christianity in a very forcible manner. In 1779 he published an address to the people of Scotland, on the alarms which had been raised by the bill in favour of the Roman Catholics; in which address he considers the doctrine of the Gospel with regard to perfection; the conclusions to which would lead us in the toleration of the papists; and the proper and Christian expedients for promoting religious knowledge, and reprefenting error. This address exhibits a striking evidence of the liberality of the author's mind, with respect to those who differ from him in opinion, and of his dislike of every speeies of intolerance and persecution. In the same year he published a sermon on the happy influence of religion on civil society, which was preached at the small fees at Aberdeen. In this valuable discourse the preacher has shewn, in the most satisfactory manner, that "Religion is highly conducive to the exaltation and felicity of the body politic, or nation, by the tendency and extent of its laws, by the affiffance which it gives to the civil powers, both in securing fidelity and in discovering truth; by the nature and importance of its functions; by the positive enforcement of equity and good government on the rulers, and of obedience and submission in the people." The last work which Dr. Campbell lived to publish, was his "Translation of the Four Gospels, with preliminary Disquisitions and explanatory Notes," in two 4to. volumes. His pithy and laconic work, entitled "Lectures on Ecclesiastical History," has been already mentioned. See Keith's Account of the Life and Writings of Dr. George Campbell, prefixed to his "Lectures."
CAMBELL, the father of an American captain, Charles Campbell, who obtained a patent for it in 1751; from the governor of Virginia. Since the discovery of salt-water, and the manufacture of salt in this district, it is become very valuable, and many thousands of people are now supplied with it from a superior quality, and at a low price. It consists of about 300 acres of salt marsh land, in which pits are sunk for obtaining the salt water. The bell is found at the depth of from 30 to 40 feet; and after passing through the rich soil or mud, from 6 to 10 feet, you come to a very brittle lime-rock rock, with cracks or chasms, through which the salt-water issues into the pits, whence it is drawn by buckets and put into the boilers, which are placed in furnaces adjoining the pits. The hills, that surround this flat, are covered with fine timber; and a coal-mine has been discovered not far from it.

CAMBRIDGE-town is a royal borough in the county of Argyle, Scotland, seated on the banks of the lake of Killerran, on the easterm shore of Kintyre, of which it is the prebathy seat. This place was merely a small fishing village till 1701, when it was constituted a royal borough, and obtained its present appellation. Previous to that period it was called Ceann-loch (Loch-head) which it still retains in the provincial language of the country. From the establishment of a fishery here, and the advantage of a good harbour, this place has greatly increased in size and consequence. The harbour is about two miles long by one broad, and affumns the form of a crescent. It is surrounded by high hills, and protected at the entrance by an island. The anchorage is good, and meafures from fix to ten fathoms water. It is appointed the rendezvous of the buffies engaged in the herring-fifby, which is the principal trade of the place. Beside the fifby, here is a confiderable trade in the dilillation of whifkey. The parish of Cambridge-town is about 12 miles by 8, and includes the greater portion of the district called Kintyre. It is narroved in the middle by the bay of Machyr-hanifh on one fide, and the loch of Killerran, or harbour of Cambridge-town, on the other. The foil of the parish is various, but the arable land is well cultivated and fertile. At the distance of three miles are two coal-pits, and a canal has lately been finifhed to communicate with the collieries and the town. A quantity of fullcr-earth, or a kind of foamy rock, is obtained in this parish. In 1791 the population amounted to 3,795. This town, with Air, Irvine, Inverary, and Rothsay, unite in sending one member to the imperial parliament. It lies 176 miles W. by S. from Edinburgh.

CAMDEN-town, a large and flourishing town of America, in North Carolina, feoted on a branch of Cape Fear river, 100 miles above Wilmington; the refort of many inhabitants and travellers, who carry on a continual commerce by waggons, from the back cettlements, with large trading boats. - Alf, a village in Dauphin county, Pennsylvania, feated near a water of Quittipinna creek; 13 miles E. of Harri- bury, and 96 N. W. of Philadelphia.

CAMDEN, or CAMDEN-CHIPPING, anciety CAMBER-DEE, is a borough and corporate town of Gloucesterfhire, England, situated in a fertile valley, surrounded by cultivated halls and hanging woods. Its remote origin may be inferred from the circumstance of the Saxon kings afluming here, in the year 687, to confer on the mode of carrying on the war with the Britons. They were interdicted by a public spirited attorney, named Robert Dover, of Barton-on-the-Heath, in Warwickshire, and, like the Olympic games of the ancients, confided of noth kinds of manly exercises. The victors were rewarded by prizes distributed by the projector, who for many years superintended the games in person. Ben Jonfon, Drayton, and other poets of that age, wrote verses on this festivity. These were collected into one volume, and published under the title of "Annales Daurbrefia," in 1636. The breaking out of the civil war terminated these diversions; but the remembrance of them is yet preferred by an annual meeting of...
of young persons on Dover-hill, an eminence about half a mile from Campden, where the principal games were celebrated.

CAMPEACHY, a town of America, in Old Mexico, or New Spain, situate in the province of Yucatan, on the west shore of a bay of the same name in the gulf of Mexico. Its houses are well built of stone; when taken by the Spaniards, it contained 3000 houses, and had considerable monuments of Indian art and industry. It has a good dock and fort, with a governor and garrison, commanding both the town and harbor. It has been often formed and taken, both by the English and French buccaneers, viz. in 1633, 1678, and 1689, and the last time these buccaneers plundered the whole country within 15 miles about it, set fire to the fort and town, which the governor would not consent to ransom, and burnt to the value of 70,000 l. of Campeachy wood, which was a part of their share of the plunder. The port is large but shallow; and it used to be a flatted market for log-wood, of which great quantities grew in the neighborhood, before the English landed there, and cut it at the illaus, which they entered at Trieste island, near the bottom of the bay, 40 leagues S.W. from Campeachy. The chief manufacture is cotton cloth. N. lat. 19° 30'. W. long. 91° 30'.

Campeachy, or Campeche Wood, in Botany. See Hæmatoxylon Campechenum.

Campeggi, Lorenzo, in Biography, an eminent civilian and prelate of the Romish church, was born at Milan in 1473; and having been educated to the profession of the civil law, taught it first at Padua, and afterwards at Bologna. After the death of his wife, he entered into the ecclesiastical statute, and in 1540 was made auditor of the Rota at Rome. In 1521 he was advanced to the bishopric of Feltre by Julius II. and deputed as his nuncio to Milan and into Germany. In 1517 he was created a cardinal by Leo X.; and in 1516 lent as legate to England to collect the tithes for the war with the Turks; but he only succeeded in obtaining the bishopric of Salisbury. In 1524 he was appointed bishop of Bologna, and delegated by Clement VII. to oppose the progress of Lutheranism in Germany. His legation to Henry VIII. of England, with which he was intrusted in 1528, was a very difficult charge, as, in conjunction with Wolsey, he was to pronounce sentence concerning the king's divorce from his queen Catherine. When Henry could not be prevailed upon to renounce his project, Campeggi tried to persuade Catherine to consent to a voluntary separation, that he might thus save the honour and authority of the church; but his endeavours were unsuceedful. In the following year he was recalled to Rome, and commissioned to attend as legate at the diet of Augsburg. He died at Rome in 1539; having, as a man of learning, enjoyed the esteem of Erasmus and of other eminent scholars, and having approved himself a faithful servant of the church, in times and circumstances peculiarly critical and embarrasing. His constitution for the reform of the German clergy, and his letters, throwing light on the history of his time, of which the principal are found in a collection of letters written to Frederic Nautes, and printed at Basle in 1550, are the only literary remains of him that are extant.

His brother, Thomas Campeggi, who succeeded him in the bishopric of Feltre, was a learned canonist, publised several works relating to the canon law, and died in 1564. Moreri. Tiraftobhi.

Campello, in Geography, a town of France, in the department of the Ille and Villaine, and district of Redon; 54 leagues S.W. of Rennes.
and impatience, of which, however, only two parts were published; viz. "Demonstrationes Anatomicae. Pathologicae et Medicinae," Liber primus, continens brachii humani fabricam et musculos, in folio maximo, cum quatuor figuris," Amsterdam, 1752; and "Liber secundus, continens pelvis humanae fabricam et musculos," 1756. The plates, which are commended for their accuracy, are from drawings made by the author. A small time before his death he published in a Dutch journal at Amsterdam "An Account of a Method of performing the Operation of Lithotomy at two different times, by Peter Camper, M.D. &c." The process was communicated to him, he says, by M. Louis, who assured the author that since he adopted it, he had not lost a single patient by lithotomy. The operation is performed at twice, that is, on the first day the surgeon makes the incision into the bladder, the patient is then to be put to bed, and the extraction of the bone deferred until the second, third, or fourth day. By this delay, the bone was at length taken away with greater facility, and with less pain to the patient, than when the whole of the bone was completed at once. The method is not, however, new; it had been recommended by Peter Francesco, who lived more than two centuries ago, and it has long since been laid aside again, as attended with much greater inconveniences than the advantage expected compensate. A translation of this paper is published in the tenth volume of the London Medical Journal for the year 1783.

In 1789 his son, M. Adrian Gilles Camper, published at the Hague, in Latin, "A Diflertation on the fracture of the Patella and Olerason," by his father, 4to. The object of this dissertation is to inquire into the various circumstances attending the accidents which are distinguished by the general name of fractured patelle. It is enriched with a large number of cases, and with quotations from, and references to, the most celebrated authors on the subject; and it is accompanied with two plates, which do not reflect much honor on the artist. The last describes the perfect cure of a fractured patella, though the upper and lower parts of the bone remained four inches distant from each other. In 1791 his son published at Utrecht in 4to. another work entitled "Verhandelingen van Petrus Camper over het natuurlyk Verhulder Wezenbreken," &c. "i.e. Treatise of the late Peter Camper on the natural difference of features in persons of various countries and ages; and on beauty, as exhibited in ancient sculpture and engravings. Followed by the description of a method of delineating various forts of heads with accuracy. The professed object of this publication is to prove that the principal rules laid down by the most celebrated painters and limners, are very defective; that they enable the student neither to delineate national characteristics in the countenance, nor to imitate the beauties of ancient sculptors and artists. He contends that the observations of the abbé Weinckelman, concerning ideal beauty, are not well founded; and he professes to have discovered, in what that species of beauty really consists. It is in consequence of the imperfectness of rules, he observes, that men of eminence have been so defective in their portraits of national characters; thus, in the paintings of D. Wit the chief signature of a Jew is a long beard; and Guido Reni, C. Marat, Rubens, and others have given no other characteristic of Moors than a black complexion. He denies the propriety of making either the oval, as is the most common method, or the triangle, as some artists have proposed, the foundation of portraits to be taken in profile; and he proposes more certain principles in their place. Neither the author's principles nor his mode of illustrating them, can be well understood without the plates that accompany this work. The general doctrine, however, is, that the difference in form and cult of countenance proceeds from the relation which the cranium is found to bear to the direction of an horizontal and a perpendicular line. Let us suppose a frame of wood, similar to that of a picture, to be made perfectly square; and that the upper part he graduated into 90 degrees, proceeding from the right to the left. Let the cranium or head be placed in the centre of this frame. Draw an imaginary line from the lower part of the upper lip to the forehead, which the professor terms the linea facialis, and observe in what degree it intersects the upper part of the frame; and this will give one characteristic, and the situation of the maxilla, respecting the perpendicular side of the frame, another. E. G. the linea facialis of the orang will intersect the horizontal line at 58°; that of the Negro at 70°; that of the European; at 80 or 90°; while, in the Greek antique, the facial line will project ten degrees beyond the limits of the frame, forming an angle in a different direction. In the ape, the negro, and the cannuck, the maxilla project in various proportions beyond a perpendicular line drawn from the lower part of the forehead to the chin; in the European, the maxilla are on a plane with the perpendicular; and in the antique, they recede within it. According to this position of the linea facialis, are every other part of the head, the position of the eyes, of the mouth, ears, &c. regulated. This Camper proves by various examples.

In 1792 the professor's son published at Utrecht, in 4to. a sequel to the preceding treatise, entitled, "Reden voeringen van wylen Petrus Camper, &c." i.e. Lectures of the late Peter Camper on the manner of delineating the different emotions of the mind in the countenance; — on the striking resemblance between quadrupeds, fowls, fishes, and the human species; — and on the constituent beauty of form. Illustrated by plates. The first lecture treats of the manner of representing the different emotions of the mind. For this purpose the first object, he says, is to become well acquainted with the form of the cranium; — the second, with the principal muscles of the face; — and the third, with the nerves which act these muscles in motion. E. G. a person under the influence of sorrow and melancholy, suffers his head to sink, as it were, under the weight of the oppression, or he supports it with his hand. The muscles of the neck no longer maintain the equi-poise; that is, the nerves belonging to the neck are rendered inert by the influence of this passion. On the contrary, a person under the influence of mirth and of violent laughter, elevates his head; his brow is agitated; he holds his lides with both hands; his legs begin to fail him, and he would roll on the ground, if the fit continued. A man in a rage, beats with his hands, flamps with his feet, and his face is violently convulsed. Respect impedes speech; an inward trembling takes away the power of motion, the heart beats, and the livid eyes look downward; if shame accompanies the emotion, the blood paints the face, neck, and breast with crimom. Thus, in all emotions, particular nerves are affected; and, consequently, it is the business of every painter to make himself acquainted with these, &c. Conformably to this plan, the professor has first given to his audience a general idea of the form of the cranium, of the principal muscles of the face, and traced the course of the nerves, proceeded to point out, by various drafts or sketches, the changes produced in the countenance in the emotions of surprise, contempt, complacency, laughter, sorrow, weeping, wrath, and in death. The second lecture treats of the similarity which exists between quadrupeds. The professor maintains that in all the larger animals, inhabiting the three elements, there is one part of the body common to all, and very similar in its form; that the great diversities observable in the animal creation, from man down to the finny tribe,
proceed from the diversity which takes place in the appendages to this central part; and that these diversities are according to the nature of the animal, to the element which it is defined to inhabit, to the kind of food by which it is nourished, and to the particular manner of obtaining this food. The permanent part is the trunk, that is, the vertebrae of back and loin, with the ribs. He then illustrates this general idea in the horse, camel, elephant, greyhound, &c. and then deduces the following self-evident conclusion, that the more perfectly an artill is acquainted with the nature of animals, and the designs of their formation, the better he will succeed in delineating them. In the sequel of this lecture, various rules are laid down, and examples given, by which artills may be enabled accurately to delineate the horse, cow, dog, camel, &c.; or, with a few strokes of the pencil, to convert the one into the other, merely by an attention to these rules, and to the deviations which take place in consequence of the particular nature of the quadruped. In the third lecture the idea is extended to birds and fish.

In the year 1803, a collection of Camper's works was published at Paris, in 5 vols. 8vo. and a folio atlas of plates, under the title of "Oeuvres de Pierre Camper, qui ont pour Objet l'Histoire Naturelle, Physiologie, et l'Anatomie Comparée, &c." i.e. The works of Peter Camper, which treat of natural history, physiology, and comparative anatomy. To these volumes a general account of his life, by his son, is prefixed, by which we have availed ourselves in the compilation of this article. The first volume comprehends a dissertation on the origin of the orang outang, and some others of the monkey tribe, a memoir on the double-horned rhinoceros, another on the rein deer, and conjectures relative to some petrified bones found in the mountain of St. Pierre, near Maestricht, which professor Camper considers as the bones of fish. In his account of the orang outang, the professor remarks, that immediately below the skin and platyma myoides, two bags made their appearance on each side of the wind-pipe, the right extending over the clavicle, the left being much less. These bags were empty, and each of them communicated with the cavity of the larynx, by means of an opening passing between the thyroid cartilage and the es hyoïdes, and terminating at the side of the epiglotis. Some species of monkeys had one bag of a similar kind, but the possession of two of the professor confers as peculiar to the orang outang. This organization seems to have been known to Galen; but its uses are unknown, except that these cavities can be filled with air, and compressed, at the pleasure of the animal. The professor observed a conformation in the throat of the rein-deer, resembling that noticed above, with regard to some kinds of monkeys. The second volume is chiefly occupied with an interesting account of the elephant; and this article is followed by two essays, one on the physical reasons which render man subject to more diseases than other animals, and on the means of establishing health, which can be derived from comparative anatomy; the other on the origin and the colour of the negroes. Their origin is ascribed to our first parents, and their colour to the long continued effects of the climate in which they lived, the food by which they were nourished, and the diseases to which they were subject. The third volume contains lectures on an epidemic disease of horned cattle; a dissertation on the physical education of children; lectures read to the Academy of Painting; an account of the generation of the pipa, or American toad; observations on the croaking of male frogs; and an account of the structure of the bones in birds. In his lectures delivered to the Academy of Painting, the author discourses the subject of physical beauty, and his general conclusions are the following: viz. That no philosopher, or artist, has ever proved or taught what properly constitutes physical beauty;—that we have no innate idea of this, as we have of moral beauty; and that it is only by means of fancy that we arrive at the knowledge of what is beautiful in the imitative arts;—that physical beauty, whether in man and other animals, or in architecture, does not consist in a certain proportion or symmetry of parts;—that in giving different forms to men and animals, nature has not aimed at endowing them with a certain degree of beauty, but only at bellowing upon them what is useful in their particular sphere;—that all which relates to physical beauty is founded only on tact, content, habit, and authority;—and that the true and only beauty which exists, and such as the greatest masters have introduced into architecture, painting, and sculpture, can be referred to nothing more than the care which they have taken that their works should imitate nature as faithfully as possible; while they, at the same time, avoid the faults which necessarily result from the imperfection of vision, and the refraction of light. No particular form, says this author, can, abstractedly considered, constitute beauty; the real basis of beauty, according to his reasoning, consists in the means being adapted to the end; and, exclusively of this, our ideas are influenced by customs, national prejudices, and implicit confidence in the taste and opinions of others. This is a subject which has been treated with metaphysical acumen by Burke, Smith, Alison, and Sayer. See Beauty.

The essay on the structure of the bones of birds, which terminates this work, contains an account of the same peculiar conformation which was described by Mr. John Hunter in the Philosophical Transactions for 1774; but it appears that this curious structure was discovered by professor Camper three years before Mr. Hunter's publication of it, and that it was soon afterwards made known to many scientific men on the continent. The account of the professor's discovery was mentioned in a dissertation read by M. Charnack, at a public meeting of the university of Groningen, August 25, 1773, but Mr. Hunter's paper was not read to the Royal Society till the February following. See Bird. The atlas accompanying these volumes contains a number of well executed plates.

Campestre, in Antiquity, a sort of cover for the privities, worn by the Roman soldiers in their field exercises; being gilt under the navel, and hanging down to the knees. The name is supposed to be formed from campestre, the field or place where the Roman soldiers performed their exercises.

Campestris, in Entomology, a species of Cimex, commonly found in meadows. The colour is yellowish, with a ferruginous spot on the wing-cases. Fabricius.

Campestris, a species of Cicindela, common in most countries of Europe. It is of a green colour, with five white dots on the wing-cases. Linn. &c. inhabits sandy fields chiefly. Donovr. Brit. Inf. &c.

Campestris, in Ornithology, a species of Alauda, about seven inches long, that inhabits Europe. The tail-feathers are brown, with the lower half, except of the two middle ones, white; chin and breast yellowish. Linn.

This is called by Briston Alauda Campestris, and by Ray and Willughby, Alauda minor Campestris, Spiolette by Buffon, Brachyderhe by Fretch, and meadow-lark by Latham.

Campshire, or Campitor-tree, in Botany. See Laurus camphora.

Campophor is a white translucent vegetable product, somewhat unequulous to the touch, and tenacious between the teeth; it may be crumbled between the fingers without difficulty; it has a peculiar fragrant odour, not unlike that of
of rosemary, which diffuses itself to a considerable distance: its flavour is aromatic and bitter, giving at first the sensation of heat, but afterwards of remarkable cold. Its specific gravity is 0.966, so that it will float on the surface of water: when exposed to a moist and warm air, it readily volatileises: by the contact of flame it immediately takes fire, burning with a large white flame, and much smoke; if pure it is wholly consumed, without leaving any residue. When heated in a fipon, it diffuses into an oleaginous liquid.

There are two species of trees from which the camphor of commerce is procured. That with which Europeans are acquainted, is the bums camphora, a large forest tree, that grows wild in the islands of Borneo and Sumatra. Of this tree, the leaves, the fruit, and every other part, when bruised, give out a strong odour of camphor, and the wood is much sought after as a material for chisels, &c. because its peculiarly aromatic smell renders it impenetrable to ants and other destructive insects. The oldest trees in general contain the largest proportion of camphor, and it is reckoned a good sign if the natural crevices in the principal branches have for some time past yielded spontaneously a quantity of oil of camphor. The camphor itself is found in perpendicular veins near the centre of the tree, or concreted in the knots of the wood. The larger pieces are picked out with a sharp instrument, and the smaller ones are procured by means of mops, to which the camphor adheres, mixed with small bits of wood and other impurities. The flame tree yields also the oil of camphor, which appears to be a very fluid kind of resin, strongly fenching of camphor, and from which a considerable portion of this latter substance may be extracted by distillation. This oil exudes spontaneously from the older trees, but is chiefly procured by incision, in the following way: a cavity capable of containing about a quart is cut in the trunk, into which a lighted reed is introduced for about ten minutes, this draws the juices towards the cavity; which, in the space of a night, is completely filled with oil; the fame copious flow of juice continues for three nights longer, after which, by a fresh application of heat, a further but less plentiful supply is obtained.

In Japan are large forests of another species of laurus, which yields camphor, though not in such abundance as that which we have already described. In this tree the camphor is not contained in concrete masses, so that in order to procure it, distillation must be had recourse to. For this purpose, the roots and extremities of the branches, being cut into thin chips, are put into a net or upon a wooden framework, and founted within a kind of alembic, at the bottom of which is a little water: by the application of a boiling heat, the steam penetrates the contents of the net, and carries the camphor along with it into the capital, where it is deposited like snow on the rice straw with which the capital is lined.

The Sumatran camphor is much more esteemed in the East than the Japanese, from which it may readily be distinguished by its superior adhesiveness, in consequence of which, it is much less volatile than that which has been procured by distillation. All the camphor which comes to Europe is the produce of Borneo or Sumatra, and arrives in the form of irregular lumps of a yellowish grey-colour, which are fongy and very light, and when broken discover a crystalline granular fracture.

The purification of crude camphor is an art that is carefully kept secret by those who are in possession of it. Venice had formerly the monopoly of this manufacture, afterwards it was successfully practiced in Holland, and at present large quantities are refined by none of the English druggists. The process is understood to be very simple, and probably confits merely in mixing the crude camphor with chalk or lime, and subliming it as high a heat as can be safely applied. Spirit of wine has been proposed and employed on a small scale for the purification of camphor, but is insoluble, both on account of its expensive nature and being incapable of separating any residuum which the camphor may be dignified or accidentally mingled. Simple sublimed camphor differs from the refined camphor of the flaps in being of a hoary fpongy granular consistence like snow, but it may easily be made to assume the close and folidated textures of the latter, by simple folution in closed vessels.

Although the camphor of commerce is obtained only from the laurus camphora and a kindred species in Japan, yet its existence has been proved in many other species of plant. Thus the roots of the cinnamon tree (laurus cinnamonum) of the caña (laurus caña), of the lilafita (laurus jaffafras), may be made to yield real camphor by distillation, though not in sufficient quantity to balance the expense. The distilled water of balsam has been found to deposit crystals of camphor by long standing. It has also been discovered in the fresh roots of galanga, zedoary, and ginger, and in the seeds of cardamom and long pepper. It is probably contained in all the essential oils, and has actually been procured from those of juniper, fage, byflop, thyme, peppermint, rosemary, and lavender. The deposition of crystalline gums similar to camphor in old essential oils had been observed by many of the older chemists, but no important investigations took place in consequence of this discovery, till Proust took the subject in hand, and showed, from accurate and large experiments, that camphor may be profitably prepared from the essential oil produced in the southern countries of Europe.

This able chemist having accidentally observed that the essential oil of lavender, distilled in the province of Murcia in Spain, deposited a large proportion of camphor, and that the other essential oils of this district were remarkably fragrant, selected the essential oil of rosemary, marjoram, fage, and lavender, as the subjects of the following experiments. Equal portions of the four oils were placed in shallow earthenware vessels, and exposed to spontaneous evaporation at a temperature not exceeding 37° Fahn. and in proportion as the crystals of camphor were deposited, they were taken out and drained, and kept in well-stopped vials. By this simple process the oil of rosemary yielded 6.25 per cent. of camphor.

The oil of lavender appears to be fully saturated with camphor, for although when heated it will take up about 5% of its weight more of this substance, yet it deposits by cooling a greater quantity even than it was made to diffusle. When exposed to spontaneous evaporation the filaments of camphor begin to appear in about twelve hours, and continue to be deposited till almost all the oil is evaporated. In the other oils the crystals are later in shooting, according to their relative proportions of camphor, and when about four-fifths of the oil are evaporated, the residue becomes thick, and ceases to deposit any more crystals. The camphor produced by each of these four experiments, being dried by slight pressure before filtering paper, was in dry almost pulverulent crystals as brilliant and almost as white as snow, and for little of the peculiar odour of the oil remained, that it was by no means easy to ascertain, from the smell alone, from what species of oil any particular parcel of crystals was obtained.

The proportion of camphor procurable from these oils depends,
camphor was made to boil, the produce of camphor will be considerably diminished, and part will sublime into the capital of the alembic. The camphor from oil of lavender, by either of these methods, is not absolutely pure, for when sublimed at a gentle temperature, it leaves behind a small portion of brownish retin still mixed with camphor. The most economical way of refining this camphor is to mix it with half its weight of chalk, or lime, or washed wood-ashes, and sublume it, by which operation it loses about $\frac{1}{2}$ of its weight. The produce of refined camphor, therefore, by spontaneous evaporation of the oil of lavender, amounts to about 2.4 per cent., and, by distillation, is equal to 19 per cent.; this latter method is, however, by far the most economical, notwithstanding the additional expense of fuel and apparatus, as it fuses both time and the oil, which would otherwise be entirely lost.

The production of camphor by the action of muriatic acid on oil of turpentine, is a discovery of very late date: it was first effected, accidentally, by M. Kneip, in preparing the arithritic liquor of Pott; the experiment was then repeated by Tammendorf with the same result; and, lastly, the Société of pharmacy at Paris being informed of these facts, nominated three of their members to repeat the investigation, and make a report on the subject; from which forerun the following facts are derived.

A small quantity of camphor may be obtained from oil of turpentine by simple distillation, provided the process is carried on sufficiently slowly. Eight ounces of this fluid were distilled in a glass alembic, at the temperature of about 124° F.; four ounces of very highly rectified essental oil passed into the recipient, and the capital was found lined with small crystals of real camphor.

This substance, however, is procured in much larger proportions by the affinage of muriatic acid. Four pounds of oil of turpentine were put into a Woolf's apparatus, and the retort being charged with an equal weight of decrepitated common salt, and half as much sulphuric acid, the whole of the muriatic acid gas that could be obtained by a moderate heat from these materials, was transmitted into the oil of turpentine, and wholly absoled by it. In consequence of this, the oil became exceedingly hot, and acquired a light lemon-colour, and towards the end of the process, a clear transparent brown, a small quantity of a thick oily fluid being gradually discharged and sinking to the bottom. The liquor being allowed to cool for twenty-four hours, was found converted into a thick crystalline mass, from which, when laid on a sloping surface, the brown liquor drained away. Being then wrapped in filtering paper, and subjected to moderate pressure, twenty-four ounces of a perfectly white crystalline matter were left behind of a peculiar odour, in some degree participating both of oil of turpentine and muriatic acid. The liquor which had drained from the crystals was put into a cold cock, and, in the space of a few days, was found to have deposited four ounces more of crystals, and two ounces additional were obtained by expelling it to a powerful freezing mixture. Thus four pounds of oil of turpentine yielded thirty ounces of crystals, or not far short of half its weight.

The crystals thus obtained required a dazzling white colour simply by washing them with water, but still retained a terebbinate odour; and the washings were acridulous to the taste, having taken up a little muriatic acid, but were also highly aromatic. Another portion of crystals being washed with a weak solution of per erectus, was found to resemble common camphor in its odour, that of turpentine having nearly disappeared. It was thought that sublimation would be more effected than washing, in purifying this camphor; accordingly, two portions of it were mixed, one with an equal weight of charcoal, and the other of quicklime, and were heated in glass alembics; the crystals soon became covered with radiating crystals of a brilliant white colour, entirely free from the terebbinate odour, and resembling that of camphor, only not quite so powerful. In this state it floats on the surface of water, and communicat to it a camphoric flavour, is very inflammable, soluable in alcohol, and precipitable from it by the action of water. Nitric acid acts upon it in the same manner as on East Indian camphor, but more slowly; but it appears to be wholly insoluble in acetic acid.

The presence of camphor having been shown in such a variety of substances, in all of which, when brought to the highest degree of purity, it appears to be absolutely the same, that it may be considered as one of the secondary vegetable principles; hence an inquiry into its chemical properties and composition becomes of considerable interest.

Camphor, on account of its volatility, requires to be kept in well closed vessels; it is not, however, by any means so easily evaporable as is generally supposed. According to Koenemulder, pulverized camphor spread thin and exposed to the air at a temperature not exceeding 52° Fah. does not lose more than half its weight in 16 weeks; the ratio of volatilization, however, rapidly increases with an increase of temperature. The moistness of the air also has a considerable effect, the loss of camphor being much greater in a humid atmosphere than in a dry one. The degree at which camphor melts is fixed by Venturi at 502 Fah., and by dividing a mass that has been slowly cooled in the direction of its lamina, it appears to crystallize in octohedrons.

Water has little or no action on camphor; at a boiling heat it takes up, however, enough to acquire both the odour and flavour of this substance. By the allusion of gum-mucilage or sugar it forms with water a whitish emulsion.

Alcohol at the usual temperature will take up between a seventh and an eighth of its weight of camphor, and when boiling it will dissolve half its weight, the greater part of which is again depoited by cooling. If equal parts of camphorized alcohol and sulphuric acid are distilled together, the produce is a camphorated ether, and a tenacious black resinous mass remains in the retort. Camphor is also copiously soluble in sulphuric, and probably in all the other ethers. When camphorized alcohol or ether is mixed with water, nearly the whole of the camphor separates in thick curdy masses, which, when dried, exhibit the camphor unaltered in any of its properties. Oils, both the expressed, the eential, and the emplastic, come here with camphor, and do the reflex and balancing. The hard and dry retins are converted by it into a soft tenacious mass, remarkably soluble in alcohol. The alkalies, whether in their caustic or carbonated state, have no action whatever on camphor, nor will they unite even when affixed with oil or fosp.

Sulphur and camphor will combine together by means of very
CAMPHOR.

very gentle fusion; the resulting mass is brittle when cold, but soft and tenacious when warm. The alkaline sulphates will also unite by fusion with camphor, and retain it when dissolved in water; the addition of an acid to this solution throws down the sulphur and camphor in a state of intimate combination with each other.

When set fire to in atmospheric air or oxygen gas, camphor burns with a copious white flame and black smoke, and is entirely consumed. A large quantity of carboxic acid and carbonated hydrogen is produced. The ultimate combination of parts of camphor appears to be carbon, hydrogen, and oxygen, but in what proportion is not yet ascertained.

Camphor when distilled per se is volatile; but if mixed with musk in the proportion of four parts of the latter to one of the former, and subjected to dry distillation, it is converted to a butyric acidness; and by a second distillation with an equal quantity of fixed oil is entirely resolved into a fluid colourless oil, and a small portion of watery acridulous oil, smelling strongly of camphor; the oil at the fame is reduced to a black sparkling powder being almost entirely deoxygenated. Clay, according to La Grange, produces the same effect. This oil of camphor, according to Kofegarten, is nearly colourless, has a peculiar odour like that of thyme and rosemary, and bears a close analogy to the efffluent oils. It is soluble in alcohol and separable unaltered from its solution by agitation with water. It forms favonules with the alkalies, and is easily volatile for the malt part by a gentle heat. Nitric acid produces no other effect than tinging it of a reddish colour, and even a mixture of this acid with the concentrated fulphur only deepens the colour of the oil still more, and brings it to a somewhat thicker consistence. Both vinegar and carboxic acid will distil a small portion of camphor. The muriatic and fluoric acids when in a state of gas take up a considerable quantity, but do not nearly the whole by the contact of water. Concentrated fulphuric acid distillos camphor largely even in the cold, but by the assistance of a moderate heat it takes up so much as to form a thick homogeneous mass, of a brown or black colour, and a sulphureous odour, which when warm is fluid, but coagulates by a moderate heat, and by evaporation is brought to a refrinous consistence. This is soluble in alcohol, but is decomposed by water, the camphor being disengaged with little or no alteration, and the mixture now longer exhaling a sulphureous but a camphoric odour. The action of oxymuriatic acid on camphorized sulphureous camphor is remarkable: if one part of camphor is disengaged in eight parts of sulphureous acid, and this mixture is poured in a retort upon four parts of black oxyd of magnesia and as much water, the result of a flow distillation of the materials will be acetic acid mixed with a small portion of unde-composed camphor.

Nitric acid, when somewhat concentrated, distillos camphor in considerable quantities at the usual temperature. The solution is of a very dilute yellow colour, and separates by sanding into two distinct liquids. The lower consists of a mixture of nitric and camphoric acids. The upper fluid is of the consistence of oil, and is called acid oil of camphor: it is a combination of camphoric and nitric acid. This oil is soluble in alcohol, but is decomposable with precipitation of the camphor by water or alkalies. The conversion of camphor into a camphoric acid was first practised by Kofegarten, and was afterwards more fully elucidated by La Grange.

The process of Kofegarten is the following: Put one part of camphor into a retort, with 12 parts of strong nitric acid, and distil it slowly to dryness: a large quantity of carboxic acid and nitrous gas is disengaged, and the acid in the receiver is covered with a thin film of acid oil of camphor; a small portion of camphor sublimes into the upper part of the retort, and the mass at the bottom of the vessel is camphor approaching to the state of a vegetable oxyd. It has no longer the peculiar odour of the original substance, and when laid on a hot coal it evaporates with some what of a resinous odour, but without undergoing combination: it is soluble in alcohol but not in water. This oxygenated camphor by being twice distilled to dryness, with ten parts of nitric acid at each process, is converted to a white phosphorous salt, soluble in hot water, and which has obtained the name of camphoric acid.

The method of La Grange differs chiefly in requiring a smaller quantity of nitric acid. He takes one part of camphor and four parts of nitric acid, and distil the mixture by a very gentle heat; the acid that passes into the receiver being mixed with four parts more of the same acid, is returned upon the matter in the retort and again distilled. This is repeated five several times with twenty parts of nitric acid in the whole, and the operation is known to be finished when the liquor in the retort crystallises on cooling. The produce of camphorized acid by either of these methods does not much exceed one half of the camphor made use of.

Camphoric acid, when crystallized hastily, appears as a mass of white fibrous filaments: but by slow cooling assumes the form of parallelopipedal or rhomboidal plates, which effloresce on exposure to the air. To the taste it is slightly sweet and bitterish. It reddens syrup of violets, and tincture of litmus. It diffuses easily in alcohol and in hot water, but requires 200 parts of this latter fluid at the ordinary temperature for its solution. When heated it gives out a thick aromatic smoke, and is entirely disintegrated in slow vessels it sublimes unaltered, if the heat is not too great. The alcoholic solution of this salt is not decomposed by water, a circumstance that distinguishes it from henzic acid, to which it bears a considerable resemblance. It is soluble in the expected and efffluent oils, and in the mineral acids, and forms a precipitate with the muriat and sulphat of iron.

Camphor acid unites with the soluble bases forming a genus of salts, the CAMPHORATS. Of these very little is known. The neutral and earthy camphorats, which are the only ones that have as yet been the subject of any experiments, are all decomposable by heat, except the camphorats of ammonium, which sublimes unaltered. When exposed to the blow-pipe, the acid burns off with a blue flame. The camphorats are decomposable with abstraction of the base by the mineral acids, and with abstraction of the acid by most of the metallic, barytic, and calcareous salts. The camphorats of lime, barytes, and magnesia, yield their acid to alcohol.

The use of camphor in the arts is to assist the solution of the resins in various menstrua. It is employed with success in cabinets of Natural History to prevent the approach of insects which appear to be stupefied and killed by the pungency of its odour. For its medical properties and application see the next article.

CAMPHOR. Medical uses of, and pharmaceutical preparations.

Camphor has long been considered as an article of high importance in the materia medica, and is in daily use for a great variety of purposes, in which its beneficial operation is unquestionable. Yet it is chiefly as an auxiliary that it is referred to, and though a valuable medicine, it does not appear to deserve the very high encomiums that have been given to it by many eminent writers.

In a moderate dose, camphor when taken into the bowels, (mixed with some vehicle which will allow of its being divided and distributed over this organ) increases the real heat of the body, though its first effect is often a sensa-
tion of colds. It soon produces a strong tendency to perspiration; but the pulse is not sensibly affected in quickness by a dose capable of producing copious sweat, and an elevation of spirits like the beginning of intoxication. In a febrile irritable state of body, accompanied with spasmodic affections of the muscles, camphor may be given with safety and advantage; and it acts very decidedly as an antispasmodic, and very materially affixes the action of opium. Experience shows that the action of camphor is sudden and very extraordinary, resembling in this respect that of the essential oils, only it must always be remembered that on account of the extreme solubility of this substance in most of the animal fluids, unless it be very minutely divided, it will remain long unaltered in the alimentary canal; and thus the same effect may in fact be produced by the length of time in which it remains in contact with the organs, as if its operation were highly permanent.

Experiments have been made both on the human body and on other animals with regard to the effects of camphor in excursive doses, which shewed it to be possessed of extremely active deleterious powers, and teach some caution in the use of this remedy. Camphor gives rise internally to small animals, such as birds, cats, dogs, &c. produced severe effects in all. The first operation appeared to be that of an excursive acid fluxus on the flamch, producing foaming at the mouth, violent convulsive twitchings over the body, sometimes with vomitings; accessions of fury in dogs and cats; symptoms resembling intoxication; and lastly, constofe stupor and death. On opening the body, the flamch was found violently inflamed, and the intestines dilated with wind and froth. Twenty four grains proved a pretty certain poison to cats. The effects of an over dose of this substance on the human body were accurately shewn by the experiments to this express object, which Dr. Alexander made on himself. On taking one scruple the pulse soon fell from 63 to 65; two scruples more gave a great and at first agreeable sense of warmth in the flamch, but soon followed by excessive anxiety and creeping of the flesh, nausea, gid-diness, tremors, convulsions, loss of recollection, and delirium, coma and quickened pulse. On drinking warm water, much of the camphor came up from the flamch three hours after it had been taken, and with very speedy relief, and the whole of the formidable train of symptoms brought on by this rash experiment subsided rapidly and left no permanent inconvenience.

To infect and very small animals, the effluvium of camphor, even at a common temperature, is obviously excessively harrowing, as they quickly avoid it; but if confined in a close vessel with a piece of camphor, it proves fatal to many species.

Camphor is a very powerful antifeptic; and from this and its stimulant powers, all the medicinal virtues attributed to it have been usually derived. Indeed, to the very great antiseptic power which it possesses, may be attributed the somewhat exaggerated praise which it has received as an internal medicine in the cure of typhus, and (so called) putrid fevers, in the fever attending local gangrene, and similar diatheses; for its efficacy in these is certainly not comparable to that of other medicines. In the typhoid diatheses attended with spasmodic motions of the limbs (at all times a most formidable symptom) camphor is peculiarly serviceable, and much affixes the action of opium. In rheumatic complaints or other disorders where a copious sweat is wanted, there are three medicines so certain as a mixture of camphor and nitre, about five grains of the former, and from 15 to 20 of the latter, taken at short intervals.

A very common, and generally cordial and grateful drink, (besides being a good vehicle for other medicines), is the

*majura camphorata, or camphor jube*, made by rubbing one dram of camphor first with a little spirit of wine to bring it to a powder, then with half an ounce of sugar, and adding a pint of boiling water. When cold, the water takes strongly and pleasantly of the camphor, though almost the whole seems at the top unmix'd; and so little camphor is diffolved that neither by evaporation nor by any other method can any visible quantity be extracted from the water. A very elegant preparation of camphor, often of singular use in spasmatic irritability of the flamch, and incessant vomiting, is a solution of camphor in water saturated with carbonic acid. If pulverized camphor is diffused in water in a Nouth's manner or any similar contrivance, the water as it takes up carbonic acid diffuses also a very small portion of the camphor, though it is doubtful whether it takes up in this way more than in the common camphor jube.

Almond emulsion with camphor diffused in it is a much stronger solution of this substance than the former preparations, the almonds much affixing the solution of the camphor. One scruple of camphor, (rubbed to powder, with a drop or two of alcohol), two drams of almonds, one dram of sugar and half a pint of water, make the "emulsion camphorata." It is used for the same intention as the camphor mixture, and it is also much employed as a drink in stricture, difficult micturition, the ardor urinis of gout, and other painful affections of the urinary organs. It is said that magnesia much affixes the solubility of the camphor in this emulsion, and is besides often an useful addition as a medicine.

Camphor and opium are very frequently joined both in the liquid and solid form. The commonest liquid preparation of the two is the "tinctura opii camphorata," or "elixir paragonicum," a medicine of undoubtedly utility in coughs, oppression of breathing, and many other complaints; and perhaps of all others the commonest, (and we may add, one of the safest and the best) of the domestic medicines. Camphor is thought peculiarly to counteract the heating and unpleasant effects of opium, and, together, to determine gently to the skin, and to allay spasmotic irritation. They may be well combined in the form of pills, but to divide the camphor and increase its solubility, it should be rubbed down with a drop or two of alcohol, or spirit of ammonia. A bolus is, perhaps, a better form, and the solubility of camphor in the flamch is further increased by being triturated with gum arabic.

Camphor is largely employed as an external application, sometimes as a stimulant and antifeptic conjoined, as where it enters into the composition of the fomentations of aromatic herbs used in gangrene or phaeacels; sometimes as a stimulant and supposed diuretic to indolent tumors, rigidity of tendons, and the like; sometimes as a simple stimulant, as for example, when used as a collyrium to chronic complaints of the eyes, &c.

Camphor for external use is diffused either in oily or in spirituous menstrua. Olive oil diffuses it largely, especially when pulverized and affixed by a gentle heat. The solution is quite limpid, and often greenish. It is a very valuable application of itself, or when brought into a kind of soap by spirit of ammonia. Palm oil with camphor, makes a common and very excellent liniment of the fomulentating and diuretic kind. It is yellow and of the confidence of butter. Marinated ammonia in very fine powder, rubbed with camphorated palm-oil, makes a most active and valuable liniment.

Camphor is often mixed with resinsous substances in the harder and compound plasters and ungueants. Here the apothecary should be aware of the remarkable power of camphor
diligence; his pencil was remarkably tender and soft; his
colouring a just representation of nature, and very transpa-
rent; and his perspective accurate and well contrived.
His pictures, as he left off painting at the age of 18 years, are
scarce, and fetch considerable prices. When he relinquished
his profession, he became tutor to the sons of lord Nieuport,
and was recompensed for his discharge of the trust with the
office of secretory to that nobleman. The designs which he
executed by drawing with a pen are highly valued. Til-
kington.

CAMPIAN, Edmund, a distinguished popular martyr
in the reign of queen Elizabeth, was born at London in 1550,
and brought up at Christ's hospital. He was admitted a
scholar of St. John's college at Oxford, in 1553, and hav-
ing taken his degree of M. A. in 1564, entered into orders,
and became an eloquent Protestant preacher. When queen
Elizabeth visited the university in 1566, he delivered an
elegant oration and kept an act in her presence, with
great applause. In 1567, he went to Ireland, where he
became a convert to popery; and upon being discovered in
making profelytes, he was apprehended. However, he
made his escape into England, and from thence into the
Low Countries, and entered into the English college at
Douay. At Rome he was admitted into the society of Je-
fnuits; and having been sent by the general of the order into
Germany, he at length settled at Prague, and for five years
taught rhetoric and philosophy in the Jefuits' college. Hav-
ing established his reputation for recovering to the church
many persons who had separated from it, he was recalled to
Rome, and deputed by Gregory XIII. in 1589, on the
dangerous mission to England. Here he was zealous in his
endeavours by his discourses and writings to make profely-
tes; and he procured to be printed at a private press,
and industriously circulated at Oxford, a kind of challenge
to the clergy, entitled, "Rationes decem oblati certaminis
in caufa fidei, redditae Academicae Angliae." After he
had for some time concealed himself, he was at length dis-
covered in disguise at the house of a gentleman in Berkshirve,
and conveyed to the tower in procession, with a paper affi-
thed to his hat, upon which was an inscription, "Edmund
Campian, a most pernicious Jesuit." Soon after, he was
convicted of a charge of high treason, and in December,
1581, he was hanged and quartered at Tyburn. None have
questioned his abilities, honesty, and moral character; and it
has been also allowed, that he was well skilled in the learn-
ing of his age and profecion. Among severall works, written
by him, were "An Universal Chronology" and a "Narra-
tive of the Divorce of Henry VIII. from his Queen Catha-
rine," both in Latin; and "Various Conferences on Re-
ligion held with Protestant Divines in the Tower of London."
Whilst he was in Ireland he wrote in 1570, two books of the
history of that kingdom, published by Sir James Ware,
at Dublin, in 1633. Wood's Athen. Oxon. Nicholson's

CAMPICURSIO, in the Ancient Military Art, a march
of armed men for several miles, from and back again to the
camp, to instruct them in the military pace. This exer-cise
was nearly akin to the descurfo, from it which only it differed,
in that the latter was performed by horsemen, the former
also by foot.

CAMPIDOCTORES, or CAMPIDUCTORES, in the
Roman Army, were officers who instructed the soldiery in
the discipline and exerceses of war, and the art of handing
their weapons to advantage. Thence are also sometimes called
campigeni and armillatores.

CAMPIDUCTOR, in Middle Age Writers, signifies
the leader or commander of an army, or party.

CAMPILIA, in Geography, a town of Italy, in the
duchy of Tuscany; 26 miles S. of Volterra.

CAMPILLO, a town of Spain, in the county of Se-
ville; three leagues W. of Antequera.

CAMPION, Francois, in Biography, one of the claim-
ants to the invention of the theory of perspective. It is recorded in Walter, that besides several useful elementary tracts for
the Theorbo and Guitar, in 1705, he published a treatise
on accompaniment and composition, according to the rules of
the octave, a work generally useful for transposition, to
all those who fluddy figuring and stringed (keyed) instruments,
or even a single base part, which it will inform them how to
figure.

Campion, in Botany. See Agrostemma, Cucuba-
lius, Lychnis, and Silene.

Campion, in Geography, a town of Tartary, which
was the capital of the kingdom of Tangut, or of the country
lying immediately to the N.W. of the Chinefe province of
Shensi, and formerly remarkable for being a place through
which the caravans passed in the road from Bucharia to China.
It is distant 60 miles N. from the great wall of China.
N. lat. 40° 27'. E. long. 104° 53'.

Campioni, in Biography, an agreeable French com-
poser of the Italian school, student in 1750 at Sienna;
whence removing to Florence, he was taken into the service of
the grand duke, and composed a Te Deum for the birth of
his imperial highness's eldest daughter, full of curious
anons and other ingenious contrivances, which was per-
formed by a band of 200 voices and instruments. But
though this composition was with propriety written alla Pa-
 federio, his printed tritos were in the modern Italian style,
and in great favour in England, for more than 10 years,
during the middle of the last century. They were in an
easy and graceful taste, and pleased universally till the su-
perior force and genius of the elder Stamit and Boccherini,
created new wants and expectations.

Campion, in Botany. See Agrostemma, Cucuba-
lius, Lychnis, and Silene.

Campstron, John Gualseert, a French dra-
matic writer, was born at Toulouse in 1636, and mani-
festcd an early taste for poetry. Being discouraged from indul-
ging in by his friends, he abruptly left them, and went to
Paris, where he put himself under the direction of Racine.
His first compositions were two tragedies, entitled "Vir-
ginia" and "Arminius," which were followed by two others of
superior merit and more permanent reputation and popu-
arity, viz. "Andronicus" and "Alcibiades." He was
recommended by Racine to the duke of Vendome, as a pro-
per person for composing a new opera for a magnificent festi-
vial which he was preparing to give to the dauphin. The
piece produced on this occasion was the heroic pastoral of
"Acis and Galatea," which being the means of introducing
him to the duke, laid the foundation of his fortune. The
duke, engaged by his talents for conversation and convivial-
ity,
CAMPILHON, tired at length, both of the camp and the court, withdrew to his native city, of which he was appointed, in 1701, "Capitoul," or chief magistrate, and in the same year he was admitted a member of the French academy. In 1710 he married, and palled the remainder of his life in the circle of his family and friends. His death was occasioned by an apoplexy in 1728. Besides the dramatic pieces already mentioned, he published several others, among which are his "Phœnix," "Adrian," "Tridates," "Pharnaces," and "Jaloux défahû;" and these contributed to support the reputation of the French theatre, though in an inferior degree, after it had lost Corneille and Racine; neither of whom he could rival. His style, however, was pure, natural, and sometimes elegant; but his distinguishing excellence consisted in the disposition of his plots, the modelling of his characters, and the knowledge of stage-effect. Nine editions of his "Theatre" were printed at Paris during his life; but the last and best was published since his death, in 1750, in 2 vols. 12mo. His brother, Louis Campilhon, was a Jesuit, and cultivated French poetry. He also wrote funeral odes on the death of Louis XIV. and the death of his friend. He died in 1733, aged 77. Moreni. Nouv. Dict. Hist.

CAMPILHON, See CHAMPART.

CAMPITAE, in Church History, an appellation given to the Donatists on account of their assemblding in the fields for want of churches. For a similar reason, they were also denominated Montenfas and Rupitanis.

CAMPITELLO, in Geography, a town of the island of Corfica; 14 miles S. of Balia.

CAMPÓ, a town of Italy, a sief of the empire, in the state of Genoa; 13 miles N.W. of Genoa.

CAMPÓ Basso, a city of Naples, and capital of the Molise, seated in a fertile plain, producing all the necessaries of life. The air is delicious, and the inhabitants, estimated at about 6000, carry on a considerable trade in articles of cutlery.

C. F. G., a town of Naples, in the province of Abruzzo Ultra.

C. L. I., a town of Naples, in the county of Molise; 14 miles E. of Molise. — C. Magnes, a town of Naples, in the province of Bafclica; 14 miles S.E. of Acrenen.

Alfo, a town of Italy in the Tortones, belonging to Piedmont.

C. Marino, a town of Naples, in the province of Capitanata; 3 miles S.E. of Termoli. — C. Maresc, a town of Genoa, deriving its name from the quantity of mulberries growing in its vicinity; 11 miles N.N.W. of Genoa.

C. Mayor, a fortified town of Portugal, in the province of Alentejo, containing about 3500 inhabitants; 10 miles N.W. of Badajos in Spain. N. lat. 38° 50', W. long. 7° 24'. — C. Marlo, a place of Italy, in the duchy of Perugia, near which Hannibal is said to have defeated the Romans. — C. St. Pietro, a town of the state of Venice, in the Paduan; 13 miles N. of Padua.

CAMPOBELLO, a town of Sicily, in the valley of Mazara; 14 miles N.E. of Giurgiuto.

CAMPÓ-BELLO, a long and narrow island on the east coast of Washington county, in the district of Maine, in America, and the north-easternmost of all the islands of the district. The north end of this island lies in about N. lat. 44° 48'. The south end is 5 miles north-Weyster from Grand Manan island.

CAMPOCHIARO, a town of Naples, in the county of Molise; 11 miles S. of Molife.

CAMPOLI, a town of Naples, in the province of Abruzzo Ultra; 3 miles N. of Teramo. N. lat. 42° 8'. L. long. 15° 55'.

CAMPOLONGO, AEOLIUS, in Biography, born at Padua in 1550, and applying early to the study of medicine, attained such eminence as to be noticed, and employed by the first families in the city; and in 1573 to be appointed professor in that science, an office he continued to hold till the time of his death in 1621. The principal of his works are, "De Variola, et de Arthrifite," 1450; taken principally from the works of Galen, in which he was intimately conversant. "Methodi Medicinales," conjointly with Alb. Botutto, 1880. "Nova cognomographia Morbor Methodus," 1601, 8vo.; and after his death, from his papers. "De Lue Venere, Libellus," Padua. 1635, lat.; and "De Verminibus, de Usuris Affildibus, et de Mortis causis," 1636. Alfr. de Morb. Ven. Halfer, Bib. Med.

CAMPOMACHIA, in Botany, Bofe Nouveau Dict. Flor. Peruv. Clufs and order, veftens monogynea. Nat. ord. Hepperdes. Linn. Myth. Jul. Gen. Chi. Cal. perianth five-leafed, permanent: segments egg-shaped. Cor. petals five, egg-shaped, concave. Stam. numerous, inserted on the calyx. Pfl. germ inferior: style inclined: stigma target-shaped, umbilicated. Fere. berry globular, compressed, one-celled, crowned with the style. Seeds about twelve, kiney-shaped, attached to a filicous receptacle. A tree found in Peru, of which no further details are given. Bofe observes, that it is an intermediate genus between Myrtus and Pifium, and that it appears to agree with Decasperum, a genus transformed by Flurler, for a plant which has since been received as a Pifium. The present plant, perhaps, ought to be admitted into the same genus. The form of the style, and the manner in which the seeds are attached to the receptacle, seem to constitute the only difference. To ascerten what ought to be the precise boundaries of a genus, and to determine what particulars, in the structure of the parts of fructification, should be considered as solid generic distinctions, is a problem which has not hitherto been, and probably may not be, resolved for many ages yet to come.

CAMPORA, in Geography, a town of Naples, in the Principato Cita; 15 miles N.W. of Poliastro.

CAMPRA, ANDREW, in Biography, a French musician, born at Aix, in 1663, settled at Paris in 1667, and first became known by the composition of motets for the churches and private concerts. He afterwards devoted his talents to compositions for the opera, and almost rivalled the celebrated Lulli. He set a number of ballets and serious operas, which are still occasionally performed; and also published various kinds of music, which have been held in estimation. The king appointed him music-master of the royal chapel, and gave him a pension. He died at Versailles in 1744. Moreni.

CAMPREDON, in Geography, a town of Spain, in the province of Catalon, at the foot of the Pyrenees, taken by the French, who destroyed its fortifications in 1651, and again in 1704; 27 miles N.N.W. of Gerona. N. lat. 42° 29', W. long. 2° 56'.

CAMP-SHEETING, CAMP-lot, or CAMPESTEAD, In Island-Navigntion, denotes a facing of piles and planks in the front of banks of wharfs, to prevent the banks being worn away.

CAMPSES, in Botany, (Loureiro). See INCARNILEA.

CAMPTON, in Geography, a small township of America, in Grafton county, New Hampshire, situated on the east bank of Pemigawaset, the north head water of Merrimack river; 67 miles N.W. of Portsmouth. It was incorporated in 1761, and contains 395 inhabitants. N. lat. 43° 57'.

CAMPUGIALI, in Geography, a town of the duchy of Tuscany; 9 miles W.N.W. of Arezzo.

CAMPUS, in Antiquity, a field or vacant plain in a city not
not built on, left vacant either on account of floods, combats, executions, or other ills of the citizens.

Campus Martius, in Ancient Geography, an anniversary assembly of our ancients, held on May-day; where they con- federated together for defence of the kingdom against all its enemies.

Campus Martius, a large plain field in the suburbs of ancient Rome, lying between the Quirinal and Capitoline mounts, and the Tiber; thus called because consecrated to the god Mars, and set apart for military sports and ceremonies, to which the Roman youth were trained; as the use and handling of arms, and all manner of acts of activity. Here the races were run, either with chariots or single horses; here also stood the sella publica, or palace for the reception of ambassadors, who were not permitted to enter the city. Many of the public consular were held in the same field, part of which, for that purpose, was cleaned out. The place was also noble decorated with statues, arches, columns, portraits, and the like structures.

Campus Martius is also used in a more general sense by Middle Age Writers, for any large plain open place near a great city, wherein the inhabitants were trained to the exercitium of arms. Of such we find mention at Verona, Tries, Dorne, and even Constantinople.

Among the French, campus maritius was an appellation given to the yearly assemblies of the people called by the kings, either for enacting new laws, or deliberating on the great affairs of the nation. They were thus denominated, either because usually held in the month of March, or in imitation of the campus maritius of the Romans, which was allotted for the like use. In aftertimes they were called campus major, and by corruption, campus maritus, and magialis, became the time of holding them was altered by Pepsin to the month of May. Under the third line of kings, their assemblies took the denomination of rates-general, state general.

Campus Soredere, a place without the walls of ancient Rome, where the vellals, who had violated their vow of virginity, were buried alive. See Burying alive.

Gen. Ch. Cal. perianth tubular, hairy, tubercled; border five-lobed; segments unequal. Cor. monopetalous, tubular, bilabiate; upper lip awl-shaped; lower lip egg-shaped. Stem. Filaments five, unequal. Fil. germ superior; stigma five-lobed. Peric. capsule nearly globular, five-celled, many-seeded.

Camrup, in Geography, a district of Alagam, (which see) on the isle of 'Daciancloth, situated between three high mountains, at the distance of four days' journey from Cherong. It is remarkable for bad water, noxious air, and confined prospects. It was the part to which the raja banished those of his subjects with whom he was angry.

Camtoos, a river of southern Africa, on the south coast of the colony of the Cape of Good Hope, formed by a collection of waters from the same part of the country with that of the Gaviret river (which see), but somewhat more calmer. It falls into a wide bay of the same name, in which the only secure anchorage is opposite to the mouth of a small stream called the "Kromme," or crooked river. Though Camtoos river, just within the mouth, is a wide bason, deep enough to float a ship of the line, yet the bar of sand across the mouth is fordable upon the beach at high water, and frequently dry at low water. Barrow's Africa, vol. ii.

Camudolanum, in Ancient Geography. See Camulodunum.

Camul, in Geography, a town of Tartary, at the extreme of the kingdom of Chuls, and on the borders of that of Tungut. N. lat. 67° 15', E. long. 157° 5'.

Camulodunum, in Ancient Geography. See Camulodunum.

Camunium, in Botany. See Muraya Exotica.

Camunlodunum, in Ancient Geography, a town of Albion, aligned by Prolemy to the Brigantes, and placed by Horalph at Orchard, near the river Calder, in Yorkshire, but Camden and Baxter place it near Almondbury, about six miles from Hulian, on the same river. Roman antiquities have been found at both these places, and there are still visible vestiges of walls and ramparts. It seems to have been the same with the Cambodunum of the Itinerary of Antonine in the second route, between Calcara and Tadcaster, and Man- nucium or Manchester.

Camuri, in Botany, one of the synonymous names of Dioscor Hystrix among old writers.

Camus, probably derived from ."Cone, I bend, a person with a low, flat nose, hollowed or sunk in the middle. The Tartars are great admirers of camus beauties. Rubruquis observes, that the wife of the great Genghis Khan, a celebrated beauty, had only two holes for a nose.

Camus, John-Peter, in Biography, an eminent French prelate, was born at Paris in 1582, and nominated by Henry IV., on account of his distinguished reputation, to the bishopric of Bellay, before he had attained the canonical age, to which he was consecrated in 1609, having previously obtained a dispensation from the pope. His attacks on the Mendicant orders, for their indolence and relaxed discipline, both from the pulpit and the press, were so acrimonious and fever, that the monks applied to cardinal Richelieu, in order to obtain a cessation of hostilities. His mode of attack, and style of preaching, may be discovered in the following passages, extracted from his sermons. "Father," says he, in a discourse delivered before the Cordeliers on St. Francis's day; "Admire the greatness of your saint; his miracles surpass those of the Son of God. Jesus Christ, with five loaves and three fishes, only once in his life, fed 5000 persons: St. Francis, with an ell of cloth, by a perpetual miracle, feeds daily 40,000 flagellants." "My friends," such was his delicate desire; on another occasion, a young gentleman is recommended to your charity, who is not rich enough to make a vow of poverty." The bishop, with a view of checking the ardour for reading romances, which prevailed in his time, and of directing it to some useful purpose, composed a number of rival works of a pious nature and tendency, which in some degree answered the purpose. After performing his episcopal duties with zeal and diligence for 20 years, he resolved to withdraw from the world; and having obtained leave to resign his bishopric, he retired first to the abbacy of Aulney, and afterwards to the hospital of Incurables at Paris, where he died in 1652, after refusing two considerable bishoprics. Camus was distinguished by a lively and warm imagination; and he composed with wonderful facility, in a style that was partly grave and partly burlesque, abounding with figurative metaphors and images, often striking and sometimes hideous. He is said to have written 200 volumes, consisting of homilies and treatises, moral and devotional, pieces against the monks, pious novels, pastoral directions, &c.

His works, that are now read are; "L'Esprit de S. Francois de Sales," 6 vols. 8vo. reduced to one by a doctor of the Sorbonne; and "L'Avouement des ProtEans avec l'Eglise Romaine," republished in 1703 by Richard Simon, under the title of "Moyens de reunir les ProtEans avec l'Eglise Romaine." Simon asserted, that Bossuet's explication
position of the Catholic faith was no more than this work in a new dress. Materi. Nom. Diet. Hist.

Cana, Stephen s, a French prelate, distinguished by his penitence, mortification, and attention to the duties of his profession, was born at Paris in 1632, and became a doctor of the Sorbonne in 1650. In early life he was borne away by the torrent of court dilapidation; but relieved on reformation, he was nominated by the king in 1671, after having been his abuser for several years, to the bishopric of Grenoble. His general conduct corresponded to the outward tokens of penitence which he manifested. "He always wore a rough hair-suit and lay down. He rose at two in the morning, recited his breviary, read the Scriptures, and at five called up a domestic who wakened the others. At half past five he read the common prayers, recited prime at six, and then said mass. He then retired to his closet till nine, when he gave audience. At eleven he dined with his household. His chaplain sat next him; and at another table were his steward and domestics. One of the laquays read. To the prelate were served legumes only, with a small measure of wine, half of which was reserved for the defert. He went to rest at eight. Such was the mode of living of this man, who was a prince as well as a bishop." Some time before his death, when his bodily infirmities increased, an order was procured from the pope to add fish and flesh to his diet. In visiting his diocese, for which he devoted three months in every year, he commonly travelled on foot; and visiting 100 parishes in a year, he completed his tour of the whole in three years. He everywhere preached with the same zeal, and distributed alms to the utmost extent of his revenue. He founded a number of charitable establishments. In 1686 pope Innocent XI., from a mere regard to his virtues, advanced him to the cardinalate. He died in 1707, and made the poor his heirs. His publications were Pastoral Letters to his Clergy, a collection of excellent Synodal Ordinances, and a Disputation in proof of the perpetual virginity of the virgin Mary. Moreri.

Camus, in Ancient Geography, a town of Asia, placed by Polybius in C celebrity.

Camius, in Ancient Geography. See Camiro.

Can, in Sc Languag. A pump's can, is a sort of wooden jug or pitcher, wherewith scamen pour water into pumps to make them work.

Can-bury. See Buoy.

Can-book, an instrument used to sling a caulk by the ends of the slates; it consists of a broad and flat hook fixed to each end of a short rope, and the tackle which serves to hoist or lower it is fastened to the middle of the rope.

Cana, in Entomology, an European species of Apis, of a grey colour, with the legs of the abdomen edged with whitish. Muf. Le£.

Cana, in Ornithology, a species of Motacilla, of a cinnereous colour; with the quill feathers edged with whitish; tail feathers black, the exterior ones nearly all white. Gmel. &c.

Obs. This is the grey-throated warbler of the Arctic Zoology. Buffon calls it Figuier cendrè à gorce cendrée. It inhabits Louisiana.

Cana, in Ancient Geography, the name of two cities of Galilee in Palestine; one called by Jerom Cana the Greater; the other, Cana the Lesser, or commonly Cana of Galilee. The former is mentioned by Joshua (chap. xix. 28.) and was situated in the tribe of Asher; the latter, which is more frequently mentioned in the sacred writings, (See John ii. 11. iv. 46. xxii. 2.) was feated in the tribe of Zebulun, N.W. of the sea of Galilee or of Tiberias, or the like of Geumafeth, on the confines of the upper and lower Galilee. This was the country of the apostle Simon, hence called the Canaanite (Matt. x. 43.) and of Nathaniel (John xxii. 3.) here Jesus wrought his first miracle; and as it was situated to the north of Capernaum, he is said to have gone down from Cana to this city; and after his return thither, the nobleman whose son was sick at Capernaum visited him there. It is of this Cana that Josephus speaks in his Life: p. 1057 and 1239.

Cana, or Canaan, a town of Palestine in the tribe of Ephraim, according to Encephus and Jerom; and also a river of the same name on the western limit of the territory of the Ephraimites. John. xvi. 6. xviii. 9.

Cana, a promontory of Aoln, with a small town and mountain adjoining it, at the termination of the bay of Adventistum.

Cana, a town in Culefria. See Canath.

Cana, in Geography, one of the smaller western islands of Scotland, about 8 miles S.W. from the island of Skye. N. lat. 5° 19'. W. long. 6° 10'.

Cana, El, a town of Asia Minor, in the province of Aladhas; 36 miles S. W. of Maltasia.

Canaan, in Scripture Biography, the fourth or youngest son of Ham, according to the order in which his name is introduced in Genesis, ch. x. 6. The Hebrew word Canaan is derived from כנן, to humber or abase, and with the prefix כannah it denotes a merchant or trader, as the Canaanites or Phcenicians were. If we join the נ and ר or אב and א into one syllable, and pronounce it as the Jews do, the word will be Canaan, and it will more nearly resemble the Chn of Sanchoniatho and Stephanus Byzantinus. The time of his birth and the length of his life are not known; but some have supposed that he was born in the ark during the period of the deluge, and it has been fancifully said that he was a wicked man, because he was the fruit of an unfeemly incontinence. The irreverent action of Ham in discovering the nakedness of his father Noah was retaliated on Canaan. 'To this purpose Noah, with the spirit of prophecy, pronounces his malediction on this branch of his posterity, "Curfed," says he, "be Canaan; a servant of servants shall he be unto his brethren." Gen. ix. 25. As this curse was denounced, not against Ham the immediate transgressor, but against his sons, who does not appear, from the words of Moses, to have been at all concerned in the crime, many conjectures have been employed to solve this difficulty in the sacred history. Some commentators apply the term כנן, or younger son in ch. ix. 24. to Canaan; and imagine that he joined with his father Ham in this mockery and insult upon Noah; and the Jewish rabbins have a tradition, that Canaan was the first who faw Noah in this posture, and then went and called his father Ham and concurred with him in his act of irreverence. Origen in Genef. p. 32. vol. ii. ed. Bene dicci. Bocharti Phaleg. l. iv. c. 37. col. 308. But this is a very arbitrary and unfounded method of interpretation; because no previous mention was made of Canaan, and of what he had done, but only of Ham the father of Canaan; and of him, therefore, the phrase of "little son" or "youngest son" must be understood. Others have alleged, that this curse was so far from being pronounced upon Canaan for his father Ham's transgression that it was not pronounced for his own, nor was it executed several hundred years after his death. It is in reality to be understood not so properly of Canaan, as of his descendants, the Canaanites. Accordingly, it is said, that God, foreseeing the wickedness of these people, which began with their father Ham, and greatly increased in this branch of his family, comminished Noah to pronounce a curse upon them, and to devote them to
the fervitude and misery, which their more common vices and iniquities would deserve. It is added, that this account was written by Molos for the encouragement of the Israelites, to support and animate them in their expedition against a people, who by their sins had forfeited the divine protection, and were destined to slavery from the days of Noah.

Some biblical critics have proposed to correct the text, supposing that Canaan is here erroneously placed for Ham, which is the reading of the Aldine edition of the LXX. and of 7 of Holms MSS. Others suppose that ΛΝΕΝ, ΛΝΕΗ, Ham the father of, are wanting before Canaan, and supply them accordingly; partly from the Arabic version ΛΝΕΗ, and partly from the rules of Hebrew metre, laid down by bishop Hare; ΛΝΕΗ being necessary to fill up the verse. But neither of these authorities, says Dr. Geddes, is sufficient to justify an alteration in the present text, in which there is no variety of reading either in the Samaritan or Hebrew copies, and with which all the other ancient versions perfectly agree. Besides, if this alteration were allowed, it would not much mend the matter; for if Ham was only to be curbed, why curfe him under the denomination of the father of Canaan. The text, in Dr. Geddes's opinion, is sufficiently clear as it stands; and highly expressive of what we may suppose to have been the feelings of Noah on this occasion. On awakening, he learns that Ham had used him most irreverently, while his other sons had shewed him that filial regard which was due to such a venerable father. To express his indignation at so infamous a conduct, he curfe Ham in his progeny, and in him of his progeny, who was, probably, most dear to him, as being his youngest son, perhaps just then born; and whose very name, which imports the idea of depreffive humiliation, might readily offer a paronomasial allusion, so common in the malédicitions and benedictions of the patriarchs. Dr. Geddes proceeds with reflections which we can by no means approve, and which, in our opinion, are altogether unnecessary to vindicate this part of the Scripture history. "Whether this malédiction," he says, "were prophetic or imprecatory; whether it were really made by Noah, or whether the whole be not a poetiform talle, contrived by the Hebrew historiographer for the purpose of throwing an odium on the Canaanites, and justifying the conquest of their country; are points which I mean not now to discuss: but it is pretty clear, that the story, true or false, is here introduced, to pave the way for a more special command from heaven to conquer and extinguish the Canaanite nations." See CANAANITES.

The curse pronounced by Noah on Canaan was peculiar to this son of Ham and his posterity, and does not seem to have extended to the rest of his brethren. And, indeed, considered as a prophecy, the declaration that Canaan "should be a servant of servants to his brethren," seems to have been wholly completed in him, though its accomplishment was dull and gradual. It was completed with regard to Shem, not only because a considerable part of the seven nations of the Canaanites were made slaves to the Israelites, when they took possession of their land, as part of the remainder of them were afterwards enslaved by Solomon; but also by the subsequent expeditions of the Affrians and Persians, who were both destined from Shem; and under whom the Canaanites suffered subjection, as well as the Israelites; not to mention the conquest of part of Canaan by the Elamites, or Persians, under Chedorlaomer, prior to them all. With regard to Japheth, we find a completion of the prophecy, in the successeive conquest of the Greeks and Romans in Palestine and Phoenicia, where the Canaanites were settled; but especially in the total subjugation of the Carthaginian power by the Romans; besides some invasions of the northern nations, as the poffersity of Thugarmuth and Maccob; wherein many of them were, probably, carried away captive. "Egypt," says Bishop Newton, "was the land of Ham, as it is often called in Scripture; and for many years it was a great and flourishing kingdom; but it was subdued by the Persians and afterwards by the Greeks, and it has ever since been in subjection to some or others of the poffersity of Shem or Japheth. The whole continent of Africa was peopled principally by the children of Ham; and for how many ages have the better parts of that country lain under the dominion of the Romans, and then of the Saracens, and now of the Turks? In what wickeds, ignorance, barbarity, slavery, misery, live most of the inhabitants? And of the poor negroes how many hundreds every year are sold and bought like beasts in the market, and are conveyed from one quarter of the world to do the work of beasts in another?" "Nothing," says this prelate in the clofe of his account of this prophecy, "can be more complete than the execution of the sentence upon Ham as well as upon Canaan."

Canaan is supposed to have lived and died in a country called after his name. His posterity was very numerous. His eldest son Sidon founded the city of Sidon, and was the father of the Sidonians and Phoenicians. His ten other sons were the fathers of as many tribes, dwelling in Palestine and Syria; viz. the Hittites, Jebusites, Amorites, Gerges, Hivites, Arkites, Sinites, Arvadites, Zemarites, and Hamathites.

Canaan seems to have been known to the ancient heathens. Sanchoniatho occasionally mentions Canaan, who is known to be Canaan, as the first Phoenician. There is reason to think, says the learned Bryant, that the Egyptians and other neighbouring nations, Canaan was expreffed Canaan. This by the Greeks was rendered ΚΑΝΑΑΟΝ, and ΚΑΝΑΑΟΣ; and in later times ΚΑΝΑΑΟΝ, Cnaa. Bryant adds, that, by prefixing the term ΚΑΝΑΑΟΣ, which is to be found in the composition of many words, particularly such as are of Amonian original, Cnass, or Canaan, was signified Ur-nas, and the Gentile name or pollef- tary was ΚΑΝΑΑΑΟΣ, ΚΑΝΑΑΑΟΣ, which was changed by the Greeks into ΚΑΝΑΑΟΣ, of Cussans; and from ΚΑΝΑΑΑΟΣ they formed ΚΑΝΑΑΑΟΣ; hence he derives the Cynus of Lucian, and the ancient poet, who was represented as the father of Phaethon and transformed into a swan. With regard to Cynus and his brotherhood, the vocal ministers of Apollo, the story, as he conceives, which is told of them undoubtedly alludes to Canaan, the son of Ham, and to the Canaanites, his posterity. Accordingly he observes, that the swan was the emblem of Canaan, as the eagle and vulture were of Egypt, and the dove of Babylonia; and that, wherever we may imagine any colonies from Canaan to have settled and founded temples, there is some story about swans. The Canaanites, it is said, wherever they came, introduced their national worship; part of which consisted in chanting hymns to the honour of their country god, who was the same as Apollo of Greece; and on this account Lucian, in compliance with the current notion, says, that the Cyni were formerly the allenns and ministers of that deity. By this, says Bryant, we are to understand, that people of this denomination were in ancient times his priests. Mede's works, vol. i. p. 378. Anc. Un. Hist. vol. i. p. 88. Geddes's Crit. Rom, vol. i. p. 76. Bishop Newton on the Prophecies in his works, vol. vii. p. 11—23. Sve. Leland's Deitical Writers, vol. iii. p. 254, &c. Bryant's Anal. Anc. Mythol. vol. i. p. 369, &c.

Canaan, land of, in Scripture Geography, so named from Canaan,
Canaan, the son of Ham, whose posterity possessed this country as well as Egypt, or Mizraim, lies in the western part of Asia, and extends from about 31° to 33° 20' N. lat. and from 34° 50' to 37° 15' E. long. It was bounded, to the north, by Cade-Syria, or the mountains of Libanus and Anti-Libanus; to the south, by the Mediterranean sea; to the south-west, by Arabia Deserta; and to the south and south-west, by Arabia Petraea and Egypt. Its extent has been variously ascertained; but from the late and most accurate computation, it was about 200 miles from north to south, that is, from Dan or Caesarea-Philippi to Beer-sheba, and about 100 miles in breadth. According to this reduced extent, if we consider its extraordinary fertility, the number of its inhabitants, and the many cities and villages which it contained, it was so far from being an inconsiderable spot of ground, as some have misrepresented it, that, exclusive of what it was in the reign of David and Solomon, (Ezra, iv. 20.) and many ages after, it must have been always regarded as one of the most opulent and considerable kingdoms of the East; and it must be allowed, that the Israelites, according to the acknowledgment of the king of Tyre, (1 Kings, v. 7.) were a "great people." Indeed, the description of its wealth, power, and population, seems very extraordinary; even allowing it to have been cultivated with the utmost diligence, by men well acquainted with every branch of agriculture.

Before the Israelites obtained the possession of it, Moses defended it as a country fitly called fertile and productive. See Deut. viii. 7. &c. Its wonderful fecundity was owing to several circumstances: such as the excellent temperature of the air, which was never subject to excessive heats or colds, the regularity of its seasons, especially the former and latter rain, and the natural fertility of its soil, which required neither labor nor manuring. It was famous for its large and delicious grapes, for its palm-trees, and its dates, for its balsam fir, which produced the celebrated balm of Gilead, for the constant verdure of its fruit trees, and for its citrons and its oranges. Its vines yielded grapes twice, and sometimes thrice, in a year; its honey was abundant; its inhabitants cultivated sugar-canes with great affluence; and their cotton, hemp, and flax, were mostly of their own growth and manufacture. Its vicinity to Libanus afforded them an ample supply of cedars, cypresses, and other flax and fragrant trees. They fed large herds of cattle, both great and small, and their hilly country afforded them not only a variety and plenty of pasture, but also of water, that deflected themselves into the valleys and lowlands, which it fertilized. But the most fertile, fertile-ground, were on the edge of the river Jordan, besides those of Sharon, or Sarona, the plains of Lydda, Janamia, and some others, which were then justly famed for their fecundity. As for fish, their rivers, the lake of Tiberias, and the Mediterranean sea, afforded great plenty and variety. The lake Alphænites yielded abundance of salt, with which they seasoned and preserved their fish, and which Galen affirms to have been preferable to any other. It ought further to be considered, that the country was then inhabited by an industrious people, who knew how to improve every inch of this land, and had made even the most desert and barren places to yield some kind of produce, by proper care and manuring, so that the very rocks, which now appear quite naked, produced corn, pulse, or pasture; for every little hillock was formed into a terrace covered with mould, which, through the laziness of succeeding proprietors, has been since washed off by rains and storms. The fecundity of Palestine hath been extolled even by Julian the apostate, a sworn enemy to Jews and Christians, who frequently, in his Epistles, mentions the perpetuity, as well as excellence and great abundance of its fruits and produce. The visible effects of divine displeasure, which this country has felt, not only under Titus Vespasian, but much more frequently that emperor's time, in the inundations of the northern barbarians, of the Saracens, and of the more cruel and destructive Chiliasm, during the holy war, and in the oppression it now feels under the Turk's yoke, are causes more than sufficient to have reduced the far greater part of the country into a mere desert. If we were to judge by its present appearance, nature itself has rendered it incapable of cultivation.

The land of Canaan was divided into two unequal parts, of which the western was considerably the greater, by the river Jordan, which rises in the mountains of Hermon (a branch of the mountains of Libanus,) and running south through the lake of Gennesaret, or the sea of Tibersias and Gilece, after a course of 150 miles, loses itself in the Alphænite Lake, or the Dead Sea. See Alphænite Lake.

The country to the east of Jordan was given to the tribes of Reuben, Gad, and the half tribe of Manassish; the kingdom of Moab lay to the south; the kingdom of Ammon to the coast of Gad; and the mountains of Hermon bounded Manassish to the north-east, beyond which lay Trachonitis and Idumæa. Weft of the Jordan, to the north, were placed Naphthali on the river, and Apher, which bordered on Phœnicia and the Mediterranean. Zebulan and Issachar had inland districts; but the other half tribe of Manassish and Ephraim reached from the sea to the river. Dan (upon the coast) and Benjamin, were south of Ephraim, and north of Simeon and Judah. The country allotted to Simeon bordered upon the Mediterranean, and extended to Egypt; but the Philistines, who inhabited the coast, were never entirely driven out of their possessions. The country of Judah bordered upon the Dead Sea, which separated it from the kingdom of Moab (for both Simeon and Judah lay considerably more south than the tribe of Reuben), and adjoined the mountainous country of Idumæa, or Edom, and Arabia Petraea, to the south. The next remarkable division, next to the distribution, by lot, among the twelve tribes, was made by king Solomon, who divided his kingdom into 12 provinces, or districts, each under a peculiar officer; but the most fatal division of all was that which obtained under his immediate son Rehoboam, when ten of the twelve tribes revolted, under the conduct of Jeroboam, who became head of this new monarchy, lilyed the kingdom of Israel, in opposition to that of Judah, the title which distinguished the named kingdom of Rehoboam, from that time downwards. Under the second temple the distinction lasted a considerable time, and the same imaginary hatred and hostilities continued between these two kingdoms; that of Israel taking the name of Samaria, from its capital. See Samarla.

After the return from the Babylonian captivity, the eastern division of the land of Canaan was called Peræa (more properly the country which had belonged to Reuben and Gad, for the northern part, sometimes called Gaulonitis, was included in the district of Trachonitis), and the western part was divided into Galilee to the north, Judea to the south, and Samaria in the middle. See each of these articles. Judea Proper extended from the Dead Sea and the Mediterranean to Egypt, and included the countries of Benjamin, Dan, and Simeon, beside that of Judah. Under the Romans the land began to be divided into tetrarchies and toparchies: the larger were those of Judea, Samaria, and Galilee, upper and lower; the lesser, those of Geraritica, Sarona,
Saron, and others of less note; all which lay on this side of the Jordan. The rest, on the other side, were those of Gilead, Peraz, Gileonitis, Auranitis, Batanata, and Decapolis. Josephus (Antiq. i. xiv. c. 12.) mentions another division, made in the time of Gabinus, into five districts, or, as he styles them, *περιπυρος, or councils, agreeably to the Roman manner; these were Jerusalem, Jericho, and Scythopolis, on this side of Jordan; and Gadara and Amathus on the other. The whole country was also called *Palestine* (which see), from the Philistines or Philinities, who inhabited the western coasts, and were first known to the Romans; but it was more commonly called *Judaea* (which see), or Judea Palestina, from Judah, whose tribe was the most considerable of the twelve, and possessed the finest and most fertile part of the whole. Christians, as well as Jews, have dignified it with the title of "Holy Land," partly on account of its metropolis, supposed to have been the centre of God's worship, and his peculiar habitation; but chiefly for its being the native country of Jesus Christ, and the scene on which he accomplished the great work of our redemption. It has also been distinguished by other apppellations: such as the "Land of Promise," or the "Land of God," or the "Land of Israel," and sometimes, by way of preeminence, the "Land." In modern writers, all distinction is frequently lost in the general name of *Syncr, which is given to the whole country east of the Mediterranean, between the sea and the desert. As many of the old inhabitants of the north-west of the land of Canaan, particularly on the coasts of Tyre and Sidon, were not driven out by the children of Israel, this tract seems to have retained the name of Canaan a long while after these other parts of the country, which were better inhabited by the Israelites, had lost the said name. The Greeks called this tract inhabited by the old Canaanites, along the Mediterranean sea, *Perea* (which see); the nearer inland parts, as being inhabited partly by Canaanites, and partly by Syrians, Syro-Phenicis; and hence the woman said by St. Matthew (ch. xv. 22.) to be a woman of Canaan, whole daughter Jesus cured, is said by St. Mark (ch. vii. 25.) to be a Syro-Phenician by nation, as she was a Greek by nation and language. The principal mountains of the land of Canaan or Palestine are Libanus or Lebanon, Anti-Libanus, Hermon, Tabor, Carmel, Olive, Colvary, Moriah, and Gilboa, which see respectively. The most noted valleys are the valley of Beiting, or Be'erkah, in the tribe of Judah, on the west side of the lake of Sodom, and in the wildernees of Tekoah; the vale of Siddim, famed for the overthrow of the Chedorhemmon and his confederate kings (Gen. xiv. 2, &c.); and for the cities of Sodom and Gomorrah, now making the Asphaltite lake; the valley of Shaveh, or royal valley, where the king of Sodom met victorious Abraham, after the defeat of the confederate kings; the vale of Salt, in which the Edomites were subdued by David and Amaziah (2 Sam. viii. 13. 2 Kings, xiv. 7); the valley of Jeruel, famed for the death of Jezebel, the idolatrous wife of Ahab; the valley of Maure, famous for the oak under which Abraham dwelt, about 15 miles from Hebron, and 25 from Jerusafem; the vale of Rechaim, or of the Titans and Giants, near the city of Jerusafem, the vale of Jeohophat, in or near Jerusafem; the valley of Hinnom, near the walls of Jerusafem, notorious for the burnt offerings and bloody rites performed in it by the saddest ages; the valley of Zebaim, near the Dead Sea; the valley of Achor, near Jericho; the valley of Bochina, or of the mourners (Judg. ii. 15, &c.), at a small distance from Jerusalem; and the valley of Elah, famous for the defeat and death of Goliath by David, and for the victory which the Israelites obtained against the Philistines (1 Sam. xvii. 2. &c.). The country had also several noted plains, the most remarkable of which is that through the midst of which lay the course of the river Jordan, computed to be about 150 miles in length, from the city of Sicythopolis northward to the Asphaltite lake. In this country were also several forests, such as those of Haroth, of Ephraim, of Lebanon, in which Solomon had a magnificent palace, and of Bethel. The seas of Canaan are commonly reckoned five, viz. the Mediterranean, called by the faced writers the Great Sea; the Dead Sea; or Lake of Sodom; the Sea of Tiberias; the Samacdonite Sea or lake; and the Sea of Jazer. The most considerable river is Jordan, which see. For a further account of this country and its inhabitants, see CANAANITES and PALESTINE.

CANAAN, in Geography, a thriving township of America, in Lincoln county, and district of Maine, seated on Kennebeck river, about seven miles north of Hancock, incorporated in 1788, and containing 254 inhabitants.—Alfo, a township of Grafton county, in New Hampshire, 10 miles E. of Dartmouth college; incorporated in 1751, and containing 1,750, 453 inhabitants.—Alfo, a township of Lenox county, in Connecticut, E. of Hoatstonick river, with Massachusetts on the north. It has a forge and furnac, and tradesmen excellent men. The mountains abound valuable minerals, particularly lead and iron. It is distant 60 miles from New Haven, and 33 N.W. from Hartford.—Alfo, a township of Middlesex county, in Vermont, being the north-easternmost town in the state.—Alfo, a township of Columbia county, in New York, between Kinderhook and the west, and Maschuchett on the east. It has 6,652 inhabitants, including 35 free.

CANAANITES, in Scripture History, the pofterity of Canaan by his eleven sons, who are supposed to have settled in the land of Canaan, for about the division of Jacob. Five of these are known to have dwelt in the land of Canaan; viz. Hezib, Hebus, Hemor, or Amor, Girgash, and Hemi or Hiv; and their, together with their father Canaan, became the heads of so many nations. Sina or Sini was another son of Canaan. whose settlement is not so precisely ascertained; but some authors infer, from the affinity of the names, that the descenf of Sin and much Sinah, were the place of his abode, and that they were so called from him. The Hittites inhabited the country about Hebron, as far as Beer-sheba, and the brooks border, reckoned by Moses the southern limits of Canaan. The Jehuites dwelt near them on the north, as far as the city of Jubes, once called Jerusafem. The Amorites possessed the country on the east side of Jordan, between the river Amon on the south-east, and mount Gilead on the north, afterwards the lot of Reuben and Gad. The Girgashites lay next above the Amorites, on the east side of the sea of Tiberias, and their land was afterwards posseed by the half tribe of Ma-nafeth. The Hivites dwelt northward, under mount Libanus. The Perizzites, who make one of the seven nations of the Canaanites, are supposed, by Heylin and others, to be the descendants of Sina or Sini; and it is probable, since we do not read of their abode in cities, that they lived dispersed, and in tents, like the Scythians, roving on both sides of the Jordan, on the hills and plains; and that they were called by that name from the Hebrew, *pharajjas*, which signifies to *dispers*e. The Canaanites dwelt in the midst of all nations, and were surrounded by the roll. This appears from the sacred writings to have been the respective situation of those seven nations, which are said to have been doomed to destruction for their idolatries and wickedness, when the Israelites first invaded their country. The learned have not absolutely determined whether the nations proceeding from Canaan's
Canaan’s other six sons should be reckoned among the inhabitants of the land of Canaan. The prevalent opinion is, that they were not included. As to the customs, manners, arts, sciences, and language of the seven nations, that inhabited the land of Canaan, they must, from the situation they severally occupied, have been very different. Those who inhabited the sea-coast were merchants, and by reason of their commerce and wealth scattered colonies over almost all the islands and maritime provinces of the Mediterranean. See Ptolemais. The colonies which Canaan carried to Thbes in Bocotia, and his brother Caleb into Cilicia, are said to have proceeded from the Rock of Canaan. Sicily, Sardinia, Malta, Cyprus, Corfu, Majorca, Minorca, Gades, and Ebbitis, are supposed to have been peopled by the Canaanites. (See Bochart’s Canaan.) The other Canaanites, whose situation was inland, were employed partly in husbandry, partly in tillage, and they were also well skilled in the exercise of arms. Those who dwelt in the walled cities, and who had fixed abodes, cultivated the land; and those who wandered about, as the Perizzites seem to have done, grazed cattle, or carried arms: so that among the Canaanites we discover the various classes of mercenary soldiers, and, consequently, marines of artificers, soldiers, shepherds, and husbandmen. We learn, also, from their history, that they were all ready, however diversified by their occupations or local interests, to join in the common cause: that they were well appointed for war, both offensive and defensive; that their towns were well fortified; that they were sufficiently furnished with military weapons and warlike chariots; that they were daring, obdurate, and almost invincible; and that they were not delinquent of craft and policy. Their language, we find, was well understood by Abraham, who was an Hebrew, for he conversed readily with them on all occasions; but as to their mode of writing, whether it was originally their own, or borrowed from the Israelites, it is not easy to determine. Their religious feems to have been preserved pure till the days of Abraham, who acknowledged Melchisedek to be priest of the most high God; and Melchisedek was, without doubt, a Canaanite, or, at least, dwelt at that time in Canaan, in high esteem and veneration.

But we learn from the scripture history, that the Hittites in particular were become degenerate in the time of Isaac and Rebekah; for they could not endure the thoughts of Jacob’s marrying one of the daughters of Heth, as Elise had done. About this time, then, we may date the origin of those abominations which desolated them to the divine displeasure, and made them unworthy of the land which they possessed. In the days of Moses, they were become incorrigible idolaters; for he commands the Israelites “to destroy their altars, and break down their images ( financially and pillars), and cut down their groves, and burn their graven images with fire.” And left they should pervert the Israelites, the latter were strictly enjoined not to intermarry with them; but “to hate them, and utterly destroy them, nor shew mercy upon them.” Deut. vii. 1—5. They are accused of the cruel custom of sacrificing men, and are said to have passed their heed through fire to Moloch. Levit. xviii. 21. Their morals were as corrupt as their doctrine; adultery, belliosity of all sorts, fornication, incest, and all manner of uncleanness, are the sins laid to their charge. The Canaanites, says Mr. Bryant, (Anc. Anc. Mythol. vol. i. p. 371.) as they were a filter tribe of the Mizraim, resembled them in their rites and religion. They held a heifer, or cow, in high veneration, agreeably to the customs of Egypt. Their chief deity was the sun, whom they worshipped, together with the Baalim, under the titles of Ourchol, Adonis, or Thammuz. The Canaanites, at Byblos, Erytus, Sidon, and afterwards at Tyre, used, in imitation of the Egyptians, mournful daces for the loss of Adonis or Thammuz, who was the same as Thamus and Osiris in Egypt; and their measures and harmony seem to have been very affecting, and to have made a wonderful impression on the minds of their audience. This infection made of worship prevailed to such a degree, that the children of Israel were forbidden to weep, and make lamentation upon a festival. See Nehem. viii. 9. 11. Joseph. Antiq. i. xi. c. 5. p. 563. Among the Canaanites, this manifestation of sorrow was encouraged, and made part of their rites.

As to the government of the Canaanites, they seem to have been comprehended in a great number of states, under subjection to limited chiefs, or kings, as they are called; and transacted all their business in popular assemblies.

When the measure of the idolatries and abominations of the Canaanites was completed, God delivered their country into the hands of the Israelites, who conquered it under Joshua. However, they refilled with obdurate valor, and kept Joshua employed six years, from the time of his passing the river Jordan, and entering Canaan, in the year B. c. 1451, to the year B. c. 1445, the fabbatical year beginning from the autumnal equinox; when he made a division of the land among the tribes of Israel, and refted from his conquests. As God had commanded his people, long before, to be treated with rigour (See Deut. vii. 2.), Joshua extirpated great numbers, and obliged the rest to fly, come into Africa, and others into Greece. Procopius says, they first retreated into Egypt, but advanced into Africa, where they built many cities, and spread themselves over those vast regions, which reach to the Straits, preferring their old language, with little alteration. In the time of Athanarius, the Africans still said they were descended from the Canaanites; and when asked their origin, they answered, “Canaan.” It is agreed, that the Punic tongue was nearly the same as the Canaanitific or Hebrew.

After the Canaanites had been successively defeated, and, at length, dispersed and reduced, the Anakims, a fierce and barbarous race, who inhabited some of the mountains of the land, of a distinct origin from the Canaanites, were invaded and cut off; and thus, by degrees, the Israelites became masters of the greatest part of the land of Canaan. However, the Canaanites of several denominations were strong and powerful, and retained no mean share of the country; and, for 10 or 20 years, the remainder of Joshua’s days, they were very little molested. At length, when the division was completely settled, the Canaanites were, on all sides, invaded again by the tribes of Israel, who wished to drive them out of their respective lots. However, in the conflicts thus occasioned, the contending parties seem to have been pretty equally matched; so that although multitudes of the Canaanites were slain in the wars with Joshua, and many of them fled in quest of more quiet habitations, yet, after all their calamities, they appear to have been little inferior to the Israelites; nor do we find that any one tribe of them was missing, except the Girgasithes, who, it is said, fled into Africa, and settled in that country. Thus it appears, that some of the more immediately devoted nations, viz. the Canaanites, Hittites, Amorites, Hivites, and Jebuites, were allowed to dwell in common with the children of Israel in their promised land. See Judges, ch. i. ii. For this exercise of mercy and toleration reasons of a political and religious nature have been assigned. Thus the Israelites were prevented from sinking into a flagitious and incautious state, as they had enemies to excite and exercise their courage, and...
CANAANITES.

to keep up among them martial discipline; they were thus preferred in a condition of immediate dependence on God, and directed to look constantly to him for succour; and it was thus provided, that no part of the country, which was too extensive to be every where inhabited by the Israelites at their first settlement, should be left desolate, so as to become a refuge for wild beasts, which, by their increase, might prove a more dreadful and pernicious enemy than the Canaanites. Besides, it has been very justly alleged, that though the order for extermination was positive and absolute, the promise of power to fulfill it was limited and conditional. It was not till after the Israelites had forsaken the Lord, and worshipped other gods, that the Lord would no more enable them to expel the Canaanites. The Canaanites seem to have been able to have maintained their ground in several parts of the country; and particularly in Jerusalem, till the reign of David; when that city, which had been held by the Jebusites, was taken by force. They were also invaded in Gezer by Pharaoh; their city was burnt, and they were all put to the sword. Thus oppressed by the Israelites on one hand, and by the mighty power of Egypt on the other, the remaining Amorites, Hittites, Perizzites, Hivites, and Jebusites, were reduced, in the reign of Solomon, to a state of slavery, and employed in the labour of carrying on his vast and sumptuous works; and this severity was entailed on their posterity. 1 Kings, ix. 20, 21. Ezra, ii. 55, 58. Nehem. xi. 3. Although upon their first reduction, they became prostrate to the Jewish religion, yet it has been thought, that they were distinguished from the Jews, and reckoned of a more ignoble blood, born to drudgery. Among the tribes of the Canaanites above enumerated, who became subject to the yoke of Solomon, the Canaanites, peculiarly so called, are omitted. These, we may therefore conclude, bore no part of the burden imposed upon the others; but remained free and independent in their possessions on the sea-coast, rose afterwards to great celebrity, and, continually improving themselves in navigation, commerce, and the useful arts, were comprised under the appellation of Phoenicians. Anc. Un. Hist. vol. i.

The destruction of the Canaanites, and the expulsion of them from their country by a divided order, whilst some of them were allowed to remain in opposition to this order, have afforded a theme, on which sceptics and infidels have vehemently declaimed; and which they have urged as an unanswerable objection either to the truth of the scripture history, or, admitting the fact, to the moral providence of God. This objection has been lately flated in its full force by a learned commentator and critic (Dr. Geddes) in the preface to the 2d volume of his "Translation," and also in the 18 volume of his "Critical Remarks," p. 423, &c.; and instead of obviating it by argument, or admitting the sufficiency of the solution of the difficulty, proposed by other ingenious and learned writers, he boldly cuts the Gordian knot, refuting the order supposed to be given by God for the extermination of the Canaanites; deeming this method preferable to the unsuccessful endeavours of other scriptural writers to unite it. Instead of according to any of the arguments which have been employed in defence, or even in extenuation, of this supposed cruel and fanitical measure, he denies that any such order proceeded from God, or even from the mouth of Moses. He suspites it to be "the fabrication of some posterior Jew, to justify the cruelties of his nation." Of course, he supposes this fabulous and universal inspiration of the Hebrew writers. It is beside our purpose to enter at large into the discussion of this subject. But when we consider, that the extermination of the Canaanites forms a leading and prominent part of the scripture history, and that it is, more directly or indirectly, referred to as the consequence of a divine order, in a great variety of passages, the idea of the fabrication of such an order by a posterior Jew, seems to us to be altogether imdissipable. The account of this event, and of the circumstances succeeding and attending it, pervades the whole Jewish history; and if we suppose that the providence of God had no concern in the conduct and execution of it, we must be led to admit a great number of fabrications and interpolations in the detailed account which the scripture has given us of it, and we shall ultimately undermine the truth of the history itself, and find it difficult to determine what part of it is authentic and true and what is forged and false. But we are of opinion, that the objection itself, which has been repeated by Tindal, Morgan, and Bolingbroke, and last of all by the author of the "Age of Reason," has been as often satisfactorily refuted. To this purpose it has been argued, that the Canaanites were guilty not only of the grossest idolatries, but of the most execrable vices, some of which have been thought to deserve death, and have been so punished in all civilized countries. God expressly declares, after warning the Israelites against these abominable crimes, that because of these things "he abhorred those nations and cast them out." Lev. xx. 23. It is plain, then, that the wick- edness of the Canaanites was the true cause of the punish- ment that was inflicted upon them; and accordingly it is given as a reason why they were not long before expelled and destroyed, that the "iniquities of the Amorites was not yet full." Gen. xv. 16. It was not, therefore, till the measure of their sins was completed, and their wickednesses became universal and incorrigible, that the threatened judgment was inflicted. Now it can be denied, that God, who is the sovereign arbiter of life, and who, may, and actually does, whenever he pleases, take away men's lives without injustice, may in such judgment cut short the lives of persons for their crimes, and bring general destruction even upon communities of people or nations? Why, it may be asked, should the destruction of a small part of the inhabi- tants of the earth be pronounced to be incompatible with the divine attributes, while the destruction of the whole world by the deluge is passed by without any comment? The general destruction of the human race in the latter case, and the partial extermination of the Canaan- ites, are to be accounted for upon precisely the same principle. In both cases it was the enormous wicked- ness of the people which drew upon them such signal punishment. This kind of punishment of individual or na- tional wick- edness may serve the purpose of instructive example and warning to the world in general; and in the case before us it was highly expedient, and even necessary for the instruction of that age of mankind, that the Supreme Ruler should make a signal and striking example of a nation so far sunk in idolatry and corruptions of all kinds, as all the inhabitants of Canaan are said to have been. With re- spect to the mode of the punishment of the Canaanites, it may be observed, that if God had destroyed them by famine or by pestilence, if he had caused fire from heaven to con- sume them, or exterminated them by an inundation or an earthquake, none could have preferred to arrogate the wisdom and justice of his proceedings; although in ex- emplifications of this public nature infants must have suffered with adults; and since the righteous individuals must have been involved in the common ruin. In such a case it could not have been said,
that this was contrary to the law of nature, or that it was not conformable to the usual conduct of Providence. But then it would not have been so apparent, that this calamity of their extermination was inflicted by way of punishment for their idolatry and detestable wickedness. It might possibly have been attributed to some natural cause, or have been regarded as an unaccountable and fortuitous event. But when they were ordered to be exterminated for their abominable crimes by an express command of God, attended by a series of the most amazing miracles and divine interpositions; and this was appointed to be executed by another nation, peculiarly set apart by their own constitution to the acknowledgment and worship of the one true God, and of him only, and to whom God had given the most excellent and holy laws, threatening them at the same time with similar punishments if they committed the like crimes,—in this case, the reason of the judgment was as apparent as when a malefactor is put to death by an officer of justice for a crime, in execution of the sentence of a just magistrate. Nor in such a procedure is there any thing, that can be proved to be inconsistent with the wisdom and righteous acts of the Supreme Being, or contradictory to his own laws; since there is no law of nature that dehors God from executing judgments on particular persons, or guilty nations, for their crimes and vices, even to extermination; or from employing, if he thinks fit, one or more nations to execute his judgments upon others. In this instance the word of God is in perfect harmony with his works and those manifestations of the divine attributes that are discernible in the book of nature.

Although God cannot dispense with the absolute and immutable obligations of doing whatever is just and right; yet a command from God may either make or imply some change in the circumstances and relations of things, on which the moral fitness of the human conduct depends, and consequently it may be fit and right to do that in virtue of a divine command, which it would not have been fit to do without it.

Lord Bolingbroke, indeed, (vol. iii. p. 206. vol. v. p. 148.) has compared the invasion of Canaan by the Israelites, and what they did there, to the cruelties exercised by the Spaniards in America, and to the ravages of the Huns under Attila, who, he says, were much more merciful than they; but he seems to forget the difference between these cases: viz. that the latter had no motive or pretence, but their own ambition, avarice, and cruelty; whereas the former acted in execution of the express command of God, and by a commission from him, the truth of which was confirmed by a series of the most extraordinary divine attestations that the world ever saw. This can, therefore, furnish no precedent for any other nation to do the like, except they can produce the same or equal proofs of a divine commission. The same general answer will suffice for obviating several of the inferences deduced from this event by Dr. Geddes, ubi supra. It would be a sufficient reason for the extermination of the Canaanites by the sword of the children of Israel, if, as is very possible, this was the best method of impressing the minds of the Israelites themselves with a just idea of the heinous nature of idolatry, and to make sufficient provision against their being induced into the same abominable practices. If their living only in the neighbourhood of idolatrous nations was so unsafe for this people, as their history shows it to have been, what danger would they not have been in, if they had spared the old inhabitants of Canaan, and suffered them to live unmolested among them? It ought also to be considered, that in all the other wars in which the Israelites might happen to be engaged, with their neighbouring nations, they were expressly enjoined to pursue different and more humane maxims, sparing all except such as were found bearing arms. In this particular case only they were expressly commanded to "exterminate utterly." That the Israelites were not influenced by the usual passions of conquerors, but acted under an authority which controlled their natural desires, is manifest from their sparing even the cattle, and even refraining to appropriate to themselves the treasures which they found in Jericho, which was the first fruits of their conquests, and to be devoted to God. The Israelites have often been compared to barbarous conquerors and cruel murderers; but let other conquerors and spoilers be produced, who refrained from plunder as they did. That they were not actuated by mere rage and revenge is evident from their having received no particular provocation, not indeed having had any personal intercourse with the inhabitants of Canaan. Their motives must, therefore, have been very different from those of common robbers and murderers; and in the judgment of reason, it is the motive that determines the nature of the action. It is also remarkable, that notwithstanding the passion which the Israelites may be supposed to have had for war, which would have been inflamed by the rapidity of their conquests, they were forbidden to extend them beyond the boundaries of the land of Canaan; and the constitution of their government was altogether unfitted to extensive empire.

The learned Mr. Bryant in his Treatise on the authenticity of the Scriptures, (p. 245. &c.) argues against the objections which we have been considering, that the Canaanites were usurpers, and had acted in direct defiance of an ordinance of God, by seizing upon the land appropriated from the beginning to the children of Israel. Moreover, according to the learned author, the land of Canaan was their peculiar inheritance, Deut. xxxii. 7, 8. In the Eusebian Chronicle of Scaliger it is mentioned, that Canaan the son of Ham, first made an innovation in the world. "He transgressed upon the rights of his brethren, and seized upon the land, which had been appropriated to God's future people." When the Israelites, therefore, were brought to Canaan, they came to their own inheritance, and those who usurped their property knew it, and knew by whom it had been appointed.

After all, we may observe, that the order to exterminate utterly in the case of the Canaanites, though expressed in absolute terms, is supposed by some to have been conditional in fact; and that their lives were to have been spared upon their submission, and especially upon their forsaking idolatry. Accordingly, it is plain in fact, that the Israelites either did not understand the command to be absolute, or they knowingly transgressed it, even in the most and most flourishing part of their affairs. To this purpose we have already remarked, that many of the Canaanites lived in subjection to the Israelites even to the times of their kings (1 Kings ix. 20, 21.) nor do we ever read that they were blamed for the favour they showed them. Moreover, the reason and end for which the order for the extermination of the Canaanites was given, viz. left the children of Israel should be checked by them into idolatry, entirely cut off from their submision, and abandoning their idol worship, which was generally the case. Besides, it is pretty clearly inferred, that this order was conditional, from the circumstances, that if the hearts of the Canaanites had not been hardened to oppose the Israelites, they would not have been cut off. Josh. xi. 20, 25. Accordingly it has been alleged, that the severity of the judgments inflicted upon the Canaanites for their extreme wickedness, of which the Israelites were the instruments, was not executed in the degree of
to the extent which has been supposed. This has been maintained with great strength of argument by learned and impartial judges; by Maimonides and others of the full account among the Jews, and also by many Chriftians of our own and other countries. Grubbis, in particular, on Deut. xx. 10. maintains, that the law, Exod. xxxii. 31, 32. and Deut. vii. 2, was to be extended only to future people as did not surrender themselves on being summoned: as is evident from Joshua xi. 19, 20. We shall further add, that idolatry, under the Jewish theocracy, was a crime of peculiar malignity; and therefore, although God has not thought fit to enact a general law obligatory on all mankind for punishing idolaters with death, and without his appointment it might not be executed; yet when it pleased him for wise ends to select a particular nation, and among them to erect a peculiar sacred polity, and to appoint that the worship of the one true God and of him only should be the very basis of their constitution, on which all their privileges, their national property, and their right to their country depended, it is evident, that under such a constitution to revolt to idolatry and polytheism was in the most criminal sense to be traitors to the community: and of course to arraign a law for inflicting a capital punishment upon idolaters under that particular constitution is highly absurd. Nor should it be forgotten, that the idolatry of the ancient Gentile world, and especially that of the inhabitants of Canaan, was by no means a fyllem of merely speculative opinions; but a course of the most atrocious and abominable practices, enjoying the cruel murder of numberles innocent children, as well as other human victims, and the most shocking lownefs, together with other vices of the most detestable nature. And surely it becomes a wise legislator and the moral Sovereign of the universe to restrain, by the most authoritative and awful sanctions annexed to his laws, the commission of such destructive vices as these.

Mr. Wakefield, in his "Reply to the Second Part of the Age of Reason," by Thomas Paine, suggests, that some qualifications and softening in the cafe of many relations and occurrences in the scripture history, may be properly admitted, without any danger to the main fabric of revelation, upon the ground of exaggeration from national vanity, and the pride of individuals. Hence, he says, we may presume upon enlargement in the part of the narrative on the splendour of their victories, the number of the slain, and the extent of their defolations. He further intimates, that the Jewish historians had been accustomed to speak of every tranflation as preferred by the exprefs injunctions of Jehovah, when we are under no necessity, as he conceives, of supposing a specific and actual interference in the cafe, but may very rationally, and in conformity to the rules of accepted interpretation, have recourse for a solution to that predominant and universal persuasion, from their infancy, of the peculiar superintendence of Jehovah, not only over the political welfare of their state, but the private concerns of individuals. He adds, that it is a point worthy of investigation how far Joshua, and his fellow fuditors, in conformity to the ferocious character of the times, and the fanguinary propensities of military men, may actually have exceeded their commission, and indulged themselves in unauthorized acts of murder, rapine, and devastation. Having collected a variety of opinions on this interefting subjeft, we must refer for a further discussion of it to the authors already cited, and to the following publications: Leland's Anfwer to Chriftianity as old as the Creation, vol. ii. p. 429, &c. Leland's Deific Writers, vol. ii. p. 446, &c. Prieftley's Institutes, vol. ii. p. 22, and Prieftley's Notes on all the Books of Scripture, vol. i. Preface, Sermons, &c. by Joseph Nicol Scot. vol. i. Lindley's Conversations on the Divine Government, p. 80—83. Bifhop of Lincoln's Elements of Chriftian Theology, vol. i. p. 70, &c.

**CANADA.**

In the year 1759 Quebec was captured by General Wolfe; and Canada was ceded to Great Britain by the treaty of Paris in 1763. From this period till the year 1774 the internal affairs of the province were regulated by the ordinance of the governor alone. In pursuance of the Quebec bill, which was then passed, a legislative council was appointed by his majesty, and the number of its members was limited to twenty-three. But by an act passed by the British parliament in 1791, the executive power in each province was vested in the governor; and a legislative council, and an assembly, were appointed for each of the provinces of Upper and Lower Canada, having power to make laws with the consent of the governor; but the king may declare his dissent at any time within two years after the bills are received, in which case they become void. The legislative council of Lower Canada consists of 15 members; that of Upper Canada of seven. They are summoned by the governor under the king's authority, and appointed for life, unless they forfeit their office by an absence of four years.
years, or by swearing allegiance to any foreign power. The assembly of Lower Canada consists of 50 members, and that of Upper Canada of 16; and they are chosen by the freetholders in the towns and districts. The assembly is not to continue longer than four years, but it may be dissolved sooner; and the governor is bound to convene it at least once in each year. The governor, together with such of the executive council, as shall be appointed by the king for the affairs of each province, are to be a court of civil jurisdiction for hearing and determining appeals; subject, however, to such appeals from their sentence as heretofore existed. All lands in Upper Canada are to be granted hereafter in free and common fociage; and also in Lower Canada, when the grantee shall define it, subject, nevertheless, to alterations by an act of the legislature; and the present system of judgement in each province was established by the Quebec bill of 1774. But whilst the French laws were suffered by the Quebec bill to be stricken, in order to conciliate the affections of the French inhabitants, who were attached to them, although the abolition of these laws would be favourable to the interests of civil liberty; the criminal law of England was happily elaboured through every part of the country. The whole of British America, Canada included, is superintended by an officer styled governor-general of the four British provinces in North America, who, besides other powers which he possesses, is commander in chief of all the British troops in the four provinces, and the governments attached to them, and Newfoundland. Each of the provinces has a lieutenant-governor, who, in the absence of the governor-general, is invested with all the powers requisite to a chief magistrate.

By an act passed in the 18th year of his present majesty's reign, the British parliament has the power of making any regulations, that may be found expedient, respecting the commerce and navigation of the province, and also of importing, export duties, retributed to the use of the province, and applied in such a manner as the laws made in the council and assembly direct.

Every form of religion is completely tolerated in both provinces; but the Roman catholic religion is that of a great majority of the inhabitants; and by the Quebec bill of 1774, ecclesiastics of that persuasion are legally empowered to recover all the dues, which, before that period, they were accustomed to receive, as well as tithes, from the Roman catholic inhabitants; nevertheless, they cannot exact any dues or tithes from Protetants, or from lands held by Protetants; although such lands might formerly have been subjected to dues and tithes for the support of the Roman catholic church. These dues and tithes are, however, still to be paid to persons appointed by the governor and reserv'd in the hands of his majesty's receiver-general, for the support of the Protetant clergy actually residing in the province. By the act of the year 1791, it was also ordained, that the governor should allot out of all lands belonging to the crown, granted after that period, one-fourth of the benefit of the Protetant clergy, to be solely applicable to their use; and it is required that all such allotments should be particularly specified in every grant of wattle-lands; otherwise the grant is void. The governor, with the advice of the executive council, is authorized to constitute parishes or rectories, and to endow them out of these appropriations, and to present incumbents to them, ordained according to the rites of the church of England. The clergy of this church, in both provinces, consist at present only of 12 persons, including the bishop of Quebec; whereas those of the church of Rome amount to 130, viz., a bishop, three vicars-general, and 116 curates and missionaries, all of whom are resident in the lower province, except five curates and missionaries. The number of the dissenting clergy, in both provinces, is considerably smaller than that of the clergy of the church of England.

The population of Upper Canada has been lately stated to amount to 40,000, by others to 20,000 British and French inhabitants, exclusive of 10,000 loyalists, who are settled in the upper parts of the province. Lower Canada, according to a census, ordered to be taken by general Haldimand in 1784, contained 11,928 inhabitants. Both provinces may probably now contain more than 50,000 persons; and their number is multiplying both by a natural increase and by emigrants from other countries. The number of savages has been estimated at 50,000. About nine-tenths of the inhabitants of these provinces are Roman catholics; and about five-sixths of those of Lower Canada are supposed to be of French extraction. Some of the lower classes of the French Canadians possess all the gaiety and vivacity of the people of France; but others have, to appearance, a great deal of that lowness and bluntness in their manners which is characteristic of the people of the United States. vanity, however, is the predominant feature in the character of all of them. Few of the men can read or write, and in this respect are more inferior to the women; but both men and women are fond in ignorance and superstitious, and blindly devoted to their priests. The French language is universally used; English being restricted to the few British settlers. The houses in Lower Canada are in general well furnished with beds, in the French style, very large, and raised four or five feet high. The houses are for the most part built of logs; but they are much more compact and better constructed than those of the United States; the logs being fitted more closely together, planed and white-washed externally, and generally lined with deal boards within. However, the inattention of the inhabitants to the admittance of air, by occasionally opening their windows, renders them very disagreeable and even unhealthy. The expences of the civil lift in this province are estimated at 20,000l. per annum, one-half of which is defrayed by Great Britain, and the other moiety by the province, out of the duties paid on the importation of certain articles, such as spirits, wine, sugar, molasses, coffee, tobacco, salt, and spirts of various kinds. The expences of the civil lift in Upper Canada is estimated at about a fourth of that of the lower province. The military establishment in both provinces, together with the repairs of fortifications, &c., is computed to cost Great Britain 100,000l. annually; and the like sum is chargeable for presents to the Indians, and salaries to officers employed among them in trade, &c., in Upper Canada. These expences, however, are thought to be counterbalanced by the advantages of the commerce with this country, which is paid to employ about 7000 tons of shipping annually. The imports into Canada consist of earthen-ware, hard-ware, and household furniture, various articles of woollen, linen, and cotton, haberdashery, holiey, &c. stationery, leather, and its manufactures, gro-cery, wines, spirits, West Indian produce, &c. &c. cordage of every description, and the coarse manufactures of iron. Some domestic manufactures of linen and of coarse woollen cloths are carried on in molt parts of Canada; but the greater part of these articles is supllyed by Great Brit-ain. The exports from Canada consist of wheat, flour, biscuit, timber, flaxes, and lumber of various kinds, dried fish, oil, ginifeng, and various medicinal drugs, but principally of furs and peltries. The eastern part of Lower Canada, between Quebec and the gulf of St. Lawrence, is mountainous; and a few scattered mountains also occur between Quebec and the mouth of the river Utawas; but higher up the river St. Lawrence the face of the country is flat. The soil consists principally of a loofe dark-coloured earth.
C A N A D A.

carr, 10 or 12 inches deep, lying on a bed of cold clay. This thin mould, however, is very fertile, and yields plentiful crops, although it is worked every year by the French Canadians, without being ever manured. The manure chiefly used, since the practice of manuring has been introduced, by those who are the best farmers, is marl, which is found in great quantities in many places along the shores of the river St. Lawrence. The soil of Lower Canada is peculiarly adapted to the growth of small grain. Tobacco also thrives well in it, but the culture is neglected, except for private use; and more than half of what is used is imported. The snuff produced from the Canadian tobacco is held in great estimation. Culinary vegetables arrive at great perfection in Canada, which is also the case with most of the European fruits. The currents, gooseberries, and raspberries are very fine; the latter are indigenous, and are found very abundantly in the woods. A kind of vine is also indigenous; but the grapes produced by it in its uncultivated state are very poor and few, and not much larger than fine currants. In the forest there is a great variety of trees; such as beech, oak, elm, ash, pine, lycamore, chestnut, and walnut; and the sugar maple-tree is found in almost every part of the country. Of this tree there are two kinds; the one called the swamp maple, being generally found on low lands, and the other, the mountain or curled maple, from its growing upon high dry ground, and from the grain of its wood being beautifully variegated with little stripes and curls. The former yields more sap than the latter, but its sap affords less sugar. A pound of sugar is frequently procured from two or three gallons of the sap of the curled maple, whereas no more than the same quantity can be had from six or seven gallons of that of the swamp tree. The maple sugar is the only sort of raw sugar used in the country parts of Canada, and it is also very generally used in the towns. See Sugar.

The air of Lower Canada is very pure, and the climate uncommonly salubrious, except in the western parts of the province, high up the river St. Lawrence. From Montreal downwards the climate is very much resembles that of the states of New England. This difference of salubrity in the two parts of the province is ascribed by Mr. Weld to the different aspects of the country; to the east, Lower Canada, like New England, is mountainous, but to the west it is an extended flat. According to his account, the extremes of heat and cold are amazing; Fahrenheit's thermometer, in the months of July and August, rising to 96°, and yet in winter the mercury generally freezes. The transitions from heat to cold are less sudden, and of course less injurious to the constitution in Canada than in the United States; and the seacons are much more regular. The snow begins to fall in November; which is the most unpleasant, cold, and gloomy part of the year: but in December the clouds are generally diffused, the frost sets in, and the sky assumes a bright hue, continuing for weeks without a single cloud. The greatest degree of cold occurs in January, and it is sometimes so intense, as to endanger a person, who is exposed to it, being frost-bitten; but the coldest days have intervals of warm weather. The winter in Canada is the season of general amelioration; and the Canadians transport themselves over the snow by means of their cariolas and sledges, each of which holds two persons and a driver, and is usually drawn by one horse, with woolen clothed bases, as well as great pleasure. With the same horse, says Mr. Weld, it is possible to travel 80 miles in a day. The Canadians contrive to guard against the cold by several robes placed in their huts, from which flues pass to their different apartments, and by double windows and double doors to their houses. When they go abroad, they cover the whole body with furs, except the eyes and nose. In May the thaw comes on very suddenly, and in its progress, the ice in the river St. Lawrence breaks with the noise of a cannon, and pades towards the sea with a tremendous rapidity and violence. As soon as the winter terminates, the rapid progress of vegetation is astonishing. Spring has scarcely appeared before it is succeeded by summer. In a few days the fields are clothed with the richest verdure, and the trees regain their foliage. The grain is found in grain time in May affords a rich harvest by the latter end of July. At this season of the year, however, Fahrenheit's thermometer seldom rises above 84°; in July and August it sometimes rises to 96°. The fall of the year is a most agreeable season in Canada, as well as the summer. It is observed, that there is in general a difference of about three weeks in the length of the winter at Montreal and at Quebec; and of course in the other seasons. When green peas, strawberries, &c. were entirely grown at Montreal, they were in full season at Quebec.

Mr. Weld, to whom we are indebted for a great part of this article, (see his Travels, vol. i.) has pointed out some inconveniences attending the tenures of land in Canada, which ought to be removed; more especially as in such a climate there is no occasion for a barrier against colonization. The botany of Canada differs little from that of the United States; and the chief singularities in the zoology are the moose, the beaver, and some other animals described by Mr. Pennant in his Arctic zoology. The reindeer appears in the northern parts, and the puma and lynx are not unknown. Both the Canadas are much infected with rattle-snakes. The humming bird is not uncommon at Quebec. The mineralogy is of little importance; and though iron ores have been discovered in various parts of the country, works for the smelting and manufacturing of it have been erected only at one place, in the neighbourhood of Trois Rivières. The works are now the property of the British government. The bank of ore that supplies them is nearly exhausted. We learn from Kalm (vol. ii. 349.) that there are lead mines which yield some silver; and it is probable that copper may be found, as it appears in the south-west of Lake Superior. Coal has not yet been discovered in Canada. The country soil remains to be examined, and it is highly probable that important discoveries might be made. Its chief natural curiosities seem to be its rivers, lakes, and cataracts.

One of the most remarkable accidents which history records of this country, provided that it were satisfactorily ascertained, is the earthquake of the year 1663, which is said to have overwhelmed a chain of mountains of free-stone more than 300 miles long, and changed the immense tract into a plain. We shall enumerate and describe the principal towns, lakes, rivers, and cataracts of this country in their proper places.

Canada, bay of, lies on the east side of the island of Newfound, between White and Hare bays, which last lies north of it.

Canada creeks are three creeks of North America; one a water of Wood creek, which it meets four or five miles N. N.W. of Fort Stanwix, or New Fort Schuyler. The other two are northern branches of Mohawk river; the upper of which mingles its waters with the Mohawk in the township of Herkimer, on the German flats, 16 miles below Old Fort Schuyler, and is crossed by an ingeniously constructed bridge; the other empties into the Mohawk 13 miles below. Both these creeks are long, rapid, and navigable streams, and supply the Mohawk with a considerable accession of water. The lands adjoining them are rich and valuable, and furnish inviting settlements.

Canada, sea of, or sea of Huron, a name which might be given to the large inland sea, that is formed by the lakes,
Superior, Michigan, and Huron, and which is about 350 miles in length, and more than 100 at its greatest breadth. See each of these articles.

**CANADA Saginaw lake. See SAGINAW lake.**

**CANADENSIS, in Ornithology, a species of Tetrao, that inhabits Hudson's bay. The tail feathers are black, and at the tip tawny, and near the eyes are two white stripes. Ginel.** This is supposed by late authors to be the male bird of the Linnaean Tetrao CANACE, which is described as having the tail entire, with a white spot behind the claws and nofilis. Syst. Nat. ed. 12.

**CANADENSIS, a species of Axdea, or Heron of the hard kind, distinguished by the name of the brown crane of Canada among Hebrew authors. The forehead is naked and papillous; body cinereous; wings tellacious on the outside. Ginel. Obi. This is the brown and ash-coloured crane of Edwards, La Grue brune de Buffon, and La Grue de la Baie d'Hudson of Brissot.**

The length of this bird is three feet three inches. Bill three inches and three quarters long, of a dusky colour, with the tip of the upper mandible pale flesh colour. The top of the head is covered with a red skin thinly befeft with hairs; checks and throat whitish; head and neck cinereous; upper part of the back, fcapulars, and wing-coverts pale rufous margined with brown; breast, belly, thighs, and fides ash-coloured; tail deep ash; legs and bare part of the thighs black. This bird is peculiar to America. It subsists on corn, and Indian maize occasionally. Among the natives of North America it is known by the title of Samak-uchcheaux.

**CANAJOHARY, in Geography, a post-town of North America in Montgomery county, New York, seated on the south side of Mohawk river, and comprehending a large district of fine country; 40 miles W. of Schenectady, and 56 miles from Albany. In the late census of 1790, 730 of the inhabitants appear to be electors. A creek of the same name enters the Mohawk in this town. This was the principal post of the Mohawk Indians, and abounds with apple-trees of their planting, from which is made excellent cider.**

**CANAKAMPALEAM, a town of Hindooftan, in the Mysore country; 12 miles E. of Satticamugurn.**

**CANAL, Canal, in general, denotes a long, round, hollow instrument, through which a fluid matter may be conveyed. In which sense, it amounts to the same with what we otherwise call a pipe, tube, channel, &c. Thus the canal of an aqualung, is the part through which the water passes; which, in the ancient edifices of this kind, is lined with a coat of malleable of a peculiar composition.**

**CANAL, a duct or pipe (as its derivation from the Latin Caue, a cane, or reed, leems to imply), in which sense it is used by anatomists in describing the passage through which some of the animal fluids pass: the term Canal has also been applied to denote any piece of water, especially if of a considerable length in proportion to its width, and especially such as are navigable, or have not the fall and natural motion which rivers have. Canals may be either for pleasure or ornament, such as are common in the vicinity of palaces and great houses; or applied to the purposes of inland navigation. The artificial carriages for conveying streams of water for the supply of cities or other purposes, as was done by the famous aqueducts of antiquity, and in modern times by the new rivers near London, and others, have sometimes also been called Canals.**

**The importance and utility of canals have been so long and so generally acknowledged, that it is hardly necessary to introduce the subject with any observations to this purpose. Few persons have more attentively considered or better understood the political and commercial interests of nations than the late Dr. Smith; and no one could be a more zealous advocate for the extension of inland navigation, as an effectual means of improving the country, in which it is encouraged. To this purpose he observes, in his 'Wealth of Nations' (vol. i. p. 297), that good roads, canals, and navigable rivers, by diminishing the expense of carriage, put the remote parts of the country more nearly upon a level with those in the neighbourhood of large towns; and on that account they are the greatest and all improvements. They encourage the cultivation of the remote parts, which must always be the most extensive circle of the country. They are advantageous to towns, by breaking down the monopoly of the country in its neighbourhood; and they are advantageous to all parts of the country, for though they introduce some rival commodities into the old markets, they open many new markets to its produce. "It is not more than 50 years ago," says he in 1776, when the first edition of his work was printed, "that some of the countries in the neighbourhood of London, petitioned the parliament against the extension of the turnpike roads into the remoter counties. Those remoter counties, they pretended, from the cheapsale of labour, would be able to sell their grain and corn cheaper in the London market than themselves, and would thereby reduce their rents, and ruin their cultivation. Their rents, however, have risen, and their cultivation has been improved since that time." "All canals," says an intelligent writer on this subject (See Phillips's General History of Inland Navigation, Intro.), "may be considered as so many roads of a certain kind, on which one horse will draw as much as 30 horses on ordinary turnpike roads, or on which one man alone will transport as many goods as three men; and 15 horses usually do on common roads. The public would be great gainers were they to lay out upon the making of every mile of a canal twenty times as much as they expend upon a mile of turnpike road; but a mile of canal is often made at a less expense than the mile of turnpike. Consequently there is a great inducement to multiply the number of canals."**

The advantages resulting from canals, as they open an easy and cheap communication between distant parts of a country, will be ultimately experienced by persons of various descriptions: and more especially by the manufacturer, the occupier or owner of land, and the merchant. The manufacturer will thus be enabled to collect his materials, his fuel, and the means of subsistence, from remote districts, with less labour and expense; and to convey his goods to a profitable market. As canals multiply, old manufactures revive and flourish, new ones are established, and the adjoining country is rendered populous and productive. To the occupier of land, canals are useful in a variety of ways. In some cases, they serve the purposes of draining and of irrigation; in others, they furnish manure at a cheap rate; and they facilitate the conveyance of the produce to places where it may be disposed of to the greatest advantage. The land-owner must of course be benefited, by the increasing value and advanced rent of his estate, in consequence of the improvement it receives from the utility of the occupier, excited and encouraged by an immediate recompense. The wholesale trader and merchant are likewise enabled to extend their commerce by means of canals; as they can thus export greater quantities and varieties of goods from places remote from the sea, and easily supply a wider extent of inland coun-
country with the commodities that are imported from foreign nations. Nor are they merely the means of extending and increasing foreign commerce, but they serve also to create and augment an internal trade, which, with all the advantages attendant on foreign commerce, may probably far exceed it in extent, value, and importance. We might add, that an inland communication between parts of a country, at a great distance from one another, contribute to the security, as well as to the extension of commerce, in the boisterous months of winter, and in times of war, when the navigation of the seas would be attended with danger. "Were we to make the supposition of two states," says Mr. Phillips (ubi supra), "the one having all its cities, towns, and villages upon navigable rivers and canals that have an easy communication with each other; the other possessing the common conveyance of land-carriage; and supposing, at the same time, both states to be equal as to soil, climate, and industry; commodities and manufactures, in the latter state, might be exported 30 per cent. cheaper than in the latter; or, in other words, the first state would be a third richer and more affluent than the second." Should it be objected, that navigable canals waste or occupy too great a portion of land in the countries through which they pass, the objection may be obviated by the consideration, that one mile of a canal, 14 yards wide, takes up little more than five acres of land.

If we advert to fact, and consult the records of history with regard to the state of different nations, we shall find, that civilization and commerce have very much depended on the facility with which the inhabitants of remote districts have maintained intercourse with one another, as well as with distant countries. As the ocean serves to connect distant countries, navigable rivers and canals unite the different provinces and districts of the same country; and as navigation, by means of the ocean, produces an intercourse and mutual exchange of productions between different kingdoms, inland navigation, in like manner, facilitates a communication between different parts of the same kingdom, and consequently promotes trade and industry. In North America, the plantations have constantly followed either the sea-coast or the banks of the navigable rivers, and have formerly any where extended themselves to any considerable distance from the one or the other. The nations that appear to have been first civilized, were those that dwelt round the coast of the Mediterranean sea, which, from a variety of circumstances, was extremely favourable to the early navigation of the world. Of all the countries on the coast of the Mediterranean, Egypt seems to have been the first, in which either agriculture or manufactures were cultivated and improved to any considerable degree. Upper Egypt extends itself nowhere above a few miles from the Nile, and in Lower Egypt that great river breaks itself into many different canals, which, added by a small degree of art, seem to have afforded a communication by water-carriage, not only between all the large towns, but between all the considerable villages, and even to many farm-houses in the country: yearly in the same manner as the Rhine and the Maesë do in Holland at present. The extent or facility of this inland navigation was probably one of the principal causes of the early improvement of Egypt. The improvement in agriculture and manufactures seems likewise to have been of very great antiquity in the provinces of Bengal in the East Indies, and in some of the eastern provinces of China. In Bengal, the Ganges and several other large rivers form a great number of navigable canals, in the same manner as the Nile does in Egypt. The same is the fame in the eastern provinces of China, where several large rivers form, by their different branches, a multitude of canals, and by communicating with one another afford an inland navigation much more extensive than that either of the Nile or the Ganges, or perhaps of both of them united. It is remarkable, however, that neither the ancient Egyptians, nor the Indians, nor the Chinese, encouraged foreign commerce; but they all seem to have derived their extraordinary opulence from this inland navigation. On the other hand, those nations that have been delirious of the means of inland navigation, either by rivers or canals, have remained from one age to the other in the same barbarous and uncivilized state. This observation is exemplified in the state of all the inland parts of Africa, and of that part of Asia which lies at any considerable distance north of the Euxine and Caspian sea, the ancient Scythia, and the modern Tartary and Siberia. The commerce that may be carried on by means of a river, which does not break itself into any great number of branches or canals, and which runs into another territory before it reaches the sea, can never be very considerable; because it is always in the power of the nation who possesses that other territory to obstruct the communication between the upper country and the sea. Thus the navigation of the Danube is of very little use to the different states of Bavaria, Austria, and Hungary, in comparison of what it would be if any of them possessed the whole of its course till it falls into the Black Sea. To these general observations, we shall furnish a brief account of the principal canals that have been formed among the nations of antiquity, and among foreign nations in later times; reserving the principal part of this article for an enumeration of the canals of our own country, and for an illustration of the principles on which they are constructed, the regulations to which they are subject, and the various uses to which they are applied.

In the history of ancient nations we discover various trances of canals, formed for military, agricultural, commercial, or other purposes. The "foroantes Philistina" of Pliny (l. iii. c. 16.), which were large canals at the mouth of the Eridanus in Liguaria, are ascribed by Mr. Bryant to the Ca naenites, and particularly to the Caphtorim, who at a remote period migrated from Philistia; and hence these outlets of the river were named "Philistia." We learn from Herodotus (l. i. c. 174.) that the Cnidians, a people of Caria in Asia Minor, formed a design of digging a channel through the Íthmus which joined their territory to the continent; but they relinquished the undertaking, because they were interdicted by an oracle. Strabo informs us (l. ix. p. 465, &c.), that canals and pits were dug in Bactia, at a very remote period of antiquity, for drawing off the water of the lake Copais, which would otherwise have overflowed the whole country. This lake near the sea terminates in three bays, which advance to the foot of mount Pitous, situate between the sea and the lake. From the bottom of each of these bays numerous canals were made to diverge and traverse the mountain through its whole breadth, some of which were more than a league in length, and others of a much greater extent. For the purpose of excavating or of cleaning them, very deep wells had been sunk at slanted distances on the mountain. The labour of forming and the expense of maintaining these canals must have been immense. They have since been almost wholly neglected, so that most of them are choked up, and the lake seems to be gaining on the plain. The inhabitants of Babylonia or Chaldæa guarded against the detrimental inundations of the Tigris and Euphrates by a great number of artificial rivers and canals, which served to distribute the waters, to benefit the country in
in general, and to effect an easy communication and intercourse between the occupiers of different parts of the country. The Euphrates, according to Ptolemy (l. v. c. 17.), above Babylon, near a town in Mesopotamia, called Siphiara, divides itself into two branches, one running to Babylon, and the other to Seleucia, where it falls into the Tigris.

The latter, from Pliny (l. xi. c. 26.), was partly artificial; and he places Seleucia at the commencement of the Tigris, adding that the Euphrates was conveyed to it by a canal. Ptolemeus, (Cons. h. i. part. ii. p. 107;) on his authority, supposes that branch to have been artificial, and ascribes it to Nebuchadnezzar. Between these two branches an artificial canal was cut from the Euphrates, above Babylon, to the Tigris at Apamea, 60 miles below Seleucia. This canal, which was large and navigable, was called Naxorabdris, which see. From the Naxorabdris the emperors Trajan and Severus, in their wars with the Parthians, dug a new canal to the Tigris, near Cocius on the wall, and Tersiphon on the call side of that river. At the distance of 500 furlongs from Babylon, to the south was another canal, called by Arrian (Exped. Alex. l. vii.) Pallacippus, and by Appian (Bell. Civil. i. ii.) Pallacippus, derived from the branch of the Euphrates that fell through Babylon and conveyed water to certain lakes or marathes in Cilicia. On this canal, or river, as Arrian calls it, Alexander failed from the Euphrates to these lakes. Strabo (l. xvi.) describes the course of this canal, without naming it. But it is impossible to trace out, with accuracy, thele and the other numerous branches and canals which watered the ancient country of Babylon, which see. Many of those that were formerly considerable are now lost; and others have been formed since, that did not exist in ancient times; for a country so much watered, so low in situation, and so subject to the violence of extraordinary inundations from the two large rivers, the Tigris and Euphrates, and so neglected as it has been for several ages, must have often and very considerably changed its face since the time of Ptolemy; and it is almost impossible to describe it as it was while it continued to be the seat of empire, when the inhabitants were rich enough to take care of its numerous banks, and to keep them in repair. See BABYLONIA.

Both the Greeks and Romans proposed to make a canal across the isthmus of Corinth, which joins the Morea and Achaia, and thus to make a navigable passage by the Ionian sea into the Aegea. Demetrius Poliorcetes, Julius Caesar, Nero, and Caligula renewed the attempt, but without success. Plin. l. iv. c. 2. After the death of Alexander the Great, Seleucus Nicanor attempted to make a canal between the Euine and Caipian seas, but he undertaking proved abortive. Travellers, however, assure that traces of very deep vallies are to be seen, through which the canal is said to have passed. Selim III. and Peter the Great, renewed the attempt, but they were prevented from succeeding, not so much by the impracticability of the scheme as by other collateral circumstances. The Romans, more intent on conquests than on commerce and the arts, afforded us few instances of canals for internal navigation. We find, however, that Drusus, under the emperor Augustus, having conceived the design of marching into Germany without harrying his troops by a long and difficult march, facilitated the execution of it by making a canal that communicates from the Rhine with the Ielch, extending from the village of Egelto to Doebourg. This canal received a great part of the waters of the right branch of the Rhine, which became by that means much less considerable. At the same time he opened a third mouth from that river into the sea, mentioned by Pliny under the name of "Fluviam Olifium." But the face of the country has been much altered from that time. Lu...
Necos, the son of Pharnamcticus, and continued by Darius king of Persia; but left imperfect in consequence of the advice of some persons who affected that it would lay Egypt under water, because the land was below the level of the Red sea. Ptolemy II., however, finished the undertaking, and constructed, in the most convenient part of the canal, a dam, or sluice, ingeniously contrived with pipes and sluices, and immediately closed again. Hence the river which discharges itself into the sea, near the city of Arisinoe, has received the name of Ptolemy. From this sluice, says baron De Tott, it is plain, that the sluices still existed in the time of Diocondus. The entrance of the canal near Suez yet remains, and might easily be restored navigable, without employing sluices or locks, as the difference of the level is very small, and without endangering Egypt with inundations. This part of the illusmus, says the baron, affords land very favourable for such an excavation, through the small interval of 12 leagues, which separates the Arabian gulf from the arm of the Nile which approaches it; and afterwards falls into the Mediterranean at Timch. Strabo adds (ubi supra) that this canal was afterwards cleansed by Trajan. Its width, being 100 cubits, of 22 inches to a cubit, was sufficient for admitting the passage of two galleys abreast; and its depth was such as to bear the largest vessels. Phiny, in his account of this canal, (lib. vi. cap. 29.), states its breadth at 100 feet, its depth at 40, and its length to the bitter fountains (near Arisinoe) at 37 miles. By means of this canal, the valuable commodities of India, Persia, Arabia, and the kingdoms on the coast of Africa, which were brought by sailing to the Red sea, were conveyed to the Nile; and thence distributed by the Mediterranean not only to Greece and Rome, but to all the surrounding nations, until the Portuguese discovered a passage to India by the Cape of Good Hope. It did not, however, long serve the useful purposes of commerce, which were at first expected. Merchants were dissatisfied with the delay occasioned by going to the very bottom of the gulf, and afterwards with the inland navigation of the canal, and that of the Nile, to Alexandria. They found it much more expeditious to unload at Berenice, near the coast of the Red sea (see Berenice) and after three days' journey, to send their merchandise directly down to Alexandria. Accordingly, this canal was disused, and goods were conveyed from Berenice to the Nile by land; a mode of conveyance occasionally used at this day. Strabo and others have asserted, that this canal was again opened about the year 635, by Amru, governor or prefect of Egypt, under the caliph Omar, for the conveyance of the corn of Egypt to Arabia, which was then grievously distirred by a famine. Elmacin, or Al Makin, says, that a new canal was opened for this purpose, and called by Amru the river of the emperor of the faithful; but it has been more generally supposed, that he only restored the ancient canal, the navigation of which, towards the decline of the Roman empire, had been much neglected. The authors of the Modern Universal History (vol. i. p. 333.) discred the relation of Elmacin and Eutychius; and allege that there never was any passage for vessels dug between the towns of Al Pollat, on the eastern bank of the Nile, and Al Kolzom or Colzum on the Red sea. The river, or rivulet, denominated by them the river of the emperor of the faithful, may these authors, was undoubtedly no other than the Amnis Trajanus of Ptolemy, or the Khalig, which annually supplies the city of Cairo, as well as the neighbouring country with water. For the present state of this canal, see Cairo. They suppose, therefore, that, on the occasion now referred to, the caliph Omar ordered Amru to make the Khalig more navigable, by clearing it of the gravel or sand with which it was then choked up; and that, for this reason, it received the name of the river of the emperor of the faithful. Elmacin further informs us, that the Alexandrian canal was flopped again, at the end next the Red sea, by the caliph Abu Jaafar, or Almanzor, in the year of the Hegira 150, A.D. 767. Some traces of this canal arc still fulfilling; and M. Boutier, in 1762, discovered that end of it, which riles out of the most easterly branch of the Nile. Hist. Acad. Sc. for 1763, p. 115, &c.

The canal of Alexandria, cut from the Nile to this city by Ptolemy, during the inundation of the Nile, receives its water at Latf, opposite to Founah, and has three bridges over it, of modern construction. Near the former, by the sea-fide, is the entrance of the subterraneous aqueduct, that carries a supply of water for the Alexandrians into the cillerns, the arches of which supported the whole extent of the ancient city, but they are now incapable of being traced out. The mouth of this aqueduct is now blocked up; but when the water of the canal had arrived to a certain height, in consequence of the rise of the river, the principal magistrates of the city went in great ceremony to break down the dam. When the cillerns were full, it was again built up, and the water of the canal continued to fall into the fan at the old port. It was by this easy communication that merchandise was formerly conveyed through Egypt. The dangerous passage of the mouth of the Nile was thus avoided, as well as the perils of the sea. But beside furnishing the city with water, and facilitating its commerce, this canal, which passed along the upper part of the cultivated lands, on the left hand of the Nile, contributed very much to their fertility. In process of time it was shamefully neglected. However, it was cleansed by order of Bonaparte, in his irruption into Egypt, as far as Rhamania. See Alexandria.

Egypt is intersected in various directions by many other canals. Several of them issue from that arm of the Nile which runs to Damietta, and contribute to facilitate the province of Sharkin, which, making part of the illusmus of Suez, is the most considerable of Egypt, and the most capable of a great increase of cultivation. Others run through the Delta, and of these, says baron De Tott, many are navigable. The canal of Menouf communicates with the two branches of the Nile, 10 leagues below the angular point, called the "Belly of the cow." See Menouf. The canal of Bahira proceeded from the lake Marcotis, near Alexandria, and having sent off branches which joined the western branch of the Nile at Eihim, Shabur, and Nadir, passed on to Upper Egypt. The other principal canals of Egypt will be mentioned in connexion with the towns or districts to which they belong.

There is no country on the face of the globe that abounds more with canals and navigable rivers than China: to which article we shall refer an account of its inland navigation. Hindooftian likewise furnishes instances at a remote period of the acknowledged importance and utility of canals. As the country between Delhi and the Panjab was formerly supplied with water, the emperor Feroce I., who died in 1388, undertook, says major Rennell (Memoir, p. 71.), the noble, as well as useful, task of supplying it better, and at the same time of applying the water, so furnished, to the purposes of navigation.

The immediate object of the canals, projected and executed by Feroce, for an account of which we refer to Ren- niel (ubi supra) seems to have been the junction of the Seo- lege and Jumna rivers, through an interval of 240 geographical miles, and remotely that of the Indus and Ganges. If this grand design of Feroce had been completed, it must have ranked with the greatest works of this kind; "for we should
C A N A L.

should then have seen two capital rivers, which traverse a large part of Southern Asia, which enter the sea at the distance of 1,500 British miles aounder, and which directed their arms, as it were, to meet each other, united by art: and those by nature to a third; so as to form an uninterrupted inland navigation from the frontiers of China to those of Persia." The country of Bengal is so interlinked in various directions by the natural canals of the Ganges and Burunpooter rivers, together with their numerous branches, as to form the most complete and only navigation that can be conceived; and it is supposed, that this inland navigation furnishes constant employment for 50,000 boatmen, who are employed in conveying by water through the kingdom of Bengal and its dependencies, all the salt and a large proportion of the food consumed by 10,000,000 people, and in transporting commercial exports and imports, probably to the amount of 2,000,000l. sterling per annum.

The improvement of inland navigation engaged but little attention in Russia before the reign of Peter the Great. With him, after his return from Holland, where he had observed its useful effects, the construction of canals became a principal object. Of those projected and hastily executed by him, we may mention that of Cronstadt, that of lodoga, that of Vihiine-Volohok, and that for forming a communication between Moscow and the Don. For an account of the canal of Cronstadt, which was left unfinished by czar Peter, see Cronstadt. The Ladoga canal was begun in 1728 by his order, and finished during the reign of the empress Anne. It was carried out first only as far as the Ka-bono, a rivulet which enters the lake to the call of Schulsfelfburg; but now reaches, without interruption, from the Volkof to the Neva. The length is 67 1/2 miles, and its breadth 70 feet; the mean depth of water in summer is seven, and in spring ten feet; it is supplied by the Volkof and eight rivulets. The banks enter through the ditches of the Volkof, and go out through those of Schulsfelfburg. In 1778, four thousand nine hundred and twenty seven vessels passed through this canal. A scheme has been projected, and in part executed, for uniting the White Sea and the Baltic, and thus improving the commerce between Archangel, Peterburgh, by forming a communication between the Ladoga and Bilo-Ozero to the Dura. The canal of Vihiine-Volohok, forms a communication by water between Africcan and Peterburgh, or between the Caffian and the Baltic. This canal was begun and completed under Peter the Great; but it has been considerably improved by the empress Catharine, so that vessels reach Peterburgh in half the time which they formerly employed. In order to form an idea of the course of this inland navigation, a map of Russa should be consulted; and it will be seen, that the river Shina forms the lake Malfino, which gives rise to the Mastra; this, after a course of 224 miles falls into the lake Ilmen, from which issues the Volkof; and this, running 130 miles to the lake Ladoga, supplies the Neva; so that, in effect, the Shina, the Mastra, the Volkof, and the Neva, may be considered as the same river flowing into and through different lakes. By uniting, therefore, the Shina, which communicates with the Baltic, with the Tvertza, which flows by the Volga into the Caffian, the canal of Vihiine-Volohok completes the communication between these two seas. In autumn the navigation from Vihiine-Volohok to Peterburgh is performed in little more than a month; in summer in three weeks. In one year 3485 banks have passed through this canal.

The grand project of uniting the Caffian and the Baltic with the Black Sea, by the junction of the Don and Volga, was planned by Peter the Great. These two rivers approach each other within the distance of 10 miles in the present of the Caffian; and two rivulets, the Holma which joins the Don at the Caffanmouth lying into the Volga, are separated by an interval of five miles. If these rivulets could be made navigable, and united by a canal, the Black Sea would be joined with the Caffian and Baltic. Repeated attempts have been made for this purpose, but they have hitherto failed. However, as the Volga and the Don are but 40 miles distant, and land carriage in this country is very cheap and safe, the advantages resulting from the projected canal would be scarcely equivalent to the expense of forming it. In 1687, a beautiful chart was published, exhibiting a view of all the canals in Russia, that have been formed between the White and Black Sea, and between the Baltic and the Caffian. The inland navigation is already carried through such an extent in Russla, that it is possible to convey goods by water, 4472 miles from the frontiers of China to Peterburgh, with an interruption only of about 60 miles; and from Africcan through a tract of 1474 miles. Cox's Travels in Poland, Russia, &c. vol. iii. Tookes view of the Russian Empire, vol. i.

The first sovereign of Sweden, who duly appreciated the utility of inland navigation, was Guillaume Vafla. Having made Lodock (now Gothenborg) a staple-town of trade, he conceived hopes, that in order to prevent the merchandise bound to Sweden from being obliged to sail through the Sound, the merchandise might, at some future period, be transported from thence to Stockholm, by means of the Wener, Hielmar, and Maeler, when the rivers and lakes uniting with them should be rendered navigable. Eric XIV. disinclined to executing his father's plans, directed a survey to be made of the waters communicating with those lakes, and plans to be formed for joining them by artificial canals. But the turbulence and misfortunes of his reign frustrated the accomplishment of his desine. The same object was kept in view by succeeding sovereigns. Charles IX. promoted it by the Carlignf canal, and Charles XI., by that of Arboga. Guillaume Adolphe wished to encourage the design, but could not find persons competently qualified to execute it; and Charles XI. was discouraged by the report of Dutch engineers, who declared it impracticable. Charles XII. however, approved the proposal of the celebrated engineer, Polhem, for rendering the eataracts of Trolsbatta navigable, and for opening a communication, not only between Gothenborg and Stockholm, but also with the Wener, the Vette, and Nordkoping, sufficient for the passage of large vessels. The execution of this plan was immediately begun by his order, and, after his death, revised by Adolphus Frederic. It comprehended three principal parts; viz. the junction of the Maeler and the Hielmar, of the Hielmar and Wener, and of the Wener with the German Ocean. The two lakes of the Maeler and Hielmar are united by the Ulvson, and the canal of Arboga. This canal (see Arboga) is, for the most part, of sufficient breadth to receive two banks a-breadth, and its lowest depth is eight Swedish feet. It is chiefly supplied with water from the lake Hielmar, which is 80 feet higher than its level; and this fall is broken by eight sluices. With a view of joining the Hielmar and Wener, many schemes were proposed, but difficulties occurred which prevented the completion of them. The junction of the Wener with the German Ocean has been attempted by the Carlignf canal, the canal of Trolsbatta, and the sluices of Akerstram and Edet. The Carlignf canal, so called from Charles IX., who commenced it, connects the Wener with that part of the Gotha, where it is first navigable. In 1758 a new sluice to supply the place of that of Polhem, carried away by the water, and of that called
called Tellin, found insufficient, was completed; and demonstrated the efficacy of Gustavus. This superb work is a cut of 200 feet, partly perforated through the solid rocks, and consisting of two locks, each 200 feet long, and 36 broad; the sides being strongly faced with brick and stone. The greatest depth of water is 13, and the lowest 6 feet. This canal is commonly navigated by vessels of 80 tons burden. From the end of this canal to the village of Trolhatten, including an interval of five miles, the navigation of the Gotha is interrupted; but when it burths at once into the cataracts of Trolhatten, called the "gulls of hell," all further navigation becomes impracticable through a space of about two miles. Here it is divided into four principal cataracts, separated by whirlpools and eddies, and descending through a perpendicular height of 100 feet. Nevertheless, an attempt has been made to form a canal through these cataracts. The first attempt, after much labour and expense, failed; and another plan was adopted. The length of the canal was to be 1970 feet, its breadth 36, and its depth in some parts above 30; and it was to consist of nine aqueducts; but the whole of the cut was to be excavated through a bed of red granite; and though it should not be condemned as impracticable, the difficulties attending it appear to be almost insuperable. After all, it has been doubted, whether the enormous expense attending the execution of it will be compensated by the advantages resulting from its completion. Gustavus III., soon after his accession, visited the works, and ordered all of them to be suspended, except the flues of Gustavus and Aker. But, in order to facilitate the conveyance of merchandise from the districts bordering on the Wener to Gotheborg, a wooden road has been constructed on the side of the river, from the beginning to the end of the cataracts. About a mile below the cataracts, the course of the Gotha is again interrupted by a fall, called Akerlarm; and here a canal has been made through a rock, 185 feet long, including the fluce, 26 deep, and 36 broad. From Akerlarm the river is clear to Gotheborg, excepting at Edet, where it is intercepted by a bed of rocks. On one side of these rocks another cut has been made, 600 feet long, 20 deep, and 18 broad. The iron and other merchandise are now transported across the lake to Wenerborg, through the Cargraf canal, and down the river Gotha to Trolhatten. At the cataracts they are unloaded, carried over the wooden road two miles to the end of the falls, again embarked, and passing through the Akerlarm and Edet fluces, arrive without further impediment at Gotheborg.

The principal canal of Denmark is that of Kiel. This canal was designed to complete the inland navigation, which, for the purpose of facilitating the communication between the Baltic and the German Ocean, is formed across the duchy of Holstein, and it unites with the river Eyer, which passes by Rendsburg, and falls into the German Ocean at Tonningen. It begins about three miles N. of Kiel, at the mouth of the river Lauenfawke, which heretofore separated Holstein from Schleswig, and will become a new boundary between these two duchies. The distance from its beginning to the fall fluce at Rendsburg is 27 English miles; but as the Eyer is navigable about 66 miles above Rendsburg, the cut necessary for completing the communication between the two seas is only 204 miles. It was begun in 1777, and was opened in 1785. The perpendicular fall towards the Baltic is 25 feet six inches; that towards the ocean 23; and the vessels will be raised or let down by means of six fluces. The breadth of the cut is 100 feet at the top, and 54 at the bottom; the fluces are 37 feet broad and 100 feet long, and the lowest depth of water is 10 feet. Merchants of about 150 tons burden will be able to navigate this canal. The utility of this important undertaking is indisputable. At present, even the smallest vessels, trading from any part of the Danish dominions in the Baltic to the Northern Sea, must make a circuit round the extremity of Jutland, and are liable to be detained by contrary winds. This navigation is so tedious, that goods shipped at Copenhagen for Hamburg are not usually sent by sea only to Lubeck, and from thence by land. The object, says Mr. Coxe, of those who planned this canal, was to draw by Kiel into the Baltic, the commerce of Bremen, Hanover, and Wollphalia, which is now carried down the Weter, and by Glückstadt upon the Elbe, to Hamburg and Lubeck; and to facilitate the transport of merchandise from Holland and the North Sea to the ports of the Baltic. But the difficult navigation of the Eyder between Rendsburg and Tonningen, occasioned by numerous shoals of shifting sands, will prevent the complete success of this canal. Ships sailing from the Baltic to English or French ports, will without doubt prefer the navigation round the Cattegat, with all its dangers and difficulties. The trade of Kiel, however, will at all events be greatly increased by this canal; but the principal repository of the merchandise will be at Rendsburg. Coxe's Travels, vol. v.

The canals of Holland and Flanders are innumerable; and they serve the purpose of our public roads, so that the inhabitants may travel by means of them in their trechfuyts and barges, and convey commodities for consumption or exportation, from one part of the country to another, as occasion requires. An inhabitant of Rotterdam, it is said, may, by means of these canals, breakfast at Delft or the Hague, dine at Leyden, and sup at Amsterdam, or return home again before night. By them also a prodigious inland trade is carried on between Holland, France, Flanders, and Germany. When the canals are frozen over, they travel on them with skates, and perform long journeys in a very short time, while heavy burdens are conveyed in carts and sledges, which are then as much used on the canals as in our streets. The profits which have accrued from these canals have been immense; and their amount almost exceeds belief. It is said, that they have yielded more than 250,000L. for about 40 miles of inland navigation. The canals of Holland are generally 60 feet wide, and fix deep, and are kept cleansed; the mud, as manure, being very profitable. They are generally level, and need no locks; and they are commonly elevated above the country for the purpose of carrying off the waters, which in winter inundates the land. In the province of Delfland, not more than 60 miles long, 200 wind-mills are employed in spring to raise the water into the canals. On the dunes or banks by which they are bordered, and which are kept in repair at a very considerable expense, depends the security of the country from inundation. The canals of Flanders, ever since their trade has declined, and the cities erected on their banks have decayed, have been very much neglected. They indicate, however, the former flourishing and prosperous state of the country. So early as the 12th century, large canals were cut; and they answered the purpose of inland commerce as well as of draining the land. The spacious canal of Bruggis, begun in 1531, and completed in 1560, extends from this city to the Scheldt, which opens a communication with Holland, and by the canals of Flanders with the ocean. The canals of the other Dutch and Flemish towns will be mentioned under their respective articles.

France has from a very distant period exercised its ingenuity and activity in the construction of canals for inland navigation. We must content ourselves with a cursory mention
A Canal.

mention of some of the principal. The canal of Briare, called also the canal of Burgundy, was begun under Henry IV. and finished in the reign of Louis XIV. It opens a communication between the Loire and the Seine, and then between Paris and the western provinces. Commencing at the Loire near Briare, it parallels Montargis, joins the canal of Orleans, which was begun in 1677, and has 22 miles, and falls into the Seine near Fontainebleau. It has 42 locks and sluices; and is of great use in inland commerce. The canal of Picardy connects the river Somme with the Oise; and beginning at St. Quentin, joins the Oise, and affords a ready conveyance to Paris for the grain of Picardy, the seasonal, wood, butter, copper, and spices from the northern provinces of the kingdom, and from Holland. The most considerable work of this kind is the canal of Languedoc, called the canal of the two seas, which forms a junction between the Ocean and the Mediterranean. It was first projected under Francis I., but begun in 1666, and finished in 1681, under Louis XIV., during the minority of Colbert, and by the skil of Riguet, the engineer. It established a ready communication between the two fertile provinces of Gienne and Languedoc, and extends from Carcassonne to the Garonne below Toulouse, being provided at proper intervals with 114 locks and sluices. In some places it is conveyed by aqueducts over bridges, under which other rivers pursue their course. Near the town of Beziers, it was conveyed under a mountain by a tunnel, then thought singular and extraordinary, but now common, 730 feet in length and lined with free stone. At St. Feriol it derives a supply of water from a reservoir containing 555 acres. Its breadth is 14 feet, including towing-paths; its 16 feet deep, and its length 64 French leagues, or about 180 miles. The expense of its construction was about 52,900l., defrayed partly by the king, and partly by the province of Languedoc. On the reduction of the army and navy in 1782, after the conclusion of the American war, the disbanded soldiers and seamen were employed in the construction of three navigable canals; viz. one, called the canal of Deune, extending from Chalon-sur-Saone to the town of Dijon on the Loire, through an interval of 21 leagues, and forming a junction with the Saone and the Rhone: a second, called the canal of Burgundy, reaching from St. Jean-de-l'Aine to the village of Roch, between St. Florentine and Joisy, through a space of 52 leagues, and opening a communication between the Saone, the Rhone, the Yonne, and the Seine; and a third, called the canal of Neuf-Brislach, which commences at the village of St. Symphorien, on the Saone, and passing the city of Belançon, is continued below Strohburg, forming a junction of the Saone with the Rhone, and of the Ill with the Rhine. By these canals goods may be conveyed at a cheap rate from Marseilles, the Mediterranean, Italy, and Switzerland, to the bay of Biscay and the Ocean, and also to Holland and Germany, as well as to Flanders and the Austrian Netherlands; and during any future war with England, France will be able to supply, by these canals, her dock-yards at Marseilles and Toulon, and also her grand arsenal and dock-yards at Breid and Rochfort, with all sorts of commodities from the Baltic, without hazarding a voyage by sea. It would be endless to enumerate all the canals, projected or actually executed in France, and forming an easy intercourse between the different districts of this extensive country. A survey has lately, in 1802, been made of the little river Buzeg or Bureg, with a view of its being brought to Paris in the same manner as the New River is brought to London, and of being laid into the streets and houses by pipes, fire-plugs, and engines, for the purpose of cleaning the streets, as well as accommodating the houses. Phillips's Inland Navigation, p. 75. 8vo.

Spain has not been altogether inattentive to the improvements likely to result from inland navigation. At former periods it has been often proposed to drive a canal through the province of Daren, from Nime to Duero, and thus to make a ready communication between the Atlantic and the South Seas, and to open a straight passage to China and the East Indies. The project, however, has been considered as chimerical, and treated with ridicule. The improvements meditated at home are of much greater importance: but though the inland navigations of Spain have been commenced upon principles both of grandeur and utility, they have been suffered to languish through the want of resources, and the tardy measures of the court. The great canal of Arragon afforded, in 1785, some hopes; but it seems to remain in an imperfect state. Two branches, however, are completed: those of Taudete, and the imperial canal, both of which begin at Navarre and terminate in the river Ebro, and they have already proved sources of industry to all the districts through which they flow, and rendered the fields fertile. One of these canals is conducted over the valley of Kinjalon, by an aqueduct 710 fathoms in length, and 17 feet thick at the bottom. Another canal called the canal of Caltile was projected to begin at Segovia, about 40 miles N. of Madrid, and to extend to the bay of Biscay, through a distance of 140 leagues. This canal is 56 feet wide at the top, 20 feet at the bottom, and nine feet deep, but the completion of it will require many years. The canal of Guadarama was planned in 1754, and being conducted with spirit, is probably now completed. It was to commence at the foot of the mountains of Guadarama, near the Ecuatorial, and to proceed to join the Tagus, afterwards the Guadiana, and terminate at the Guadiana, above Anduxar. Another canal was also begun to join the river Manzanares to the Tagus; but the work was suspended. The canal of Murcia was found, after its commencement, to be impracticable. Phillips's Inland Navigation, p. 75, &c.

The Americans possess a country capable of great and easy improvement by internal navigation. To this object they are not inattentive. For an account of their projects and actual progress in this business, we must refer to Phillips's Inland Navigation, p. 571, &c., or to the Journals of Mr. Elkanah Watson.

Canals, the Britifh, from the great influence which they appear to have had, among other canals, during the last half century, in promoting the rapid increase of our commercial greatness as a nation, have induced us to lay before our readers a very full account, not only of the present existing canals, but of the principles and practice of canal making, in the united kingdoms. As very few of the English, Welsh, Scotch, and Irish rivers, are of sufficient magnitude, and free from shoals, to answer the purposes of navigation far into the country from the sea, without the aid of art, conducted upon similar principles to those used in canal making; and as nearly all our canals connect with the navigable rivers, and act in some measure, as extensions of them further into the country, we have found it expedient to include under this article, whatever we have been able to collect on the subject of the Inland Navigation of the United Kingdom.

That the navigation of our rivers, by ships or smaller vessels has long been an object of considerable importance, will appear from magna charta, which has made a special provision in the 23d chapter, for the putting down of weirs and other obstructions in the rivers of England; and from Stat. 25 Edw. III. c. 4. which fets forth, that "whereas the common
The general laws of the land proving so very ineffectual for protecting internal navigation from the encroachments of individuals and the effects of neglect, this probably suggested the propriety of those particular grants or statuts which we find enabling corporations, and in some instances individuals, to take particular rivers under their charge, and to receive tolls or dues from the vessels navigating within their particular district. In process of time, as population increased, and the advantages of water carriage became more apparent, further grants and acts of parliament were made, authorizing companies or individuals to extend the navigation on certain rivers further into the country, generally to reach some city or great town; these acts, some of which we shall particularize hereafter, generally enabled the parties to deepen, and in some instances to straighten the course of their rivers, to embank them where too wide, to erect jetties and sluices, to make shallows into navigable waters; and in later times to erect pound-locks for gaining the access to the different mills-dams upon the river. But the consequent tendency of rivers being specially rapid ones, to call up banks of sand or gravel in particular places, their deficiency of water in times of drought, and superabundance in times of flood, the ravaging effects of these last in destroying the works erected for the use of the navigation; as happened on the river Aven between Crilchurch and Salisbury; on the river Stour, between the Severn and Streetbridge; on the river Calder, between Wakefield and Edland, and on several others which might be mentioned; the great labour and difficulties of towing or dragging vessels against the stream, especially where there was not a towing-path for horses near the channel of the river, and yet not subject to be overflowed and rendered useless in times of floods; the very lengthened course of mill rivers, arising from their serpentine, and, in some instances, varying channel, was not also among the smallest of the difficulties attending them: these, at length, suggested the propriety of leaving the bed of the rivers in some instances for a new cut for the navigation across, or at least, in some, of land, with a pound-lock at its lower extremity. As these side cuts and pound-locks were increased in number, to shorten the course of the rivers, their superior advantages be-

 came so apparent, that a company of gentlemen and merchants, who had in 1755 obtained an act of parliament authorizing them to make Sankey Brook navigable from the Mersey river to near St. Helens, in Lancashire, with the powers at that time usual in navigation acts, for the purchasing of land and other things necessary for the intended navigation, at a fair estimate to be made by commissioners named in the act; they determined, after mature deliberation, to avoid the bed or channel of the brook altogether, and to make one entire new cut or canal, as near as convenient to the bed of the river, with locks therein, in such places as the falls of the ground should render necessary; and this canal they accordingly effected about the year 1760, supplying its highest pound or level with water, by a cut or tender from the Brook. Thus navigable canals had their rise in England; but, a less fortunate set of gentlemen, who under the power of an act obtained in the year 1735, for making the river Stroudwater navigable, from the river Severn to near the town of Stroud, although the act empowered them "to make as many new cuts as they may judge proper, and of what length and breadth they shall think convenient"; yet when they had, about the year 1774, determined upon following the example of the Sankey proprietors, and in imitation of the duke of Bridgewater's, and several other canals, which had then been executed or were begun; by cutting a canal on the side of the Stroudwater river, they were flopped by an expensive law-suit, carried on by certain mill and land-owners in the neighbourhood: whereby the distinction between the river navigation acts, and canal acts was established by the Court of Exchequer, before which the case came to be argued.

About the year 1757, the Duke of Bridgewater, acquainted fully, no doubt, with what had been near 80 years before effected, on the canal of Languedoc, in the South of France, and since in different parts of the Continent, conceived the idea of a canal for the purpose of conveying coals from his estate at Workley in Lancashire, to Salford near Manchester. His grace, profiting as no doubt he did, by the works of that great French engineer, Francis Regnaud, and by the advice of that great natural and self-taught genius James Brindley, whom his grace called off, about the year 1756, from his employment as a millwright and engineer-maker in this country, to perfect, and carry into execution, the great and important schemes which he had projected, and for which he proposed and brought into parliament the first act, with powers adequate to the great and extraordinary undertaking, of cutting a canal of several miles in length, not in the direction of any river or stream of water, but crossing the course of several brooks, roads, &c. and through the lands of a vast number of different persons, all of whom were to be fully compensated, though deprived of the power of withholding their lands or waters, or in any way obstructing the design. In these respects, the Duke of Bridgewater has not improperly been called the father of canals in England, while his engineer, the late Mr. Brindley, by his skilful performances on the Duke of Bridgewater's canal, altered and extended as the scheme thereof was, by three subsequent acts of parliament, has secured to himself, and well it should seem, from a comparison of the great features, and minutiae of execution in this the first canal, with most others in this country, even of the latest construction, long continue to hold, that rank among the English engineers, to which Mr. Riquet seems entitled among foreigners.

The canal was happily opened by the Duke of Bridgewater, was quickly followed by new sets of adventurers, who were seen applying to parliament in almost every session for powers to make a joint lock on transferable shares, and
to make and maintain canals in most parts of the kingdom, many of which have been long completed, as our subsequent account of them will show, and have contributed in a most eminent degree to the improvement of the country, as well as to the enriching of the individuals concerned in a great number of the inhabitants; in the laudable zeal of adventurers to extend, and of the people of great towns and proprietors of mines and great manufactories to receive, the benefits of inland navigation. Numerous schemes have been adopted, where from the actual scarcity of water, or its previous appropriation to mills, a canal with locks was impracticable. One of the first of these schemes for dispelling with locks, was that of Mr. Bridge, about the year 1759, upon the Stroudwater river before mentioned, where the cargoes of the boats were dispensed in a number of boxes or frames, just adapted to the size of the boats; which boxes of goods were drawn up by cranes to be lodged in other boats on the higher level, and the reverse in descending; which method was afterwards more successfully practiced on Bridgewater’s canal at Worlesley, at Bickley Hill on the Shropshire canal, and other places. The next mode seems to have been adopted by Mr. Davis Dredkarl, near the Tyronese colloquies on the intended connection with Blackwater navigation in Ireland, about the year 1776; and afterwards by Mr. William Reynolds on the Killey canal, where the boats were dragged up or let down inclined planes, not very different from the rolling bridges, long before in use in Holland and Flanders. The necessity of an expedient and cheap mode of conveying coals from the pits to the keels or ships, had, as early as the year 1680, introduced the use of wooden railways, for the wagons to move upon, between the Tyne river and some of the principal pits, and these by degrees became extended to a great number of other coal-works. Since the more general introduction of cast iron, and its cheaper conveyance by means of canals, iron rails have been substituted in the place of the wooden ones before mentioned, and the use of inclined planes, or parts of the railway, having a much greater declivity or slope than it is practicable to drag carriages up by means of horses, has become very frequent in places where the rise of the ground required it, machinery being on these inclined planes adopted to supply the place of horses.

Several years ago, an act of parliament was obtained by Homfray, Hill, and Co. for an iron railway, or tram-road from Cardiff to Merthyr, by the side of, and as a rival scheme of the Glamorganshire canal, for nine miles or more in length; since which, several other acts have been passed for railways, and several of them executed, to the great benefit of the country, and the companies who constructed them; it has also become common within the same period, to authorize canal companies to construct railways, as collateral branches from their canal, to mines or other great works or to large towns within a certain distance of such canals; by which their benefits have been amazingly extended; most of the latter acts have also authorized the adoption of railways, of inclined planes, or of any of the expedients above-mentioned, or as substitutes for locks, in such parts thereof, as are not readily to be supplied with water, adequate to the waif which locks occasion. So many of these compound schemes for lessening the expense of carriage have been already executed, or are in hand, that we have found ourselves compelled, in order to prevent our readers with a connected and useful view of the subject, to include what we have to say on the subject of rail-ways, in the present article, as well as treat therein of navigable rivers, for the reasons before stated.

Great Britain as well as every other island, and even a continent taken as a whole, has a range of high land passing nearly its whole length, which divides the rivers and strait waters that fall to the opposite coasts; we shall call this range dividing the eastern and western rivers of Britain the grand ridge, and shall in our accounts distinguish it in which one, or how each canal is situated, in respect thereof; and here it will be proper to remark, that no less than 30 of our canals now do or are intended to pass this grand ridge, forming as many navigable connections between the rivers of the east and west! these are the Liffey and Foss William, Forth and Clyde, in Scotland; the Leith and Liverpool, Rochdale, Huddersfield, Trent and Mersey, Staffordshire and Worcestershire, Wey-ley and Eppington, Birmingham, Dudley, Worcester and Birmingham, Stratford, Warwick and Birmingham, Coventry, Grand Junction, Oxford, Thames and Severn, Wilts and Perks, Kent and Avon, Dorset and Somerset, Grand Western, and Bude and Launceston in England; and what is not a little remarkable is, that the Dudley canal crosses this grand ridge twice, the two ends being on the eastern side, and the middle part on the western side thereof; the Kent and Avon crosses the eastern and western branches, into which it divides on the Chalk Hills, west of Marlborough, by which parts of this canal are in the drainage of the west, the fourth, and the east seas! the Coventry canal also, by means of its Bedworth branch, crosses the grand ridge twice. The populous and remarkable town of Birmingham is situated on high ground, near to the grand ridge, and has six canals branching off in different directions, either immediately therefrom or at no great distance, and what is singular, owing to a loop, or hidden bend of the ridge at this place, no less than five of them traverse the grand ridge, either by means of tunnels or deep-cutting.

When we propose to lay before our readers a more full and methodical account than has been given of the British canals, on which large sums of money have been expended by individuals, and from which important and illing benefits have been derived by the inhabitants in their immediate vicinity and by the kingdom at large; it is needless to state any formal arguments, in answer to the mistaken objections, which were 40 years ago commonly circulated, whenever a new canal was in contemplation; such as their walling of land, producing noxious and humid vapours, destroying the breed of our draught horses, lessening the coating trade and the furniture of leasem, injuring old mines, and established works by enabling new ones to be opened, introducing pilfering workmen and boatmen into the country, &c. &c. To the more serious objections, arising from the cutting of estates and fields in two; the taking of water from mills, &c.; interfering with former navigations by canals or rivers, and even with roads, on which, in some instances, large sums have been expended, and remain not reimbursed; to these and many others, we shall have the best opportunity of replying, when we come to mention the equitable provisions which individuals have proposed, and the legislature have in so many instances enforced, for securing to every one an adequate compensation for what he is called upon to give up.

General arguments in favour of canals are superceded by the rapidly improving and thriving state of the several cities, towns, and villages, and of the agriculture also near to most of the canals of the kingdom, the immense number of mines and iron, linen, &c. and great works of every kind to which they have been conducted, and to which a large portion of them owe their rise, are their best recommendation. Justice requires our acknowledging the assistance which we have received in compiling this account, from the General History of Inland Navigation by John Phillips, from the three numbers
members which are published of John Cary’s Navigable Canals of Great Britain, from C. Smith’s, George Allen’s, and Laurie and Whittle’s maps of the canals, &c.; from J. Cary’s Large Map of England, Wales, and part of Scotland; from Robert Fulton’s Treatise on Canal Navigation, from William Chapman’s Observations on Canal Navigation, from Joseph Plough’s Agricultural Report of Shropshire, from Zach. Altis’s Confidurations on the Navigation of the Thames; from Thomas Lindeblad’s, and from Neth. Kindley’s Accounts of the Navigation of Lyon and Wifchoek, &c. from the Agricultural and Monthly Magazines, from Dr. Anderson’s Re-creations, from the Annual Register, from Thomas Telford’s Reports on the Calculated Canal, &c.; and from the writings of others, to whom we particularly refer.

To Mr. William Smith, engineer, of Buckinghain-street, London, we are indebted for many valuable hints and information given on many points, as we are also to Mr. Benjamin Brown, engineer, of Leighton Buzzard, Beds.

When it is proposed to form any canal, the choice of a skilful and experienced engineer is an object of primary con-}
embrace as many as possible of these objects, particularly coal-works; for it has been remarked, that the carriage of coals gives rise to the principal revenues of most canals; and some have even contended, that no canal can answer to the proprietors unless the carriage of coals be its principal object: there are, doubtless, some exceptions to this rule. It may be concluded, upon the whole, that no canal can be completed and brought into use, but the inhabitants and the agriculture of the district will chiefly feel great benefit from it, whatever may be the refit to the proprietors; yet in the flage of the business of which we are treating, it is the peculiar duty of the engineer to study the interest, and bring forward the probable advantages of the proprietors, fairly and without exaggeration, in order that the subscription may fill, and the work be enabled to proceed. Before determining upon the route of a canal, its connection with the neighbouring canals or river-navigations should be well considered, and the engineer should inform himself accurately of the quantity of benefit or injury likely to result to each of those exciting navigations by the effecting of the new one, or how far their rivalship, or that of any other scheme which may at the time be in agitation, is likely to affect the one he is employed upon; in all the practicable routes, which prefent themselves for the new canal.

The most eligible route for the canal being settled in the engineer's mind, he will then proceed to make a rough calculation of the quantity of goods of each different kind, which may be expected to pass upon the line in a given time; he will also examine all the canals and rivers which the proposed canal is to connect with, and ascertain the widths and depths thereof, the sizes of their locks, and of the vessels usually navigating them. The engineer will now be able, well considering the nature of the ground the canal is to pass over, to determine on the most proper dimensions for the intended canal, and whether the probable supply of water renders it practicable to effect the risings and falls by the ordinary mode of locks; or whether inclined planes, or any other of the expedients which we shall more particularly enumerate hereafter, should be adopted: or even, whether a railway, in whole or in part, may not be preferable to a canal. The mind of the engineer will properly be exercised upon these questions, before a more minute and extensive survey and planning of any particular line are entered upon; because, the line, though passing through the same tract of country, will generally require to be conducted in a very different place for great lengths together, according to the size of the proposed canal; and inclined planes, or a railway in whole or in part, will introduce a still greater diversity in the routes that ought, under the different circumstances, to be pursued.

Robert Fulton, in his 4to. Treatise on Canal Navigation, published at London in 1790; William Chapman, in his 4to. Observations on the various Systems of Canal Navigation, London, 1797; Thomas Telford, in J. Plymley's 8vo. General View of the Agriculture of Shropshire, London, 1803; Edmund Leach, Dr. James Andergon, and others in London, have recommended and enforced, upon principles more or less general and true in their application, a variety of schemes and methods of conveyance, by small canals, inclined planes, rail-ways, &c. of which we shall take notice under their proper heads, and of which the engineer will of course avail himself, as far as they appear applicable; as well as of any other inventions, which his own ingenuity or that of others may supply. Long levels may, in some instances, be obtained, without inordinate expense; and will often prove of great utility, in the saving of the time and trouble of passing locks in the neighbourhood of great towns, as in the cases of Coventry, which has the benefit of more than 74 miles of level navigation on the Coventry, Aple de la Zouch, and Oxford canals; and of Manchester, which has 74 miles of level water by Bridgewater's, and Little and Trent canals, including 32 miles in the tune to the bridge of Bridgewater's coal-works in Worsley Hill: Birmingham has 43 miles of still water, by means of the old Birmingham, the Worcester and Birmingham, the Dudley and the Stratford canals; and this upon so high a level, that the three last canals cross the grand ridge in that space: Lancaster and Preston have 42 4 miles of level on the Lancaster canal; Wolverhampton enjoys the benefit of a level 40 miles in length, on the old Birmingham, and Walsall and Ellesmere canals; Liverpool has 28 miles of level on the Leeds and Liverpool, and Blackburn, 24 miles upon the same canals; Biblethwaite has 22 miles upon the Basingstoke canal; Wirksworth 21 miles upon the Ellesmere; Devizes 28 miles upon the Kennet and Avon; Batedford 26 miles upon the Grand-bahn; London enjoys the benefit of about 19 miles of level to Paddington, upon the Grand Junction canal; Cheltenham 15 miles on the North and Clyde; Gloucester to have 18 miles upon the Gloucester and Berkeley; Shrewsbury has 15 miles on the Ellesmere; Stainton 15 miles on the Shropshire and Wellington; and Birmingham 14 miles on the Bredgwood and Abergavenny; Market Harbourn 151 miles on the Leicestershire and Northamptonshire Union; Shrewsbury 141 miles on the Shrewsbury; and Cromford 11 miles of level on the Cromford canal. Another benefit will sometimes occur from long levels, by the bringing of all, or of a considerable number of the locks near together, as at Runcorn on Bridgewater's canal, by which they are more effectually looked after and kept in repair. Should it be necessary to return the water let down by the lockage, again into the higher pound by the power of engines, as is done on the old Birmingham, the Barley, and many other canals, the having of considerable falls in one place will be of material consequence; but still more so if inclined planes are to be used instead of locks, as on the Shropshire, Shrewsbury, and Kelsall canals. In conducting the line of a canal, it will always be advisable, if other circumstances will permit, to bring two or more locks near together, and to erect a lock-house for the residence of a careful and proper person upon the spot, to look after and afford the garrisons in working the locks; where this had not been attended to upon some canals, but single locks were placed at great distances from each other, the company have, from experience of the damage such locks sustain, found it necessary to employ great numbers of lock-keepers, and often to build houses for the superintendence of single locks. Mr. Chapman, who appears to have well weighed the question, whether large or small canals ought to be adopted under different circumstances, observes, 'that the syllum of small canals is particularly eligible in all countries where lime-fore, coal, iron-ore, lead, and other ponderous articles, not liable to damage from being wet, or likely to be roten, are the objects chiefly to be attended to; and where the declivity of the country runs transversely to the course of the canal, which will generally be the case along the sides of mountains, at an elevation above the irregular ground at their feet. In those situations, the great falls or inclined planes may be made at the forks of rivers, so that the upper levels may branch up both the vales, and thus give the most extended communication. A situation fitted for those canals will often be found in countries that are not absolutely mountainous, but where the ground regularly declines towards the vales of large rivers.' The principles for which Mr. Leach has so strenuously contended, of re-
tering the usual order of beginning navigations at the lowest points or the sea, and extending them up the valleys towards the summits, and, instead thereof, beginning near the summit or source of the water, and continuing the level till the greatest practicable falls are obtained for inclined planes, would, unless the most enormous expenses were incurred for tunnels, deep-cutting, and embankments, prove too crooked and circuitous for a ready conveyance, as happened on the Bude and Launceston canal, which was proposed to pursue a terrapentine course of 8 miles, between two places whose direct distance is no more than 29 miles! The long level of the Oxford canal, at its northern end, of which we have spoken above, appears among the most crooked of those canals, which have been executed, and is particularly ill adapted, to the great thoroughfare or communication which it forms with other canals. Canals which are to form an immediate connection between the sea or tide-way at different places, as the Severn and Fort William, Grimsby, Forth and Clyde, the Life of Dogs, and the Gloucester and Berkeley, must be of large dimensions, or the principal advantages of such a communication would be unattainable; in like manner, the communications between the sea, and docks or harbours, will some of them require to be of still larger dimensions, as the Grimsby, Ulverstone, Dee new channel, &c. A system compounded of watertiers, or lengths of canal on different levels without communication by locks, may sometimes be found advisable, as on the Shropshire, Shrewsbury, Kelby, Leicester, &c. The advantages of being able to conduct a canal, in many instances, upon water-tight tracts, instead of rocky or porous soils, and perhaps without losing flight of any of the other important considerations mentioned, are sufficiently great to induce engineers to become acquainted with the arrangement and particulars of the firth within their districts, by a minute and careful examination, or to call in the assistance of those well informed on such points. We have purposely omitted, till now, to mention the consideration of the value or quality of land to be purchased for the use of the projected canal by different routes; convinced that some late canals have been materially injured by the narrow-mindedness of those who would avail themselves of cutting through common or low-priced land; even the general consideration of expense, in the works of a proposed canal, should hold but a subordinate place in the mind of an engineer in the present stage of the business, because contracted views in this respect may frustrate the attainment of a great portion of the benefits to be expected; and it cannot be doubted that any scheme of conveyance will befall answer to the adventurers and the public, when conducted upon the principles most adapted to the cafe, let the expense be what it may; and fortunately, the commercial and public spirit, aided by the means of individuals collectively in this country, has long shewn itself equal to any enterprise however bold, where advantages can be shown materially to preponderate.

In the particular survey of the line proposed, all the knowledge of the most expert and competent engineers, with the most able assistants, will be requisite. The rough section of the proposed line, before taken, will enable the engineer to see the places of the heights and breadth of the various summits, or ranges of high land that are to be passed, and whether any two or more adjacent ones can be connected by a long summit level, without deferring any considerable town or point of trade, which will diminish the difficulties of supplying the canal with water, as every such junction of summits prefers the water of two lockages, besides presenting so many more points at which the canal can be supplied with water, from springs and rivulets above its level, or where, in less favour-
It may happen, in case of a change of the direction of the valley, rendering it necessary to leave it, that some other valley may be at no great distance, into which the canal must be conveyed by a tunnel; and in order to render this practicable, it may be necessary to go back, and conduct a good deal of the line that had been done upon a new and much higher level, by omitting some of the locks, in order that the level may be continued through, and finally the proposed tunnel; in accomplishing this, the former obstacles may recur again, or new and more formidable ones may be presented. In this way, the patience, perseverance, and abilities of the engineer must be exercised, until a practicable line of some length is obtained, and flaked out; when the affiant land surveyor must follow, and make a correct and particular plan of the line of the several proposed locks, embankments, tunnels, &c., upon the same, and of the several fields or pieces of land through which it passes, or that come within ten or fifteen yards of it in any part: it will likewise be the business of the surveyor to ascertain, with the utmost care, the boundary of every parish and township, in which each of the proper names of the owners and occupiers of every piece of land in each, however small, upon or within that distance of the line, with reference to the same upon his plan; and to describe correctly all public and private roads and paths that cross or intersect the line, and to add, from what places they lead, the course of all brooks or streams of water, and particularly such as lead to, and contribute to the supply of any mill; the situation of the houses and towns upon the line, or within some miles of it, should also be determined; the nearer they are the greater accuracy will be necessary. We will now suppose the engineer proceeding with the line, from the end of a tunnel into a new valley, the course of which downwards is in the proper direction; the same process is to be repeated as was pursued in defining from the first summit, until this new valley changes its direction, or until some great town or work has been reached, and it becomes necessary to change the course of the canal, and begin to ascend some new valley or plain towards a new summit, or towards some mine or work, at which the canal is to terminate: to the new summit it will be necessary to proceed, and after setting the height of the summit level, and taking all the preparatory steps for ascertaining the supply of water, and other circumstances of this summit, as described respecting the first, the levels will be traced from this summit downwards, working backwards or up again, as often as obstacles may render it necessary, until the former work in the valley is met, and a proper junction of them contrived: the whole of this part being adjusted, the surveyor may proceed as before, with his plan and particulars; while we suppose the engineer returned to the first summit, and from which he will conduct his line, and avoid the obstacles thereon, in the best way that his ingenuity can suggest, until he arrives at the navigation or sea-port, at which his canal is to terminate, and where basins or docks, more or less capacious, according to the expected trade, and wharfs, cranks, and other conveniences, may want planning, for the accommodation of the traders and the public; all which the surveyor will proceed to survey and plan, as before mentioned. It may be necessary to remark, that every town, mine, or work, which happens to lie higher than the line, and to which a collateral cut is to be carried, must be considered as a separate summit, and provision for supplying the lockage thereof must be made, and such of the examination before described gone into, as may appear necessary; such towns, &c., as lie below the line, and are to have cuts or branches to them, will require water to be let down out of the line to supply their lockage; on which account, it is highly defirable, whenever the same is practicable, to conduct the line upon such a level, that the collateral cuts may be upon the same level, by which the trade thereon is much facilitated, and less water required.

A complete plan of the line, and all the projected collateral cuts, feeders, refervoirs, &c., being finished, the engineer will enter on a most careful revisal of the whole scheme, with this plan in his hand; on which all the places where culverts or drains will be required, are to be marked, as also the proper places for the bridges, and the necessary alterations of the roads and paths, which will be cut off by the canal, so that the public may not be inconvenienced and turned long distances round about, and still, that as few R a bridges
bridges as possible, and those in the least expensive places, may be erected. In some instances new channels will require to be cut for brooks and water-courses, to a considerable extent, in order to have culverts, or bring them to the most definable spots. For proper locating, against accidental errors, the work of the levelling should now be gone over again, and the usual bench-marks compared, and renewed with the utmost care by the engineer's assistant, while he is proceeding with the necessary inquiries and calculations, for an estimate of the whole expense of the undertaking.

In a great number of instances it will be found, that the supplying of a canal with water, occasions no inconsiderable share of the whole expense, either in the first cost of mills or streams of water, in land for, and labour in, Constructing referfors, engines to pump up water, &c.; or annually over afterwards, in the fuel for, and repairing of, engines, hire of water from mills in dry seasons, &c.; this subject should, therefore, employ the most sedulous attention of the engineer, both to make the most economical use of what streams he finds, to procure other supplies of water at the least expense, but above all, to secure an abundant sufficiency. The dimensions and height of the locks, and breadth of the canal being settled, an accurate calculation made of the quantity of water required to fill a lock; and, with the largest probable number of boats that will pass in a day, the quantity required daily to be conveyed in every part of the canal; this, with a due allowance for the evaporation, from the surface of the whole canal and its referfors, and for the loss by which will take place into the banks, however well they are constructed; will show the number of locks full of water that will be required, from all the different sources. We have spoken of the steps proper to be taken for ascertaining the whole supply that can be had above the summit's level; and it will often be necessary to make a similar investigation, on points below that level, and to construct referfors in such situations, to supply the necessary lackage, for local trade upon the line, near any great town or works, which does not extend to the summit, as also to supply the evaporation and lossage of long lengths, in situations where feeders or springs cannot be taken in the way; another use of referfors in less elevated situations may be, to compensate mills that are lower down the streams for the water that is taken for the use of the canal from the higher branches, or near the sources of such streams. For Mr. William Jeffes' observations on this subject we refer to William Pitt's General View of the Agriculture of Staffordshire, and to the Repository, vol. iii. p. 243.

There appears no reason, under the present state of things, why the owner of a mill or stream of water should not be compelled to part with the fame, for the purposes of a public canal, any more than another man to part with his field, except the accommodation which the public receive from such mill; and where the fame, or a superior accommodation, can be ensured to the public, surely this species of property ought to be put upon the same footing with land in general. See Dr. James Anderson's Essays, vol. iii. p. 68 to 70.

It ought to be considered, that the present state of our canals and inland navigations, and especially the extension of them, which we are now fupporting, remove one of the principal objections to steam engines, by enabling new mines of coal to be daily opened, and the products thereof, as well as of the old mines, to be regularly and cheaply conveyed to every situation where engines can be wanted. We would not, however, be fupposed to recommend the annihilation of water-mills; on the contrary, it hath long appeared to us, that their number and their power might, in some, and perhaps in most instances, be greatly increased, and yet all the purposes of canals be fully answered, and those most capital improvements of irrigation and drainage at the same time extended, to very large tracts of land; for this purpose it would be necessary, that an entire valley of considerable extent, that has a good stream of water through it, as the Colne, or the Lea near London, for instance, should be put under a system of improvement. A thoroughly competent engineer being employed upon such a work, would be able to conduct a canal rather of large dimensions perhaps, along one side of the valley downwards, until three or four locks, or a fall of 20 to 30 feet was obtained; and, the water in the pound below such set of locks to be a small distance below the level of the surface of the ground, in the lowest part of the valley at that place, as this would enable the whole stream of the river to be taken into the next length of level, as often as occasion should require it: this new level would be traced, until, by the fall of the valley, it has reached the sides of the hills, and proceeded with until another set of locks, three or four in number, can be obtained, and a defect made again to the level of the lowest point of the valley; this proceeds to be continued through the whole length of the valley, under improvement. The next consideration would be, a deep and efficient drain, to be carried up through the whole length of the valley, purifying the lowest ground, and the middle of the valley nearly, in such parts where the hills on each side rise equally abrupt; but where, as often happens, the descent to the valley on one side is very sudden and steep, and on the other side long and gradual; in all such cases the drain should be conducted nearer to the abrupt than to the easy side of the vale, because here the peat or alluvial matters, with which such valleys are choked up, will be found the deepest, and the springs in the gravel underneath such peat, the most copious and the most confined; the new drain ought, in general, to reach the gravel under the peat or silt and where this shall be found impracticable, large auger holes ought to be bored at short distances from each other, quite through the consolidated peat and silt, to the gravel, to let the confined springs therein at liberty. These principles of draining a hilly valley we have been successfully practised in the village of Crawley, below Woolham in Bedfordshire, by an agent of the late worthy Duke of Bedford.

If the fall in the new drain should be found very considerable, the fall must be reduced, by placing weirs or wellfalls at proper places, to let the water down in a harmless manner, which would otherwise displace the gravel and sand under the peat, and the fame would cave in, so as to fill up and destroy the drain: another excellent use of these wellfalls or weirs will be, to furnish so many points, where the whole stream, including the springs, can be taken out to supply the upper end of the levels of the canal before mentioned, or for the purposes of irrigation; as was intended and provided for, in the Crawley vale that we have been speaking of. To all the existing mills, which are not too ruinous or badly contructed to be worth improving, the channels to the water-wheels should be deepened up from the main drain, or, perhaps, in most instances, new and more direct ones cut. It will now be practicable for the engineer, in most if not in all cases, to construct an over-shot water-wheel upon the same axis that before carried an under-shot one, turning the same way and with the same velocity as before, so that the internal machinery of the mill will need no alteration, and the requisite quantity of water for working these new wheels, which in most cases will be incomparably, may be conveyed from the canal on the side of the adjoining hill, in
aqueducts or elevated troughs of no very expensive contruction, perhaps of cast iron, or in pipes, which may be conducted underground, and rise up to small reservoirs or pen-troughs above the wheel. As many of the mills will be found situated on the opposite side of the vale from the canal, it may be proper and advisable in many cases, to construct a cut or water-carriage of sufficient dimensions, and with a very slight fall, along that other side of the vale, beginning frequently at the weirs or well falls in the main drain or new brook, and pursuing the level nearly, as far as is found requisite; which cuts will much extend the benefits of irrigation, and give opportunities, perhaps, of constructing new mills, with over-shot wheels of large diameters and proportionate power, to be supplied therefrom. In like manner, several new and powerful over-shot mills may perhaps be constructed near to the several facts of locks upon the canal, without endangering the sufficiency of water for the lockage: this practice of uniting navigation and mill improvements at the same time, we were much pleased to see enforced by Mr. Thomas Telford, in his Report of 1801, printed by order of parliament, upon the intended Intersex and Port William canal, p. 46; and the same has been illustrated to the Woolverton embankment on the Grand Junction canal; see the Agricultural Magazine, vol. vii. p. 24. New and improved mills may often be constructed where the point of a hill at a great and sudden bend of the river can be tunnelled through, from the river on the upper side, as appears to have been done at Shrewsbury on the Severn, and at Stanley on the Towy rivers.

Where the new drain or brook course connects with the levels of the canal in the improvement of a valley, as above proposed, if floods are to be apprehended, or the water is ever found very thick and muddy, weirs or over-falls sufficiently large to let the flood escape down the drain must be constructed, and float-planks provided to be put down across the canal occasionally, or a lock capable of a very small fall constructed, to be occasionally used, to prevent very muddy waters from entering the canal to fill it up. It will frequently happen, that brooks which are making their way laterally into a valley under improvement, may, by an alteration of their channel for some distance up the collateral valley, be brought into the canal in places where a considerable elevation on the side of the hill has been attained, in such cases a circular weir or well-fall should be constructed in the centre of an enlarged part of the brook, before it arrives at the canal, as has been done by Mr. James Bridgwater, at the mouth of Medlock brook at Manchester, on Bridgewater's canal; a provision for float-planks, at the junction with the canal, will also be proper, to be enabled to turn occasional muddy water down the well-fall instead of into the canal. In order to preserve a sufficient elevation in the water-course, for supplying of mills, or for irrigation, after the canal has defended a set of locks, and is consequently too low for this purpose, a cut or water-carriage may be taken out of the summit's level, and carried on along the side of the hill with a proper fall, as far as may be necessary. This sylen of improvement in a valley, is capable of being combined with an extensive application of reservoirs, for equalizing the head and collateral streams which supply such valley, as recommended by Dr. W. Jelf.

In cafes where the land or park owners cannot be brought to concur in a general system of improving a valley, it would often be worth while for a canal company to obtain power from the legislature to purchase all or most of the mills in a valley, through which their canal is to pass, paying, in the first instance, the utmost value for them; and being also bound to erect the same number of mills, of equal or greater power, and adapted to the same purposes, to be supplied from higher levels in the manner we have been describing; such new mills to be offered at a fair price, to be fitted by indifferent persons, to the owners of the adjoining old mills, before the fame are disburdened in the site of the old mills, and in case of their refusal to purchase, the same to be next offered to the persons who may be tenants to the old mills (in order that they may not be thrown out of employ); and then to any other persons inclined to become purchasers, on such terms as they and the canal company could agree upon.

Sometimes it may be practicable to make a bargain for taking weekly into the canal, a stream of water which supplies a mill, only from Saturday night to Sunday night, paying a fixed rent for the same, to be secured by the act; an influence of which occurs upon the Montgomery canal.

The subject of supplying water for a canal having been amply illustrated, we shall now return to the revival of the furey, and making an estimate of the expense of the undertaking, on which we supplanted our engineer to be employed. In revising the survey of the line, it may be proper for the engineer to examine holes to be dug at certain distances, as deep as the canal will require to be cut, or deeper, to inform himself more perfectly of the soil to be cut in, and the expense attending the same, noting particularly the height to which springs may rise in the several holes. And here it may be proper to notice a very common error, into which the persons entrusted to execute canals have fallen, in such parts where springs appeared beneath the surface in the cutting, by concluding that the canal would make water, as they term it, in such parts, and that puddling was unnecessary; but where too often it has afterwards happened, that such springs, from having a variety of other vents or outlets, at or very near to the same level, and were, therefore, incapable of being dammed or raised much higher than they then appeared; when the canal has come to be filled with water to a higher level, the course of such springs has been reveral, and the porous strata through which they passed have served to absorb and discharge the water at other places, to a very fatal extent. Land-springs, or such as run only in winter, have generally the same effect, and in summer as copiously take in water, when their own source fails, as they before discharged it. The difficulty of puddling or lining out springs, on account of the powerful effort they make to force their way through the lining, as long as the canal remains empty at first, will induce a careful engineer, to examine for springs to avoid, if practicable; all springs that will not at all times rise to a higher level than the water is to stand in his canal. It will be part of the benefits of this revival of the line, to examine what can be done to straighten the canal, we mean as to sudden bends, by small lengths of deep-cutting, and others of embankment, to correct the plan accordingly, and to estimate the extra expense of all such works. The lengths and solid contents of the several embankments, and the distance from which the fluff or soil must be fetched for the same; the lengths and dimensions of all the deep-cuttings, and the distance to which the fluff must be removed; the lengths of the tunnels, and number and depths of the several shafts or tunnel-pits that will be necesssary; the lengths of headings or fooughs that will be wanted to drain the tunneling works; these, and all the great variety of other works, some of which we have already mentioned, and others that we shall have occasion to mention in the sequel, being particularly fixed, and prices affixed to each species of work and kind of material; and these prices ought by no means t.:

below the current prices of the bêt articles of the kind at the time, but due allowance should
should also be made for the advance of prices, which will take place during the execution of the work. The total probable expense, with a due allowance for contingencies, being thus obtained, the engineer will prepare his general report and estimate, to be laid, with the plan, before a meeting of the adventurers or proposed proprietors.

The next step in the progress of this business, after the appointment of a solicitor of competent legal knowledge, is an application to parliament for an act, empowering the parties concerned to complete their undertaking.

From the earliest times, the parliaments of this country have found it necessary to adopt certain funding-orders, or general rules, to be observed by the parties who applied for any act of a local or private nature; and these seem to have guided the conduct of canal projectors, till the number and variety of such applications showed the necessity of adopting, on the 7th of May 1754, thirteen special resolutions, as funding orders, relating to the introduction and passing through the house of commons, of any acts for navigable canals, or aqueducts, or for the navigation of rivers; to these another was added on the 16th June 1799, respecting intended railways and feeders to a canal or navigable; and another on the 25th June 1799, in the former order to railway or drainage, as far as the same are applicable.

The house of lords has a nearly similar set of funding orders, and one requiring a sufficient number of copies of an engraved map of the intended canal, &c. to be delivered for the use of each member of that house.

The number of clauses, relating to the construction and management of a canal, are necessity very numerous, and it were much to be wished, that the proposition of Mr. John Cennel, in several periodical works, for a general canal act, to contain all their general clauses and provisions, in the same way as the general highway and turnpike acts, and the general inclosure act, could be accomplished; it would much shorten and simplify the business of canal acts and management.

Another general measure, relating to canals, we beg here to mention, although the application to parliament for the petition just now passed (1807) did not prove successful; we mean the proposal for a general canal company, for raising a large fund, to be invested in shares of canals not yet finished, and for lending money at interest, to line canals companies as may require it, to enable them to complete and render their several concerns more generally beneficial.

Mr. William Chapman, when speaking of the navigations of America, says, (Observations, p. 64.) "It will be advantageous in a rising country, to lay out the lines of canals approximately on its first settlement; referring a proper width for them, in the original grant of the lands, with power to exchange the land of that line, for any other found more convenient, on a full investigation; and thus avoid all the difficulties attendant on those measures in England." Does not the period of the inclosure of a parish here furnish the same opportunity of considering the eligible line for a canal; and of so contriving the allotments that very few, or perhaps only one person's land may require to be cut into, upon the adoption of such measures, and that without cutting up or deranging the fytum of his or their estate? We were happy to see this idea acted upon, as far as irrigation is concerned, in the parish of Maulden, in Houghton-Regis near Dunstable, (into which a cut from the Grand Junction canal was proposed to be brought,) and in some other parishes in Bedfordshire, about the year 1797, by the late duke of Bedford's agent.

One of the first objects of a canal act is, to incorporate and make a body politic of the proprietors, by a certain name and style, by which they shall have perpetual succession and a common seal, and by which they may sue and be sued, and have power to purchase lands, to them, their successors, and assigns, for the use of the undertaking, without incurring the penalties and forfeitures of the statutes of mortmain; and to enable the company to sell any lands so purchased. The feclusion of the name for a canal, is of more consequence than would at first sight appear. Since canal and railway companies have multiplied to very much, it is necessary on all occasions to adhere to and use their incorporated or parliamentary names, a circumstance which has not been attended to sufficiently, but such a variety of names have been used, in the printed accounts of events upon or relating to our canals, that it is often impossible to avoid mistakes.

It has been usual to enable the company to raise a fixed sum of money, equal to or exceeding the total amount of expenses, by debenture or shares; and, in cases of this proving inadequate, to borrow a further fixed sum upon interest, or on mortgage of the tolls. The many and expensive acts of parliament that canal companies have been obliged to obtain in the course of their work, for powers to raise further sums, and even for regulating and enforcing the mode of raising the sums first authorized, threw the necessity of the engineer and solicitor paying great attention to this point, and to be careful to apply for powers sufficiently ample.

The usual amount of shares in canal companies is 100l. but influences of 50l. shares, and others of less or greater value, occur in several of these establishments. These circumstances ought always to be particularly attended to in comparing or quoting the prices of shares in different concerns; and we strongly recommend all future shares to be 100l. ones, especially as the legislature will permit of half shares, or even lower divisions, down to the eighth of a share, as appears in the Grand Junction act, 43 Geo. IV.

To prevent the intertis of any individuals from preponderating, and to increase the number of persons having an interest in the success of the undertaking, it has been usual to limit the number of shares which any individual can hold, under forfeiture of all above that number, except they came to him or her by will, marriage, or other legal proceeds.

The election of a committee of management, and all questions agitated in the house of commons, are disposed of by votes, not personally, but according to the number of shares held by each person, to a limited extent, and usually two half shares carry one vote. The usual limitation to prevent any individuals from possessing too great a power in the company is, that no more than 15, or sometimes 20 votes shall be given by one person; while in the Newcastle-under-Line only 6 votes are allowed; and in the Croydon, Peal, and Thames and Medway, no more than 5 votes can be given by any one proprietor.

General meetings of all the proprietors are provided for, on any important occasion, as well as annually to elect the committee and officers.

Provision should be made for progressive calls on the proprietors, by the committee, for their several subscriptions; these should be on as long notice as is eligible; but they must be prompt and strictly enforced, or the progress of the works will suffer.

The enactments relating to purchasing of lands, and ascertaining the value thereof, where the parties and the company's servants do not agree, by means of the commissioners, will be necessary, who generally confit of all the considerable land-owners of the county, or of a jury to be impunctured for such purpose, these ought to be very clear and explicit; so should the regulations and forms for selling and transferring shares in the concern.

The most ample powers should be given to enter upon, and
and dig, and construct, both the permanent and all temporary works which may be necessary; with provisions, in case of refusal, to accept the compensation offered for damage; that the commissioners or a jury shall settle the fame without delay or further appeal, except in some instances, to the next quarter-fellow of the county.

A clause is generally inserted, confining the company to the line that is laid down in the plans that have been deposited with the clerk of the peace and with the house of commons, or within certain limits on each side thereof; the usual deviation distance allowed is 100 yards; however, many instances have occurred, which are so very important as to the proprietors, that the line of the canal, and every probable cause for the necessity of deviation, should have been thoroughly examined and weighed by the engineer, and the line ultimately adjusted, before the plans are completed and delivered.

The prudent precaution of the legislature, has always limited the width of land which canal proprietors have been empowered to purchase for their canal, in ordinary cases, without the free consent of the owners; this has been 25 and 30 yards, in the greater number of instances, but in others the space allowed for the canal towing-path and fences has been less or greater, according to circumstances.

Where wharfs, docks, or basins, or places for barges to turn and pass each other, or where deep-cutting or embankments are required, it has been usual to allow 100 yards in width to be purchased; but from this allowance there have been occasional deviations.

Except in some rare and peculiar instances, like the London Docks in Wapping, the parliament will not give to any company the power of purchasing houses or other buildings, gardens, orchards, yards, parks, paddocks, or planted walks or avenues leading to any house, except the previous consent of the owners thereof be obtained; and where this has been got, it is the safest way to infer a bill of all such owners, with a description of the property they have agreed to give up, as a schedule to the bill; and the name of all material contracts for mills, streams of water, or springs, which the company may have made. Houses built, or orchards, &c. made as obstructions, since the survey was made, and notices given, will not meet with the same protection; and a clause ought to be inserted to put them upon the same footing with lands in general.

Powers should be given for erecting public wharfs, and for demanding and enforcing certain equitable rates of wharfage for goods, according to the length of their continuance on the company's premises.

The toll, or rates of tonnage, which the traders are to pay to the company per ton per mile for the liberty of navigating upon the canal, or its various branches, railway's, or inclined planes, require the most deliberate consideration, that every species of trade may pay its proportion, and none be discouraged or injured by the expences of conveyance.

In some cases provision has been made, that when the net profits of the concern exceed a certain rate per cent. the tonnage or tolls should be reduced.

There have been exemptions from toll, on several canals, in favour of officers and foldiers on their march, with their horses, arms, and baggage. Timber for the use of his majesty's navy, and government stores of all kinds sometimes pass toll free; so do gravel or other materials for the making or repair of roads in most instances. In some cases, canals have been projected principally with a view to tonnage on lime, and other manures and agricultural objects and produce; but with this exception, it has been usual to allow lime and all manures to pass, either on very low tonnage, or absolutely toll free, on the levels, and through the locks also on fees, particularly when the water actually runs over, or is within a quarter or half an inch of the top of the lock-walls; in some instances, several hours notice is required, of boats with manure or road-materials intending to pass any locks toll-free. In some instances, where a canal is to run parallel to a turnpike road, and is expected to lessen the tolls thereof, by the diminution of heavy waggons and carts, it has been usual to compensate or indemnify the creditors on such roads; and it forms equally just, where a turnpike road invites a canal, and is likely to have its tolls both ways increased, that they should not be entitled to receive materials by the canal tonnage free.

Mile-toll is generally directed to be fixed on banks of meridional canals, for regulating the distances and tonnage; in some instances, they are directed to be placed every half mile, and in others one is to be placed at the end of every quarter of a mile.

We should far exceed our due limits, if we were minutely to recount the various expectations that have been adopted for conculcating the owners of lands, parks, mills, &c. who may more or less be affected by different canals. These must depend on a variety of local and incidental circumstances, for the adjustment of which no general rules can be prescribed. But in all cases of this kind the canal companies have usually proposed, and the legislature has sanctioned, an adequate compensation. Proprietors of land and their tenants are sometimes allowed the use of the towing-path, as a drift and bridge-way between their different lands, or to some public road; the owners of the adjoining lands are often allowed to make, not only docks and basins communicating with the canal, but collateral cuts of considerable extent, for their mines and other works; but previous notice of all such intentions ought to be given to the company, that their engineer may examine the ground, and direct the necessary puddling and other precautions, to secure the line of canal from losing water to a prejudicial extent thereby.

The company are often empowered, and sometimes required, to make collateral cuts, or railway branches to particular towns, mines, or works; and a very proper precaution seems to have been adopted in the Somerset Coal canal act, that the parties to be benefited by such branches should first give the company security to make up the tolls thereof, by an annual payment, in case of their falling short of a reasonable interest on the money expended upon such branches.

In some instances it may be necessary, particularly on railways, to permit individuals to construct and manage such part of the works as pass through their own park or ground, but subject to the general system of management laid down in the act; as is done by the duke of Beaufort on the Swansea canal, and by sir Charles Morgan on the Sirhoway tram-road; also to construct particular parts, on being paid for the same, as was done by the Dee river company, at the crossing of the Ellesmere canal.

Clauses are generally inserted, requiring the canal company to remove and clamp the top soil, or vegetable mould, to the depth of nine inches, from the whole width of the intended works; which, after the same has been completed, and all the banks and excavations properly sloped down, is to be returned and spread upon them, so as to render all the land, not actually occupied by the canal and works, capable of cultivation; but a small part of this top soil is wanted in general upon the banks, and it might, more profitably for all parties, be filled by the company's men into the carts of the neighbouring farmers, to be spread upon the poorer parts of their lands.

Watering places for cattle are generally directed to be made, especially...
especially where the fields may have been deprived of their old ones by the cutting of their canal. In counties where irrigation is much practiced, as in Wilts and others, it has been common to appoint skilful and reputable persons to guard the interests of the irrigators, on the cutting of canals.

On the duke of Bridgewater's canal, irrigation trunks were laid below the bottom of the canal, so that, by means of a harrow, or rather a large hoe, drawn along, the mud of the canal was drawn to the valve or orifice of the trunk when open, and the mud was thus conveyed to the meadows below. A successful experiment was here also made, of bringing up barges laden with feaflph, or mud taken up at low water, in the Mersey, and this was gradually poured or thrown out into the canal, over the irrigation trunks while running, by which means this valuable manure was at once conveyed to and effectually spread on the meadows below. We have been greatly surprised to find irrigation so little practiced upon the lands below canals, which so perfectly admits of that improvement; were this subject properly attended to, in situations where water is plenty, we doubt not but some proprietors or lessees of land would be found, who would readily contract with the engineer, on the part of the company, before the canal is completed, to pay an annual rent for certain quantities of water, to be let out by the company's agents, at flatted times, through a trunk, which might be laid beneath, or level with the bottom of the canal for such purpose, at a very easy expense, before the water was let into the canal; and even after canals are completed, there are situations where the interest of all parties might be served, by laying trunks for irrigation; and perhaps farmers ought not, except in some few instances, to be debarred from constructing or using proper weirs at the same immovable height, or a little higher than those at the lock-gates, to take off the surplus water for irrigating during the winter season.

Sometimes it will happen that a canal can be conducted on a proper level to suit the admits to mines, as at Wordley on Bridgewater's canal, and some others; or perhaps the tunnel through a hill may be applicable to mining purposes also, as at Morwoodham down, on the Tavistock, near Ripley on the Cromford, the Harecastle tunnel on the Trent and Mersey, and others.

Coal-mines may be allowed to have the necessary passageways for their works under a canal, but should be restricted in the number, width, and height of these, as on the old Birmingham canal; or if the vicins are near the surface, the ground may be so entirely broke in, that the canal would be destroyed, as has actually happened on some of the branches of the above-mentioned canal, near to Wednesbury.

Refusing mills, it may be necessary sometimes, where the canal is to be conducted near to established mills, that they should be secured against other mills in the same line of business being erected on the canal at that place, as in the Sankey canal act. Sometimes gauge-weirs, or self-regulating sluices, may be necessary to be maintained, to supply mills or other canals with a regular and constant quantity of water; the experiments of which occur on the Rochdale canal, and at the Adelphi weir, on the Nottingham canal; the theory of the regulating sluice, in the latter place, will be found in the Gentleman's Diary, 1799, p. 43, by that eminent mathematician and coal-worker, Mr. Thomas Walker, of Bilborough; and if theorems for the widths and heights of sluices to discharge given quantities of water per day be wanted, Nichol-son's Journal, 8vo. vol. iii. p. 29 and 34. may be consulted with advantage. Those who may wish to see how the integrity of mill-owners can be exercised to secure themselves against possible injury, or even to thwart a canal scheme, may perhaps consult the Cropton canal act, for the clauses relating to the Wandle river.

Where a connection is to be made with any other canal lying upon a higher level, or even the same level, where leakage or wafF of water is to be apprehended, that would be prejudicial to either of the canals, it is usual to provide, that a lock-gate shall be erected at or near the junction, which canals may be connected so that either are discharging or receiving the water, and that a sluice is provided for curbing the afflux or ebb of water, in the lower of the two canals, as would endanger the supply or lower the level of the other; clauses for these purposes will be found in the Deane and Dove, Dudley, Stratford, Warwick and Birmingham, Dudley and Evesham, and other acts. And when any canal joins another, coming down from a hilly country, it is usual to require tall gates to be erected, with capacious weirs for preventing of floods from the upper canals making their way into the lower one, as in the Aberdon canal. It will very often happen, that tolls or dues will be to be paid by barges for entering any of the existing navigations from the new canal, or vice versa.

And where the new scheme can be supposed to interfere materially with the trade on any former one, it has not been unfrequent to guarantee that their net profits or tonnage shall not be less, after the completion of the new canal, than before; or sometimes annual payments are agreed to be made as compensation for the expected losses to older navigations; and in some instances, where the rivalry is expected to be very formidable, as on the Douglas River by the Leeds and Liverpool, and the Derwent River by the Derby canal, provision has been made, that the old concern shall be purchased by the new proprietors at a fixed sum; the settlement of the various compensations that may be necessary on a canal are often such as to require the exertion of the utmost abilities of the engineer, with the most able assistance, as the very long and complicated clauses in many acts will shew.

On applying to parliament for any considerable extension of a canal, or to raise more money, there are influences, and perhaps very proper ones, of enacting that the shares of certain discontented proprietors should be purchased out of the new funds, as on the Dudley, the Keenu and Avon, and others.

So attentive has the legislature been, even to the comfort of proprietors or inhabitants near intended canals, that it has been enacted, as on the Barnsley canal, that where steam engines were to be erected in certain places, for the use of the canal, their fire-places should be constructed, as to consume the smoke.

Ample provisioins should be made, for powers to make bye-laws for regulating the trade upon the canal, for the form and dimensions of the barges or boats to be used thereon, and for passing the locks, inclined planes, etc. that may be thereon. It is necessary to declare, that the canal is not to be subject to the interference of the general commission of lcers; manorial rights, and sheriffies in old streams, or waters ought to be reserved; and it would be well for the encouragement of the great national improvement, if the legislature would permit a canoe to stand, as in the older acts for Bridgewater's and other canals, that the proceedings and writings of the company should be void without stamps.

It has been usual to enact penalties for a variety of offences likely to be committed upon the canal, and for malicious damaging or detroying of the works to declare the offenders guilty of felony, and liable to transportation for seven years. There are many other things which will require to be taken into consideration at the period of framing the act of parliament, some of which we shall avoid repetition by mentioning, when stating what occurs to us on the practice of executing
and managing canals, to which we are now anxious to proceed.

The act of parliament for a canal being passed, and therein the time and place for the first meeting of the subscribers or proprietors thereof being fixed; one of the first business of such meeting will be the election of a general committee of management, consisting of the most independent, respectable, and generally informed persons among the proprietors. The committee of management will then proceed to elect a chairman and subordinate officers; to fix upon their place of meeting, and to arrange the order of their business.

It will not often happen that the engineer can spare himself from the projection and superintendence of other great concerns, to attend to the cutting of the canal and erection of the several works, without the assistance of a resident engineer, or more than one, if the line be of considerable length, and distant parts of it are intended to be proceeded with at the same time; and the committee will do well to leave it to their engineer to recommend all such skilled or resident engineers from among those who have been brought up or employed under him, or are well known and approved by him, for their mathematical knowledge and practical skill, experience and attention in the several kinds of works that are to be executed. The attention of the committee should be directed to fixing upon some land-surveyor and valuer of experience and great practical knowledge, who has been used to the acquisition of addresses in the negotiation and settlement of purchases and exchanges of property of different kinds; and if he has before been employed upon canals he will be much the more fit. In this stage of the business it may be well also for the committee to consider whether any local committees, or a select committee, may be necessary, to pay the more minute attention to, and to bring before them, the concerns of particular districts of the canal, and to ferre other purposes.

The body of the proprietors, assembled in a general meeting for the purpose of completing the organization of the affairs of the company, will proceed to the choice of a certain number of auditors of their accounts, and to settle the salaries of all the persons that are employed.

Most canal acts direct, that two copies of the plan of the canal and book of reference, with any amendments or alterations that may have been made in parliament, are to be certified by the signature of the speaker of the house of commons; one of which is to be lodged with the clerk of the peace for the county, and the other with the clerk to the company, who are required to produce the same, and further copies or extracts therefrom to be at any time taken by any person, and to produce the original before the committee, or any jury who may be called on to decide, any matter or dispute relating to the making or maintaining and using of the canal.

The engineer being now informed of the exact bounds within which the law has confined his operations, and of the several restrictions or alterations that may have been imposed or made since his former surveys, will, in all probability, find it necessary to look over the line and all the proposed works again, accompanied by the intended resident engineers; and, in such reviſal, it will be proper to divide the line of canal, and the several works thereof, into the necessary number of parts, and to give concise and definite names to each, that are to be used in future, in contracts and bills, &c. of which different parts or divisions a separate account of the expenses should be strictly kept by the resident engineer, the overseers, or counters as they are generally called, (that the engineer is to recommend or employ upon the works) and by the office-clerks in a ledger, with proper heads for each length of canal, set of locks, tunnel, embankment, deep-cutting, reservoir, aqueduct, or other great work, that may form a separate division: such particular and divided accounts of the works will prove of the most essential service to the committee, and to all others concerned, in informing and maturing their judgment on the actual or probable expense of every different kind of work; and will enable the committee to account to the proprietors how great, and sometimes unavoidable, as well as unexpected, expences may be incurred.

The committee should now well consider and inquire, whether any particular part of the line can be completed and opened with advantage, before the whole length can be got ready; and this being determined upon, the engineer should compare and consider, from the estimates and particulars that he possesses, the comparative length of time that every particular work upon the length intended to be first completed will require; and in this order, or with a proportionate exertion and number of men, should the several works be entered upon. Immediately after the plan has been settled, preparations should be made for providing all necessary utensils and implements.

The Act for a canal should give the company and their servants power to enter upon and occupy, for the temporary purposes of their works, heaps of foil, &c. any land except parks, orchards, and gardens, within the limited distance, on condition of their making a full and ample satisfaction, by annual rent, to the former occupier or lessee, and for all damage to the owner and occupier, to be as the works are completed, and the leas, &c. can be removed or levelled down, and covered with foil. The tunnels, cuttings, embankments, or other great works, that are first to be begun, and the levels, widths, &c. of which we suppose to be completely settled, should be marked upon the ground, with the necessary allowance of width for the tops, and the spoil-banks, which the engineer may judge right to remain the permanent property of the company.

The land-surveyor should now proceed to treat, under the direction of the committee and the engineers, with the several parties who are entitled to the land that is wanted; for this purpose, it will be right for the surveyor to prepare correct and explicit plans and admeasurments of every piece of land, and, in many instances, to deliver copies of the same to the parties; to consider well the intrinsic value of the land to the owner, and of any extrinsic or artificial value which it possesses, with ample allowance for the injury that his remaining property will sustain by being detached, or by the fields being cut into inconvenient and awkward shapes, or on any other account.

It is generally provided, in canal acts, that where any person's estate is cut in two by the canal and a part, containing less than a certain quantity, is severed from the rest, the company shall be compelled to purchase such detached part, if the party wishes it. And it ought to be provided, that the company are not to be obliged to make an occupation-bridge for less than a certain number of acres, unless the dwelling-house or farm-premises of the estate happen to stand upon such small detached part.

As soon as the surveyor has made his contracts or short agreements with the parties, containing a full description of the lands or other property to be purchased, the same will probably be put by the committee into the hands of the clerk to the company, with directions for him to enquire into the nature of the titles of the parties, and prepare conveyances accordingly, in the short and summary form that the Act ought to provide for such purpose: in like manner, where
where the parties who own the estate could not be come at, or have not been brought to agree by the surveyor, he should furnish the committee with the particulars of such property, the price offered, and other particulars of the negotiation; in order that the clerk may be directed to prepare the necessary notices for a meeting of the commissioners described in the act, or a warrant to the sheriff of the county for empaneling a jury to hear the evidence, who are to be summoned on the part of the company, and those produced by the owner of the estate, and to view and examine the premises if necessary, and to give their verdict or allowance of the sum that is to be paid by the company, and accepted by the parties.

The ground for the necessary reservoirs, to supply the part of the line that is to be begun, ought to be among the first that is marked out, including space for the head or new embankment that is to be made, and should be treated for and purchased by the surveyor, and conveyed as above mentioned. The ground wherein the locks are to be built, or any wharf or walled basons are to be made, should also be carefully ascertained by the engineer, and purchased in an early stage of the business, in order that the summer seascorn may be fully embraced, for the building of all the masonry and brick-work.

The modern acts for canals usually contain a clause, requiring all the top-foil to be removed. This, of course, will be attended to before any of the works are begun.

It has been found, from experience, that the banks of canals against which the water is to lie, ought, in general, to have their slopes so apportioned, that one foot in depth will give a horizontal base of one and a half foot; and to these or some proportions near them, rather above than below, as slopes of 3 to 1 are in general too small, will the width at top and bottom, and the depth of the intended canal probably be fixed by the engineer; and it has been found convenient and proper to make up the banks of canals one foot higher than the water is intended to stand in them.

We are now to suppose the resident engineer to be proceeding with the setting out of the canal, being furnished with a map of the several fields through which it is to pass, the line that is provisionally settled for its course, but with liberty to deviate within certain limits therefrom, and with bench-marks which the engineer has left and described at certain distances, to regulate the top-water level, or height of the water in the intended canal; and, as above observed, one foot higher will be the level of the top-bank, or height of the banks.

It will be proper for this engineer, and we shall in future, for the sake of distinction, denominate the other the principal engineer, to trace the levels accurately of each pound or level reach of the canal, and to put in level-pegs or small flakes, at every two or three chains, more or less according as the ground is more or less undulating, as he proceeds; wherever the canal is conducted along the side of a hill, as will happen in a great portion of its length, the level-pegs are not to be placed exactly along the line that the principal engineer has marked out, but either above or below that line, as the slope of the hill may occasion, exactly at that point in every place, where the level of the top-bank (traced by means of a good spirit-level, with telescopic sights) cuts or intersects the surface of the hill. In some places it will be found that the principal engineer has drawn his line across the point of a hill, so as to occasion deeper cutting than usual, to avoid going round it; or, on the contrary, crossed a vale or low place, so as to require less cutting or perhaps none at all, to avoid taking a circuit up that vale to follow the level of the ground; and if either of these deviations should be so considerable that the level-peg would fall more than two chains or thereabouts from the line, down or up the slope of the ground, the plan of having level-pegs upon the surface must be departed from, and holes should, in the first case, be dug at proper distances in the line, and pegs put into the same with their tops to the right height; or, in the second case, longer and flouter flakes should be used, particularly in the fences that are crooked by the line, or other places where they will not be liable to disturbance, and drove firm into the ground till their tops mark the right level. In tracing these levels, the engineer will refer to and compare his work with all the bench-marks before described, and at each end of a level or reach, will level up and down to the bench-marks of the reach above and below the one he has been working at, and compare the same with the fall that the locks at each place are intended to have. And we recommend particularly to the engineer to be very punctual in entering minutely in his field-book the particulars and situations of the several level-pegs, and to make one or more of the men who assist him in levelling, perfectly acquainted with the situations and distinguishing marks of them, and frequently to cause them to be looked over and renewed; or continual repetitions of considerable lengths of the work will be necessary, owing to the disturbance and loss of the pegs by the cultivation of the fields and treading of the cattle, or by the interference of idle and mischievous persons of the country. Too much caution cannot ultimately be taken, by frequent reference to the bench-marks, with due allowance for any accidental variation that may have been discovered among them, and repetitions of the levelling, to avoid those disgraceful blunders into which some loose capable and less careful engineers have fallen.

We are now to consider, that the great desideratum in canal digging is, that the fluid that is dug from one part of the work, shall, with the least labour or disturbance of moving, exactly supply or form the banks that are to be raised in another; so that on the completion of the work, no spoil-banks or heaps of useless soil shall remain, or any ground be unnecessarily rendered useless by excavations or pits. Six different cases will be found frequently to occur in the cutting or forming of a canal. (Plate I. Canal, figs. 1, 2, 3, 4, 5, and 6.) A A E L P P', being in every case, the line or surface of the ground across the canal; A B C E, in the first five cases, the bank on which the treading-path is to be made, and therefore generally the width; L I K P in figs. 1, 2, and 5, the off or smaller bank; C I is the top, F G the bottom, and C F and I G the sloping sides of the canal, in every case. The bench or berm, K I, in figs. 3 and 6, is provided to retain and prevent the looie earth that may mound down from the upper bank P K from falling into the canal. Sometimes the interference of proprietors, or other causes, may occasion the treading-path to occupy the bank, or place of the bench I K, instead of B C, which will cause a considerable difference in the calculation or measure of the fluid to be moved in figs. 4, 5, and 6, but the same do not properly form new cases. The first case occurs most frequently in cutting across or along level meadows, and we were not so well able, when treating of the first survey or projection of a canal, as we now are, to explain a limitation which ought to be attended to in all such level-cutting, especially if of any considerable length, viz. that the height or level of the canal should be so contrived, that in any cross section, as fig. 1. the sum of the areas of A B C E and L I K P shall just be equal to E F G L, the part excavated or dug. It will readily be perceived that

need be calculated to.
The engineer will now proceed to
put in a (take oppofne to each level-peg, at the proper calculated dillancc down the flope, for the approximate or fuppofed middle line of the canal thefe ftakes will feldom be
found for any conliderable diftance together, to range in a
ftraight or in any other regular line, that will be proper for
the canal : and a very difficult and nice part of the engineer's
duty is now to be performed, in Itaking out a new line
with a taller or a quite different fet of ftakes from thofe formerly ufed, to avoid confufion ; this is called flaking the
middle range of the canal.
The requifites in this new line
or range for the centre of the canal is, that it fhould as
nearly coincide in every part with the flakes that were lafl
put in by the calculation, as poffible ; that, where, in order
:

to preferve a regular and

handfome line, and avoid the aukward, inconvenient, and unmeaning crooks and bends, with
which too many of our canals, and even fome of the lateftconllruction, are

conducted higher than the calculated flakes for one or more;
ftakes together, care muft be taken that it (hall quickly be
conducted below others, fo that the redundancy in cutting
deeper into the hill in one place may be as exactly as poifible balanced by a deficiency juft by, owing to the line
being conducted below the leveUkkes.
Befides the confideration above, it will be the time now to ettimate and confider
the quantity of ftuff that will be wanted to land up every
bridge and lock, and to give extra thicknefs to the banks
on which any toll-houfes, warehoufes, or other buildings,
are to be erected, or trade carried on.
In narrow canals, or branches of that defcription, it will
be neceffary to provide for wider places at fliort intervals,
for barges to turn, and to lie in while others pafs them;
confidcrable (kill and care are requifite in the choice of proper places for fuch purpofe
they ought to be fo finite
that barge-men can mutually fee each other approaching
on
narrow canals or branches, and provide for pafiing, without
either of them having to drag their barge back again to

ought to be chosen, if possible, in such hollow or low places
as will admit of widening the canal without much extra
cost. Another consideration is, the excavation of basions,
docks, or wharfs, from which fluff may accumulate, which
ought to be used up, if possible, in embanking the line just by.
Many canal companies have seen it their interest, on proper
and timely application from land-owners, who were defrains
of erecting wharfs, to direct their engineer to calculate upon,
and to excavate the additional width necessary for such pur-
pose, at the company’s expense; and this the extra or
deeper cutting that there must always be, in the approach to
a lock on the lower side, and of embanking on the same
approach on the upper side, should also be well considered and
accurately calculated; and full and explicit memorandums
ought to be entered in the engineer’s field-book at the time,
where the fluff was calculated to be had from for every
embankment, and where the fluff is to be disposed of from
every deeper cutting or extraordinary excavation. These
memorandums will prove of the most important use in the
renewal of the whole length of line or district that is about to
be fixed on in contracting for and letting of the work afterwards, by being able, without fear of mistake,
to point out which way every part of the fluff is to be
thrown or wheeled, as fast as it is dug, and that no part
of the same may want moving a second time, or any wide
or gouty places be made to disfigure the canal for finding fluff;
or, what is often of more fatal consequence, the canal being
dug deeper than usual for such purposes.

After the line shall have been thus marked out with the
utmost care, it will still be prudent for the engineer to revite
it again, and to make pretty accurate calculations of the
quantity of fluff wanting, or to spare in particular places;
in these kinds of calculations the engineer will find the most
important aid in a ready use of the slide-rule; and we beg
him to note generally that a gentleman who has long distinguish
himself by the various and important uses to which he has
made the slide-rule subservient, has prepared a short but
complete treat on its application in the concerns of an
engineer, which it is hoped that he will ere long publish.
Perhaps, on the review of the line, the curves or bends
thereof may in some cases be changed, and beauty and conve-
nience may be more fully attained without much, or even
any extra expense. The Drottwich canal has been mentioned
as one on which these points have been the most fully atten-
ted to. The portion of the canal that has been thus
flaked out and revised, may now have the boundary lines
marked out of the land to be purchased; and the surveyor
should proceed without delay to survey the same, and to
execute the purchase for the purpose, as we have before
mentioned. It will be among the first works to dig out for
the foundations of the locks, if they are not already in hand,
and for the bridges, if the season of the year and supply of
the bricks and workmen will admit of their proceeding immedi-
ately: the several drains or culverts that are to pass under
the canal should also be dug out, and prepared for the ma-
fons or bricklayers, and the several safety-gates, float-
backs, weirs, and other erections, which we shall notice
more particularly further on. It may be proper here to
caution the engineer, that in the case of pipes of any water-
works, or that supplied any gentleman’s house, croft the line
of the canal, such pipes should be laid at one, two or three feet
beneath the bottom of the intended canal, with an easy de-
cent and ascent therefrom, and the ground made good agianso as soon as possible, both to prevent their being dam-
aged in cutting the canal, and being exposed to froll, or
to thieves, if of lead, by lying bare; and in case such pipes
are found old or decayed, new ones of lead or cast iron
should by all means be laid in the deep part under the canal.
The top foil should be carefully removed; and in order to
determine readily and correctly the places of the slope-holes
at E, and L, fig. 7, and E and P, fig. 8, the engineer will
find it useful to calculate the distances of d E and d L, and
d P, by a general theorem, in terms of h b and h i, and to
make tables for the several values of the data, that are
likely to occur. The values of d P and d A, fig. 7, would
be alike useful in a table for determining the limits of the
banks that are to be raised.

Before cutting out the lock-spit, or small trench between
the several slope-holes, as a guide to the men who are to
dig, the engineer ought to cause holes to be dug in the line
of the canal, near every second or third level-peg, or oftener,
if the foil be variable, in order to prove the foil to a greater
depth by two or three feet than the cutting of the canal is
to extend; and each of these the engineer ought carefully
to inspect, in order to determine what puddling or lining
will be necessary; and what will be the difficulties of digging,
owing to the hardness of the fluff, or to water that must be
pumped out, &c., and all which circumstances, as well as the
extra distance that any part of the fluff may require to be
moved, must be well considered before the work can be let
to the contractors or bag-masters.

The puddling or lining of a canal, to make it hold water, is
a matter of the greatest importance, and we shall consider five
cases, in figs. 9, 10, 11, 12, and 13, that are likely to occur
or prevent themselves in the search, into the foil that is to
be dug, by sinking holes as above mentioned: the first case
we suppose to be that in which the whole is clay, loam, or
other water-tight stuff, as shewn by the dark shading in fig.
9: all foils that will hold water, and not let it soak or per-
culate freely through them, are called water-tight. Our
second case, fig. 10, is that in which the whole cutting will
be in sand, gravel, loose or open rock, or any other matters
that will let water easily through them, and such are called
porous foils or fluff. The third case we suppose to have a thin
stratum of water-tight fluff on the surface, shewn by the
dark shading in fig. 11, and to have porous fluff for a
considerable depth below, here distinguished by dots. The
fourth case may have porous fluff near the surface, and
water-tight fluff at the bottom of the canal, as in fig. 12. The
fifth case is that where water-tight fluff appears on the sur-
faced, as fig. 13, below this a stratum of porous fluff, but
having again water-tight fluff at no great distance below the
intended bottom of the canal. The new raised banks that
are left unshaded in all the five figures, are always to be
considered as porous fluff, as indeed they will always prove
to be, and in a great portion of foils they would ever re-
main so, unless either puddling or lining was applied; all
ground that has been dug or disturbed must also be consid-
ered as porous. It should also be remarked that any kind of
foil which is perforated much by worms or other insects,
should in canal digging be considered as porous fluff. Puddle
is not, as some have attempted to describe it, a kind of thin
earth mortar, spread on places intended to be secured, and
suffered to be quite dry before another coat of it is applied;
but it is a mass of earth reduced to a semifluid state by work-
ing and chopping it about with an spade, while water just
in the proper quantity is applied, until the mass is rendered
homogeneous, and so much condensed, that water cannot
afterwards pass through it, or but very slowly. The best
coarse sand or fine gravel in it; very strong clay is unfit for
it, on account of the great quantity of water which it will
hold, and its disposition to shrink and crack as this escapes;
vegetable mould or top-soil is very improper, on account of
the
the roots and other matters liable to decay and leave cavities in it, but more on account of the temptation that these afford to worms and moles to work into it, in search of their food: where pudding-fluff is not to be met with, containing a due mixture of sharp sand or rough small gravel stones, it is not unusual to procure such mix to the loan, to prevent moles and rats from working in it; but no loaves larger than about the size of musket bullets ought to be admitted. That the principal operation of puddling confines in confounding the mafs is, we think, evident, from the great condensation that takes place: it is not an uncommon cafe, where a ditch is dug, apparently in firm soil, that though great quantities of water are added during the operation, yet the soil that has been dug out will not more than two thirds fill up the ditch again, when properly worked as pudding. It should seem also, that pudding is rendered by that operation capable of holding a certain proportion of water with great obscurity, and that it is more fit to hold than transmit water. It is so far from true, that pudding ought to be suffered to get quite dry, that it entirely spoils when by exposure to the air it is too much dried; and many canals which have remained unfilled with water during a summer, after their puddling or lining has been done, have thereby become very leaky, owing to the cracks in the puddle-ditches and linings. One of the first cares of an engineer, when beginning to cut a canal, is to discover whether the good puddling-fluff is in plenty, and if it be not, it must be sought for and carefully wheeled out or refured wherever any is found in the digging; or perhaps procured at considerable distances from the lane, and brought to it in carts. It has happened in some floe-brach or loose rocky soils, that all the puddling-fluff for several miles of the lane, required to be brought to it; but even this exigence, serious as it may be, ought not to induce the copying of those, who have left miles of such banks without any puddling, and have made a winter canal, but which no stream of water that is to be procured can keep full in the summer months. It is usual in canal acts to insert a clause for the security of the land-owners, to require the company to cause all the banks that need it to be secured by puddling, to prevent damage to the land below by leakage; and it would have been well for all parties in many instances, if this clause had been enforced. It appears that the Dutch have been in the habit of making puddle-ditches to fence the banks of their canals from embankments, from time immemorial; and that operations similar to our puddling have been long known on the continent, but it is not clear at what period it was introduced into this country; we think that the fens of Cambridgeshire and Lincolnshire, in which so many works have at different times been executed by Dutchmen, are the most likely places in which to search for early evidence of its use. We cannot think that James Brindley was the first who ever used it in this country, although we might admit that the Bridgewater's canal was the first in which it was systematically used as at the present day. If we compare our first, fourth, and fifth cafes, fig. 9, 12, and 13, we shall find in all of them a water-tight stratum the bafis; and the practice in these cafes is to make a wall of puddle, called a pudding-ditch, or pudding-gutter, within the bank of the canal, as shewn in fection, by a, in the above figures: these pudding-gutters are usually about three feet wide, and should enter about a foot into the water-tight fluff, on which they are always to be begun: and they should be carried up as the work proceeds to the height of the top-water line, or a few inches higher. Our second and third cafes, fig. 10 and 11, evidently will not admit of the above mode, because we have here no water-tight stratum on which to begin a pudding-gutter as a bottom: in these cases, therefore, it is usual to apply a lining of puddle to the sides and bottom of the canal, as shown by the cross-sectioning in figs. 10 and 11: the process of puddling and lining will occur more properly further on, as we proceed in describing the operations of digging and forming the canal.

In order to describe more intelligibly the process of setting out and digging a canal, in the two cafes where puddling or lining will be requisite, we have repeated our first and second cafes, but on a larger scale, in figs. 14 and 15; wherein p is intended to represent the hole that has been before supposed to be sunk, in order to prove the soil; and, according as this terminates in water-tight or porous fluff at the bottom, that puddle-ditches, q, r, and s, &c. in fig. 14, are laid in the manner of H G F D. fig. 15, is to be applied; D H being the height to which the water is to be raised in the canal. The engineer will in the first cafe determine the places of E and L on the ground, and dig small holes or mafs to mark the fame, called slope-holes; but in the second cafe other marks must be made at n and w about five feet from the former, to direct the beginning of the cuttings, with allowance for the lining. A skilful and very handy workman is now required to mark out the line upon the ground, called the lock-spit, between the slope-holes at E, fig. 14, above-mentioned, which we have supposed to be made at about two or three chains from each other. This is done by laying down and stretching a strong line upon the ground, between two or more adjoining slope-holes, and if the canal is not to be straight in that part, with small pegs to give it the gradual and regular bend in every part that the canal is to have; the workman then proceeds, holding his spade or grafting tool over the spit, as the same is laid, so as to guide himself by the fluvet of E, that the bank of the canal is to have, and strikes it successively into the ground close to his line, until the whole length of the line is marked out; by this means, if the ground has sudden undulations, or hollows, as continually happens, owing to the ridges and furrows of cultivated lands, and other causes, yet a regular line coinciding in every part with E is marked out upon the surface; before the line is taken up, another labourer follows on the other side of it, and strikes in his tool inclining the contrary way, by which a more regular bit of piece of earth is cut and thrown out; a similar lock-spit must be cut on the other side of the canal at L; and the same at n and w in fig. 15. If wettines and regularity are properly consulted, lock-spits for the extremities of the banks at A and P will also be proper, especially if the land A and P is valuable, and the damage by the scattering and laying of the fluff would be considerable. The engineer has now to determine, in fig. 14, the points c and d for the beginning of the puddle-ditches, and thence he ought to chafe such, that if the same were carried upright to the top-bank, k c or i a would be about one foot: if this is not strictly attended to, the labourers or navigators, as they are called, will for their own convenience begin their puddle-ditch much too near the canal at E and L in some cafes, and not make it upright but hatching back to arrive at a b; and puddle-ditches so made are apt, owing to the settling of the bank, to get broken and be spoiled. It may be proper here to remark, that canals set out with the scientific precautions and care that we have recommended, will always have the proper quantity of fluff to allow for the settlement of the banks, because A B C E + L K P = E F G L, in the same settled or consolidated state, that the latter part was before the digging commenced: it will, however, be proper to give the contractors a table or rule flowing, according to the height, as a, what extra height a suddenly raised bank is required to be, to allow for settling: and it is evident that the
the slopes of such banks must be fleeper in the first instance, than they are intended ultimately to be.

We may now suppose the engineer to proceed to the letting of the cutting of certain lengths of the canal to contractors or bag-makers, who will employ a number of navigators under them, in digging and puddling the canal. It is usual to let the work at a certain price per cubic yard of digging, and to pay for the puddling and lining either at a certain price per cubic yard, or per yard run of the canal. This engineer ought to inform himself thoroughly on the difficulties and facilities which attend the work he is about to let, and to draw up a short but explicit contract to be signed by the contractor. We cannot but recommend that all contracts for material or large jobs of work, not only in cutting, but for the masons', and other works in particular, should be submitted to the principal engineer for his approbation, before they are signed or finally concluded on. The prices allowed ought to be fair and liberal, according to the circumstances, so that the contractor may have no pretence on account of low prices, to slight his work, particularly the puddling; and they ought in every instance to be strictly looked after, and made to undo and renew immediately, any work that shall be found improperly performed. We recommend it to the engineer to keep a strict account, by means of his overseers or counters, of all the men's time that are employed upon the works; distinguishing particularly the number upon each work, and whether employed by the day, under the company, or upon the work that is let to contractors. These particulars are most essential towards knowing, what money ought to be advanced to the contractor during the progress of his job, and towards informing and maturing the judgment of the engineer, in the length of time that a certain number of men will he in performing any future work that he may have to direct; and a calculation ought to be made in every instance of the day-work, and compared with the contract price, by which alone a correct judgment can be formed of the proper prices at which work ought afterwards to be let, so that the labourers may receive proper wages, proportionate to their exertions, and the contractor be amply paid for his time, skill, and superintendence; and yet economy and the interest of the company be duly consulted. Barrows and wheeled-planks, forking-blocks, and other implements, are generally found by the company, and it is usual to consider 20 to 25 yards, to be a flag of wheeling, and a price per cubic yard to be fixed, according to the number of fages that foil is to be moved; where this distance exceeds 100 yards, it will not often be able to perform it by wheel-barrows; and runs of planks with an easy descent, if the ground is practicable, should be then laid for large two-wheeled barrows, or trucks to be used thereon.

The cutting of a canal being let, the work is usually commenced by a labourer, on the part E, fig. 14 or 15, on the lower side of the canal; and from the lock-fret at E he marks out a certain width to g, such that he can throw the clay as he digs it, to the part A, and so that the heap may not obstruct the intended puddle-gutter cd. The side E F he is careful to cut down in the proper slope of the bank; the other side is usually cut straight down, and this work is continued until he comes to the bottom of the intended canal at F A, and this space E F b g is called the "reaching." The same process is followed on the lower side of parts that want lining, as fig. 15, except that n r b k g is the reaching in this case, and that there is no necessity to throw the clay further in this case, than that it may lie upon A without rolling back into the work; and it is usual, if the reaching will not be very deep, to lay two or three rows of soil; or found spots of earth, with regularity in the face of the slope n g to form part of the bank, and to throw the other stuff over these. Reachings are also to be dug on the upper side of the canal, as i k G L, or at least as much stuff is to be thrown out therefrom as can conveniently be flowed upon d P and e P, figs. 14 and 15.

It is now time to commence the puddling in fig. 14, and a labourer begins by digging out the bottom of the intended puddle-ditch c e d; if the soil dug out is good puddling-stuff, he lays it on the part d E, if otherwise he throws it at once on to the heap on A c. A careful examination of the face E F of the reaching will show to what depth the puddle-ditch d f ought to be carried in every part, to reach and intersect any faulty places, or veins of lighter foil, or worm, rot, or mole-holes that may accidentally occur in the bank. After the puddle-ditch is dug clean out to its p o per depth, and this is a circumstance that the engineer or some careful overseer ought always to look particularly to, about 9 to 10 inches thereof is to be filled lothly up with puddling-stuff, either from that which comes out, or from the nearest heap in reserve, all large stones, slacks, flaws, or other external matters being carefully picked out of the stuff as it is sprinkled in: by this time, unless the season is very dry, it is probable that some water will be collected in the bottom of the reaching F A, and this should be laded out with a sump into the puddle-ditch, so as to give the stuff therein a good wetting; if the puddling-stuff be of the flatter kind, or was very dry, it will be right for the labourer to take himself to some other part of the work for two or three hours, but perhaps giving his stuff another sprinkling of water in the interim; he may then proceed with the puddling; and for this purpose he ought to be provided with a stout pair of puddling-boots, that will keep out water; he begins at one end of the trench, and keeps chopping with his tool into the stuff and quite through it, giving his tool a luning motion every time before it is withdrawn, so as to let the water run down and into every part of the puddling-stuff; if more water is wanted, another labourer is set to lafe it out of the reaching as before; and the puddler thus proceeds, chopping down at every inch or thereabouts as he slowly advances, and rambling about at the same time as much as he can with his feet, which greatly affiis the operation: when arrived at the end of the trench, he returns and repeats the same operation, until every part of the puddle is properly worked; which is known by the tool going equally easy into it in every part, which it would not do if any dry lumps remained, and the whole being in a semifluid state; giving the puddling-stuff just the due quantity of water is very essential to its working well, and this, experience will soon point out.

Very great care and management will, in general, be required on the part of the engineer, to furnish water for the puddling: it will often require to be brought in temporary trenches, perhaps across several fields from some mill-dam, large pond, or spring of water above the canal; for which purpose general powers ought to be given in the act, upon condition of levelling and making all such trenches good again as soon as possible, and paying for the damage; often times puddling water is not to be had without pummpering it up, and conveying it considerable distances in troughs, of which great numbers will be required. It will very often be requisite to convey the water across the canal in troughs to the different puddle gutters, and plenty of treffles should be in readiness for supporting these troughs at the requisite heights. Considerable care will be necessary to turn off the surplus water, into some channel where it can run off without flooding the works; or to stop it at its source; this last ought always to be adopted, when the supply is not very plentiful,
plentiful, or the owner of the stream or pond might be injured by taking a constant stream from him, during the progress of the work. The first or bottom course of puddle being properly worked as above, it should then be suffered to stand two or three days undisturbed, and without any more water being given to it; when it will be found sufficiently set that a man may step on it without sinking in; it is then ready to receive a second course; the first step is to scrape off and remove any lumps of earth, stones, and other matter which may have fallen into the puddle-ditch; about 10 inches thick of pudding-fluff is then to be sprinkled lightly into the ditch as before; and water is to be applied either from the reaching, or from some of the troughs which we have been mentioning; some hours time is to be allowed for the fluff to soak, unless it be light loam, and moil at the time of putting it into the ditch; in such case, the puddling may be begun almost immediately: care must be taken that the tool be made to penetrate a small distance into the old puddle at every chop, in order that the two courses or layers may be properly incorporated. After this course is properly wetted and worked, it must stand the proper time to set as before, but by no means to get dry, otherwise it will be found full of cracks and must be worked anew: and in cafe, owing to any temporary suspension of the work, it should be necessary to leave a puddle-ditch before it is finished, it ought always to be covered, and left with a dry or unworked course of pudding-fluff upon it, to keep the air from it, and preserve the proper moisture in it.

When a sufficient number of courses of puddle have been added, to fill up the ditch c e f d, two or three rows or courses of sods, or spots of earth, must be laid on each side, to raise the ditch so much higher; at the same time that the heap of fluff on A e is levelled down, and other fluff is brought by the men, who are wheeling from the bulk g b k i that is left in the middle of the canal, and laid on d E to back up the spots or sods; after cleaning the surface of the puddle, if properly set, it will be ready to receive another course of pudding-fluff, the water must be turned on, it must have time to soak, if necessary, and then be worked and flanked to set as before; other rows of spots or earth may then be laid, to raise the sides of the puddle-ditch, and the bank may be made up to the same height by fresh fluff wheeled in from the canal; and care being taken to lay spots of earth to form the slopes A B, and E C, as the works proceed upwards, particularly the inside slope C E, which should be well trod and consolidated by strokes of the tool to prevent its falling down, or being disturbed by the water when the canal is filled; another course of pudding-fluff is then to be added, and all the same processes gone through till the puddle has arrived at q w, the height of top-water, or an inch or two higher, which being properly set, the bank is to be made up, covering the puddle completely up with common fluff, to the intended height of the top-bank. B C, with proper allowance for the settling; and observing that the puddle will not settle near so much as the other fluff, if at all. The processes is no way different, by which the other bank L I K P, and its puddle-ditch, are to be carried up, and completed to the intended height. The part of the canal, with puddle-gutters, fig. 14, of which we have been speaking, has, in general, a lump or ridge of fluff remaining in the middle of its bottom, until the very last, a different system of which, however, to be purified with such parts, fig. 15, as require to be lined; here the banks A B g n, and g v K P may be at once made up, and the whole of the space n r s v ought to be cleared for certain distances, before the lining of the bottom can be begun. A great deal of management is required by the overseer or contractor, to manage all these parts of their business, so that there is no hindrance of any part of the work, that every man is provided with fluff by the wheelers, when he wants it to make up his banks, or puddle, and that the parts to be lined are cleared in time.

To accomplish all these objects, a good part of the fluff cannot be wheeled directly out to the near or opposite points of the bank, but it must be worked forwards and backwards obliquely, on the runs of wheeling planks by the wheelers, as occasion may require. It may often be necessary to exceed one or two, or perhaps more, stages of wheeling, to avoid taking out the fluff and channelling it, by which it would require filling again, damage would, in most cases, be incurred on the adjoining lands, and frequently the puddling and working of the banks would be impeded, by clogging them to land the fluff.

A length of the canal that is to be fixed being cleared, and the bottom levelled and cleaned smooth down to the line r z, a course of pudding-fluff about 10 or 12 inches in thickness is to be spread over it, with all the precautions, to extract extraneous and hurtful matters, which have been before given, and the whole is to be wetted and allowed to soak if necessary, as before: the working of this puddle is now to be begun; and as the extent will generally be large, several men may be employed, at once, upon it, so as to make it work while for an overseer employed by the company, to attend them constantly to see that no part of the work is lighted: as the bottom in this case is filled up to be sand, loose rube of a rock, chalk, or other matters, that would injure the puddle if mixed therewith, we have recommended a thicker course at first than is usual of puddling-fluff, and in working the same the men ought not to strike their tools deeper or even quite so deep as the bottom of the pudding-fluff to avoid disturbing the bottom. When this course of puddle has been added to, another course of about nine inches is to be added, and treated as before, till about three feet of puddle is added, if the soil is very porous; and the top course being set, a course 18 inches or two feet thick of the common foil or fluff should be laid evenly upon it and the bottom levelled; this covering of the bottom should be rather dry, and not in large heaps, or with great flanks or licks in it.

The lining of the sides is now to be proceeded with as follows; the top covering of the bottom should be removed for three feet in width next each of the sloping banks; and the surface of the puddle be carefully cleared of dry lumps, stones, &c.; a thickness of nine inches of good puddling-fluff is now to be laid in this place and wetted and worked, and allowed to set as before directed, when another nine inches is to be added in like manner; some common fluff from the digging of the canal is then to be brought in spots or sods, and carefully piled up for two feet in width, and about nine inches in height, hatching-back before and behind, agreeable to the slopes F E and G I, and leaving a space or puddle-ditch behind, next to the sides r n, and s v; the surface of the puddle at the bottom of these is to be carefully cleared, nine inches of puddling-fluff applied, wetted, worked, and allowed to set as before: more spots or sods are then to be piled in the front, as a facing to keep up the puddle, and their interlites should be filled with fine fluff to make the whole solid; when puddling-fluff is again to be applied behind, and the same process repeated till the puddle and facing arrive at q D and H G, when the remainder is to be made up with dry fluff and spots to the top-bank level at C and I, as directed in the former case.

The last of these ways of making a canal water-tight is the more tedious and expensive of the two; it is however general, and may be applied in any situation with perfect success.
success. Mr. Thomas Telford, in Plynley's Agricultural Report of Shropshire, 8vo. p. 295, when speaking of the Shropshire canal, says, "This canal, carried over high and rugged ground, along banks of swelling loam, over old coal-mines, and over where coal-mines and iron-flume are now actually worked under it, is a satisfactory proof that there is scarcely any ground so difficult but where, with proper exertions and care, a convenient water conveyance may always be obtained." And we have heard of instances of canals being conducted over ground so rocky, and abounding with such great chasms, and loose pieces of rock, that many yards together of the canal bottom might have fallen in, had not the precaution been first taken, of removing all the smaller and loose flats of rock, and thorough wedging in the large loose pieces of rock with flumes, set in mortar, and then rendering the foundation found, on which to fill up the inequalities, and a lining and facing was applied as above, with perfect success. We have already observed, that some persons have thought it right to omit puddling or lining, where springs appeared in the bank of a canal; and the matter is of so much consequence, that we beg farther to observe, that the appearance or non-appearance of springs ought in general to have no effect in determining the propriety of these essential measures; if a spring is of any use to a canal it will rite, owing to the puddle-ditch or lining, and run over the same into the canal, and no water will be thereby lost; and if it will not so rite, it may safely be ranked as a drain of the most mischievous kind, instead of a supply, and therefore very essential to be stopped up.

In case it is found that there is fluff to spare after completing the banks, it will sometimes be advisable to remove the top-foil from A A in low places, and after spreading the extra fluff so as to make the ground good, to return and spread the soil upon it: the part P P will often admit of similar treatment, and sometimes sudden hollows there may be filled up, so as to have a fall to the top-bank 1 K, and avoid a deep ditch through an adjoining swell or rise of the ground at P, to carry off the rain water to a culvert where it is to pass under the canal: where it happens that P P is waste or ground of little value, or the company is possessed of a piece of land that has been obliged to purchase and cannot readily dispose of, it may be proper to make a heap or spoil-bank of any extra-fluff, to be afterwards boiled away as occasion may require. If a deficiency of fluff is experienced to complete the banks, the part P P furnishes a good resource in many instances; the top foil being removed on the higher parts, an excavation like P y P', fig. 14 and 15, may, and indeed must in many instances, be made with a proper fall for conveying the rain-water that falls in every part above the canal to the brook or culvert that is to take it off; the slope P y ought to be so easy, and the top-foil so spread, that the land shall be as fit for agricultural purposes afterwards as before. Another resource ought in an earlier stage of the business to be provided, in the deep-cutting, by marking out a yard or two or more width of ground to be purchased on the upper or deeper side, than is actually wanted, by which a great deal of fluff may be procured at a comparatively small expense of land: it must be evident, that the resources we have pointed out above are inadequate to receive any great redundancy, or to supply any great deficiencies of fluff, and are only sufficient where the canal has been cut out with scrupulous care; bungling, or careless canal-makers must be content to leave laching marks of their incapacity or folly behind them, in the many fudden bends into the hill that they are obliged to make to obtain fluff, and out of it to dispose of the fame in other places, with numerous wider or deeper places on the canal to make up the banks, or in enormous spoil-banks or useless excavations. Where a reserve of fluff has been made in the deep-cuttings at several points on each level or reach of a canal, as above-mentioned, it will be the better fault of the two, to experience a deficiency of fluff; because as soon as the bottom of the canal has been cleared, and the lining of the bottom and sides for some height performed, or the puddle-ditches carried up, the canal may have 18 inches or 2 feet of water let into it, and dirt-boats may be used to carry fluff from the deep cuttings to make up the banks in other places; whereas all redundant or spare fluff must be got out before the bottom lining can be applied, or any effectual use made of boats to move fluff from place to place; and the same advantages will be experienced in situations where puddling-fluff is only to be procured at particular points on the line, by clearing out and completing the bottom part of the canal for considerable lengths, so that dirt-boats may be used to bring the fame for the puddling or lining of the upper part of the banks, which, if there is spare fluff, cannot be effected without heavy expences in moving the fame and forming spoil-banks. Where the line of a canal is to cross an extensive flatum of valuable brick earth, or one of good gravel for making of roads, it will often be advisable, especially if the line can be rendered more direct thereby, when setting out the canal, to cut pretty deep into such materials, and even quite through the gravel, if the same is practicable, as might have been done at Dawley-deep, between Paddington and Uxbridge, on the Grand Junction canal; for although considerable expense will in the first instance be incurred in digging and in damage for spoil-banks, yet such materials, as good brick-earth and gravel, will in almost every instance find a market as soon as the canal is opened; such a situation of the canal may prove of essential service to its trade, by enabling the adjoining proprietors to work the whole thickness of their brick-earth, gravel, or other useful matters, and destroy but very little of the surface of the ground, and without being annoyed by water, but which the canal would catch in very considerable quantities perhaps, instead of losing water by preferring a high level through porous fluff. It is highly to the interest of a canal-company to give facility to the getting and conveyance of all useful articles within their district, at the cheapest possible rates, as the only means of opening new sources of trade or manufactures, by which their concern will be in the most essential degree benefited. In districts where flume and gravel for making and repairing of roads are scarce, it will be proper to pay the labourers certain rates per cubic yard for all the flumes or gravel that they may collect out during the work, and stack in proper places; as refoures for the making of the towing-path C F, fig. 15, and for making good the landing or alcent to the several bridges, and the several pieces of new road that the engineer will have to form, near to the canal and bridges; the lock-banks and all wharfs and landing places should also be covered with good gravel to render them safe and convenient for use; if good gravel can in places be interlaced in deep-cuttings, much of the above expense, as well as of cartage, may be saved, by an early use of dirt-boats in the bottom of the canal. It cannot, we think, have failed to strike every reader ere this, how very important and various the duties of the resident engineer are; but the same will be much more apparent, when we shall have finished, in the following pages, the more particular observations that occur to us under the heads of refoures, feeders, aqueducts, embankments, culverts, safety-gates, weirs, tunnels, deep-cuttings, locks, substitutes for locks, inclined planes, rail-ways, bridges, towing-paths, fences, drains, boats, towing or moving.
ing hats and teams, cranes and implements, &c. of which we
shall proceed to treat; after observing, that none but men of
the strictest integrity and extensive knowledge ought to be
employed as competent engineers, and that the committee and
principal engineer ought not to hesitate in offering and pay-
ing such men a very liberal salary, to engage the whole of
their time; and, that too great a length of line or extent of
business should not be put upon such a man. This is the
proper sphere, where young men or others, of knowledge and
practising industry, who are coming forwards in their pro-
fession, should exercise and give specimens of their abili-
ties as engineers; and it will prove of the utmost importance
to such, as well as to a company who have an extensive line
of canal to construct, to employ more than one of such men
at the same time, upon adjoining lengths of the canal; where
their emulation may be excited in an honourable contest, as
to those who shall execute their portion of business in the
most complete, orderly, and economical manner.

One of the first considerations relating to the cons truc-
tion of a Reservoir for supplying a canal, is the supply of water that
is to be expected for it, and in what proportions at different
times of the year: for this purpose we suppose the engineer
to be furnished with an accurate survey of the vale or vales that
lie above the intended reservoir, so as to be able to calculate
exactly, how many square miles and fractions of surface
will drain towards or want their rain-water through the part in-
tended to be embanked for the reservoir; it will be very
proper also to be furnished, if possible, with the exact gauge
or quantity of water that has actually in former years been
discharged by the brook or stream that is to be embanked;
as also with the quantity or depth of rain which usually
falls within the drainage of the intended reservoir. If the
length of time that has elapsed, since the situation of the
reservoir has been determined on, has not allowed of careful
and accurate experiments being made on these points, the
engineer must assume them from the best data that the infor-
mation of millers and other persons will afford, and the
printed tables, or journals of rain, kept by curious persons
in the nearest familiar situations, must be consulted: it is par-
cularly necessary to attend to this last circumstance, because
there are, we believe, instances of places where the annual
depth of rain does not amount to a foot, and others in which it
exceeds five feet; while 25 inches is about the medium
depth of rain annually, at or near London. The most perftc
method of obtaining true information on this subject, is to
gauge the different springs or streams, from whence the sup-
plies of water are to be derived, and thus to ascertain the exact
furrows, after the mills are amply furnished. In the great
contests about the Rochdale canal, Mr. Rennie had all the
streams, which could be affected by the proposed reservoirs,
gauged for about a year. He first ascertained the rate of
these streams at a time when the mills were amply supplied
with water, and had proper gauges fixed upon them. The
daily difference was measured, and the furrows thus ascer-
tained amounted in the year 1793 to fifteen times the
ordinary produce of the river. The evaporation that
takes place, from a given surface of water in different places,
hast not yet been so accurately observed as the importance of
the subject to canal engineers deserves: Mr. Bevan's obser-
ations thereon, at Leighton-Buzard in Bedfordshire, con-
tinued for five years, to the end of 1804, gave an evaporation
of 25.92 inches at a medium per annum, while the depth of
rain there, in the same period, was observed to average 23.25
inches; in some years the evaporation considerably exceeded
the depth of rain, and in others it fell as much short of it or
more. On this subject, see the article Evaporation.

VOL. VI.

It will sometimes happen, that the valley in which the
reservoir is to be made, has other vales parallel to it, or
one or both of its sides, such, that by beginning a short
or small tunnel above the level of the reservoir, continuing
it with a small rive through the adjoining hill, and from
this further end continuing a ditch or feeder along the side of
the hill rising gently as it proceeds till it intersects the bot-
ttom of the vale, a brook or considerable stream of water
may at times be thereto added, and brought into the res-
ervoir; or, another case may happen, in which the adjoin-
ing vales instead of being parallel to, proceed directly
from the reservoir valley, and yet feeders may be let out,
so as to collect great quantities of rain and spring water,
from the sides of the hills that slope towards the adjoining
valleys, and through which it would otherwise escape. Both
these methods are found successfully practised about the year
1769, for increasing the supply to the new water meadows
which the late Duke of Bedford had directed his agent to
construct near Woburn. A parallel valley, which crosses the
turnpike road at about 4½ miles from London, has its
stream of water diverted at that point, and through a short
tunnel into the Woburn vale, which it otherwise would not
have reached for a mile or more, and at a much lower level.
From the lowest point in the ridge of high land that sepa-
rates the Woburn vale from one that proceeds through
Postgrave parish towards Leighton, a trench or feeder was
begun, and carried for a mile or more along the side of the
hill in Postgrave, by which the rain water of 3 or 400 acres
of land was brought into a reservoir in a branch of the WO-
burn vale, to be reserved for use.

The engineer, who has well considered and ascertained
all the circumstances of the vales in or near to which his
reservoir is to be constructed, will be able, by help of a num-
er of levels, carried round to where the surface of the wa-
ter will extend at every 5, 10, 15, &c. feet in depth, or
often, if the nature of the ground requires it, to calculate
to what height the head of the intended reservoir must be
embanked to retain all the water that his valles can supply,
between the times that it is fed by rains and springs, and
required to be let off to the canal or mills, or such quanti-
ty only as it may be necessary to retain, according to the
principles before laid down.

The necessary height of the head or embankment for a
reservoir being determined, the next step will be to examine
minutely the nature of the flata and soil that are to be cov-
ered with water, and whether the whole or any part of the
same is so porous as to require lining with puddle, as also
the nature of the stuff which is to be used in forming the
head or bank, as thereon will depend, in a great measure, the
degree of slope which the banks ought to have; 15 to 2 feet
above one to height feems the usual slope; but if the soil
should prove a flippy clay, as at the Aldenham reservoir,
belonging to the Grand Junction canal, a greater fl- pe
should be given, as well as the precaution taken, of putting
in frequent layers of sand or coarse gravel, to lessen the ten-
dency of such soil to slip. If the reservoir will require bot-
tom lining, yet fill it will not sometimes be right to trust to
lining for the head of the reservoir, but to carry up a puddle-
ditch in the centre of the head, because if the inside of the
head should happen to slip, the lining would be broken and
disturbed. The ditches being intersected, it will be right to make
a cross section of the valley at the place of the centre of
the head, as A C B (Plate I. Canals, fig. 16.) and to determine
by levelling, and mark out the places of, as many perpen-
diculars or equidistant ordinates a, b, c, &c. as the width of
the head and the nature of the sides of the hills A C and

T
CB may require; we are next to consider, that the section of the intended bank at every one of the points a, b, c, &c. will be nearly triangular, as DGF, fig. 17. (except wanting a small triangle GHI at top) KE being equal to the ordinates a, b, c, &c. in every case; the base DF, or width of the head at the different places, varying according to the height KE, and according to the inclination or fall of the ground DF, compared with the horizontal lines FL and IH. A theorem for ED and EF will readily be obtained with the above data, and these distances being calculated and laid off on the ground, so many points for the bottom of the flops will be determined, and a careful workman will find no difficulty, by pegging down his line and holding his drafting-tool in the inclining position HD and IF, (as before mentioned reflecting marking out the canal) to mark out a lock-fpit, as a boundary or base for the intended embankment.

If the several triangular sections DGF are taken near enough to each other, A a, b, c, &c. and are carefully calculated (for whatever purpose in very large works, tables framed from the theorem will be found the readiest way), by deducting a triangular prism, whose base is HGI, and length A B, figs. 16 and 17; the solid contents of the required bank will be very exactly obtained; and the most eligible spots for obtaining that quantity of fluid, as near as may be, without endangering the stability of the bank, may be indicated; and the work will then be in a state to be let to the contractors who are to execute it. But before this is begun, it will be necessary to provide for the escape of the surplus water when the reservoir shall be full, as also for letting out the water for use; for these purposes an arch of brick-work, or of stone, may be begun at the lower limit of the bank in the lowest ground or brook course, as at D, in fig. 18, and continuing the same on a level to a point M, some distance within the head DHE of the reservoir; D'L' being the lowest ground or longitudinal section of the valley. This arch should be high enough for a plank to be supported and fixed on iron or bearsers across it, about a foot from its bottom, on which a man can conveniently walk along; and, for this purpose, the arch had better be made elliptical, or higher than it is wide; a secure iron gate should also be provided, to be kept locked at a few yards into the arch from D, for excluding improper persons. At the termination of the level arch at M, there should be a circular well of 6 or 8 feet diameter more or less, according to the greatness of the floods that may be expected, to be sunk 6 or 7 feet deeper than the arch DM; its bottom should be formed either of one very large flat stone, or of a few well jointed ones laid on a course of pudding, and on this the fining of the well should be begun, with bricks of the very best quality, well keyed up and embedded in cement; and, having a course of pudding of 9 inches or a foot thick, worked all round behind them, allowing the same to set as the work advances in height; this well, and the arch D M, are to be firmly groined into each other at M; near to this groin, or within reach of a man standing on the end of the plank above mentioned, which should not advance quite up to the well, should be a large brass cock worked into the walling; the mouth of this cock should be turned down, so as to discharge its stream of water exactly in the direction for the centre of the bottom of the well; and from this cock should proceed a large pipe of lead or cast iron behind the wall of the well at some distance, for which purpose it will require a considerable bend, and this pipe should proceed, soundly embedded in good pudding, towards a convenient place as S, in the bottom of the reservoir, where it should terminate under a large and stout box full of holes, or a fine grating, to prevent the entrance of silt or any thing that might choke the pipe or cock. In constructing the arch before mentioned, after it has proceeded from D as far as the intended puddle-ditch ed; the puddle-ditch should be dug out for some distance on each side across the arch; the same should be continued down to water-tight fluit, or at least for some depth into other matter, if unfortunately such is not within reach; and, when the puddle is carried up and set, as also a course of pudding in the bottom of the arch course d M, which should have been dug deeper for such purpose; the bottom of the remainder d M of the arch should be carefully laid on the puddle, and a centering for the arch is to be laid on the same and firmly secured down; this precaution being necessary to prevent the fluid puddle that is to be applied successively without the arch, as it is carried up, from floating or burying up the centering along with the lower part of the arch. The work is thus to proceed until the part of the arch d M is completed, and inclosed completely in a cafe of good puddle, thoroughly and completely joined at one end into the puddle-ditch a e f b, and into the puddle that surrounds the well N M at the other. When the well-finishing has been carried up to the M, it will be necessary to increase the thickness of the pudding-wall round it, to three feet or more, taking care that the extra work is firmly built upon undisturbed and solid earth. The well is intended to be carried up in the same manner, surrounded by puddle, and by a conical embankment of earth of O P Q R, to within two feet of the height of the bank HI, leaving a channel of several yards wide, and of considerable depth, 1 O P, between it and the bank or head D H I E. It will be necessary for the engineer to calculate and mark out the base of this conical embankment upon the ground, with allowance for ample flops to prevent slipping; or its washing down by the waves: it will also be proper, for ensuring stability to the work, to reduce the whole of the top of the work to one level as K L, as soon as can be, by successive layers of fluit thereon, and of puddle in the ditch a e f b, and round the well N M; and, if the bottom of the reservoir will require lining, owing to the porosity of the soil; it will be right, after levelling and treading the part b R perfectly, to cover the same with 3 or 4 courses or linings of puddle, joining the same perfectly with the puddle-ditch, and the puddle round the well, to which courses of puddle the bottom lining is afterwards to be carefully joined; and after this is properly set, the remainder of the bank L H I E, and of the cone O P Q R, may be proceeded with, as we have before mentioned, when treating of the rearing of canal banks with puddle-ditches in them. The bank or head being completed to HI, and the well N M, and conical embankment O P Q R, being also carried up to the proper height, the well should then be copped with a layer of the best hewn flines cramped together, and the top reduced to a perfect level; and for security, it will be right to pave the surface of the top P Q, and for some distance down the sides of the conical embankment, with paving flines pretty well jointed, and set their longest way into the soil, filling their joints with mould, and sowing grass-seeds therein, to prevent the waves from afterwards loosening the flines or wearing the bank; this conical bank is for enabling the water to fall into the well on all sides; if the well was made in a corner of the reservoir, much digging would be required, both for the arch or pipe to let out the water, and for the discharging arch D M.

We have been thus particular in describing the circular weir or well-fall above recommended, from having seen the beneficial effects of one, in the reservoir for Worley mills near
near the duke of Bridgewater's canal; and the mischief that is sometimes done to the banks of a reservoir and the adjoining lands, by letting off the flood-waters by common works or tumbling banks at the corners of the reservoir, and allowing it to fall or rather run its own way down into the valley. Reservoirs constructed on the above principles would be secure almost from accident, however high the embankment, or sudden and copious the floods, if the well is made sufficiently large, and deep of water at the bottom, to receive the shock of the preceding column of water. If the floods are so considerable as to bring down timber and other large floating matters, it will be necessary to fix a strong grating or circle of bars round the top edge of the well bank PQ. It will sometimes happen, that a reservoir is over or near to the navigable tunnel of a canal, and might be let down into the same by a pipe and cock, as at Ripley on the Cromford, and near Brampton on the Grand Junction. It will be proper, that the core or plug of the cock to a reservoir should be turned by an endless screw, or by toothed wheels, so that considerate power and nicety in the adjustment of the stream let out, by the turning of the cock, may be attained; and a regilier should be provided of the number of turns, and fractions of a turn, that is given to the winch or handle in any cafe. It will be proper to flanch a small pipe to the large one, and connect the same with an inverted glass fathom filled with mercury, in the arcli near the well, so that by turning a cock, the height of the mercury should indicate on a scale attached, what depth of water there is in the reservoir above, or how much it wants of being full at the time. A series of accurate experiments should be made, by gaging the stream of water at D, or at the first convenient place below it, which the cock discharges per hour or day, when the water is at different heights in the reservoir, and with different turns of the cock-gives; these shall all be repeated, and sufficiently numerous, to enable the engineer by interpolation, to fill up and form a table, (that the committee ought carefully to preserve copies of) by which at any given height of mercury, the cock can readily be set to discharge any number of locks full of water that may be required per day. No great difficulty would attend the forming of a gauge-puddle, instead of, or by the side of the brafs cock that should regulate itself, and discharge any regular and continual quantity of water that the reservoir could supply: see Leybourn's Repository, vol. ii. p. 165. It will be right also for the engineer and committee, to have tables for readily shewing the quantity of water that every reservoir contains, at each foot or shorter portion of its depth, indicated by the mercury in the fathom, or by a graduated gauge-foil fixed up in any part; for forming a table of this fort, where a complete survey had not been made or preferred at first, the time of a hard froil should be chosen, and a sufficient number of holes at equal distances, in a great number of parallel or equidistant lines, should be bored or cut through the ice sufficiently large to let down a plummet to found the depth, and if this is done with care when the reservoir is full or nearly so, a most correct table of its content at different depths, can be thus obtained by calculation. Some of the considerable reservoirs that have been constructed principally are, at Aldenham, Rivington, and Wigan on the Grand Junction; Kifflon on the Forth and Clyde; Brandstone, and Denton on the Grantham; Ripley on the Cromford; Amlforth on the Nottingham; Littleborough on the Rochdale; Marfen on the Huddersfield; Oxendon on Leicestershire and Northamptonshire Union; in Rudyard vale near Leek, for suppling the Caldon branch of the Trent and Mersey canal, which covers 150 acres, has its head 30 feet high, and the water in general very deep. Mr. Hornblower has calculated about the year 1870, on the canal of Luné in the south of France, occupies a space of 553 acres, and is 1000 feet round with a branch, and its waters let out without, by a large pipe. In engineering fioors or channels to convey water to a canal from springs, brooks, or reservoirs above its level, the same care must be taken to examine the nature of the soil in each part, and to apply a being of puddle, as has before been mentioned respecting the line of a canal, whereby porous fluid is to be cut through. Where there are a great number of inundations in the ground, through which a feeder is to be conducted, that would occasion it to be very crooked and much impede the cultivation of the land, it will be proper, in many instances, especially if the land be valuable, to cover over the feeder in a culvert or small arch of bricks, of 12 inches or 2 feet diameter, or larger, if the supply fluid at any time require the same: in very porous soils, these culverts, inclosed in puddle, will be the most effectual way of preparing and conducting small streams of water, and no land will thus be lost to cultivation. In some places, feeders will require considerable embankments and aqueducts, to cross valleys and streams of water, and preserve their level, or gradual and small fall; and in many of such cafes it will be cheaper and better to use cast-iron-pipes well jointed and flanged, and laid within the ground, down one side or bank of the vale to be passed, and up the other, securing each end carefully with a strong box full of holes, or a fine grating to keep extraneous matters out of the pipe. In the case of smaller feeders, particularly those temporary ones, which are required to supply water to puddle with, and to fill the bottom of the canal for the temporary use of dirt-boats while making it, as before mentioned, cast-pipes in short lengths, in which the most crooked parts of large trees will come into use, may be advantageously used in crofting hollow roads, or other hidden ravines, if the same be jointed by short hollow double cones of cast iron as recommended by Mr. Hornblower: see Repository, vol. x. p. 25. It has often happened, where reservoirs are situated at some distance above a canal, and a brook-course led from the reservoir to the canal, that the water was left to take its ancient course on being let out of the reservoir; an expert engineer will, however, carefully examine all such feeders, for thus they ought to be considered, and fill up all deep holes, and lower the shallows in the brook-course, so as to reduce the channel nearly to an uniform width and depth; and very accurate gauges of the water ought to be made at different seasons of the year, of the quantity issuing out of the reservoir, and the quantity received into the canal; if these differ materially, intermediate and comparative gauges should be made of the stream, under the faulty or leaky ground is discovered, probably some fathom of sand or open-jointed rock; over which the brook-course or feeder ought to be carefully lined with puddle: and, if puddling-fluff be scarce, the foil very porous, and the brook-course very crooked, it may be the most effectual way, as well as the cheapest in the end, to pass such leaky ground by a small culvert, inclosed in puddle under ground, by the side of the brook-course, as straight as the course of the valley will admit. Except in situations, where mills in the vicinity of an intended canal are much in want of water, or their owners or others dissatisfied with the scheme, has been usual to allow the company to search for, and divert to their use all springs of water, within certain limits on each side of their line; in the acts for the Newcastile underline Junction, the Southampton, and Salisbury, and the upper part of the Tamron Manure canals, this limit is fixed at 1000 yards; in the Aberdeen, Polbrook, Tammar,
Tamar Burne, lower part, Thames and Medway, Wills and Berks, and others, is fixed at 2000 yards on each side of the line. In such cases, an accurate investigation and knowledge of the Strata, upon Mr. Smith's principles, will be of the most essential importance, in order to collect and retain springs that are above the summit level, or even in lower situations, where a local trade is to be provided for. It has been usual in some mining districts to require, that engines near an intended canal should lift their mine-water into such canal, or high enough to be conducted into it by a feeder, as on the Birmingham and Finsbury canal. It will be worth considering, on a summit, where water is scarce, whether a tunnel may not be more eligible than deep-cutting, on account of large springs which would be interfered with by the lower level of the former, when the deep-cutting tunnel perhaps be in porous stuff, or perhaps in dry open rock. As the summit levels or low points of most canals are in deep-cutting, through a considerable portion of their length, it is often attended with but little additional expense, except in the case of tunnels, to make such summit levels or two feet deeper in water than usual, as on the Derby, Cromford, Manoe, Alton, and Oldham, Oxford, and other canals, in order that such additional depth, being filled in winter time or wet seasons, may act as a reservoir for drier ones: but it has not always been considered, that such deeper levels, when filled 18 inches or 2 feet fuller than is necessary, occasion the necessity of letting off twice that extra depth of water, over the area of a lock, each time that a vessel passes the summit; by which, such refree of water is in a great measure diffipated before the dry season for which it was intended. We should recommend, either the use of reservoirs, so much above the summit level of the canal, that they could be emptied into the same, when the continuance of dry weather required it; or, if such deeper summit levels be made, on account of their considerable length for holding water, that a lock capable of penning 18 inches or 2 feet, and of flushing very tight, should be made in each end of the summit, to be used as long as the summit water is higher than usual, but which might at other times be left open, when the water was level on each side of them. Before we quit the subject of supplying a canal with water, we beg to mention, that it may be worth the while of the engineer, where water is to be pumped up to supply the lockages, as we have before mentioned, to design and calculate the expense of wind-machines, capable of doing the required work, and of the probable expense of their repair; and to compare the same, with the cost of erection, expense in fuel, attendance and repairs, of well constructed steam-engines to do the same work.

On the erection of Aqueducts for conveying a canal over any very deep and wide valley, or over a large or navigable river, we beg to mention, that a most secure foundation must be sought for, by sinking, or obtained by piling, for the piers of an aqueduct-bridge, and that the arches ought, in every case, to be arches of equilibrium, because the load setting in brick or stone bridges, by letting through the water, may prove of the most fatal consequence. That the plan of an aqueduct-bridge should be curving inwards, that is, the ends should be wider than the middle, the walls should not be upright, but battering or diminishing upwards without, to give greater strength and liability to the whole; the materials, if of stone or brick, and the cement, should be of the very best quality, and the work executed in the summer season only. In Plate II. Canals, figs. 19, 20, and 21, we have given a plan, section, and elevation of an aqueduct-bridge, proper for crossing a considerable river, where, in fig. 19, A is the river, B the canal, C the towing-path, and D D the wing-walls, for keeping the embankments at each end of the bridge; in fig. 20, C is the towing path, and a a a lining of paille to secure the canal B from leaking. Care should be taken that all the joints of brick or stone are worked as close as possible in an aqueduct-bridge, and thoroughly filled with cement; the spaces within, and the bottom for the canal, should be made rough, that the puddle may the better adhere to them, and that the puddle may not slip, owing to the steepness of the sides, which must be more than in other parts of the canal, to avoid unnecessary expense of masonry or brick-work in the width of the bridge. The lining as above is, however, liable to be soon cut away by the barges. Since the year 1795, a new kind of aqueduct has been introduced into this country, composed partly of cast-iron, which promises the greatest advantages, except perhaps, where free-streams of an excellent and durable quality is found upon or very near to the spot, or where the space is very distant from any iron mine, or of the navigations that comport with such.

In the year 1797, Mr. Thomas Telford, the engineer, wrote an account of the inland navigation of the county of Salop, which has since been printed in J. Playne's Report to the Board of Agriculture, on the Agriculture of Shropshire, and we beg to extract therefrom what he says on this subject when speaking of the Shrewsbury canal. p. 296, as follows:—

"This canal passes over the valley of tern, at Long, for a distance of 62 yards, upon an aqueduct made all of cast iron, excepting only the nuts and ferrules, which are of wrought iron; and I believe this to be the first aqueduct for the purposes of a navigable canal which has ever been composed with this metal. It has completely answered the intention, although it was foretold by some, that the effect of the different degrees of heat and cold would be such as to cause expansion and contraction of the metal, not being equal to extend or draw back the whole mass of the aqueduct, would operate upon the separate plates of iron so as to tear off the branches which connect the plates lengthwise, and break the joints. Others said, that the expansion of freezing water would burst the sides, and so break off the branches which connect the sides with the bottom plates: but after the trial of a summer heat, and the very severe frost of the winter of 1796, no visible alteration has taken place, and no water passes through any of the side or bottom joints. After the frost had continued very severe for three or four days, and the water had not been drawn off (although there are means of doing so), but it had frozen in the aqueduct above the height of two feet six inches, the ice had then frozen to the thickness of an inch and a half, but instead of having forced out the sides, it was melted away from them, and quite loose upon the surface of the water. The idea of having this aqueduct made of cast iron was first suggested and recommended by Thomas Eyton Esq., then chairman of the committee: after due consideration, it was approved by the committee, and the principles of construction, and the manner in which it should be executed were referred to Mr. William Reynolds, and the writer of this article, Mr. Telford who, after several consultations, and forming and considering various plans, at last determined upon that which is represented by the annexed engraving. (Plate III. Canals, fig. 22.)"
In March 1796," Mr. Robert Fulton, an American engineer, who happened to be in this country at the time, seems to have availed himself of what was going on at Long aqueduct as above, and of the machinery of various kinds, in use upon the Keelby and Shroffsbury canals, and to have prepared drawings and models of a variety of such machinery, with many improvements of his own, and submitted the same to the examination of a committee of the Board of Agriculture, in March 1796. These have since been published in a handsome quarto volume, entitled, A Treatise on the Improvement of Canal Navigation, by R. Fulton, from which, p. 113, we beg to extract what he says on constructing aqueducts of cast-iron for a narrow canal as follows: "The butments and piers being raised, it will only be necessary to extend two pieces of timber across the span; each to be braced back to the piers, and covered with cloth to form a flange or scaffold, which will suffer every purpose of centres necessary to works of iron. The iron-work, in the section (Plate III. Canals, fig. 23 and 24.) may all be cast in open mould, and of the following dimensions: Superfposing the span 100 feet and the spring one-sixth of the span. First, three segments of a circle, each in three pieces, about 36 feet long, eight inches by four diameter, to be united, as at A. Second, three straight bars, to extend from one pier to the other, to be of the above diameters, may also be cast in three pieces, which bars are to extend along the top of the segments to the piers, and form a line parallel to the horizon; the bars and segments to be united by perpendicular flanges like B, ten or fifteen feet distant from each other. The mortar in the lower end of the flange being thirteen inches long, will be sufficient to secure the segment, and leave room for a hole two inches square, through which a cast-iron C, is to pass; and fallen in the time and expense will be considerable; the brace to have a mortise, cast on each side of the flange, in order to tighten the work by wedges. On the top of the flange, the square hole to receive the cross brace may be beneath the mortice, as in the figure; by which means the whole may be combined, and form an iron flange to support the troughs. The troughs should be at least one inch thick, the side plates six feet broad, and as great a length as can conveniently be cast; which may be performed twelve feet, and perhaps more in length; the flange to be outside on these plates. The bottom plates may be six feet wide, thirteen feet long, seven feet plate, and four arms projecting, each three feet long, in order to support the horse-path and braces, as exhibited at D. Two of these plates laid across the flange, and screwed together, with a flange under, will compose a length equal to one of the side plates, which may either meet or break joint as is thought proper. The whole may, in this manner, be screwed together, on packing of wool and tar, and have the seams pitched like those of a ship. On the plates composing one side of the trough, small brackets, about three feet from the top, must be cast, as at E, in order to support the horse-path; perpendicular rails, eight feet long, being raised from the arms of the bottom plates, will support the outside of the horse-path, also the iron railing, as in the section. By this mode, two patterns will answer for the whole of the trough-plates, and but few will be required for the springs, rails, and spurs; while the saving in time and expense will be considerable; particularly where it is necessary to bring the flange by long land carriage; for the arches being dispensed with, and the work not more than one third of the dimensions necessary to an aqueduct of stone, will most materially reduce the quantity of masonry. "In aqueducts of stone, one of the great difficulties is to line and puddle so tight as to prevent the water penetrating into and injuring the masonry; but in one of iron, should a leak take place it will instantly appear; and on shutting the stop-gates at each end, and discharging the water, it may be slapped in a few hours, if not in minutes, by this circumstance in aqueducts as, perhaps, one of the greatest prejudices; they are not occasionally liable to injury, and only feel it to the corroding tooth of time." Since the above period, a most improving work of this kind has been undertaken by Mr. Jelfey, on the Eids famine canal, and is now nearly or quite completed, for crossing the Dee river at Pontyfynydd, about 20 miles S.W. of Chester; where nineteen massive conical pillars of stone, at fifty-five feet each, have been set, being supported by the middlemost of which, no less than 135 feet in height, support between the top of every pair, a number of elliptical cast-iron ribs, which, by means of uplifts and horizontal bars, support a cast-iron aqueduct about 329 yards long, 20 feet wide, and six in depth, composed of massive sheets of cast-iron, cemented and riveted together, having on its south side an iron platform and railing for the towing-path. In May 1796 Mr. James Jordan took out a patent for suspending aqueducts from ribs of cast-iron above them, in the same manner as his suspended iron bridges. See Repertory, vol. vi. p. 252. Among the most considerable aqueducts of stone or brick are those at Lancaster on the Lancaster canal, for a description of which see our article Bridges. At Kirkintilloch and at Kelvin on the Forth and Clyde, Chink on the Ellesmere, Marple on the Manchester Ashton and Oldham, Monk-bridge on the Trent and Mersey, Whaley-bridge on the Peak Forest, Avoncliff and Dunns on the Kennet and Avon, &c. while at Burton on Bridge-water's, a navigable river is passed, and near Wigan on the Leeds and Liverpool, another canal (the Lancaster) is passed upon aqueducts. It was thought a bold and visionary scheme by many, which Mr. James Bridley proposed, of crossing the Mersey river at Runcorn Gap, by an aqueduct bridge, but no doubt he could have accomplished it.

The making of Embankments appears to have been long practised in China, where we read of parts of their canals of 200 feet wide, that are embanked 20 feet high, for great lengths together; the rivers through the towns of Cambridge and Lincolnshire in this country, have also been long confined thus, by artificial banks. Most of the embankments of which we have been speaking above, have less or greater lengths of field mounds or embankments for forming the canal upon, to the proper height, and for joining them to the aqueduct bridges; all the observations and remarks which we have made, respecting the setting out and ascertaining the dimensions of the head of a reservoir, will apply to embankments; except that a prism whose base is the figure G H L M N O I. Plate IV. of Canals, fig. 25, and length A B, fig. 16. Plate I. is to be calculated from the triangular embankment D G F, first to be calculated, instead of the triangular prism G H I. The angle of the figures ought to be determined by the result of similar inquiries, and the same precautions used to prevent slips, in soils that are so disposed, as were mentioned respecting reservoir heads; it will generally be a safer way to carry up a puddle-ditch in each bank of the canal, as at a, b, f. fig. 25, than to trust only to lining of the canal L M N O. In every considerable embankment there will be required one or more arches to carry a brook or river under the canal, and, perhaps, others for roads to pass through; such arches should always have an inverted arch turned below them, deep enough for the bottom of the brook, and below the roads, and the arch itself should be one of equilibration. To avoid making a very large arch for a brook or small river, it is usual to make a road or communication arch near it, with.
its bottom well paved, and no higher than the surface of the meadows, which will serve to vent the sudden flood in rainy seasons.

Great care should be taken to slope off and finish the ends of arches under an embankment, agreeable to the slopes or sides of the banks thereof; by which the banks are prevented from moulderimg down into the brook or road-way, and awkward projections in the slopes of the banks are avoided; at the entrance or upper side of a water-arch, or of road-arches which will occasionally become such, return or wing-walls of brickwork or stone should be made, for some distance along the bottom of the slope of the embankment, and the sharp corners of the entrance of the arch should be a little rounded off, to prevent the rapidity of sudden floods from wearing or injuring the bank. It is to be observed, in conducting a canal along the side of a steep and high hill, as Plate L, fig. 3, that after a certain degree of steepness of the ground A B D, it will not be possible to cut the canal, upon the principle that the excavation E F G I K shall just form the bank A B C E, but such banks will often require stuff to be provided from other places, and such are indeed cases of embankment: and here it may be proper to advise, that new banks, as A B C E, ought not to be placed on very steep ground, as A E, without considerable care in first forming it into levels like steps, to prevent the slipping of the new part, as happened near Bradford on the Kennet and Avon canal, after all the care that was taken, and great lengths of the canal banks slid down into the Avon river below, the making of which good again cost, we were told, near 1000l. Among the considerable embankments that have been made for canals, are those at Bollin and Stretford on Bridgewater’s, and Wolverton, Weedon, and Bugbrook on the Grand Junction, &c. but the greatest extent of high embankment known, is that in the valley of the Boyne, in the Grand canal of Ireland; and the highest bank in the world is also to be found on the fame canal in the valley of the River Rye; it is above 90 feet high. We are told, that Mr. James Brindley used a kind of caisson of planks, in forming his great embankments, in which dirt boats were used, to bring stuff from the higher ground, that had been cut through.

We have next to speak of Safety-gates, Stop-gates, and Stopplanks, which are different contrivances for stopping the water of a canal in case the banks are falling in any part, or that any part wants repairing to repair the works. Advantage is generally taken of the walls under the bridges, for constructing these contrivances, where the face is thrown in the proper pitch; otherwise the canal must be contracted by upright walls, the same as is done at the bridges on purpose for them. For explaining the nature of safety-gates, we must retrace to fig. 26, where A B is supposed to represent the top of the wall, or height of the towing-path under a bridge, C D the surface of the water, and Q S the bottom of the canal; E F G H is a pier of hewn stones, or a piece of found oak timber let into the wall, its face being flush therewith; I E G and H F K are reccefs about two inches deep in the wall; similar provision is made in the opposite wall, for receiving doors or gates L M and N O across the canal, turning on centres or hollow-quoins at M and N: each gate is so balanced by a counter weight, that they rest always in the position represented; and they are intended to operate thus; suppose, owing to the sudden breaking of a bank, the water in the canal should acquire a current from Q towards S, the floor would pass under the gate at P L, to facilitate which, the corner of the floor at P is flopped off; the gate would be turned up into the position M E, and the canal would be thereby closed up. The like would happen by the other gate N O, in case of a current the contrary way. Safety-gates should be placed at proper distances on every long level or pond of water, especially if the fame is much embanked; both to prevent the loss of so much water, in case of a bank breaking, and the mischief that the fame would do to the lands, mills, &c. below the breach. We read of a new bank breaking on the Warwick and Birmingham canal, and destroying a gentleman’s park-walls; and in the year 1783 to great a breach suddenly happened on Bridgewater’s canal, near London bridge on the Chelten road, that three barges were carried through the fame a great way out into the fields. A single safety-gate ought to be placed at the end of every long embankment, to stop the water in case of a breach happening in its banks. Stop-gates are similar in their construction to the safety-gates above described, except that the gate lies flat on the bottom of the canal instead of being balanced, and has a chain by which it can be hauled up, whenever occasion may require the canal to be stopped. Stopplanks are a simple, though not so expedient a provision for stopping a canal as the last; a groove is provided in the two opposite walls under a bridge, or in a narrow and walled place, and a sufficient number of well jointed planks are provided, to be dropped into the groove whenever the water is required to be stopped, and hence these are often called drop-planks. In very large works like the London docks, a barge or vefsel is built in the place, whose head and stern posts exactly fit into a groove as above, and the vefsel can be floated into and out of its place, or sunk therein as occasion may require. The engineer will also have to make provision, while the canal is digging, for fhop-bars at the several intended toll-houses, or other places where it may be necessary to stop barges in the night, or in case of any dispute about their landing: these bars are composed of a large baulk of fir timber floating on the water; and a small arch capable of containing such a floating beam of the proper length is provided under the bank, so that when the trade on the canal is required to be stopped, the toll-clerk has only to draw out the beam by means of a cord attached to it, until its end enters a recess in the opposite wall, and then to lock the beam fast.

We shall next describe the Water-gates, Trunks, Tumbling-ways, or Wires, that must be provided, for letting off the furious water of a canal in wet times, for keeping the water to one certain height, or drawing it off in case any repairs may be wanting. Water-gates are sluices of the common kind, in the side of a canal, where any considerable quantity of water is required to be let out, and are to be drawn up, either by a rack and pinion, a chain and roller, or a number of holes for a crow-bar, as circumstances may render most eligible; where lesser quantities of water are to be let out, or for emptying certain lengths of the canal between the stop-gates or planks, when occasion may require; trunks formed of oak or elm planks, well jointed, should be laid into the bank, at the bottom of the canal, and carefully inlaid in puddle, with a valve or shuttle that will shut very tight, and can be readily drawn when the water is required to be let off: we beg to recommend, wherever wooden trunks are used for any such purpose, that they should be funk so low, or the mouth where they discharge should be made up, so that the trunk may always remain quite full of water, and the air be let all times excluded; in which situation wood will last much longer than if wet and dry alternately.

In the choice of situations for weirs, to discharge the surplus water of a canal, care must be taken not to let off any considerable quantity at any time, but into a brook coulfe or bottom of a vale, that is crossed or proceeds up to the canal, and has ditches through which the water can escape, without
without tearing or doing injury to the land adjoining. The most frequent tumbling-bays or weirs to discharge water from canals are composed of stone walls of brick or masonry, as see, Plate IV. Canals, fig. 27, whose top y is capped with heum and well jointed stone, or with a flat fill of oak, the top of the same being just level with the top-water line. A B Y M is a paving of large stones for the water to fall on, and escape at A, and A B Y C are wing-walls at the ends of the weir, to keep up the bank and confine the water. These weirs are generally on the towing-path side, on which a low plank bridge, as C D, is supported over it, called a weir-bridge. When these weirs are wanted of considerable length, the wall y c ought not to be straight but on a circular plan, curving inwards in the middle, by which it will be better able to support the lateral pressure of the bank behind it; a puddle ditch should be carried up immediately behind the wall, allowing the course of puddle to fet thoroughly, before others are applied, that the great pressure of the confined puddle may not overtop or disturb the wall; and the paving AC should be of large and well jointed stones, and if let upon an arch of puding it would be a further security against their washing away, which too often happens. We have seldom seen any considerable weirs or tumbling-bays of the above construction, but where it would have been better to have followed the example of Mr. James Brindley, on Bridgewater's canal, and have made a circular- weir, or well-fall, on the upper side of the canal; we have spoken of these when treating of the general improvement of a valley, as also in the making of reservoirs, but it may be proper here to refer to a section of such a well fall in fig. 28, where A B P is supposed to be the section of a vale crossing the canal C F G; A M is an arch of brick-work, secured on its upper side at head, with a covering of puddle, and MN is a wall, whose footing or lining of brick or stone is groined into the arch at M, having a well paved floor, three or four feet below M, according to the height NM, that the water is to fall, and a coping of hewn stone, or a large curb of sound oak at its top. I O P Q R P is intended to represent the section of a side pond or wider place in the canal, from which the water may drop quietly into the well at N from all sides, and run off at A.

For letting a proper quantity of the surplus water of a canal forwards into the ponds below, a small weir is generally constructed in the walls at the head of each lock, which lets the water down into the puddle-holes, or crooked arches that convey the water for filling the locks, and hence such are called puddle-weirs or lock-weirs. The upper gates or doors of the locks are often boarded no higher than the top-water line, and therefore act as weirs for discharging surplus water into the lock; and gates of this sort are called flood-gates.

On the construction of Culverts, or drains under a canal for conveying away water from the upper to the lower side of the canal, it remains for us to say, that they should be carefully apportioned in size to the stream that is to pass through them in floods, and should be constructed of sound brick or stone work, and inclosed, or at least well covered on their upper side with puddle. Many engineers have used wooden trunks for this purpose, but except wood be in great plenty, and of the best quality, and good bricks or stone very difficult to be procured, it is not advisable to use perishable materials in such situations. If the ground be moory or bad, and a culvert must lie pretty near to the bottom of the canal, and have but a slight covering, it may be proper, in some situations, to use cast-iron cylinders flanked together, as was done under or near the Staffordshire and Worcefter canal; and such may be made cheaper and easier of carriage, by being in two or three segments longitudinally, to be flanked together before they are laid down; and in such situations, possibly leaden rivets might be cheaper and more durable than wrought iron ones, or nuts and screws. If bricks are to be used in culverts, over soft and moony ground, or quick-founds, a cradle composed of ribs of wood and boards or rails, such as are used for centering, should be prepared, suitable to the outer curve of the intended culvert, and such a cradle should be carefully embedded, in the proper place to receive the bricks of the lower segments of the culvert; for want of such precaution many a culvert has sunk partially, perhaps owing to the springs excavating the land or fill from below, and has been broken, to the great injury of the canal. Culverts are of so much importance, that too much care can hardly be taken to make them solid and secure, and to cover them effectually with puddle; another hint we would here give, respecting the choice of places for the culverts; they should never, if possible to avoid it, be made exactly in an old brook-course, ditch, or flough, but in the nearest found ground; and where often they can be got down to the proper depth, without any trouble from water, or lands, the same can be easily pumped out; and the stream need not be admitted to the work, until the old brook or flough is required to be filled up. In this way it is often willing that, culverts may remain during the winter following their construction, completely excluded from the frost, and therefore may be done later in the year, by filling in the stuff upon them and at their ends, and the mortar be completely set before the new channel at the ends for conducting the water through them need to be cut. And we beg to remark, that by an attention to this circumstance in making new arches under roads, and keeping the bottom of the arch much lower than is generally done, or indeed practicable in the old channel or flough, half or two-thirds of the whole expense will generally be saved; for a deep and new channel being cut to the new arch; with scouring out the brook-course for some distance below, old ford-places, if the deficient to them be easy and convenient, will not require immediately to be filled up or altered; but during any extraordinary flood, the same, if composed of gravel and hard stuff, may act the part of a weir for a short time, in carrying off the water, without injury to the road or material inconvenience to the passengers. It will sometimes happen, that a small stream of water is required to pass under the canal, in places where it is not embanked; in such cases a crooked or broken-backed culvert is to be made, as m o n, fig. 29, for passing the water from m to n under the canal C F G; this will require puddling as before described, and a strong box full of holes, or grating, should be fixed over each of its ends, as well as pits or holes be made at the upper end, deeper than the mouth of the culvert, to receive and detain the land and gravel which the stream may bring down in high rains, otherwise these, or the flumes that mischievous boys might throw into it, would in time choke it up between o and n.

The construction of Tunnels, or subterraneous arches, for drawing off or conveying of water, has been known from the earliest periods, as appears by the celebrated works of this kind between lake Copais in Boeotia and the sea; between the lakes formed by the inundations of the Nile in Egypt and the Mediterranean; as also by the cources of the Roman aqueducts, many of which were tunnelled through hills of great extent. In the mining districts of this country, we have long had levels or audits of considerable extent to mines; in the neighbourhood of Matlock in Derbyshire, the Helcar Sough has been cut through the solid rock for nearly four miles.
miles in length, for the purpose of draining the several lead mines in the vicinity; *Hunsford Moor* and *Cromford* springs, of two miles in length, and many others of less note, are also to be found at great depths in that neighbourhood. The first tunnel that was real, or, as considered for the purpose of navigation, was by M. Riguet, near Banneux, on the *Langedoc* canal, in France; and the hill in this country, was the entrance made by James Brindley to the duke of Bridgewater's coal mines at Worley near Manchester; while the first of our tunnels undertaken for the purpose of general trade, or as a thoroughfare, was by the same engineer at Harecastle on the *Trent and Mersey* canal.

It is very essential to the convenience as well as the beauty of a tunnel, that the arch thereof should be quite straight, and exactly level; considerable care will therefore be necessary in obtaining an exact section, by levelling, of the hill that is to be perforated, when a line in the exact vertical plane of the tunnel is fixed and flaked out over the hill; in doing which, it will be right to choose the narrowest place that the hill presents at the proposed level, and where also the hill rises rather boldly from such level; otherwise an expensive and troublesome length of deep-cutting would be necessary, or of the tunnel that must be dug out from above and then covered up again, before a sufficient depth of turf over head would be come at, to admit of working under ground; it will also be of consequence, when determining the exact line for a tunnel, to avoid having the deep-cutting and entrances in alluvial or disturbed and slippery foils, but, if possible, to enter at once upon the solid and undisturbed *farda* of which the hill is compos'd.

It will but very rarely happen, and that only on short tunnels, made for the purpose of preferring the level of a canal, that the workings will not be in foil more or less full of springs of water; therefore one of the first operations, after the line and level of a tunnel is finally determined on, is to search by levelling for a place in the nearest vale or brook that is some feet below the proposed level of the bottom of the tunnel; this must be more or less, according as the intended tunnel is of greater or less length; and from this point a large ditch must be opened, with a very small rife towards the end of the tunnel, as far as is practicable, and then a heading or fough must be begun, just large enough for men who are used to such works to work in, and to line it securely with bricks as they proceed, but leaving proper openings in the sides for the springs to collect freely from all sides into their heading. Some perfons have supported their headings with boards and props of wood, instead of arching them; but which practice we cannot recommend: all such works ought to be durably constructed, or should any accident or circumstances, as the want of money, &c. delay the completion of the work for some years, all this tedious and expensive work will perhaps require doing again; it ought also to be considered, that after some years or ages have elapsed, the tunnel may want repairs or alterations, and that the same headings may be again opened and used, to lay it dry in a short time, if durably constructed, which may be of the most material consequence in lessening the period of interruption to the trade by such repairs or alterations. It will be necessary to begin a heading, as above-mentioned, on each side of the hill, and work them up towards each end of the tunnel, along the line of which it is to proceed from each end, rising gently as it advances towards the middle point, that the water may run freely off; the headings should be a few feet below the bottom of the working, that will be necessary for the inverted arch of the tunnel, and a few yards off the side of it; and crofs headings or foughs must, at slanted distances, be run under the line of the tunnel, into which, openings can afterwards be made to let off the water which collects in each separate working. If the soil be rather stiff, and the quantity of water in it not very considerable, one heading may suffice; but where porous soil, with great quantities of water are intermixed, it will be necessary to branch off an additional heading, to proceed along the other side of the line, the more effectually to draw off the water; by which, perhaps, if the headings are done a sufficient length of time before the tunneling is begun, a quick sand, or similar running of the stuff, may in several places be prevented. If in driving the headings, any fissures or cavities filled with sand or loose matters, are intersected, and are found to bring a considerable quantity of water from one side of the line, it may be right to drive a crofs heading for some distance into such porous stuff, for intercepting the water before it reaches the intended workings of the tunnel.

The next operation will be to set out a line very truly parallel to the line of the intended tunnel, and to mark thereon, at equal distances, about 150 yards apart, or oftener if great expedition in completing the tunnel is required, the place of the several tunnel-pits, that are to be sunk for drawing up the stuff excavated from the tunnel, and letting down the centres, bricks, and other things wanted in the work; it will be well to contrive the line of the headings and tunnel-pits, so that they may coincide; and in great lengths of heading shafts or tunnel-pits may be sunk at intervals, to give air to the headings, and through which the stuff excavated therefore may more ready be drawn up; and it may be advisable, in some instances, to set out a line on each side of the tunnel, for the tunnel-pits to be come on one side and some on the other of the tunnel, and that both may in places intersect the headings. If bricks or flones are not at hand when the tunnel-pits are begun, and wood is plenty, the shafts or tunnel-pits may be made square, and have their sides supported by boards and struts of wood; otherwise they should be made round, and lined or fleined like a well as soon as they are done; if the soil should prove loose and full of water, it will be necessary to line the shaft as soon as such soil is reached, and to work afterwards from underneath the curb, and let the fleining sink, as is done in well sinking. Some tunnel pits have been made over the line of the tunnel, but such do not admit of being fleined with safety, on account of the weight thereof, which would damage the crown of the tunnel, where they were groined into each other; and such of them as are left afterwards for air shafts, if the soil is wet, will let an unpleasant dripping of water down upon the goods or passengers in passing through the tunnel, as we once experienced in passing through Brandton tunnel on the *Grand Junction* canal. A common roll and winch will be sufficient for drawing up the stuff and water, and letting down bricks to fill with, unless the quantity of water is considerable; but it will be proper to erect a horse gin, or turn beam, such as are used at the shafts of coal-pits, for the cheaper and more expeditions drawing up the stuff and letting down of materials, when the workings have commenced. We have before recommended a line to be flaked out exactly parallel to the line of the tunnel for the centres of the several tunnel-pits, and care should be taken that no gin, or other obstruction, be erected in this line, so that a line of firing can at any time be stretched across the top of any of the tunnel-pits, and be adjusted without fear of mistake in the exact range of this line, or parallel to the intended tunnel.

When a tunnel-pit is completed and lined, and a communication formed with the heading to keep the same clear of water; two points must be fixed in the fleining near its bottom, by letting fall or suspending plumb-lines, at the time that there is no wind to disturb their verticality, and adjusting another
another fine line between the two points on the finoing be-
low, so as to be exactly under and parallel to the line above
and consequently to the intended tunnel. The engineer
should carefully repeat his levels and transfer the level of the
bottom of the intended tunnel, or the surface of the water of
the canal therein, and mark the fame carefully in the finoing
of each tunnel-pit: and thus the workmen who are to under-
take the work will be furnished with the direction, level, and
distance of the tunnel they are to form under ground.
The work commences, by excavating a passage from the
tunnel-pit into the line of the intended tunnel, and supporting
the same properly with timber, or walls and an arch, as a
passage into the work. A piece of the intended tunnel, a
yard or more in length, according as the soil is found to
fland, is then excavated, in the proper form, place, and level.
ascertained from time to time by stretching a fine line be-
tween the marks, on the finoing before-mentioned, and mea-
suring therefrom, and using a common plummet for trans-
fering the level from the level-mark on the finoing be-
fore-mentioned; great numbers of ribs for centring should be
prepared in different segments, and in readncss to put
Together with nuns and ferews, leaving as much room in the
middle or centre as can conveniently be done, for the men to
work and pass through after the fame are put up; the parts
of two of these ribs are then taken let down the tunnel-pit, and
to be put together and fixed up in their proper place and
distance afo to the tunnel; short lengths of boards or laths
are to be prepared and fixed on their outsides, as the turning
of the arch proceeds; which, as well as every other part of
this very difficult work, requires the utmost care and expe-
rience to make it found and substantial; when this first yard
of length in the tunnel is turned and securely keyed up, the
fame is secured by ramming in clay, or proper flour, as to
fill every cavity above or without the brick-work. The workmen
then begin at each end of the piece that is
turned, one party working one way along the line of the
tunnel, and another the contrary way, until another yard or
other length of the tunnel is excavated, when other ribs are
put up and fixed together, boarded, and the brick-work is
turned round or behind, the fame as before; the utmost care
being taken to joint these courses evenly and neatly into the
former ones: the vacant space is then rammed up with earth,
and a new excavation proceeded with at each end as before.
The engineer ought frequently to renew his level-marks from
fixed and good bench-marks on the ground, and to examine
and adjust the ranging line, and also himself most carefully
inspect each working of the tunnel, and examine, by stretch-
ing a fine line along its centre, and measuring and levelling
to his ranging line in the tunnel-pit, to see that every part of
the work is proceeding exactly in the fame line, and so
that when in progress of time each adjacent working shall be
joined, and the tunnel be completed, the whole may form one
exact and truly straight arch. If the ground proves
loose and bad for flanding, it will be proper to continue the
work, by different sets of men, without any intermixture;
and care should be taken that the work never is left, even for
a night, without templetts, or short pieces of plank, being
put up to cover the roof, that is necessarily left open to admit
the men's heads and arms, while they are turning and back-
upping their last length of work at the crown; and these
templetts should be securely shored up by spars or fritts, to
prevent the earth from settling or falling in, which has
actually happened in some tunnels, owing to the neglect of
this simple and necessary operation, so that a considera-
ble length of the tunnel required to be dug out from the surface
of the ground to repair the breach. When the tunnel and
ends are completed, ditches are to be dug out, across the
headings, near the entrances of the tunnel, and a substantial
paddle-ditch carried up, to effectually dam them up, and
force the water that afterwards collects in them to rise up
into the tunnel, through cross-headings, to be left for that
purpose.
The tunnel at Bisworh, on the Grand Junction canal
being the let that has been completed (Feb. 1825) we have
ascertained the following particulars relating to it, in order
to give some idea of the present state and expenses of tunnel
making. The internal width of this tunnel is 7 feet, the
depth below the water-line to the inverted arch 7 feet, and
the foit or crown of the arch is 11 feet above the same line.
The side-walls are the segments of a circle of 20 feet radius,
the top arch of one of 8 feet radius. The sides and top walls
are 17 inches, or two bricks thick, and the bottom or inverted
arch 13 inches, or 1/2 brick thick; every fifth course of the
top arch, and every eleventh of the side walls, is composed of
two heading bricks, or wedge-like, one inch thick on the
inside and three at the back; also, every fifth and eleventh
course as above (but between the courses of heading bricks
are composed of bricks laid obliquely across the others, the
front and back corners being cut off for that purpose in the
making, for more effectually breaking the joints, of work
obliged to be done in such short lengths. The mortar that
was used, was composed of one handful of Southampton
(blue hat) and three of good sand. Six inches below the water
line, on each side of the tunnel, side-rails of fir, 5 inches
square, to keep the barges off the walls, are fixed by pieces
of oak let into the wall below them; which rails project 9
inches from the wall, and have at every 9 feet, a chock of
wood upon the rail, for the bargemen to let their pole against
for shoving their barges along. And we were told that this
tunnel was contracted for, at 15l. 13s. per yard run; the
foil principally a hard blue clay, with two or three thin rocks
in it. Sufficient headings had been executed several years
before at the company's expence. The fame contractors
were paid 20/ d. per cubic yard for excavating the deep cut-
ing at one end of this tunnel, and 11d. per cubic yard for
the other. The expence of driving the above headings were,
we understand, from 50s. to 42s. 6d. per yard run. Nineteen
tunnel-pits, some of them 60 feet deep, were sunk for the
use of the above tunnel, which cost about 305. per yard in depth
including lining. In our inquiries respecting Braunston tun-
nel, on the same canal, we were told, that 320 yards of the
fame was drove in quick-fands, and that it cost 4800l. extra
on that account. The Foulridge tunnel on the Leeds and
Liverpool canal, of 1630 yards long, proved to be in such very
loose and bad ground, that the whole of it, but about 750
yards, was obliged to be dug out from above; in some parts 30
yards wide at top, and near 20 deep, and immense works of
timber were necessary to support and keep the banks apart,
while the tunnel was turned, and the soil filled in again.
Some part of this work, done about the year 1794, cost 24l.
or more per yard run.
After a good length of the tunnel has been completed
and well backed up, and been allowed some days or weeks for the
earth to have settled regularly upon the brick-work, the cen-
tering may be removed, by loosening the screws and taking it
to pieces, to be again put up and used further on in the same
working. In tunnels upon high levels in porous soils, and
in others sometimes near their ends, or in croffing any dry
and porous stratum, it may be necessary to excavate the
bottom a foot or 18 inches deeper than usual, and to fill the
fame up again with well wrought and thiftiess paddle, and to
turn the inverted arch, and as much of the sides as are below
the water-level, upon the same, when fit. Mr. William
Chapman, page 52 to 54 of his Observations, &c. before
quoted,
quoted, has given several directions for lettings out tunnels, where coal-pits are intended to be intersected and worked thereby, as at Worley on Bridgewater's, and Harcassle on the Trent and Mersey canals. It will be a matter of some importance, for the engineer to attend to the removing of the top-soil from a sufficient space near each tunnel-pit, and to cause the same to be evenly covered, or the holes therein filled up, with the stuff that is drawn up and wheeled away from the tunnel-pits; and as fail as the different parts of the tunnel are completed, retaining sufficient stuff to fill up future tunnel-pits as are not to remain for air-shafts, to cause the top-soil to be returned upon such places, to avoid a heavy expense for spoil banks, besides putting the farmers and neighbourhood out of temper by seeing the apparent waste and devastation that such works make, when carelessly or negligently performed. The want of a towing-path through a tunnel must be very apparent, to all such as have seen the tedious and barbarous process in use, of a man lying at length upon the gunnel of the barge, and pawing the walls with his feet; in narrow boats this is still more evident, where a plank is obliged to be laid across the barge for the men to lie down upon their backs, in order to be able to reach and paw the walls with their feet! The tunnel near Aitcham on the Shrewsbury canal, though of 970 yards in length, has a towing-path through it; and has one at Newbold on the Oxford canal, and many other short ones in different places. In all short tunnels, and even in long ones, if the ground proves, on examination, sound and good for tunnelling, it certainly would be worth while to give the necessary width to the arch, to admit of this essential appendage.

Among the most considerable tunnels that we have, are those at Worley on Bridgewater's canal, 18 miles in length! Marsden on the Huddersfield, 5360 yards; Sapperton on the Thames and Severn, 4350 yards; Penfax on the Leafield and Kingston, 3850 yards; Lapla on the Dudley, 3776 yards; Bifworth on the Grand Junction, 3580 yards; Ripley on the Cromford, 3000 yards; Dudley on the Dudley, 2936 yards; Harcassle on the Trent and Mersey, 2888 yards; Norwood on the Chesterfield, 2852 yards; Well Heath on the Worcester and Birmingham, 2700 yards; Morweliham on the Tavistock, 2500 yards; Oxenhall on the Hereford and Gloucester, 2102 yards; Braffon on the Grand Junction, 2045 yards, &c.

The longest tunnels that have been proposed, besides the above, were one of 5 miles on the once proposed extension of the Manchester Bolton and Bury to the Calder river; and one of 4½ miles on the Portseaouth and Croydon, through the chalk hills south of the latter place. The towns of Manchester, Kidderminster, and Southampton appear to be tunnelled under by the Bridgewater's, Stafford and Worcs, and Southamton and Salisbury canals respectively.

The execution of deep-cuttings appears to have been long familiar to the Chinese, since we read of one of their canals that are in places excavated 80 feet deep! and of others that are cut 20 feet deep for seven or eight miles in length! The setting out and determining upon the slopes of a deep-cutting of considerable depth and length, are objects deserving more of the engineer's attention, than has in too many instances been belittled upon them: the first Rep, after the line and the level of the intended canal are determined upon, should be to examine minutely the soil in every part that is to be cut in, and to prove the same by the backing of five vertical bays; if any of these, towards the centre of the hill, should be found in loose and porous soil full of water, while the ends of the intended cutting may appear to be in sound stuff; it will be worth while, in such fuch cafes, to put down pumps and erect a temporary steam engine, to pump up the water during the work, and to drive headings from such pump-shafts, on one or both sides of the intended cutting, and below its bottom, as has been before mentioned, preparatory to driving a tunnel. Should the whole of the cutting appear to be in loose alluvial stuff, full of water, and disposed to slip, or a part only of the ground at one end, as happened at the south end of the deep-cutting near Tring, on the Grand Junction canal, it certainly will be right to begin such part, by driving a heading up from a proper point below the intended cutting, and to give time for the spriung to drain off before the cutting is begun, which may afterwards proceed in separate lengths at the same time, and with much greater certainty and dispatch, by the help of cross headings, to drain off the water, than is practicable without such precaution, unless expensive and very powerful pumps or machines are used in the works to clear them of water in different places, while the tendency to slip is much increased by such sudden and partial drawing off the water. Ships are among the most formidable accidents to which canal-works are liable, and can hardly be too much guarded against; by giving an extra slope to banks in such places; but particularly by driving headings behind such parts, some time before the workings is begun, in order that the spriung may be intercepted, by which the most porous and loose stuff like quick-fiards may, in many instances, be converted to found and good standing stuff. After all, where the ftrata alternate very fast, and have a considerable dip, and any slippery matter like fullers earth or potters clay intervene, adjoining to a porous soil that can supply it with moisture, it is almost impossible to avoid slips, that will prove most disafturous in their consequences, both in expense and delay of the works; as happened in the Tring deep-cutting above mentioned, on the Gloucester and Berkeley canal, and many others which we have heard of.

When the engineer has, by a thorough investigation, as above recommended, ascertained the nature of his ground, and its tendency to slip, he can determine what slope the upper banks A B and P K (Plate 1, Canals, fig. 6.) ought to have in every part; for these ought not to be regulated by the slopes C F and I G, against which the water is to lie, and the waves of the canal to act, but be as steep as the ground or rock will stand, in every considerable length together; and the degree of the upper slopes will be liable to vary accordingly; if these are too much sloped, a wale or land of land and of labour in excavating and making spoil-banks will be occasioned, while if they are made too steep in slippery or loose wet ground, slips may happen that will occasion still more serious expenses, and delay also. All these preliminaries being settled, and the width in every part calculated, a number of slope-holes must be dug at A and P, and a lock-fipt dug out to join them, by a careful workman, as mentioned before on the marking out of the canal; and the top-soil being removed and clamped, from a sufficient space for flowing the stuff, the work will then be ready for the contractors to begin digging. This will be our proper place to notice several machines, and contrivances for facilitating the operation of excavating of canals, docks, or other deep-cuttings. The most simple and usual method for small depths is by runs of wheeling-planks, supported in an oblique direction up the side of the bank upon horining-blocks of different heights, on which the labourers wheel out the stuff. In larger works, turn-banks or soap-firn are erected on the bank, and a level-grade or scaffolding erected over part of the deep-cutting: two ropes wind and unwind contrarily ways off the drum or barrel of the gin, and pass over pulleys fixed over the end of the stafge; these ropes terminate in three smaller ones, two of which have at their ends
rings, and the other a hook, of iron. When a loaded barrow arrives on the run below the slape, a labourer stands ready to flip one of the rings on to each of the handles of the barrow, and to hook the other end into the felies of the wheel; when the revolution of the gin draws up the loaded barrow up the slape, another labourer, who had previously hooked the three rings, and affixed them in like manner to an empty barrow that is to be let down, while a full one is advancing as before, by the other rope. The loaded barrows are wheeled away upon the slape, and run thence to any place above that is desired. At the London Docks, we saw a very simple method used; two strong poles were set fast into the top of the bank of the dock, at 40 or 50 yards from each other; and at about five or six feet high on each, a large common pulley or ship's block was fastened, by a short length of rope; through these blocks a strong rope was run, whose ends terminated in two small rings, with rings at their ends, as before mentioned: the length of this rope was so adapted, that one end reached to the bottom of a very steep run or plane of planks that were laid and fixed on the bank, pointing up to the poll at top; while the other end was nearly at the top of another similar plane at the other poll. At a proper place between the two pulleys, the whipple-tree of a horse's harness was attached or lashed on to the rope. The operation was conducted, by a man arriving at the bottom of the plane with his loaded barrow, the wheel standing at the foot of the plane, the end of the rope being at the bottom of the plane, and the horse standing still near the poll at its top; the labourer then flipped the two rings on to the handles of his barrow, and the horse being in motion towards the other poll, the barrow was drawn up the plane, and the man also with it, who made use of his feet, retaining himself from falling backwards by holding fast by the barrow handles, which he at the same time was enabled to guide; when arrived at the top, and entered upon a plane there of less inclination, the horse had arrived almost at the other poll; and while he was stopped, and was turned round ready to return again, by the boy who attended him, the labourer flipped the rings off his barrow handles, and wheeled the same away upon the upper run; another labourer instantly flipped these rings on to the handles of his empty returning barrow, and the return of the horse let him and his barrow down the plane again, the handle going first, and the man holding them as before, but with his back to the barrow; while the other ends of the rope were drawing another labourer and his loaded barrow up the other plane as before. The simplicity, dispatch, and perfect operation of this contrivance, do great credit to its inventor. In very considerable works, it will be attended with the greatest dispatch, as well as ultimate saving of expense, to use trains and temporary iron rail-ways; and if the height and quantity of stuff to be delivered at any one place be very considerable, inclined planes, with steam-engines of small dimensions, (such as are now every day manufactured and improved) should also be erected, to draw up the trains, as at the London Docks above mentioned. It is evident, that the simple and straight course for the horse, attached to the middle of a rope as above, may often be substituted for the expensive turn-beams above mentioned, particularly where dispatch in setting the apparatus to work is an object.

Mr. Ralph Dadd appears to have contrived a machine to be worked by men, by the means of levers, for excavating canals, which was tried in the year 1794, in the deep cutting at Dawley near Hayes on the Grand Junction canal. Mr. Carnes machine for the same purpose, but worked by a horse at length, appears to have been used in 1794, in the deep-cutting near Colton Hacket, on the Worcester and Birmingham canal. In the Monthly Magazine, vol. ii. p. 594, we have the following account of the operation of E. Hefferns patent excavator: 'This machine takes the soil from the bottom of the canal, at 40 feet deep, with equal facility as at six feet from the surface! One of them is at work upon the Gloucester and Berkeley canal. By the assistance of two men only, it removes 1,500 loaded barrows from the bottom of the canal, to the distance of 40 feet, in 12 hours; and is so contrived, as to take up the loaded barrows, leave them at top, bring down the empty ones in regular rotation, and leave them at the bottom. It can be moved along the canal to the distance of 26 yards in 10 minutes, by the two men that work it.'

In October 1793, Mr. Joseph Sparrow took out a patent for a machine, consisting of a box, with its bottom opening on hinges, suspended by a port of unselfish grief or crime, the whole moving upon wheels; which he strongly recommends for elevating and discharging the soil dug out of the canal. See Repository, vol. i. p. 77.

Among the most considerable deep-cuttings, are those at Ashton on the Lancaster, Trinity on the Grand Junction, Colton Hacket on Worcester and Birmingham, Burbage on the Kennet and Avon, Little-borough on the Rochdale, Smethwick on the old Birmingham, &c.

The construction of locks is so important a part of canal-making, and they are so very essential to the system itself, that we shall give some brief particulars of their history. Mr. William Chapman, in his "Observations on the various Systems of Canal Navigation," has devoted his 7th chapter to an account of the internal navigations of China, compiled from Sir George Staunton's and other authentic accounts. He observes, that our pound-locks are unknown in China, (although explained to them by the French missionaries in 1685;) and it appears from his account, page 76, that their grand or principal canal is, in fact, only a river or stream navigation, although greatly diverted by art from its ancient course in some parts; the current of the water being low, and prevented from running off too rapidly by its defile being occasionally checked by flood-gates, consisting of two abutments of stone, one projecting from each bank, and leaving a space in the middle just wide enough to admit a passage for the largest vessels employed upon the canal; and to prevent unnecessary waste of water through the flood-gates, the passages are occasionally closed by planks let down transversely and separately one above another, their ends reining in a vertical groove in each abutment, and he observes, at page 80, that it was probably between the years of the Christian era 603 and 618, that these were introduced. At page 87, he says: 'The Chinese method of overcoming aecents appears to be long subsequent to the attempts of the Egyptians, under the succors of Alexander, who, according to Monf. Huet, bishop of Avranches, had the art of constructing sluices, or locks of one set of gates, so as to stop the impetuosity of the current, and be occasionally opened. Though termed gates, the openings were most probably closed with beams of timber, let down in grooves; as gates of large width and depth could not be opened without difficulty, even against a small difference of level. There are, however, such sluices with gates upon several of the running canals on the verge of the Shonan. They were erected about the middle of this century, (1750) and are of difficult use, because of the force requisite to open them. These running canals are on the Chinese principle, and nothing more than new channels for a portion of the river; which, when it is low, are stopped as in China, to retain a head of water sufficient to pass the boat." And Mr.
upon, and cause the gate to open and shut easily: the height of the roller above mentioned is made adjustable by a screw, so that the gate can at all times be kept from dragging on the sheeting; and instead of handles to open such gates, ropes and chains, and caplans, erected on the banks for the purpose, are used to open and shut them. The upper gates are hung and constructed nearly like the lower ones, except that they have no paddle-holes in them, and are usually hoarded no higher than the level of the paddle-ways behind them, in order to allow as weirs in carrying off a superfluity of water; but these are often attended with bad consequences, the fall of the water wearing, and in time damaging the breadth of the lock; and in floods, the stream or splashing of the water may damage goods in, or even endanger the linking of, heavy laden boats, in the lock; the same may also happen with deeply laden boats when the paddles are drawn in ascending, if the paddle-holes do not enter the chamber of the lock at some distance below the surface of the water, and in a proper direction: on the Shannonshire Canal the paddle-holes are both united, and discharge themselves through the breadth of the lock into the chamber; a peculiar arrangement to which it is mainly owing that many of its new locks were soon found to be filled with rubbish, the upper paddles, or those behind the upper gates, are drawn by a rack and pinion, &c., by means of a winch-handle, (which each bargeman and lock-keeper carries with him) in the same manner as those in the lower gates, which we have described above. Guard-rails or curving pieces of timber, &c., fig. 36, ought to be strongly bolted on to piles driven for that purpose in the front of the wing-walls just above the surface of the water, to guide the boats into and out of the locks, without striking the walls; which is far preferable to the huge flumes let into the wing-walls in some places, called pumping flumes, and calculated rather to break and destroy the barges, than protect the walls. It will be necessary also to provide a strong piece of wood formed to the curve of the breadth-wall of the lock, &c., fig. 37, before which it should be suspended a few inches above the water when the lock is empty, by means of two or three chains; these are called bumping pieces, and are intended to receive the stem of the boat, and prevent it striking the wall when the fame is not flapped or hopped in proper time; a practice, however, for which the bye-laws or clauses in the act should provide adequate fines or punishments: and flapping poles should be let firmly into the ground in the proper places for the bargemen to wind their rope, or flap as they call it, and by easing it out by degrees, to flop the velocity of the boat before it arrives at the gates or breadth of the lock that it is entering. The gates should also be furnished with two or three strong upright planks on the lower side, &c., fig. 39, to receive occasional blows from the noes or items of the boats, and prevent the planks of the gates being broken or started thereby. There is room for the skill of the engineer to be exercised, in forming the lock-fills and gates to that particular angle which will render them stronger for the same width and depth of lock, than they would be if they met more acutely, or were shorter and met more obliquely. In very large and wide locks, the gates should not be straight or plane, but a little curving to give them greater strength. On narrow canals, it may not be necessary to make double or angle gates, but one gate slanting square across the lock may be strong enough to answer every purpose, and be opened more readily than two gates on the opposite banks can be: the upper gates in particular, on account of the comparative shallowness of the water there, may be fingle, while the lower gates, if the fall is considerable, may be double. In setting out canals, where the fall of the ground is very gradual and easy, it may be necessary to avoid long lengths of deep-cutting below, and of embankment above, or making the line very crooked, to make shallow locks, if water is plenty; and under the same circumstances only, will it be allowable to make 12, 12, or more feet locks in particular places, however well the ground may suit the fame; many of these double locks were at first erected, as on the old Birmingham canal, and the Calder and Hebble navigation, where about 18s. single locks were obliged to be subtiliated, to avoid the waste of water, before pointed out.

We have not yet noticed an inconvenience and waste of water, which attend the placing of locks nearer to each other than about 200 yards, or having basins between them, equal in area to about that length of the canal, as was done at Salter Hebble in 1753; in the alteration above mentioned; without which precaution, a boat in descending lets down more water than the pond below will hold, without raising its surface so as to leave a good deal over the lock-weirs, and fill and empty basins happen in ascending, for the short pens are so much lowered by filling the lock below, that laden boats are unable to proceed for want of water, until a supply is let down to waste through the upper lock, to help them forwards. As many locks as can conveniently be brought near to each other, on the principles above, and before explained, should be contrived, if it can be done, to be in sight of each other, and of a length of canal each way; and the lock-keeper's house should be so placed, that he can when at home at his meals, or otherwise, in bad weather, see barges approaching the locks, in time to meet them before they enter the locks. Mr. Fulton who wrote in 1769 says, that the coil of locks for 25 ton boats, was about 701. per foot rife, and for 40 ton boats, about 100l. per foot rife; this may serve to give some general idea of the cost of locks at that time; but we would observe, that the decrease of the value of money, and the exceptions to all general rules on these subjects are so many, no dependence ought to be placed on such modes of estimating. If sufficient water-way is given in the paddles, and there is sufficiency enough to draw both the paddles, and open and shut the gates at the same time, a boat may pass each lock of the usual construction and rife, in three minutes time, but in general, 5 or 6 minutes will be nearer to the average time lost at each lock, as observed by Mr. Beau on the Grand Junction canal. Theorem for the time of filling a lock of given dimensions, and with given paddles and fall of water, should be found and compared with many experiments on the locks under the care of our resident engineers. (See Nicholson's Journal 8vo. No. 9, vol. iv. p. 36.) It should be considered, that a boat going up lets down or consumes twice the weight thereof (boat and cargo included) in water, more than in going down through each lock; for the boat on entering the empty lock, expels as much water into the lower reach as its own draft of water, which is made good out of the upper pond when the boat enters the same; while a descending boat expels its own flotation bulk of water from the full lock into the upper pond, where it is retained on the slanting of the upper gates; the mean of a passage each way will be a lock-full for each boat, unless they go always loaded one way, and empty the other. Mr. Fulton says, that the consumption of 25 ton boats through eight feet locks, will in general be about 103 tons of water in ascending, and 103 tons in descending; and Mr. Chapman informs us, that boats passing and repassing a summit, laden one way, and returning empty, will require nearly 13 times the weight of their lading of water for their passage, out of the summit pound.
The saving of water in the use of locks is a consideration of so much importance in most of the canals which exist, that it is necessary we should mention several of the expedients which have at different times been proposed, or practised for that purpose. Some of the most obvious of these are, a minute attention to the fitting of the gates and paddles, constructing every part of them of the most feaoned and durable materials, with the utmost precautions against partial wear or liability to accidents, by which the gates or paddles would leak and waste the water; and should such leaks happen, the establishment for working the canal ought to be such, as to detect the same immediately, and apply the proper repair or amendments without delay. It is of great importance, to adapt the plan or surface of the water in the lock, to the size of the boat or boats that are to be used, leaving as little water uncovered in the chamber of a lock as possible, and for this purpose, where water is scarce, it will be necessary to enforce the regulations, that the act ought to contain for the length, width, and form of the boats that are to be used; and on canals for large and small boats, to see that two or more of the smaller boats are so contrived as to lie close together in the lock, and occupy the whole space thereof as one of the large boats would do: less than this number of small boats must not, when water is scarce, be allowed to pass, or without paying such increased tonnage or lock dues, as will act as a prohibition.

The "waiting for turn," particularly by empty or lightly laden boats, ought also to be provided for, and it may be necessary on some occasions to enforce the same; viz. to suffer no boat to pass down, until there is another arrived below, and ready to ascend as the lock is filled; or any boat to ascend, till another is ready above to descend with the same lock-full of water. Where small or short boats are in pretty general use upon a canal, as on the Stour and Severn, it may be right to adopt the practice which Mr. Thomas Telford has described, who says, "the locks are so formed as to admit of either one, three, or four boats pausing at a time, without the loss of any more water than what is just necessary to regulate the ascent or descent of the boat or boats that are then in the locks. This is accomplished by having gates that are drawn up and let down perpendicularly instead of being worked horizontally; and each lock has three gates, one of which divides the body of the lock, so as to admit of one, three, or four boats at a time." See Pyleley's Report before quoted, page 599.

A very sensible writer, who has given a full account of the Grand Junction canal, in the Agricultural Magazine for 1803, vol. viii., under the signature of a constant reader, suggetts at page 204, the propriety of an additional set of narrow locks on each side of the summit which is in want of water, for the use of the narrow boats, to which they should be exactly fitted; as also, to avoid the expense of lifting or pumping water, that can be collected in reservoirs or leaders at some distance below the summit level, by using shallow locks of only three or four feet rise each, between the summits and the points where such waters can be taken in without lifting. The pumping of water from a lower level to supply the want of lockage, by means of team engines, has been practised with success on the old Birmingham, the Bury, and several other canals; the Crown was to be constructed with a dependence on this mode of supply, as appears by its act; and on the Grand Junction, engines have lately been erected near Tins and near Braithwaite, for raising water to the summit-levels. A very considerable power is lost in the defcent of the water through the paddle- holes, to fill the lower part of a lock, and again through the gate paddles in emptying the upper part of the lock; we have often thought that it might be practicable to apply this power for returning a certain quantity of water into the upper pound, either by making the descending stream act on a wheel, or on vane like those of a screw-jack, or by means of hydrostatic pressure, or momentum machines. See Monthly Magazine, vol. vi. page 124.

Side-ponds are an expedient for retaining part of the water, from the upper part of a lock when it is to be emptied, and to use the same towards filling the lock again for the next boat: they are said to have been invented by M. Dubie, and one with 3 divisions was tried in a lock of 20 feet fall, on the canal of Tour, near 100 years ago; they are described by M. Belidor. On the 5th July, 1791, Mr. James Playfair took out a patent for this mode of saving water in using locks. See Reporty, vol. iii. 302. And in the same work, vol. i. p. 377, Mr. W. Pitt has described three side-ponds, in form of sectors of a circle. We read that in April last, (1805) an experiment was made on the Grand Junction canal, and two of these side-ponds, with earthen banks like a canal, and each about the same size as the lock, were tried near Berkhamsted; into one of them, whole bottom coincided with about half the height or altitude of the lock, the upper quarter of the water of the lock, for a descending boat, was drawn, and it was there retained by a close shuttle; the shuttle of the other side-pond, whole bottom was about level with one-fourth of the height of the lock, was then opened, and about another quarter of the water in the lock flowed into it, and was there retained by the shuttle; the remainder being emptied by the gates-shuttles into the lower canal; and the boat having pafted out, and another ascending one taken its place in the lock, the side-pond that had lain been filled was emptied into the lock, and then that also which had been first filled; these together filled half the lock, before the upper paddles were drawn to fill up the remainder, the shuttles of the side-ponds being first shut down; by this means, two boats were passed, by letting down only half a lock-full of water into the lower pound; and the lock remained full, ready for another descending boat, as before. The time taken up by the above operations was about nine minutes for each boat that passed, or 5½ minutes more than if the side-ponds had not been used.

We understand that side-ponds are becoming common on different canals; their construction offers a very curious exercise for the abilities and skill of the engineer, so to appor-
During the expense of construction, loss of time in felling, and the saving of water that is effected, the result may be the most advantageous.

It appears, that Mr. Michael Logain took out a patent in 1804, for raising or forcing water into a lock; also, that in January 1791, Mr. Joseph Brooks obtained a patent, for a method of raising the water in a lock, from a deep side-pond or well near a lock, and by that means filling the lock with water, until a barge had passed up, or another was ready in the lock to defend, when the water below being again let down, the watertide by the same commuting current that had brought it into the lock, it was again emptied, and the boat able to proceed on the lower canal, without having waisted or let down any water. See Repertory, vol. vii. p. 361.

Mr. Lawson Huddleston has communicated, through the medium of Nicholson's Journal, 8vo. vol. iv. p. 236, a method of raising the water in a lock, from a deep side-pond or well as above, by means of a solid or heavy plunger that can be let down into the well, by means of machinery that sustains it when the water is to be raised, and drawn up when it is to be allowed to sink again; the plunger being balanced in all its different degrees of immersion by a counter weight acting on a spiral or spiral curve.

Mr. Robert Salmon has invented a different mode of accomplishing the same thing; his plunger being hollow, and so buoyant as possible; and for forcing the same down into his cistern or side-pond, when the lock is to be filled with water, he has contrived a very curious apparatus; it consists of a very heavy carriage on four low wheels, or heavy rollers of metal, connected together by a frame to answer the same purpose. Two frames or planes are prepared, that turn on fixed centres, as a door does on its hinges, but horizontally instead of vertically; the other two ends of these planes rest on the two ends of the plunger, by means of uprights therefrom and moveable joints; upon these planes the carriage rolls, in such a manner, that when it is drawn forward, by means of a rope or other machinery, the weight advances upon the plunger, and the planes being at liberty to turn on their joints, it sinks the plunger by degrees, until at length the four wheels rest exactly over the joints at the ends of the plunger, centering the whole weight of the carriage and carriage, to keep it down and elevate the water in the lock; on the carriage being withdrawn, the weight on the plunger lefles, and it rises, until at length the four wheels rest just over the hinges or fixed joints, and no part of the weight of the carriage or wheels is then exerted upon, or to counteract the buoyancy of the plunger, and the water retreats from the lock into the space under the plunger. That this carriage, which must be extremely heavy for large locks, may not be subject to run forward or back on the planes; Mr. Salmon has contrived one of them with a peculiar curvature or bend, so that the tendency of the carriage is as great to advance as to retreat, in every part; and a constant and small weight, hung on the end of a line over a pulley, in the model, will cause it to move either way, with a regular and ready motion. During the last session of the Society of Arts, in the Adelphi, Mr. Salmon presented a model and description of his invention, for which he was honoured with a premium; the model is lodged in the Society's collection, for public inspection, and a particular description of the same is expected to appear in their next, or 23d volume of Transactions. Mr. Salmon has hit upon a method of mechanically constructing the curve above-mentioned for one of the planes, which is found to approach very nearly to the arc of a circle. A mathematical friend of Mr. Salmon, who was shown the model in an early stage of his experiments thereon, has proposed as the 36th question in Leyden's Mathematical Repository, the determination of the nature of the curve in a particular application of Mr. Salmon's principle; we are sorry, however, to see this question still unanswerable by the ingenious correspondents of that very useful and learned work; because this curve promises to be applicable on several occasions in the construction of hydraulica machines. We have been treating of various contrivances for saving water in the use of locks of the common construction; and we shall now proceed to mention severall substitutes for locks in overcoming obstructions on a canal or river, but in which the boat continues floating in water; before we proceed to inclined planes, or other schemes, in which the boat is to be drawn or suspended out of the water, or the goods to be removed by cranes, &c. to other boats.

Substitutes for locks, have been called for in some situations by the actual scarcity of water, in others by the previous and necessary appropriation of the whole of the streams to mills or the practice of irrigation, and not in a few cafes by the jealousy and opposition of mill, park, and land owners; the intertemporal zeal of some projectors may have operated, who do not hesitate to prognosticate the annihilation of lock-canales, by "improved science; in like manner as improvement in machinery renders the old apparatus useless." See R. Fulton's Transact., page 28 and 110, &c.; also, W. Chapman's Observations thereon, page 2, &c. Several canals have, like the Herfingan, been restricted from erecting locks in particular places, without the mill-owners' consent; it is therefore no matter of surprize, that various schemes have been proposed to obviate the necessity of common locks. On rivers where the boats are hauled up against the stream, it is not unusual to lighten a boat by shifting part of its cargo into other boats, called lightening boats, so that their diminished draft of water may enable them to be dragged over any particular rapid; and in more extreme cafes, the whole of the lading may be taken out, and be conveyed by land to meet the boat again after it has been dragged empty over the rapid. Rapidis may themselves often be made navigable by jetsies, or contraction of the width of the stream in such places, and if the fall is rendered very considerable thereby, capstans or machinery may be erected for the hauling up or emptying down of boats; these methods have doubtless been in use from the earliest periods; and we read of great numbers of men in China being employed with ropes to haul boats up their artificial rapid or falls. The methods of using float-planks occasionally to cause an artificial flood in Egypt, China, Thandra, and Ireland, as before-mentioned (when speaking of the invention of locks), are also very ancient, and such are still in use upon several of our rivers; on the Ivel river below Biggleswhite, we think we remember seeing upright narrow planks used against a moveable beam at top of the water, and a fixed fill at the bottom of the name, for penning the water and producing a flood or flood of water, when the planks are removed and a boat may be passed. On most of our old rivers navigation there are gates erected to pen the water, and the name are drawn up to occasion a sudden flood while a boat is to pass. At the entrance of the Worleymine on the Duke of Bridgewater's canal, we remember a large door that was drawn up for our boat to pass under it into the tunnel, and then let down to pen the water therein three or four inches higher than it flood in the canal. The difficulty of opening large gates, to produce a flood of water or to let a boat pass,
has been before noticed; and in the *Mémoires de l'Acad. des Sciences* for 1707, we find the description by *M. de la Hare* of gates calculated to obviate this inconvenience in part, by having a large pair of doors in the gates opening the contrary way, or with the stream, which, on the drawing of a pin can be let to open by the prefire of the water; after which the great gates can be opened with ease, and when opened, the doors can as readily be shut again and pinned, owing to their being in the direction of the stream; and the gates then are ready to be shut again as soon as the head of water is run off, or the boat has passed. It appears, that in extending the navigation of the Seine river in France, gates were introduced, which the Duke of Reuens had invented, and which are described in the *Mémoires de l'Acad. des Sciences* for 1669, consisting of two upright gates, rather wider than half, and as deep as the channel of the stream or river, hewn into the arc of a circle of about 48 feet radius; to each of these gates several long beams of wood were fixed, meeting in or near the centre of the circle, of which the gates formed a part; and here being firmly united, they abutted against a solid pier of stone, or worked on a centre-pin fixed in a strong pile, drove very firmly into the earth by the side of the channel, at 48 feet below the place where the gates were intended. A notch was formed in the bank of the channel on each side, in form of sectors of circles, sufficiently large to contain the two gates and their beams or centers as above. By this construction, the whole of the prefire of the gates when shut and the water penned by them, was brought to act on the two upright pins or centres; and a very moderate force applied to the head of each gate would draw them apart and into the sector-like receptacles prepared for them, leaving the channel or course of the stream perfectly free of any obstacle, to check either the current or a boat in passing through. By a small adjustment of the places of the centres, gates of this kind may at all times be made to fit close to each other in the centre of the channel, on its bottom, and also to the side walls of the channel above them, and yet on being moved a small space from each other they may clear those walls and be free to move into the receptacles, in the bottom of which there may be small rollers to carry the gates with less friction, or rollers under the gates may be used for the same purpose. See *Jacob Leupold's Theatrum Machinarum*, folio, published in 1726 at Leipzig.

Dr. James Anderson, of Edinburgh, has continued, and published in 1794, in his *General View of the Agriculture*, &c. of the County of Aberdeens, a method of elevating or depressing small boats, floating in a coffin or large tight open cafe full of water, that can at will be made to coincide and connect at one of its ends with either the upper or lower canal; into or from which the boats may pass without the loss of more water than is necessary to fill the narrow space between a draw-gate at the end of each canal and at the ends of the coffers, when the same is prefixed and retained close to the end of the canal, and a small additional quantity to restore the equilibrium and give motion to the coffers, of which there are two exactly of similar dimensions suspended and connected together by strong chains. *Mr. Chapman's concise description of this invention is so much to our purpose,* that we beg to use his words, who says, "the doctor there observes, that, for all the purposes of commerce, no more width of boat is requisite than four feet, or more than two or three feet depth; and that the length might be infinite, so as not to be inconvenient for ascending and descending between any two levels of canal, which he proposes to be done in the following manner, viz. that the lower level be Vol. VI."

On the 24th December, 1798, *Mr. James Foulis* took out a patent, (see *Repertory*, vol. i. p. 7.) for a method differing in principle from that of *Dr. Anderson* above described, only in having an axle and two wheels thereon, at a distance from each other on the middle pier, and under his coffers or receptacles, similar axles with a pair of wheels, and instead of his coffers or receptacles being suspended from the two ends of a chain passing over the wheel, as in *Dr. Anderson's method*, *Mr. Foulis's two chains are fixed to the tops of the side walls, passing under the wheels of his receptacles, and over the wheels and axle on the middle pier*. He also describes rollers or guides by the sides of his lock-pits to steady the receptacles, and a toothed wheel on the middle shaft or axle connected with a fly or brake wheel to regulate the motion of the chains and receptacles; he also provides the gates or hatches at the end of his receptacles, to be balanced by counterweights, and to draw down into a cavity prepared for the purpose, when a boat is to be passed in or out, instead of drawing up. And if the fall be very considerable, he suggests the propriety of a short tunnel or arch to conduct the lower canal into the lock-pit, instead of an open notch or perpendicular wall cut in the hill for the lower canal. It appears that this balance-lock of *Mr. Foulis's* was put in practice, or at least tried, on the *Donof* and *Somerfield* canal, near Frome, on the 6th of September, and 17th of October 1830, on a 21 feet fall, and with boats of ten tons burthen; delays in completing the above canal, and forming a communication with the sea, prevented this lock from being made use of for a long time afterwards, but we believe that the state of a late writer on the above experiments, found it was a subcription was set on foot in 1822, to raise money to make a lock in this very place, originated entirely in mistake.
the axis or barrel for the rope, to give motion to the ropes and cradles with their contents, when a sufficient quantity of water had been let into the upper chell by a valve and pipe contrived for the purpose, or out of either of the chells by means of a dring attached to their valves, till an equilibrium of the two chells, cradler, and boats upon them were obtained. By this apparatus it was proposed, that in general one boat should be ascending upon one of the planes while another descended on the other; but the cauliens were large enough to admit of sufficient water from the upper or lower level being taken into one of the chells, to balance a loaded boat on the other. The captain worked by men was proposed to be used, for dragging boats out of the upper canal over the upper plane and platform on to the cradle in order to descend. Walking-wheels, to be worked by men, were also proposed instead of water-wheels, where the water was very scarce in the upper canal. The canals above-mentioned were never carried into execution, although an act of parliament were obtained for the former, nor have we heard of any of Mr. Lead's planes being brought into actual use.

Mr. William Reynolds, of Ketley, in Shropshire, was the first who contrived and executed an inclined plane (which was completed in 1789) for the passage of boats and their cargoes, which was found fully to answer, and continued in practical use. Mr. Thomas Telford has thus described the fame, in Pliny's Agricultural Report of Shropshire, p. 291. Mr. Reynolds "having occasion to improve the mode of conveying iron-stone and coals from the neighbourhood of the Oakenshaw to the iron-works at Ketley, these materials lying generally at the distance of about a mile and a half from the iron-works, and at 73 feet above their level, he made a navigable canal," called the Ketley canal, "and instead of defending in the usual way, by lock, continued to bring the canal forward to an abrupt part of the bank, the skirts of which terminated on a level with the iron-works. At the top of this bank he built a small lock, and from the bottom of the lock, and down the face of the bank, he constructed an inclined plane, with a double iron railway. He then erected an upright framework of timber, in which, across the lock, was fixed a large wooden barrel; round this barrel a rope was passed, and was tied to a moveable frame; this half frame was formed of a size sufficient to receive a canal boat; these boats were 20 feet in length, 6 feet 4 inches wide, 3 feet 10 inches deep, and carried 8 tons; and the bottom upon which the boat rolled was preferred in nearly an horizontal position, by having two large wheels before and two small ones behind, varying as much in the diameters as the inclined plane varied from an horizontal plane. This frame was placed in the lock, the loaded boat was also brought from the upper canal into the lock, the lock-gates were shut, and on the water being drawn from the lock into a side-pond, the boat settled upon the horizontal wooden frame, and as the bottom of the lock was formed with nearly the same declivity as the inclined plane, upon the lower gates being opened, the frame with the boat passed down the iron railway on the inclined plane into the lower canal, which had been formed on a level with the Ketley iron-works, being a fall of 73 feet. Very little water was required to perform this operation, because the lock was formed of no greater depth than the upper canal, except the addition of such a declivity as was sufficient for the loaded boat to move out of the lock; and in dry seasons, by the assistance of a small steam engine, the whole of the water drawn off from the lock was returned into the upper canal, by means of a short pump. A double railway having been laid upon the inclined plane, the loaded boat in passing down brought up another boat, containing a load nearly equal to one-third part of that which passed down. The velocities of the boats were regulated by a brake acting upon a large wheel, placed upon the axis, on which these ropes connected with the carriage were coiled." It appears that this plane has an inclination of about 22°, except near the extremities, where it diminishes to about 11°; and that about 400 tons of coals usually descend thereon daily. In 1789 a copper medal, or halfpenny, having a representation of this plane on one side, and of the cast-iron bridge at Coalbrook-dale on the other, was struck, and issued by the Coalbrook-dale company. Since the practicability of inclined planes has been established, by the success of the Ketley plane, but few acts have been passed for new canals, without a clause authorizing the company to erect inclined planes, instead of locks, if they should be found most advisable. Before proceeding to mention the inclined planes of different constructions, which have been since made or proposed, we shall notice the under-ground plane at Walkden Moor, which was completed in October 1797, upon Bridgegewater's canal, it being so similar to the Ketley plane above described.

The Duke of Bridgewater, in the year 1800, caused an account to be presented to the Society of Arts, in the Adelphi, London, of the inclined plane which he had erected and brought into use, under the direction of his agent, Mr. Benjamin Balthers, between two different levels of his tunnels or subterraneous canals from Worlehy near Manchester; for which the Society voted his grace their gold medal, and published plans and sections, and an account thereof, in their 18th volume of Translations; to which we refer, only mentioning, that this plane, which is 35 1/2 yards high, and 121 yards long, through an inclining tunnel hewn in the solid rock, at near 60 yards below the surface of the ground, differs from the Ketley plane, in having, upon 57 yards of the lower end of the plane, a single railway only, to or from which the two railways above join by cary curves, to proceed up to the locks by one railway, or down by the other. A winch and pinion are provided, to be occasionally worked by two men, into cogs in the large brake wheel, for lifting the boats in motion. Rollers are placed between the iron rails, for the slack part of the great ropes to run upon, and for further preventing the wear of these ropes, they are lapped round with a small cord. About 12 tons of coals are let down in each boat, and a boat and cradle on which it runs, weigh about 9 tons more. About 16 minutes is consumed in palling a pair of boats: the boat-crades are 30 feet long and 1 1/2 feet wide, moving on 4 iron rollers. A small bell gives notice from the bottom to the top of the plane, when the boats are placed on the cradles, and the machine ready to work. The water of the locks is let down by a paddle, through a perpendicular shaft, to the middle canal, and acts as a water-bellows to force fresh air down into the extensive tunnels and works that are on the lower level. The upper gates of the locks turn in hollow grooves like a common lock, but the lower gates draw up in grooves, by means of windlasses, to let the boats pass out or in when the water is let off.

Mr. William Reynolds has the honour of introducing another fort of inclined planes, on the Shropshire canal, where there are three planes in use of 120, 126, and 277 feet rises! The act for this canal palled in 1788, and it was completed, under the direction of Mr. Henry Williams, as refit engineer, and opened in 1792. These planes are upon the same construction as those at Ketley, except that there are no locks at the top of the descending planes, but the same are continued above the surface of the water in the upper canal, and terminate in a crose beam, from which another plane and rail-way descend into the upper canal: this is for avoiding
avoiding the waste of water which looks at the top of the plane or sluice. A small steam engine is used for working the axis of the rope barrel, at some distance from which, on the upper side, there is a large pulley or wheel, fixed at a proper height, for the great rope to pass over, to draw the boats up or let them down the long descending plane; another smaller axis and rope placed are provided, which can, like the larger one, be call in or out of the engine-geer at pleasure; this last is used for hauling the boats up the short ascending plane, from the upper canal. The engine can also be used to draw empty boats occasionally up the long plane, in case such want to pass, when there are no loaded ones ready to descend, and draw them up, as we have before described. The wheels or rollers under the cradles appear on these planes to be equal in diameter, and not of different sizes, so as to bring the two ends of the boat to a level, as on the Kelpy; they do not, therefore, appear applicable to very steep planes or to long boats. On the windmill plane, which is 1,000 yards in length, and 126 feet high, its boats have been passed down, and fix taken up within the hour, the steam-engine and three men only being employed: the boats here are of the same length and breadth as on the Kelpy, but shallower, so as to carry but few tons; and such boats are said to be passed down these planes for three pence each, and the empty boat taken up gratis. At Wombrook on the Shrewsbury canal, Mr. Thomas Telford has since erected a plane, 223 yards in length, and 75 feet high, exactly on the same construction as the above, of which an account, with plans and sections, may be seen in Pym-ley's Report, p. 294.

On the 19th of June, 1793, Mr. Jofhua Green took out a patent for the use of double inclined planes and rail-ways, on which cradles for the boats are to be used, consisting of a frame of wood, and the bottom corded by strong ropes across each other like the common bedsteads, that the boat may not be strained; in order to introduce wheels of four feet diameter for the cradle to move upon, a strong frame is to surround the cradle, and be firmly bolted to it, but leaving an interval sufficient for the four or more wheels to move between it and the cradle, by which the axles can be fixed to the wheel, and work in guides at each end, with less friction than common wheels or rollers. To his brake-wheel handlespokes are adapted, for men to affix in setting the machine in motion, instead of a winch as before described on Bridge-water's; the ropes are to be capable of adjusting to the proper length as they stretch or contract, by a screw or otherwise. A third inclined plane is directed to be made, for the purpose of carrying a counter weight or vessel, whose rope is to pass over another axis with a brake and handle spoke wheel, for hauling the cradles and boats out of the upper level to the ridge or crofs beam, or to cafe them down into the same. He recommends spare vessels laden with water to be in readiness to pass up or down the opposite plane, as a counterpoise to any single loaded boat that may arrive at the plane. Alfo that single planes, and with less inclination, may in some instances be adopted. See Reper-tery, vol. v. p. 11.

Earl Stanhope, in the year 1793, in recommending the Bude and Hatherleigh canal, proposed, between the different ponds or water-levels of the intended canal, to have iron rail-roads of gradual and easy ascent, on which boats of two tons were to be used, suspended between a pair of wheels of about 6 feet diameter, and to be drawn up or let down the fame by a horse, in order to be launched in the upper or lower water-level, or canal.

On the 8th of May, 1794, Mr. Robert Fulton obtained a patent for the use of a double inclined plane, wherein cradles having giffons or califons under them, so very differ-ent from Mr. Leech's above describ'd, except that the boats were in some cases to be taken on to the cradle planes or cogges instead of length ways; that was propelled to be accomplished by short inclined planes, on which the boats, when upon wheel carriages, were to be drawn out of the upper, and lower canals by means of ropes working on the sides of water-wheels; a brake is to be used for regulating the motion of the boats and cradles, when brought nearly to an equilibrium by the valves; brace-blocks, or pulleys, to be used for shortening or lengthening the large ropes, when necessary. See Repertory, vol. vii. p. 222.

Mr. William Chapman, at page 59, of his Observations, which were written principally in relation to Mr. Fulton's treatise, fuggles this false enunciation of inventions on inclined planes, as before-mentioned, not knowing, as we apprehend, of Mr. Fulton's patent above-mentioned, because it was not published till 1797; and it is indeed singular, that Mr. F. Shoulb, in 1795, have written 114 quarto pages on the subject of canals, and not once have given a hint of his having taken out a paten in the year before for none of the principles therein explained, and so highly recommended, nor does his long letter in the Star News- paper of the 39th of July 1795, announcing this work being in the printer's hands, make the laft reference to his patent. The Board of Agriculture muff, we are confident, have been equally in the dark, in March 1796, or they would not have given Mr. R. the opportunity of putting into notice, a subject wherein he was a patentee through their means. We beg here to remark, that our duty, in treating this part of our subject, seems to require the mention of all the inventions and methods which have come to our knowl-edge; and though we should have more pleasure in making known the inventions of those who lay the fame at once open to the community, yet, as all of these will be in a few years, we have not thought it right to exclude or be less particular in the mention of, inventions or contrivances so circumstanced: but to give the dates of such patents wherever we could, that their termination (at the end of 14 years) may be known.

Mr. Robert Fulton, in his 410. work, entitled "Treatise on the improvement of Canal Navigation," published in London in 1796, with many plates, has propofed the use of narrow canals and inclined planes, on which small and shallow rectangular boats are to be used, having low wheels, or rather tracks fixed underneath their bottoms; he propofes to have on his double inclined planes, an endless chain passing up the track of one plane and down the other, round or over wheels that are of the proper size and fixed in proper places and directions at top and bottom of the planes to suit the swag or curvature of the leading chain; these are made to revolve at pleasure, with power sufficient to drag a loaded boat up one of the planes, (by means of a short double chain belonging to the boat which is to be hooked into, and will at the proper time discharge itself from the leading chain), by means of toothed gee attached to the upper wheel, on which there are flubs to prevent the chain from flipping; which connect with a water-tub depending in a perpendicular shaft, discharging itself at bottom by means of a valve, and returning again to the top, when call out of gear, by means of its counter weight, balance-chains, and fly, ready to be again charged with water from the upper canal. The motion of the whole is regulated by a pair of fanners or an expanding fly; a smaller axle and cog wheel are provided, working into the tub-shaft gear, when necessary to draw the boats up a short plane that descends into the upper canal, on to a bridge or curving
C A N A L.

This page describes a system for propelling boats through a canal, using a mine-engine. The page mentions the use of inclined planes for raising and lowering boats, and describes how to balance the loads on these planes. Mr. Fulton is credited with inventing the system, and the page includes diagrams showing the process. The text is replete with technical terms and descriptions of the mechanics involved in the system.
water to fill the cradle, making it act as the chamber of a lock; the lock-gate being opened, a boat might enter the cradle, from which it would expel great part of the water into the upper canal again, if the boat and cradle were nicely adapted to each other; the lock-gate and baffle should be again shut, when the water might be drawn off into a cistern, (to be returned if necessary by a water-wheel or any of the methods before mentioned), the cradle be unfastened from the lock, and be let down the plane by any of the regulators before proposed. For pausing the boat out of this cradle at the bottom of the plane, the back or other end of the cradle might open, or, perhaps a better method would be to continue the plane deep enough into the lower canal, that the cradle, which should in this case be heavy enough to sink in water, might defend low enough for the boat to float out or in, over its end; side rails should, in this case, stand up from the cradle, to draw its place when under water, and for guiding and fixing the boat over it, with liberty to sink into the cradle, as it is drawn up the plane to the surface of the water.

Mr. Chapman informs us (page 7), that for avoiding the friction of the gudgeons of rollers, when charged with the weight of a loaded boat on an inclined plane, Earl Stanhope has proposed, that rollers between the boat's bottom and a smooth plane should be used, moving or rolling with the boat, for half the boat's length; the rollers then to return to their places by means of weights acting over pulleys, and connected by a chain to the ends of each roller. Mr. Fulton, he says, proposes to use moving rollers, attached to, or going under and through the cradle that contains the boat, the gudgeons at the ends of the several rollers being paffed through the links of an endless chain or collar, by which the rollers are returned in a cavity under the boat, that is rolling in the cradle; this endless chain of moveable rollers for lowering of friction, appears to be claimed as part of A. G. Eebehart's patent of the 31st of January, 1795, for various machinery; see Repertory, vol. ii. p. 305.

The principles of setting out canals, where inclined planes are to be used, are similar to those we have explained, in recommending several locks to be brought together to form a part of such, or a considerable fall in one place; it will, however, be necessary, in determining the place for an inclined plane, to choose ground which slopes as regularly as possible between the intended upper and lower levels; if any part of the ground for the intended plane is springy and disposed to slip, the springs must be cut off by effectual and durable underdrains. It will be better to contrive the plane, if practicable, that little, if any, filling up of hollows shall be necessary in forming the plane, to avoid new made ground, which on a considerable declivity would perhaps slip, after heavy rains had faturated it with water; the foundations for the floes or bearers must also be carried through such newly made ground, and into the firm-fll. The staff which is removed in forming an inclined plane, should be carefully levelled, or disposed of in holes, so as not to form spoil-banks, and be covered with the top soil previously taken from those places. In case a perpendicular shaft and fough thereto is wanted at the head of the plane, the knowledge of the strata, or matter which compose the hill, may be of considerable importance, in determining the best place for the mouth of the fough; which may not always be the neareast point at the proper level, to the intended shaft, if the strata or measures of the hill are various and dip considerably. The plane being formed of a sufficient width on the ground, a strong framing of timber braced across may be used, if good and durable hewn flone is not in plenty, fixed firmly down to a sufficient number of piles drove into the ground, the interfaces between the framing being filled with good rubble flone, or gravel rammed very tight down. On these frames two or four fil or rails of sound oak, according as the plane is to be single or double, should be laid parallel and at the proper distances from each other, and firmly bolted down; and on these the slips or ribs of iron are to be evenly and smoothly fixed, for the wheels of the boat, or boat-cradle to run upon, and upon which they are to be confined from getting off sideways, by a rib flanding up for that purpose, either upon the wheels or on the rails. If good flone is in plenty, it will be proper to cover the whole of the plane with ashlar or well jointed flones, taking care that the courses across the plane at proper intervals are formed of large flones let some distance into and firmly bedded in the ground; and to the rear the cast-iron rails (that are used on good and durable planes) may be fastened by pins called into a hole with lead. Or, if wooden rails are to be used instead of cast-iron ones, strong planks of wood should be worked into the paving of the plane at proper intervals, on which to roll and fall down the rails.

Care should be taken, in all works of this kind, where large or heavy flones are used, to let no part of the mortises or holes which are cut in such flones remain open or united with lead or cement, to prevent the rain filling them with water, which would in winter time expand with the frost, and in mott illiances split the flone. It is unnecessary for us to point out to experienced engineers, the great care and precaution which ought to be used in works of this nature, to make every thing substantial and more than sufficient to sustain all the weight or strain to which it will be subjected, and which ought in mott cases, particularly the moving parts, to be previously calculated, and before the apparatus is put together for actual use, every rope, chain, framing, wheel, &c. &c. should be subjected to a greater strain than can occur in practice, to avoid the unpleasant, and perhaps fatal accidents, which might otherwise happen, by which a prejudice might at the onset be excited against the scheme, to powerful as to cause it to be laid aside without proper trial. It would much exceed our limits to enter fully into this subject, we shall therefore proceed to those other considerations for overcoming acent on canals, where boats have been lifted out of the water, or proposed to be, by a perpendicular acent; after which, there will still remain to describe the methods which require the shifting of the cargoes of boats into other boats, or to railway wagons, &c.; first mentioning that on the Shropshire canal, an inclined plane is used for pausing the boats over part of the acent, while the lock is opened for the other parts; and Mr. William Chapman, at pages 54 and 59 of his Observations, &c. recommends whenever coals in large quantities, lime, lime-flone, or other minerals, are to be conveyed along canals, or are brought in by branch canals on a small scale, there being a quantity of water which refloors cannot remedy, where it can be done in setting out the canal, in addition to the locks, to overlap the levels in a steep place, and communicate by an inclined plane for boats (or a double rail-way for tram-wagons) leaving the lock communication to answer all the general purposes of commerce. The same author observes, that the portage of articles from one level to another, and carriage of the boat itself is still practised in various parts of North America, as the falls of the Mohawk, from the Mohawk to Wood Creek, at the falls of Orangina, &c.; also at several places called Tarbets, in the Highlands of Scotland, as in Cantyre, Loch Lomond, Arrcharach and Long, Jur, &c. Among the principal inclined planes for boats, are those of Hay, Windmill-hill, and Wrockardine-wood on the Shropshire canal, Walkden Moor on Bridgewater's, Ketley on the Ketley, Wormbridge on the Shropshire, &c.

On the 8th of May, 1794, Mr. Robert Fulton took out a patent
patent, as before-mentioned, in which he describes (see Reportroy, vol. vii. p. 227.) either a rectangular upright notch in the steep face of a hill, to the top and bottom of which the two levels of a canal are brought, or a large perpendicular shaft and tunnel at the bottom for the lower canal, through which notch or shaft boats are to be drawn up or let down, in a pair of water-tight cradles, suspended at the two ends of strong ropes of chains, that are to pass over pulleys fixed above the top of the shaft, and connecting with a brake-lever or wheel, to regulate the descent of a boat in one cradle, and of another in the other, after they have been brought to an equilibrium by the letting out or in of water by proper values. The boats are to be drawn into and out of the cradles, by short inclined planes, in the upper and lower canal, on which the boats on water-tight carriages are to be drawn by ropes winding on the axis of water-wheels, to be turned by water let out of the upper canal thereon; brace-blocks are to be used for adjusting the length of the great rope, and capstans may be used instead of water-wheels, for pawling the boats on and off the cradles.

Mr. Fulton, in plates 11 and 12 of his "Tractate on Canal Navigation," and his description thereof (pages 97 and 105) has more fully described this method; and proposes for a descending trade, that the full boats should draw up the empty ones, and instead of inclined planes for getting the boats on to the cradles, a cage of iron should be used, into which the boats on the lower canal can be floated; and for discharging them into the upper canal, he proposes two lock-carriges, or large water-tight boxes, open at one end, moving on iron rail-ways, and which can be advanced by rakes and pinions over the shafts, while the boat is suspended high enough to clear its bottom; the open end of this lock-carridge is made to fit, and be retained against the frame of a lock-gate at the end of the upper canal, (as in Dr. Anderson's and Fufell's methods, and the water-tight cradle which we have lately mentioned), when the water being admitted by a valve, to float the boat in the lock-carridge, to the level of the upper canal, the lock or draw-gate thereof is to be opened, and the boat floated out of the cage to proceed on the upper canal; to the pulleys or drum-wheel over which the chains act, a fly or fanke is proposed to be connected to regulate the motion; as also an axis with cranks to work pumps, by which the water that is drawn off again from the lock-carridge into a fixed reservoir may be pumped up again into the upper canal, that no water may be lost. For an alternate trade, to which it may be at will adapted, or the necessary parts applied afterwards, an additional shaft must be sunk, in which a water-tub is to be suspended, instead of another cage and boat, as a preponderating weight; this is to be filled out of the water received in a cistern that is drawn out of the sliding lock-carridge.

Mr. Robert Fulton (see his "Observations," p. 94, and plates 9 and 10), particularly describes a species of Cranes, by which boats are intended to be drawn up, in an iron cage, through an upright notch or shaft, and by the motion of the jibs, are to be moved over the upper canal and lowered down to float therein, or the reverse in descending; for this purpose a perpendicular notch or shaft for the boats, and another for a water-tub, as a counter-acting and motive force, is to be provided; a reservoir is to be formed by the side of, and about 5 feet from the bottom of the tub-shaft, into which the water is discharged from the tub, when at the top, can be conveyed by a proper valve and spout; provision is to be made, by valves and spouts, for filling the tub from the upper or lower level of the canal, as occasion may require; and a valve is to be provided, opening by a pin in its bottom, for discharging the water when it rests on the bottom of the tub-shaft; over the tub-shaft a drum is to be fixed, for the tub-chains and crane-chains to wind round, and to this drum a fly or forner is to connect by toothed wheels and axles, to regulate the velocity of the motion. The crane-chains are to be double, and proceed to two separate jibs fixed on centres, at proper distances from each other, having the ends of their jibs connected by a coupling rod of the same length, by which they will always move parallel, and suit the distance of the hooks on the top of the iron boat-cage. For raising a boat out of the upper canal, the same being floated on to the cage suspended from the cranes or jibs, and the water-tub (to which balance-chains are to be adapted) being near the bottom, water is to be drawn, by a valve and spout, out of the reservoir into the tub, till it preponderates and draws the cage and boat out of the upper pound; the jib is then to be moved over the boat-shaft, and the water emptied from the tub by sufferance it to descend a little further and strike the bottom, when the boat will be lowered easily, by means of the fly, to the lower canal, where it can be floated out of the cage; and the reverse on ascending. If water is very scarce in the upper canal, and a fough or tunnel can readily be driven, for emptying the tub-shaft, the same may be made deep enough to draw water from the lower instead of the upper canal, for the preponderating power. We have not heard that any of these perpendicular lifts for boats have been executed, we shall therefore proceed to the other kinds of cranes and perpendicular lifts for the cargoes of boats.

Mr. Bridge, of Tewksbury, about the year 1759, contrived, for the navigation on Stroudwater river, a kind of cranes, with double jibs, that could be either used singly or together, and act as a balance to each other; these were erected on a strong walled bank, that separated the upper and lower levels of the river at the several mills. The boats to be used on each different level, or mill-stream and dam, were all of one size, and made exactly to suit and contain a certain number of strong wooden boxes, without any loft space. The goods or lading of the boats were placed in these boxes, and when they arrived at the first crane, one end of the chain thereof was hooked to a box, while the other was hooked to a similar box of goods in the other level, and by a peculiar structure of the crane, worked by two men at windlasses, both boxes were drawn up and suspended, somewhat higher than the bank of the upper canal, when the jibs were turned half round, and the boxes of goods were lowered down and replaced each other in the boats; the same operation was repeated with each of the remaining boxes, when each boat was ready to proceed with its new lading upon its own level to the next cranes. It can hardly be necessary to add, that the expence and delay of this method caused it to be soon laid aside.

Mr. Edmund Leach, in his tractate before quoted, proposed boats to be unladen and laden with boxes of goods as above, but to work the cranes by water-wheels, or by wheels for men to walk in.

The duke of Bridgewater's tunnel from his canal into the coal-works at Worsley, after it had proceeded for a great way fraught into the hill, came at a great depth to be under a small brook or confluent stream of water, by the side of which a large water-shaft was sunk, and a drum and large brake-wheel erected over it, of sufficient size that a man who stands before the lever thereof has his two hands at liberty to pull the lines which connect with the valves, and give signals to those below, while by lunging, or dipping accordingly, with his breast against the lever, he can in an instant stop the machinery in any part of its motion, or regulate the same at pleasure. There are two water tubs, which are very large, and have a valve and pin to empty themselves quickly when they arrive at the bottom; they are suspended by large ropes
or cables from the drum, while other large ropes descend from one to another, or coal shaft, by the side of the middle or principal tunnel, into and over the navigable tunnel, which there is at, we believe, 60 yards lower level. On this lower canal boats are used, similar in their dimensions to those above, and containing boxes, which being filled with coal at the several terminations of this canal, in the banks of coals; the boats are pulled along by means of ropes that are fixed at the ends of the tunnel, at the proper height for a man, who walks on the top of the coals, to lay hold of, and shove the boat along by. The boat being arrived under the coal-shaft, and one of the water-tubs being at the top of its shaft, the coal-ropes answering thereto is hooked on to the box of coals, and the defect of the water-tub, immediately from the opening of a hall, drawing the fdace to the bank of the principal canal, where being drawn aside over an empty boat, it is lowered into the same by a short lever or balance of the motion of the machine; when the interval of emptying the tub at the bottom by its valve, gives time for hooking another box to the other rope which is at the bottom, when the other water tub is filled, and the machine suffered to move, by the man who leams against the brake. This very complete and economic machine was contrived and erected by Mr. James Brindley, and it is so constructed, that when coals are not drawing, the alternate defect of the water-tubs work some very large pumps, which are sufficient to lift all the mine-water of the lower level into the middle canal and keep the lower canal always at the proper height for navigation.

The same tunnel of Bridgewater's canal being continued a great way farther into Worsley hill, till under Walkden moor, another subterraneous canal or tunnel there begins, at 35½ yards higher level, this last being near 60 yards from the surface; from the surface two shafts were sunk, one terminating in and over the upper tunnel or canal, and the other in and over the middle or principal canal; there is another canal still lower, which we have been left speaking of, after passing close by the canal above: between these shafts a large drum was erected on the surface, with a brake wheel and a pair of strong ropes. Two boats being arrived at the shafts on the upper canal, one of them loaded with boxes of lime-stone, that was wanted at the surface, and another with boxes of coals intended to be transferred into an empty boat in the middle canal; the ends of the two ropes were fastened to a box of coals and a box of lime-stone, when the superior size and weight of the coal-boxes drew the lime-stone to the surface, to be there handed to and the box; at the same time that the box of coal was deposited in the lower boat, ready to proceed on the canal to Manchester or other places. This method was in 1797 superseded by an inclined-plane for letting down the boats laden with coal, from the higher to the middle level, and returning the empty boats and boxes, as we have before-mentioned. At Brierley-hill, near Coalbrookdale, the extremity of a branch of the Shropshire canal, great quantities of coal and iron in crates made of iron were let down one of two shafts, which connected, with the termination of the canal above and the ends of a railway in a tunnel below, from which lime-stone in similar crates was drawn up the other shaft to be placed in the boat; a large barrel and brake-wheel were fixed between the tops of the shafts, and crates with jibs, by which the crates could be raised and moved over the shaft, or the reverse; these shafts, which were 120 feet deep, were not found to answer, in point of expense, so well as inclined planes, and Mr. Telford informs us (Plymley's Report, p. 306 and 307.) that inclined planes have been substituted, on which crates of coal, or iron pigs, or goods, descend and draw up other crates containing lime-stone, for the use of the iron-works above, by means of ropes, a drum, and brake-wheel, with a much less portion of manual labour, and more expence than was done by the shafts above-mentioned. For Liddick's lime-works, on Donnington Wood canal, similar shafts were erected, but are not superseded by an inclined plane. At Congoleaux, on the Sceneryhill Coal-canal, after the trial of Mr. Wilson's diving canal, inclined planes for descend ing boxes of coal were tried, and elected for some years; but the delay and expense were found to be great, that the economy effected the purchase of home mills, and under a new act of parliament, erected a large place of these inclined planes. Having inclined with the different kinds of inclined planes, by other ways of procuring the ascent of boats or their cargoe, we proceed to those which are used for overcoming the principal or sudden ascents on railways or tram roads; wherein wagons or cramps are used for the conveyance of goods, the same being drawn on the level parts or easy ascents or descents by a horse, as we shall describe shortly.

Mr. John Buddle, in the General Magazine for 1764, page 283, has given a view and description of the coal-wagon which had been then long in use on the wooden railways in the neigbourhood of Newcastle upon Tyne. This wagon moved on four wheels of cast-iron, or of wood with iron rims, having an edge standing up on the rim of each wheel, in order to guide and keep them upon the wooden rails. The wagon is in shape of an inverted prismatic, having a door or false bottom hung with hinges and fastened by a hasp, that can be let go to let out the coals when the wagon has arrived on the faith, and over the front which is to convey the coals into the ships or keels, or into a heap below as a slope; obliquely over one of the hind wheels a strong crooked lever of wood is fixed and suspended, by a strap when not in action; this lever, called a convey, is intended to act as a brake, by being let down upon the wheel when the wagon is descending down an inclined-plane, or steep part of the railway called a run; and on these occasions the horse is unharnessed from the front of the wagon and tied behind, and the wagon-man mounts allride on the hinder end of the convey, the fore-end being confined closely in a flap in the side of a wagon; and, by means of a pole that there is for his feet at the tail of the wagon, he applies just so much of his weight upon the convey as will either float the wagon or give it the proper velocity in every part of its descent down the hill or run: see the Agricultural Magazine, vol. iii. p. 241. In the year 1763, we remember seeing an inclined plane or wagon-way as above described, on which the coal-waggons descended down the hill from Wibsey-back to the town of Bradford, which is on a branch of the Leeds and Liverpool canal, their velocity being regulated by conveyways as above. But some waggons which we have seen, had the convey fixed to a moveable joint at the front of the wagon, and had a large block of wood behind, which, when the convey was set down, wedged in between the face and hind wheels, and acted most securely as a brake for stopping or regulating the velocity of descent. The empty waggons were drawn up the hill again to the coal-pits by a horse.

An inclined plane for waggons, was erected some years ago by Mr. Barnet, a coal-viewer at Bywell, near the Tyne river, of which a description is given in the Agricultural Magazine, vol. iii. p. 367, as follows: "It is a very ingenious, yet simple combination of machinery, for the purpose of regulating the conveyance of waggons laden with coals down an inclined plane, and for bringing the empty ones back again, by the same power that refixed its impetus in the descent. The length of the railway in which the waggons
gons run is about 864 yards, which distance it descends in two minutes and an half, and re-ascends in the same space of time; so that the loaded waggons can be let down with ease and safety, the coal discharged and the empty waggons returned to the pit within the compass of seven minutes. The impelling and retarding power of motion are derived from a plummet of 16½ cwt., which the waggons in descending and ascending alternately raise and lower to the depth of 144 yards. The rope, by which the waggons are impelled and accelerated, winds round the axis of a large wheel in a niche or groove in the middle, which gives the rope only space to coil round upon itself, and thereby guards against all possibility of entanglement. Near to the axis of the large coiling-wheel, there is an oblique indentation (a range of teeth or coggs) of call-iron, which corresponds with and works into a similar conformation on the rim of a smaller wheel; round which the plummet-rope is coiled or warped, and it is in consequence thereof moved round, only once in six rotations of the fulpinping and retreating wheel, which is the same proportion that the elevation of the plummet weight bears to the descent of the waggons, or to the rope from injury by dragging on the ground, rollers with iron pivots and brass sockets for it to roll upon, are elevated in the middle of the rail-way, but sufficiently low to prove no obstruction to the waggons which pass over them." On shorter inclined planes than the above, horse-gins are sometimes used, for drawing loaded waggons up, and at the same time letting empty waggons down the planes.

The construct of Rail-ways, or, as they are often called, tram, dram, or waggon-roads, requires the application of principles so exactly similar, and they are so intimately blended with our several navigable canal and river establishments, that we have before mentioned our idea of the impropriety and difficulty of separating them by deferring the account thereof to a future place in our work: the subject of inclined planes, of which we have hitherto been treating, has required the mention of so much relating to rail-ways, that we beg to proceed with and finish that part of our subject, before we resume the subject of bridges, towing-paths, fences, drains, boats, moving boats, &c. which yet remain to be mentioned. From the first opening of the coal-mines on the banks of the Tyne river above Newcastle, until about the year 1680, it appears, that the coals were conveyed in carts and wains, from the mouths of the several pits, to the keels or vellas, that conveyed them to the sides of the ship lying below the bridge. As this kind of fuel came to be substituted for wood in London and other cities, and towns on the south and eastern parts of the island, the consumption of Newcastle coals became so considerable, that we are told, that several coal-mines, as the Kinton, Benwell, Jemmond, &c. gave employment to 400 or 500 carts or other carriages each, for conveying the produce of those pits to the water-side; for the difficulty and expense of maintaining so many horses, and cost of repairing roads for such considerable traffic, occasioned the introduction, about the period above mentioned, of waggons-roads or wooden rail-ways, on which waggons of a large size, with wheels of a particular form to suit the rails, were used, and which one horse could draw, owing to the regular and easy descent with which the rails were laid. It was not until the year 1738 that this important improvement was introduced at the White-haven collieries on the western coast, and it is truly surprising to observe how slow the introduction of them was in other parts.

Way-leaves or slips of ground were let out and hired on leaves, or purchased by the different coal-owners of the several proprietors of lands, lying between their pits and the river, and this, not by the nearest route, but in such a direction as gave the most easy and regular descent. The inequalities of this fip of ground were levelled as a road, hollows were filled up, and huddled hills lowered, when sleepers or large logs of wood were laid across the same, their tops being all of a regular height; upon these, two rails, generally of beech wood, were laid parallel to each other, their ends abutting close to each other, and were firmly pegged down to the sleepers. The tops of the rails were planed smooth and round; the wheels of the waggons were low and of call-iron, or of solid wood with iron rims, which were not flat on the edge, but hollow to receive and move on the wooden rails; the inside edge of each wheel projecting near two inches, in order to confine the wheels effectually to the rails, and prevent the waggons from being drawn off the road. From all considerable works, there was a main way made for the passage of loaded coal-waggons as above; and another, or by-way by its side, for the return of the empty waggons. When coal-mines had been worked into deeper ground, and pits or shafts were opened below Tynedale, the rail-ways therefrom were conducted to the top of a range or wooden building called a flat, on the wharf or key where the ships lay; and the coal-waggons, a description of which we have already given, were either emptied at once through the spouts into the hold of the ship, or deploited in the warehouse below in store for future ships. One indifferent horse could in general draw three tons of coals from the pits to the river side upon these wooden rail-ways; which mode of conveyance became further improved by the introduction of plates of wrought iron nailed on to the rails for the waggons-wheels to run upon. Attempts were made in different parts, to introduce call-iron instead of wooden rails; but owing to the brittleness of the material, and the great weight of the waggons in use, they did not in general succeed.

About the year 1768, Mr. Richard Lovell Edgeworth contrived a remedy for the principal objection to coal iron-rails, in making use of two or three smaller waggons linked together, instead of one large one; a model of three of these he presented to the Society of Arts in the Adelphi, London, and was honoured by the premium of their gold medal. In the year 1788, the same gentleman, on some temporary wooden rail-ways for manuring of land, made several experiments, in the presence of different Mechanics, on the application of friction-rollers for diminishing the friction of waggons axles. The rail-ways hitherto constructed were private property, or for the accommodation of particular mines or works, and it was not, we believe, until about the year 1794, that Mr. Samuel Honfrey, and others, obtained an act of parliament for constructing an iron tram-road, tram-road, or rail-way, between Cardiff and Merthyr Tydrell in South Wales, that should be free for any persons to use, with drams or trams of the specified construction, on paying certain tonnage or rates per mile to the proprietors. Soon after the year 1797, iron rail-ways began to be constructed as branches to the canals of Shropshire; and, in other parts of England, Mr. Benjamin Outram, an engineer, began to construct the same upon improved principles, of which Dr. Anderdon has given an account in his Recreations, vol. iv. pages 169 and 473.

On the 25th of June 1769, the house of commons made a standing order for extending to all bills for making any ways or roads, commonly called rail-ways, or tram-roads, all the orders (of May 7, 1794) relating to the introduction of canal bills. One principal difficulty, the provision of water, does not here occur, unless for docks or basins, which are not frequently necessary, at the termination of a rail-way, at a river, or existing canal; and, as the owners of streams of water are not under dread of losing the fame by the passage of
of a rail-way near them, and the same is applicable to much more easily to the uses of the owners and occupiers, than a canals is, less difficulties will attend the obtaining of general power for making side or collateral branches, at any future period; and of connecting the same with different rivers, canals, or rail-ways, making the parties a compensation in tolls or otherwise, if such connection shall appear to draw off or lessen the trade upon any part of their line of communication, as often happens; and such ought always to be carefully investigated, and liberally embalmed by the engineer, and the company be advised to act accordingly.

In surveying a line of country for a rail-way, principles somewhat different from those which apply to a canal, are to be kept in view; in the latter case, exact or dead levels are traced out, and the cafe of towing or dragging boats thereon is nearly the same in going one way as in returning the other, whether laden or not; for the ascent or descent of the locks or planes are there overcome by a different power than that applied to towing upon the levels; in a rail-way the case is different, the horse which in going one way draws a heavy load down a slight descent, has to return again with the empty waggons, or a lighter load, up the same ascent. It will therefore be necessary, as a preliminary step to setting out a rail-way, to calculate as accurately as possible the quantity of lading which will at the first or any future period be to pass each way upon the line, or on any particular parts of it, because on this will depend, in a great measure, the slope that it ought to have, and consequently the ground which the rail-way line ought to occupy. If it should appear, on an accurate calculation, that the same weight of lading may be expected to pass one way as the other, or that the same will preponderate at some periods one way, and at others the other way, the rail-way must in this case be lifted in levels or very nearly so, and the unavoidable ascents and descents must be made by inclined planes, as before mentioned; on which either a greater number of horses must be stationed to draw waggons up, and in letting down, their wheels must some of them be flapped; or loaded descending waggons must draw up the others; the descent of a weight or tub full of water in a shaft must draw up a waggons, or more than one; or, a steam-engine, horse-gin, or walking-wheel, must be used as a moving power, with fly or brake regulators of the motion, as we have before mentioned. If the trade will always preponderate one way, as it generally will in the descent from mines to navigations, and the ground will admit of the same, the regular inclination of the rail-way ought to be such, that a horse can draw the usual lading down with the same cafe as it can return with the waggons when emptied, or with a partial lading, in case of there being a small ascending trade. If the slope of the ground shall be found greater than to suit the above calculation, the rail-way ought to be set out for as great lengths together as is practicable, with the proper slope, and then to set out an inclined plane, as before mentioned. It ought to be well considered, where a rail-way or a branch from the same appears likely to have a descending trade at present, whether, at a future period, by extending the same forwards to any town or manufactury, or by other change of circumstances, the ascending trade is likely to be materially increased, in proportion to the descending; because in such cafe, the line would require to be altered in its slope, and moved to a new place, or it must continue to be worked to a considerable disadvantage by the horses having to travel down the line unemployed, to fetch up a portion of the loaded waggons. It will readily be perceived, that the adoption of the best line, of which the circumstances of the trade and nature of the ground is susceptible, is a task requiring a degree of skill and patient research, not at all inferior to any thing required in the setting out of a canal, and it can hardly be necessary to point out the necessity of employing the most competent engineer, and allowing him proper time and assistance, in order to get the most eligible line marked out. A rough sketch of the different routes which appear eligible for a rail-way made by levelling with a spirit level, will be very useful in the first instance; from which, and, a view of the ground, the engineer will be able to determine nearly the place and extent of the inclined planes, or steeper parts of the rail-way which will be necessary; these last being always made as short as the nature of the ground and circumstances will admit. These being settled, the line of the intended rail-way must be traced on the ground, beginning at the highest point, and stretching a chain on the ground, one end being held at the point of departure, the other must be turned round upon the face of the descent, until a point marked by this end is found, which is one link or something nearer or less, according as the slope is to be) lower than the upper end; the chain being now moved forwards, till the hinder end rests on the point last determined, the other end is to be moved, accompanied by the levelling target, until a new point is found, one link lower than the last, and so on; by which, a line having the regular descent of one link in a chain, will be traced out on the ground, until the place of an intended inclined plane is reached. The flake which are put in to mark the place of each successive flake will, as in the case formerly mentioned, of setting out a level for a canal, be found very crooked in many places; and it will be necessary for the engineer to take out a new line, after a most careful view and consideration of the ground, as the approximate line for the centre of the rail-way; which must be without any sudden bends, that would occasion friction of the wheels against the sides or ribs of the rails. Single rail-ways will generally require about four yards wide, and double ones about six yards wide (exclusive of the necessary space for drains and fences), and this width will require to be levelled like a road or plane: it will therefore be proper to set out the line, that the quantity of flake which is to be lowered in one place shall always, with the least distance of throwing or bringing, make up other places which are too low. Where sudden valleys are to be crossed, it will be necessary to conduct the line, so as to cut into the hill at each side of it, to find the flake as readily as possible for forming the embankment: it will also be necessary to search carefully for gravel or stones fit for making the road between and under the rails; and if such can be got in the line, it may be a considerable saving of labour and of damage to the land, as well as a source of future advantage to the concern, to cut pretty deep into such materials, as we have before suggested and explained on the setting out of a canal; which the reader, who wishes to understand this subject, would do well to consult. A line of flake, exactly at a chain (100 links) apart, should be put into the line last flaked out, and drove successively into the ground, beginning with the highest, so that the head of each may be very exactly one link (that being the fall we have assumed) below the level of the last; of course these will either stand above the ground, or be drove in the bottom of a hole, according as the ground wants raising or sinking, and will enable the engineer, on a review of the line, to judge more correctly, or to calculate where necessary, whether the line is set out in the right place to be formed at the least expense of labour, and with the least damage to the land; and when this is
found to be the case, the necessary width of land can be determined on, and the same surveyed and described by the surveyor, for the purposes of depositing the necessary plans with the clerk of the peace and with parliament. The different regular flanks or parts of the road being determined in this manner, the deeper flanks or planes that may be necessary to join them, must next be cut out and determined, by taking the whole or difference of the levels of the two ends, and dividing the same by the number of chains that the plane is to be long, for obtaining the fall which is to be allowed between each pair of flanks, instead of a link as before affirmed. In letting out a single railway, it will be necessary, at proper intervals, to allow the width of land proper for a double railway, for a short space, in order to form passing-places for the waggons that are coming different ways. As part of the railway will in most cases be conducted along the side of a hill, or on side-lying ground, it will be necessary to consider the same in calculating to dispose of the flanks, and for the necessary ditches and drains for intercepting the springs and surface water in every instance, so that the ground of the railway may at all times remain dry. The draining, fencing, and bridges, will require to be done on the principles which we shall further on explain respecting canals; and the embankments, culverts, or tunnels, which may be necessary for preferring the proper slope in all places, are also to be done on similar principles to those of canals before treated of. It may be proper here to mention, that Mr. Robert Fulton, in his Treatise before quoted, pages 82, &c. has suggested and described different kinds of cast iron bridges for passing railways over valleys, either level across, one down a slope, and up the other of the valley, or rising obliquely up; in the first and last of which he proposc memorable to avoid any solid platform or top for carrying the horse path, and to tow or drag the waggons over this open railway, by an endless rope or chain, passing over a pulley at each end, which can be let in motion by a windlass, a descending weight, or other power. On the approach to a river or yard, where considerable quantities of coals or other minerals are to be discharged, it will be proper to keep the railway upon a high level, by embankment, or on arches, or on a stage of timber, that the waggons may be discharged from the top of a flails or stage into ships or boats, or into carts and waggons, without being moved by manual labour. Rivers, brooks, or hollow roads, must be crossed on bridges whose tops are formed to the regular slope of the plane; and where roads cross the intended railway, they must either be raised so as to be carried over, or sunk so as to pass under the same; or be made up to the same height; and the rails must, in that part, have ribs of less height and greater strength, and the whole must be so firmly embedded in masonry, that the heaviest carriages, in crossing, cannot damage it: an instance of which may be seen in Wandsworth town street, and at several other places on the Surrey iron rail way.

A considerable facility is occasioned in the constructing of Railways, after the plan of the whole is settled, the act passed, the land purchased, the work set out, and the ground levelled and properly settled, by being able to begin in any part where flone, gravel, and other materials that are wanted are to be most conveniently had, and to work from these places without the heavy expense of common carriage, except for the iron rails or blocks of flone for sleepers, if such are not found upon the line.

We will therefore suppose the work to begin at some point where the line intersects a rubble rock or a bed of good gravel, and the surface of the road is to be covered therewith for about a foot thick, and the same is to be nicely levelled, and any great or rough and out fixed stones should be carefully picked or raked off, that the whole may the sooner settle down and become one compact mass; these large stones may be thrown forward upon the uniformed part of the road, to be covered with smaller and better gravel. This covering of rubble or gravel must be nicely sacked and levelled and bed or rammed down, to make it as compact and solid as possible. A great quantity of blocks of hard and durable flone must be got in readiness, from 6 to 12 inches thick, and weighing 150 to 200 lb. each; the flanks of them is not very material, so that the bottom is liable to be firmly placed: under the stone, the top is to be chiselled to a level to receive the ends of the iron rails; in the centre of this flat part a hole must be drilled about 1 1/2 inch diameter, and 6 inches deep. Two flat and straight gauges of iron must be provided with pins riveted into their ends to suit the holes in the stones; the pins on these gauges should be at the exact distance on one of them to suit the length of the iron, generally three feet, and the other to suit the distance of the rails apart or breadth of the road, usually about 4 feet. One of the flones being laid in the proper place for the beginning of one side of the railway, and nicely bedded and rammed down upon the gravel, another flone is to be laid at 4 feet distance for the other side of the road, and for bringing them to the exact distance and level, the pins of the breadth-gauge are to be entered into the holes in each flone, and a common or mason's level is to be applied to the top of the gauge; if the flone laid is found too high or two low, it must be lifted up again, and gravel must be raked out, or more fine and good gravel sprinkled in and rammed down, until the right height is obtained; the flone is then to be laid on again, and brought to its proper place by means of the gauge and level; care is to be taken that the top of the flone is level, so that the flat ends of the gauge bed exactly and evenly on the flone all around the hole; and if this is not the case the chisel must be used to take down any irregularity and produce this bedeling of the gauge bar. A third flone is then to be laid on one side and the length-gauge pins entered into the holes, by which the exact and proper distance of the flones will be ascertained, and for trying the truth of this flone as to height, a level is to be used, in which a line is very carefully drawn by the engineer, making the exact angle with the perpendicular line that the railway is to make with the horizon; this being applied upon the length-gauge will show whether the flone laid requires more gravel under it, or any to be taken out, observing always to level the gravel carefully and to ram it down, and also to ram the flone down upon the gravel, before each ultimate trial of its proper position as to level, its distance measured by the gauge from the other flone, and its range by a line stretched in direction of the intended railway. With these precautions the flones are to be successively laid, and gravel of the best quality, and without any large flones, is to be laid in, to fill up the spaces between them; and none on the outside of the flones, the better to secure them in their places; and when a certain length is done, as no mortar or other soft material is used which requires time to dry or set, the work is ready to receive the rails, and will be then immediately fit for use, to carry forward the gravel, flones, and other materials for the work as it proceeds. We have before mentioned that the ground work should be settled; and for this purpose the levelling of the road should be performed early in the winter, and the rains and frost will effectually settle it, by the time the work gets dry enough in the ensuing spring; before
before which, the work should be carefully gone over again, to level and fill up any parts which have settled more than was expected and allowed for.

The *café Iron Rails*, in the earlier use of them, as on the extension of the Caledon branch of the *Trent and Mersey* Canal, to Mr. Gilbert's lime-works, 4 miles in length, (which was in use long before 1794,) were fastened down upon longitudinal rails of wood, which lay across several wooden sleepers, embedded in the gravel, as we have described above; these rails were three feet long, and had two holes, at 18 inches apart, to receive the wooden pins which fastened them down, or rather confined them in their places, on the wooden rails: (see fig. 31, *Canals, Make it.*) At one end there was a triangular projection, and at the other a similar notch which fitted into each other; a rib stood up along one side, to confine the waggons wheels to the track; and opposite the holes, the rail which was about 1½ inch thick and weighed about 42 lb. was made wider to strengthen that part; yet, with this precaution, such rails were very liable to break in two at the pin holes, as well as to loose their connecting triangular piece; the rib also was very liable, by the wheels or other things striking against it, to get broken off near the ends, and the waggons were not confined from running off the road in such places. The rails of the *Surry Rail-way* are represented in figs. 32 and 33, and are, we believe, of the most improved contraction; they have their ends reuting on separate blocks of stone embedded in the gravel as above described, and, instead of pin-holes through them, each rail has a similar rectangular notch in its end, which, when two of them are laid close together, forms a counter-work-hole for a square and headless spike of iron, that is to fasten the ends of both the rails. These rails consist of a rectangular plate of cast iron, 3 feet 2 inches long, 5 inches broad, and 1 thick; a piece of metal about half an inch thick is added in the casting, to increase the thickness at each end for 5 or 6 inches in length, in which to fit on the stone and receive the spike; a rib is cast on to each edge of the rail, one of them above, and serves to guide and confine the waggons wheels; the other below for adding strength; these ribs which are about three-fourths of an inch thick form by their top the segment of a large circle, being about ½ inches high in the middle, and about ½ inch at the ends, by which these ribs are calculated to give the greatest strength to the rail in the middle, where it has no bearing, and to make them not to be easily snapped or broken off, as mentioned of those rails above, whose ribs are of an equal height throughout; small circular projections of metal are cast on to the width of the rail near each end, and the fame are carefully bedded upon the stone, for preventing the rail from being overturned laterally, by the action of the wheels against the rib. For crossing of common roads, the rib, (see fig. 34,) is made only an inch high throughout, and near an inch thick, and its edges are well rounded off. In these situations, a few rows of pavement, of good square stones, such as the carriage way of the streets of London are now paved with, are kept nearly or quite as high as the ribs of the rails, by which the heaviest waggons, carts, and coaches pass over them almost without any possible jolt. Crossing-rails are used at every passing-place, or point where waggons are to pass out of one track of rails into another, which are very numerous in the company's yard, and by the side of their basin or dock for barges, in order that empty waggons or those loaded may be readily pushed into one of the tracks further off the wharf, to let other full or empty ones advance, on their proper track, to the sides of the barges. A B C D, fig. 35, represents one kind of crossing-rails, them in connection with four common rails, parts of which are represented by E, F, G, and H; a wedge or tongue of wrought iron, I, is movable round a pin, and is represented in the figure, as placed against the flub K, so that the track from G to F is clear for one of the wheels of a waggons; and by moving the wedge I till it rests against the flub L, the track from H to E would be clear; before the waggons can pass in the directions above-mentioned, the wedge will often want moving by hand to the proper position, but in going in the opposite direction from E to H, or from F to G, the action of the wheel against the wedge will always move it into the right position; there is a circular guard or flub cast on to the rail behind the joint of the wedge for preventing the wheels from striking directly against the end of the wedge.

The method in which the rails are fastened to the blocks of stone on which they rest, is by an octagonal peg or tramun of good found dry oak, fitted to the hole in the stone, so as to drive easily into the same, otherwise its felting by wet and the driving of the spike might split the stone, this plug of wood is not long enough to reach the bottom of the hole, and is sawed off even with the top of the hole; a hole is then bored through this plug of wood, and an iron spike with a flat point, and a head just fitted to the counter-bank notch in the ends of two rails, when applied endways together, is drove; by which the rails are sufficiently confined, and yet in case of any wear or settling of the stone, so that the rail gets a little loose, it is capable of moving that small space without breaking out the sides of the pin-hole in the rails. It will be proper, always to drill a small hole from the bottom of the plug-hole, quite through the stone, for the rain water to sink away into the gravel, otherwise the freezing of water in the holes would often burst the stones. Care must be taken from time to time, to keep the tread or surface of the rails clear of dirt or stones, which last would slip the waggons, and perhaps break the rails; and too much pains can hardly be taken by raking and fortifying the gravel, for the finis or top of the road, and rolling or ramming of it down, to settle the same into a compact and hard road as soon as possible, having no loose stones, which the horses are always kicking on to the rails, and while this is the case, the man who attends the waggons should always go before his horses, and look carefully to the rails, and remove any stones that may have got upon them. The waggons in most general use on the *Surry Iron Rail-way* weigh, including their loadings, about 3½ tons, the wheels are two feet five inches high, of cast iron, with 12 spokes, which get wider as they approach the hub, which is eight inches long to receive a small wrought iron axle; the fellies or rims of the wheels are two inches broad, and nearly as much thick, and the sharp angles are rounded off, so that these wheels are capable of being used without damage on any hard common road; a very principal advantage attending the modern use of rail-ways. The axes of the wheels are fixed at two feet seven inches distance; the bodies of these waggons are seven feet nine inches long, four feet five inches wide, and two feet four inches high; these are used for bringing down chalk from the *Surry Hills* to make lime, carrying back manures, &c. The founders, and others upon the line, have trucks or waggons of different kinds to suit the nature of their goods; the only apparent limitations being in the width of the wheels and carriages, the length of their axles, and weight of laden goods.

For the more ready emptying or flushing the contents of the waggons into barges lying in the dock, a strong flage is erected on the wall, which projects over the water, and in order
order to turn waggons short round and back them on to
this stage, the rail-way passes over a large circular plate of
cast iron, which is suspended on a pin beneath its centre;
there being a circular ring under its circumference, which
moves round freely, with a considerable number of small
wheels or rollers, whose axles are fixed therein, (see figs. 45
and 47, Plate VII.) upon another circular iron plate firmly
fixed below; by this arrangement, it happens, that as soon as
the fore and hind wheels of the waggons are advanced on to
this circular plate, a very small force applied to the waggons
will turn it a quarter round, along with the plate and rails on
which it rests; the waggons are then run backwards off the plate, on
the flange before mentioned, and its contents are shot into the barge
below; it is then returned upon the plate, and the same is
turned round until the rails thereon match the track, and
the waggons can then move forwards, to make way for anoth-
er loaded waggons, to be emptied in like manner, or it can
be shoved backwards to a croosing-place, as may be required.
A ton weight or more in a waggons can easily be shoved along
by a man, as he does a wheel-barrow. Rail-way branches
are capable of being conducted into every foundery, or other
great work near the line, to terminate under their large
cranes for hoisting goods, so that heavy articles can be loaded
at once on to trucks for the rail-way. The branches of a
rail-way admit of being multiplied almost without limit;
farmers and others who have but an occasional trade, may
have their own waggons to be kept locked, and left for them
by the side of the rail-way, one or more at a time, from the
gang that is palling along the line. About November 1800,
294, the adoption of a double rail-way for heavy carriages
between London and Bath; and about March 1802, Mr.
vol. i. p. 221, the experiment to be tried, on one of the great
roads, for ten miles or more out of London, of a rail-way
with four tracks, one for flow and another for fast travelling
carriages going each way, in order to avoid meeting or de-
lay; these he propos'd to adapt to chaises and stage coaches,
by means of low cradles or platforms, with wheels adapted
to the rails, on to which a coach, coach, or other carriage,
could be drawn, and there confined, in order to be drawn
along the rail-way; and which cradles the coaches might
leave at any defined point, to be drawn on the common road,
which he propos'd to have by the side of his rail-ways. Dr.
Anderfen, in the volume above quoted, recommends rail-
ways to be made from the docks in the Isle of Dogs, to dif-
fent points in the environs of London; and he propозes
the bodies of these rail-way waggons to be moveable, and to
be hoisted off by cranes with their lading in them, and be
placed on other, and larger wheels, with shafts adapted to
the fleets; which, after delivering their lading, would re-
turn, perhaps laden with other goods, to the cranes to be
replaced on the rail-way wheels. In vol. v. p. 291, of the
doctor's work, Mr. is recommended to use waggons on the
proposed rail-way with wheels large enough, and of a pro-
per construction, to be used in the fleet also. Wherever any
considerable work is to be done, as in the excavation of the
London-Docks, it has been found to answer, to lay down
temporary rail-ways; and such as admit of being moved as
parts of the works become complete. For the use of mines,
this facility of removal is often of conuenience, as the veins
or pits wear out.

Doctor Anderfen observes, that 20 tons, in a barge upon
a canal, will be drawn with ease by one horse, travelling at
the usual rate that waggons move; and that on a rail-way
the same horse would, under favourable circumstances, trans-
port the same quantity of goods in a given time; but Mr.
Fulton says, that five tons to a horse is the average work on
rail-ways, defecding at the rate of three miles per hour;
or one ton, upwards, with the same speed. Mr. Telford
observes, that on a rail-way well constructed, and laid with
a declivity of 55 feet in a mile, one horse will readily take
down waggons containing 12 to 15 tons, and bring back
the same waggons with four tons in them. Mr. Joseph
Wilkie in 1798 related, that a horse of the value of 20l. drew
down the declivity of an iron road 1/2 of an inch at a yard,
21 carrigines or waggons, laden with coals and timber, weigh-
ing 36 tons, overcoming the win inertile repeatedly with ease.
The same horse, up this declivity, drew five tons with ease.
On another part of the road, where the acclivity was 1/2 of
an inch at a yard, the same horse drew down three tons;
but it was necessary to slipper or lock the wheels here, to
prevent his being overpowered by the defecding weight.
On a different rail-way, one horse, value 30l. drew 21 wagg-
ons of 5 cwt. each, with their loading of coals, amounted to
47 tons 5 cwt. down the declivity of 1/2 of an
inch in a yard; and up the same place, he afterwards drew
seven tons; the cwt. in all these experiments of Mr. W.'s
being 120b. In the summer of 1805 a trial was made on the
Barry rail-way by Mr. Baskes, wherein a horse, taken
indefinitely out of a team, drew 16 waggons, weighing
upwards of 55 tons, for more than six miles along a level
or very slightly declining part of the rail-way.

Dr. Anderfen has calculated the expense of carrying goods
in common waggons, or turnpike roads, a distance of eight
miles, at 84d. per ton, and of carriage, the same distance,
on a rail-way, at 4d. per ton, or only one tenth part of the
former. Recreations iv. 208.

For steep descents, fedges, or flippers of iron, must be
provided, similar to those in common ufe with road-waggons,
which can be placed under the wheels of the rail-way wag-
gons, and hooked to the side of the waggons by a short chain,
in order to caufe the wheel or wheels to ride upon the rails,
whereby the tendency to defecd may be checked.

Mr. William Chapman has, in his Observations, p. 42
and 54, recommended the ufe of waggons, that are to run on
to the rail-ways that are to be prepared in the bottom of a
flat-bottomed boat, instead of unloading the contents of the
waggons into the boat; and when this boat with its waggons
has arrived at its destination, the waggons are to be run out
upon other rail-ways, to proceed forwards by land if necessary.

Mr. Carr, we are told, has introduced in the mines of
Shropshire, and other places, a flight kind of iron rail-ways,
called train-roads, for the ufe of very small waggons in their
under-ground works.

Mr. R. L. Edgeworth has suggested (Nicholson's Journ.
8vo. i. 223.) the ufe of light circular chains running
upon rollers, which are to be put in motion by small Steam
engines placed at considerable distances; to these chains he
proposes carriages to be attached, for droging them along
upon rail-ways instead of iding horses. Since Steam-engines
have been brought into ufe, to work by the expansive force of
Steam, and requiring no water for condensation, a success-
fual trial of applying them to moving the trains on a tram-
road has been made, viz. in February 1804, on the Cardiff
and Merthyr rail-way, where 10 tons of iron (long weight)
loaded on tram-waggons, with the additional weight of
about 70 perons for great part of the way, we're drawn for
nine miles upon the tram-road, at the rate of near five miles
per hour, by the ufe of one of these Steam-engines fixed on
its own waggons made by Mr. Homfray, (for which engines
Mr. Trewthick had previously taken out a patent, though it
C A N A L.

is perhaps an old invention) no supply of water for the boiler being found necessary in this distance.

The coil of a single rail-way, with crossing-places, for a defying trade, was estimated by Mr. Fulton, who wrote in 1795, at about 1000l. per mile. Mr. Wilks, in 1799, flatted, that the expense of completing a mile of single rail-way, where materials of all descriptions be convenient, and where the land lies tolerably favourable for the defect, would be about 300l. or 1000l. fenced, &c. exclusive of bridges, culverts, or any extra expense in deep cutting or high embankments.

Dr. Anderson mentions, in 1800, the sum of 1000l. per mile as the probable coil of a double rail-way in the most favourable situations, and of very flint ones in the vicinity of London, where labour is dear, not less than 300l. per mile; and Mr. Wilks says, that wherever the quantity of goods to be conveyed on a rail-way, having a descent of not more than 1\(^{1/2}\) an inch in a yard, amounts to two-thirds of downward, and one-third of upwards loading; it is a doubt, if it will not, in that case, be a cheaper conveyance than by a canal, besides the rail-way being more certain, where dispatch is necessary, on account of frost and dry seasons.

Another advantage attending rail-ways is, the greater certainty of the estimates for the same, when made with care and judgment, and the facility with which the whole work may, in general, be contrived for, to be completed at a flatted time. The principal rail-ways which have been executed, are the Cardiff and Merthyr, the Cannenboile, the Sirhowy, the Surrey, and the Swanysey and Ogysthurn; and such branches will be found to the Abbey de la Zouch, Cowford, Derby, Ercweath, Lancaster, Leeds and Liverpool, Peak Forest, Shropshire, Somerset Coal, Trent and Mersey, and several others, to which number almost every day is adding.

The constructing of Bridges for crossing canals and navigable rivers, often occasion a very tedious part of their whole expense, and this circumstance occasioned the attempt in some of the earlier canals, to subdivide paves \\

ford in many instances; Mr. James Brindley proposed these at first, for some places on the Trent and Mersey canal, and on the canal which Mr. Davis Dutch construction to the Tyrone colliers in Ireland there, were subituated in place of bridges.

Mr. Fulton has recommended the general adoption of fords on his small canals, but Mr. Chapman observes, that the water in such canals must not exceed two feet nine inches in depth, as otherwise hay, sheaves of corn, &c. in common carts would be liable to get wet in crossing. On the China canals we read, that there are elliptical arches of stone over their canals, the longer axis being vertical, and high enough for the masts of their vessels; these bridges being only intended for foot passengers, and are ascended and descended by leps. On our canals, bridges for foot passengers only are generally constructed of wood, and are mounted by leps, as at Paddington on the Grand Junction. In all large and important bridges the arches should undoubtedly be so formed that the materials thereof are in equilibrium, independent of the cement that may be used between the flones or bricks; the principles of which arches will be found in our articles Arch and Bridge: but for the common bridges for crossing of canals, which are wanted in such great numbers, flat semi-elliptical arches have been, in general, adopted, on account of such giving width for the canal and towing-path underneath, without raising the top any unnecessary height, which fo enhances the expense of landing up, or forming the slopes to the bridge. From the habits which necessity has in a great measure introduced with canal bridge-makers, of using only the best materials, performing the work with great care, and not fliking their centres too soon, such bridges are found to stand tolerably well, although very far removed from an equilibration figure; yet infusions are not wanting on most canals of their setting, and even falling down in some cases. A kind of brick bridges have long since come into almost general use on canals, of which we have given a plan, section, and perspective view. See Canals, Plate IV. figs. 40, 41, and 42. The form of these bridges is well calculated for saving of materials, and giving strength at the same time, the whole of the walls being more or less battering, and the side walls are playing outwards at their ends, to make the entrance on to the bridge the more easy, by which the side walls are rendered curving inwards in every part. In the building of bridges the utmost care must be taken to sink the foundations down to found fluff, or to drive piles on which to begin the work; it is a good practice to have wedge like or arching bricks made, on purpose to use after a certain number of courses of key bricks, or those forming the slits of the arch, and to introduce oblique courses of bricks for the more effectual tying of the work together, as we have mentioned in speaking of tunnels. Large bricks made of the bold earth and well burnt, should also be used, placed on edge upon the top of the walls of the bridges, as a coping, unless very good stone is near at hand, the top corners of the coping bricks or flones should be carefully rounded off in the making, in order that the same may present as few angles as possible for the weather or the traffic to catch hold of.

We have before mentioned the care which ought to be taken in every instance, to find fluff with the least possible expense of moving it, for landing up the bridges from these having, in some instances, been left too steep for the convenient and safe use of the public; it has not been uncommon, in later acts, to make provisions on these subjects; on the Grand Western it is enacted, that the acents to the bridges shall not exceed 2\(\frac{1}{4}\) inches in a yard, and on the Wilts and Berks this rate is limited to 3 inches in the yard at the most. The width of the carriage-way, on the bridge, in the narrowest places, is also fixed in some acts, whereas we have seen 12 feet mentioned as a limit in some cases. We have before observed, that the canal ought, if practicable, to be conducted into deepsea cutting, wherever a brick or stone bridge is to be erected, in order that the fluff may be thereby procured, for landing up each side of the bridge, and that the abutments of the bridge may be the more solid, and the foundations more likely to reach found fluff, without an extra depth of walling, or the necessity of piling for such purpose. On this account it is, that the tail of a lock generally presents a proper place for a bridge, and where the walling, which must have been made for wings, below the lower lock-gates, is avoided, or turned to account in the bridge. In places, where from the great traffic that is to be expected, or other cause, a towing-path will be wanted on both sides of the canal, the bridges should be made on a scale large enough to admit of a towing-path on both sides under the bridge, as in the two or three bridges nearest to Paddington balloon, on the Grand Junction.

For occupation, or accommodation bridges, and even on some public roads, as on the Skney canal, and others, a kind of lying or swing bridge has in general been adopted, of which some mention has been made under our article Bridge. See fig. 42 Canals, Plate VII. A flat platform of wood strongly framed together, covered with planks, and having side rails, is prepared, wide enough for the purposes of a bridge, and about half as long again as the canal is wide, in the contracted walled part intended for the swing bridge. One end of the platform for this bridge is framed as light as can be consistent with strength, and the other very heavy, with provision for flowing large flores.
stones or pigs of cast iron therein, so that the same will rest in equilibrium on a point at about one-fifth of its length from the heavy end; under this point, a large circular plate or ring of cast iron is fixed, having a smooth circular hollow sunk therein. An exactly similar plate is embedded, and firmly fixed on the solid wall at the side of the canal, except that this half has a strong iron centre or point flaring up, to enter a hole sunk in the upper plate to receive it. On this pin the bridge is suspended in equilibrium, and in order that no impediment may arise to turning the bridge round, when its balance is by any circumstance destroyed, a number of smooth cast iron balls, of two and a half or three inches diameter, are placed in the circular groove or hollow ring in the two plates, which act effectively as rollers for lessening the friction between the circular plates, in turning the bridge on and off the canal; or, a ring containing several rollers (figs. 45 and 47), is substituted instead of the iron balls above-mentioned, between the lower and upper plates (figs. 44 and 46). A recess is formed on the bank just to receive the bridge, when a boat is to pass, and when the bridge is turned across the canal, each end of the bridge (which ends are rounded into circular arcs, struck from the centre pin), slides on to a similar circular recess in the road, with a firm bearing at a very small distance below the ends of the bridge, when it is in equilibrium, on the centre pin and balls or rollers; by this arrangement it happens, that the heaviest loaded carriage crossing the bridge, is not able to depress either end of the bridge on which it passes, in any sensible degree. The engineer should carefully avoid the use of these swinging, or indeed of any moveable bridge, where the towing-path is to change from one side of the canal to the other, because the bridge must remain across the canal until a barge in passing, is got near enough for the towing-horse to cross over the bridge, and the bridge must then be turned off the canal before the boat can pass, and it continually happens, unless the towing-line is of great length, or is cast off at some distance before the boat arrives at the bridge, or the greatest dexterity is used, that the boat strikes the bridge before it can be turned off the canal into its recess; where several boats are closely following each other, these difficulties are much increased, and great delay must take place, or the bridge will soon be knocked to pieces. Swivel or turn bridges have sometimes been erected on the towing-path side, but they form there a most serious obstacle to the towing of boats; and on that account are generally placed on the off bank, and as no methods have hitherto been brought into general use, of turning them or shutting such bridges for persons to pass over them, except the persons, or some others, are at the time, on the same bank of the canal on which the bridge stands, in order to turn it over the canal; this has occasioned the necessity of clauses in every act, or set of bye-laws, requiring boatmen always to flush to every swing-bridge, or drawbridge, as soon as their boat has passed. The great loss of time and labour in thus continually turning the bridges on and off, the wear that such continual use occasions, and the frequent damage which such bridges sustain from boats striking against them, if, by the lesser delay of the boat-men or accident, they are not turned off before the boat gets up; have occasioned our thinking a good deal on the subject, in hopes of devising some method of turning the bridge on when wanted, from either side of the canal; because such a contrivance would authorize the alteration of the present regulations, and require each swing-bridge to be left open, and out of the way of the navigation, except during the time that it was actually in use, by persons or carriages passing over it: another material evil would thereby also be remedied, that is, the difficulty which now exists of preventing the farmers' cattle, in the fields on the off side of the canal, from passing over the bridges, and creeping along the towing-path, without an expensive circle of fencing and a gate to separate the bridges from the fields, for no gate or obstacle can conveniently be made on the towing-path side to obstruct their passage. Chains and pulleys under the canal, and motion conveyed upon Brunel's patent principle, in pipes under the same, were considered among others, as the means of turning the bridge on, when wanted; but, our speculations heretofore were, happily, at the moment of writing this (October 1835) interrupted by the information of a method, which was successfully brought into practice very lately, by Mr. Benjamin Bevan, the engineer upon the middle district of the Grand Junction canal, viz. near the steam-engine on the Wendover branch, where a swinging-bridge of the common construction, with a railing or fence on each side of it, has an addition made to it, on the side that is next the canal when the bridge is open, or in its recesses, at about three-fourths of its length, from the centre pin on which the whole turns; this consists of a job like that of a crane, or the bars that are sometimes used for flpping carriages at the ends of ftreets; an upright piece of wood is hung by two hooks and thimbles, like those of a common gate, to the standard or upright on the side of the bridge; to the top of this a rail of 4 or 5 feet long is fixed horizontally, supported by a brace underneath, from near the bottom of the upright piece; on the top of the horizontal piece are two strong staples fixed, adapted to receive the thickest end of a very slender and light pole, such as are used for the handles of hay-riakes, but they must be longer, and rather larger for wide canals; a nail driven in between the staples through the pole fixes the same, and makes it form a light and easily removable continuation of the top rail quite across the canal, so that a person, wanting to cross the bridge from the towing-path, can take hold of the end of the pole and pull by the same, and thereby turn the bridge over the canal; or, if a person has crossed the bridge towards the towing-path, he can with equal facility take hold of the end of the pole and shove the bridge round to the other side. The hinges of the jib that carry the pole are so adapted, that the pole has a tendency to hang directly across the canal, to the most convenient point for being taken hold of; but, at the same time it is with the least force turned round on its hinges until it is brought along-side of the bridge, and quite out of the way of boats that are passing. This very simple and cheap apparatus, we are told, answers effectually; no impediment is offered to the horse or towing-line; but when a boat arrives, whatever part thereof strikes against the pole, it recedes and suffers the boat to pass, and then by its own weight resumes its situation across the canal, ready for turning the bridge. The solid part of the jib is not made long enough to be liable to be struck by the boat, or a man flanding thereon; and poles in plenty, of the proper size and length, can be in readiness, for replacing in a minute any pole which is worn out or broken by accident.

Bridges which have no towing path under them, present a great obstacle to towing, because the line must in those cases be cast off from the barge; except, occupation bridges, like the wooden one at Rotterdam in Holland, could be introduced, where the bridge, we are told, consists of two separate segments, each supported firmly on its own bank, and leaving a flat quite across the bridge for the towing-mast to pass through, and thus they avoid casting off of the line: this flat need not be so wide but that foot passengers can with ease and safety step across it; and, on the passage of horses or carriages, a moveable flap turning quite flat back upon hinges, might be turned over to complete the road. Where
Where fixed bridges of great width and strength are required, and need but seldom to be turned off, as for admitting ships at high water to the HoA India and London Docks, double wooden or cast iron fixed bridges are in use, with a movable frame under each part, constituting parts of the ribs of the bridge, which frames turn on a hinge or joint, and are taken up or supported by a screw at the other end, to clear the walls of the bridge when the sense is to be turned off; and which, when the bridges are turned over to meet in the middle, can be let down by turning a winch, so as to fall in strong grooves prepared in the coping of the walls, and complete the abutments of the ribs of the bridge, as strongly almost as a fixed wooden or iron bridge could be made; an excellent example of which may be seen in Wapping dock, crossing the entrance to the London Docks, as mentioned under the article BRIDGES. It appears that Mr. H. Sneckrowell was rewarded for some improvements to swivel bridges which he suggested to the Society of Arts. See their Transactions, vol. viii page 327.

Draw bridges are not uncommon as accommodation bridges on some canals; the frame or platform of which, with their side rails attached, is moveable on strong hinges upon the top of the wall or one side of the canal, and, when down, slants into a groove prepared on the opposite wall, so as to prevent any projection or obstacle to the road over it. For raising these bridges, two strong and tall poles are fixed upright on the bank of the canal a little behind the hinges of the bridge; on the top of these poles are two very long and tapering pieces of timber called balance beams, which turn on a hinge near their middle, their small ends being connected by chains to the further end of the bridge, to which the thick ends of the balance beams are made to be a counterpoise, by means of lead or iron nailed on to the same if necessary; when the bridge is raised, or prepared for raising over, the balance beams, by their horizontal, there being a chain attached to the thick end of each, which hangs down and can be reached by a man or boy, and by pulling at which, he can rear the bridge up upon its hinges for boats or vessels to pass. For croffing the Docks in Liverpool in different places, very large draw bridges are in use, supposed to be the largest in England. But we are informed by Mr. Rennie, an engineer of the first eminence, that he has seen much larger draw bridges in France. On the Rhine and Clyde canal the draw-bridges are double, meeting in the middle of the canal when shut down. It appears that the Chimpole have a sort of draw, or rather rising bridges over the piers of the flood-gates of their canals, which, to prevent interruption to the mails of vessels, are constructed so as to be easily withdrawn when vessels are about to pass; they are flat wooden bridges, narrow and light, resting on rollers fixed in their frame, and running on a couple of hoist spars that are withdrawn after the bridge. Wooden bridges are very often wanted for carrying the tow path over the entrances to docks, or the side branches of a canal, and from their great span, to avoid a narrow place at the cutting; these are often attended with considerable expense; they should be constructed of very sound and durable timber, well truss’d, and as light as is consistent with strength, as they are seldom made wide enough to be used except by men and horses. We cannot too often advise that bridges of wood or iron, and those ones also of large span, should be wider at the abutments, and diminish by a proper curvature of the sides to the middle, to prevent the strain of the materials on a sudden lateral impulse, from causing them to give way and cripple sideways.

The ingenuity and enterprise of British artists have given rise within the last 30 years to an improvement of the management of navigation, by the introduction of iron bridges of great size and strength, by the adoption of which, in favourable situations, locks may be dispensed with, and thus the navigation may be made more commodious to the canal and lock makers. The iron bridges which are employed are generally composed of an iron arch or arches, placed within the arch, are prop’d by Mr. Ablomey on the Society of Arts, who calle the face, and presented to the Society of Arts, in whole collection, or may be seen by any one who enters in the Act of 1804: see their Transactions, vol. iv. page 327.

Bridge of iron over the Severn, within two miles of the town, we have already described in the article referred to, and have only to add, that Mr. Thomas Telford, the engineer of this bridge, has given a plate of the same in his "Agricultural Report on Shropshire," page 479. For the principles on which the Wearmouth bridge, which we have described, is formed, Mr. Resident Bridge at the 15th September 1793, took out a patent, which is in the Register, vol. vi. page 51, where a view of this very curious structure will also be found. We are sorry to add that we heard lately in conversation, that this bridge is shewn symptoms of pulling or giving way in late years, which have greatly alarmed some persons for its safety. The cast iron bridges at Bridge-water on the Forest river, and at Staines on the Thames, have been mentioned in our article referred to above; the latter, owing to the mistaken economy of the trustees, in having vaults made in the abutments, which ought to have been of solid masonry, gave way, and has been entirely taken down, as the new stone bridge erected before it, was obliged to be from the same cause. We cannot too much admire the prudent precautions of the select committee of the House of Commons in 1820, who investigated the different proposals for rebuilding London Bridge. (See Johnson’s Philological Mag, vol. x. page 137.) They confuted the opinions of the most eminent professional men, and had a very accurate test of models, confuted in brass by Mr. Byrne, the successor to the celebrated Roman. Under the direction of Mr. Atwood, for illustrating the nature and properties of equilibrium arches. One of the designs which were presented to this committee, and which has since been engraven by Mr. Wrefen Lowry and published, is that of Miers, Telford and Ropes, for a single arch of cast iron of 400 feet span, and rising 65 feet above high-water mark: as this scheme has not yet, nor ever may be carried into execution, it would be swelling the present article too much to detail the excellent provisions which the contrivers had made, for the execution and stability of this grand work. We proceed, therefore, to mention, that Mr. Fenton, in his treatise so often before quoted, has given designs (plates 14, 15, and 16), and explained the principles, page 120, of different bridges of cast iron. On the 24th May 1796, Mr. James Gordon took out a patent for constructing bridges which should be suspended from ribs of iron above; see Register vol. vi. page 220, and on the 6th February 1797, Mr. John Nisfe obtained a patent for a method of constructing bridges of hollow quoin’s of iron, that can be filled with masonry or other solid matter after the bridge is put together; the pieces of bridges he proposes in like manner to con...
bridge of hollow cases of iron, to be filled with masonry after they are brought to their proper places: see Report of surveys, vol. vi. page 361. Of wooden bridges for large and navigable rivers, we have given an example in the once jolly famous Schafthauen bridge over the Rhine, in our article Bridges. Mr. Fothergill mentions a very famous one at Wettingen in Switzerland; and has given us designs for bridges for newly settled and woody countries, wherein large timbers dovetailed together, supply the place of key-stones, above which the platform for the road is to be supported. The same gentleman has proposed in constructing the above kind, or iron bridges that are very flat and low, to obtain the necessary stability of the butments, by continuing the line of key-timbers or ribs with their proper curvature for some distance into the bank on each side. We have before spoken, under the article Bridges, of the proper form of the projecting angles of the piers of a bridge, and shown that for navigable rivers, sharp corners should be avoided, from the damage that such might do to the boats and vessels.

Bridges will be wanted in the construction of rail-ways for carrying the rail-road over rivers, sudden valleys or roads; some of these may require cast-iron arches; some of them must be of stone or brick; but oftener, such may with propriety be constructed of wood, taking care that they are effectively trussed, or formed on the best principles, also that the joints are effectively secured from wet, and the whole covered with a coating of mineral tar or paint, to be renewed from time to time, to keep out the weather. One other thing remains to be mentioned respecting bridges, i. e. owing to the contraction of the canal and curvature of the towing-path at a bridge, the towing lines are apt to fret and wear away the corners of the bridges, occasioning also a great waste in ropes: for remedying this, light hollow cylinders of wood should be placed upright, or nearly so, according as the wall is upright or battering, at all the corners of the bridges or other obstructions to the direct line of the towing-path; these cylinders being hung on centres or pivots, at top and bottom, they turn round by the action of the rope, and prevent friction and wear.

The Towing-path, horse-path, or haulway of a canal, should always be on the lower side if practicable, the traffic on the same having a tendency to consolidate the new made bank, to prevent the accumulation of weeds and the harbour of vermin, that by lodging in and perforating the bank might endanger the same. The towing-path should change as little as possible from one side of the canal to the other, and when this is unavoidable, it should be always done at some fixed bridge, to avoid the inconveniences before pointed out; the change ought never to be made in deep-cutting, as has been done near Tring on the Grand Junction. The towing-path ought never to be interrupted if the same can be avoided; and, besides having a way under all bridges (except those where a change of sides is to be made) we hope to see the example followed, which has been set at Atcham on the Shrewsbury, and Newbold on the Oxford canals, of continuing the towing-path through the tunnels, wherever the same shall appear practicable. On the proposed Bude and Launceston canal, it was intended to form a towing-path on both sides; a hint that may prove very useful in some situations of greater traffic, than there ever was likely to be on this canal. It is often provided in the act, that the towing-path may be used by the owners and occupiers of land on the line as a bridle-way, or as a drift-way for their cattle; as on the Afgy de la Zoch, Gratham, Leicesterfairs and Northamptonshire Union, Oakham, &c. Frequently, permission is given to persons to use the towing-path as a foot-path or bridle road, and we think it would in some instances be proper to obtain the power of laying a small toll on horse passengers; if the company should at any future time see it right by public necessity to prevent their towing-path to be abused. It seems unprovable to the object of a towing-path, to make public drift-ways of them in any case, on account of the damage which loose cattle would do to the banks and fences, and the impediments which doves of cattle would prevent to the hauling-horses and lines. In forming the towing-path, care must be taken to make the ground sound, and to cover it with a proper thickness of good gravel; and we cannot but recommend the making or frostig of this as it is laid on, throwing the large or irregular stones forward to be covered with better gravel, so that the surface may be smooth and even, without rough and large stones to throw the horses down, and render the use of the path unpleasant. On the duke of Bridgewater's canal, where proper materials for road-making are very scarce, the flate and flates, or refuse coals from the mines are brought out and calcined, or burnt in very large heaps, the cinders of which are used for making and repairing the towing-paths upon his canal. The height of the towing-path ought not to be less than one foot, or more than two or three feet above the surface of the water, or top-water line.

The fencing of the sides of a canal is a business deserving of more attention than has been usually paid to the same. Quick-fet or other live fences ought by all means to be made, except in the case of a rocky country, where good and durable walls can be built at an easy expense: rail or pale fences are very improper, except in and near towns, on account of their heavy expense in repairs. The continual wearing which quick-fences require, the great injury which the plants fallain from weeds, if the same are at any time suffered to grow up, and the damage which the pulling or towing of them is repeatedly done, is worn away the soil, and more or less exposing the roots of the quicks, and besides these, the plants being often wounded in their tender bark by the hoes used by the weederists, are most serious difficulties in the raising of quick-fences, wherever our experience has extended, except in the north-eastern parts of Norfolk, where the spirited and intelligent tenants, that there abound, have a method of raising fences, which they which are continually doing during the currency of their leases, that we are happy, in this instance, of being able to mention, because it has not yet, we believe, appeared in print. The line of an intended hedge and ditch being marked out, the first step is to collect carefully all the top-soil or vegetable mould into a ridge where the centre of the bank is to be, and if this vegetable mould proves too abundant, the extra quantity is thrown into heaps further off, in order to be mixed with dung, or carted to some parts of the land, which wants a greater supply of mould. This done, a row of spits or heaps of earth out of the ditch are laid carefully in the front of the bank, and on these, when reduced to a regular line by paring with the spade, the white-thorn fets are placed a little inclining upwards, at about four or six inches apart; care is taken in laying in the fets, that their roots are bedded in the vegetable mould, that is to form the centre of the bank; when this is done, another row of spits or heaps is dug out of the bottom of the ditch, and laid upon the quicks, which being patted down and leveled at top with the spade as before, another row of quicks is laid in, taking care that each plant in the upper row is over a space in the lower one, and that their roots are included in the top-soil. Other fods are then dug out of the ditch and piled up, with the proper slope or batter, until the bank is raised to the intended height; the vegetable mould is then drest up into a regular bank at the back, and the remainder of the fluid
fluff from the ditch is thrown over, and is afterwards carefully spread and laid up against the back of the bank, so as entirely to enclose the vegetable foil in a caafe of dead earth, or fluff taken from below, where cultivation has depopulated the foils, or mature the vegetation roots of such plants. Still further to accomplish this exclusion of the foil in the bank, from the action of the sun, air, and other flammable materials, vegetation, at a proper feaon in the spring, a quantity of dead earth is piled up from the bottom of the ditch, and worked and chopped about, until it is in the state of puddle, before deforbed. The top of the quacks are cut off neatly even with the ground, after which, a labourer carefully platters every part of the face of the bank with this prepared or puddle-like fluff; and after it is laid on, having a puddle-full of water at hand, to wet its spade if necessary, he works this platter about, giving the flat surface of his spade exactly the circular and plattering motions that platters use when at work on a ceiling or wall. If it should appear that frogs have molested down, or injured the face of the bank, the same is carefully repaired and worked again, as above, before the feaon for the vegetation of the quack. All such as the white-thorns have put forth their leaves in the spring, a careful labourer walks along the ditch, with a knife in his hand, and wherever a plant is springing, from among those which have footten, he digs in the point of his knife with care, to find and release the top of the set, which other-wise might be smothered and conformed by the plattering of the bank. The benefit of this procedure is inconceivably great, in almost totally preventing the growth of weeds, and in confining the moisture in the vegetable mould from escaping in dry foils. At a time in the summer, when every part of the surface was covered with vegetation, we have with pleasure examined some miles in length of quacks treated in this manner, and although the quacks had made the finest foils which could be imagined, not a vestige of vegetation of any kind beside was to be found on the bank; and thus, with proper care in renewing the plattering or working of the bank, many of them remain until the quick is grown up to be a fence; and it is almost literally true, that weeding is here unnecessary, although no foil can be more congenial to, or worse foiled with the foils of annual weeds, than some of those were of which we have been speaking. The ditches are made deep, and the sides of them as steep as the foil will stand in the general, so that dead or guard foences are generally omitted on that side; and so they are often on the other, or back side, and a prick-hedge is substituted, which, with care, and the letting of steep only foole in rich fields, answers the purpose very well. Some time before the bank is made up to the intended height, the labourer goes along upon the top of it, shovels off the loofe top, and treads down the top of the bank so as to form a flat of perhaps 12 or 14 inches wide; into the centre of which he pours water, and gets the foame a longing motion, so as to open a narrow and deep notch in this operation he repeats, until a notch of this form is opened the whole length of the bank; then he proceeds to lick this with short and rough bushes, so close as to make a complete hedge; he then throws up out of the ditch as much fluff against the bushes as will lay on the plane or top, in which the hedge is struck, and beats the face down strongly with his spade; the foame proceeds at the back of the hedge, by which these bushes are so securely set into the bank, that they will often stand until the quick is become a fence; in places where the destructive piltering of the poor is properly repressed. Some may perhaps consider us as going here too far into the subject of fencing, but we requent of such to consider how important the subject is to a canal-

company, which may have to raise much more than a hundred miles in length of quick-fences, as was the case a few years ago with the Grand Junction canal company, and some others, some of whom are still feeling the very heavy burden of fencing their quicks, two, three, or four times annually; which an adoption of the above principles would, we are certain, have tended to reduce most materially. See our articles INCLUDING, FENCING, &c.

The quick for a canal ought to be placed a little above the level of the towing-path, and be separated from it by a small ditch, to prevent the towing-horses from being in trampling on the quick; but the principal ditch, where the sudden falling away of the off-bank does not afertain the same purpose, ought invariably to be on the field side, for keeping the farmers' cattle at a proper distance from the quick, and to check their attempts at jumping through or over it. The quick ought not to lie placed too near the towing-path, and the hedges should be carefully cut and placed about every twelfth year, both to preserve them vigorous and in good growth, and also to preserve the towing-path clear. On the Oxford canal, near Brentford, we remember that the hedges were so close above the towing-path, in the year 1799, that it was quite dangerous riding along them, and the horses were driven so near the edge of the canal, by the intrusion of the hedges on the path, that the bank was suffering materially. In places where the canal is embanked, it will be proper to place the hedge at the bottom of the slope, in order to enable the company the better to prevent the growth of rank and large weeds, and the consequent harfoning of vermin, which would lodge in the bank; steep embankments might also be materially damaged by the treading of cattle on their sides. Through common fields, or very large pastures, it is sometimes not necessary to fence off the towing-path thencefrom, but at the boundaries or entry to such fields, a gate is placed in the towing-path, to prevent the intermixture or escape of the cattle; and generally these gates are double, falling rather forcibly towards each other, by which construction the cattle are prevented from pushing, or the wind from blowing open the gates, as would otherwise often happen.

At the terminable of every principal estate or farm that adjoins the towing-path, it is usual to place a flying wing across the fame, to prevent cattle getting away, in case they should break, or by accident get into the towing-path. Cylinders should be placed, as before described, against each of these gates for the towing-line to run upon; and fide rails should be placed inclining up to the top of the poles, to affil the rope in getting over the fame.

Draining is another expensive business, of which a canal company will have a good deal to perform, in most cases. Soon after a canal is filled with water, and often sooner on the upper side, owing to the course of the land springs, and that of a more permanent character being intercepted by the puddle ditches, wet places will appear on the land, which would, if neglected, become unfit for cultivation; these are often of considerable extent below the canal; and the committee of the canal company must not be surprized at hearing the farmers attribute many wet places in such situations, to the roofing of their canal, that really are not affected thereby. It would be of use, and the source of much satisfaction, if the resident engineer were to note down in his book all the wet and springy places that appeared on the sloping land, below the level of the canal for a considerable distance, and the condition or run of water from each before the canal was made; because the appearance of new quakes, as the farmers in many parts call them, or the increase or enlargement of others, is often the first and only indication of...
an increasing and hurtful leak from the canal. The committee should not be nice in drawing the line, as to the extent of draining which they order to be done; but it would, on the contrary, be highly to the credit of their concern, and the interest of future canal schemes, to bear the whole or a portion of the expense of effectively draining all the land, whose wetness could, even in mistaken prejudice, be ascribed to their canal. The execution of these operations ought not to be confined to the quackery of boring a hole here and there in a trench, without any theory or meaning; but the resident engineer, or some professional man employed expressly for the purpose, should, by a judicious application of his experience and knowledge of the firsts in every place, apply that particular method of draining, as to the situation and depth of the drains, &c. which every spot may require. And these operations are more various and important than what any person, who has not made the subject his particular study, can possibly be aware of. See our article Drains.

There is a danger attending drains made near a canal, from rats or moles working their way unobserved beneath the surface, between the drain and the canal; for detecting which, or other leaks, it will be proper for the resident engineer to enter in his book a minute description of the situation of the mouth or vent of every drain, choosing situations for the same, when they are made, in ditches, where they can be readily got at, and not be liable to be damaged by time, or the trampling of cattle. The length and direction of every branch of under-drain which vents at that month, should be noted down, and the quantity of water which the drain discharges should also be carefully estimated, at some short distance of time after the same is finished; and a regular and periodical inspection of these drain-mouths by the engineer with his book in his hand should be made, by which any secret leak could hardly fail of being detected. It is almost unnecessary to point out the importance of an attention to these circumstances, in situations where water is very scarce.

The construction of Boats for canals and rivers requires some notice in this place. Mr. Chapman, who has given some excellent directions respecting the form of boats liable to overfet or be injured by heeling, has very properly observed (Observations, p. 102.), that the area of a crois section, of a boat to be used on a canal, ought not to approach so near to the area of a crois section of the water in the canal as 1 to 3, or considerable inconvenience will arise, both from the increased resistance of the boat, and the damage to the banks, from the counter current to fill up the space the boat leaves in her rear. This circumstance requires particular attention, particularly in boats that are to move quick, like the passage-boats from Manchester and Paddington, on Bridgewater's and the Grand Junction canals; in the former of these, we observed a constant elevation of the water before the passage boat, as it moved along, of at least 2 inches, and perhaps more than a foot at times; and the rapidity with which the water ran backwards, between the boat and the sides of the canal, appeared to have a most destructive effect upon the latter, particularly on the towing-path side; and often this was laid quite under water, for considerable distances together, by the surge or wave opposite to the head of the boat as it passed along; while the labour of towing was most materially increased. We regret that we had not the means of ascertaining, how much the head of the boat was elevated upon this artificial wave in the general, and up which inclination the towing mules were contantly draying it. Some attention ought to be paid to the form of the head and forepart of the boat, with a view to its letting the water pass freely off by its side: flat headed boats, and those whose ends are rectangular in particular, ought not to be towed fast, or great loss of labour and damage to the banks will be the consequence, unless the canal is very wide and deep. It has been proposed to form boats sharp at one end and flat at the other, so that the flat ends being joined, two of them may form a body, diminishing properly at each end, for easy passage through the water, and for steering. Mr. Nicholson King, an American, has proposed boats in four parts, that can be detached when the fame are to pass an inclined plane, and he afterwards rejoined. Since the use of calk-iron has become so general, Mr. John Wilson has contructed boats and barges of iron, some of which are used on the Severn river, and others upon the different canals in Staffordshire, Worcestershire, &c. Mr. Robert Futing, in his Treatise, p. 31, has proposed and described a kind of rectangular boxes, with low wheels (or rather trucks, as the axle and them are to be call in one piece) fixed under their bottoms, to be used upon canals instead of boats, on account of the use which he proposes to make of them, upon inclined planes and railway-passages, as well as on the water, as we have before mentioned. Mr. William Chapman, who has examined this system particularly, in his Observations, has proposed and given drawings of wheeled-boats of a different construction, larger wheels let into the bottom of the boat being used; and his boats are so contrived, that several of them, linked together by their ends, can be used together either upon a canal, or a railway, or plane. The same author has recommended and described a kind of flat-bottomed boat, with a sngle or double rail-way on its floor, which he proposes to receive or discharge a loading of railway-waggons, as it lies in a shallow dock, from which the water has been drawn, and to which it is to be again admitted when the boat is to float out into the canal. For ease in getting loaded waggons in and out of these boats, a pair of leaver, or water-tight slaps, are contrived to let down, and permit the junction of the fixed railway on the land and the part thereof that is on the floor of the boat. A curious method of steering boats is in use on the Bedford, Ouse, the Cam, and others of our eastern rivers: two boats are always used together, one of them having a strong pole, or bow-sprit, projecting horizontally from above its prow; this is brought over the stern of the boat which is to go before it, and the prow or stem of one boat is fastened by a rope close to the stern-pole of the other; to the first boat the towing-line is fixed, and the bow-sprit of the latter boat is used as a tilter to set or retain the hilt boat to any required angle with the first, by which the hilt boat acts very effectually as a rudder for steering the first. Mr. Chapman proposes to adopt this principle with small boats upon canals. The wili-country bargemen, on the Thames, guide or flop their boats, as they are floating down the stream, alone, or with others, by harnessing a horse at the bottom, and a cross handle at top, round which they dexterously wrap a short rope, fastened to the side of the hilt; the pole has struck into the bottom of the river. For speedily emptying the cargoes of small boats into larger vessels, Mr. Davis Dukart contrived, on the navigation to the Dungannon Colliers, to float his small boats on to cradles or wheeled carriages, on which they were dragged up a short inclined plane, and upon a railway conducted over the barges in the basin; and then the boats could be turned over, and their contents shot at once into the barge. A different method, as Mr. Chapman informs us, is practised in South Wales: it consists in continuing the canal (which may be a wooden trough) to the place of discharge, and terminating it on a caisson, suspended on a traverse centre; the boat being arrived at its place, the end of the canal is closed.
The meaning of Boats upon canals or narrow rivers, where sailing is impracticable, has always appeared attended with considerable difficulties. Where the width and depth of water will admit, long oars have been used, worked by one or two men on each side of the vessel, as is done on the coal barges and lighter on the Thames in or near London. On the Tyne river at Newcastle, their keels are said to have been in use ever since 1578, and are rowed by an immene one on one side, another being used at the stern to steer by, and counteract the tendency of this strange mode of rowing. It is said that the large car is hung by an iron ring, so as to admit of its being laid on the gunwale of the keel, when not in use, but not of its being removed. Owing to the want of any regular and proper path on which horses could travel by the sides of the river, the first hauling or towing of boats was performed by men, as still continues to be the case on the canals of China; and in this country most of our navigable rivers were without horse towing-paths till of late years. Within our recollection, ten or fifteen men were seen tugging at the hauling line of a barge on the Thames, in the meadows of Twickenham. A good horse-path now begins at Putney bridge, on the south side, and continues uninterrupted on one side or other of the river to the extreme points of the navigation. These appendant appendages to navigation are not now completing on the Severn river, which has been so long famous for its navigation. The towing-path on many of our old navigations is continually interrupted and broken off, by mills and other obstacles, without any bridges for the crossing of the towing-horses and boys. On the Ouse river, below Bedford, we have observed the towing-path to be interrupted at the end of almost every field, by high and dangerous dikes, over which the ill-fated navigation-horses have to leep, encumbered by their harness and the heavy rope. No regular path is maintained, in a great part of the distance, by the owner of the navigation; but frequently the fine meadows there are cut up, by the track of the horses being at a considerable distance from the river, across the many bends that it has: and the farmer's grubs, between this path and the river, is rendered of little value, by the fouling and dragging of the hauling-rope over it; the banks of the river are also miserably worn away, by hauling so far from, and consequently so obliquely to, the direction of the stream. In many places, where the river is wide, there is no track for hauling, except along the bed of the river itself; where often the horses, with a wretched boy upon one of them, are seen sometimes wading, and at others swimming, along the course of the river! Nothing is more common than seeing the horses and boy have to swim over from one side of the river to the other, when the hauling-way changes; not unfrequently this is impracticable, from the total want of a way on either side, and the poor horses are obliged to leap from the bank, perhaps when at a considerable height and distance, into the head-room of the barge, to the great peril of their bones and neck: shortly after, these wretched animals, and probably with a boy on their back, are forced to jump out again, and perhaps plunge into the deep river and swim on shore, to resume their labour of towing. A correspondent of Dr. Anderson has expatiated (Recreations, p. 319.) on the hazardous light of six horses harnessed at length, towing a barge up the Thames above Putney, by a single line of insufficient length, by which the hind horses were in continual danger, in spite of their utmost exertions, of being precipitated into the river: what would this humane gentleman have said, if his walk had been along the banks of the Ouse, or a piercing winter's day? It is owing, in a great measure, to the enormous difficulties and expense of construction, and maintaining a proper horse-path by their side, that the navigation of many of our rivers is so imperfect. In all flat countries, except the river is embanked, as in Cambridgeshire, Lincolnshire, &c: and without any wide walk or fore-ground within the banks, the towing-path often cannot be made up above the reach of the floods, but, during every floods, will be under water and unfruitful: and when, perhaps, the water subsides, it will be found carried away by the force of the current for great lengths together. On some of our canals, the practice at first prevailed of towing by men; and the fame full continues on the Stroudwater canal, whose towing-path has flakes upon it, like those of a foot-path, at the divisions of different persons' lands. Horses are now, in general, used for towing boats on our canals, except the late duke of Bridgewater's, who reared a large and fine herd of mules, that were found to answer so well, that none others are used to this day, we believe, on that canal. Except with passage-boats, and flies or pocket-boats, for the expeditions conveyance of packages and parcels, the usual rate of tracking or towing upon our canals is about 3/4 miles per hour, including the time lost in pulling the locks, which, if of 8 feet wide, will require about 3/4 minutes each.

It is certain that there is hardly any limit to the load, which one horse can move, in a number of barges attached together, when going with a proportionally slow pace; and this has occasioned some canal advocates to assert that one horse will, on a canal, draw as much as 60 on the road; while Mr. Robert Mulehall has asserted, that horses will not be able to move more than 15 miles per day with deep laden barges on a level canal. On most of the wide canals it is usual to employ a horse to each barge, or two pair of boats of half the width each that the barges are. It appears, that on the Kelsey canal, on Bridgewater's canal between Worsley and Manchester, and others, several of the small boats in use thereon are linked together, and drawn by one horse or mule; there being projecting and smooth rails provided on the Kelsey, at all the convex points of the bank, to keep the boats in their proper track. Mr. Fulton has imagined, that 15 or 20 of his small rectangular boats, linked together, could be drawn by one horse, and be kept in their proper line upon the canal by a man with a boot-hook walking by the side of them on the towing-path. Besides the methods of towing and tracking, which we have been mentioning, on the Tyne, the Thames, and most of our rivers, hitches, fets, pсуs or poles, are used for shoving of barges along: the gunwale of the keels or barges is made wide and convenient to walk upon, and the boatman, being at the head of the barge, fets his hitcher against the bottom and shoves against it, walking along the gunwale of the barge until he has arrived at the stern; when he draws up his hitcher quickly, and returns to the head to repeat the same operation, and this sometimes on one side of the barge and sometimes on the other, unless there are two men employed, whose equal action could keep the barge in its direct course. This last method might be more useful than it is upon canals; but from the necessity which most of them have found, for prohibitory chutes in their act, against the use of any pointed poles, particularly such as are fixed or tipped with iron, on account of the damage which such often do, by penetrating and disturbing the lining and banks of the canal, the necessity of it has to be allowed. We have heard of an attempt lately, to introduce a kind of hitcher-iron on the Grand Junction Canal, which should present a flat end or surface, sufficient to prevent its penetrating the facing on the bottom or sides of the canal, and having a small turn up at the.
the point, which might remedy the loud complaints of the boatmen, at being dabbard a hooked pole on board their boat, by which a comrade, who has the misfortune to fall overboard or into a lock, might be dragged up to the surface of the water. We have thought that it might be worth while, particularly in crooked and difficult parts of a canal for hauling, and where rubble flow or gravel is in plenty, when a wide canal is cutting, to form the covering of the lining, or the facing of the bottom, and perhaps of the lower part of the sides also, of gravel or rubble instead of earth, and carefully to level and ram or roll the same down like a road, so that hitches might be used freely thereon as on the bottom of a river. There would still, however, require very strict and well enforced regulations, to prevent the walls of the bridges, locks, tunnels, &c. from being pecked and greatly damaged by the points of the hitches. Slide-rails will also be necessary, in and near the locks or tunnels, as we have mentioned in speaking of the Bilworth tunnel, which can, without damage to the walls, be removed, when decayed or worn out. Before we proceed to the subject, that has perhaps produced the greatest number of unparalleled mechanical inventions that are any where else to be found, we mean for making boats by an impulse from within or accompanying them, we have one other thing to mention, viz. that Mr. James Jordan, in his patent of the 24th of May 1796, for bridges, before quoted, has proposed the use of circulating chains across an aqueduct bridge, for towing boats over the same; and avoiding the expense of the extra width for, or lateral support of, a towing-path thereon.

The volumes of the machines approved by the Academy at Paris, and the cabinet of M. de Servier, printed in 1719, contain plates and descriptions of many different contrivances, designed for propelling or rowing of boats on canals and rivers; one kind of these, which we shall first notice, depends upon gaining an impulse or hold against the ground at the bottom of the river or canal; in one of which, a small boat moved by oars was proposed to be employed in successively carrying forwards and dropping anchors whose ropes were to be attached to a horse-gin on board of a barge, which was designed to tow or drag a great number of others. In another, a spiked wheel was proposed to roll on the bottom of the canal, attached by a frame moveable on hinges at the stern of a barge, where a roller turned by a wheel, was to give motion to the spiked wheel and propel the barge, by means of an endless rope or chain. See also Walker's Lectures, 4to. page 330. A second kind depended upon the same principles as an oar, except in the construction and mode of applying the power. On the 20th of July 1796, Mr. Thomas Potts took out a patent, for the use of a large flap or ear, moving on an horizontal hinge, upon a framed lever at the stern of a barge, intended when the handle of this lever was lifted up by several men, to turn on its hinge and project but little rellitance; but on the descent of the lever, its whole surface was by the action of the men at the lever, to be exerted on the water for propelling the vessel; see Repertory, vol. vi. p. 160. In the year 1801, Mr. Edward Steers took out a patent, of which we have seen only a short extract in the Monthly Magazine, vol. ix. p. 486, from which we understand his invention to differ but little from the above, except in having two paddles or oars. Mr. Robert Barlow took out a patent, for applying the principle of fluffer-boards or venetian-blinds to several purposes, which he has explained at length in his Essay printed in 1798; and at page 60, proposes to propel ships by large oars or fins of this kind to be hung on the sides thereof by hinges, and worked by a lever, as a rudder is by its tiller; poles with square frames fixed on their ends, to push against the water behind the vessel are also described. A third kind, depending on the reverse of the action of an under-shot water-wheel, lies had many advocates; the first that we have met with in our own country, is Mr. Thomas Savery in 1698, whose contrivances are shown in Harris's Lexicon Technicum, art. Engine; it consisted of 6 or 8 paddles like those of a water-wheel on each side of the vessel, fixed on an axis across the same, on which was a trunnell head, and under this a wheel working into the same, by the force of a capstan to be turned by men. We are told, that in the year 1751, the abbe Arnal proposed to apply the power of a steam-engine on board of a vessel, for working paddles, something like the above, we believe. Soon after this period, we remember seeing on the shore of the Thames at Wapping, a small barge with a water-wheel in a cavity in its stern with a steam-engine for working it, which was laid to be the contrivance of Mr. Stanhope, and had been tried with success against the tide in the river. In the year 1797, a vessel having rowers by its side, that made 18 strokes per minute, from the action of a steam engine on board, was tried on the Stanhope canal, by which it was propelled 10 miles and back again to the same place: see Monthly Magazine, vol. iv. p. 75. In the same year, Mr. Walker (the lecturer) made some experiments on the Thames at Reading, and caused a boat to row itself against the stream. See his Lectures, 4to. page 349. About the year 1820, Mr. H. Hunter and Dickenson took out a patent, for a propeller for ships, which was tried in January 1801, on board of a government sloop off Deptford on the Thames, and the ship thereby made way against the tide at the rate of three knots an hour. Monthly Magazine vol. xi. p. 195. In the Journals of the Royal Institution, about the year 1822, there is a description of an improved application of the steam-engine, to the turning of a wheel for propelling boats; the cylinder of this engine is horizontal, and the wheel with paddles is in a cavity in the stern of the boat, which therefore has two rudders, one on each side of the wheel, connected together by crosst reds. A vessel of this kind was constructed for the Forth and Clyde canal company, under the direction of Mr. Symington the inventor, and in a trial made in December 1821, it drew three vessels of 60 or 70 tons burthen each, at the rate of 2 1/2 miles per hour on their canal; see Agricultural Magazine, vol. vii. p. 152. We read in the late mentioned work, vol. ix. p. 218, that Mr. Robert Fulton exhibited a vessel on the Seine at Paris, in August 1803, having two wheels with paddles, worked by a steam-engine, and two other vessels were towed by it against the stream at the rate of 3 miles per hour. A fourth kind of boat propellers, has depended on the rotary motion of a ferret, or fliers like those of a fmaok-jack; Mr. Daniel Bute, in his attempts to navigate sub-marine vessels, as related in the Transactions of the American Philosophical Society, vol. iv. p. 523, used oars, placed near the sides and top of the vessel, formed upon the principle of a ferret, the axes of which entered the vessel, and by turning the same one way, the vessel was made to advance or descend, as it was to recede or ascend by a contrary motion of the ferret. Mr. John Vildler has contrived a vessel, which has been lying, and occasionally tried in the Thames at Wapping, for 2 or 3 years past, that has a bowm hung by an universal joint (Hook's) at the stern thereof, to a rotative axis, turned by a capstan upon the deck of the vessel; at the end of this bowm is fixed a circle of strong flyers, just like those of a fmaok-jack, which by stricking the water obliquely as the bowm is turned round, propel the vessel forwards; near to the flyers there is a collar on the bowm that turns easily therin; to this collar ropes are attached.
attached, which go to different parts of the helm of the vessel, and by which the boom, when in motion, can be drawn up quite out of the water, if its propelling action is wanted to cease on any temporary occasion, or if the ice thereof can be let down into the water to any depth which may be required, or be turned aside from the direct line of the vessel to steer her on any course, without waiting so much of the propelling power upon the rudder as is usually done in steerage; a rudder is however applied to the vessel ready for use when occasion may require. The fifth and last method, which we recollect to have seen or read of, consists in pumping water, by a force-pump through an orifice or pipe at the helm, or end of the keel of the vessel, with such force as to propel the vessel along, by the stroke of the moving column of water against the water in which the vessel floats; we are sorry that our memory does not serve us to mention the name of the inventor of this method, or the work wherein we saw a description of the apparatus. In the British Magazine, vol. i. p. 397, it is mentioned, that in the year 1805, a vessel was constructed at Liverpool with a steam-engine in it, which was moved along without the intervention of any machinery: we think this as likely to have been, an application of the pumping principle above mentioned. Although, as we hinted above, none of the mechanical contrivances here mentioned have been adopted in practice, we trust our readers will not be displeased, at the short notice which we have given of each, with a view to preserve their memory, and in hopes that the thing may yet be accomplished.

On the repairing of canals we think it necessary to say something; and to begin, by recommending the adoption of a system of management, by which the called notice of any defect, or want of repair, will be obtained: that in harbours, at proper places on the line, a flock of oak, elm, and deal timber should constantly be kept, cut out and felled, ready for replacing any of the timbers or planks in the locks or other works, with the least possible delay to the trade; a circumstance which, if not attended to, may prove of incalculable injury to the credit and success of the concern. Sound and good bricks, and stones, ready for replacing any which are liable, or offered to be likely to want repair, should also be in readiness, and good cement should always be kept in readines, on some part of the line from whence the quantity wanted may be speedily transported to any part where a repair of the walls, bridges, culverts, &c. may require the same: however, before emptying any part of the canal, or interrupting the trade for any repairation, a strict search should be made throughout every part in that level, or on the adjoining ones, to discover all the defects therein, that arrangements may be made beforehand for repairing the whole at once, or with as little delay as possible, while the trade is interrupted on the line. In every lock-house a considerable number of the pile-planks before described should be kept piled up in readiness, for making temporary flanks or dams, in order to empty any particular part of a level, which may have a culvert, trunk, sluice, stop-gate, lock-gill, or other thing which is damaged, out of order, or decayed. It is surprising, to those who have not seen such works performed before, with what facility the workmen who are used to this business will drive two rows of pile-planks so regular and close to each other, that by the help of the tongues or flaps in their grooves, and often without, a tight flank is made without any earth or other loose matters to float the water; and between two of these flanks, if such are necessary, they will empty the water, by chain pumps, or water-screws, to get at any culvert, or other matter, to be repaired or altered; there have been instances of these operations being performed, and of the part being filled with water, and the plank-piles drawn up again for the trade to pass, in the space of eight or nine hours. Should any part of the canal appear to want new lining or puddling, owing to a neglect at the time of making of the canal, or to any subsequent accident, care should be taken to choose the time for such works, when the trade can best bear an interruption; and as, on the average of seascapes, the trade is in two or three weeks interrupted by ice; during the months of January and February, it may not be amiss to embrace that period, on some occasions, although the work may be longer after; and some additional expense may be incurred by covering up the work with earth, before it is left at night, to prevent its freezing, and in removing all such puddle, &c. again in the morning, or at beginning work, which shall be found frozen. Precise and explicit notices should be given of all intended interruptions to the trade, as long beforehand as is necessary, to enable the traders to supply stocks of articles at the places of consumption on the line, and to avoid having their barges locked in, and perhaps lying idle, when they might have been employed if they had been on a different part of the canal.

It is an essential point of good management to have experienced mole and rat-catchers employed from time to time upon the line of a canal, to extirpate these hurtful vermin; and in every instance of discovering one, to trace out all his burrows and holes, and have them carefully filled up and filled in every part, as well for preventing the haubouring of other animals of the same sort, as for preventing the water from making its way into and through them. On a canal in Surry, we are told by Mr. Robert Marshall, in his examination of a canal and road, &c. that a mole or rat hole only, occasioned, after the hard frost of 1795, the rupture of the canal in a high embankment, by which more than 100 yards in length of a lofty bank was precipitated into the meadows and river below, and that a large which before lay enveloped in the ice on the canal, was hurried down through this gulf into the river! It is impossible to take too much care against such fatal disasters as these, and the duty of the mole and rat-catchers ought not to be limited to the company's ground, but in all fields, banks, ponds, or brooks within 200 yards or more of the canal, on each side, they ought to be equally attentive to the destruction of such vermin, and the demolishing of their secret retreats. The same men might very properly be employed in pulling up and extirpating all large and spreading weeds from every part of the banks of the canal, and in mowing down the herbage occasionally; these circumstances being not less essential for the neatness and beauty of the canal, than to prevent the first harbour of vermin of different kinds. The banks of the canal will be very apt to continual wear at the surface of the water, and for some height above and below that level, if a proper kind of herbage is not encouraged upon the slope of the bank: considerable care should be taken to suffer no plants to take root on or near a canal bank, or spread its seeds, (if possible to prevent it otherwise,) as the water, even when it flows by a feeder, which will grow in deep water, or whose roots are large, hollow, and strike deep into the ground, left the former of these should choke the canal in time by weed-beads, and the latter render it leaky by the formation of numerous open tubes through the lining into porous stuff. None but those who have seen many drains or new ditches opened in wet and boggy ground, can be aware of the depth, size, and number of hollow roots, which some of the aquatic plants, as the equisetum palustre, or marsh horsetail, the iris pseudacorus, or yellow flag, and several others, send forth into the ground.

Paddle-ditches, in the banks that are raised or made up, are a great security against the bank being washed down, in
in case of the water, often by any sudden thunder-flower, or
other inordinate rain, breaking over the top of it; as soon as
the puddle is reached, the effect of the stream to tear and lower
the bank will often be stopped; for good puddle, when pro-
perly let and hardened in the centre of a bank, is so compact
as not to be liable to be broken or suddenly worn by a
current of water. In case of the breaking or flooding of a
bank, in that a considerable and wide breach is formed, and
still increasing, it is a good practice to drive in two rows of
common field hurdles, at a feet or less apart, filling the same
two together by cart and securing them by strong stakes
drove down behind them, and if the stream of water be deep
through the breach, it will be necessary to drive other long
stakes obliquely into the ground, and securing their tops to
the hurdles and upright stakes by lops of cord, that these
hurdle may act as struts to prevent the whole being borne away
into the cavity between the hurdles; straw or hulks should
then be put and trod down, beginning at each end, and
working towards the middle, in order to prevent the current
being turned, with fresh impetuosity, against the sides of
the breach; such a dam as this will prevent the loss of any con-
fiderable further quantity of water, and will render the water
free from, so that a row or more of pile-planks can be drove
to cut off the connection with the breach, which can then be
emptied of water, the hurdles and straw removed, and the re-
paration begun, with proper puddle-ditches for its security,
as before described. At the famous Dagshahm breach of
the embankment of the Thames, dove-tail, or plank-piles
were used, we are told. It will be necessary to defend many
places of the banks of a canal that are obliged to be untimely
swept, as in the approach to a bridge or lock, a weir, &c.,
with a facing of planks, called 

camp footing; this consists of
strong piles driven into the bottom of the canal, with the
proper inclination, with horizontal pieces, or land ties to
their tops, on to which piles found and durable planks are
spiked. In some places, owing to the accidental or unavoi-
dable admission of very thick water into a canal, or in more
cases by the ordinary deposit in length of time, the canal
will become choked with mud. In these cases a machine
with buckets, like a chain pump, to siphon the bottom of
the canal, and afterwards discharge the load of mud into a
barge, might be used, such a machine, worked by horses,
having now in use in the 

West India Docks. See also Walker's Lectures, 4to. p. 35.
The late Mr. Brindley, we are told,
contrived a plan for the purpose of clearing the docks at
Liverpool from mud.

By neglecting it will sometimes happen in canals, that 
Weeds

grow up from the bottom, and form an insufferable imped-
ment to the motion of the barges; and this is almost unavoid-
ably and generally the case in river navigations, if careful care
is not used to tear them up, or cut them down. On the great
Ouse, and other river 

canals, a machine has been long in use,
called a 
hearinng, for tearing up strong weeds by the roots.

About the year 1796, the 

chevalier Bentenouce Molina

presented to the Society of Arts, a model of a barge, having
a windlass in its stern, which gives a circular motion to a pair
of knives or scissors, or a lever giving an alternating motion
to knives for mowing off weeds close to the bottom of a

canal, in which the barge is to float, or on the sloping sides
of the canal; for which purpose, the knives can be made to
revolve at any depth below the surface of the water, and
either horizontally, or inclined in any angle; this model may
be seen at the society's house in the Adelphi, and a descrip-
tion and view of it will be found in their 

Trans. of the R. A. vol.

In molt winters it hap-

pens, 

that an ice not more than an inch or an inch and half

thick, continues for a considerable length of time on canals,
and other flagrant waters; this, or even a leaf thickness of ice
is sufficient to stop the trade upon canals, unless the ice is
broken; and, for this purpose, it is advisable, every morn-
ing of a frost, unless the ice should be found more than usually
thick, and the frost increasing, and likely to continue,
to break the ice on each pound; this is usually and effectually
done by a strong and square headed barge, whose floating or
projecting head is covered with strong iron plates. One of
these barges being drawn along the canal, and into each lock,
by several horses, has a constant tendency to rise up upon
the ice, and thereby breaks it down before the barges: about
the lock-gates it will be necessary to break the ice by flamp-
ring with the end of a pole. Mr. Symington, whole barge,
with a 

steam-engine in it, to propel it along, and tow other
vessels, we have lately mentioned, has provided the head
of his barge with flammers, to be worked by the engine, for
breaking of the ice before it, in frosty weather.

Leaks in a canal may sometimes be stopped without em-
ptying the water, if the depth will permit it, by preparing
good puddle in a flat-bottomed daw-bath or flat, and
dropping the fame in spadefulls equally over the surface, and
when a certain length is done, taking the fame about with a
rake, with short teeth to join the pieces together, and level
the bottom. The difference in specific gravity, in different
loams and earths, is so considerable as to make some of them
much more proper for the lining and facing of a canal than
others; the heaviest that can be found should be used when
leaks are to be stopped, and the water remain in the canal as
above. We have passed along the branch of a canal on a
chalk foil, where the lining of the bottom was fo light, that
the motion of the barge filled enough of it up into the wa-
ter, which was before nearly clear, to make it almost as white
as milk behind us; this light stuff has since been taken out,
and a substantial lining and facing of proper stuff brought in
bars for the purpose, and laid on the bank before the water
was let out, has been applied, by an able engineer, who suc-
ceeded those of too different a description who constructed
this very leaky branch.

Some Implements and machines are used in the making or
working of inland navigations, which we have not had occa-
sion yet to mention or describe. In every considerable work
it will be necessary to erect rolling-dones for grinding and
preparing of the cement or mortar that is to be used in the
waterworks. As Westley, on Bridgewater's canal, the
power of a water-mill is applied to turn two pair of
large stones on edge, like those used by tanners, gunpowder-
makers, &c.; in some of those the stones rested round on a
fixed stone, in others a large cast-iron flat pin, in which the
materials to be ground were put, was turned round under the
stones, which were thus made to revolve round their own
fixed axle on the materials. What appeared singular in the
proceeds at this place was, that the lime and other ingre-
dients were ground with water for a long time, in the flat
of thin mortar, which was then removed into cisterns to dry,
and before the flame was become too hard, it was cut out by
a spade, into lumps of about half a cubic foot each, and
heaps of them were preferred in a fire-room, where they be-
come quite dry, and as hard as chalk, or harder, for use at
distant periods of time, in the repairs of the walls and works
under water. At the 

London and 

E. India docks steam-
engine, of twenty horse power in one cafe, were used for
grinding their cement; but the pozzolana, lime, and other
ingredients are here mixed and ground together in due pro-
portion in a dry state (as Parker and Co.'s patent Roman ce-
ment is done), and it is not wetted, but carefully preferred
from
from mole, till a very short time before it is to be taken in the wall. See "The article Rolling-hous." The driving of Piles is a very considerable business in many large concerns; at the entrance of the London Dock a steam-engine was erected for driving the vast number of piles which were required for the cellars. Mr. S. Bunce contrived a very simple and effective kind of pile-driver, to be worked by men at a wheel. M. Hervet contrived a double pile-driver, which is described in the "Transactions of the Society of Arts," vol. xi. p. 177. The double pile-driver contrived by M. Painbow cannot, from the small immensity of models, plates, and descriptions, which have been printed of it, since the building of Greenwich Bridge, be unknown to any of our readers. Mr. J. P. Volland contrived a machine, and perfected a model of it to the Society of Arts, (see their "Transactions," vol. viii. p. 282) for cutting off the tops of piles after they have been drove, beneath the surface of the water. See the article Pile.

Some of the navigator's tools and implements, as barrels, huling-blocks, grating-tools, floats, and compasses, have been represented in figs. 14 to 32, "Canals, Plate VII.

Cranes for the hoisting of goods will be required on the wharves of canals and rivers. See our article Crane.

On the general management, and office department, of a canal concern, it is unnecessary to enlarge. The committee with which the conduct of it is entrusted will, without doubt, direct their attention to those various circumstances on which its prosperity depends. Accordingly, they will appoint proper officers in the several subordinate departments, and give them such instructions for the regular discharge of their duty as occasion may require. It may not, however, be improper to suggest, that the canal committees should direct their resident engineer to establish proper rain and evaporation gauges at several lock-houses upon the line, to be kept by the lock-keepers, and register daily or weekly with great care: these observations, preferred in the company's books, or, what would be better, published in some of the magazines, would prove of great advantage to mariners, and to canal undertakings in general. In canals of considerable length, particularly if some parts of them are indifferently supplied with water, or leaking, it will be right to fix gauges or graduated rods on each upper lock-gate, that shall show at all times how many inches depth of water there is at the time, in the shallow part of that pound; and to cause the lock-keepers to mention the same at the foot of the printed permits or pass tickets, that the toll-keepers should give to every barge-man who passes, containing the number and description of each barge, and the description and weight of its load; these, transcribed regularly to the toll-collector, would enable him, or some other person, to keep for the information of the committee, a register of the daily state of each long or leaky pound of water; at the same time that the lock keepers, toll-keepers, &c. at each extremity, and on different points of the canal, would always be acquainted with the state of the water, and the loading which a barge could pass with at every particular place; and could inform bargemen; for want of which knowledge great delay and expanse are often incurred, in dry seasons, by letting off with more lading than can be carried through, for want of a sufficient depth of water, and part of the same is obliged to be left on the road, or taken into other boats. All the regulations contained in the act, for working of the canal, and such by-laws as the committee may find it necessary to make, for regulating the conduct of the bargemen and others on the canal, should be printed, and stuck up at every whirl on the canal, and in every toll-keeper's house; and all the company's agents and servants shall be made acquainted with the rules and regulations, not by alteration in the place, but by immediate notice, in writing or otherwise, and the particular of the time, place, and name of the barge, or under which ladder or whistle it is made, or any other proper particular, is to be given verbally, and recorded: and, though we speak of the toll-keeper, whose duty is punishing on that subject, yet a little on the line, by showing the officer on the line the committee would be prepared to proceed against it; and, we may say, particularly if the parties were written to, to them, and not to the toll-keeper, to prevent the barge-passers from being informed, the report was sent to the company.

Tollage Tickets, fully and explicitly stating the toll or tonnage payable to the company, its agents, or articles of every different kind, on different parts of the line, if often happens, these vary, should be printed, and stuck up at all the wharves and toll-houses, for preventing all doubts or alterations between the company's servants and the traders. At some convenient place on the line of the canal, a weighing-place should be prepared, consisting of a dock, yard, and wharf, large and deep enough to contain the largest vessel which are to navigate the canal; this dock should be furnished with a draw-bridge to let down, or doors to fast, when an empty barge has entered, in order to regulate the water quite full within the dock. Gauges, or laden weights of 2 cwt. each should be provided, and a course to hoist the weights readily in or out of the barge, and place them in any part of the same, so as always to load her evenly. To this weighing-place, the act or by-laws should require every barge to be fast, have the name thereof, and the owner's name and residence previously painted on the item of it, before it is allowed to trade on the canal: the empty barge, being arrived in the dock, the gauging-matter fixes four small plates of iron, each containing the number that this barge is in future to be distinguished by, two on one side, and two on the other, against the grapple, near the head and stern. These plates are all fixed at the same distance from the surface of the water, when the barge is empty; this distance, in inches and tenths, is entered into the gauging-matter's book, under the number of the barge, name, owner's name and residence, date, and other particulars: two tons or weights are then hoisted into the barge, and regulated until the distance from all the four plates to the water's surface is the same, which distance in inches and tenths is also entered in the book against two tons; two tons more of weight are then hoisted in and adjusted, and the height of the number-plate above the water is taken, and entered against four tons as before; these operations being repeated until the utmost lading of the barge is on board, when the weights are taken out again, and the barge removed from the dock. For measuring the height of the plates at the Paddington weighing-house, a tin tube is used, that is furnished with a float moving freely in it, to mark the surface of the water, which carries a light float graduated to inches and tenths, to show the height of the number-plate against which it is applied. At every toll-house on the Grand Junction canal similar floating-rams are kept, and to every laden barge which pays this gauge is applied against the number-plate, at each end, and to those on the other side, if the barge appears to heat at all to either side. If the dry inches and tenths shown by the gauge, between the number-plate and the water's surface, be different, they are added together, and divided by the number of them for the mean height. It is the business of the gauging-matter to calculate, from the particulars entered in his book, of each barge as above, the weight to the nearest of 1/10 of a ton, which answers to every inch and tenth.
...
The Principles of constructing River Navigation require some further notice in this place, in addition to the particulars which we have already had occasion to notice respecting them in this article.

Mr. Thomas Telford has given an account of the navigation of the river Severn, which is printed in "J. Thelwall’s Agricultural Report of Shropshire," pages 284 and 317, from which we shall collect some particulars, and remark thirteen, with the view of paving an example, what are the nature and extent of the difficulties which navigation has to contend with, upon natural rivers. This fully famous river is navigable up to Wrekinpool, a distance of 155 miles by water, from the mouth of the Bath Avon river; the extreme branch of this river may be traced for about 45 miles above Wrekinpool, to Philominham Hill, and numerous other branches extend for great distances into the country on both sides; the whole of this great length of river navigation was till lately unimproved by art, it having no locks, weirs, or other excisions throughout its whole length for surmounting the numerous shallows and irregularities, which the current over variable 

The greatest trade is carried on the canal, in the shape of merchandise, goods, and manufactures, that are conveyed from one place to another, by means of which commodious and convenient means the commercial intercourse of England is still more favored; and the pleasing and healthful agreeably to natural rights, and respecting their rightful and honest claims; and the navigation of the Severn river is no exception to this rule.
gations, or in extending the navigation thereon above the tide-way, it is of importance to examine the state of the whole country, to which the river in question acts as a drain, to observe accurately whether cultivation, or the breaking up of lands, and the practice of draining have been going on, or are likely to be so in any considerable degree, within a reasonable period; as also to observe particularly the state and extent of the valleys and meadows, over which the waters are or have been spread in ordinary floods, and the probability of such being further prevented byBrightening or enlarging the beds of the brooks and rivers, or embanking the courses of the streams; these, with the most correct information that can be obtained from different millers and others, who live on the banks of the river, or from scientific individuals, who have caused accounts to be kept of the height of the water, will be necessary data for determining the magnitude and nature of the works which will be necessary on the proposed navigation.

Mr. William Chapman, in his Observations, often before quoted, page 74, when treating of the canals of China, which are in effect but new channels for a part of the streams of China, occasioned by the floods of the Yen, has referred to observations on the crookedness and unequal factions of rivers, and on the effects of shallows, weeds, and other impediments, upon the velocity and height of the streams, that we must reluctantly for the present pass over, referring the reader to our article RIVER. As an influence of the fall and velocity of large natural rivers we are told, that the Ganges for 60 miles, having the mean width of 3-4ths of a mile, and depth of 15 to 20 feet, was found to have a fall, in a direct line, through the immoveable flats and rice-fields on its side, of 9 inches in a mile, but by following all the bends of the river's course, the fall was reduced to 4 inches per mile, and its velocity therein did not exceed 3 miles per hour. On ascertaining really the velocity of streams of water, and comparing the same with theory, see Nicholls's Journal, Bro. vol. iii. p. 52 and 87.

Mr. William Chapman seems to incline to the opinion, that locks may not always be eligible on river-navigations, and says (p. 74) that "during the flooded state of rivers, all small falls are equalized, as they necessarily rise higher below than above a rapid; therefore I am far from saying, that running canals with a small fall are not, in many instances, eligible on the shores of great rivers; and that well devised flops, easily opened and closed, (not such as lift up like the slips described in China, nor open against the stream as gates,) are not sometimes preferable, to impeding the fall of the locks. In other nearly similar instances where locks are eligible, their piers and gates alone, will be sufficient without any other floor or tide walls, than a concave and battered pavement, continued through the bottom and up the sides of the space between the piers. The eligibility, and the particular construction of these works, will much depend on the nature and extent of the beds of the rivers, the difference between their low and flooded flats, the height and also the permanency of their shores, and the quantity of floating ice.

The greater number of rivers through which new navigations are now required to pass, will be found occupied by mills, at shorter or longer distances from each other, according to the fall of the water in most instances; at the tail of most of such mills, will be found a large and deep pool, which the fall of water from the mill-courses and flood-gates has torn and excavated, and a short distance below this pool a shall or bed of gravel. or other materials, will in general be found, that would prove so expensive to remove, and would in general be so subject to accumulate again by a further excavation of the pool from the increased fall of the water into it, that it will in general be the cheapest and most effectual way to begin a new cut for the navigation below this flood, and continue the same up by the side of the pool to the bank of the mill, wherein a pound lock must be constructed, either of timber or masonry, for gaining the ascent to the mill-dam or upper pound. In rapid rivers subject to great floods, the utmost care and attention of the engineer to the construction of such works will be necessary, to prevent their being demolished by the flood perhaps after their erection. Where mills do not intervene, and rapid and of course shallow places occur in the bed of the river which is to be made navigable, a side-cut must be begun from above such shallow, and if practicable at the beginning of a considerable bend of the river which the side-cut may cut off and shorten; in continuing this side-cut downwards towards the place where the lock is to be placed, and the junction below the same is to be formed with the river below the shallow, care must be taken to conduct the side-cut, which is to be upon a level as far as the lock, as soon as possible across the flat meadows to the borders of the high ground, where it should skirt, to the summit of the lock; this is practicable, on account of the width of the meadows, otherwise a counter-drain or parallel cut must be taken up from below the lock, as far as is necessary, on the land side of the side-cut, to drain off the water, and prevent a swamp or pond being formed above the lock and between the side-cut and the high ground, as is almost invariably done by the ancient mill dams on most rivers and streams: it is, however, with the utmost care and precautions that the counter-drain should be adopted, otherwise, in time of floods, when the meadows are overflowed, such a current would rush into and down the declivity of the counter-drain as to endanger the bearing thereof, and of the bottom and sides of the cut or bed of the river, into which it vents below the lock. We have seen large and expensive sluices erected upon and near to the vent of counter-drains circumvented as above, of greater height than the top of the floods, which were found necessary to be built, and kept shut on the approach of a flood to prevent the action of the counter-drain, until the flood had subsided so far as not to overflow the meadows adjoining the counter-drain. Across the bed of the river at the most convenient place below and near the upper end of the side-cut, an opening-weir must be constructed, by which the water in the river can always be kept at a proper height for covering the shallows and bed of the river, and to a proper depth for the navigation; several of these opening-weirs have within these few years been constructed on the Thames, one of which near Windsor has been described and drawn by Mr. Zach. Allnutt in his Considerations on the left Bank of improving the River Thames, 1807, p. 22. It consists of several strong piles or posts driven firmly into the bed of the river at 20 to 25 feet apart, in a straight line across the river: the intervals between these piles are driven and nicely filled up with lug-piles, or dovetail piles, as before described in this article; these last are afterwards faced off straight and even with the bottom of the river, and have a strong and found nail nicely fitted and spiked on to them, and into each of the large piles at its end; by this means the water is prevented from leaking or making its way, except through the rectangular openings between the several piles, which should be as least as high as the highest floods, and have their tops connected by strong crofs pieces of timber bolted on to them: these crofs pieces, and in the fill below, a number of holes are prepared for placing at equal intervals as many upright pieces of wood, called timbers, with rebates in their sides, for
for temporary gates to slide down in, and refill against; after these riners are put in, a sluice or gate, with a tall handle to refill against the upper, or crost piece, is put in between each riner; and, above these, another set of gates, called overfalls, with similar handles, are fitted, to be occasionally used in dry seasons, when none of the water is to be suffered to escape, except by the tide cut and lock-paddles. In time of floods, all these gates, overfalls, and timers, are taken away, by persons who go in a boat for that purpose; which operation, we are told, can be performed in three hours, and the water is suffered to take its free course through the openings: the water subdues, a few of these gates are put in at a time, leaving the water its course through the others, until all of them are in, when on any small fall of the water, the same falls over the tops of these gates into the bed of the river below; when a greater depth of water is wanted above, the overfalls or upper gates are faced directly put in upon the others; these fall being of such a height that the water can fall over their tops before it would overflow the meadows in case of its rising, and the men not attending or being expeditions enough in taking away the overfalls, and then the gates, if the proper rise of the river should need it necessarily. Mr. J. Rymer in his report before quoted, page 316, has given a plate of a weir of this fort for a river, which is called a gate sluice, with 17 gates, but we have looked in vain for any description or account thereof in his volume. In the Thames and several other rivers, Jetters, or Weir-bridges have formerly been made, for diminishing the width of the river below the several shoals, in order to make a deeper but narrower and more rapid current over the same, as is done, we are told, on the China canals; but the rapid and dangerous currents which these and the under-water weirs occasion, particularly in high water times, have been so justly and loudly complained of, that we trust the same will, ere long, give place to the side-cuts, pound-locks, and opening-weirs, above described. The principles on which jettries are made to raise the water in rivers, and the mode of calculating their effects may be found in Nicholson's Journal, Svo. vol. ii. p. 35.

For improving the navigation of rapid, confined, and variable rivers, like the Severn, Mr. Thomas Telford, in 

Plymley's Report, p. 187, has recommended the deepening of the lower part of the bed of the river in the shallow places, in order to equalize the declivity and current of the river: a very experienced engineer has suggested, that deepened shallows, without jettries or similar constructions, would soon be again filled up in many places. In the higher parts, Mr. T. proposes to erect solid and durable weirs of masonry across the river upon the shallow places, with side cuts and pound locks by the side of them, for the navigation; and the river when thus directed may, as he justly observes, be applied to many important purposes of machinery, and for irrigating of the meadows, which would thus be brought within its reach. There is no doubt but this method is practicable, and would ultimately answer well; but the expense would be very great of erecting substantial weirs, and making the banks of the side-cuts, and walls, and gates of the locks, high enough to prevent the floods from breaking over into them, a condition which seems necessary, if barges are to be able to proceed at all times, the towing-path should also for the same purpose be made up with a regular sloping bank next the river, presenting no inequalities or projecting objects to catch or wear the towing-lines, so that its top or path shall be always above water. On a river which rises 16 or 17 feet or more, these works would be attended with a most tedious expense and difficulty, particularly where cliffs rise almost perpendicularly up from the bed of the stream. Machinery on such a stream, unless great expense indeed was incurred to obviate it, would be subject to have its work interrupted by every large flood: the working of barges on a river with such cuts, locks, and towing-paths, as we have mentioned, would be attended with considerable difficulties; tall masts must be used for attaching the towing-line in dry times to bring the hou on a level, or nearly with the barges, and in floods it must be fixed lower down, or to a shorter mast; and, in such cases, the utmost care might not always be able, where the works are necessarily confined by rocky banks, to prevent barges from sometimes missing the entrance of the side-cut, and being precipitated down the current over the weir, and being sunk. A towing-path, locks and banks of a level height, so that the floods would frequently cover them, besides their being totally useless in such times, would be liable to be damaged and washed away, (unless constructed in the most careful and expensive manner,) and the cuts and locks to be filled up in a great measure by land, or gravel, in rapid rivers.

Mr. William Reynolds gives an example which has since been followed, on a great length of the Severn's bank, of constructing a towing path for barges, instead of the devious way over projecting rocks, hilly lands, mud, and every other obstacle which the men who used, from time immemorial, to perform the flave-like office of hauling the barges along, were obliged to travel: we are not acquainted with the height of these new towing-paths, or whether they are at times, and how frequently, covered and useless by reason of the floods. Mr. Allbutt informs us, that one horse commonly tows a barge of 130 tons burthen down the Thames above Richmond, at the rate of two and a half miles per hour. While on the running canals of China, or George Staunton observed a boat of a light construction, with only 1.4 tons lading, of eight feet width of floor, about 10 feet width of water-line, and 50 of extreme length, drawing two feet three inches of water, and sharp at the ends, dragged against a stream whose whole velocity was 54 English miles per hour; and, although there were 28 trackers, or men hauling at the hou fastened to the boat, besides three men in the boat pulling it on, it advanced only at the rate of 4 of a mile an hour; although the channel was not materially constructed in either width or depth of water-way, in proportion to the section of the boat. Mr. Thomas Telford has (p. 288.) proposed another method of improving the Severn river, by collecting the flood waters into reservoirs, the principal on of to be formed among the hills in Montgomeryshire, and the inferior ones in such convenient places as might be found in the dingles, &c. along the banks of the river. By this means, the injuriousness of the floods might be greatly lessened, and a sufficient quantity of water preserved to regulate the navigation of the river in dry seasons, and likewise to answer many other useful purposes, such as the forming ponds for inland fisheries, the supplying of artificial canals, and the watering of land. This, it is thought, might even prove the simplest and least expensive mode of regulating navigable rivers, especially such as are immediately on the borders of fully countries." An engineer of the first reputation in his profession (Mr. Rennie,) intimates, that after what has been said respecting the extent of flood water in the river Roch above the ordinary supply, the idea of correcting the floods of the Severn by reservoirs, must appear to be ridiculous. Mr. William Jeffery, on another occasion already referred to, says, that the rivers may be rendered nearly uniform throughout the year by reservoirs.

The old clumpy stone or brick bridges upon rivers are a very principal interruption to the navigation thereon, by preventing the continuation of the towing-path in a place where it generally took effort to surmount the rapid fall occasioned by the contracted water-way under the

bridge;
bridge; the masts of vessels are also obliged to be struck. These
circumstances recommend the more general imitation of the
spirited individuals near Coalbrookdale, who have erected
two iron bridges over the Severn, which, single and capa-
cious arches remedy these evils. We have already spoken
of them under the article Bridges, and in the present one, and
therefore proceed to the only remaining subjects that at
present occur to us, relating to the deepening of rivers: the leav-
ing of boughs, or taking up of sand, gravel, or other loose or soft
matters from the bottom of rivers, is usually performed by a
strong pole, having a flat ring or hoop of iron fixed on its end,
to which a strong leathern bag is fastened, like what is called a
landing-net among fishermen; or for taking up gravel only,
a fine and strong net is used instead of the leathern bag; the
edge of this hoop is made sharp, so as to strike into the bot-

Canal.

Pressing the method of arrangement, we found it in
expedient to follow those who have attempted to give an ac-
count of some of these concerns, in the order of time in which
they were projected or begun; because so many of them, in
distant places, were projected at the same periods, while some
were quickly begun and completed, and others re-
mained a great while in hand.

The great length of force of these works or undertakings,
the thrifts of others, their various directions and their ge-
neral and multiplied interections with each other, rendered
any geographical arrangement of them, as from north to
south, or otherwise, equally difficult and improper. We
thirll, therefore, that our readers will approve of the plan
which we have adopted, of giving the whole of these un-
terakings, rivers, canals, railways, &c. in one alphabetical
series, arranged according to the incorporate or parliamentary
name of each, where the same are under special acts of par-

Aberdare Canal. This undertaking was begun under
an act of the 3d of Geo. III.; its general direction (begin-
ing at its lowest end, as we shall always do in these descrip-
tions) is about N.W.; it is 7/4 miles in length to Aberdare,
hence an extension thence, in nearly the same direction, by a
rail-way for 1/4 miles further; it is in latitude in the county of
Glamorgan in South Wales, and is not far from the sea-coast,
very greatly elevated above the same. The great coal and
iron mines, and works near Aberdare, Fermo Vaughan, &c.,
with its principal objects, begins in the Glamorgan

Aberdeenshire Canal. Acts 56 and 41 Geo. III.—
The general direction is about N.W. for 19 miles in length, in
Aberdeen county in Scotland; it is near the sea-coast, and is
greatly elevated in any part; the principal objects seem the
supply of the town Aberdeen, the exportation of granite stone
from the famous quarries on its banks, and to form a communi-
cation between the harbour of Aberdeen and the vales of the river
Don. It begins in the tide way in the Dee river in Aberdeen
harbour, and follows the course nearly of the Don river,
in which it terminates at Inverury bridge; and passes the pa-
rishes of Old Machar, Newhill, Dyce, Kirmelady and Kin-
tol.
The river is 170 feet by 17 locks; the width of the
canal is 20 feet, and depth of water 14 feet. The harbour
of Aberdeen, (connecting with the Dee river near its mouth,
at the S.E. end of this canal), was surveyed many years ago
by Mr. John Sawant, and lately by Mr. Thomas Triffor, who
has, in his reports to parliament, recommended making
it capable of receiving ships of 14 or 20 feet draught of
water. It appears that this canal was completed and opened
in June 1807. The company might by the first act raise
50,000l. shares 50l. each; and by the 2d act 20,000l. more
might be raised on 20l. shares, bearing 5 per cent. interest.
Half-mile locks to be erected. Pleasure-boats of twelve
feet long, and four broad may be used on the ponds.

**ADUR RIVER.**

The general direction of this river is nearly
east for 13 miles in the county of Suffox: its objects
are the import of coals, deals, &c., and the export of
farming produce. New Shoreham and Steyning are
considerable towns on or near it. It commences in the sea at
Southwick below Shoreham harbour, and terminates at
Bines-bridge in Welf-Grinstead. In September 1807, notices
were given of the application for an act for extending
this navigation from Binesbridge to Baybridge in Ship-

**Alford and Wainfleet.** In July last (1803) a survey was
ordered for an intended canal from Wainfleet haven to the
town of Alford, the general direction of which line is nearly
north, and about 12 or 13 miles in length, in the county
of Lincoln: this line is near the coast, and seems but very
little elevated above the sea: its principal objects from the
supply of Alford, and the export of husbandry produce: it
is proposed to pass the town of Burgh. Wainfleet
haven is said to be a very good harbour for trading ships.

**ANCOLME NAVIGATION.** Act 42 of Geo. III. — The
general direction of this navigation is nearly north: it is al-
might straight (except the last four miles), and about 26
miles in length, in Lincolnshire. It is situated within
15 or 20 miles of the coast, and runs nearly parallel thereto
through towns and level grounds for great part of its length.
Its objects, besides a better drainage of the sea fens by a wide
and straight cut, instead of the old course of the river
Ancolme, seems the supply of Market-Raisin of
and of Cailor (by means of the Conflar canal, which joins it
at South Kelsey), and the export of husbandry produce.
It begins in the tide-way in the Humber river near Wintrin-
gham, and extends to the town of Market-Raisin, passing
near the town of Brigg.

**ANDOVER CANAL.** Act about the 50th of Geo. III.
Its general direction is nearly north, and pretty straight,
following the course nearly of the Aton river (which is na-
vigable to Runyem) for 22° miles in length, in Hamp-
shire; it is near the coast, and not very greatly elevated
in any part above the level of the sea. Its principal objects
seem to be to supply the country, and to export its surplus
of farming produce. It connects with the Southampton and
Suflbury canal, the latter entering it at Red-bridge, and leav-
ing it again at Kimbridge mill. The town of Southampton,
being its fourth end, is the 6th in the order of British
population, having 7,915 inhabitants. This canal begins in
the tide-way in Southampton-water at Redbridge, and termin-
ates at Barlow's mill near the town of Andover; the
towns of Runyem and Stockbridge being on its course. Its
rise is equal to 176 feet, and it is fed at its upper end
from Pilhills brook. This line was surveyed by Mr. James
Brindle in the year 1770, and an act proposed, but the
opposition of the land-owners prevented one being ob-
tained, until it had been again surveyed in 1789, by Mr.
Robert Whitehough; in a few years after which it was com-
pleted for use.

**Ashtow and Ouse.** In 1799, Mr. William Chapman
surveyed the vale of the Ouse river in Ireland, and recom-
mended to render the improvement of Ashtow harbour,
which was then intended, more beneficial to the adjacent
country, by connecting therewith a system of small canals in
the rapidly ascending vales of the Ouse, by rising 70 or 75
feet at once in proper places, by some of the substitutes for
locks, of which we have before spoken.

**ARUN RIVER.** This navigation has nearly a north di-
rection for 15 or 16 miles in the county of Sussex. To sup-
ply coals, and export farm produce, from its principal ob-
tects; which are facilitated by the Arundel canal, that joins
it near Stopham bridge, and would be further accomplished,
were the Sury iron rail-way extended to it at Wilborough-
green bridge, as was proposed in the year 1801. It pro-
cceeds from the sea at Arundel haven to Wilborough-green
bridge, paffing the town of Arundel in its course.

**ARUNDEL CANAL.** Act 31 of Geo. III. — The general
direction is west for about 11 miles, following the course of
the river Rother, in the county of Sussex. It is about 12
or 13 miles from, and nearly parallel to, the sea coast, above
which it is but little elevated. The supplying of the inhabi-
tants with coals, and exporting of husbandry produce, from
the principal objects of this canal. It commences in the
Arun river near Stopham bridge, and terminates at the lower
plats near Midhurst, with a side cut of about one mile in
length to Haslingbourn bridge in Petworth parth. The
line being through the parishes of Stopham, Coldhawtham,
Burley, Fittleworth, Erqdon, Coates, Sutton, Petworth,
Dunfton, Burton, Tillington, Lodworth, Selham, Arundel,
Eafebourn, Woolavington, and Midhurst. This canal is the
property of that public spirited nobleman the earl of Egremon,
but open to the use of the public, on pay-
ing certain specified tolls.

**ASHBY DE LA ZOUCH CANAL.** Act 34, Geo. III. — The
general direction of this canal, though in a serpentine
course, is nearly north, 40 miles in the counties of War-
wick, Leiceliller, and Derby. It commences near and
almost upon the grand-ridge on its eastern side, and near its
other extremity is tunnelled through a yet higher side-branch
of the great ridge. The conveying away of the coals and
lime-stone from this last ridge, and the supply of the towns
on its borders by means of the Coventry canal, with which
it connects, are its principal objects. Coventry, which is
near it, is the 24th town for population in Britain, having
16,054 inhabitants; while Hinckley, which is upon the line,
has 5,970 persons, and is the 120th in order. Market Bof-
worth and Ashby-de-la-Zouch are other considerable towns
near or on the line; the commencement of which is at
Marston bridge near Nuneaton, on the Coventry canal, and
the termination is by a rail-way (of 32 miles) at Ticknall line-
works; there also is a rail-way branch of 62 miles to Cloud-
hill lime-works; another to Mr. With's Nenham colliers
of 3 miles: a cut of 24 miles to Swadlingcote coal-works;
another of 2 mile to Staunton lime-works; another is to be
made to Staunton-Harold park (if desired by the earl of Ter-
ers, the proprietor thereof); and there is another short cut of
200 yards to Hinckley wharf. The first 33 miles of this ca-
nal are level, extending to Oakthorpe engine on Ashby woulds,
and forming with parts of the Coventry and Oxford canals,
a level of 73 miles in length, being, without the branches, the
longest in the United Kingdoms, and rendered more singular
by being on so high a level, as to crofs the grand ridge with-
out...
CANAL.

out a tunnel. From Oakthorpe engine to the Boothorpe feeder, 13 mile, is a rife of 140 feet, thence the summit-level of 44 miles extends, through the principal tunnel to its north end; thence to the Cloudhill branch, 1/2 of a mile, is a fall of 84 feet, and thence to Ticknal works is it level. The Cloudhill, Swadlingcote, and Hinckley branches, are level with the line, and the Staunton branch falls 28 feet therefrom. On this canal are two tunnels, one near Althby de-la-Zouch town of 700 yards in length, and the other near Snarlon of 200 yards. At Shackerston and at Snarlon there are aqueducts; and at Boothorpe a refervoir with a steam-engine for pumping up its water into a feeder for the summit-level of the canal. The rail-way branches, and some part of the canal were completed previously to May 1802, but it was not until about May 1805, that the whole of the line was completed and opened. The company were authorized to raise 200,000l, the amount of shares 100l. each. Public wharfs are provided on Althby wold, and at Green-hills near Sutton Cheney. Sir George Beaumont, the owner of collieries at Coal-Orton, to which rail-ways had previously been made at great expense connecting with the Leicifter navigation, is to be compensated, and the company may purchase certain annual quantities of his coal for such purpose. This company is also bound to indemnify the Leicifter navigation, and to allow them a rate of 26. 6d. per ton on all coals carried upon this canal or its branches beyond a certain point from the coal-pits in the neighbourhood of their water-levels or rail-ways. To the Coventry canal company they are also bound to pay 5d. per ton for all coals, and some few other articles, which pass upon any part of this canal or its branches, and afterwards upon any parts of the Coventry, the Oxford, or Grand Junction canals, or from either of those canals to this: and for duly enforcing this half compensation, the Coventry company are authorized to erect toll-houses and bars, and station their own collectors when and where they may chuse upon the works belonging to this company. The rates of tonnage allowed, vary from 2d. to 2½d. per ton per mile on different goods, while some articles are to be allowed to pass toll free. Our limits will not allow of stating these particulars, which will be found in Phillips's History of Inland Navigation, 4to. Appendix, p. 128. In June 1795, a survey was made by Mr. Whitworth for connecting the north end of this canal, by means of the proposed Commercial canal, with the Trent and Mersey and the Chelfer canals, and opening the long wihed for communication between London, Hull, Chelfer, Liverpool, Manchifter, &c. for river-boats of 40 tons burthen. In consequence of the failure of this scheme, in the January following, it was proposed to extend this canal to the Trent at Burton, and to the Trent and Mersey at Shobnall.

Avon River, (Bath.) The general direction of this navigation is about S. E., in length 26 or 27 miles, by a crooked course in the county of Somerset, and skirting that of Gloucester: it opens into the Severn river, and is most of it a tide-way. The objects of this navigation are as various, as the imports and exports of such large places as Bath and Bristol, and a populous neighbourhood require; besides its connection with the Kennet and Avon canal, and the other canals therewith connected. The city of Bristol is the 7th place in the order of British population, having 68,645 inhabitants, and Bath is the 12th, with 32,300 inhabitants. The commencement of this river is in the King's road in the Severn river (here about seven miles wide), and its navigation ends at Bath, near the commencement of the Kennet and Avon canal. About the year 1803, or 1804, an act was obtained by the Bristol Dock company, for converting about 70 acres of the old and crooked course of the Avon into a vast floating-dock for ships, and to cut a new channel for the river. About May 1804, these works commenced, under Mr. W. Jephson, and great progress has been made towards their completion. Two cast-iron bridges are erecting over the Avon near these works; one of them from Clifton-down to Leigh-down will, it is said, be 200 feet high above the surface of the water, and the other sufficiently high for ships to pass under it. That effcctual appendage, a towing-path, was wanting on this river, until the above company was established, who are making one on each side of the river, from Pill up to Bristol, and one thence to Hamburgh mills; from which place up to Bath, a towing-path is proposed to be extended, under an act, for which notices have just been given; this last part of the river is also intended to be improved in other respects. We have, also, lately seen a notice for a further application to parliament by the Bristol Dock company, for erecting a dam and overfall, with sluices, &c. at Red-cliff in Bedminster, to keep up the water for the new floating docks, and for other amendments of their former acts; in 1796 it was proposed that the Kennet and Avon canal should be extended to this river at Bristol. At Bitton below Bath, it was lately proposed, that the Glouceftcr-rail way should connect. In 1792, Mr. Stratford gave a design for a new stone bridge in Bristol of one arch, 150 feet span, and 32½ feet high, which Mr. John Smeaton examined and approbated; and in 1795, the last mentioned engineer gave a design and estimate for a floating dock nearly as above; after which, Mr. Campion made other designs.

Avon River, (Salisbury.) The direction of this navigable river is very nearly north, and its length near 30 miles, in the counties of Hants and Wilts. The general objects of this navigation are the supply of Salisbury, and the adjacent country, and the export of its agricultural produce. Near Salisbury, it connects with the Southampton and Salisbury canal. Salisbury contains 7,668 inhabitants, and is the 7th place in the order of our population; Fording-bridge, Ringwood, and Chrift-Church, are likewise considerable towns on the line. The commencement is at the sea in Chrift-Church harbour, and termination at Salisbury. The locks and works of this navigation had not been long completed, before a sudden flood happened, which swept away the greater part of them; in which state it lay until 1771, when Mr. James Brindley surveyed its course, and recommended a new canal by the side of the river; this was not however adopted, but the river-works have since been repaired; and the imperfection of them, was, we believe, among the most powerful motives for the adoption, in 1795, of the Southampton and Salisbury canal above mentioned. Mr. Smeaton examined Chriftchurch harbour in 1764, and recommended another pier to be built west of the old one.

Avon River, (Stratford.) The general direction of this navigation is about N. E. by a crooked course of near 40 miles in Worceftershire and Warwickshire: the lower end thereof is but a few feet higher than the tide-way. The trade thereon is very various, depending in a great measure on the connection which it forms between the Severn river and the Stratford canal. Tewksbury, Perifore, Exefham, and Stratford, are considerable towns upon it. It commences in the river Severn at Tewksbury, and terminates at Stratford on Avon, near the junction of the Stratford canal. George Perrot, esq. is the proprietor of this navigation, and entitles to certain tolls, which were not to be levied by the new communication with the Severn, which the Worcefter and Birmingham and Stratford canals were to open, but they
they were, by the act for the latter concern (13 Geo. III.), to make good any falling off in their tolls. About 1792, the Stratford and Croydon was proposed to proceed from this river at Stratford to the Oxford canal.

Avon River. The general direction of this navigation is almost S. E. from about 11 miles in length by a crooked course in the county of Somerset; it is but little elevated. Its chief objects are the import of coals and export of farm produce, Axbridge being the only town of any importance upon it. It commences in the Bristol channel near Uphill, and terminates near Axbridge. An act of the 42d Geo. III., passed, for altering and improving that part of it which is between Beydon and Axbridge. At Ilmum the Bristol and Taunton canal was once proposed to join this navigation; as the Exeter and Uphill was designed to do at Uphill.

Axmouth and Langport. In 1769, Mr. James Brinkley surveyed this line, which is nearly north, and about 30 miles in length, in Devonshire, Dorsetshire, and Somersetshire, crossing the south-western branch of the grand ridge. The objects of it seem to have been the supply of coals, exporting the products of the country, and opening a communication between the south coast and the Bristol channel, by means of the Parrett river. Axmiller, Chard, and Ilminster are the principal towns which this line was to approach; commencing in the tide-way at Axmouth, and terminating in the Parrett river at Langport.

Avon and Calder Navigation. Act 9 of 10 of Will. III. The general direction of the Avon river is nearly west, for about 40 miles by a serpentine course, from which the lowest part of the Calder river branches, nearly south-west, by a crooked course of about 15 miles, all in the Weft Riding of Yorkshire. The first of these rivers, though an interval one, begins near the level of the tide-way, and no parts of either of the navigations thereon are much elevated. The objects of this navigation were at first very considerable, in the imports and exports of the populous, manufacturing, and coal country through which it passes, and they are greatly increased, since it has formed part of the grand communications between the port of Hull, or the German Ocean, and the towns of Manchester and Liverpool, or the Irish Sea, by means of the Leeds and Liverpool, Rochdale, and Huddersfield canals, and others joining them. It connects near Saugh with a branch of the Don or Dun river; at Leeds, with some considerable rail ways extending to collieries from the coal-field; near Wakefield it connects with the Barnley canal. Leeds is the 8th place in point of population in Britain, having 51,162 persons, and Wakefield the 6th, with 81,181 persons; Hunslet, near it, is the 10th, with 57,599 persons; Snaith, Selby, and Pontefract, are also considerable places near this navigation, which begins in the Osfer river near Armyn (to which place 50 and 60 tons ships come up), and terminates its north-western branch at Leeds in the Leeds and Liverpool canal, and its south-western branch at Wakefield in the Calder and Huddersfield navigation. It has also a branch of canal about 7 1/2 miles to the Osfer river at Selby, for shortening the distance to York, &c.; and another of 1/3 mile near Matlock, between the Ayre and Calder rivers, for shortening the voyage between Leeds and Wakefield. The boats generally used hereon are 56 feet long, 134 wide, and draw 3 feet water, with 28 tons laden; the 53 boats often go down the Hunter, and round the course of the Welland and Great Ouse river. The proprietors are authorized to exact a high rate of tonnage as 16d. per too in winter, and 15d. in summer, between Leeds and the Osfer. It is provided in the Huddersfield act, 34 Geo. III., that if any communication is hereafter made with that canal to the cayford, the proprietors of this are to be compensated. The opposition of these parties proved fatal, in 1769, to a canal which Mr. Gridley surveyed between Selby and Leeds.

Barnsley Canal. Act 9; of Geo. III. The first part of the course of this canal is south, and the remainder well, about 15 miles in length, in the West Riding of Yorkshire: its western end is considerably elevated above the level of the sea. The principal objects of it seem to be the export of coals and potato-fines, and forming a short communication with Rotherham and Sheffield (by the Dearne and Dod canal, with which it commences at Eyming wood near Barnsley), and Leeds. Wakefield, Halifax, Manchester, Liverpool, &c. Wakefield is the 6th town in the order of population, with 81,311 persons; Barnsley is also a considerable town. This canal commences in the lower part of the Calder river, or Ayre and Calder navigation, a little below Wakefield town, makes a turn when it arrives at the Dearne canal, and terminates at Barnby-bridge near Cawthorn; there is a branch of 2 1/2 miles to Haigh-bridge in Wooley parish, and railway branches to Barnsley town 1 mile, and to Silkhole 1 1/2 mile. From the Calder to the junction of the Dearne and Dod canal, about 9 miles, is a rise of 129 feet; this is effected by three locks together, near Agbridge, having a low level or side-cut brought up to near the upper pound, with a steam-engine for pumping up the water again, which is let down by the lockage; by 13 other locks near Watton, and a long side-cut, from which engines pump up the water to supply the pound above these; and, near Bargy-bridge, by 4 other locks, a side-cut, and engine. On the Haigh-bridge branch there are also 7 locks together, with a low side-cut, and a steam-engine for pumping up the water required for lockage. At Eyin is an aqueduct-bridge. This canal is adapted to the ufe of the same sized boats as navigate the Calder. It is provided, that any railway or turn-roads, that may be made northward from Bargy-bridge (or mill) shall be discontinued or removed, if a cut shall be made from the Calder and Huddersfield navigation, to connect therewith: also, that the steam-engine near Warmfield shall be so contrived as to burn its own smoke, to prevent any nuisance to the inhabitants. The company were authorized to raise 57,000l. shares, 100l. each. This canal was completed and opened 8th of June 1799. The rates of tonnage on different articles are various: some fixed at 6d. to 4d. for the whole length of the canal; and various others at 3d. to 5d. per ton per mile, with several exemptions, rates of wharfage, &c. See Board's History, 410. App. p. 40 to 43. The engineers were Mr. William Jefferys, Mr. William Wright, and Mr. Gell.

Barrow River (Ireland). This is one of the rivers, for the improvement of whose navigation the Irish parliament granted several sums of the public money, between the years 1753 and 1771, amounting to 13,000l. It is probable that less than the half of this amount, raised and expended by individual proprietors, with that circulation which fell interest can alone inspire, would have effected what we are told, this expenditure has left very imperfect. At Portarlington and at Monesteren this river was to be joined by different branches of the Grand Canal.

Basingstoke Canal. This line of canal was first proposed in 1772, as an extension of, or appendage to, the canal between the immediate vicinity of the River Thames, between Reading and Maidenhead; but it was many years before the first act for this was obtained, in 1778; the other act is the 33 of Geo. III. The general direction of this canal is nearly west, by another a crooked course of 37 miles in length, in the counties of Surrey and Hants; the summit-pout thereof of 22 miles in length is upon a high level, near the south-east branch of the grand-ridge on its north side. The principal objects thereof seem the import of
of coals, and export of timber and agricultural produce, from
and to the Thames. Basingstoke and Oldham are considerable
towns on or near its line, which commences in the Wey
river at Welley, (about two miles from its junction with the
Thames,) and terminates at Basingstoke. A cut of 6 miles in
length, and with the summit-pound, was proposed
northward to Turgis Green, but has not yet been begun, as
we understand. The first 15 miles from the Wey river has a
rise of 195 feet by 29 locks to Dabbrook, (the part at each
lock being about 7 feet) from whence to Basingstoke it is
level: 45 ton boats are used on this canal. At Grewel is a
tunnel, part of which interferes the chalk strata, (about 4
mile in length) that had the misfortune of falling in; but the
fame has, we are told, been subitaeniously repaired. At
Alderhot there is a large revoir for the supply of this canal,
(which was begun in 1788 and completed in 1796, at the ex-
pense to the proprietors of 160,000l.) and a feeder from the
river Loden. There are 72 bridges over the canal, and several
culverts across, to convey the water from the upper to the
lower lands. The company were authorized to raise 185,000l.
The price of freight from Basingstoke to Hamborough wharf,
London, for coarse and heavy goods, was, in 1800, 15l.
per ton; to the dockyards, as far as Deptford, 16s. and
to Blackwall docks, 17s. per ton for timber, &c. The
length of a passage is three or four days. In the year 1796
there was an intention of extending a branch from near
Grewell tunnel, of about 22 miles in length, to the naviga-
tion that connects with Southampton water; about 1794
there was an expectation of its being joined by the canal
which will next be mentioned; and in 1801, notices were
given of an intended cut from Chilton-n Moor to Baghot-
green in Windleham; for want of these or other fome other
junctions that shall throw a greater trade into this canal, has,
though improving, been as yet rather unproductive to the
share-holders. In 1800 there was a proposal for extending
the Grand Surrey to meet this canal at the Wey river.
Basingstoke and Hampstead. About the year 1793, a line
of canal was projected, and notices given, extending from the
Basingstoke canal at that town, to the Kennet, and Avon
canal at Hampstead, 2 miles above Newbury, the length of the
line was laid to be 22 miles; we have since heard no-	hing of this scheme.
Belfast to Loch Neagh. This line of canal was be-
gun under an act of the Irish parliament several years ago,
for forming a communication with the sea at Carrick-furgus
Bay and the above inland lake or loch, as also, for export-
ing marble from the quarries thereof near its line.
Belper Canal. In September 1801, notices were given
for a proposed canal, rail-ways, &c. from the Cromford
canal at Bull-bridge, to Black-brook-bridge, through the
parishes of Crick, Heage, Ashley, Hay, Belper, and Duff-
field; all in Derbyshire.
Bingley-and Hertford. Several years ago a proposal
was made, for joining the lea river at Bingley-with the
Lea river at Hertford, by means of a canal passing the town
of Hitchin, by which an internal communication between
Lynn and London would be opened; but the difficulty of
supplying a summit-level near Stevenage with water, teems
a greater obstacle than the expected trade would pay for
surfounding.
Birmingham (old) Canal. Acts the 8th, 9th, 11th,
23d, 24th, and 34th of Geo. III. the last but one of which
acts, unites the concerns of this company with those of the
Birmingham and Fazeley canal below; but as these canals
were constructed and remain under distinct provisions in the
acts, and take different directions from the town of Bir-
mingham, where they meet, we have deviated from our
usual rule and continued them separate in our account. The
general direction of this canal is about S. E. and 32^1
miles in length by a crooked course, through the counties
of Stafford, a detached part of Salop and Warwick: it
forsage near the grand-ridge on its eastern side, at a
high a level as to cross it near its northern end without any
deep cutting or tunnel; and, in that high situation is wholly
supplied by revoirs for fower waters, and steam engines
which pump up the water again, after it has been let down
for lockage, or out of old and difused coal-pits. The prin-
cipal objects of this canal are the carrying away of the coals
from the numerous mines on its banks and branches, and the
manufactured goods of Birmingham to Liverpool, Man-
chester, &c. It connects near Farmer's bridge at Birming-
ham, with the Worcester and Birmingham, at Tipton Green
with the Dudley canal, and near Wolverhampton with the
Wyrley and Essington canal. The great towns on and near
the same are, Birmingham, the 6th in the order of popula-
tion, containing 735,606 inhabitants: Wolverhampton, the
33d, with 12,565 persons; Walfal, the 47th, with 10,390
persons; Dudley, the 97th, with 10,177 persons; and Bil-
don, the 87th, with 6,914 persons: in the centre of so large
and active a population as this, the wonder in a great mea-
sure ceases, that this canal, constructed and carried on under
such peculiar disadvantages, should nevertheless have proved
the most lucrative concern of the kind in the kingdom.
This canal commences in the Staffordshire and Worcesterfield
canal at Aldersley or Authority, near Wolverhampton, and
terminates in the Birmingham and Fazeley canal, at Farmer's
bridge, near the upper end of the town of Birmingham, the
line being double in two places, viz. at Tipton, where a
tunnel of near 1000 yards, and a canal of 11/4 mile in length,
between Bromfield and Deepfield has been made since
1794, for avoiding a zig-zag loop round Tipton hill, of 4
miles; also at the Smithwick locks, where two canals with 3
locks on each have been made, since 1757, for accommodating
the immense traffic which is hourly passing. The collateral
cuts are very numerous, the principal one extends from near
Bromwich to the town of Walfal, by a crooked course of
64 miles; from this branch nine or more branches strike off
to as many coal-works, &c. on each side of it; the termi-
nation of some of these, near Wednesbury town, at
Bowlfad's Broad-water engine, Toll-end, Bradley, Bilston's
Ram-farm, and other coal-works: the lengths of all which
are several miles. From the line there is also a cut of about
one mile, to Oker-hill coal works; another to Meffis.
Bolton and Watt's famous Soho foundery, and another to
Newhall-ring bafon and wharf in Birmingham. In the first
mile and three quarters, the rise from the Stafford and Wor-
cester canal is 151 feet, by means of 20 locks, then 184
miles are level; a descent of 18 feet then takes place, by 3
locks (on each of the two branches before-mentioned); the
remainder of the line about 43 miles is level, to the junc-
tions of the Birmingham and Fazeley and the Worcester and
Birmingham canals at Farmer's bridge. The Walfal branch,
where it leaves the line, has a fall of 18 feet by means of
3 locks, and about two miles further near Rider's green,
a further fall of 48 feet by 6 locks, whence to Walfal is level;
the Toll-end branch has a rise of 15 feet by 3 locks, and
the Bradley of 20 feet by 4 locks, all the other cuts being
level. This canal was originally cut 28 feet wide at top, 16
at bottom, and 43 deep; but by constant wear and widen-
ing it is now 40 feet wide at the top on the average. The
locks are 70 feet long and 7 wide in the clear, and the boats
carry about 22 tons. At the coal-works near Farmer's bridge,
and at its side cuts, 40 boats can unload at the same time;
the Newhall-bafon of 2 acres, is for the unloading and loading
of timber, stone, slates, and general merchandise, no wharf-
age is charged at either of these wharfs. Originally, there
was
was a summit-level on the line of about one mile in length at Smithwick, 18 feet higher than a precedent, (of which 1000 yards were deep-cutting 48 feet in the deepest part) and it was supplied until 1787, by a steam-engine at each end; and, when, owing to the increasing trade, this summit was cut down, and 6 locks removed, making the deep-cutting one mile in length, and 46 feet deep in one place; and though this work was 2½ years in hand, and cost £5,000, yet it was so managed, that the passage of boats was only 14 days interrupted thereby. There is a considerable reservoir near Oldbury, and another near Smithwick, with feeders for conveying their waters into the summit level. The celebrated Mr. James Brindley was the original engineer, and on the 6th of November 1769, he completed 10 miles of the line and branches next Birmingham, by which coals were first brought by water to that great town from near Wednesbury, and their price to the inhabitants was lowered at once from 1½s. and 1½s. to 7½d. per ton! In October 1772, the line was opened, and in June 1799, the Walsall branch was completed. The proprietors were authorized to raise £115,000 before the consolidation of this and the Birmingham and Fazeley concerns. At first the shares of these were 100l. each; but were by the second act 9th Geo. III. reduced in number and made 100l. shares; those created since the 24th Geo. III. are 170l. shares. The original tonnage on all goods, (excepting lime-flour) was 1½s. per ton per mile, and for lime-flour and lime, 3½d. per ton, except for manufacturing the lands of the adjoining proprietors, and road materials were allowed towards toll-free; but the subsequent alterations in the several acts since would much exceed our limits to mention, those who are curious of further information will find it in Mr. John Cary's Island Navigation, 4to, pages 36 to 45. By the Dudley act, 25th Geo. III. this company are entitled to certain tolls on goods passing on or off of that canal to this; and, by the Wyre and Eflington act (32 Geo. III.) to other rates for the junction therewith; all which may be seen as above. About the year 1790, a cut was proposed from this canal (instead of the Dudley junction) to Netherton colliers 12½ miles, by a tunnel through the grand-ridge near Oldberry, of 2,078 yards, and 184 feet under the hill: in 1796, a foundery and large works belonging to Meffrs. Bolton and Watt, were erected on the banks of this canal 5 miles from Soho. This canal extending across a country full of coal, it was apprehended that the fining of the old pits might damage the same, and the company have power to enter and examine mines to prevent their working within 12 yards of the canal, except by passages of 4 feet wide, and 6 feet high; for want of more strict attention to this, some of the branches near Wednesbury have been undermined and broke into, so as to caufe the canal to be abandoned in that part. From some of the old worn out coal-mines shafts near Billitone, a lambent blue flame arose in the night, of which a great deal has been said and written. Probably from the carbon in these yards of this canal, or its branches, may make coal wells thereupon.

BIRMINGHAM AND FAZELEY CANAL. Acts 23d, 24th, 25th and 34th of Geo. III.; the second of these acts is for confolidating this concern with the old Birmingham above; but each part of the canal remains subject to its own original regulations, as above observed, and the last but one is for confolidating ¼ of miles of the Coventry canal herewith, subjéct to the original powers of the Coventry act (8th Geo. III.) under which it was first out and made. The general direction of this canal is S.W. exclusive of the late Coventry part, which lies in a direction between N. and N.W. from the original termination at Fazeley: the length of the whole is 204 miles in the counties of Stafford and Warwick: the whole of this line of canal is considerably elevated, but particularly the S.W. end in the town of Birmingham, which is situated near the grand-bridge on its eastern side. The great objects of this canal are, the export of the manufactures of Birmingham towards London or Hull, and of coal; the supply of grain and other articles to Birmingham and its populous and busy neighbourhood; it connects with the Wyrely and Eflington canal near its commencement at Whittington-bridge, with the Coventry at Fazeley, with the Wharf and Birmingham at Dibeth, and with the Warwick and Birmingham canal near its termination at Farmer's bridge. Birmingham, as before observed, is the 6th British town, with 73,670 inhabitants, and Tamworth near the line, is a considerable place. The commencement of this canal is in the detached part of the Coventry canal, at Whittington-bridge, and its termination in the old Birmingham canal at Farmer's-bridge at the top of Birmingham town. From the N.E. entrance of the town of Birmingham, a branch skirts the town to the lower part of it called Digbeth, and there connects with the Warwick and Birmingham canal. From the detached part of Coventry canal at Whittington-bridge, to its junction with the line of that canal at Fazeley, and thence palls the small aqueduct bridges near Middleton-hall, about 8½ miles are level with the Coventry canal; from thence to the aqueduct bridge over the Tame river at Salford, 10¾ miles, has a rise of 50 feet by 14 locks, thence to the Digbeth branch, near 12½ miles, has a rise of about 71 feet by 11 locks; thence to the old Birmingham canal at Farmer's bridge, about 12½ miles, is a rise of about 85 feet by 13 locks; the Digbeth cut, of about 11 mile in length, has a fall of 40 feet, by 6 locks to the Warwick and Birmingham canal. The width of this canal is about 30 feet, and its depth 2½ feet. The locks are 70 feet long and 7 wide in the clear, carrying boats with about 22 tons of lading. There are a wharf and baston at Dibeth for the accommodation of the lower part of Birmingham. The Salford aqueduct bridge has 7 arches over the Tame river of 18 feet span each. The Digbeth cut is tunnelled or rather arched over in the town of Birmingham; there is also a short tunnel on the line where the Liverpool road croffes. The Coventry company being unable for want of money to proceed with the essential part of their line, between Fazeley and Fradley, where it joins the Trent and Mersey canal, the latter company for the sum of 500l. over and above the actual expences, undertook to complete this length, by agreements of the 29th October 1783, which the act (of 23d of Geo. III. above) confirmed; this they accomplished, the half year after Fradley in January 1787, which the Coventry company in Oct. 1787, purchased of them, agreeable to the 23d Geo. III. (which occasions them now to have a detached length of canal); the other half, between Whittington-bridge and Fazeley, was completed in October 1789, and on payment of the colt thereof by this company, it was conveyed and made over to them, agreeable to the act above quoted. On the 12th of July, 1792, the aqueduct bridge at Salford being completed, as well as the line of canal, the same was opened, and the water communication between Birmingham and Hull or London, was thereby effected. The sums of money to be raised for this canal, were not distinguished in the acts from what was intended for the extension and improvement of the old Birmingham canal, the amount of each share was £170; but the act 24th Geo. III. limited the number of shares to 500, they feem now to be variable. The rates of tonnage are too complicate for us to attempt their particulars, and we must refer the readers to J. Cary's Inland Navigation, pages 40 to 44, and pages 75 and 77. By the Warwick and Birmingham act (32d Geo. III.) certain duties are secured to this on goods passing from or to that canal, which may be seen in Cary, page 44. It is provided that
that the tonnage per mile on coals, is to be the same on this and the Coventry and Oxford canals.

Bishophportford and Cambridge. In the year 1785 Mr. John Phillips, in a quarto treatise, recommended a line of canal from the Stort river, at Bishophportford, to the Cam, at Cambridge, either by way of Littlebury and the Granta river, or near to Royston by the upper part of the Cam; which might be done, he says, for little more than 20,000l. but no levels, or other essential particulars are given; nor do we hear of any such, when Mr. R. Dodd again revived this idea in 1851, and wished to make this line part of his North London canal.

Bishophportford to Wilton. In 1780 Mr. John Ronnie was employed by several gentlemen of Elles to survey and report on a line of canal from Hifs, near Wilton, on the Brandon or Little Ouse river, at the edge of the fens in Suffolk, to the Stort river at Bishophportford; the distance from the little Ouse to Ugley, the beginning of a proposed tunnel (of 2 of a mile) near Eppingham, 43 3/4 miles, with a rise of 25 1/4 feet; thence to Fuller's-end, near Eppingham, 24 miles, and level; and thence to the Stort at Bishophportford, 44 1/4 miles with 83 feet fall; a cut was proposed to Darwell on a branch of the Cam river, and it was to cross the Lark river. Several large reservoirs were designed, and three tunnels, two of them being necessary to reach the town of Saffron-Walden, and to make Audley park. The estimate was 175,000l. and a bill was brought into parliament, in 1790, for the same, but it there met a fatal opposition.

Blackwater Navigation (Ireland). This river falls into Loch Neagh, and for extending a navigation therefrom to the Dungannon and Tyrone collieries, the Irish parliament, between 1753 and 1770, granted various sums of the public money, amounting to 11,000l.; a canal with 8 locks, terminating in a basin, was constructed before Mr. Davis Du-kart the engineer was employed thereon; who, finding the three miles with 200 feet rise, which remained to do to reach the Tyrone collieries, to be too great for a canal with locks, he contrived, about 1776, four water-levels, with three inclined-planes, of 70, 60, and 50 feet rise; to connect them, on which small boats were made to ascend and descend, as we have already mentioned, these being the first inclined-planes for boats brought into use in the United Kingdom; it appears, however, that these were soon laid aside in this place, and a railway was substituted. This navigation was intended to connect with the Newry canal.

Blyth River. This river, between Northumberland and a detached part of the county of Durham, appears to be navigable but a small distance above Blyth harbour; but we understand it has several considerable railways connecting with it, for bringing down the produce of the collieries to the shipping.

Boyne River (Ireland). This is one of the rivers on the east coast of Ireland, for which the parliament, between 1768 and 1771, granted 9,507l. for improving its navigation. At Edenderry it was proposed to be joined by a cut from the Grand Canal.

Bradford Canal. Acts 11 and 42 Geo. III. The general direction of this short navigation is south nearly, and 3 miles in length, in the Welf Riding of Yorkshire. It is not considerably elevated; its objects are the export of coals, iron, and flone, the produce of the neighbourhood of Bradford, and the supply of Bradford town, which is the 95th in the series, with 6,593 inhabitants. It commences in the Leeds and Liverpool canal at Wibsey, in Idle parish, and continues to Bradford, where railways of considerable extent connect with it, one of them goes to the collieries and iron-works on Wibsey Slack; and the descent is so steep that the waggons run down without horses, having their velocity regulated by a man who rides behind and uses the convey or brake upon the wheels, as occasion requires. From the Leeds and Liverpool canal to Bradford is a rise of 51 feet by 7 blocks; the width of the canal at top is 24 to 32 feet; and its depth is 5 feet; the locks are of the same width and length as those of the Leeds and Liverpool canal. The company were empowered to raise 600l. in 100l. shares. Boats passing the whole or any part of the distance on this canal are to pay 6d. per ton for clay, bricks, stone, coals, lime, dung, and manure; and 1d. for every ton of iron, timber, and all other goods. This canal was finished in 1774. The last act was found necessary, in order to make good the title to those lands which had been long before purchased for the works.

Brecon and Abergavenny Canal. Acts 33 and 44 of Geo. III. The general direction of this canal is about N.W. 33 miles in length, in the counties of Monmouth and Brecknock in South Wales; it begins a few miles from the coal, and soon after comes near and follows the course of the Usk river, no part of it being very greatly elevated. Its objects are the exportation of coals, iron, and other mineral products of the country round Abergavenny, by means of the Monnowshire canal, and the supply of Pontypool, Abergavenny, Crickhowel, and Brecon towns, that are near its course. It commences in the Monnowshire canal, 1 mile from Pontypool, and terminates at the town of Brecon; it has several railway branches: viz. to Abergavenny 1 mile; to Wain-Dew collieries and iron-works 44 miles (near 24 miles of this last being double on each side of the brook); and, to Llangroin 14 mile. From the Monnowshire canal, the first 14 miles are level, 7 miles above the Abergavenny branch, thence to Brecon is 18 1/4 miles, with a rise of 68 feet. Near its commencement it crosses the little river Avon, on an aqueduct, and shortly after passes a tunnel of 220 yards in length. The engineer is Mr. T. Dastford jun. - The Wain-Dew rail-ways, and the canal above them, up to Brecon, appeared to be finished in June 1822, and by this time we expect the whole is completed, or nearly so. The company were at first authorized to raise 150,000l. and a further sum by their second act, shares 100l. each. The rates of tonnage are to be the same as those on the Monnowshire canal, which fee in J. Phillips's History, 450. App. p. 18. Horses, mules, and asses are to pay 1d. and cows, sheep, and cattle 1d. each at certain toll-gates on the rail-ways. The Monnowshire canal, on account of the great benefit this will confer on it in tonnage, agreed to pay this company in March 1794, the sum of 35,000l. In May last (1802) it was proposed to extend a railway branch from this canal to connect with the river Wye.

Brecon Railway. About the year 1793 it was in contemplation to make a railway and canal from the famous lime-works at Brecon to the Trent river, opposite to Welton Cliff; and in consequence, a clause is inserted in the Derby canal act, of 33 Geo. III. binding them to make a cut from the Trent at Welton Cliff to the Trent and Mersey canal, which runs parallel with the Trent, whenever this scheme shall be adopted, in order to give this lime a readyer course into Derbyshire.

Bridgewater's Canal. Acts 32 and 33 of Geo. III., the 2d, 6th, (Trent and Mersey act) and 35th of Geo. III. The general direction of the principal line of this canal is nearly N.E. (and not a great way from its eastern end, a main branch goes off in a N.W. direction nearly); the length is 40 miles, in the counties of Chelten and Lancaster. It begins in the tide-way; above which the whole of it is elevated 24 feet at low-water, except about 600 yards, which the locks occupy
CANAL.

occupy to gain this ascent. The great objects which induced the late excellent and patriotic duke of Bridgewater to undertake and to expend a princely fortune on the completion of this canal were, the supply of the town of Manchester with coals from his collieries near Worsley; the cheaper and more expedient conveyance of goods, between Manchester and Liverpool, than the Mersey and Irwell river navigation then furnished; and between both of these places and the interior and most remote parts of the country, by means of the Trent and Mersey (which it joins at Preston Brook), and its connecting canals. Other and more direct communications have since been made between it and the interior and eastern parts of the kingdom, by means of the Rochdale canal and those connecting therewith. Manchester is the 3d place in Great Britain for population, having 144,000 inhabitants. Liverpool the 4th with 77,057 inhabitants, and Warrington the 45th with 10,567 inhabitants, these towns being near this canal. The commencement of this canal is in the vicinity of the Mersey river at Runcorn-gap, and one of its terminations in the Rochdale canal at Castle Field in the town of Manchester, the other (or Worsley branch) is at Pennington near the town of Leigh, the junction of these branches being at Longford bridge; near Manchester there is a communication with the Mersey and Irwell navigation, and Manchester Bolton and Burley canal, by means of Medlock brook. Under the town of Manchester are arched branches of the canal of considerable length, from one of which coals are hauled up by a coal-gin, through a shaft out of the boats below, into a large coal-yard or store-house in the main street, at which place the duke and his successors, are by the first act bound to supply the inhabitants of Manchester at all times with coals at only 4d. per cwt. of 140lb.; a circumstance which must have had a great effect on the growing population of this immense town within the last 40 years. At Worsley is a short cut to Worsley mills, and another to the entrance banon of the famous under-ground works or tunnels, of 18 miles or more in length in different branches and levels, for the navigation of coal-boats; some of which are as much as 60 yards below the canal, and others 33½ yards above the canal; these last, to which the boats ascend by means of an inclined-plane, that we have already described, extend to the veins of coal that are working at a great depth under Walsden Moor. Most of these tunnels are hewn out of the solid rock; from the lower one, the coals in boxes are hauled up out of the boats, as they are in Manchester town mentioned above, and the whole of the lower works are prevented from filling with water, by large pumps worked by the hydraulic machine, which we have already mentioned in this article, and the water is thereby always kept at the proper height for navigation on the lower canal. Near Worsley, a branch of about 15 mile in length, proceeds on to Chat-Moss and there ends, across which celebrated morasses, it was by the first act intended to proceed, to the Mersey and Irwell navigation at Hollin Ferry near Glazebrook; but, like the cut proposed by the side of the Mersey to Stockport (7½ miles with a rife of 60 feet) was never executed, and the necessity for them is now in a great measure done away, by other plans which have been carried into effect. The rife of 82 feet in the first 600 yards from the Mersey, by 10 locks, is the only deviation from one level on this canal (except in the Worsley coal-mines above mentioned); and this length of level-water is further increased; by 18 miles on the Trent and Mersey canal which connects therewith, making in all 70 miles of level. The width of the canal at top is 52 feet on the average, and depth 5 feet; the boats that navigate between Worsley mines and Manchester are only 4½ feet wide, the others are 50 ton boats or upwards; there are also numerous boats for passengers; large warehouses have been built for goods, at the Castle Field in Manchester adjoining the canal.

Besides the tunnels under Manchester and at Worsley mines, we have been through a short one in passing a gentleman's house and a church, we think at Groppenhall. On this canal are three principal aqueduct bridges over the Irwell at Barton, where it is navigable, and over the Mersey and Bollin rivers, besides several smaller ones, and many road-aqueducts. There are also several large embankments, one over Stockport meadows, is 500 yards long, 17 feet high, and 112 feet wide at the base; that at Barton bridge is 200 yards long, and 40 feet high; at Bollington is also a tremendous embankment. The principal feeders for this canal are Worsley brook, and the mine-water there collected, the Medlock brook at Manchester, and the lockage of the Trent and Mersey canal; and water, which never was scarce in this canal, now is abundant, since the increase of supply by the lockage of the Rochdale canal.

Mr. James Brindley, the engineer, owed much of his well earned fame to the happy contrivance and complete execution which he displayed in every part of this great concern; since the decease of Mr. Brindley, Mr. Gilbert and Mr. Benjamin Sobben his Grace's agents, have done themselves great credit, by the mannerly manner in which they have conducted the canal concerns of their noble employer, and improved and extended his works, as Mr. Thomas Bury has also in the mining department, so intimately connected therewith. The tunnelling at Worsley, and the canal between that and Manchester, were begun immediately on the passing of the first act; on the 17th of July, 1761, the Barton aqueduct was completed, and coals were soon after conveyed thereby to Manchester. On the 31st of December, 1772, the 10 locks at Runcorn were opened; in August, 1774, two packet-boats began to proceed regularly part of the way between Manchester and Liverpool, and on the 21st of March, 1776, the whole of the works which were then intended were finished; the extension to Leigh has been made since 1795. The illustrious duke of Bridgewater, justly filed the father of British Inland Navigation, died greatly lamented in March 1803, and left this immense concern, (which cost at first 229,000l. it was said, and probably in the whole twice that sum, as the tunneling at Worsley alone has been estimated at 108,000l.,) to earl Gower, the present proprietor, whose second son is to inherit it; the net proceeds are paid now to be from 50 to 80,000l. annually. The tonnage has not been increased since the first act, although the length of the canal has been increased to nearly four times what was at that time intended; boats may navigate the whole course or any part on paying 2s. 6d. per ton. Vessels passing out of the Trent and Mersey at Preston-Brook and into the Mersey at Runcorn, or the reverse, pay 1d. per ton for that distance; and all vessels passing to or from the Rochdale canal to this canal at Manchester are to pay, for passing through 4d. per ton, and for all other articles 14d. per ton. It is provided, that flour shall not pay any tonnage on this canal, if the wheat whereof it was made had already paid. Irrigation, or watering of meadows, is practiced in a very judicious and profitable manner, by water let out of this canal at Worsley and other places. The price of land-carriage for goods between Manchester and Liverpool was, on the passing of the Duke's third act, 40s. per ton, and by the navigation on the Mersey and Irwell 128s. per ton, but his Grace limited his price to 6s. per ton: yet, such has been the increasing trade of these two places, that it was in 1794 seriously
seriously maintained, and made the ground of another proposed navigable communication, by a junction of the Manchester Bolton and Bury, and the Leeds and Liverpool canals, that both the Duke's canal and the river navigation were inadequate to carry the trade between Manchester and Liverpool, and that the most frequent and ruinous delays were experienced by the merchants. In 1802, we find the idea again revived of a cut from the Leeds and Liverpool canal to the Leigh branch of this canal. About 1772, the Liverpool and Runcorn was proposed as an extension of this canal from Manchester; in 1799, the Manchester Bolton and Bury, was proposed to be joined directly with this canal, by means of aqueducts over the Irwell and Medlock at Manchester.

Bristol and Gloucester. In the year 1797, we were told, that surveys were making of the line for a proposed canal from the Bath Avon at Bristol to the Severn at Gloucester, and also, of a continuation of the same across the Stratford Avon to the Severn at Worcester.

Bristol and Taunton. Several years ago, a canal was proposed, we are told, from the Avon river at Bristol to the town of Taunton, with cuts to Nailsea collieries, to the Axe river at Brean, and to the town of Langport, but we are not further acquainted with its objects or particulars.

Brothric River. This is a small river on the coast of Angers county in Scotland, and navigable, we believe, but a small distance up from the harbour of Aberbrothick at its mouth, which harbour is of great antiquity, and appears to have had piers and works erected for its improvement and security, for long back as the year 1194; the spring tides here rise 15 feet.

Bude and Hatherleigh canal. In 1793, the Earl of Stanhope proposed a line of water-levels and railway-ways, between the sea in Bude Haven, on the Brigliton-Channel part of the Cornish coast, and the neighbourhood of Hatherleigh in Devonshire, paffing the town of Holdsworthy, for carrying up sea-fand, (which in this bay consists of a congeries of broken shells), as a manure, and exporting of farming produce; the rise on this line was upwards of 500 feet, up whose lordship proposed, that his 2 ton boats should be conveyed at proper intervals on inclined-planes, whose peculiarities have been already mentioned in this article. In April last (1805), we find a scheme on foot, for improving the harbour of Bude and building a pier for the protection of ships.

Bude and Launceston, or the Tamar canal. This is one of the few inlinces, in which an act (14th of Geo. III.) was obtained, without any part of the scheme having been carried into effect. Mr. Edmund Leach the projector of this, in his Tractate on Inland Navigation, proposed, that it should proceed from the tide-way in Bude Haven, Cornwall, on the Brigliton Channel, and proceed near to Launceston, and into the tide way of the river Tamar near Callistock, in the S.E. part of Cornwall. There was a provision, that the powers of the act were to cease in 10 years, if the canal was not proceeded with; it was proposed, to purchase only 39 feet wide of land, and not to be allowed to cut more than 39 inches deep into the earth on the lower side, in any part, except for docks, &c.; the canal to be 21 feet wide at top and 12 at bottom, with a towing-path on each side of it, 10 ton boats to be used; the direct distance of the two extreme points is only 38 miles, but owing to the extremely serpentine course of the level which was to be followed, its proposed length was 81 miles, and was estimated to cost 1000l. per mile. Locks were not to be used, but inclined-planes for boats of Mr. Leach's contrivance, of which we have already given an account in this article. From the sea at Bude, was to be a plane of 54 feet rife, thence a level of 69 miles, then a plane of 130 feet rife, then 4 miles of level, and a third plane of 60 feet rife to the summit-level, which extended 34 miles to Launcheon town, and 34 miles beyond; then, a plane with a defect of 120 feet, then 2½ miles of level, and a fifth plane, at Kelly Rock, of 120 feet fall to the Tamar navigation. A cut or feeder of 3 miles was proposed, from the Tamar to Llanell to St. Tankins on the Pack-faddle (being a low point on the south-western branch of the grand-ridge). Mr. Leach, however, tells us, that these levels are not to be entirely depended on, and mentions 25½ feet as the elevation of the Pack-faddle. The principal objects of this canal were the carrying of salt and flinty sand from the coast into the interior of the country as manure (an object since in part accomplished by the Tamar manure, and the Severn canals). In 1785, Mr. Leach wished to revive this project, and to shorten the course to 45 miles, by cutting down the summit 18 feet, and making a tunnel of 100 yards; and to form another communication with the sea at Wemmouth-bay, where the same broken shells abound; the cost was now estimated at 53,100l.

BurrEstowness Canal. The act of the 8th of Geo. III. (for the Forth and Clyde canal) established a set of proprietors for this canal; its direction being nearly west for about seven miles in the counties of Linlithgow and Stirling, in Scotland; from the tide-way in the harbour of Borrowtowns, on the Firth of Forth, to the Forth and Clyde canal, near its eastern terminus at Grangemouth. Its objects are flated to be, the avoiding part of a dangerous and difficult navigation on the Forth, and for improving the lands of Kinnel and Beercrofts, through which it passes. Borrowtowns, Linlithgow and Falkirk are considerable towns near this line. The depth to be seven feet, and width and size of the locks at the entrance proportionable thereto, the canal being level. The company are authorized to raise 8,000l. for each. The shares to be 50l. each. The tonnage of lime, lime-fine, and iron-fine 3d. per ton per mile, all other goods and articles (except road-materials and manures) 1d. per ton per mile.

Burry River. This river, or estuary, connecting with the Brigliton Channel, is between the counties of Caermarthens and Glamorgan, in South Wales, and is navigable a distance of ten or eleven miles to Llwythor or Longllyr, in nearly an east direction; at the flats in Llanell it is joined by the Caermarthenshire rail-way, and another railway has lately been laid from this river to the Penclawd copper-works: in 1801, the Llannerry and Llanelly canal was proposed to join at the Spitty in Llanell; and, in October 1805, a wet dock was proposed to be made on the east side of the Llanell pier, to communicate with the Caermarthenshire rail-way.

Caerdyse. This is an artificial channel or ditch, as ancient as the time of the Romans in this country, from the Neva river, a little below Peterborough, to the Wibun river, three miles below Lincoln, of near 40 miles in length; it appears to have been very deep, though now almost grown up; and it is rather doubtful whether it ever was intended or used for the purposes of navigation.

Caermarthenshire Railway. Act 42 Geo. III. The general direction of this line of railway is nearly north for 14 or 15 miles in Caermarthenshire; it commences on the coast, and is not very greatly elevated in any part; its general objects are the export of coals, iron, lead, &c. from the country through which it passes. Llandilow Vawr is the only considerable town near its course. It commences in the Burry river, at the new basin for ships; at the flats near Llanell, and terminates at Caeiil y-Garry line-works in Llanhafangel Aberbythick. In the deep cuttings for this
this rail-way near Munydd Mawr several unknown veins of good flint-coal were discovered, and some of lead ore; in November 1804, the embankment near this place, consisting of more than 40,000 cubic yards of earth was completed, with the rail-way upon it. In October 1805, it was proposed to make a wet-dock for ships at the commencement of this line, on the east side of Llandyli pier; in 1801, the Llandowery and Llanelly canal was proposed to pass through nearly this line of country.

Caistor Canal. Acts Geo. III.—The direction of this line is east 9 miles in the county of Lincoln; it is but little elevated above the sea. Its objects seem the importation of fuel and other articles, for the supply of Caistor town, and the export of farming produce: it commences in the Aneholme navigation, at South Kelby, and terminates at the town of Caistor. The company were empowered to raise 25,000l., shares 100l. The rates of tonnage are from 2d. to 8d. per ton per mile on different goods, with other rates for corn, &c. See Phillips’s 4th Hist. p. 47. All flues for the use of government, or materials for roads, to pass free at all times, and manures for the adjoining lands, when the waters run over the lock-weirs. In 1804, there was a proposal for extending this canal from Caistor, along the foot of the Wolds, thence, to Hambleton Hill, in Tealby, near Market-Raisin, the expense of which was estimated at 6,500l.

Calder and Huddersfield Navigation. Acts Geo. III.—The general direction of this navigation is nearly west, about 23 miles in length, in the well riding of Yorkshire; it has a considerable elevation above the sea at its west end: the general objects are the communication between Liverpool, Manchester, and Hull, by means of the Rochdale and Huddersfield canals, and Ayre and Calder rivers, the import and export of goods from Halifax, and the export of paving-stone (now so much used in London, called Yorkshire paving) from the famous quarries at Ealand-Edge and Cromwell-Bottom, and lime from Houghton, Brotherton, and Fairburn: at Cooper’s Bridge it is joined by Sir John Ramsden’s canal (leading to the Huddersfield canal), and at Dewsbury by the Dewsbury and Birstall rail-way. Halifax is the 58th British town, with a population of 8,886 perfs; Wakefield the 64th, with 8,151 inhabitants; and Huddersfield the 81st, with 7,678 persons. This navigation begins in the Ayre and Calder navigation on the latter river, at Wakefield, and terminates in the Rochdale canal, at Sowerby-Bridge. There is a rail-way branch of about half a mile to Bradley colliers; it has a cut of about half a mile in length by the side of the Hebble river, to Salter-Hebble; and provision is made (in 33 Geo. III. for Barfley) for a cut to Barg-hill, on a branch of Barfley canal; there are several locks; one of them near Salter-Hebble, of 10 or 12 feet rife, was in 1783, removed, and two new ones, of half that height, with a bason between them, were substituted by Mr. William Topp; some of the locks here erected in 1761, by Mr. Smeaton, have single gates at their heads. At Salter-Hebble are a bason and large warehouses, and others at Sowerby Bridge, for the accommodation of the town of Halifax; near Ealand is a large weir across the Calder river. This navigation was planned or superintended by Mr. James Brindley, and afterwards by Mr. John Smeaton. About 1765, the navigation was brought up to Ealand quarries, and about 1776, to Salter-Hebble, and to Sowerby-Bridge warehouses. The stone and white flate from Ealand-Edge are carried in carts and four-wheeled carriages, to be put on board of the keels at Bridghofe wharf, on account of the great height of the quarries above the Calder; the Cromwell bottom-flume is put on board at a wharf there. From the

Vol. VI.

quarries of Thomas Thornhill, Esq. at Lillton’s Wood, near Ealand, a long and wide maintain plate, of about 45° of elevation, was, about the year 1774, made from the Calder river, and paved with large flat flumes, on which a barge deflected loaded with stone, and by means of a rope passing over a wheel and axle, drew another empty flume up the plate; this continued in use for some years; but this flume was finished before the year 1783. In 1761, a violent flood happened on the Calder river, which destroyed many of the works therein; the Mr. Smeaton repaired, and in 1774 another happened, so destructive that the navigation was for near a year suspended, before they were repaired; the fall of this river is no less than 3 feet per mile for more than 20 miles together. By the act 34 Geo. III. for Huddersfield canal, this navigation was guaranteed against a diminution of its tolls, by any other communication to the eaitward opened therewith. In 1794, the Manchester Bolton and Bury canal was proposed to be extended to join this at Sowerby-Bridge. In 1803, the Wibsey and Dewsbury railway was proposed to join at Raven’s Bridge, and notices have in the present autumn (1805) been given for the Wakefield and Eller rail-way, intended to join this navigation at Bottom-Boat near Wakefield: a side-cut is now making near Bridge-houfe, for avoiding the mill-dams, and improving this navigation.

Can River. The general direction of this navigation is about south-well, for 14 or 15 miles in the county of Cambridge; it is but little elevated above the level of the sea; its principal object is the supply of the town of Cambridge, which is the 59th in the order of our population, with 10,087 inhabitants: Ely also, near this navigation, is a considerable place. It commences in the great Ouse river, at Harrimere, and terminates in the town of Cambridge. It has a cut or reach of 3 miles to Reche, and another of 3/4 miles to Burwell, at which last place the Bishopsgarford and Wilton canal was, in 1780, proposed to join. The Can river is embanked above the adjoining fields through all its lower parts, is without locks in some parts, and has sluices for making sluices of water, to enable boats to pass the shallows and hard.

Can River. The general direction of this navigation is about south-east for near 8 miles, in the county of Cornwall; it is within the flow of the tide, and is chiefly used in the import of coals and export of agricultural produce; it communicates at Guineaport, near Wobegby, with the Pelbrock canal. Padlow, on its banks, is a considerable town; it commences in the Irish channel, at Stepper Point, and terminates at Waterhead.

Canterbury and Newborl-Bay. In the year 1802, a canal was proposed, and again in 1803, and surveys taken, for a canal on a level, capable of carrying sea-built vessels, between the sea at St. Nicholas Bay, near Margate, to the city of Canterbury, about 10 or 11 miles in a south-west direction, there to connect with the Stour river, and with a canal then proposed, called the Medway and Rochester canal. Canterbury has 9,000 inhabitants, and is the 57th place in the order.

Cardiff and Merthyr-Tydyl Ral-way. Acts about 35 Geo. III.—This line is nearly in a north-west direction, for 24 miles, in the county of Glamorgan, in South Wales. The general object of this railway is the export of iron from the great works at Merthyr Tydyl, Dowlais, &c. Cardiff, Caeplhill, and Merthyr are considerable towns on or near this line, which commences at the floating-dock, in the Severn at Lower Layer, the termination of the Glamorgan canal, by the side of which, very nearly, it proceeds to Merthyr Tydyl, and thence the lime-works at Penton, in Merthyr parish; at Quaker’s yard a branch of

C. C. 9.5 miles.
6 miles goes off to Caron mill, in Bedwellty; Howfrey, Hill and Co. are the proprietors of this part of the tram-road, and it was, we believe, constructed under the first act of parliament ever passed for this kind of roads; the width of land allowed to be purchased was 7 yards. On the 21st Feb. 1804, a trial was made of one of Trevithick's high-pressure steam-engines for driving trains on this tram-road, as before mentioned, and 12 tons of iron and 70 persons were drawn for 5 miles by the power of steam, without the use of conducting-water. At Merthyr there is a curious and suspended water-wheel, of 50 feet diameter, made of cast-iron.

CARON RIVER. The direction of this river is well, in the county of Shropshire, in Scotland, and for 3 miles it is navigable, from the Ercall river to Caron bridge, for vessels drawing 5 or 8 feet water at high-tides; at Caron there is a cut from the River and Gyle canal; and near Caron bridge are the famous Caron iron-works.

BART RIVER. The direction of this navigation is nearly south, for about 3 miles in Kentchurch, in Scotland; its objects being the supply, and the export and imports of the great manufacturing town of Peterley, which is the 15th in the order of British towns, and contains 31,779 persons. Renfrew is also a considerable town near the fame; this navigation commences in the Clyde river, near Inchinnan, and terminates at the town of Paisley, at which place it was proposed, in 1803, to be joined by the Glasgow and Saltwater canal.

CHELMEER and BLACKWATER NAVIGATION. Acts 6 and 33 Geo. III.—The general direction of this navigation is nearly east for 134 miles in the county of Elfs; its general objects are the supply of Chelmsford and its neighbourhood with coals, deals, &c. and the export of farm produce. It commences in the Tide-way, at Collier's Reach, in the estuary of Blackwater river, and proceeds by the course of the Chelmer river to the basin at Chelmsford town, with a cut near 4 of a mile to Malden. Chelmsford and Malden are considerable towns. From low-water in the basins at Collier's reach to Heybridge-mill, on Blackwater river, 14 miles, is a rise of 12 feet 6 inches, thence to Bedly or Bally-mill, on Chelmer river, 15 miles, is a rise of 7 feet 6 inches; thence to the basin at Chelmsford is 105 miles, with a rise of 5 feet 6 inches; the branch has a rise 6 feet 8 inches in the basin at Malden. Mr. John Sweaton surveyed this line in 1762, and recommended 13 miles of new canal, and estimated the sum at near 160,000l.; Mr. John Reeves was afterwards employed. The basin at Collier's reach was opened for ships in February 1790; the company were authorized to raise 60,000l. of the shares 100l. each; in 1802 these were so depreciated, that they were paid not to be worth 5l. each. The spring-tides flow 5 feet at Bally-mill- mill, and 8 feet at Malden bridge; the neap tides do not raise the water above one foot at the last place.

CHELTENHAM and Tewksbury. In 1801, notices were given for a proposed canal from the Severn river, near the junction of the Avon therewith, at the town of Tewksbury, to the town of Cheltenham, through the parishes of Tewksbury, Tredington, Elingham-Hardwick, Uckington, Swindon, and Cheltenham, a course nearly south-east for about 8 miles, in the county of Gloucester. Tewksbury and Cheltenham are considerable places.

CHESTERFIELD CANAL. Acts 11 and 17 Geo. III.—The general direction of this canal is about south-south-east for 18 miles, in the county of Chester; it is not greatly elevated above the level of the sea; its principal objects are the export of farming produce, and the import of coals and lime for Nantwich town, and the surrounding country; it forms a double communication between two points in the line of the Ellesmere canal, at Cheltenham and at Frankton common. Cheltenham is the 25th British town, with a population of 15,072 persons. Nantwich is also a considerable town. This canal commences in the tide-way in the Derwent river, in the town of Chester, near to where the Ellesmere canal crosses the same, and terminates at the town of Nantwich; at Stoke, in the parish of Acton, it is joined by the Whitchurch branch of the Ellesmere canal; from Cheltenham to Barbridge, near Tiverton, the distance is 143 miles, with a rise of 170 feet 10 inches, and thence to Nantwich it is 82 miles, and level. The canal passes Cheltenham, Tiverton, Whitchurch, Nantwich, and Chester, and terminates at Manchester; at Workop, near Tiverton, 9 miles, the level of Dee proposed, the communication burthen Renfrew/hue, in Scotland; there is a tunnel made at the level of Dee; and a branch is made to join the Loddon canal, near Tiverton, 9 miles. This branch was intended to form a connection between the Derwent and the Tiverton, and to join the Trent and Mersey canal, but not into it. Although this branch, intended for bringing salt to Cheltenham, was not executed, the expenses amounted to 60,000l. and the shares became perhaps the most depreciated of any concern in the kingdom, being held at one time, as we are informed, for one per cent. of their original value. In 1793, a junction was proposed near Nantwich, with a branch of the intended Sandbach canal; in 1793, a rival scheme to the Ellesmere, called the Eastern Grand Trunk, was proposed to join at Crow's nest; and in June 1796 the Commercial canal was proposed to join at the same place, in order to form by means of the Aledy-de-la-Zoumb canal, and others, a communication for 40 ton boats, between Liverpool, Cheltenham, Hull, London, &c.

CHESTERFIELD CANAL. Acts 10 Geo. III.—The general direction of this canal is nearly south-west, by a crooked course 46 miles in length, in the counties of Nottingham, York, and Derby; the western end is considerably elevated; its principal objects are the export of coals from near Chesterfield, and lead from the Derbyshire mines, and the import of lime, corn, timber, &c. Chesterfield, Workop, and Retford are considerable towns upon this line, which commences in the Trent river, near its junction with the Idle river, at Stockwith, and terminates at Chesterfield town; from the Trent to Workop the distance is 94 miles, with a rise of 253 feet; thence to Norwood it is 9 miles, with a rise of 85 feet; and thence to Chesterfield it is 23 miles, with a fall of 45 feet; the number of locks is 65; the lower part of the canal, from the Trent to Retford, is for large boats of 50 or 60 tons burthen; above this the width is 26 to 28 feet, and depth of water from 4 to 5 feet; the boats here used being 70 feet long and 7 wide, and carrying 70 to 22 tons each. In 1794 such boats as those of 500l. new, 500 to 1000l. each. The boat-owners here usually pay their bargemen by the ton of goods which they convey rated distances, instead of weekly wages. At Norwood is a tunnel through Hartwell of 3050 yards in length, being 12 feet high and 9 feet wide, in the forest of Gresford, and 30 feet below the surface of the hill; this tunnel was begun in November 1774, and finished the 9th May 1775; at Drake's-hole is another tunnel of 1533 yards in length. Mr. James Brindley projected this canal, and directed its execution until his death in September 1772, when his brother-in-law, Mr. Heyshott, succeeded, and completed the whole in 1776. The tonnage is 12d. per ton per mile, and in calculating the same 4th of a mile is taken into account, and 4th of a ton. It appears that the canal cost 163,000l. and the shares were at first much depreciated, and sold for a long time.
time below par: in September last (1825) the profits amounted to 61 per cent. annually. In Mr. Bridley’s time, a junction was intended at Chelford with the proposed Chelford and Swarkestone canal; and in 1822, an extension of this canal was proposed of 5 or 6 miles in length, nearly south to Alloa.

**Chelford and Swarkestone.** The late Mr. Bridley, about the year 1771, proposed a canal from the Trent and Mersey canal at Swarkestone to the Chelford and at the latter place, the direct distance being about 25 miles nearly north, the line being through a country very rich in coals. Derby, the 45th town, with 10,623 inhabitants, was to be in the line of this canal, and the town of Belper is also near it.

**Cheister Haven.** This inlet of the sea, on the coast of Hampshire, is of considerableness, in different branches, navigable for ships, surrounding Thorny Isle, and connecting with Langstone and Portsmouth harbours. Havant and Chichester are considerable towns near it. In September 1805, notices were given for cutting a short canal, to commence with a sea lock in deep water in this haven, and proceed to Upper Southgate field, in Chichester, there to terminate in a spacious basin or dock.

**Clithy River.** This river has nearly a north-east course, in the county of Pembroke, in South Wales. It commences in the tide-way in Milford Haven, and terminates at Cannister bridge, near Narberth, which is a considerable town; and Pembroke on another branch of the haven is also a considerable place.

**Clay River.** Acts 34 Geo. II. and 9 and 11 of Geo. III.—This river or frith commences with a bold noble and capacious estuary, in the northern or Irish channel, and extends nearly north, to Groonoo, when its direction changes towards the east, and its width diminishes gradually to Glasgow, where the navigation terminates. Glasgow is the 5th town in Britain, in point of population, containing 77,385 inhabitants: Paisley, in the vicinity of this river, is the 15th town, with 31,179 persons; Greenock, the 20th, with 17,749 persons; and Ruthay, (on the Isle of Bute) the 118th, with 5,487 persons: Ruthven, Glenfinn, Dumbarton, Port-Glasgow, Irvine, and Ayr, are also considerable places on or near the banks of this river. At Glasgow below a branch of the grand Forth and Clyde canal joins this, as also the Monkland canal, and Edinburgh and Glasgow canal; near Luchman the Fort canal joins, and at Dalhousie the Forth foot; the western termination of the Forth and Clyde is in this river; while the navigable locks and founds which connect therewith below Dumbarton are both numerous and important; by means of locks, Fine, and Gilp, there is a connection with the Crinan canal. In the year 1805 an act (45 Geo. III.) was obtained by the earl of Egbyton and others, for building new piers and improving Arrofdin harbour, and building wet-docks, &c., near Saltcoats, on this river, and in this harbour, as also at Glasgow, the Glasgov and Saltcoats canal was, in 1823, proposed to connect therewith; at Ruthay, on the Isle of Bute, piers have been built, and the harbour connecting with this river improved; Greenock harbour is also under great improvement, in conformity of an act of 45 Geo. III. The trade on this river is very immense and various; it appears that Greenock alone employed 175,551 tons of shipping therein in the year 1820.

**Cononock Brook.** Act 7, Geo. III.—The direction of this navigation is nearly north for about 6 miles, in the north riding of Yorkshire, commencing in the Swale river near Topcliffe, and extending to the town of Thirsk, for whose accommodation it is intended.

**Conon River.** The general direction of this navigation is nearly N.W. for about 8 miles, in the county of Westmorland; its objects are the import of coal, deals, &c., and the export of produce, and of all the produce of the banks below Wivenhoe. Colchester is the 45th place in Britain, with a population of 11,730 persons. It commences with an avenue at Mersea Island, and terminates at the town of Colchester, to which place small sail-built vessels can get up. Larger ships navigate to Wivenhoe, where there is a dockyard for building frigates and large trading vessels.

**St. Columb Canal.** The general direction of this canal is nearly N. for seven or eight miles, in the county of Cornwall; although near the coast, it is considerableness. Its objects are the export of a particular species of stone found about St. Dennis, called China-dune, naked in great quantities in Wedgodwood’s, and other patterns near the line of the Trent and Mersey canal, and the import of coal, and of a sea-fand confidant of broken blocks for manure. This canal was proposed to proceed across the western branch of the grand ridge to the south coast; not one third of which length has, however, been carried into effect. St. Columb Major, St. AUSTELL, and Grampton, are towns near the line. It commences at the sea-shore of the Irish channel near St. Columb Minor, and terminates at present within about two miles of St. Columb Major; from thence it went to Pons St. Dennis, St. Stephen, St. Ewe, and arrive at the sea again near Pentewan, not far from the famous Polgarrath mines and engines. The part which was completed about the year 1775, commenced on the top of a very high cliff, and pursuied the course above mentioned, without locks, we believe. The canal was a narrow one, and at its west end, the cliff was with great labour hewn down, into a steep inclined plane, that was covered with planks: the canal was conducted to the very top of this plane, and the boats which were rectangular ones, were brought, when loaded with stone, to the termination of the canal, where they were hauled by a fort of hinges; strong ropes were then attached to the stem of the boat, and by means of a wheel and drum, worked by a horse-gin or wench; the boat was hauled up an end, and the stones were thereby shot out, and rolled down the plane to the landing below, from whence boats conveyed them on board the ships. The frame wheel and drum was adapted for drawing boxes of coal or Shelly sand up the plane, in order to their being loaded into the returning boats. Near to its eastern termination the canal was conveyed over by an aqueduct bridge over a road. We have been favoured with these particulars by a Cornish gentleman, from whose account of inclined planes was written, or we should have noticed this (the plane on Pons St. Dennis canal and another on the Calder and Helles) as early instances of the use of inclined planes for boxes of goods, &c. For seven or eight years this canal continued in use, but whether like the Moraweg canal, in its neighbourhood, it has since been disused, we are not at the present moment able to learn.

**Commercial Canal.** In the year 1766, Mr. R. Port Whitemarsh was employed to survey this line, proceeding from the Chelfer canal at Nantwich to the Abbé de la-Tonich canal near that town; it was proposed to join Sir Nigel Griggy’s canal and the Newkyle under-kin canal, to cross the Trent and Mersey canal near Burton, and proceeding by Uttoxeter, to cross the Trent and Mersey canal again, and the Trent river at Burton. The objects of this proposed canal were, the forming of a communication for larger boats (40 tons) than the Trent and Mersey is calculated for, except below Burton, and contributing towards the wished-for passage of large boats between Liverpool, Manchester, Chelser, Hull, London, &c.

**Conway River.** This river has nearly a south course for
14 or 15 miles, betwixt the counties of Caernarvon and Denbigh in North Wales; its principal object seems to be the supply of Llanrwll and Aberconwy, which are considerable towns. It commences at the tide-way in Conway bay, and terminates at Llanrwll town. In June 1802, it was in contemplation to straighten the course of this river, about a mile below Llanrwll, by a new cut 502 feet long, 88 feet broad at top, and 50 at bottom, with a dam at its upper end across the old crooked channel. At Llanrwll, there is a curious stone bridge of three arches, built by Inigo Jones, over this river; and in 1802, it was proposed to construct a temporary cast iron bridge over it at Aberconway ferry, in order to facilitate the communication with Ireland by way of Holyhead, in the Isle of Anglesey; another iron bridge being intended at Bagor ferry, on Menai strait.

COOMBE-HILL CANAL. Act 32 Geo. III. — The course of this canal is nearly S. E. for 34 miles, in the county of Gloucester: its general objects are the export of coals from the mines near it, and shortening of the length of land carriage to Cheltenham, which is a considerable town; and so to Tewkesbury near its western end. It commences in the Severn river at Fletcher's leap in D.arrnville, and terminates at Combe hill in the parish of Leigh, the river being 15 feet only. This canal was constructed at the sole expense of three persons, viz. Thomas Burgess, William Miller, and Sarah Almford.

Coventry Canal. Acts 8, 25, (for Trent and Mersey) and 26 of Geo. III. — The general direction of this canal is nearly S. E. for about 22 miles (exclusive of the detached part beyond the Birmingham and Fazely canal, and the branch to Coventry) in Staffordshire and Warwickshire. Its situation is high, particularly the eastern part, which crosses the grand ridge near Bedworth, without a tunnel, and its Seefwood branch does the same. Its general objects are the line of communication between London, Birmingham, Manchelter, Liverpool, &c. the export of coals from the numerous mines near it, and the supply of Coventry city, which is the 24th on the list of British population, with 10,044 inhabitants. Nuneaton, Atherstone, and Tamworth, are also considerable towns near the line; and Hinckley, the 120th, with 5,070 inhabitants, is also in its vicinity. It commences in the Birmingham and Fazely canal at Fazely, and terminates in the Oxford canal at Longford; its detached part of 54 miles in length, commences at the termination of the Birmingham and Fazely canal at Whittington brook, and terminates in the Trent and Mersey canal at Bradley heath; near to Whittington brook, it connects with the Wyreley and Elwington canal, and at Marston bridge the line is joined by the Atherstone canal. There is a cut of about one mile in length to Griff coilleries, belonging to Mr. Roger Newdigate; another to several collieries by different branches near Seefwood-pool and Bedworth, five or six miles in length; there is also a cut of half-a-mile from the line to Bedworth; the branch to Coventry is 42 miles in length, and there is a railway-branch to Oldbury coal works. The detached part is level with the Trent and Mersey canal, which level continues (through 54 miles of the Birmingham and Fazely) to the commencement of the line of this canal at Fazely; from thence to Atherstone, a distance of about 10 miles, the ride is 56 feet, by means of 13 locks; from thence to the Oxford canal, about 12 miles, is level; so is the cut to Coventry, and thence to Griff, Seefwood-pool, Bedworth, &c. The left or highest level of this canal forms, with part of the Oxford and Atherstone, the longest level that is to be found in Britain, being upwards of 82 miles, we believe, including side branches. This is a narrow canal, but the company have bound themselves to widen the same to the width of the Grand Junction, if the proprietors of that canal shall at any future time require it. A stop-gate is maintained at the end of the Oxford canal at Longford, to prevent this canal, which is sometimes low in Summer, from drawing off their water. Mr. James Brindley was the original engineer to this concern, and 164 miles of the level part from Coventry to Atherstone was completed in 1786, when the works were suspended for near 10 years; at length, the Trent and Mersey company undertook to complete 11 miles of this original line north of Fazely; half of which they afterwards sold to the Birmingham and Fazely company; and the other half, on the 4th of February, 1787, was purchased by this company, who thus came to have a detached part of their canal. The line of communication was opened by the completion of this canal in June 1790. This company have been authorised to raise 120,000l., their shares being 100l. each. Some years after the completion of this and the Oxford canal, the shares hereon had obtained the great price of 400l., but owing to the rivalry of the Warwick and Nene canal, they were, in 1802, reduced to 350l., and their dividend to 8l. per cent. Since the completion of the Grand Junction, this concern has been flourishing, and the dividends are now 10l. per annum per share. The tonnage allowed on this canal is 4d. per ton per mile for line and lime-stone, and 14d. per ton per mile for all other articles, (except road or paving materials and manures used upon the ponds, or when the water runs to waste at the locks.) On the completion of the adjoining canals, the tonnage on coals was, by their general consent, reduced to 1d. per ton per mile upon several of them. It was agreed, between this and the Oxford company, (9 Geo. III. Oxford) that the latter should be entitled to all tolls, except on coals, that are collected on the first 34 miles of this canal towards Coventry, for goods passing from the Oxford canal, and that this company should in return receive the tolls upon coals collected on the first 2 miles of that canal. The Acts of 34 Geo. III. for Atherstone canal, granted to this company 50l. per ton upon all goods (except farming produce, manures, or road materials, or iron or its ore, made or dug on the banks of the Atherstone canal) navigated thereon, which shall, either before or after, pass on any part of this canal, or the Oxford or Grand Junction; and a further sum per ton, equal to the tonnage hereon between Griff and Longford, on all goods which may pass any new communication that may hereafter be opened between the Atherstone and the Oxford or Grand Junction; for encaening which, this company is empowered to erect toll-houses and toll-bars, and place collectors on any part of the Atherstone canal.

CRAY RIVER. The course of this river is nearly north, for 9 or 10 miles of a crooked course, between the counties of Wigton and Kirkcudbright in Scotland; its object is the supply of the adjoining country, and of Wigton, which is a considerable town. It commences in the tide-way in Wigton bay in the Irin or Northern Channel, and terminates at Newton Douglas.

Chinam Canal. Acts 33, 39, and 43 of Geo. III. — The course of this very wide and deep canal is nearly west for about nine miles, in the county of Argyll in Scotland; its sole object is the shortening of the passage for ships betwixt
between the Irish Sea and the Clyde river (by means of the loch of Fyne), by avoiding the voyage round the peninsula of Kintyre. It commences at Loch Gilp, and terminates in lock Crinn. The rise is 51 feet, and the fall 50 feet, a rivulet near the point of division serving as its feeder. The water in this canal is 12 to 15 feet deep. This line of canal was first surveyed for smaller vessels by Mr. Watt, after which Mr. John Rennie was employed herein; it appears to have been opened some time, but farther improvements, and the building of a pier in Loch Gilp are yet in hand. The proprietors have been authorized to raise 180,000l., and they have also received 50,000l. of the public money, which parliament granted in aid of this great and important work. The shares are 50l. each. A vessel under full sail, not being stopped in proper time, before the arrived at a lock on this canal, bore the same away, and went down therewith into the next pound. A passage may, it is said, be made by means of this canal in three or four days, which frequently took up three weeks. In 1802 the shares herein were 22l. below par.

Cromford Canal. Act Geo. III.—The general direction of this canal is about N.W. for 18 miles, in the counties of Nottingham and Derby; it is considerably elevated; its general objects are the export of coals and of lead, iron, lime-stone, and other minerals from the mines of Derbyshire. Wirksworth and Belper are considerable towns near its course. It commences in the Erewash canal at Langley bridge (not far from the junction of Nottingham canal therewith), and terminates in the town of Cromford near Matlock. There is a cut to Tintock coal works of three miles in length, another to Swanwick coal works; also a railway-branches to Crich lime-works, 14 miles, and to Biggarlee coal works 1£ mile. From the Firebrace canal to near Ceducton castle, four miles, there is a rise of 80 feet, thence to Cromford, 14 miles, it is level; the Tintock branch is level, and proceeds from the upper level. The width of this canal at top is 26 feet; the boats are 80 feet long, 7¼ feet wide, and 3½ feet deep; when empty they draw 8 or 9 inches of water, and when loaded with 22 tons, they draw about 2½ feet. Near Ripley is a tunnel of 3906 yards in length, which 180 feet wide within the canal's surface, and 8 feet high from thence to the crown of the arch, which is of brick, except some parts where the rock proved hard and found enough to stand without walling: the sides, walls and crown of this arch seem to be part of an elliptisp, but where as inverted or bottom arch was wanted, the same is much flatter. For constructing this tunnel, 33 pits or tunnel-flats were sunk, some of them on the summit of the hill, being 57 yards deep. This tunnel is laid to have coil 7½ per yard in length; it intersects a valuable team of coals, which is now worked, and in filling the tunnel-pits excellent iron ore was found, which is now worked, and the furnaces are supplied with coals drawn up through a shaft from below far that purpose. There are several smaller tunnels upon the line for shortening its course. Near Butterby hall there is a considerable deep-cutting, and shorter ones in other places, to avoid the loops round the points of the hills. Over the Derwent river, near Wigwell, there is a large aqueduct bridge 200 yards long and 30 feet high, the river arch is 80 feet span. Two smaller arches by its side serve to carry off floods, and for a road. Over a small river, which comes into the Derwent near Frithley, is another large aqueduct bridge about 200 yards long and 50 feet high; besides the river arch, there are two others, one for floods, and another conveys the turnpike road under the canal; these two aqueducts are laid to have coil about 6600l. There are considerable embankments in some places on this canal. Nearly over the Ripley tunnel there is a feeder of 30 acres of water when full, the head or embankment of which is 700 yards long, 3½ feet in height in the middle of the valley, the base being there 52 yards wide, the top of the bank is 100 yards wide. This feeder is laid to have coil 660l., the mean depth of it is 15 feet, and it will contain about 285,000 cubic yards full of water, which is let out by a large pipe and cock in one of the tunnel-pits. There are two other feeders for this canal, one of 16, the other of 15 acres. At the Cromford end of the canal there is a considerable stream of water taken in as a feeder, and the whole of the 14 miles of level and branches thereto have their banks made up more than one foot higher than usual to act as a sewer for dry weather. Mr. William Jelf was the engineer to this canal, and it was completed before the year 1793. The total canal is laid to have exceeded 80,000l. For the cutting and wheeling of clay, 35d. per cubic yard, per mileage of 25 yards, was usually paid; for gravel 4½d. per yard; for flinty ground 6½d. per yard, and 4d. per cubic yard extra for all done picked out and flailed. In the year 1797, a cut was proposed from the summit-level to the new collieries in Cudham park. In 1821, notices were given for the intended Belper canal, that was proposed to join this near to Biggins bridge; and in 1822, a cut was proposed to be made from the Derwent aqueduct on this canal to near Delphick, and thence near the Derwent and Wye rivers to the town of Bakewell.

Crouch River. The course of this river is nearly west, in the county of Essex. The principal objects of this navigation are the import of coals, deals, &c. and the export of farm produce, and of oysters from near Wallhithe. Bilerica and Rochford are the nearest considerable towns to this river. It commences in the English channel (about 10 miles from the mouth of the Thames), and terminates at Hull bridge.

Croydon Canal. Act 41 Geo. III.—The general direction of this canal is nearly south for 9½ miles, in the counties of Kent and Surrey: it is not greatly elevated; its objects are the supply of Croydon with coals, deals, &c. and the country through which it passes with manures and other articles, and the conveyance of its produce to the London markets, and the export of fire-clay, flint, and fullers' earth. Croydon is the 18th British town, with a population of 57,443 persons. Deptford is also a considerable place. This canal commences in the Grand Surry canal near Deptford (two miles from its connection with the Thames at Rotherhithe), and terminates at the new Basin near the town of Croydon. From the Grand Surry canal (level with an ordinary high tide in the Thames) to the top of Pimlico hill, 13½ miles, is a rise of 70 feet, by 12 locks; thence for 4 mile it is level, and thence for 3 of a mile to the beginning of Forell wood, there is a rise of 79 feet, by 13 single and one double locks; from the near to Croydon, 7 miles, it is level. The locks upon this canal are 60 feet long and 9 feet wide; each lock has a grove for stop-planks at its head, but no paddle-wiers; the water is intended to run over the upper gates. This company are to have a basin for their boats to lie in at Rotherhithe, on the south-east side of the Grand Surry entrance basin, and another by the high road near Croydon town. There are seven road bridges and 30 accommodation swing-bridges. On the top and northern slope of Pimlico hill, there is a considerable deep-cutting, and others in Sydenham and on Penge common; and near Selhurst wood is a considerable embankment. On Sydenham common there is a reservoir of 10 or 15 acres supplied in wet times by a feeder out of an adjoining vale, and into which its waite or over-fall is to be when full; there is another
Another useful or Norwood common, which, with the long Summit pound on to ten acres, a field, will be sufficient; it is preferred, to supply the locks that are making. At the time the act passed for this canal, it then meant intended to six inclinable planes, and to pump the water for supplying the ponds up from the Grand Surrey canal by steam engines, that were also intended to wind the boats up the planes; and it seems singular, under these circumstances, that legislative provision was made, for a culvert or small tunnel through Ford-hill for conveying water from the summit-level of this canal on Sydenham common, and by aqueducts or pipes to supply several towns and places with water, viz. by a branch of near 3/4 of a mile to the top of Dulwich town, and from the end of the said tunnel to Knight's hill by a crooked course of three miles in length through Norwood, and along Knight's hill towards London for one mile; also an other branch of near one mile to Streatham town. Mr. John Rennie and Mr. Ralph Dodd were the engineers, and Mr. Clark is now employed as resident engineer thereon. About seven miles of the upper end of this canal is completed and in use, and the remainder is proceeding with great expedition. The company are empowered to raise 80,000l., which is not now expected to prove sufficient; the amount of shares is 100l. each. The sum of 40£, is to be paid annually to the city of London, towards improving the Thames river above London Bridge. This canal is to have its water kept always two feet above the surface of the ground on Croydon common, and some other severe and unprecedented restrictions are introduced in favour of the millers on the Wandle river, at some miles distance.

Croydon and Wandsworth. In September 1800, proposals were made for a canal from the river Thames at Wandsworth, following nearly the course of the Wandover river to Croydon in Surrey; but the same was given up shortly after, in favour of the north Surrey iron rail-way, which passes through nearly the same tract.

Cyfarthfa Canal. The general direction of this canal, or water level, is nearly N.W. for about 3 miles, in the county of Brecknock; it is on a high level, and was constructed some years ago by Mr. Bacon, to bring coals and iron ore from the mines in the mountains, to his furnaces at Cyfarthfa, near Merthyr Tydfil. The whole is upon one level, and it does not connect with any other canal or navigable river; it is now the property of Mr. Cragasfa, the great iron master. It is situated near to the northern ends of the Glamorganshire canal and the Cardiff and Merthyr railway.

Darent River. The course of this river (called Dartford creek), is south for near 3 miles in the county of Kent; it commences in the tide-way in the river Thames, and terminates near the town of Dartford, for whose supply it is principally used.

Dart River. The general direction of this river is nearly N.W. for about 10 miles, in Devonshire; the tide flows through its whole length; its principal objects seem to be the supply of Totnes with coal, and the country with shell-fish and mussels, and the export of farming produce. Dartmouth and Totnes are considerable towns; its commencement is in Start bay, and it terminates at the Mill weir, about one mile above Totnes; this river is plentifully furred with trout.

Dean Forest Rail-way. In the year 1852, it was proposed to construct a railway from the river Ure, near to the town of Beaufort, to the forest of Dean, its object being the conveyance of the immense flues of coal and iron, with which it abounds; Colfior is a considerable town near its route. In the preceding year the Severn and Wye rail-way was proposed to pass nearly the same track.

Dean River. Act 12 Geo. III.—The direction of this river is nearly S. for about 2 miles, in the county of Nottingham; it is not greatly elevated above the level of the sea; its principal object is the supply of Newark, the 9th town in the list of British population, with 6730 inhabitants. It commences in the river Trent, at Crakley's, in South Markham, and terminates at the upper weir near the town of Newark; the works hereon were completed in Jan. 1797. In 1793 the Newark and Bolsthed was proposed to join this at Newark.

Dearne and Dove Canal. Acts 33 and 40 Geo. III. —The general direction of this canal is about N.W. for 9 1/2 miles, in the Well Riding of Yorkshire, its northern end is considerably elevated; its objects are the communication between Sheffield, Wakefield, Halifax, Leeds, Manchester, Liverpool, &c. and the export of the coals and iron-ore, &c. to plentifully found on its course. Barnley and Rotherham are considerable towns on or near it, so in Doncaster, the 110th town, with 5697 inhabitants. It commences in a side cut of the Don, or Dun river, between Swinton and Mexborough, and terminates in the Barnsley canal at Eyming's wood, near Barnsley, there is a branch of 3 miles to Rockhill bridge, and another of 12 miles to Colne Ing. From the cut of the Don navigation to Knoll Brook the distance is 14 1/2 miles, with a rise of 4 1/4 feet; thence to Aldham Mill, 2 1/2 miles, is a rise of 24 feet, (the Colne Ing branch being on its highest level); thence to the Barnsley canal is 2 1/2 miles, with a rise of 30 1/2 feet; the Colne Ing branch is level; the Rockhill branch begins from the summit-level, and 1 1/2 mile to Wentworth bridge is level; thence to Rockhill bridge, 1 1/2 mile, it has a rise of 56 feet. The locks on this canal are built with excellent hewn or ashlar stones, and are calculated for boats of 50 or 60 tons burthen, the same as navigate the Dun river, and the company are required to keep a depth of water equal to 4 feet on their lock-fills, and in every part of their line; and for guarding against loss of water on the summit, a stop gate is to be erected hereon, near the termination in the Barnsley canal, and on that canal below the junction, both of which may be flung and locked when the supply of either canal fails, and it would confuse the water of the other. The aqueduct and other bridges hereon are substantially constructed of hewn stone. Tumbling-bays and gauge-weirs are to be erected for supplying several mills. There is a large reservoir near Elleslie. Proprietors of mines may make rail-ways to this canal, if within 1000 yards, or 2000 yards near Wath. Mr. John Thompson is said to have been the engineer, and it was completed in the year 1804. The company were empowered to raise 100,000l. The amount of shares 100l. each. The rates of tonnage on this canal are too various and complicated for the room we can allot to this subject; they will be found in Phillips' 340. History, p. 62 to 66; but it must be observed, that the last act (40 Geo. III.) made an increase of 50 per cent. on these tolls. Boats are to pay for 6 miles of tonnage, however short a distance they may have navigated on this canal. In May 1797, Earl Fitzwilliam proposed, at his own expense, to extend the Colne Ing branch to his Elleslie collieries, on being allowed water for the same from the Elleslie reservoir.

Deben River. The course of this river is nearly N.W. for about 10 miles, in the county of Suffolk; its objects are the importation of coal-loads, &c. and exports of farm produce; it commences at the sea near Felixstow, and terminates near Woodbridge, which is a considerable town.

Dell River (Aberdeen). This river takes its course about well for 2 miles, between Aberdeen and Mearns county in Scotland, the tide flowing through the whole navigable length; it commences in the harbour of new Aberdeen, where
where it is joined by the Aberdeenfoir canal. New Aber-
deen is the 19th town in Britain, with 17,597 inhabi-
tants, and its harbour was improved by a pier of 260 yards in length, begun under the direction of Mr. John Smout, in 1775, but was not completed in 1778, to make further improvements. In 1781, Mr. Thomas Telford was employed to design new works and improvements hereon, so that ships of 20 or 20 feet draught of water may be accommodated. There are excellent granite quarries near this river.

**DEE RIVER (Cheifer).** The general course of this river is nearly S.W. for about 32 miles, in the county of Flint, and skirts the county of Chelford: the first 9 miles are by a wide alluvial opening to the Irish channel, and from near the town of Flint thence, a new cut was made for the river up to Chelford, under the direction of Mr. Nathaniel Kindler-
by, about the year 1749; before which time the old channel was so choked with sand, that ships of 100 tons could not come within 7 or 8 miles of Chelford; the new straight cut, that was at first 8 feet deep in general, principally through marshes, soon recovered itself out, so that ships of 200 tons could come up to the town, and where the time of high-water became earlier by 2 days of an hour, then when the tide had to make its way through the old crooked and shallow channel. Chelford is the 25th town, with 17,607 inhabitants, Holywell near it, is the 31st, with 5,657 persons, and Flint is also a considerable town. On the N.W. side of Chelford the Ellesmere canal connects with this navigation and crosses it, for which goods pay 20. per ton to this company; it is also to receive from the Ellesmere company whatever its tolls may fall short of 21cl. annually. At Chelford this river is joined by the Chelfer canal.

**DEE RIVER (Kirkcudbright).** The course of this river is nearly N. for about 6 miles, in the county of Kirkcud-
bright in Scotland, being an alluvial opening to the Irish sea. Kircudbright is a considerable town thence, and where the Galloway canal connects therewith.

**DERBY CANAL.** Act 33 Geo. III. — This canal runs nearly N. for about 9 miles, in the county of Derby; it is not greatly elevated above the level of the sea. Its ob-
jects are, the supply of the town of Derby, and the export of coals and iron. Derby is the 44th British town, with a population of 10,612 persons. It commences in the Trent river at Swarkestone bridge, crosses and interchanges with the Trent and Mersey canal, and terminates at Little Eaton, near 4 miles above Derby, from which town a cut of 13 miles goes off to a place between Sandiacre and Long Eaton, and there joins the Erewash canal. There is a rail-
way branch of 31 miles, to Smitey-houses near Derby, another to Horley collieries, and another of 31 mile to Smalby mills. In enlar railway, or canal, should be hereafter made. S. of the Trent from Bredon lime-work, this company has engaged to make a cut between the Trent and Mersey canal and the Trent, at Welton chie, opposite thereto. From the Trent to the Trent and Mersey, 1 mile, is a rise of — feet; thence to Derby, 31 miles, is a rise of 12 feet; and thence to Little Eaton, 34 miles, is a rise of 17 feet; the Erewash branch has a fall of 29 feet. This canal is 44 feet wide at top, 24 feet at bottom; the 5 feet deep, except the upper level near Little Eaton, which is made 6 feet deep to retain the water of wet seasons like a reservoir; the locks are 20 feet long, and 15 feet wide inside: adjoining the town of Derby is a prodigious large weir or tumbling bay, where the canal crosses the **Derwent river**, that was navigable to this place for many years back, but the tolls thereof were expected to fall off on the completion of this canal, and it was therefore agreed, that this company should purchase the whole concern for 399L. A little W. of the river above-mentioned, the canal crosses a branch in a cast iron trough under aqueduct. This canal was finished in 1797; the company were authorized to borrow 50,000l. the value of shares being 100l. Separate rates of tonnage were fixed on different goods, between the Trent and the Trent and Mersey, between that and Derby, and on the different cuts and railway branches, which are too long for us to mount, they will be found in Phillips's 4th. History of Canals, p. 55 to 59. Malters are to pay toll-free, and parchmen or clagers of wood, to be used as supports in the several coal-mines, also road materials, except for turnpike roads; and if the Manfield turnpike-road tolls are reduced below 4 per cent. on their dues, this company is to make them up to that sum. The profits of this concern are not to exceed 8 per cent. but after 1700 is accumulated as a stock for contingencies, the tolls are to be reduced. Five thousand tons of coals annually are to pass hereon toll-free, for the supply of the poor of the town of Derby. Horses pay 10. and cattle 4l. each, for liberty of passing along such railway branch.

**DERWENT RIVER, (Derby).** The course of this river is nearly N.W. for about 9 or 10 miles, in the county of Der-
by; its principal object was the supply of Derby, previous to the making of the Derby canal, when this concern was sold to that company, as mentioned above. It commenced in the Trent river at Wilden-ferry, (where the Trent and Mersey canal commences), and terminates at the town of Derby.

**DERWENT RIVER, (New Milton).** The general course of this river is nearly N. for about 37 miles, in the Earl Riding of Yorkshire; its objects are the supply of New Milton (a considerable town) with coals, deals, &c. and the export of farm produce, chalk, &c. It is but little elevated above the sea; it commences in the Oford river at Barnby, and termin-
ates at the town of New Milton. In January 1804, it was in contemplation to make this river navigable up to Yedingham bridge.

**DERWENT RIVER, (Workington).** The course of this river is nearly E. in Cumberland. Workington, on its
banks, near the Irish sea, is the 189th British town, with 5,768 inhabitants; to the vicinity of this town there are several rail-
ways, which bring down coals from Mr. Curwen's, and other coal-mines, for exportation from this place.

**DEVON RIVER.** The general direction of this river is nearly N.E. in Clevelamannahshire in Scotland, from near Cambus quay, on the Frith of Forth (two and a half miles above Alloa) to Medlockton. Mr. John Smout was, in 1765, and again in 1768, consulted, about making this river navigable, or a canal by its side, the rive being 394 feet, in order to bring down the produce of several coal-mines near its banks, to be shipped on the Forth, wherein the spring

**DERWURBY AND BIRSTAL RAIL-WAY.** The general direction of this railway is nearly N. for about 3 miles, in the West Riding of Yorkshire, and its object is to bring down coals to the welfs in the Calder river; it commences in the Calder and Hebble navigation at Dewsbury, and termin-
ates at Stubkly coal mines in Birstal parish, which are worked by Messrs. Thomas Chelfer and Sons, who are also the sole proprietors of this iron railway, which was completed in the present month (October 1825).

**DON, (or Don) RIVER.** Act 12 Geo. III. The general direction of this river is nearly S.W. for near 110 miles in the West Riding of Yorkshire, (including what is, in some maps, called the Dutch river, near to the Ouse,) the southern end of this navigation is rather elevated. The original objects
of this navigation were principally the supply of Sheffield, and the export of the iron-wares and iron from Sheffield, Rotherham, &c. since which period, the Dearne and Dove canal, which joins at Swinton, and the Stainforth and Keadby, at Fishlake and at Hangman Hill, and the cut to the Ayre river near Smith, have opened new sources of supply, and for the export of coals, flues, iron, and manufactured goods of several kinds, which this rich track of country produces. Sheffield is the 14th British town, with 31,314 inhabitants, Doncaster is the 100th with 51,927 persons; Rotherham, Doncaster, Thorne, and Smith are also considerable towns on or near this navigation. The commencement is in the Ouse river, at Goole bridge, and it terminates at Attercliffe, within 2 miles of Sheffield, and has a cut to the Ayre, as above, and side-cuts with locks between Muxgbury and Swinton, and in other places; the tide flows above the junction of the river Went. The Stainforth and Keadby, act 33 Geo. III. has directed rates for boats passing out of this into that canal by the cut of this river. In September 1803, notices were given, for a new act for weirs and side-cuts to this river in Muxgborough, Sporborough, and other places, and a new course for the Dearne river. And, in February 1803, there was a design of extending this navigation to Sheffield by a canal from Tinsley, 4 miles, for which 30,000l. was subscribed.

DOSSET AND SOMERSET CANAL. Acts 36 and 43 Geo. III.—The general direction of this canal is nearly S. for about 40 miles in the counties of Wilt, Somerset, and Dorset: the middle part of it is on a high level, and crosses the western branch of the grand river. Its principal objects are the supply of the manufacturing towns and neighbourhood through which it palls, with coals from the mines bordering on Mendip, and the opening of an inland communication between the Bristol channel, the Severn, the Thames, and the southern coast of the island. Tosome is the 60th town in the order of population, with 8,748 inhabitants, and Bradford, the 78th, with 7,302 souls; Bruton, Wincanton, Stalbridge, and Sturminster are also considerable towns near the line. The commencement is in the Kennet and Avon canal at Widbrook near Bradford, and the termination in the Stour river near Gains-crofts in Shillingstone-Okeford; from near Frome a branch of about 9 miles proceeds to Nettlebridge collieries in Midsummer-Norton. The Nettlebridge branch was first cut, in order to supply coals to Frome and its neighbourhood; and water being scarce thereon, one of Mr. Fuggle's balance-locks was erected on a 21 feet fall at Mells near Froome, and was publicly tried on the 6th of September, and 13th of October 1800, and in June 1802, as particularly described in a previous part of this article. An aqueduct bridge was erected several years ago over the river near Froome, but it is with flow pace, we fear, that the works are proceeding towards a final completion. The company were by the first act authorized to raise 225,000l. and a further sum under the second, we believe, the amount of shares being 100l. Stones are to be erected at every half mile: pleasure-boats of 12 feet long and 5 broad may be used on the ponds, 30 yards in width are allowed, in general, for the company to purchase, and 100 yards wide for docks, wharfs, &c., springs may be taken and refervoirs formed any where within 2000 yards of this canal.

DOUGLAS RIVER (Lower Navigation.) Acts 6 Geo. I. and 10 and 23 Geo. III. (for Leeds and Liverpool). The course of this navigation is nearly fourth; for 9 miles in Lancashire it is but little elevated above the sea; its objects are the export of common and canal coals, and farm produce, and the import of lime-stone; it commences in the tide-way in the estuary of the Ribble river near Halskeith, and terminates in the Leeds and Liverpool canal at Brier's Mill. From the Ribble to Solom, about 5 miles, the river Douglas (or Afland) is navigable, and thence to Brier's Mill is a canal 4 miles, with a rife of 8 locks, the whole rife from the Ribble being 49 feet. The width of the canal is 24 to 30 feet, and depth of water 5 feet; the locks are 70 feet long, and 15 feet wide. The first act above authorized Meffrs. William Squires and Thomas Steers to make the Douglas river navigable from the Ribble to Mery-lane end, near Wigan, which they effected about the year 1727; being allowed 2s. 6d. per ton for goods, whatever distance they might be navigated thereon; by the first act for the Leeds and Liverpool canal (10 Geo. III.), their successors were authorized to make a junction with the Leeds and Liverpool canal at Newbrough by a cut of 35 miles long, parallel to this river, with a fall of 12 feet, which they completed in 1774, and the same now forms part of the Leeds and Liverpool canal, S.E. of Newbrough aqueduct bridge, in consequence of the purchase which that company made of the whole of this concern, in pursuance of their act of 23 of Geo. III.; since which, the canal from Brier's Mill to Solom above described, as part of the lower navigation, was cut and opened in 1783, and the river navigation between Solom and Wigan, 12 or 13 miles (on the upper navigation) has, we believe, been defued since the Leeds and Liverpool canal was completed by its tide to Wigan, and the communication by the lower Douglas navigation to the Ribble, above described, was opened.

DOUGLIDGE RIVER. The course of this river is nearly north in the county of Pembroke in South Wales, from the tide-way in Milford-Haven to Haverfordweft bridge, its object being the supply of that town.

DRIFFIELD CANAL. Acts 7 and 41 of Geo. III. The course of this navigation is nearly north, for about 11 miles in the East Riding of Yorkshire; it is but little elevated above the sea; its general objects are the import of coals, deals, &c. and the export of farming produce; it commences at Aike-beck mouth in the Hull river, and terminates at the town of Great Driffield; the first five miles is by the course of the Hull river to Fifth-holm elough, and the remaining 6 miles is by a canal; the course of the Hull river serves also as a branch of 1½ mile in length to Frodingham bridge. In 1764 Mr. John Neaden was consulted on this intended navigation.
In 1824 it was in contemplation to deepen the Frodingham branch, and about 2 miles of the canal up to Snakeholme lock, nearly 2 feet deeper than it was before.

Droitwich Canal. Art 8 of Geo. III. The general direction of this canal is about N.E. for 54 miles in the county of Worcestershire; it is not greatly elevated above the sea; its objects are the export of salt and the import of coals, of which 13,500 tons are annually imported, and used in the boiling of salt, except what the town of Droitwich consumes. It commences in the river Severn, at Hawford, and terminates at Chapel Bridge in the town of Droitwich; it has a rise of 90 feet by 8 locks. This canal was executed by Mr. James Brindley, and it is said to present a pattern to canal-makers by the neatness and regularity of its curves, and the stability and excellency of all its works. The proprietors were authorized to raise 33,000l. the amount of shares being 100l. The tonnage on every quarter of grain, or 6 bushels of meal, is 2d. and on every ton of salt, coals, or other matters, 1s. 6d. By the act for the Worcester and Birmingham canal (31 Geo. III.), the shares herein are guaranteed to produce 5 per cent. annually, and are to be made up by that company in case of their failing below that sum. Owing to the overflowings of the copious salt springs near Droitwich, this canal presents the curious spectacle of a salt-water canal, in the interior of the country, in which water very little.

Drumglass Canal. This is a canal in Ireland, concerning which our information extends no further, than that the parliament of that country, between the years 1768 and 1771, granted 3000l. of the public money towards carrying on the works.

Drumglass Canal. This is a canal connecting with the Drumglas collieries in Ireland, towards the works of which canal, and those collieries, the parliament of that country, between the years 1753 and 1771, granted no less than 117,741l. of the public money!

Dudley (and Owen) Canal. Acts 16, 25, 30, 33, and 36 of Geo. III. The general direction of this canal is nearly N.W. by a crooked course of 13 miles in Worcestershire, a detached part of Shropshire, and Staffordshire; it is situate very high, its two ends are on the eastern side of the grand ridge, while its middle, by means of two very long tunnels, is on the western side of the same. Dudley is the 49th British town with a population of 10,107 persons, and the busy and rich country through which this canal passes, furnishes an ample tonnage in the export of coals, iron, and lime, while its communication with the Stourbridge canal, by the Black-Delph branch, and the terminating canals, occasions a very considerable carrying trade thereon. This canal commences in the Worcester and Birmingham canal at Selly Oak, and terminates in the old Birmingham canal at Tipton Green; from near Dudley there is a branch of 2 miles to the Stourbridge canal at Black-Delph in Kingwinford, there is another branch of 1 1/4 mile to near Dudley town, and a branch from this last of 2 1/2 miles to a bridge of Dudley coal-works. From the Worcester and Birmingham canal to the Black-Delph branch, 1 1/4 miles are level, thence to near the entrance of the Dudley tunnel, about 1/2 of a mile is a rise of 31 feet by 5 locks, thence through the tunnel it is level, and from thence, in the last 1/4 of a mile, is a fall of 1 1/3 feet by 2 locks, to the old Birmingham canal: the Black-Delph branch has a fall of 8 1/2 feet by 9 locks to the Stourbridge canal; the Dudley branch has a rise of 6 1/4 feet in the first 1/2 of a mile, the remainder thereof being level, and the colliery branch level therewith. The depth of water in this canal is 7 feet; the width of the locks on the Black-Delph branch is 7 feet. To near Lapal, or Laplat, this canal passes through a tunnell 3776 yards long, at Godby hill it passes through another of 62 1/2 yards, under a collateral branch of the grand ridge, and at Dudley there is another tunnel of 3260 yards in length, on the summit-level of the canal; the arch of this last tunnel has a height of 138 feet. At Cradley-pool is a large reservoir for supplying the leakage of the Black-Delph branch. It is provided, that level cuts may be made from this canal towards any coal-mine, to the extent of 2000 yards. A stoplock is erected at the junction with the Worcester and Birmingham canal, by which either company has a power of preventing the other from drawing off their head of water. The Black-Delph branch was first executed, which was then united with the Dudley part of the canal which had been constructed by lord vinceount Dudley and Ward; these were completed and in use before the extension or main length to Selly Oak was designed. The company has been authorized to raise 229,100l. the amount of shares being 100l each originally. Owing to the different acts under which the parts of this canal were progressively undertaken, the rates of tonnage being different thereon, and to the variety of rates on different articles, we cannot attempt an account thereof in this short abstract, they will be found in Cary's Inland Navigation, p. 53 to 55, also p. 43, where certain rates are made payable to the old Birmingham company on account of the junction therewith, (but which have been hitherto varied by the 34 of Geo. III. for Birmingham canal) and at p. 70, will be found other rates, in consequence of the junction with the Worcester and Birmingham canal. In the Stafford act (33 Geo. III.) are several regulations relating to tolls on goods passing to or from this canal; and this company is bound to make up the profits of the Stourbridge canal to 12l. per share annually, but not exceeding 3l. on each share.

Dudham and Chester-le-Street. In February 1797 Mr. Robert Whitworth made a report in favour of a proposed canal from the Tyne to Chester-le-Street, and thence to Durham, it was estimated to cost 79,000l. and the probable advantage thereon to subinbers was stated to be near 29 per cent. Durham is the 74th British town, with 7,530 inhabitants; this country abounds in coals.

Eden River. The general direction of this river is nearly S.E. for about 12 or 13 miles in the county of Cumberland; its principal objects seem the export of coals, and the supply of Carlisle, which is a considerable town. It commences in the tide-way of the Solway Firth, and terminates at Carlisle Bridge. In 1705, the Newcastle and Carlisle canal was proposed to join this river at Carlisle. In 1779 a road-way from the earl of Carlisle's coal-works, near Brompton, to this river, was opened; and in 1803 another was intended from lord Lowther's coal-works at Warrall, about 11 miles distant from Carlisle.

Edinburgh and Glasgow Canal. This canal, projected about the year 1766, appears to have nearly a well direction for about 50 miles in the counties of Edinburgh, Linlithgow, and Lanark in Scotland; its objects are the export of coals and lime from Clyde-side, through which it passes, and the opening of a third communication between Edinburgh and Glasgow. Edinburgh (and Leith) being the 31 British town, with a population of 62,990 persons, and Glasgow the 31st, with 75,483 inhabitants; from the scanty materials to which we have at present access, it seems that this canal commences in the tide-way of the Forth, in the harbour of Leith, and terminates in the tide-way of the Clyde, in the town of Glasgow, and was finished in 1822; that at Glasgow it connects with the Monkland, and in 1823; the Glasgow and Saltcoats was proposed also to join it.

Edil and Skiff canal. In the year 1803 Mr. Thomas Telford was surveyed
surveyed this line of canal, being a length of 3 miles from the tide-way in Loch Eil within some miles of the west end of the Invernog and Fort-William, or Caledonian canal, to Loch Shiel, a fresh-water lake on the Highland coast of Scotland; Loch Shiel was found 77 feet higher than Loch Eil, and in order to conduct a 12 feet deep canal out of the former to the flour of the latter, it appears that deep cutting will be required, for about a mile to the depth of 47 1/2 feet, there being no water on the summit to supply a lockage up and down.

**Ellesmere Canal.** Acts 3, 2, two of the 36, 41, 42, and 44 of Geo. III. 1.; the general direction of this canal is nearly forth for 57 miles, by a crooked course through the counties of Chelfer, Flint, and Denbigh, (North Wales) and Salop; its principal summit is considerably elevated above the sea; its great object is said to be the improvement of the agriculture of the extensive and fertile tracts, through which it passes, for uniting the Mersey, Dee, and Severn rivers, and exporting coals, lime, and slate, from the coasts of the Welsh hills. Liverpool is the 4th British town, with a population of 77,653 persons, Chelfer is the 25th with 7,452 persons, Shrewbury the 30th with 14,730 persons, and Ellesmere the 41st with 5,553 persons; Wrexham, Whitchurch, and Oswestry, are also considerable towns on or near this canal or its branches. This canal commences in the Mersey river (9 miles above Liverpool) at Ellesmere-port in Netherpool, and terminates in the Severn river at Bagley bridge, very near to the termination of the Shrewsbury canal, to which it is proposed to be joined: at the N.W. part of Chelfer city, it connects with the Chelfer canal, and near the same place crosses and connects with the tide-way in the Dee river; from near Palford a branch of 4 miles is proposed to Holf; from near Gwerfel a branch of—miles to Talwerr coal-works in the parish of Mould, near the head of the Cegedog valley, where there is an opportunity of constructing a reservoir of 82 acres to supply the same (this branch to pass Frood collieries, Brummy iron-works, and Nant-y-frith lime-works); another short cut from Gresford to Allington; and a railway branch to Ruskobrook; and to the river Dee at Llandkamin; from near Pont-Cyfylty, a branch to Acrefair coal-works; from Francon common, is a branch of about 25 miles passing the town of Whitchurch, to the Chelfer canal at Stoke in Aclon parish near Nantwich; from which branch, another of about 7 miles proceeds from Pen-Mols to Press Heath; from Hordley, on the main line, a branch of near 11 miles proceeds to the line of the Montgomery canal near Llanymynech, and the Vernick river; there being from this branch another to the termination of the Montgomery canal at Portwyain lime-works near Llanbydowel; and another short one is intended to Marfa bridge near Oswestry. From the Mersey to the Dee (sometimes called the Wirral branch) the distance is 8 miles; from the Dee river to the Brunno or Talwerr branch it is 11 3/8 miles, with a rise of 380 feet; thence along the summit pound, and through the Chirk tunnel 8 1/4 miles are level; thence to the north end of the great iron-aqueduct, 3 3/4 miles, is a fall of 75 feet; thence to St. Martins moor, 1 mile, it is level; thence to the Whitchurch branch at Francon-common, 2 1/4 miles, is a fall of 13 feet; thence to the Llanymynech line at Hordley is 3/4 of a mile with 33 feet fall; thence to Ormond park, 14 1/2 miles, is level; and thence to the Severn river at Shrewbury is 2 miles with a fall of 107 feet. The Holt branch is level, the Whitchurch branch to that town, 14 miles, is level, and thence to the Chelfer canal, 11 miles, has a fall of 128 feet; the Press Heath branch is level, the Llanymynech branch, 12 miles, has a fall of 19 feet. The depth of water in this canal is 4 3/4 feet, and the canal in general is calculated for boats of 70 feet long and 7 wide; but the Wirral branch is formed for boats of 70 feet long and 14 feet wide. There is a tunnel near Chirk of 775 yards in length, and another at Winton-Lullingfield of 487 yards in length. At Pont-Cyfylty, this canal is carried over the river Dee in an immense aqueduct trough, composed of cast-iron plates, 20 feet wide, 6 feet deep, and 320 feet long; this is supported on 19 pair of conical stone pillars at 72 feet asunder, and the middle ones 125 feet in height! At Chirk is a very large stone aqueduct bridge of 10 arches, 200 yards in length and 65 feet high, over the Cering river; and over the Allen river there is also an aqueduct bridge. This canal is fed from the Dee river by the Llandinillo branch, and that river is compensated by a cut from Bala-pool, and, all springs within 2 miles of this canal may be taken for its use. Near Ruohon, one of Rowland and Co.'s balance locks was, in 1797, tried on a 12 feet fall for saving water, as before mentioned. The engineers employed on this extensive work, were Mellor, William Jeffy, Thomas Telford,—Fletcher, and Thomas Danford; the most considerable progress was first made at the northern end of the line, and in February 1796, flats laden with coals began to arrive at Chelfer from the Lancaster collieries by the Wirral branch, and soon after convenient passage-boats were established, for the regular conveyance of passengers towards Liverpool or back, at lower rates than is charged on Bridgewater's canal, according to distance. In January 1797, the navigation was continued to Belfton brook; and in the same year the southern end of the line was opened from Shrewbury to the Winton-Lullingfield tunnel. The immense aqueduct at Pont-Cyfylty was in hand in 1804, and was more than half completed before the end of that year, as was also the stone aqueduct at Chirk. The company are authorized to raise 500,000l., the amount of shares being 100l. which it seems were, in 1802, at 20l. below par. The rates of tonnage are, for coals, culm, lime-flower, lime, and salt, 13d. per ton per mile; for free-flower, timber, flake, iron-flower, lead-ore, iron, and lead, 2d., and for all other goods 3d. per ton per mile, except road materials and manures (but not lime) upon the pounds, or when the water flows wide over the lock-works. On crossing the Dee river at Chelfer, goods pay 2d. per ton to the Dee company, and their tolls are guaranteed to the amount of 20l. annually. While this canal was projecting, a rival scheme was started, called the Eastern Grand Trunk from the Severn at Shrewbury to the Chelfer canal at Crow's nest, with cuts to Vable-Cruise, to Bonham-Furnace, Holf, and other places.

**Evesham Canal.** Act 17 Geo. III. 1.; the general direction of this canal is nearly north, 114 miles along the foot of the county of Derby, near to Nottinghamshire; its northern end is considerably elevated above the level of the sea; its chief object is the export of coals from the numerous collieries on its banks, and those on the banks of the Nabuck canal which joins it at Stanton, and the Nottingham canal which joins it at Long Eaton, and the Trent canal near Sawley. It commences in the Trent river near Sawley (opposite nearly to the Longborough navigation or Soar river), and terminates in the Cromford canal at Langley Bridge, the rise being 1085 feet; there is an iron railway branch to Brinsley coal-works, on which experiment was, as before related, made about the year 1800, on the load which one horse could draw both up and down the declivity. By the act of 33 of Geo. III. for Derby canal, a reduction of the rates between the junction therewith and the Trent river was made, conditionally, that no other junction be made between this canal and Derby, but the present one near Sandiacre; and by the 34 of Geo. III. for Trent river, the annual rent of 5l. is commuted for a toll of 6d. on every laden boat which shall cross the Trent between the Soar and Trent river.
SAY river and this canal. A reservoir belonging to the Nottingham canal has a gauge-flume, which furnishes a regular and daily supply of water to this canal. The first survey for this line of canal was made in the year 1770.

**EXE RIVER. (Montrose).** This river is navigable but a short distance in the tide-way from the German Ocean to the town of Montrose, in Angus county in Scotland. Montrose is the 67th British town, with 7,374 inhabitants.

**EXE RIVER, (Whitby).** The navigable part of this river is but short, in a S.W. direction in the Fall Riding of Yorkshire; it commences at the German Ocean, and extends to Whitby bridge. In 1755 Mr. John Smout was consulted about clearing this river and the harbour of Whitby, of the sluic or refuse ore, from which alum had been manufactured, and whereby the harbour had become in time nearly choked up. Whitby is the 72nd British town, with a population of 7,183 persons; within a few years past, a pier has been built with free stone, under the direction of Mr. John Remie, for the improvement of the mouth of this harbour.

**EXE RIVER.** The course of this river is nearly N.W. for about 10 miles in the county of Devon; its principal object seems the supply of Exeter and Topsham; near Topsham it is to be joined by the Great Western canal. It commences in the English Channel at Exmouth, and terminates at the city of Exeter, which is the 21st town in Britain, with 17,508 inhabitants: from Exeter it was in 1803 proposed to continue the navigation to Crediton; and in 1769, the Exeter and Uphill canal was proposed to be made from the same place.

**Exeter and Crediton.** In the year 1800 it was proposed to make the rivers Exe and Crediton navigable, from Exeter city to the town of Crediton, about seven miles, above Exeter quay on the river Exe.

**Exeter and Uphill.** In 1769 Mr. John Brindley surveyed the country for a canal from the river Exe at Exeter, by Tiverton, Wellington, Taunton, and Glastonbury, to the British Channel near Uphill; the objects of which have been since embraced in the Great Western canal.

**Fergus Canal.** This is one of the Irish inland navigations, in 11 of which, public money was from time to time granted, although in the present state we are told it amounted to no more than 3½.

**FORTH RIVER, (or Forth).** This principal river of North Britain has its course nearly west for about 70 miles between the counties of Fife, Haddington, Edinburgh, Linlithgow, Stirling, Perth, and Clackmannon, the first 52 miles being a very wide estuary, the next 18 miles are filled of considerable width, and the last 12 miles next Stirling are remarkably crooked. An immense general trade is carried on upon this river, and for the supply of the metropolis of Scotland, assisted by the Edinburgh and Glasgow canal, that joins it at Leith, the Burrowflowens at that town, the Forth and Clyde, or great canal at Grangemouth, the Caron river near Rochkennar, and the Devon river near Cambus Quay. Edinburgh (with Leith) is the 5th British town, with 82,500 inhabitants, Dunferline is the 72d, with 9,500 persons, and North Berwick, Crail, Anluther, Dysart, Kirkaldie, Kinghorn, Dunblant, Inverkeithing, Muffelburgh, Queen's Ferry, Burrowflowens, Linlithgow, Falkirk, Cullrof, Clackmannan, Alloa, and Stirling, are also considerable towns on or near this fine river. It commences in the German Ocean, and terminates at Stirling bridge, and is navigable for ships through a great part of its course; at Cambus Quay the spring tides rise 20 feet, but below this there are tides called the Thрак Shallows, concerning the removal of which, Mr. John Smout was consulted in 1767. In 1801, the channel south of Luch Keith Isle was deepened, to enable ships to approach Leith harbor safely and readily. Leith harbor has undergone great improvements of late years, under the acts of 182, 183, and 45 of Geo. III., by the fall 25,000l. of the public money was granted for the wet-docks and other works which have been carrying on there under Mr. John Renie, since the laying of the foundations, in May 1831. Leith harbor on the north side of the Forth is also under improvement, and by the 45 of Geo. III., 2,000l. of the public money was granted towards the building of the pier there. In the year 1767, Meffrs. Watt and Murdoch surveyed the upper part of the Forth river, and proposed to extend a navigation from Stirling bridge to the face of lime quarries in Aberfoyle, on which the opinion of Mr. John Smout was also taken.

**Forth and Clyde Canal.** After 8, 13, and 22 of Geo. III. — The general direction of this great canal is nearly west for 35 miles, in the counties of Stirling, Dunbarton, and Lanark, in Scotland: it crosses a low part of the grand-ridge between the tide-ways of the east and west seas; its principal object is a communication between those important rivers, the Forth and the Clyde, and between the northern metropolis, and the great manufacturing towns of Glasgow, Paisley, &c.; near to Grangemouth the Burrowflowens canal joins it. Glasgow is the 5th British town, with a population of 77,385 persons, and Falkirk the 59th, with 8,935 inhabitants. Kirkintulloch and Dumbarton are also considerable places near the line. This canal commences at Grangemouth harbour in the Forth river, and terminates at Bowlings bay near Dalmeny Burnfoot, in the Clyde river. There is a cut of 24 miles to the town of Glasgow, where it joins the Clyde river, the Monkland canal, and the Edinburgh and Glasgow canal; and it was in 1803, proposed to join the Glasgow and Saltcoats canal; there is another cut with a lock into the Caron river at Caron-shore, near the great Caron iron-works. From low-water in the Forth in Grangemouth lock, N2° 10', is a rise of 156 feet; the width of the canal is 36 feet at top, and 27 feet below, and the depth of water 8 feet; each lock is 75 feet long, and 20 feet wide in the clear, and values of 70 and 80 tons are used. This canal is crooked in 33 places by draw-bridges, has 33 culverts or arches under it, and 12 large aqueduct bridges; that over the Kelvin is 420 feet in length, and 70 feet high above the surface of the river, (see figs. 19, 20, and 21, Canals, Plate II.) and there is a large aqueduct which crosses the turnpike road from Glasgow to Stirling at Kirkintulloch. At Kilmananmurr is a scarp valve of 70 acres extent, and 22 feet deep at the sluice; and near Kilcruth is another of 50 acres, 24 feet deep for supplying the summit-level of this canal. In Bowlings-bay, and near the Kelvin aqueduct, are dry-docks, and other conveniences for repairing of vessels and boats. Mr. John Smout was first employed to survey this line in 1764, and he laid the present design, and executed a considerable part of the eastern end before 1775, when the work flood fell for some years, after which, Mr. Robert Whitworth was called in; he completed the remainder, and it was opened with great solemnity on the 28th of July 1792. The design of a canal between the Forth and Clyde has been at times entertained ever since the reign of Charles II., and besides the above engineers, since the year 1723, Meffrs. Gordon, Mackell, Watt, Brindley, Golborne, Thomas Yeoman, &c. have been consulted or employed. The canal was first made to commence in the Caron river, about a mile from its mouth, but was afterwards continued into the Forth at Grange-
mouth harbour. The proprietors were authorized in their first act to raise 200,000l. in 100l. shares; after which, 50,000l. of the public money was granted to aid the work; in 1785, 212,000l. had been expended, and no dividend or interest had been paid on the shares. The rate of tonnage is 0.5d. per ton per mile on all kinds of goods, except lime and lime-stone, which is to pay 1.6d. per ton per mile, while road-materials (except lime-stone) and manures are to pay toll free. For unloading or loading of British or Irish vessels in Grangemouth harbour, 1d. per ton is to be paid, (by 24 Geo. III.) and for foreign vessels 2d. per ton. Rafts of fir timber are allowed to be floated upon this canal and paid the locks, these often contain 70 tons each. An accident is related of a vessel coming down from the wellward on this canal, when the wind blew strong from that quarter, and not being stopped in time at one of the locks, the bore down the gates, and went down suddenly into the pound below. In December 1801, a vessel constructed by Mr. Symington, (as already described) was tried on this canal for dragging or towing boats, by the operation of a steam-engine; to the head of this vessel flappers were applied, that could be worked by the engine for breaking ice, when the canal is frozen over.

**FOSS-DYKE CANAL.** The general direction of this navigation is nearly S.E. for 11 miles, in the counties of Lincoln and Nottingham; it is upon one level, not much elevated above the sea, though a great distance from it, and presents the curious instance of a canal discharging its waste water into one river (the Witham,) while flood gates are necessary at the other end, to keep out the waters of the other river (the Trent); its object is a communication between these two rivers, for supplying coals and exporting farm produce. Lincoln is the 76th British town, with a population of 7,4598 persons. This canal commences in the Trent river at Torksey, and terminates in Brayford pool, a natural pool in the Witham river, near Lincoln. It has a lock at Torksey, constructed on the principle of a sea-lock, that is capable of penning the water into the canal, or out of it, according to the circumstances whether the Trent or it may be the lowest; between Brayford pool and Lincoln high-bridge, a hard of gravel or shallow, called Brayford head, held up the water in this canal, to about 23 feet deep, which otherwise would, in dry times, have been emptied into the Witham, too low for navigation. Mr. John Smeaton and Mr. John Grundy were consulted in 1792, and the former engineer again in 1782, when he recommended raising the banks of this canal to obtain a better depth of water, cutting off its connection with the Witham by a pound-lock, and supplying it with water by an aqueduct or feeder, from a reservoir to be made near the Witham, south of Brayford pool. We are not acquainted with the date when this canal was first dug or made navigable; Mr. Ellifon's wharf thereon, near its east end, was, it appears, built about 1765.

**Foss Navigation.** Acts 33 and 41 Geo. III. The direction of the Foss river, which this navigation follows, is nearly N. by a crooked course of about 13 miles, through the North Riding of Yorkshire: its elevation is not very great above the level of the sea; its objects are the supply of the city of York, the import of coals for the use of the adjacent country, and to effect a better drainage of the same. York is the 23d British town, with 16,145 inhabitants. This navigation commences in the Ouse river at the city of York, and terminates at Stillington mill. It is fed by a reservoir on Oultone moor: it appears that the corporation of York were by a licence of king Richard II. required to erect and maintain proper bridges over this river. This company were authorized to raise 45,400l. the amount of shares being 100l. each. The rates of tonnage will be found in Phillips' 4to. History, Appendices, p. 81 and 82; and in the last act, by which an additional 15d. per ton, on heavy articles, were imposed, and by which the proprietors were authorized to proceed no higher than Sheriff-Hutton bridge with their works, until the necessary funds were accumulated to proceed with the remainder of their line. Some years ago, a pleasure-boat, made wholly of sheet iron, was tried on this navigation, 12 feet long, and capable of carrying 15 persons, and yet so light that two men could carry it.

**GLAMORGANSHIRE CANAL.** Acts 30 and 36 Geo. III. The general direction of this canal is nearly N.W. for 25 miles, in the county of Glamorgain South Wales. Its objects are the export of the produce of the immense iron, coal, and lime works in the neighbourhood of Merthyr Tydil, &c. and the supply of the rapidly increasing population thereof; at Eglwysilan the Aberdare canal joins, and the Cardiff and Merthyr railway runs by its side, and joins it at thofe two places. Its northern end is considerably elevated. Cardiff and Caerphilly are considerable towns on or near the line; it commences in a sea-bason, or dock, in the Severn, at the Lower-layer near Cardiff, and terminates near the town of Merthyr; it is a railway-branch from Merthyr to Dowlais iron works. From the tide-way at Lower-layer to Merthyr is a rise of near 600 feet; and while of this distance the canal skirts precipitous mountains at the height of near 300 feet above the river Tav or Taaff, which it closely accompanies throughout its whole length. The floating dock at Lower-layer is 16 feet deep, in which a great number of ships, of 300 tons burthen, can lie conveniently afloat, and load or unload, either at the spacious warehouses on its banks, or from, or to, the boats belonging to this canal, or the trains used on the Cardiff and Merthyr railway, that here commences. There is a large aqueduct bridge over the Tav near Gallygare. This company were authorized to raise 100,000l. and to the powers for raising the last 100,000l. this singular condition was annexed, viz. that the whole concern should be completed within two years, after which no further money should be applied, except for repairs. At Merthyr there is a famous water-wheel, made of cast-iron, 50 feet diameter, at Mr. Crawfords works; the water being conveyed thereto for a great distance in an iron aqueduct.

**Glasgow and Saltcoats.** In May 1803 the line of country between the Clyde river at Ardrossan, near Saltcoats, and the Clyde river again at Glasgow (pausing Paisley and connecting with the Cart river) was surveyed by Mr. John Rennie; in 1805, the subject was revived, and met the support of the earl of Eglington and many others, coupled with the design of building a pier on a ledge of rocks near Castle Craigie, and forming wet-docks, &c. to be called Ardrossan harbour, for which an application was made to parliament in the same year. At Glasgow this canal would connect with the Greenock and Clyde, the B'Verkland, and the Edinburgh and Glasgow: the line thereof is through a country rich in coals and lime-stone.

**GLENKENNS CANAL.** Act 42 Geo. III. The direction of this canal is first N.E. and then N.W. for about 27 miles, in Glenkenins, in the county of Kirkkudbright in Scotland: it is not very greatly elevated; the object of it is the export of the coals, iron-stone, and other minerals with which the country abounds; Kirkkudbright and New Galloway are considerable towns near the line. It commences in the tide-way in the Dee river at Kirkkudbright, and terminates in the boat-pond at Dalry. There is provision made for branches to the neighbouring mines and railway-ways, and inclined planes may be substituted, instead of a canal and locks in any part. The company is authorized to raise
A tunnel the I' Phillips' 127 thence is 1,.. g population Adingham has miles 'miles 25^ Naafown The yai [n n irri agitation. it; this! panes t tub- 1 u coal new tut feet. nearly 48^ i)H'^ < the it or tl\ L. In 5 fmce paffes thi cginii Glouceftcr nearly canai, in

William Heslop, &c. In the year 1779 this canal had proceeded from Dublin into the town of Allen, when, owing to mismanagement, it flood fill for several years, and it was not until the beginning of 1804 that the whole line was firi nished and opened. The sums of the public money which have been granted by the parliaments to aid this work are immense; between 1753 and 1771 they amounted to 78,211. It has been proposed to reduce the falls or tonnaage since the opening of this canal. In the beginning of the present year (1805) it was proposed to continue a branch from this canal, near Athy, for 9 miles, to the foot of the Drumne Hills, in Queen's county, and thence to tunnel two miles into the hill, to drain the rich veins of coal therein, and bring out their produce.

Grand Junction Canal. Acts 35, 36, 37, and of Geo. III. — The general direction of this canal is nearly north-west for 921/2 miles, in the counties of Middlesex, Hertford, Buckingham, Bedford (a very small distance), and Northampton. It has a summit of considerable height near Tring, which it passes without a tunnel; and near its northern end it crosses the grand-ridge by a tunnel. Its principal objects are, a communication between the metropolis and the various canals of the midland counties, the supply of coals, deals, flake, &c. to the several towns on the line and branches, and the export of the agricultural products, lime, flints, &c. of the country through which the canal passes; at Northampton it joins the Nene river by a rail-way branch, and the same is intended there also to join the Leicestershire and Northamptonshire Union canal. London, as is well known, is the first town in Britain for population, with 864,845 inhabitants, and Northampton is the 85th, with 7,260 persons; Brentford, Uxbridge, Rick manworth, Watford, St. Albans, Hemel-Hempstead, Berk hamstead, Tring, Wendover, Aylesbury, Leighton-Buzzard, Fenny-Stratford, Newport-Pagnell, Stony-Stratford, Buckingham, Towcester, and Daventry, are also considerable towns on or near this canal or its branches. The commencement of this canal is in the river Thames, near the extremity of the tide way at Brentford creek, and its termination in the Oxford canal at Braunston. From Bull bridge a branch, 131/2 miles in length, goes to Paddington, one of the environs of Lon don; to the town of Rickmansworth, there is a cut of about 4 of a mile, with a lock at its entrance; from Bulburne head a branch extends for 63/2 miles to Wendover; from Cropgrove a branch of 1 1/2 mile extends to Stony or Old Stratford, and thence 9 1/2 miles further to Buckingham; and from Gtayton a rail-way branch of 5 miles extends to the river Nen, and the intended termination of the Leicestershire and Northamptonshire Union canal at Northampton. To Watford a branch of 2 miles, and thence about 5 miles farther to St. Albans, has been surveyed and provided for in the acts; another to Aylebury of about 6 miles, and another to Daventry of 1 1/2 mile in length, but these last are not executed. From the Thames at Brentford to Two-waters is 223 miles, with 269 feet rise; thence to Cropgrove is 7 1/2 miles, with a rise of 127 feet; thence to the Wendover branch is 3 1/2 miles, of the highest summit-level; thence to the crossing of the Ouse river, between Wolverton and Cropgrove, is 2 3/4 miles, with a fall of 192 feet (this being the lowest place); thence to Stoke Bruern is 3/4 miles, with a rise of 112 feet; thence (through the Blisworth tunnel) to the south end of Whilton parish, 1 1/2 miles, is level; thence to Whilton mill, in Long Buck by, 24th of a mile, is a rise of 60 feet; thence along the summit-level, and through Braunston tunnel to its north end, 4 1/2 miles, is level; and thence to the Oxford canal at Braunston, near 1 mile, is a fall of 37 feet. The Paddington branch is level (at about 50 feet above the Thames, and 43 feet above the Strand-pavement at Exeter change).
change. The Wendover branch is level, and connects with the Bulbourne or Tring summit pound: the Buckingham branch has a rise of 15 feet; the Northampton branch has a fall of 120 feet, and the cut to Daventry is to have a rise of 60 feet. The width of the main line is 36 feet at top, about 24 feet at bottom, and 4½ feet deep in water: the Wendover branch is 28 feet wide at top, 18 at bottom, and 4½ feet deep; and the Buckingham branch is only 20 feet wide at top, 10 at bottom, and 4½ feet deep in the general. The Northampton rail-way, which is now (October 1805) nearly or quite finished and ready for opening, is of iron, and double, that is, has two roads for the carriages going different ways. The locks on the line are 86 feet long, 15 feet wide in the clear, and rise about 7 feet each on the average, requiring about 9330 cubic feet, or 250 tons of water to fill them each time that a barge passes. On the line there are 101 locks, besides the 9 spare ones in Wolvarton-valley 3 on the Buckingham branch there are 3 locks. Two kinds of vellies are in use upon this canal, barges with square heads and flaps, and flat bottoms, that carry 50 tons, and boats with sharp ends, or nearly so, of half the width, that carry 25 tons. At White-friars, just above Blackfriars-bridge, on the Thames, this company built extensive warehouses, over a dock, in which barges lay afloat from one tide to the next; there are now let to Mr. Pielford, the great waggons and boat-maker. At Paddington a spacious bason or straight out, 400 yards long and 30 wide, has been formed with wharfs at its head, and others are daily extending wellward along its sides; behind this, on the north side, is a spacious yard for a vegetable and a hay and straw market, with immense sheds, under which loads of those articles can stand in the dry when it rains; and on the south side pens are erected and provision made for a large cattle market. The number of wharfs erected on this extensive line and its branches by individuals are too great for us to attempt to particularize them. The number of culverts or small water-courses under the canal and its branches are very great. And on the towing path there are a number of large and high wooden bridges for croffing the entrances to branches, docks, or over streams of water; for some distance from Paddington provision is made under the bridges for a towing path on each side of the canal. The tunnel between Stoke-Breram and Bliworth (already described), is 3060 yards in length, 17 feet wide, and 19 feet high, at 66 feet below the top of Bliworth hill, through which it penetrates. Braunjton tunnel, between that place and Daventry, is 2435 yards in length: another tunnel was at first intended near King's-Langley for avoiding Chalishobur, and other parks in the Colne valley; but an agreement was afterwards come to with their owners for a passage through them, instead of tunneling. Between Cow-rost and Bulbourne there is an immense deep-cutting for passing the great range of chalk-hills near Tring; this extends for 3 miles, and is 30 feet deep in the highest part; near Dawley there is a great length of deep-cutting through the immense bed of gravel at that place; at the ends of the Bliworth tunnel, and at several other places there are also deep-cuttings. Between Wolverton and Cosgrove a stupendous embankment, with three aqueduct arches under the same, has been constructed, since the locks were made for croffing the Ouse river, as above mentioned, over which the canal has, since August 1805, been conducted, and by which 4 locks on the south side of the valley, and 5 locks on its north side, are avoided, except a lock of 18 inches rife, near the north end of the embankment, by which 12 miles in length of level pound is held up (on the line and Buckingham branch), and separated from 10 miles of level pound south thereof, to beyond Penny-Stratford town, (where another lock of only 18 inches rife occurs, to build up a pound of fome miles in length that was intended, but for a mistake in the levelling, to have been in one pound); this embankment is ¾ a mile long, and 30 feet high, where it crosses the Ouse. At Weeton-Beck, and at Bugbrook, there are also moft stupendous embankments, and river and road aqueduct-arches, and many leffer embankments and aqueduct bridges occur on the line and branches: those over the Brent river, and over Bays-water on the Paddington branch are considerable. On Harefield Moor there is a very wide and large piece of water on the canal: others at Great Berkhamstead, at Halton park, and two other places on the Wendover branch. Five considerable reservoirs have been constructed for preserving water for this canal, or the mills, whose streams have been diverted for its use; that at Aldenham covers 68½ acres, at Willi:one is one of 5 acres, and that at Watton-Turville, Braunjton, and Daventry, are all of very considerable dimensions. The principal feeder for the southern summit is at Wendover, and there are others at Little Tring, Tring, and Milswell (the last being arched over for ¼ of a mile). The middle and lower part of the line is supplied by a feeder at Soulbury, and the northern summit is supplied by a feeder from Watford, near Daventry: besides which, that summit has had its banks raised to accumulate an extra depth of water in wet times, and a steam-engine has recently been erected for pumping the water out of the level of the Oxford canal to that summit, that is let down therefrom by the lockage. At Little Tring an engine was, in June 1803, erected for pumping the water collected in Willi:one reservoir into the Wendover branch of the southern summit-level; and at Nash mill, some distance below Two-waters, in the Colne valley, an engine is now erecting to return the lockage water of 4 locks that are there placed near to each other. On the north and south sides of the Tring summit, several pairs of tide ponds have been lately added to the locks, for having part of their consumpation of water. Where the Towcelfter river (the Tove) is croffed and joined there are very considerable weirs or tumbling-bays, and others on the old course, in the Wolvarton valley; and, between Great Berkhamstead and Uxbridge, there are continually occurring, owing to the canal having unfortunately been conducted into and through almost every little stream, that overfalls of lefs size are also very common on every part of the line, so are stop-gates, trunks, and every other necessary appendage and convenience to a navigable canal. Mr. William Telford was the engineer to this extensive concern; Mr. James Barnes and Mr. John Holland were employed in executing different parts of the works, on which Mr. Thomas Telford was lately employed to report his opinion; since 1803 Mr. Benjamin Bevan has been employed in repairing the leaky parts, constructing tide-ponds, &c. in the middle district of this canal. The works on this canal commenced at both of its extremities, soon after the passing of the first act; and the tunnel at Braunjton being completed, the navigation was opened, in July 1796, as far southward from the Oxford canal, as the great embankment at Weeton Beck; in June 1797, the same was extended to the next great embankment at Bugbrook; and about November in the same year, to the north end of the intended tunnel at Bliworth. Beginning at the southern end in the Thames, the navigation to Two-waters was completed in June 1798, and in June 1801 the branch thence to Paddington was opened; in the year 1799, the canal was completed to Bulbourne, and the branch thence to Wendover; in June 1806, it was extended to Penny-Stratford; and about December 1813, to the fourth end of the intended tunnel at Bliworth; at the same time a double iron rail-way of near 3½ miles in length (since removed) was laid across Bliworth Hill.
Hill, to connect the two parts of the canal, and form the much wished for grand junction; in May 1801, the branch to Buckingham was opened; it was not until March 1805 that the Blisworth tunnel was completed, and the navigation of the whole line opened; and, firstly, in August 1805, the immense Wolverton embankment was opened for improving the same, and avoiding 8 locks, but which locks still remain by its side, as a referee, in case of accident, to this immense mound of earth, or the three large arches under it. This company were authorized by their first nine acts to raise 1,453,000l. to which their first act of last session made a considerable addition; and it is feared that the expenditure will altogether exceed two millions sterling. The shares are of 100l. value each, which have at some periods of the businesf sold as high as 210l., and at others have been down at 65l. Shares in this concern are allowed to be split into such small portions among different holders, as 4th or 8th each. On the original shares no dividend or interest has yet been received, but now, as the tolls amount to full 7,000l. per month, it is hoped a dividend will begin to be made. Inland canals from the rich and inexhaustible mines with which this and other canals form direct communications, were forbid under severe penalties (although two legislative attempts to enforce the same proved inefficient) to be brought nearer to London than the N.W. end of Grove park in Hertfordshire, until the last act of the late session mentioned above, by which 50,000 tons of such coals are allowed to be brought to Paddington in the current year, on paying a duty equivalent to that paid in the Thames on sea-brought coals. The market at Paddington, after an ineffectual and most extraordinary opposition from the city of London, was opened in May 1802, for the sale of fat cattle, hay, straw, corn, vegetables, &c. By the act 41 Geo. III., this company was authorized to lay pipes in certain streets in Paddington, Mary-le-bone, &c. for supplying the inhabitants with water; but at that time, certain millers, whose dams the line had been made to pass through, were not consulted. In June 1801, packet-boats were established, that continue to pass regularly at stated hours during most of the year, for the conveyance of passengers and parcels London and Uxbridge; and for some time after the opening of the Buckingham branch, a boat went regularly between Paddington and that town; but to which number of passengers and parcels a were found inadequate to support the expense of such an establishment. Trading boats are not allowed to pass along upon this canal except in the day time, unless such as have a special licence from the company for such purpose. Mr. Pickford has a great number of boats, which proceed as regularly day and night upon this canal, and the other canals north of it, as the mail-coaches do on the roads, although with less expedition. A common trading boat has been known to arrive at Paddington in 63 hours from Coventry. In December 1799, the experiment was first tried, of bringing fat Oxen to London in boats by means of this canal. The rates of carriage on this canal were at first very low, as will be seen in Phillips' 4to. History, Appendix, p. 91. Additional tolls were provided in the 43d of Geo. III. for passing the Blisworth tunnel and Woolveton embankment; and by the first act of the last session (45 Geo. III.), the rates on the whole line and branches were varied, and increased for short distances. The act of the 33d provided certain rates, which are to be paid to the Oxford company (See Phillips' Appendix, p. 93.) for goods passing thereto or from this canal, and this company is bound (since the beginning of 1804.), to make up the same to the amount of 10,000l. per annum. This company is also bound to pay annually to the city of London the sum of 50l. for the liberty of making a junction with the Thames; and all goods, passing into or out of the same, are to pay 3d. per ton, to be applied towards improving the middle navigation of the Thames river. The intended cut to Aylesbury was, on account of the scarcity of water at Marlow, where it was to join the line, changed for a railway, and in the year 1803, the same was begun; the iron rails were actually purchased, and brought to the spot, but, alas! in one of those revolutions of fortune to which borough towns are ever liable, the work was stopped, the rails were ordered to be sold, and years may now perhaps elapse before Aylesbury is permitted to enjoy the advantage of a canal or railway communication. About the year 1799, an extension of the Rickmansworth branch of this canal was proposed to the town of Chesham. In 1793, and again in 1802, it was proposed to extend a branch from near Slapton to the foot of Puddle-hill between Dunstable and Hucknall; one object of which was the export of the valuable white freestone from the quarries at Tottenhoe; this object may, however, it is presumed, be obtained without such a cut; and some of equal quality be got in several places on the summit branch. In the year 1802, the country westward of Uxbridge was surveyed by Mr. John Holland, with the intention of extending a branch of this canal from below Cowley lock, (continuing the level of the Paddington water) to the Thames at Harlesdon in Great Marlow parish; it was also proposed, after crossing and uniting with the Thames at this place, to extend this branch, by a rise of three locks, to a side-cut of the Kennet river at St. Giles's in Reading, with a branch therefrom to the Thames at Summing: the objects of this branch were, a more direct communication with the Bridgford channel, by means of the Kennet and Avon canal, the supply of the country bordering on this canal and its branches with peat manure from near Kedington, the better supply of, and communication with London, by means of a canal without a lock, between the Thames at Great Marlow, and Paddington, the gaining from the Thames that supply of water, which had been denied from the Colne for the intended water-works, and the lockage of the London canal; which, in 1802, proposed to extend from the Caen of this canal at Paddington to the London Docks, and thereby to communicate with the Thames; after which a railway was, in the same year, proposed to extend from Paddington over nearly the same ground. It was before 1773 that a canal was first proposed from Paddington to Uxbridge, nearly in the route of the line now accomplished; and in 1773, Mr. James Sharp proposed an extension of this to the Kennet river. In June 1803, a survey was taken for extending the intended Aylesbury branch by Tame to the Thames and its navigation, and Wilts and Berks canal near Abingdon. And in the same year, the Leicestershire and Northamptonshire Union canal was proposed to be joined to the line of this canal at Long-Buckby wharf near Daventry, instead of joining its Northampton branch at that town.

**GRAND SURRY canal. Act 41 Geo. III.**—The general direction of this canal is nearly S.W. for about 12 miles, by a crooked course in the county of Surry, and through a small part of Kent. It is not greatly elevated in any part of its objects are the supply of the neighbourhood through which it passes with coals, deals, manures, &c. the bringing of vegetables, and other articles for the supply of London: forming a communication between three points of the Thames river, and with the Croydon canal, which it joins near Deptford. It commences in the river Thames at Wilkinson's gun-wharf in Rotherhithe, and is to terminate at the town of Mitcham; near Wallworth, a branch of about 2 of a mile goes off to join the Thames at Vauxhall.
Vaughall creek by Cumberland gardens. There is to be a
cut of near 1½ mile to Horfemonger lane; another of ½ a
mile to Peckham; another of one mile to But-lane Dept-
ford; another of ½ of a mile to his majesty's victualling
office and the dock-yard at Dapford, and another of ½
of a mile into Greenland dock, by which it will again
communicate with the Thames river.

From the river Thames to the junction of the Croydon ca-
nal the distance is 2 miles, and nearly level with high
water in the tide-way of the Thames, at which height the water is
to be held up by tide or entrance locks; thence to the Vauxhall
branch at Kennington common it is 3 miles and level;
then at Brixton-cutoff, ⅔ mile, it has a considerable
rise; thence to the proposed Kingston branch, ⅔ miles, it is
level; and thence to Mitcham town it is ¾ of a mile; the
Vauxhall, Horfemonger-lane, Peckham, But-lane, King's
yard, and Greenland-dock branches, are all level. This
channel is calculated for wide or river boats; near the
commencement, at Wilkinford's wharf, a large basin is
designed, and a smaller one at But-lane near the Greenwich road:
across Rotherhithe to Brixton-cutoff an inclined plane
is intended. Mr. Ralph Doll was, we are told, the con-
tractor of this canal, and under his direction the works were
begun, and considerable progress made between Rotherhithe
and the Peckham branch; but for more than two years past,
little further progress appears to have been made.

The company were authorized to raise 60,000l. in 1001. shares.
The tonnage on this canal varies from 2d. to 6d. per ton per mile
on different kinds of goods. The company are to pay a rent
of 60l. per annum to the city of London for communicating with the
Thames river. Collateral cuts to the extent of 1,500 yards may be made by consent of the land owners.
In 1803, it was intended to extend this canal 6½ miles fur-
ther to the Thames river on the south side of the town of
Kingston, which was to pass the Survey iron road-way at
Merton abbey, by an aqueduct bridge 11 feet high in the
clear, and the Wandle river by another 15 feet above its
surface; from Norbiton common this was intended to branch
again to the town of Epsom, 5½ miles, and from Mitcham
the canal was there also proposed to be extended to the town
of Croydon. In the same year there was also a pro-
posal for extending the intended Kingston branch to the
Wey river (near the commencement of the Basing-fleake canal),
as part of one of the lines between Portsmouth and London.
The Croydon canal company are to have a dock or basin for their
boats by the side of this canal near the Thames at Rotherhithe;
which when the entrance lock and basin of this canal, are now
cuttin, and form on a scale calculated for small ships.

Grand Western Canal. Act 36 Geo. III.—The
general direction of this canal is nearly E.N.E. for about 35
miles, in the counties of Devon and Somerset: it crosses
the eastern branch of the grand-ridge; its objects being a
connection between the southern coal and the Bristol
channel, the supply of the country with coals, deals, &c.
and the export of farming produce. Exeter is the 1st
British town, with a population of 17,508 persons; Wil-
lington is the 73d, with 7,532 persons; Tiverton the 24th,
with 6,505 persons, and Taunton, the 108th, with 5,704
persons; Topsham, Bradninch, and Cullompton, are also
considerable towns near this line; which commences in the
tide-way of the river Exe at the town of Topsham, and termi-
mates in the Tone river at Taunton bridge; it has a cut of
about seven miles to Tiverton, and other short ones to Cull-
ompton and Wellington. It is provided, that the brick
bridges shall not have a rise of more than 2½ inches in a yard
on the aleent of the road over them. Two reservoirs are to
be made in the valley of the Culm river, and two in the
river Tone valley. Springs within 2000 yards of the line
may be taken, and cuts to any place within five miles may
be made by consent of the land owners. The company are
authorized to raise 35,000l., the amount of shares being
100l. each. We have not been able to learn that any pro-
gress is yet made in the cutting of this canal, although one
through this line of country has been so long desired, as
appears by Mr. Brindley's survey for the Exeter and Up-
bill canal, that was proposed in the year 1760.

Grantham Canal. Acts 37 and 39 of Geo. III.—
The general direction of this canal is nearly eall, by a crooked
course of 33½ miles, in the counties of Nottingham, Leic-
sfeft, and Lincoln: its eastern end is rather elevated.
Its objects are the supply of Grantham and the neighbourhood
through its course with coals, lime, deals, &c. and the ex-
port of farming products. Nottingham is the 17th Brit-
town, with 28,661 inhabitants; and Grantham the 89th,
with 7,914 persons; Bingham is also a considerable
town. This canal commences in the Trent river, near
Holme-pierpoint, (almost opposite the Nottingham canal,
to the Trent canal, and to the town of Nottingham,) and termi-
minates at the town of Grantham the Trent; there being a
branch of three miles in length to the town of Bingham.
From the Trent river to Cropwell-bishop, 63 miles, is a rife
of 82 feet; thence to Stainswith-clothes, 20 miles, is level;
thence to Woolthorpe point, 11 mile, is a rife of 58½
feet; and thence to Grantham, five miles, is level: the cut
to Bingham is level. This canal, which is through a clayey
district, is wholly supplied by proprietors, of which, one at
Denton is 20 acres, and nine feet deep, for supplying the
head-level; and that at Knifton for receiving the flood
waters of the Devon river, was 60 acres, and nine feet deep,
and in 1804, the bank or head of this last was raised four feet
higher. The company were authorized to raise 124,000l.,
the old shares being 103l. value each, and the new shares
(200 in number) 120l. each. The tonnage on all goods
pa\ning to or from this canal and the Trent river is to be
3½d. per ton, and 1½d. per ton per mile for navigating on this
canal: manures and road materials to pass toll free, ex-
cept lime-flone, which is to pay 3d. per ton per mile. The
Narrow and Bottesford canal was at this time (1793) in con-
templation to join this near Stainworth; and the tolls for
entrance therefrom, or on goods passing into that intended
canal, were settled in the first act above. The profits to the
proprietors of this canal are limited to a dividend of 8 per
cent. per annum, and after 5 years, are collected and de-
posited as a fund, the above tolls are to be lowered, as much as
circumstances will admit. The Trent river proprietors are to
take certain tolls on goods passing into or out of this canal
to the Nottingham canal, in consequence of their deep-
ening the river near the entrances to these canals; and goods
pa\ning from this canal on the Trent are not to be liable to
their new rates of 34 Geo. III. unless they pass on the
Trent canal, to be made under that act above Nottingham.

Grimes's Canal. Act 15 Geo. III.—The
direction of this canal is about N.W., and level, in the county of
Stafford: it is situated very near to the grand-ridge on its
eastern side. Its objects are the supply of the town of New-
castle-under-line with coals from Apdale collieries, and the
export of coals from the mines to the west of it, by means of
the Newcastle-under-line Junction canal, which now joins it at each of its ends. This canal was constructed at
the sole expense of Sir Nigel Grimes, bart., who was bound by
the act, for 21 years after 1775, to supply the inhabi-
tants of Newcastle with coal at £8 6d. per ton of 2,400lbs. or 3½d. by the single cwt. (£20 lb.); and during the
following term of 21 years, their price was not to exceed
In 1796, the Commercial canal was proposed to connect with this canal at each end, as the Newcote-under-line Junction afterwards did in 1798.

Grimsby Canal. Act 36 Geo. III.—This canal has a S.W. direction for 1/4 mile, in Lincolnshire; it is one of the largest cuts in England, and calculated to admit ships of 700 to 1,000 tons burthen. It commences in the tide-way in the Humber river near its mouth, and terminates in the spacious wet-dock in Grimsby harbour. The lock to this canal is 116 feet long, 36 feet wide, and the walls are 27 feet high; the cost of it, we are told, was £4,500. Besides the piling for the foundation, although bricks were delivered there at 1s. 6d. per thousand, and flume at 3d. per cubic foot. The depth of water in this canal is 20 feet; it was constructed, under the direction of that able engineer Mr. Robert Threlfall. In the year 1804, three acres more surface was excavated in addition to Grimsby wet-docks, and the same was re-opened, after a temporary interruption, on the 24th of July.

Harrow River. This river, or rather efluary, has nearly a north course for about nine miles, between the counties of Cornwall and Devon on their southern coast; it is frequented by the largest ships of the royal navy. Plymouth is the 9th British town, with a population of 43,194 persons; Plympton-Parke and Saltash are also considerable towns near this efluary, which commences in Plymouth found near Dawlish bay, and terminates in the river Tamar near St. Mellion. Near Warley the Towy river falls into it; and Cat-water, Sutton-pool, and Stone-houfe creek, are branches from this efluary. In 1767, Mr. John Swaton was consulted about a new bridge and causeway over Stone-houfe creek. In 1801, it was in contemplation to build a pier from Pinle to the better security of ships lying in Dawlish bay from the E.S. E. winds. By an Act of 45 of Geo. III. 4,000l. of the public money was voted towards cleaning and deepening Cat-water and Sutton-pool; and it is now in contemplation to construct a floating-dock in Sutton-pool capable of holding 100 merchants’ ships always afloat.

Hampton Gay and Isleworth Canal. In the year 1702, a canal was proposed, to take a course nearly N.W. for about 60 miles, in the counties of Middlesex, Buckingham, and Oxford; commencing in the Thames river at Isleworth, and terminating in the Oxford canal at Hampton-Gay. It was intended to effect that junction between the metropolis and the midland canals, which the Grand-Junction now accomplishes: it was to pass the chalk hills by a tunnel at Wendover, and to have a cut of three miles to Aylesbury.

Hartlepool Canal. This is only a very short cut of 300 yards in length, on the coast of Durham, from the sea into Hartlepool harbour; it was cut in the year 1764, at the expense of Sir John H. Dussell, through a solid rock, to the great depth of 19 feet. In 1796, Mr. Ralph Dodd proposed, we are told, some improvements of this harbour.

Hasingden Canal. Act 33 of Geo. III.—The general direction of this canal is nearly north for 13 miles, in the county of Lancashire; it is considerably elevated, crossing the Hasingden and Liverpool branch of the grand-ridge. Its objects are the export of the rich flours of coal, limestone, &c. on its course, and a communication between Manchester and the Leeds and Liverpool canal. Bury is the 84th British town, with a population of 7,072 persons; Hasingden is also a considerable town. It commences in the Manchester Bolton and Bury canal at Bury, and terminates in the Leeds and Liverpool canal at Church.
HULL RIVER, (or Hale.)—The course of this river or rather eltuary is nearly south for two miles, in the county of Cornwall, on its north-east coast: it commences in St. Ives bay, and terminates at the town of St. Erth: it is navigable only for small vessels, being almost choked at the entrance of the bay. In 1766, Mr. John Swaton was consulted on the building of a north-east pier at the entrance of St. Ives bay; the spring-tides here rise 26 feet.

HORNCastle NAVIGATION. Acts 3; and 40 of Geo. III. —The general direction of this navigation is nearly N.E. for about 11 miles, in the county of Lincoln; it is not much elevated above the sea: its objects are the supply of Horncastle and its neighbourhood with coals, deals, &c. and the export of agricultural products. Hornville and Tatterhall are considerate towns on this line. It commences in the old Witham river near Tatterhall, and occupies the site of Dyson’s and Gibbon’s former cut to Tatterhall, passing that town to Horncastle by the course of the Bain river. The company were authorised to raise 45,000 l., the amount of each share being 50l. The dividends are not to exceed 8 per cent.; but after 1000l. is accumulated as a fund for contingencies, the tolls are to be lowered, to keep the profits within that limit. The first rates of tonnage are given in Phillips’s 4to History, Appendix, p. 24, but these were varied and increased by the last act above. This company purchased the old Tatterhall canal, and were, by their first Act, to contribute jointly with the Witham and Seafoord companies in the expenses, during the next seven years, in improving and deepening the course of the Witham between Lincoln high-bridge and the Penfold-ridge canal, in order to facilitate the passage of goods to and from the Trent river, and in consequence, but half the accumulated Witham dues were to be paid for goods passing to and from this navigation. In September 1802, this navigation, and the baloon at Horncastle, were completed and opened.

HUDERSFIELD CANAL. Acts 33 and 40 of Geo. III. The general direction of this canal is south-west for 154 miles in Yorkshire and Lancashire; it crosses the Grand-Ridge, at a great elevation, by one of the longest tunnels in this kingdom, in a rocky mountain: its objects are the carrying of coals that are found both in its extremities, the supply of part of the country with lime, the conveyance of farming produce to the great towns, and the forming of a more direct communication between Hull and Manchester and Liverpool. Hudersfield is the 9th British town, with a population of 7230 persons: Alton-under-ridge is also a considerable town. This canal commences in Sir John Ramsden’s canal near Hudersfield, and terminates in the Manchester Alton and Oldham canal, at Duckenden Bridge, near the town of Alton-under-ridge (near which the Peak Forest canal also joins it). From Ramsden’s canal to Marford the distance is 72 miles, with a rise of 436 feet; thence and through the tunnel to near Saddleworth it is 4 miles, and level; and thence to the Manchester Alton and Oldham canal, 15 miles, is a fall of 334 feet. The lock at the entrance from Ramsden’s canal is 8 feet wide, this canal being only intended for narrow and long boats. The Tunnel through the Stannage Hills near Marford is to be three miles in length, near to which, on the summit-level, the company are authorized to make reservoirs to contain 20,000 lock-falls of water, (each 180 cubic yards), and may make others if they prove insufficient. About the year 1798, that part of the line between Hudersfield and Marford was completed and opened; in the same year the head of a large reservoir near Marford broke, and the torrent of water let down thereby did considerable damage to the country below it. The company are authorized to raise 274,000l.; the amount of shares being 100l. These became greatly depreciated in value, about the year 1800, owing principally, it is supposed, to many of the original subscribers not being able to answer the calls for money, by which the works were retarded, and the canal remained in an unproductive state: the Tunnel under the Stannage Hill is now proceeding. The rates of tonnage are from 4d. to 3d. per ton per mile for different goods, (see Phillips’s 4to History, Appendix, pp. 135, 136.) besides which is 6d. per ton is to be paid extra, on all goods which pass through the tunnel: let’s rating than 15 tons is not to pass any lock, unless the water runs wide thereof, without constant; no rates are to be taken by Sir John Ramsden for the goods which pass between his workhouse at Huddersfield and this canal, this company to amend and keep that part of his canal in repair, in consequence, and are to guarantee his tolls not being lessened, taking an average of three years before this canal is cut. This company is also bound not to make any branch or extension of the canal to any other navigation to the eastward; but, in such case, the tolls thereof are to be divided between Ramsden’s, the Calder and Hold’s, and Ayre and Calder proprietors, instead of being taken by this company.

HULL CANAL. The course of this river is nearly north, for about 12 miles, in the East Riding of Yorkshire; it is but very little higher than the sea: its objects are the supply of Beverley and the adjacent country with coals, deals, &c. and the supply of Beverley and Hull with farm produce. Kingston-upon-Hull (or Hull) is the 16th British town, with 29,416 inhabitants; and Beverley is the 45th, with 6001 persons. This navigation commences in the tide-way of the Humber at Hull, and terminates in the Driffield navigation upon the same river at Aike-beck mouth. In Leven parish (between Ecke and Leven-bars) this is joined by the Hull and Leven canal.

HULL AND LEVEN CANAL. Acts 41 and 42 of Geo. III. The course of this canal is nearly easterly for about three miles, in the East Riding of Yorkshire; it is in a very low situation; its objects are the supply of Leven town, of lime to the country east of it, and the export of the agricultural produce thereof for the supply of Hull and Beverley. It commences in the Hull river, and terminates at Leven bridge. Mrs. Cleasby Bethell is the sole proprietor of this canal, on which Mr. John Dennis, Mr. William Jefcoft, and Mr. France were consulted. This canal was finished some time ago; and the act of last session was for raising the tolls, which were found disproportionate to the expense of its construction and management.

HUMBER RIVER. Act 23 Henry VIII.—This noble river, or rather eltuary, has nearly a west direction for about 40 miles between the counties of York and Lincoln. The tide flows with great rapidity through its whole length, and the depth of water is sufficient for ships of considerable burthen, which trade in valn numbers to the port of Hull, and with the numerous eastern rivers which connect with it. Hull contains, as above stated, 25,316 inhabitants; and Barton is the 95th British town, with 6197 persons. Grimby, Pattrington, Headon, and Burton are also considerable towns on or near to this river. It commences in the German Ocean at the Spurn Head, and terminates in the Ouse and the Trent rivers, at their junction at Trent-fall: it is joined at its mouth, near Ternay, by the Louth river; at Grimby, by the Grimby canal and docks; at Kingston-upon-Hull, by the spacious Hull docks and by the Hull river; in Wintringham, by the Ancholme river; and at Pools-duck; a few miles, by the Market-Weighton canal. The port of Hull, and the communications of this river, have been greatly improved, by the constructing of
wet-docks at Hull; the acts 14, 42, and 45 of Geo. III. having failed for these purposes, the first dock was opened in September 1798. In 1802, the new Harbour-dock was proposed, from Myton-gates to Hesel-gates, on the site of the old ramparts, to form four acres of water, to which a 50 gun ship may have access from the Humber, and 70 feet of ships may lie conveniently, to be surrounded in part by spacious warehouses. By the act for the same, 30,000l. in 1803, was to be raised: these shares have since borne a premium of near 50 per cent. The act of the late session was for raising more money to complete this vast undertaking, now in great forwardness. In September 1822, a small dock was begun on the shore of the Humber for market and ferry boats; a number of dolphins or floating buoys were, about the same time, placed on the banks of the river. In 1774, Mr. John Smeaton was employed to build two light-houses on the Spurn Head, at 500 yards apart, which, in June 1776, were in imminent danger of having their foundations undermined by a great gale: in September 1803, the lowell of these light-houses was burnt down by accident. Coal-ships, palling the Humber's mouth for London market, pay 1d. on each charge of their cargo, towards the support of these lights. In 1829 it was in contemplation to erect a light-house at Stallingborough, on the fourth shore of the Humber. In 1802 the Gillingham and Hull canal was proposed, to connect with this river at Hull; in the same year, the Keyingham-Level navigation was proposed to join at Stone-creek. In 1805 the Heckno and Paul canal was proposed to connect with it at Paul.

Isle of Wight. The course of this river is nearly as well for about 10 miles, in Nottinghamshire: it commences in the Trent river at Stockwith, (near to the termination of the Chesterfield canal,) and terminates at the town of Bawtry. At half a mile from the Trent is Misterton fast or flounce, with an opening of 173 feet, and two lock-doors 16 feet high, opening towards the Trent, to keep the floods thereof out of the low lands through which this river passes. In 1764, Mr. John Smeaton was consulted on this navigation and drainage.

Inverness and Fort-William Canal. Acts 4. 44, and 45 of Geo. III.-This grand or Caledonian canal, as it is sometimes called, has nearly a south-west direction for 50 miles, in Inverness and Argyle shires, in the Highlands of Scotland; it passes the Grand-Ridge, through a low part thereof, interfaced by deep lakes or lochs: its object is a connection between the East and West Seas, by Linne Loch and Murray Firth, for large ships drawing near 20 feet of water, and for avoiding the northern voyage by the Orkinays, or through Pentland Firth. Inverness is the 63rd British town, with a population of 8,732 persons. Nairn, Cromarty, and Fort-George are also considerable towns on this line. It commences in the 6th mile in Loch Beauty at Clachnacarry basin, and, after passing through two large and two small inland lakes, it terminates in the tide-way in Loch Et on Carphat basin. From the sea-lock at Clachnacarry to the 20 lock, about 3 of a mile, it is level, with high water in Loch Beauty, and nearly parallel thereto; thence for one mile to the 6th lock is a rise of 45 feet by 5 locks; thence through Lochs Doughfour and Nefs to Fort Augustus is 28 miles, and level; thence to the end of Loch Oich at the 13th lock, 54 miles, is a rise of 53 feet by 7 locks; thence through Loch Oich, and the deep-cutting on the grand ridge west of it, is 54 miles and level; at the end of which the lock N° 12, at the east end of Loch Lochy, makes a fall of 19 feet; thence through Loch Lochy to near Tor Castle is 1/4 miles, and level; and thence to the sea-lock at Corpach, 31 miles, is a fall of 50 feet by 10 locks: in all 23 locks, having 60 feet or extra locks. This canal in 152 feet wide at top, 50 at bottom, and 20 feet deep; the locks are 152 feet long and 28 feet wide. At Clachnacarry and at Corpach are locks, each 400 yards long and 74 yards wide. Twenty-two miles of this navigation is through a branching forth water lake, called Loch Nefs, of 7 to 14 miles in breadth, the middle part being 110 fathoms in depth! and its bottom muddy: this Loch and the next, never freeze, and it is said that the waters thereof do not corrod iron. Loch Lochy is another large lake, 104 miles in length, and from 4 to 8 miles in width, and its greatest depth, 17 fathoms, through which this navigation passes: it has a ferme little harbour, 102 fathoms long and 150 fathoms wide, at its eastern end. Another smaller lake is found on this line, called Loch Oich, 44 miles long, from 4 to 7 mile wide, and 29 fathoms in depth in the deepest part, its bottom being a soft mud. Loch Doughfour, the remaining one of the four, is 14 mile long, about 4 mile wide in its widest part, and about 40 feet deep. The number of lying buoys is 80. Here are 5 culverts, with 100 arches each, and an aqueduct of 240 feet across Lady Bridge: the deep-cutting near Largans is to be 45 feet deep on the summitt, and is estimated to cost £1,126,000. New canals are required to be cut for the river Speen, and for Fort Augustus for the river Nefs: the steep hills adjoining, rendering it necessary for the canal to occupy the old bed of the river for some distance in those places. A large weir is to be made at the east end of Loch Doughfour, to hold its waters to the level of Loch Nefs, and several smaller weirs are to be made. Loch Oich is to be deepened 1,540 yards in length, at the expense of £1,550,000. This canal is now only supplied with water on the summit, not only for the lockage, but for the working of mills out of the different pounds, which will doubtless hereafter prove of immense advantage to the country. In 1774 Mr. Watt was employed to survey this line, who estimated a 12 feet deep canal, in the place of the present one, to cost £140,000, exclusive of the land. In 1801 Mr. Thomas Telford was employed by Government to survey the canal above described, affiled by Mr. Murdoch Downie, very full particulars of which will be found in the Report, printed by order of the house of commons 14th June 1803 and 10th of April 1804; in which Mr. William Jeffry's estimate, amounting to £74,531. (exclusive of 23,000l. for land and mooring-chains) is given; and walled locks are recommended. On account of the loss of time in filling the chambers of those unwatered. By the first act above, 20,000l., by the next 75,000l., and by the last 50,000l. of the public money were granted, for carrying on this great work, under the direction of Mr. Thomas Telford. In October 1805, four miles in length next Inverness were digging, and the entrance basins were in hand. In August 1815, the new channel for the river Nefs was cutting, the first lock new Inverness was building, 1000 men being employed at this end. It is proposed to place mooring-chains on the shores of Lochs Nefs and Lochy, on account of their being too deep for good anchorage. On Loch Nefs government have had a galley of 75 tons burden since 1737, in which period, to 1843, three of them had been worn out; the storm so fatal to wood in some waters is not troublesome here. At Inverness the spring tides rise 11 to 13 feet, and the neap tides 7 feet; at Fort William they rise 12 and 5 feet. Cromarty Bay in Murray Firth, about 18 miles east of the beginning of this canal, was surveyed by Mr. Thomas Telford in 1801; the spring tides here rise 14 or 15 feet, and the two piers of this harbour appear to offer a safe retreat for ships, secure from every
every wind, and where warehouses are only wanting for the accommodation of a large fleet.

**Itchen River.** Acts 16 and 17 of Cha. II., and 7 and 8 of Geo. III.—The general direction of this navigation is nearly north, for about 14 miles, in Hampshire; it is but little elevated above the sea; its objects are the supply of Winchester with coals, deals, &c. and of Southampton with flour and other agricultural products, and the trade between these towns. At Northam it is joined by the Southampton and Salisbury canal. Southampton is the 68th British town, with a population of 7,913 persons; and Winchester the 103d, with 52,260 persons. It commences in the tide-way in Southampton Water near Southampton, and terminates at Winchester. This navigation is the sole property of James D'Arcy, Esq.; and he and his predecessors were the sole carriers, or nearly so, thereon, until 1795, when commissioners were named, in the above act, for fixing rates of tonnage, on payment of which it is in future to be a free navigation. It was intended to widen the channel between Woodmill and the Roman ditch, and to erect pound-locks where necessary.

**Ivel River.** Act 30 Geo. II.—The direction of this river is nearly south, for about 11 miles, in the county of Bedford; it is not very greatly elevated; its objects are the supply of the towns of Biggleswade, Shefford, and the adjoining country, with coals, deals, &c. and the export of farm produce. It commences in the great Ouse river at Temsford, and terminates at the town of Shefford. On the lower end of this navigation, finances with separate and moveable upright planks instead of gates are in use, as before mentioned. Soon after the passing of the act, the navigation was completed to Biggleswade; but the remainder of the distance to Shefford, 5$\frac{1}{2}$ miles, has not yet been made navigable, for want of money. In the present year (1805) Mr. Benjamin Bevan was employed to survey and estimate the expense of this part, which he states at 7,000l. the river about 26 feet, to be enforced by 5 locks; the toll on this distance is to be 16. 6d. per ton. It is stated that the part of this navigation below Biggleswade has, in the last seven years, produced a net 40cl. per annum, towards the reduction of the debt at first incurred. Several years ago the Biggleswade and Hertford canal was proposed to join this river at Biggleswade.

**Ivelchester and Langport Canal.** Act 35 Geo. III.—The direction of this navigation is nearly east for about 7 miles in the county of Somerset: it is not much elevated; its objects are the import of coals and export of farming products; Langport and Ilchester, or Ivelchester, are considerable towns; it commences in the Parrett below the town of Langport, and terminates at the town of Ilchester, following the course of the Yeo river part of the way, and the remainder by a canal; the company were authorized to raise 8,000l., the amount of shares being 50l. each; half-mile fences are to be erected on this navigation.

**Kennet and Avon Canal.** Acts 24, 25, 26, 41, and 45 of Geo. III.—The general direction of this canal is nearly east for 57$\frac{1}{2}$ miles in the counties of Wiltshire, Wilts, and Berks. The middle part is considerably elevated, and crosses both the western and eastern branches of the grand-ridge, the part between these points, crossing the heads of the valleys which fall to the southern coast, while the ends are in those vales falling to the Bristol Channel and the Thames; its objects are a communication between Bristol, Bath, and London, and the supply of the country west of Hungerford with coals from the mines connected with the Somersetshire Coal canal, which joins at Monkton Combe; at Wiltford it connects with the Dorset and Somerset canal, and at Semington with the Wilts and Berks canal. Bath is the 12th British town, with 32,200 inhabitants; Devizes is the 69th, with 7,650 persons; Bradford the 78th, with 7,320 persons; and Trowbridge the 104th or 105th, with 5,799 persons; Melkham, Hungerford, and Newbury, are also considerable towns on or near this canal. This canal commences in the Avon river at Dole-Mead in Bath, and terminates in the Kennet river a little west of Newbury; the branches that were at first proposed to Calne and Chippenham, have been superceded by the Wilts and Berks canal, and its branches. From the Avon to near Bampton is a mile is a rise of 56$\frac{1}{2}$ feet; thence to Trowle bridge, 10$\frac{1}{2}$ miles is level; thence to Devizes, 54 miles, is a rise of 30$\frac{1}{2}$ feet; thence for 20 miles along the summit-pound (and through the tunnel of 2 miles, at first proposed) to Cricklade; thence to Hungerford is six miles, with a fall of 104 feet; and thence to the Kennet near Reading, 9 miles, is a fall of 72 feet. By the second act, the company were authorized to raise a part of their summit-pound at its eastern end, so as to pass the summit by a moderate deep-cutting instead of the tunnel above mentioned, and to supply the new summit with water by a large steam-engine. This canal is calculated for 50 ton boats; at Trowbridge there is a basin 129 yards long and 60 wide, and another between Lyncombe and Wilcombe. There is a considerable deep-cutting near Burbage: there are two large iron aqueduct bridges over the Avon river, one called Dundas, the other is at Avon-cliff. Provisions were first made in completing parts of this canal at its eastern end, and in October 1798, the same was opened from Reading to Hungerford; in July 1799 the same was opened to Great Bedwin, near the beginning of the summit; in May 1801, the other end of the line was opened from Bath to Devizes. The company were authorized to raise 810,000l. besides a further sum by the last act; the original shares were 120l. each, but a great number of defaulters appeared among the subscribors, (no less than 450 shares it was said) and those remaining being called on for 17l. 14s. 7d. each, made the amount of these old shares 137l. 4s. 7d. each, before the act of 41 Geo. III. that raised the number further to these shares, and created a new set of shares of the amount of 60l. each. The shares of several discontented proprietors were directed to be purchased. This canal passes through Sydney-gardens near Bath, which are laid out and appropriated to pleasurable parties like our Vauxhall gardens. The rates of tonnage are from rd. to 24d. per ton per mile on different goods, and others are fixed for the distance between Bath and Devizes, for which see Phillips's 410. History, Appendix, pages 142 and 143. Mr. John Rennie is the engineer, whose superior skill has been shown in surmounting the great difficulties that have attended the construction of this canal; between Avon-Cliff and Bradford, a single slip coft, it is said, 100cl. repairing. A canal passing through nearly this tract of country was proposed in 1754. The new shares in 1802 bore
bore a premium, notwithstanding no interest is to be received on them until the line is completed, which was required by the Act to be done in the next year, (1806); we sincerely with this may be the case. Some years ago it was proposed to extend a branch of the Basing-stoke canal to join this at Hampstead: in 1796 there was an intention of extending this canal by the side of the Aven to Bristol.

**Kelley Canal.** The general direction of this canal, or water-level, is about E.: originally it was about 1½ mile in length, in the county of Salop; it has a great elevation, being within 7 or 8 miles of the grand ridge on its western side; its objects are the conveyance of coals, iron-ore, and lime-dine, the export of heavy iron goods, &c.; it was contrived by Mr. William Reynolds, and cut in 1785 at the sole expense of Messrs. William Reynolds and Co. and in the year 1791, 1 mile and 188 yards of this level at its cut end were sold to the Shrewsbury company, and made part of their canal; the price was 8½d. half the original cost, with the condition that Messrs. Reynolds and Co. should pay 2d. per ton per mile for their goods passing on the Shrewsbury Canal. This canal now, therefore, consists of about three furlongs of level connecting with the Shrewsbury Canal, at the head of the Wom bridge inclined-plane, and having at its other extremity an inclined plane of 7¾ feet perpendicular fall to the Kelley iron-works; this inclined plane was the first that was brought into practice in England for the passage of boats, and in 1780 a copper medal or half-penny was struck to commemorate the same. The boats used here on are 20 feet long, 61 feet wide, and 3 feet 10 inches deep, carrying 8 tons; they are floated into a shallow lock at the top of the plane in order to place them upon the wheeled carriage or cradle, which carries them down the plane, after the water in the lock is drawn off into a side-pond, to be pumped up again by a steam-engine into the upper pond, and by which no water is lost out of the upper pond or water level. The inclined plane is double, and a descending loaded boat draws up an empty one or but about one-third laden, by means of strong ropes winding round a barrel at the head of the plane, the velocity being regulated by a brake-wheel; of this plane we have before spoken. Several of these small boats linked together are towed along the level by one horse, and to guide them round the projecting turns of the bank, slide-rails are placed thereon.

**Keyingham Level.** In the year 1802, Mr. William Chapman made a survey for a navigation, and drainage-cuts, from the Humber river at Stony-creek, to Roosebridge and Ovingwick: a gate, in the East Riding of Yorkshire, the estimated expense thereof being 150£.; the canal was proposed to pass near the town of Keyingham, its objects being the import of coals, &c. and the export of agricultural articles.

**Kidwelly Canal.** The length of this canal is about 3½ miles, in Caermarthenshire, in South Wales, it is the private property of Mr. Keynam: it extends from the tide-way at the town of Kidwelly to Mancha coal and lime-works, belonging to Mr. Keynam, through whose estate the canal is also cut: its object is the export of coals and lime-works.

**Lagan Navigation, (Ireland).** This is one of the navigations which the Irish parliament have affixed with sums of money, with the view of facilitating the working of the collieries with which it connects; for this navigation and its collieries, various sums of public money were advanced between 1753 and 1779, amounting to 40,504.

**Lancaster Canal.** Acts 32, 33, 30 and 40 of Geo. III.—The general direction of this canal is nearly S. for 7½ miles, in the counties of Westmoreland and Lancaster; the greater part of its northern end skirts along near the sea-coast, but the southern end is considerably elevated, crossing within two miles of its termination the Haddington and Liverpool branch from the grand-ridge. Its objects are the interchange of the lime-dine of the northern parts, for the coals and canal of the southern parts of the line, the supply of Lancaster and Preston, &c.; it is to connect with the sea at Gladstone Dock by a cut of 4 miles from Galgate on the line of the canal; it crosses the Lune and Ribble rivers, but without connecting with them, and it likewise passes under the Leeds and Liverpool canal. Preston is the 37th British town with 13,857 inhabitants, Wigan is the 42d, with 10,930 persons, Lancaster the 50th, with 9,000 persons, and Kendal is the 88th, with 6,952 persons; Burton, Garstang, Kirkham, and Chorley are also considerable towns on this line. This canal commences in a basin at Kirkby-Kendal, and terminates in another at Well Houghton; to Wharton-Craggs lime-works there is to be a cut of 2½ miles, and another of 2½ miles to Duxbury near Chorley. From the basin at Kendal to Greenhead farm (through the Hincaster or Leven tunnel) is 5½ miles and level; thence to near Borwick, (near the Wharton branch) 1½ miles, is a fall of 65 feet; thence to the south side of the meadows south of Preston is 42½ miles and level; thence to Clayton Green 34½ miles is a rise of 222 feet, and thence to Well Houghton 15½ miles is level; the Wharton and Duxbury cuts are level. This canal is 7 feet deep, the boats are 66 feet long and 14 feet wide, carrying 60 tons; and the Gladston branch has a fall of about 52 feet. There are two tunnels, one at Hincaster near Leven’s Park of about 800 yards long, and another through the Whittle Hills near Chorley, which proved a most difficult one to execute; at Ashton near Lancaster there is an amazing piece of deep-cutting. At Lancaster there is no most surprising aqueduct bridge 51 feet high, over the Lune river, confiding of 5 arches of 70 feet span each. (See our article Bridge.) There are other aqueducts over the Ribble at Preston, the Wyre at Garstang, the Bebbo near Bethorn, &c.; and it is passed on an aqueduct 60 feet high near Bark-mill not far from Wigan by the Leeds and Liverpool Canal. At Kendal the canal is supplied with water by a feeder of 1 mile in length from the river Mint: water from all mines within 200 yards may be taken. The part of the line between Wheelton (near to Clayton Green) and the south end of the long level is at present supplied with a rail way, but we believe only as a temporary measure. Mr. James Brindley was employed in 1772 to survey a part of this line, the whole of the town was then after surveyed by Mr. Robert Whitworth, and in 1781 Mr. John Norris was employed, who has had the direction of the works upon it, which will redound to his lasting credit. The company is authorized to raise 1,414,000l. in 100l. shares, and 200,000l. more in shares of 20l. each. In July 1796, the last arch of the Lancaster aqueduct was completed: in September 1807, it was dated that the shares divided 1l. per cent. From Bolton to Lancaster and thence to Preston it was opened in November 1757, and in a few years after the whole of the long level was completed. In June 1803, the Whittle tunnel was completed, and 3½ miles of the rail-way, so that coals passed from West Houghton to Bramer-bridge, and in 1805, the remainder of the rail-way was opened for conveying coals to Preston, Lancaster, &c. At Helton this canal passes along close to the sea beach. The rates of tonnage are, for coals 1d. per ton per mile; for lime-dine, slate, salt, bricks, stone, iron-ore, gravel, sand, clay, and manures ½d. per ton per mile; for lime and iron 1d. per ton per mile, and for timber, wares, and merchandise, 2d. per ton per mile. Coals are not to pass the intended locks N. of Chorley under 25. 3d. per ton, which is to pass them for 18 miles N. of Chorley. It is provided in the
the Lark River. This river (sometimes called the Molden-
hal1) has its source nearly S. E. for about 22 miles in
the county of Suffolk, after skirt ing the bounds of Cambridge
for some miles. Bury St. Edmunds is the 7th Brit ish town,
with a population of 7,572 persons; Moldenhall is also a
considerable town on the line of this navigation, which
commences in the great Ouse river at Prick-willow, (about
43 miles below Ely) and terminates at Bury St. Edmunds.
Its objects are the import of coal, deals, &c. and the export
of farming products. The lower part of its course is em-
banked on both sides through the fields. It is generally very
short of water in the autumn. In 1759, this river was pro-
posed to be crossed by the Bishopsford and Wilton intended
canal; and in 1822 it was proposed to be joined by Bury
St. Edmunds by the Stowmarket and Bury rail-way.

Lea River. Acts 12 Geo. II. and 7, 19, and 45 of
Geo. III.—The general direction of this river is almost north
for about 28 miles, between the counties of Middlesex and
Essex and in Hertfordshire; it is not much elevated. Its
objects are the supply of Hertford and all the surrounding
country with coal, deals, &c. and the export of farming
products, of which most from Ware forms a considerable
part. At Bromley near Bow it connects with the Limehouse
canal, and near Hoddesdon it is joined by the Start river.
Hertford, Ware, Hoddesdon, Waltham-Abbey, Enfield,
and Stratford are considerable towns on or near this naviga-
tion. It commences in the Thames river at Bow-Creek
near the Essex-India Docks, and terminates in the town of
Hertford. It has a short cut to the town of Waltham-Abbey.
This river, which seems subject to floods, was originally made
navigable in some places by weirs and fluff-fluc ces, or turn-
pikes. In 1757, Mr. John Sweaton calculated one of these
flumes to let down 142 1/2 cubic feet of water per minute on
an average, a consumption which greatly injured the mills;
the early pound-locks erected on this river were without
walled chambers. In 1771 some of the turnpikes were
removed and locks built; in 1781, Mr. Sweaton was again
called in to give an opinion on the very leaky state of the locks.
In 1772, and again in 1802, this river was proposed to be
joined at Waltham-Abbey by the London and Waltham-Abbey,
with another junction therewith at Leebridge; and in 1785,
it was proposed to be joined at Hertford by the Leicest er
and London canal. Several years ago the Biggleswade and Hertford
canal was proposed to join this river at Hertford. Between
Hertford and Ware, the New River or aqueduct for the sup-
ply of London, has its rise, partly out of the chalk hills, and
partly by a feeder out of this river, and purifies its devious
course for near 40 miles. This great work was begun by Sir
Hugh Middleton in 1676; in 1773, Mr. James Sharp suggested
the making of the New River navigable, and continuing it by
a level cut to the Thames near Reading. In 1805, Mr. John
Reynolds was employed by government to survey the lower part
of the course of the Lea river, and to construct embankments
across, for filling this extensive vale with water in case of an
invasion: the gates intended to produce these effects, are ve-
"vels that can on the short notice be floated to and sunk
"n their proper places, to flop the water, as before described.

Leatherhead and Thames Rail-way. In 1801, it was pro-
posed to make a rail-way from a bawon to be made on the
banks of the Thames, in West Moulsey (opposite Sunbury)
to the town of Leatherhead in Surrey, through the parishes
of Walton, Cobham, Stoke-Dawbernon, Little Bookham,
Great Bookham and Tetcham.

Lee River, (Ireland.) For improving the navigation
of this river, the Irish parliament between 1753 and 1772,
granted 2,000l. of the public mone-

Lancashire and Liverpool Canal Acts 10, 23, 30, and
31 of Geo. III. The general direction of this canal is be-
tween N. E. and E. by a very crooked course of 179 miles
in the counties of Lancashire and York; it crosses the grand-
ridge by a tunnel, near Colne, and at Red-Moss and Afpule
crosses the Hastingsden and Liverpool branch of the grand-
ridge. Its objects are a communication between the ports of Liverpool and Hull, the export of the immense
floors of coal, canal, and lime-flows, that are found on
parts of its course, and the supply of the great towns thereon
with the agricultural products of the intermediate country.
At Brier's mill it connects with the Douglas navigation (now
belonging to this company, by a purchase under 23 Geo.
III.); near Birk-mill not far from Wigan it crosses the Lan-
caster canal (but is 60 feet above it on an aqueduct bridge.)

At Church it connects with the Hastingsden canal, at Skipton
with the Teami's canal, and at Windhill with the Bradford
canal. Liverpool is the 4th British town with 77,673 inhabi-
tants; Leeds is the 8th, with 53,163 persons; Blackburn is the
17th, with 11,960 persons; Wigan is the 42d, with 10,980;
Bradford is the 95th, with 6,931 persons, and Hulnket the
104th 105th, with 7,999 persons; Ormskirk, Chorley, Burn-
ley, Colne, and Skipton are also considerable towns on or near
this line, which commences in the town of Liverpool on
the bank of the Mersey, but does not connect therewith,
and terminates in the Ayr and Calder navigation in the town
of Leeds; there is a cut to lighten-hill collieries, another
to Mr. Walton's Altham collieries; and provision is made
for cuts to be made by the earl of Bercrares and Mr. Shuttle-
worth between their coak-works and the line. The old ba-
fon at Liverpool is 52 feet above low-water mark in the
Mersey river, from thence to Newborough, 28 miles, is level;
then to the beginning of the diminution that was laid made
in the line, near to the town of Wigan, 7 miles, is a rise of
30 feet, by 5 locks, (this last length being sometimes called
the Upper Douglas navigation, of which it formerly was a
part), thence to Bradshaw-hill near Afspule 3 miles, has a
rise of 279 feet, by 28 locks, (the Lancaster canal being cro-
osed in this distance) thence to the aqueduct over the Der-
went near Blackburn, 15 miles, is level; thence to Grimsbaw
near Blackburn, 2 miles, a rife of 54 feet, by 7 locks;
thence to the end of the diminution at Barrowford near Colne
is 24 miles and level; and thence to the beginning of the
summit pound near Colne is 3/4 of a mile with a rise of 67 3/4
feet, by 7 locks. The summit-pound, passing through the
Foulbridge tunnel, extends to near Thornton, about 62 miles
and level; thence to Holme-bridge near Gargrave is about
7 1/2 miles, with about 150 feet fall, by 15 locks;
thence to Gawthrop-hall near Bingley is 17 miles and
level; thence to the junction of the Bradford
canal is about 4 miles and 100 feet fall by 11 locks;
and thence to the Ayr and Calder navigation at Leeds is about
12 1/2 miles, and 160 feet fall, by 18 locks: the whole lockage
being 844 feet by 91 locks, which are each 70 feet in
length, and 15 feet in width; the breadth of the canal at
top is 42 feet, and it is 44 feet deep in water. The boats
are keel-bottomed, and carry 30 tons of goods, with which
they can go down the Ayr and Ouse as far as Selby; between
Leeds and Wigan, 100 flats of 42 tons but then are em-
ployed in the coal and canal trade, paffage-boats also ploy
regularly on this part. At Leeds there is a fine bawon, and
there are spacious warehouses belonging to this company at
the north-east corner of Liverpool town, and it was intended
in 1801, to connect a new bawon from the North Graving-
Dock on this canal, to the top of Plume street, for which
7000
7,000 cubic yards of earth were to be excavated, and the whole to be lined by 1,200 cubic yards of stone masonry. The coals are thrown out of the boats on a branch that proceeds near to the Mersey, and flie down a steep bank to a yard by the water side. At Foulridge there is a tunnel of 1000 yards in length, and 23 yards below the highest point of the hill; the soil which proved very loose, of the 7,000 yards could be worked under ground, the remainder was obliged to be opened from above, from 10 to 20 yards deep, and 20 to 30 yards wide at the top, although it was supported with immense labour and expense by timbers to prevent its falling, until the tunnel arch was formed, which is 18 feet high and 17 feet wide; it is arched with stone. At Furnby near Burnley, there is another tunnel. At Cottingley below Bingley, and near Gargrave there are considerable aqueduct bridges over the Ayrse river, and several feeder ones in different places. Mr. Longbottom made a survey for this canal in 1767, which was revised by Mr. James Brindley in 1768, under whom the canal was begun, after which Mr. Robert Whitworth and Mr. Fletcher were employed thereon. In 1770, the eastern end of the line was completed from Leeds to Holme-bridge, a distance of 873 miles; at the end of 1794 this was extended to near Foulridge. May 1, 1796, the Foulbridge tunnel was completed and the line opened to Burnley. In May 1801, the Furnby tunnel was finished, and the navigation extended to Enfield within 4 1/2 miles of Blackburn; and in July 1801, the Altham branch was opened. The western end of the line was begun as early as the other, and in 1770 the canal was opened from Liverpool to the Douglas old navigation at Newborogh, 28 miles; and on 19th October 1774, the present navigation was completed to Wigan. This company was authorized to raise 500,000l. the amount of shares 100l. The rates of tonnage are, on lime- and stone other stones 1s. 6d. per ton per mile, on coals and lime 1d. and on all other articles 1 1/2d. per ton per mile. No wharfage is to be taken unless goods remain 6 hours. In September 1805, the company proposed lowering their rates of tonnage on the Douglas lower navigation. About the year 1764, a branch of the Manchester Bolton and Bury was proposed to join this canal. Red-Mals near Wigan, 1830, were proposed to make a branch from this canal near Wigan to Bridge-water's canal at Pennington; also a branch or railway from it to Lowhall colliery.

Leicestershire Navigation. Acts 31, 34, (for Abbey Canal) and 35 of Geo. III.—The general direction of the line of this navigation is about south, following nearly the course of the Sear river, for 14 miles in the county of Leicesters, its Charnwood Forest branch is considerably elevated. Its objects are the supply of Leicesters with coals, deals, and general merchandise, the export of coals and limestone from the mines on its branches, and the farming products of the country. On the completion of the Leicesters Union canal it will become a considerable thoroughfare. At Turn-water Meadow in Coftington, it is joined by the Leicesters and Melton-Mowbray navigation. Leicesters is the 32d British town with a population of 16,953 persons; Loughborough and Mountsorrel are also considerable towns on the line. It commences in the basin of the Loughborough navigation at that town, and terminates in the Leicestershire and Northamptonshire Union canal, at Leicesters. From the basin at Loughborough, a railway branch of 2 1/2 miles, and a rise of 185 feet, extends outwards to a basin at Forrest-lane, at the east end of the Charnwood Forest water-level, which level extends 5 1/2 miles to near Barrow-hill, having a rise of 1/2 of a mile to Thringstone-bridge, and level. From the west end of the water-level a railway extends 1/2 of a mile further to Clouds-hill line-works, and there connects or very nearly to with a branch of the Abbey de-la-Zouch canal; there is a short railway branch of six chains to Barrow-hill line-works; the Thringstone bridge branch is also continued by a railway to Coal-Orton in two branches of 1 1/2 mile, and another of 1/2 of a mile to Swannington-common coal-works. From Loughborough station to the junction of the Leicesters and Melton-Mowbray navigation it is 4 miles, and level, and thence to the Leicestershire and Northamptonshire Union the distance is 11 miles, with a rise of 45 feet. On Charnwood Forest there is a railway for supplying the water-level, and a feeder of 1 1/2 miles in length to convey the water to it. Near the well bridge in Leicesters there is a basin for the use of this navigation. Mr. William Jeffry was the engineer; in December 1792 the part of the line between Loughborough and Siclby, near Mount Sorrel, was opened, and in February 1794 the remainder of the same to Leicesters was opened. The company was authorized to raise 84,000l. The rates of tonnage are various: see Philips's 4to History, Appendix, p. 12. On the making of the Abbey canal, with branches to the neighbourhood of the collieries connected with the Charnwood level, the company were allowed 2s. 6d. per ton on all coals dug in Swannington, Coal-Orton, or Thringstone parishes, and carried through Blackfordby, on the Abbey canal. The company are authorized to make railways to any mines within 2000 yards of the water-level, and are to guarantee the Loughborough company a receipt of 2000l. per annum, on condition of their taking 1s. 6d. or less per ton (but not less than 10d.) for coals passing from Loughborough to the Trent river.

Leicesters and London Canal. About the year 1792 printed proposals and a plan were circulated, for a canal from the Leicesters navigation at that town to the Lea river at Hertford, a distance of 77 miles; passing Market-Harborough, crossing the Nene river at Wellingborough, and connecting with the Ouse navigation at Bedford; its proposed object, as a rival to the Grand Junction, was the forming of the shortest communication between London, Liverpool, Hull, and Lynn, and the intermediate large trading towns, mines, &c.

Leicesters and Melton-Mowbray Navigation. Acts 37 and 40 Geo. III.—The general direction of this navigation is nearly E. following the courses of the Wreak and Eves rivers, for about 12 miles, in the county of Leicesters; it is not greatly elevated in any part, its objects are the supply of Melton-Mowbray with coals, deals, &c. and the export of the farming products of the country. It commences in the Leicesters navigation at Turn-water Meadow in Coftington, and terminates in the Oakham canal, at the town of Melton-Mowbray. The company were authorized to raise 45,000l. The original rates of tonnage may be seen in Philips's 4to History, Appendix, p. 13, but these were altered and increased by the late act above, and several regulations made respecting tolls with the Oakham company. This navigation was completed in a few years after the passing of the first act.

Leicestershire and Northamptonshire Union Canal. Acts 33 and 45 Geo. III.—The general direction of this canal is nearly E. by a crooked course of 43 miles in the counties of Leicesters and Northampton; its middle part is considerably elevated, and skirts along the eastern side and near to the grand-ridge for several miles: its objects are the formation of a junction between London, Hull, and Lynn; the supply of the country through which it passes with coals, deals, &c. and the export of farming products; it is to connect at Northampton with a railway branch of the Grand Junction. Leicesters is the 32d British town, with a population of 16,953 persons, and Northampton is the 85th, with 7,020 persons, Market-Harborough
is also a considerable place near the line. This canal commences in the Leicester navigation in the town of Leicester, and terminates in the New river at Northampton; there is a cut of 5$\frac{3}{4}$ miles in length to Market-Harborough. From the Leicester navigation to Fleckney near the Saddington tunnel is 12$\frac{3}{4}$ miles, with 100 feet rise; thence to Great Oxenden 131 miles are level; thence in $\frac{1}{2}$ of a mile is 50 feet rise; thence the summit-pound extends through Oxenden and Kelmehar tunnels to near Maidwell, 4$\frac{1}{2}$ miles and level; thence to the junction of the North river near Northampton are 112 miles, with a fall of 197$\frac{1}{2}$ feet, and thence to the head of the New navigation is 2$\frac{1}{2}$ of a mile and level. The Market-Harborough cut is level. At Gunley there are a bason and warehouse. There are four tunnels on this line, viz. at Foxton, of 1956 yards in length; at Kelmehar, of 509 yards in length; at Saddington, of 880 yards in length, and at Oxenden, of 286 yards in length. On Oxenden and Kelmehar brooks are the aqueducts for the supply over the summit-level, but flood-waters alone are to be taken. There are a great number of small aqueducts over the streams which it passes. Mr. John Farley, fea, and Mr. C. Stanles, jun. are the engineers. In March 1800, the tunnel at Saddington was finished, and the line opened from Leicester to Gunley, a distance of 17 miles; but small progress appears to have been made with the other three tunnels, and the remainder of the line, intended to form the union. The rates of tonnage on coals and coak are 2$\frac{1}{2}$d. per ton, per mile, but not to exceed 5$p$. for any distance; for lime, lime-flone, dung, and manure 1$d$. per ton, per mile, but not exceeding 28$\frac{3}{4}$d. per ton, on any distance; for live cattle, felines, bricks, tiles, flates, land, iron-flone, pig-iron, and pig-lead, 2d. per ton, per mile, and for other goods 3d. per ton, per mile; troops and government stores are exempted. Road-materials, and manures (except lime) for the use of the proprietors of lands on the ponds, may also pass the locks when the water runs wafte thereat. The towing path may be used as a bridle and drift-way by the owners of adjoining lands. By the first act the company were authorized to raise 300,000l. shares 100l. each; the last act was for varying some parts of the line and amending the former one. About the year 1793, the Upningham canal was in contemplation, and its junction with this canal is provided for in the first act above. In 1803 it was proposed to alter and shorten the branch to Market-Harborough, and to make a feeder from Willow brook; and in the same year Mr. Thomas Telford surveyed the line of country between Gunley bason and Buckby wharf on the Grand Junction canal, proposed as a substitute for the southern part of the line to Northampton.

**Leominster Canal.** Acts 31 and 36 Geo. III.—The general direction of this canal is nearly W. by a crooked course of 45$\frac{3}{4}$ miles, in the counties of Worcester, Salop, and Hereford; its west end is very considerably elevated; its objects are the supply of Leominster and the country with coals from the Pinfax mines near its easterm end, and the export of iron, lime, and agricultural products: Kingston, Prettigne, Leominster, Ludlow, Tenbury, Cleobury-Mortimer, and Bewdley are considerable towns on or near to the line of this canal: it commences in the Severn river at Areylcy near Stour-port, and terminates at the town of Kingston: it has two short cuts to mills near Tenbury. From the Severn river to the exit end of the Pinfax tunnel it is 3 miles, with a rife of 207 feet; thence through that tunnel, and the Soufmat tunnel to its western end, it is 9 miles and level; thence to the river Rea aqueduct is 1 mile, with a fall of 30 feet; thence to Letwiche brook, 7 miles, it is level; thence to Wilton, 4$\frac{1}{2}$ miles, is a rife of 36 feet; thence to near Ludlton, 5$\frac{1}{4}$ miles, is level; thence to Leominster, 1$\frac{1}{2}$ mile, is a fall of 18 feet; thence to near Kingland are 4$\frac{3}{4}$ miles, with 63 feet rife; thence to Milton are 3$\frac{1}{2}$ miles, with 37 feet rife; thence to Stanso-park are 2$\frac{3}{4}$ miles, with a rife of 152 feet, and thence to Kington are 4 miles, and level. At Pinfax is a tunnel of 3850 yards, and the other at Soufmat is 1250 yards in length. There are considerable aqueduct-bridges over the Rea river at Knighton, over the Teme at Woferton, and over the Lugg at Kingland: a power is provided in the act for inclined-places instead of locks, if the same should be found molt eligible; springs of water within 2000 yards of the line may be taken. Mr. Thomas Telford, jun. is the engineer. In July 1795 the difficult tunnel at Pinal-field in Soufmat was finished, and in November 1795, near 20 miles of canal, from Mamble coal-works to the town of Leominster were opened, and coals, which before sold there at 1s. 6d. per cwt., were at once reduced to 9d. per cwt. ! On the 1st of June 1797, the entrance of the canal from the Severn was opened: since which considerable progress has been made in the works: in May last (1805,) the Pinfax mining company was proposed, for opening new coal and iron mines near that place, on the line of the canal, which was expected to facilitate its completion. The Leominster company have been authorized to raise 370,000l. The tonnage rates are too long for our room, they will be found in Phillips's topo. History, Appendix, p. 5 and 6. About the year 1794, the Westpool and Leominster canal was proposed to join this at Woferton.

**Liffey River, (Ireland).** The direction of this river is nearly weft, in Dublin county, from the bay of Dublin to the entrance bason of the Grand Canal in Dublin city, where also are a Harbour and Docks that have been improved, under Mr. William Telford; the spring tides rife only 15 feet at these dock-gates. In the year 1800 it was proposed to avoid the bar at the mouth of the Liffey, by cutting a new channel or canal for ships from Dnleary to Kingland dock; it was also proposed to make Dalkey a safe harbour, and to make a cut from thence to the Grand Canal bason; the bill for this purpose was passed by the commons, but was rejected by the house of lords. Ormond bridge, on this river, was carried away by a flood, and in September last (1805,) the corporation of Dublin harbour offered premiums for the best plans for a new bridge at this place.

**Limehouse Canal.** The direction of this canal is about N.E. for 1$\frac{1}{4}$ mile, in the county of Middlesex; it is but little elevated above the level of the sea; its object is to connect the river Lea with the river Lea, and the port of London, by avoiding the circuit round the Isle of Dogs; it commences in the river Thames near Limehouse church, and terminates in the Lea river at Bromley near Bow, having a rife of 1$\frac{3}{4}$ feet. This canal was cut at the expence of the city of London, in an early part of the present reign, and its locks, which are of wood, and its other works, form a great contrat to the improved locks and appendages of modern canals. In 1773 a cut from the intended London and Walton-Abbey canal was intended to join this near Limehouse church.

**Limerick Canal, (Ireland).** This canal was cut near 40 years ago from the town of Leitrin to a morass within a short distance, for the purpose of bringing turfs, to supply the town of Limerick with fuel, and which by their cheapness superceded in a great measure the use of coals, which coming by a long coast-ways navigation were very dear.

**Liffard Canal.** In 1777, Mr. Edmund Leach proposed a canal, or rather a systen of water-levels and inclined-planes, from the tide-way in the Luce river, at Sand-place in Morval to Bark-mill-bridge, in St. Clear; this was proposed to be accomplished by two levels of 9 and 6 miles in length.
Length, (one of which, in its serpentine course, went within ½ a mile of Lillie-card town,) connected with each other and the river below by two inclined planes for boats, the principles of which have been already explained; the estimate was 17,500l. The objects of this navigation were the carrying up of lime and sea-fand for manure, and exporting corn, &c.

Liverpool and Runcorn. About the year 1771, a survey was made by Mr. James Brindley, for a canal from the town of Liverpool upon one level, to cross the Mersey at Runcorn-gap, by an aqueduct bridge, and join the duke of Bridgewater’s canal; before the great width of the Mersey at this place, a tide, which rises 14 feet, was also to be encountered.

Llandovery and Llandy. In September 1821, notices were given for an intended canal from Spitty in the parish of Llanelli, on the Burr river, through Llange-neu, Llandy, Llandybe, Llandidlo, &c. to Llandovery or Llanyged-dwyi, in the county of Caernarthen in South Wales. The objects of this canal were first accomplished by the Carmarthenshire railway, over nearly the same tract of country.

London Canal. In July 1802, a survey was made for a canal, about in a west direction, for near 7 miles, in the county of Middlesex: commencing in the London docks, (and thereby communicating with the Thames river,) to pass Well's-gardens, the mount in White-chapel road, and Bethnal-green New road, across Hackney road, through Middlesex-place across Kingsland road, near Iron-monger's alms-houses, to pass north of Lady Lumley's alms-houses at Hoxton, across the city road below the turnpike-gate, across Goswell-street, south of Goswell-place, across St. John's-street, north of Taylor's brewhouse, under the field foot of the New-river head, over the valley at Bagnige-wells, across Gray's Inn-lane at the west corner of the Well charity-school, across the New road to the caflle corner of Bedford nurseries, across Tottenham court road between St. James's burying-ground and the New-river referral, pass the fronts of the Artichoke and Queen's-head public houses, and across the Edge-ware road to the basin of the Grand Junction canal at Paddington, the rise in this distance being about 35 feet. The great number of bridges required, the paling of the field near Illington fall of water-pipes in all directions, belonging to the New-river company, by an arch under the same, and a large embankment or aqueduct bridge near Bagnige-wells, were difficulties in the way of this project, but to which the subscription for shares (which almost immediately filled to the amount of 400,000l.) would have been equal; had not the inability of the Grand Junction company to furnish the water necessary for the lockage, and the opposition of several powerful land owners, on account of its making some alterations necessary in their building projects, frustrated the scheme altogether for the present. The western branch of the Grand Junction, of which we have before spoken, was in contemplation at the time this canal was intended, and water was proposed to be obtained thereby from the Thames for this canal, the Colne millers having it unfortunately in their power, to prevent any being obtained from that river; Mr. John Rennie, who gauged the stream of the Thames, in the dry summer of 1794, at Leakeham (which is after it has received the main streams of the Colne,) found 1153 cubic feet of water to pass in one second of time, which is 134 times what would be required to be taken from this river higher up near Great Marlow, and brought by the Grand Junction level branches, for supplying the lockage of this canal, supposing 60 locks containing 1055 cubic feet each, to be used daily. After the opposing interests were found too strong to leave any prospect of carrying this canal, a faint effort was made to accomplish a rail-way, through nearly the same line, but with no better success. In 1773, Mr. Robert Whitworth made a survey for the city of London, and recommended a line of canal from the Lee river at Lee-bridge, to near the same spot which the Grand Junction basin now occupies at Paddington: it was intended as branches call and well of the London and Waltham-Abbe canal.

London Lynn and Norwich. In the year 1785, Mr. John Philips published a thin 4to. treatise, to endeavour to call the public attention to a canal between the Ouse river at the port of Lynn, and the Thames river at Limehouse in London, with a branch to the Tare river at Norwich. It appears that Mr. P. travelled through the proposed tract of country in 1779 and 1780, but took no levels or other necessary particulars, yet ventures to state, that he could execute this canal, 36 feet wide, and 4½ feet deep, for 200,000l. And it is held out, that 28,000 oak Trees, to be planted on the banks of this canal, will, in 50 years, repay all its expenses within 60,000l. In 1803 we are told that Mr. Ralph Dodd made an effort to revive this or a similar scheme, and wished to denominate it the North London Canal.

London and Waltham-Abbe. In the year 1773, at the instance of Mr. James Sharp, Mr. Robert Whitworth was employed by the city of London to survey the line for a canal between the centre of the quarters in Moorfields, London, to the river Lea at Waltham-Abbe; a distance of 14 miles, almost in a north direction in the counties of Middlesex and Hertford; this line was to be level (and about 30 feet above spring-tides in the Thames,) there was a cut of ⅓ of a mile, and 33 feet fall proposed to the Lea river at Lee bridge, and another of 4½ miles to Wellin's farm near Paddington, with 495 feet rise; nearly to the same level as the Grand Junction basin now has; also another cut of near 2 miles to the Limehouse canal near the church, with a fall of 42 feet (to the common ncp tides in the Thames.) The width was to be 60 feet, and depth 4½ feet; in Moorfields and near Holywell Mount, large basins were intended; between Stamford-hill and High-crofs a very large embankment was proposed, another at Hackney brook, and another at St. Pancras brook; at Ponder's end was to be a deep-cut to avoid the houses; 15 turnpike-road-bridges, and 22 road-bridges of lesser size were necessary, the whole expense Mr. Whitworth estimated to be 98,225l. In 1803, this or a similar scheme seems to have been in contemplation, but to join the Thames near Bell-wharf in Shadwell instead of the Limehouse cut.

Loose River. The general direction of this navigation is nearly N. for about 34 miles, on the south coast of Cornwall, it commences at the sea near East Loose, (which is a considerable town,) and terminates at Morval bridge, near which, at Sand-place, it was, in 1777, proposed to be joined by the Lifeboat canal; its objects are the carrying up of coal, and sea-fand as manure, and the export of agricultural products.

Loughborough Navigation. Act 16 Geo. III.—The general direction of this navigation is nearly S. for about 9 miles, following the course of the Soar river, except in the last mile, which is a new cut; it is but little elevated; at the basin, 300 yards from its south end, it is joined by the line of the Leicestershire navigation and by the Charnwood-forest railway branch belonging thereto. It commences in the Trent river (nearly opposite to the Erewaugh canal,) and near to the Trent canal near Sawley, and terminates at the Rushes near the town of Loughborough, which is a considerable
confiderable place; its objects are as various as the trade of the Thames, and the wants of Leicifter and other great towns; it forms also part of the line of communication which the Leicifter and Northamptonhire Union canal is to open.

On the making of the Leicifter navigation, that company guaranteed the amount of the tolls on this, to amount to 30,000l. annually, on condition of no more than 16. 6d. per ton on coals or lefs than 10d. being taken by this company.

**Louth Navigation.** The general direction of this navigation is nearly S.W. for 14 miles in the county of Lincoln, it is but little elevated above the sea; its objects are the supply of Louth, and the adjacent country with coals, deals, &c. and the export of farming produce; it commences at the fea-lock and cbb-gates in Tintey Haven (at the mouth of the Humber river), and terrimates at the town of Louth. From Tintey Haven to the Louth river near North Cockerington 92 miles is level, and but little higher than low-water mark, being a new cut through a low fenney country; thence to Kiddington old mill, 22 miles, is 24 feet rife; thence to the Leather-mill meadow, 2 1/2 of a mile, 11 feet rife; thence to Louth is 3 1/2 of a mile with 21 feet rife. Mr. John Grundy made a survey of this line, which was revised by Mr. John Swaton, in 1760, the estimate of expence being near 15,000l.

See Swaton's Reports, vol. i. p. 23.

**Lynn River.** The general direction of this river (sometimes called the Lune) is nearly N.E. for about 7 miles in the county of Lancaster; the tide flows through its whole length; its object is the foreign trade of Lancaster, particularly in cabinet-maker's wares, a branch of the Lancaster canal is to connect with it at Glasson, where a spacious wet-dock is intended. Lancaster is the 50th British town with 9,030 inhabitants; this river commences in the Irish sea at Sunderland point, and terrimates at Lancaster old bridge, some distance below Mr. Rennie's famous aqueduct bridge over this river. It appears, that in the year 1790, 52 vessels cleared out of this river for the West Indies with 11,669 tons of goods in more than 90,000 packages, worth 2,5 millions sterling. In October 1790, it was in contemplation, to construct a spacious dock at Thornbury for large ships, with a canal from thence of 6 miles in length through Glasson-dock, and nearly up to the town of Lancaster, to be wide and deep enough for the largest vessels that trade to that place.

**Lynn River.** The general direction of this river (sometimes called the Lenne, the Nar, or the Seeby) is nearly S.E. by a crooked course of about 15 miles in the county of Norfolk; it is not greatly elevated in any part; its objects are the import of coals, deals, &c. and the export of farming produce; Lynn is the 50th British town with a population of 10,096 persons, Narford is also a considerable town; it commences in the Great Ouse river near the harbour of Lynn, and terrimates at the town of Narford.

**Macclesfield and Leek.** In 1796, it was said, that a canal between these places was in contemplation, with extensions thereof to the Staffordshire potteries, in all 20 miles, on which no locks were to be used. Macclesfield is the 61st British town with 8,733 inhabitants.

**Maidenhead and Islworth.** In the year 1770, Meffrs. James Britto and Robert Whitworth, were employed by the city of London, to survey the line of a canal from the Thames river at Islworth, to the same river again below Bolter's-lock near Taplow-mill, about 1 mile above Maidenhead-bridge, and at the lower end or termination of the 3d district of the Thames and Isis navigation; the length of this line is 193 miles with a rife of 7 1/4 feet. The canal was proposed to be 50 feet wide and 4 deep, with cuts to the Thames at Windfor, and near Lakeham; in the first 5 miles 7 locks were to be built, and one in the remaining distance; the estimate of expence was 47,953l. A bill for this was brought into parliament, but the opposition of the land-owners proved fatal to it; although, as appears, by an accurate measurement and section of the river between these two points made by the above engineers (see Gentleman's Magazine for March 1771), that the length of the river-navigation is 372 miles in this distance, and greatly obstructed by shallows, some only 24 feet deep in dry leafons. In the year 1791, this scheme was revived, and in 1764, Meffrs. Robert Whitworth and Robert Mylne were employed to revife this line; their design has 12 miles of level at the upper end, and 10 of them raight; the canal to be 5 feet deep. The tolls at first proposed were 3 6d. per ton per mile on all articles; out of this revenue, it was proposed to improve the river navigation between Mortlake and Bolter's-lock; and to raife the necessary fums on life annuities, fo that after a fund was established for repairs and management, the canal might at length become free for the public use. At Bolter's lock the Reading and Maidenhead canal was proposed to join this canal, by which the navigation from London weftward would have been amazons shortened and improved.

**Manchester Ashton and Oldham Canal.** Acts 32, 34, 38, 40, and 45 of Geo. III.—The general direction of this canal is nearly E. for about 7 miles in the counties of Lancafier and Cheshire; its eastern end is considerably elevated; its objects are the supply of Manchester and Stockport with coals, canal, flone, lime, &c. and forming part of the intended direct communication between Liverpool, Manchester, and Hull, by means of the Huddersfield and other canals; by means of its Duckenfield branch it communicates with the Peak Forest canal. Manchester is the 2d British town with 84,020 inhabitants, Stockport is the 25th with 14,850 persons, and Oldham the 35th with 12,024 persons, Alhton is also a considerable town, and the country round about is full of inhabitants. This canal begins in the Rochdale canal near Piccadilly street in Manchester, and terrimates in the Huddersfield canal at Duckenfield bridge, in the parish of Alhton underline; from Duckenfield bridge is a branch of 3/4 mile in length, over an aqueduct bridge on the Tame river at Walk-mill, into Duckenfield, there to join the Peak Forest canal. There is a branch of 1 mile to Alhton town, another of 3 1/2 miles to New Mill town, 3 miles of Oldham (but 33 miles distant from the town), from which last at Boodle-wood a branch proceeds over Water-Houfes aqueduct on the Medlock brook, to Park collieries at Stake-Leach near Hollingwood, also in the parish of Oldham; from Droyladden, a branch of 6 miles proceeds to the end of the town of Stockport in Heaton-Norris parish, and from this laft, a branch of 3 miles proceeds in a N.E. direction to Beat-Bank in Denton. The line has a rife of 152 feet between the Rochdale and Huddersfield canals. This canal is 33 feet wide at top, 15 feet at bottom, and 5 feet deep in water, except the summit pound which is made 6 feet deep to act as a refervoir; the locks are 80 feet long, and the boats carry 25 tons; there are three confiderable aqueducts at Duckenfield, Ancoats, and at Water-Houfes. This company were authorized by their first 4 acts to raise 170,000l., and a further fum by the late act; amount of shares 100l. The line of this canal was completed between Manchester and Alhton about the end of the year 1796, and in January 1797, the Stockport branch was opened; some of the works on this canal subsided by a flood in August 1799. The rates of tonnage are given in Phillippo's 4to. History, Appendix, p. 21. In 1802, we were told, that the shares in this concern were 20l. below par.

**Manchester Bolton and Bury Canal.** Acts 31, and
and 41 of Geo. III.—The general direction of this canal is N.W. for about 11 miles in the county of Lancashire; its northern end is considerably elevated; its objects are a communication between the great manufacturing towns of Manchester, Bolton, and Bury, and the carriage of coals and other articles for their supply, and forming part of the line of communication between Manchester and the Leeds and Liverpool canal. Manchester is the 2d British town with 84,020 inhabitants, Bolton is the 32d with 12,592 persons, and Bury the 8th with 7,072 persons. This canal commences in the Mersey and Irlwe navigation near the junction of Medlock brook (by which it communicates with Bridge-water’s canal near the beginning of the Rochdale) at Manchester, and terminates at the town of Bolton; it has a branch of 4 miles in length to the Haffenden canal at the town of Bury. From the Mersey and Irlwe navigation, it is a rife of several locks to the basin in Salford parish; thence for about 4 miles is level; in the next 3 miles are 12 locks, the remainder of the line is level, including the branch to Bury; the whole rife is 187 feet. Previous to 1794, this canal was begun, and several locks were built for narrow boats, but on account of the branches connecting with wide canals which were proposed about that time, these were pulled up and rebuilt, and the canal widened, including some expensive deep-cutting and embanking; a want of skill or care appeared also, we are told, in the setting out of this canal by cutting deep through rocky ground which might have been avoided. There are two aqueduct bridges over the Irwell at Clifton-Hall and near Stocks; and one over the Leven at Long-fold, these are said to be 25, 16, and 10 yards high; the canal was, in 1799, supplied by a feeder from the Irwell at Bury, but in 1802, a reflovoir and feeder also was found necessary in Radcliffe parish. In 1797, this canal was completed to Bolton, except the locks to connect with the Mersey and Irlwe navigation; on the 17th of August, 1799, a great flood happened, which carried away the lower bank of this canal for 100 yards together on the summit-level, and another branch therein also happened, by which the navigation to Bolton, &c. was some time interrupted. This company were authorized by their first act to raise 97,000l, and a further sum by the late act. The rates of tonnage are for coals, lime-flone, flone, bricks, clay, &c. 2d. per ton per mile, if they pass a lock; but all thefe, except lime-flone, are to pass on the levels for 3d. per ton per mile; and when the water runs wafte at the locks, lime-flone is also to pay only 3d. on any part; the tonnage at the entrance of the Mersey and Irlwe navigation is also regulated by the firt act. Passage-boats from Bolton to near Manchester are established; but when water has been scarce, the paffengers have been required to walk paft the locks to another boat on the lower pound to avoid the wafte of lockage-water. About the year 1794, it was in contemplation to make a branch from Bolton, to connect with the Leeds and Liverpool canal at Red Mofs near to Wigan, and to make a grand extension of the Bury branch eastward to the Calder and Hebble navigation at Sowerby-bridge, paffing the grand-ridge between Littleborough and Rippondale by a tunnel of 3 miles in length! after paffing a shorter tunnel of 3/4 a mile at lower Lomax near Heyford. In 1796, it was propofed to extend a branch from the basin in Salford parish to Oldfield-Lane in that town; and, in 1799, it was in contemplation to build an aqueduct bridge over the Irwell, and connect this canal with Bridge-water’s canal, instead of lock- ing down into the Mersey and Irlwe navigation.

Market-Weighton Canal. Act 12 Geo. III.—The general direction of this canal is nearly N. for about 11 miles in the Eaft Riding of Yorkshire; it has but little elevation above the sea; its objects are the conveyance of coals, deals, &c. to Market-Weighton and the surrounding country, the export of farming products, and the better drainage of the fen lands through which it passes; it commences in the tide-way in the Humber river (opposite to the Trent river) at Fuldyke-Clough, and terminates near Market-Weighton. It has a sea-lock next the Humber, from whence it is level to within a short distance of its northern end, where it is a rise of 4 or 5 locks. Mr. John Sweton was confulted on this line of canal and drainage, in 1763, at which time a branch of this canal to Pocklington was in contemplation; for the rates of tonnage, fee Phillips’s 40th. History, p. 270. This navigation was completed long after the paffing of the act.

Mawgan Canal. About the year 1775, a narrow canal was cut of 6 or 7 miles in length; from Port Mawgan near Trenance on the N.W. coast of Cornwall, to within 3 miles of St. Columb Major, it was intended for bringing up coals and sea-fand for manure, and for carrying down china-flone and clay, subfiances found in St Dennis and St. Stephens, and used in the Staffordshire potteries; but after several of the adventurers were ruined, the scheme was totally abandoned.

Medina River. The direction of this navigation is south, and nearly straight for 4½ miles, in the Isle of Wight in Hampshire; the tide flows through its whole length; its object is the supply of Newport and the central parts of the island with coals and other articles; it commences at Cowes harbour (opposite Southampton Water), and terminates at Newport bridge.

Medway River (lower district.) Acts 32 and 42 of Geo. III.—The general direction of this navigation is nearly S.W. for about 27 miles by a bending course in the county of Kent; it is but little elevated in any part; its objects are the import of coals, deals, and other articles, and the export of Kentish-Rag lime-flone, fullers-earth, farming-produce, &c. near its northern termination, it connects with the east Swale or tide-way paffage, of about 15 miles in length south of Sheppy island, connecting with the Thames near Whitable; and, at Nicholson’s ship-yard in Strood it is joined by the Thames and Medway canal. Chatham is the 46th British town with a population of 10,505 persons, Maidstone is the 66th with 8,247 persons, and Rochester is the 90th with 6,817 persons, Sheerness, Queenborough, and Milton, are considerable towns on or near this navigation, which commences in the river Thames at the Nore, and terminates in the upper Medway navigation at Maidstone bridge. Over this river at Rochester, there is a flone bridge of 71 arches and 256 feet long. At Chatham is a very considerable naval arsenal. The powers of the above acts for repairing and levying of tolls, extend no further down this river than from Maidstone to the tide-way at Aylesford bridge.

Medway River (upper district.) The general direction of this part of the river is S.W. for about 12 miles in the county of Kent; it is not much elevated in any part; its objects are the import of coals, deals, &c. and export of lime-flone, fullers-earth, farming-produce, &c. besides Maidstone, mentioned above, Tunbridge is the only considerable town on this line; it commences in the lower Medway navigation and terminates at the town of Tunbridge. In 1802, the Medway and Rother canal was proposed to connect with this river at Yalden-lees.

Medway and Rother. In the year 1801, a survey and estimate was made by Mr. Sutherland, for a canal from the Rother river intended navigable branch at Small-Hitch, to the Stour river at Canterbury (at the S. end of the proposed Canterbury and Nicholas-bay canal), with a branch theroof
to the Middleway river at Yalden-lees, through the counties of Suffolk and Kent; its objects were the supply of the interior country with coals and other articles, the export of timber and farming products, and forming a communication between the south coalt at Rye-harbour and the Thames river, &c. Forty-ton boats were intended to be used, and the canal to be 4 feet deep. The summit was found to be about 102 feet above the sea, and nearly 50 miles of the line was to be upon one level.

**Menai Strait.** This freight separates Anglesea ile from North Wales, and has nearly a N.E. direction for about 16 miles, through which the tide flows; it extends from Caernarvon bay at Abermenai Ferry to Lavan Sands; Caernarvon and Bangor are considerable towns on this line. In 1801, and 1802, it was in contemplation to build a cast-iron bridge over this strait at Swelly rocks near Portcathory Ferry not far from Bangor.

**Mersey and Irwell Navigation.** Acts 7 Geo. I. and 34 Geo. III.—The general direction of this navigation is nearly east, by a crooked course of 50 miles in the county of Lancaster, and skirting the county of Chester; the first 20 miles being by a most spacious culvert of the Mersey river; it is not greatly elevated in any part; its objects are most important, particularly in the immense trade between Liverpool and Manchester, and Hull, also by four different routes across the grand-ridge; the navigations immediately connecting therewith are, at Ellesmere-port in Netherpool, where it is joined by the Ellesmere canal; at Woburn by the Waverley river; at Runcorn-Gap, and again at Manchester (by the Medlock Brook), by Bridgewater's canal, besides being crossed thereby on Barton aqueduct; at Tidlers-ferry, and also at Sankey Brook, by the Sankey canal; and at Manchester, near the junction of Medlock Brook, by the Manchester Bolton and Bury canal; besides which, the following commence very near to this navigation, although they do not actually lock down into it: viz. the Leeds and Liverpool, at the basin in Liverpool, the Trent and Mersey, at Preston Brook, and the Rochdale, at Manchester; to which also the Manchester Ashton and Oldham ought to be added, although a very short space of two other navigations must be passed through before you can reach the Irwell therefrom. Manchester is the 2d British town, with a population of 84,020 persons; Liverpool is the 4th, with 77,653 persons; and Warrington is the 45th, with 10,657 persons. This navigation commences in the Irish Sea, at Wallazy, about 3 miles below Liverpool, and terminates at the bridge between Manchester and Salford; but the powers of the act, as to improving the river and collecting the tolls, at first extended no lower than Bank-key, near Warrington, and hence to Runcorn Gap. The winding course of the river has been shortened in several places by side-cuts across the loops, and locks and weirs have been erected in several places, the rise in the whole length being about 70 feet; these rivers are subject to sudden and violent floods, which have at times destroyed several of the navigation works; in August 1864 a new side-cut was completed, for shortening the course of the navigation, and avoiding the shallows in the river; between Warrington and Runcorn Gap it crosses the Sankey canal. The famous wet-docks at Liverpool are an appendage to the Mersey navigation, and are indeed a part of that river, from not being excavated in solid ground, where houses formerly stood, as they did on the site of the London Docks; but all of them, except the old Dock, which was a natural creek or pool, have been formed in the front of the town, by embankments in the river, which is here ¾ of a mile wide. At the lower or northern end of these docks, as we viewed them in 1797, is a large inlet or walled tide-basin, which connects with the river, and is dry at low water, from the S.E. corner of this is the entrance of St. George's Dock, which was the third large dock that was made, and is nearly a parallelogram, of 250 yards long and 100 wide, its quay being 670 yards long, its gates are 25 feet high and 38 feet wide, and it cost about 21,000/. Palling southerly, we next arrive at a dry basin, called the old dock, for the flats to which belonging to the Mersey and Irwell company, which are about 50 in number; and some distance south of this is another large inlet to a spacious dry-basin for ships: from the north end of this basin are other gates into St. George's Dock, above mentioned, and straight forwards in the entrance to the Old Dock, or the first that was built, and is wholly within the town; this dock forms an irregular parallelogram, of 200 yards long and about 80 yards wide, its gates being 23 feet high and 34 feet wide; it is lined with bricks, but all the other dock, basin, and pier walls are of beautiful hewn stone. From the south-call of the last described dry-basin is the entrance to Salt-House Dock, which was the second made, is an irregular trapezium, of 21,028 yards in area, and has 645 yards in length of quay, its gates being 23 feet high and 34 feet wide. A considerable distance south of the last dry-basin is another inlet to a small wet-dock, which belonged to the late Duke of Bridgewater, and is used by the flats which trade between Manchester and Liverpool, by Bridgewater's canal, these carry 50 tons, and 42 of them belonged to his grace. Proceeding further along the shore southward, we arrive at another inlet and dry-basin, from the north side of which is the entrance to the King's Dock, the fourth which was made (being finished in 1788), and is a regular parallelogram, of 290 yards long and 90 wide, the gates thereof being 25 feet high and 42 feet wide. From the head, or east end of the last dry-basin is the entrance to the Queen's Dock, which was the fifth and last that was made, being also the largest and most complete of the whole, its length is 270 yards, breadth 130, its gates 25 feet high and 42 feet wide, and it cost about 25,000/. An attempt was made to form a dock in the site of the old Dock, as long ago as 1761, but it was not until the year 1797 that the first act was obtained, of which there are several, for building and regulating the present docks. In 1799 application was made again to parliament for powers to build two more large docks, one of them more northerly than any of those we have described, and the other in front of Salt House dock. The whole extent of these docks and quays will then be nearly 2 miles by the side of the Mersey! With the two dry basins last described, several convenient graving-docks connect, for the building or repair of ships, some of the latter are long enough to hold three ships in length. The space between their graving-docks and in front of the docks, is principally occupied by timber-yards. The draw-bridges over the entrances to some of these docks are among the largest and most complete in England: Mr. Morris erected and has the care of them and the docks. On the south side of the King's Dock is a spacious warehouse 210 feet long and 180 wide, for tobacco, of which it will contain 7,000 hogheads. The spring-tides here rise 21 feet, but the neap-tides only 12 feet, on which account large ships cannot enter or leave these docks for some days during the lowest tides. Fires and smoking of tobacco are on no account allowed on board of ships in these docks, nor lighted candles, except in proper lanterns, and no gunpowder is allowed on board; by a strict attention to which rules, no fire has ever happened in these docks. In the year 1797 the tolls in these docks amounted to upwards of 13,000l. annually, and their yearly expenses to 5,100l but a debt of 113,419l. still remained on them: for many of the above particulars we are indebted to W. Mepfi's Liverpool Guide. In the year 1737 Worlsey
Warley Brook was intended (and an Act passed to Geo. II.) to be made navigable; and, in 1758, a branch of Bridgewater's canal was intended to join at Hollin Ferry, but neither of these has been executed. In 1771 Mr. James Brindley proposed an aqueduct-bridge over the valley of the Mersey, for the use of the intended Liverpool and Manchester canal; and in 1801 Mr. Ralph Dodd tried to persuade the adoption of a road-bridge over the same at Castle Rock, near this place, 442 yards long, which he stated might be built for £1,000. In 1799 it was suggested that a tunnel might be made under the Mersey at Liverpool to the opposite shore in Cheshire, 3 of a mile; in the same year it was in contemplation to build an aqueduct over the Irwell, for the use of the Manchester Bolton and Hurst canal, to enable it to join Bridgewater's canal; and in 1804 it was proposed to bring the Weaver navigation to Welsford Point on this navigation, by a new-side cut, near that river from Frodsham, to avoid the shallows near the junction of the rivers. In 1798 the price of carriage on this navigation, between Liverpool and Manchester was 12d. per ton, but on the completion of Bridgewater's canal it fell to 6d. per ton.

Milkford Haven. This famous estuary and harbour for large ships, has nearly an equal course, for about 17 miles, in the county of Pembroke, in South Wales, commencing in St. George's channel, and terminating near Landshutting ferry, where it is joined by the Dougold and Clyfe rivers: it has also creeks or branches extending to Pembroke, to near Carew Castle, to Crefwell, to Nangle, &c.

Monkland Canal. The general direction of this canal is nearly east, for about 11/2 miles in the county of Lanark in Scotland, its calern end is considerably elevated; its objects are the supply of Glasgow, Paisley, &c. with coals from Monkland collieries, and the export of farming produce. It commences in the basin of the branch of the Forth and Clyde canal, and thereby communicates with the Clyde river, and the Edinburgh and Glasgow canal. Glasgow is the 5th British town, with a population of 77,585 persons. In 1803 the Glasgow and Saltcoats canal was proposed to connect with this at Glasgow.

Monmouthshire Canal. Acts 32, 37, and 42 of Geo. III.—The general direction of this compound of canals and rail-ways is nearly north, for 173 miles, in the counties of Monmouth, and Brecknock in South Wales; its northern ends are very greatly elevated; its object is the export of coals, lime, and iron from the country through which it passes; near Pontypool it is joined by the Brecknock and Abergavenny canal, at Pill-Gwenny it joins to the Sirhowy tram-road (by means of the Uske river), and at Count-y-Billa farm, and at Rifa, it joins the same again by different branches belonging to this company. Newport and Pontypool are considerable towns on this line. This canal commences in the tide-way of the Uske river, near to the Severn, at Pill-Gwenny, and terminates by a rail-way extension at Blaen-Abio: iron furnaces, having also a principal branch of canal from the line at Cr常务-Farm, near Malpas, and continued by a rail-way to Beaufort iron-works, 21 miles; from this branch are rail-way branches to Nosse furnaces, 12 miles, to Nant-y-glo works, 64 miles, and another to the Sihowmy tram-road at Rifa: from the line near Pontypool is a rail-way branch, 1 mile, to Tronfaunt furnace, and another, of 2 miles, to Blaen-Dir furnace. From the Uske river to Pont-Newydd, 121 miles, is a rise of 447 feet by the canal, and thence to Blaen-Abio, 42 miles, is a rise of 560 feet by the rail-way: from Cr常务-Farm to Crumlin bridge the canal branch rises 458 feet in 11 miles; thence for 3 miles to the rail-way bridge over Ewyby river, 3 miles, the rail-way has a rise of 159 feet, and thence to Beaufort, 7 miles, it has a rise of 460 feet; the Nant-y-glo branch has a rise of 518 feet, along the side of Ewyby-Brach river. The locks are 60 feet long and 10 feet wide, their paddle holes are, in some of them, united in the breach of the lock, and no thrust-plate, or inverted arch has been made below the lower gates. Much deep-cutting and embankments have here been necessary, to obtain the proper flowing for the rail-ways and juncled planes. Mr. Thomas Didsford jun., is the engineer: in February 1766 the canal was opened from the Uske to Pontypool, and in the same year the Beveron branch was completed. This company was authorized by their different acts to raise 227,552l. in 1801. rates, viz. in 1802 these divided at 12s. 6d. each annually; it is provided, that after the profits amount to 10 per cent. and 100l. is accumulated as a fund, the tolls are to be reduced, first on coals, so as to keep the profits within that amount. The tolls and exemptions are various, and may be consulted in Phillips's 410. History, Appendix, p. 118 and 119, where tolls are specified for cattle passing on the rail-ways. Nine miles of the Sirhowy tram-road was made by this company, who receive the tolls thereof, as also 110l. per annum from that company, on account of the junctions therewith to the Brecknock and Abergavenny company this company paid the sum of 3000l. for the benefit of their junction herewith, and their taking the fame tolls only on goods passing on it from this canal as are charged hereon. Rail-way branches may be made to any works within 8 miles of this canal or its branches. In the year 1805 it was proposed to continue this canal lower down the Uske river, to avoid its imperfect navigation.

Montgomeryshire Canal. Act 34 Geo. III.—The general direction of this canal is nearly S.W. for 27 miles in the county of Salop and of Montgomery in North Wales; it is considerably elevated, particularly its southern end; its objects are the supply of the country with lime, the export of its farming produce and of coals, slate, free-stone, iron, lead, &c. from different parts near the line: it connects with the Sirhowy river at Wellington. Wellington, Montgomery, and Newtown are considerable towns on or near this canal: it commences in the Llanymynach branch of Ellesmere canal, at Portway lime-works in Llandyblodwel, and uniting with the same again near Verniew river in Llanymynach, it terminates at Newtown: it has a cut of 32 miles to the Severn river at Wellington and to Guilsfield. From the Ellesmere branch to Newtown is a lockage of 255 feet; the Guilsfield cut is level. Mr. Thomas Didsford jun. is the engineer. In August 1797, 16 miles of the canal were finished and opened from the Ellesmere branch to Garthmill near Berwick. The company were authorized to raise 22,000l.; the amount of each share 103l. The water of Lledan Brook is to be taken to supply this canalfor 24 hours weekly, from Saturday to Sunday evening; the company are bound to purchase certain mills, if their trade is injured by the canal: and certain creditors on turnpike tolls near the canal are also indemnified: the profits are not to exceed 10 per cent. but the tonnage is to be reduced, but not so as to bring the profits below 8 per cent. the rates of tonnage and exemptions are various; see Philp's 410. History, Appendix, p. 151 and 152. About the year 1794 the Wellington and Leominster canal was proposed to join this near Wellington.

Neath Canal. Acts 31 and 38 Geo. III.—The general direction of this canal is nearly N.W. for about 14 miles in the county of Glamorgan in South Wales; and its northern end is considerably elevated; its object is the export of coals, iron, lime-stone, &c. from the mines and works near the line; which continue in the tide-way of the Neath river, at Giants-grave pill in Briton's-Ferry, and terminates in the Aberdare rail-way branch at Abernant near Furno.
Vaughan: being joined near Briton's Ferry, in the Neath river, by the New Chapel canal. Neath is the only considerable town on this line; near Merlin's Court is an aqueduct over the Neath river. This company were authorised to raise £3,500; they are authorised to make railway branches to any place within 4 miles of the line, by consent of the land-owners. In 1798 this canal was nearly finished, except about two miles at the lower end. Here is a singular provision, that the rates of warehouse-room are to be the same as are charged by the Staffordshire and Worcestershire company at the Stourport warehouses.

Neath River. The general direction of this navigation is nearly N. for about 4 miles in the county of Glamorgan, in South Wales; the tide flows through its whole length from Swansea bay to Neath bridge; at Giants grave hill near Briton's Ferry it is joined by the Neath canal, and near Briton's Ferry by the New Chapel canal; its chief objects are the supply and trade of Neath, and the export of the coals and iron brought down by the canals.

New River (lower district.) Acts Geo. II., and 34 of Geo. III.—The general direction of this navigation is about S.W. by a very crooked course of nearly 75 miles in the counties of Cambridge and Huntingdon, and skirting those of Lincoln and Northampton; this is by what appears to have been its ancient course through the Fens, beginning in the tide-way at Peter's point about 9 miles below Wisbech, passing that town, where is a bridge built of stone with one flat semi-elliptic arch of 70 feet span; and turning south-eastward by an ancient course (which is now rendered useless to navigators by the Wisbech canal, which joins this river at Wisbech and again at Outwell), to Outwell and Apwell, thence to March and Benwick, thence through Ramsey, Ugg, and Whitleafie Mea, through Horfey-bridge, and Standground sluice to Peterborough, and thence by the regular channel of this river to the commencement of the upper New navigation at Thriftpon; in after times, a navigable course has been opened, for part of the waters of this river through Well-Creek, about 5 miles in length, from near Outwell-church to the Great Ouse river at Salter's-Load; another from Standground (14 mile below Peterborough) through Catt-Water and Shire Drain of about 24 miles in length to the New river again at Gunthorpe-fluide (about 63 miles below Wisbech), this last having a cut of about 2 miles in length from it into the old Welland river near Crowland; in 1490, bishop Moreton cut a new artificial course 40 feet wide and 13 miles long, called Morston's Leam, for a part of these waters, from Standground fluice (about 2 miles below Peterborough) to near Guyhirne, and thence 3 miles by an old channel to the New again near Wisbech; also, at Benwick this river is joined by the Benwick-Meer bridge, of the Great Ouse river. The above will serve to give some idea of the principal lines of navigation belonging to this river through this surprizing country; but as all the rivers, and all drains almost in the fens are embanked on both sides, and owing to the deficiency of fall are almost still water, there are a great number of smaller navigable branches intersecting and crossing each other in all directions, so that it would be in vain for us to attempt to describe them. The powers of the commissioners under the above acts, extend only about 30 miles downwards to Peterborough bridge; the navigations through the fens are preferred by the fen corporation in maintaining their drainage works. In 1771, Mr. Nathaniel Kinderly recommended the cutting of a new channel or outfall for this river (as has been since successfully practised by him on the Dee river at Chester) from the mouth of Shire-drain at Gunthorpe-fluide straight along the N.W. shore for 2 miles to Peter's point; and the work was begun, but the mistaken notions of the people of Wisbech then, and till lately, prevented its completion: we are glad, however, to hear, that the scheme is likely now to be soon accomplished, and a greater depth of water obtained in this river, and through Croft's key's wash to Lynn and Bolton deeps. By the act for Wisbech canal 34 Geo. III., all vessels passing out of or into that canal from the New are to pay 3d. per ton, out of which 10cl. is to be paid annually to the commissioners under the above acts for improving this river above Peterborough, and the remainder is to be applied to deepening and improving the fame between the Wisbech canal at Outwell and the Ouse river at Salters-Load. Boats which have paid the above toll are to pass toll free at Salters Load, and Standground sluices on this river.

New River (upper district.) The general direction of this navigation is nearly S.W. for about 23 miles, in Northamptonshire: it is not greatly elevated; its objects are the supply of Northampton and the surrounding country with coals, deals, &c. and the export of agricultural productions. The communication between Lynn, London, Liverpool, Manchester, &c. which it now effects is also important. Northampton is the 8th British town with a population of 24,200 persons, Wellingborough, Thrapston, and Higham-Ferrers, are also considerable towns on or near this river; it commences in the lower New navigation at Thriftpon, and terminates at the railway branch of the Grand Junction canal at the town of Northampton, where also it is to be joined by the Leicestershire and Northamptonshire Union canal. This navigation has been improved by a great number of tide-cuts and pound-locks by the tide of the river in different places; it was completed and opened to Northampton on the 7th of August 1761. About the year 1793, the Leicester and London canal was proposed to cross this river near Wellingborough.

Newark and Bottesford. In the year 1793, a canal was intended from the Don river at Newark to the long level of the Grantham canal at Stainworth, passing near the town of Bottesford. In the Grantham, act 33 Geo. III., the tolls are provided that are to be paid at the junction of these canals, if this is ever executed.

Newcastle and Carlisle. In the year 1795, Mr. William Chapman surveyed the line for a canal from the Tyne river at Newcastle to the Eden river at Carlisle, through Durham, Northumberland, and Cumberland, crossing the grand-ridge for a connection between the east and west seas; and having a collateral branch of narrow canal and inclined planes to the elevated mining districts of Weardale and Teedale forests, &c. the ultimate being 355,067. On the rejection or suspension of this scheme, a canal from Newcastle to Haydonbridge was proposed as below.

Newcastle and Haydon-Bridge. In 1796, and again in March 1802, it was in contemplation to make a canal nearly following the course of the Tyne river, between Newcastle and Haydon, in Northumberland and Durham.

Newcastle and Maryport. Some years previous to 1807, a canal was projected between the tide-way in Maryport harbour and the Tyne river at Newcastle, crossing the grand ridge, and passing between the two seas, though Cumberland and Durham counties: a bill for the same was brought into parliament, but rejected, owing to the opposition that the founders of another scheme gave to it: in 1807, the scheme was again revived, but nothing effectual has been done towards its adoption.

Newcastle (under-line) Canal. Act 33 Geo. III.—The general direction of this navigation is nearly west, by a very bending course of 3 miles, in the county of Stafford: its objects are the bringing of Caldon lime for manure, and...
and the export of coals and farming products: it is considerably elevated. Newcastle is a considerable town, and its neighbourhood very populous. This canal commences in the Trent and Mersey canal (near to the end of the Caldon branch) at Quinton's Wood, in Stoke, and terminates in the Newcastle-under-Lyme Junction, at the south-east corner of Newcastle town. It was completed in a short time after the act was obtained, the company being authorised to raise £10,000; the amount of shares therein is only 501. each. The rates of tonnage and wharfage are on coals, lime-flour, and iron-flour 2d. per ton per mile, on all other goods 2d. per ton per mile, but for less than a ton of any article in a boat 6d. Between December and the 1st of April this company may take flood waters from the Trent river.

Newcastle-under-Lyme Junction Canal. Act 38 Geo. III.—The general direction of this canal is about N.W. for a short distance, in two detached parts, in the county of Stafford: its western ends are much elevated, and terminate near the grand ridge on its eastern side: its object is the export of coals and agricultural produce. Newcastle is a considerable town on its line. It commences in the Newcastle-under-Lyme canal, at the S.E. corner of that town, and terminates its eastern part in the canal of Sir Nigel Bowyer Greffey, near the S.W. corner of the town; its western part commences in Greffey's canal above mentioned, near Apedale, and extends to Partridge-Neet collieries, with a branch to Bignell-End collieries. This company were authorised to raise £12,000, the amount of their shares being 50l. only: provision is made in the act for inclined-planes and water-levels, or rail-ways, with engines to raise water or drain wells, &c. in case any of these should be found more eligible than a canal with locks, in any part. Pleasure boats to pay for 6 tons if they pass any lock. In 1795, the Commercial canal, for 40 ton boats, between the Afsby and Chelfer canals, was proposed to occupy or pass through the line of this canal, when enlarged.

New Chapel Canal. The general direction of this canal is east, by a bending course of about 33 miles, in the county of Glamorgan, in South Wales; the greater part of it is cut through a morass, but little above the level of the tide-way in which it commences, in the river Neath, near Briton's Ferry (near the entrance of the Neath canal), and terminates at New Chapel, near Swansley; it is the sole property of the owner of the land, and for whole improvement, by draining and otherwise, it was principally undertaken.

Newport and Stone. In June 1797, it was proposed to make a canal from the Donnington Wood canal (the marquis of Stafford's) at Page-lane, near Newport, by Eccleshall, to the Trent and Mersey canal, near Stone, a course of about 18 miles, in the counties of Salop and Stafford, crossing the grand-ridge; a branch was proposed to Market-Drayton: its object was the opening of a direct communication between Shrewsbury, and other places on or near the upper parts of the Severn, and the Trent and Mersey canal, for supplying the intermediate country with coals and lime, &c. In 1765, the Trent-bridge and Winsford canal was proposed, and intended to pass through nearly the fame ground as the middle parts of this canal; as was also the Sandbach on an other occasion.

Newry Canal (Ireland). This canal, from the tide-way at Fadham point to the town of Newry, was completed under the direction of Mr. Colborne, in February 1761, after being two years in hand, by which brig of 80 or 100 tons burthen can come up to Newry; it was intended to extend this to the Blackwater navigation, for conveying the Dun-gannon and Drumglis coals to Dublin; and the Irish parliament, between 1753 and 1771, granted different sums of the public money for this purpose, amounting to £1,434, but the work then was far from being completed.

Nith River. The course of this river (sometimes called the Nid) is nearly north for about 9 miles, between Dumfries and Kirkcudbright counties, in Scotland; the tide flows through its whole length, and its object is the supply of Dumfries, (the 7th British town, with 7,583 persons); it commences in Solway Firth, and terminates at Dumfries bridge, which is of stone, with 13 arches. In 1763, Mr. John Swinton was consulted on the improvements by jetties of flake and flutons for gaining land, that had been made at Cargin, Lagal, and Netherwood, on this river, and recommended the removal of some of these works at the projecting points of the river.

Nottingham Canal. Act Geo. III.—The general direction of this canal is nearly N.W. by a crooked course of about 15 miles, in the county of Nottingham; it is not very greatly elevated: its objects are the export of coals from the several mines near it, and of farming products, importing lime, deals, &c. Nottingham is the 17th British town, with a population of 28,861 persons. This canal commences in the river Trent, near Nottingham (opposite to the junction of the Grantham canal), and terminates in the Comford canal, near Longley bridge, and near to the termination of the Erewafla canal: near to its southern termination it is joined by the Trent canal, or side-cut (from the Trent and Mersey canal). A reservoir is made near Amflethworth for the supply of this canal, and has a full-regulating sluice which lets out near 3000 cubic feet of water per hour for certain mills and the Erewafla canal. In 1803, this canal was completed.

Nutbrook Canal. Act 33 Geo. III.—The general direction of this canal is nearly N.W. for 5 miles, in the county of Derby: it is not greatly elevated: its object is the export of coals from the mines near the line; which commences in the Erewafla canal, near Stanton, and terminates at Shipley colliery; it has a branch to Welf Hallam collieries. Sir Henry Hanlouce and Edward Miller Mundy, esq. were authorised to raise 19,500l. between themselves, in 100l. shares; their profits hereon are not to exceed 8 per cent.; and proprietors of adjoining lands may make side branches thereto: the particulars of the tonnage rates are very long, including some regulations with the Erewafla company, &c. See Phillips's 410. History, Appendix, p. 104 and 105.

Oakham Canal. Acts 33 and 40 Geo. III.—The general direction of this canal is about S.E., by a crooked course of 15 miles, in the counties of Leicesters and Rutland: its southern end is considerably elevated, crossing the Tilton and Burley branch from the grand-ridge: its objects are the supply of Oakham, and the country through which it passes, with coals, deals, &c., and the export of agricultural products. Oakham and Melton-Mowbray are considerable towns on this line, which commences in the Leicesters and Melton-Mowbray navigation, at Melton-Mowbray, and terminates at the town of Oakham. From the Leicesters and Melton-Mowbray navigation to Edmondthorpe, 8 miles, it has a rife of 130 feet; the remaining 6½ miles to Oakham are level, and it is fed by a reservoir for flood-waters in Langham, and another in Saxby. The engineers were Mr. William Jessop and Mr. C. Staveley, jun. In November 1800, this canal was opened from Melton-Mowbray to Saxby bridge, and in January 1803, the whole was completed. This company was authorised to raise 86,000l. in 100l. shares. The rates of tonnage and wharfage, with the exceptions therefrom, may be seen in Phillips's 410. History, Appendix, p. 106 and 107; but to which the last act made an addition, and
and the Leicester and Melton-Mowbray act, 40 Geo. III.,
also contains some regulations affecting the tolls at
the entrance to this canal. Earl Wynchellca is to be paid £1.
anually, in lieu of his customary dues on coals sold in Oak-
lam town.

OUSE RIVER (Lewes lower Navigation). Act 31
Geo. III.—The general direction of this navigation is nearly
north, for near 9 miles, in the county of Suffolk; the tide
flows through its whole length: its objects are the import
of coals, deals, &c. and the export of farming
products. Lewes is a considerable town on this navigation;
which commences in the English channel, at Newhaven
harbour, and terminates in the upper Ouse navigation, at
Lewes bridge: the meadows, called Lewes and Langhton
Levels, near this river, were subject to be overflowed, and
it is part of the object of the above act to embank the river
and its tributary streams, and to erect proper sluices, and cut
drains for the improvement thereof; part of the money
for which draining purposes, is to be raised by the commissioners
of fewers, under the act of 23 Hen. VIII., by different
rates per acre on each of the five districts into which the
levels are by this act divided, but the works are to be per-
formed by the trustees appointed by this act, who, in 1802,
completed the straightening and deepening of the course of
the river, so that the tides flowed higher and ebbed lower than
before at Lewes bridge, and to which place vessels drawing 4
feet of water can now come up. The tolls on articles navigated
on any part of this river are to be, for manures not exceeding
2d. per ton, for road-materials 3d., and for all other goods
4d. per ton, empty boats to pass toll free; these tolls are
to be not to be lowered (except road-materials to 2d.), so long as
1/4 of the money borrowed on the credit of these tolls and the acre-taxes, remitted and discharged; the tolls are intended hereafter to be so reduced, that one-third of the
whole expenses of maintaining the navigation and drainage
works shall be paid by the acre-taxes, and two-thirds by the
tolls on the river; the acre-tax is, however, to make up the
deficiency, if the above tolls are inadequate; lands below
Newhaven bridge are not to be taxed, but to maintain their
own banks. In the year 1762, Mr. John Smeston was
consigned about improving the navigation and drainage of
this river. About the year 1793, a new pier was built to
protect the harbour of Newhaven, and the entrance of
this river; in 1802, it was proposed to add a new groin thereto to the wellward, for the further security of vessels;
and, in 1804, it was in contemplation, by large flumes from
the neighbouring cliff, to extend a rough unwall'd pier
much further out into the sea, for the security of vessels on
this coast.

OUSE RIVER. (Lewes upper Navigation). Act 30
Geo. III.—The general direction of this navigation is near
north-west, by a bending course of about 22
miles, in the county of Sussex; it is not much elevated
above the level of the sea: its objects are the import
of coals, deals, &c. and carrying chalk and manures to
the lands, and the export of their agricultural products.
Lewes and Cuckfield are considerable towns on this line;
it commences in the lower Ouse navigation, at Lewes bridge,
and extends to Hammer bridge, near Slaugham, with a
branch to Offham chalk-pit, in Hamfay; the depth of
water in every part is to be made 3½ feet; the boats to be
50
feet long and 12½ feet wide, and are not to pass locks with
less than 10 tons of lading. This company were authorised
to raise £25,000. in 100l. shares, and the works were not to
commence until £10,000. of this was subscribed, and 10
per cent. thereon actually paid: it is to that public spirited
and worthy nobleman lord Sheffield that the country are in a
principal degree indebted for bringing about this useful
measure. From Lewes bridge to Barcombe mill there was
an old and imperfect navigation for small boats; on this part
of the line, the rates of tonnage are to be, on manures,
road-materials, timber, grain, &c. 4d. per ton per mile, and
on all other goods 1d. per ton per mile; on the remainder of
the part of the line, manures, &c. as above, are to pay 1d.
and other goods 1½d. per ton per mile. Empty boats to pay
1½s. for passing each lock, and pleasurable boats 3d. below and
6d. above Fretthill bridge for passing locks. Between Old
Eye, in South Malling, and Land-Port, no toll is to be
charged, on goods carried no farther. Branches may be made
to any place within 2000 yards of this river, on which the
powers of the commissioners of fewers (23 Hen. VIII.) still
continue. In 1801, it was proposed to make an extension of
the Sarry iron road-way to join this navigation at Linfield.
In 1802, the navigation was not completed up to Hammer
bridge; but, in the following year, it was said that a new
act for further powers for that purpose was in contemplation.

OSE (great) River. The general direction of this river is
nearly S. W., by a crooked course of about 84 miles, in the
counties of Norfolk, Cambridge, Huntingdon, and Bed-
ford, and skirting Suffolk for a short distance: this course
through the fen being from the tide-way in Lynn deeps; (2
miles below that town), palt Lynn, Teleny, Salter's Load,
Denver-fluice, Rebeck, Little-port-chair, Ely, Harrimore,
Hermitage-fluice, Erin, and thence by the regular channel
of this river to Bedford. Soon after the year 1630 (in
consequence of a law of fewers of the 13th of January, 6
Chars I.) the old Bedford river, (a straight cut, of 21 miles
long and 70 feet wide), was made, between Hermitage-fluices
and Salter's Load, for conveying part of the waters of this
river, and in 1652, the scheme of Sir Cornelius Vermuyden
for another navigable cut nearly parallel with the last
was carried into effect, (under the authority of an act of Crom-
well, 1649, confirmed afterwards by 15 Charles II. estab-
lishing the fen corporation); this last, called the New
Bedford river, is 30 miles long and 100 feet wide, from
Hermitage fluices to Denver's fluice, both these new cuts
falling into the great Ouse river again, at Salter's Load and
Denver's fluice (which are within about a mile of each
other, and 17 miles from Lynn); besides these, part of
the waters of this river make their way by a navigable cut of
about 12 miles in length, from Hermitage into the Nene river
at Benwick. In 1725, Mr. Thomas Badenclafe mentioned, and,
in 1751, Mr. Nathaniel Kinderley strongly recommended,
another shorter cut between Eaubrick and Lynn, for
straightening the course of this river, for which the acts of
the 35, 36, and 45 of Geo. III. have been passed, called
the Eaubrick cut, and on which Mr. Robert Mylne, sir
Thomas Hyde Pagge, and captain Joseph Hudlart are em-
ployed as engineers: this cut was, in September 1804,
marked out, and is intended to be 295 feet wide at the east
end, 204 feet at the west end, and about 2¼ miles in
length, making easy bends into the river at each end, with
banks on each side, at a distance from the cut, 6 feet higher
than the ordinary tides, of 15 feet rife, with an embank-
ment and sluice across the old channel, above the east
entrance of the new one; which important works are ere
performed, at the end of 1805. Near the harbour of Lynn
this river is joined by the Lynn river; at Rebeck, a branch of
the Nene navigation (called Well Creek); between Salter's Load and Denver's fluice it is joined by Stage river,
at Rebeck the little Ouse jogs; at Prick-willow the Lark
river joins; near Barkway chapel the Sobham-Lode; at Harri-
mere, the Cam river joins; and at Tempsford the Ivel
river also joins; the whole of the rivers and large drains in
the
Oxford Canal. Act 9, 15, 16, 144 and 30 of Geo. III.—The general direction of this canal is nearly north, by a very crooked course in its northern half, of 51 miles, in the counties of Oxford, Warwick, and Northampton; it commences on the grand-bridge by a tunnel, and its northern part skirts about near to it on both sides the Avon, to a distance of 45 miles; its object was a communication between the seaports and the metropolis, (but a much nearer route, now opened, by the Grand Junction canal,) the supply of the northern parts of Oxfordshire with coal, the export of farming products, &c. At Woolnorton is a cut of about 4 feet (belonging to the Duke of Marlborough), by which a communication with the Thames and Isis navigation at Godlawn is effected. At Napton the Warwick and Nanton canal joins this; and at Brummelton the Grand Junction canal joins. Coventry is the 24th British town, with a population of 16,033 persons; and Oxford is the 38th, with 11,694 persons. Woodlock, Deddington, Banbury, Southam, Daventry, and Rugby are also considerable towns on or near to this line of canal; which commences in the Thames and Isis navigation at Beddington's Garden, on the west side of Oxford city, and terminates in the Coventry canal at Longford. At Hillmorton and at Napton are short cuts, of about a half mile each, to the steam-engines belonging to this company. From the Thames and Isis at Oxford to Banbury, 27.4 miles, is a rise of 118 feet by 16 locks (including 2 weir locks and an entrance lock from the Isis); thence to Chilson, 74 miles, is a rise of 74.4 feet by 12 locks; thence (through the Fenny-Compton tunnel) the summit pound continues to Market; 55 miles, and level; thence to Napton on the fall 3 miles, is a fall of 53.4 feet by 9 locks; thence to Hillmorton, 16.5 miles (in which the Warwick and Napton and the Grand-Junction Join), is level; thence to Little, 3.4 miles is a fall of 19 feet by 3 locks; thence to the Coventry canal at Longford, 26.5 miles, is level. The two short cuts to the engines, and that at Woolnorton, are level. This canal is 25 feet wide at top, 16 feet at bottom, and 4.5 feet deep, except the summit pound, which is made 6 feet deep in order to act as a resevoir; the locks are 74.4 feet long, and 7 feet wide. At the toll-house near Longford is a lock-bridge, to prevent the Coventry canal in dry seasons, from lowering the water in the long pound on this; from which long pound an engine at Hillmorton pumps water into the Birmingham pound, by means of a feeder; and out of this last pound by means of a longough. Another engine at Napton pumps into the summit pound, which is also fed by three resevoirs. The number of stone and brick bridges on this line is 185, and of wooden, swing, draw, and foot bridges 66. The Fenny-Compton tunnel is 1188 yards long, 9.3 feet wide, and 15.5 feet high. At Newbold is a tunnel 225 yards long, made under the church-yard and street, 16 feet high, and 12.5 feet wide, with a tow-path through it. At Wolhamcote, also, there is a short tunnel. At Peders-Bridge near Brinklow is an aqueduct bridge of 12 arches, of 22 feet span each. At Cosford on the Swift river, and at Clifton on the Avon, are others of 2 arches each; at Wolhamcote, Adderbury, and Hampton-Cay, are other smaller aqueducts. Mr. James Bradley made the survey for this canal in September 1768; in August 1769, he began the work near Longford; and in 1775 it was completed from thence to the Napton locks; when 124,000l. having been expended, the works stood still for want of money until 5th April 1786, when they were resumed; on the 31st of March 1778 the line was opened northward to Banbury; and on the 1st of January 1790 the whole was completed. Mr. James Barnes was employed to execute some of the digging of this part. This company have been authorized

Vol. VI.
authorised to raise, by their different acts, 330,000l.; the amount of their shares is 100l. each. In January 1800 there are said to have sold for 10s. l., and in 1802 for 27s. 5d. each; the Grand Junction company being bound to make up the tolls hereon to 10,000l. annually, (if the works are kept in order) on condition of this company taking only certain tolls on goods palling to or from that canal, (see Phillips's 4to. High. Agric. p. 336.) and agreeing to widen about 35 miles of their canal and locks, that large boats may pass north of Bhamton, whenever the Grand Junction company shall require the use of them, and the Coventry company. The rates of tollage are under complicated; they will be found in Coach's Island Navigation, pages 59, 74, and 82. For parcels under 5l. the company are to fix specific rates in their printed tollage tables. Coals from the inland pits were not allowed, by the first act above, to come nearer to London than Oxford; but by the 2d act, this was extended to Reading and the Kennet navigation; and in the year 1800 the company offered 25. per ton as a premium on coals carried certain distances from their canal into Berkurk, &c. Small narrow barges used on this canal seldom venture down the Thames to London, but goods are generally shifted at Oxford into the Thames-barges. About the year 1792 the Cranford and Crewe's canal was proposed to join this at Capercy; and, at the same time, a canal from Hampton-Cay to Sloughworth was intended, to join this at Hampton-Cay.

Parke's Canal. This short canal, or rather waterway, has nearly a north direction for about 3/4 mile in the valley north of St. Aulde, (near the south coast of Cornwall) one mile above that town; it commences within an immense excavation of great depth, and open to day, which has, by the work of ages, been made in a rocky hill abounding with tin ore. It is tunneled through the solid rock for 200 yards or more, on a level to the surface of the hill, and proceeds forwards thereon to the top of an inclined plane, of about 50 feet fall, where the boats are raised up an end by a windlass to shoot out the ore, as already described on St. Columb canal. At the bottom of the plane the ore is loaded into carts, to be carted to the flamping-mills. Small square-headed boats are used, and four or five of them are linked together to be shoved through the tunnel, by means of chains which are fixed along its sides for that purpose, and they are afterwards turned along the canal to the head of the plane. This canal, tunnel, and plane, were made at the expense of Mr. Parke, who owns the mine, about the year 1770, before which the ore was drawn up to the top edge of the pit or mine, and carted from thence.

Parret River. The course of this river is nearly south-east for about 5 miles, in the county of Somerset; it is not greatly elevated; its objects are the import of coals, and the export of agricultural products. Langport is the only considerable town near this navigation. It commences in the Tone and Parret navigation at Borough-Chapel, and terminates in the Icelakefer and Langport navigation, a little below Langport.

Peak-Forest Canal. Acts 34, 40, and 45 of Geo. III.—The general direction of this canal and railroad is nearly south-east for 21 miles, in the counties of Chelfer and Derby; its southern end is very considerably elevated, and terminates on, or very near to, the Grand-Ridge; its principal object is the export of the Peak-Forest lime, and of coals from the neighborhood of this canal. Ashton-under-line, Stockport, and Chapel-le-Frith are considerable towns on or near this line; which commences in the Manchester Afton and Oldham canal, at Dukdenfield, (near to the termination of the Huddersfield canal,) and the canal terminates at the bafon and lime-kilns in Chapel-Milton, whence a railway proceeds to Loads-knoll lime-kiln quarries in the Peak. The line of the canal is 15 miles in length, and of the railroad 6 miles; there is a cut of 1/3 a mile to Whaley-Bridge, and a railroad branch of 1/2 mile to Marple. Over the Merley river, near Marple, is a grand aqueduct bridge of 3 arches, each 60 feet span and 75 feet high, the whole height of the structure being near 100 feet, which was built in the year 1799. (This bridge we have before, by mista¬
take, when treating of Aqueducts, mentioned as being on the Manchester Afton and Oldham canal.) Mr. Benjamin Outram was the engineer, and the works were completed on the 1st of May 1800. The company were authorised to raise by the first act, 175,000l. each share being 100l., which in 1802 bore a premium of 12 per cent. It has been said, on several occasions, that this canal and railroad were completed at 10 per cent. under the original estimate, and that the 2d act authorized the company to raise any unlimited sum that they might want, in which case they certainly were mistakes, because the act of the last session was for raising a further sum of money. For the rates of tollage and wharfage, see Phillips's 4to. History, p. 155. Mine¬waters may be used for the supply of this canal; but only the floodwaters of the rivers.

Pentland Firth. This height has nearly a west di¬rection between Caithness county, at the north-eastern ex¬tremity of Scotland, and the Orkney islands. This, though a rocky and dangerous passage, is much frequented by ships, on account of being the first passage which prelits itself for ships in going northward, between the East and West Seas, or German Ocean and Irish Sea. The Inverness and Fort-William canal, now cutting a great way south of this for the use of ships, is expected much to lighten the use of this firth. Scraiber road-lead, on the side of this firth, is a harbour much frequented by ships in blowing weather. Thurso har¬bour in Caithness, on the southern side of this firth, has a pier now building, and its harbour improving, under an act of 42 of Geo. III.

Poole Canal. Act 37 of Geo. III.—The general di¬rection of this canal is nearly south-east for about 5 miles in Cornwall, near its north-west coast; it is not greatly elevated; its objects are the import of coals, and the export of stone and agricultural products. Bodmin is a considerable town near it. It commences at Guinea-port, near Wadebridge, in the Camel river, and terminates at Dunmore Bridge and Stoney Lane, in the parish of Bodmin, having a collateral cut of 1/3 a mile to Rither Bridge, in the same parish. At Guinea port and at Stoney-Lane Bridge large and convenient basons and warehouses are intended. Mr. John Remie and Mr. Murray are the engineers. This company may raise 18,000l. in 50l. shares. A feeder from the Camel river and any springs within 2000 yards may also be taken for this canal.

Poole Harbour. This spacious inlet or harbour has nearly a west course for about 9 miles, in the county of Dor¬set; the tide flows into every part of its various branches and inlets, and round Branksea island, which is in the middle of it; its objects, besides the general trade and supply of the neighbourhood, is the export of a fine potter's clay found near to Corfe Castle, in the isle of Purbeck, and paving¬stones and free-stone from thence. Poole, Warham, and Corfe Castle are considerable towns near this harbour, which commences in Studland Bay and terminates at Wareham Bridge: a branch proceeds about 21/2 miles north to Creek-Moor. In 1797 several improvements in this harbour were in contemplation.

Portsmouth Harbour. This inlet or harbour has nearly
Canal.

Canals are not found, for about 5½ miles, in Hampshire; the tide flows through it, and the depth of water in most parts of it is insufficient for the large ships of the British navy. Portsmouth is the 13th British town, with a population of 32,160 persons; Gosport and Fareham are also considerable towns adjoining it. It commences at Spithead and the Channel, between Emsworth and the Isle of Wight, and terminates near Fareham Bridge, having also a branch to Cosham, and a communication thence to Langflown and Chichester harbours. On the shores of this harbour there are immense buildings and works, for the use and security of the royal navy. In 1805 several considerable additions were made to these works, and a bridge between Gosport and Haslar hospital, which Mr. Robert Forbes built five years ago, is intended to be taken down, having proved injurious to the harbour.

Portsmouth and Croydon Canal. In the years 1802 and 1803, a canal was proposed from Portsmouth Harbour to the Croydon Canal at that town, pullying Havant, Chichester, Arundel, Horsham, Rye, and Merthyr, of which the able engineer, Mr. John Rennie, prepared plans and an estimate; but the opposition of the land-owners, and favourers of a railway scheme from Portsmouth to London procured its rejection in parliament. The summit-level of this canal was to be 36 miles in length, at about 200 feet above the level of the sea: this was to be fed by several reservoirs in or near Hotham Porell, containing, in the whole 500 acres, and 340,000,000 cubic feet of water. This level was to penetrate the Chalk-Hills north of Merthyr, by a tunnel 45 miles long, and 350 feet below the top of those hills. The estimated expense was 720,000l., and 800,000l. in 100 years was proposed to be raised; the expected revenue was estimated at 100,000l. per annum. While this line was in contemplation, there was an attempt made by Mr. Ralph Dodd to draw the public attention to a different line of canal, (which Mr. John Phillips laid claim to, as being one of the fanciful ones which he has drawn in the map to his 410. Histon, 1791,) from Portsmouth Harbour, through Southampton Water and the Ichen River, to Winchester; thence to Alresford, near to Alton and Fareham, and to the Wey River at Godalming: from near Welley on that river, the proposed line of the Grand Survey canal was to be followed to Deptford and the Thames river. The estimate mentioned on this occasion was 348,753l.

Portsmouth and London Railway. In 1803, Mr. William Jeffry was employed to survey the line of a railway from Portsmouth to the west end of Stamford-Street, near Blackfriars Bridge, London; on the utility of which, and the Portsmouth and Croydon Canal above, opinions were for some time divided: in the end, neither of them was adopted. The estimated expense of this work was 400,000l.

Ramsden's Canal. Act 14 Geo. III.—The general direction of this canal is nearly south-west for about 5 miles, in the Wilt Riding of Yorkshire: it is not very greatly elevated; its objects at first were the supply and trade of Huddersfield town, but it will shortly have considerable importance as part of the short line of navigation between Hull and Manchester and Liverpool. Huddersfield is the 81st British town, with a population of 7268 persons. This canal commences in the Calder and Hebble navigation, at Cooper's Bridge, and terminates in the Huddersfield canal, at King's Mill near Huddersfield; it has a rise of 563 feet by 9 locks. Sir John Ramsden, who is the sole proprietor of this canal and of Huddersfield towm, in 1760 employed Mr. James Brindley to plan this canal; and, after his death, it was begun and quickly completed by Mr. Luke Holt. At Huddersfield spacious warehouses are built by the side of this canal, to which goods intended to be there lodged may be carried toll free along the part of this canal from the Huddersfield canal; that company guaranteeing the tolls on this not to be levied elsewhere. On the whole length or any part of this canal, coal, flags, flax, flaxen, hemp ropes, and linen, are to pay a toll of 3d. per ton, and all other goods 6d. per ton, excepting sheep and manures, which are to pass free. The proprietors' profits are never to exceed 6 per cent, upon the monies laid out therein.

Reading and Maidenhead. In 1770, a canal was proposed from the Thames river, at Bolter's Lock west Taplow-Hall, (at the western termination of the Maidenhead and Eton proposed canal) to the Thames again, at Sunning near Reading, and to the Kennet river, on which Mr. James Bradley was consulted by the city of London, the distance being near 15 miles by the canal, and by the river above 30 miles, between the same places; a barge of 120 tons being 3 days (and often in dry times as many weeks) in performing the voyage, at an expense equal to 5fl.; while, by this canal, it was calculated that a barge might at all times, except flood, perform it in 10 hours, at 4l. 7s. expense, including 3d. per ton to the trustees as a toll. This canal was at first proposed to commence at Monkey island in the Thames, which is 2 miles below Maidenhead-Bridge. No private property was to be allowed in this canal, but the money was to be raised by life annuities, out of which, and the tolls, the river navigation was to be improved between Bolter's Lock and Sunning, without any new tolls being charged thereon; and when a sufficient fund was accumulated for repairs and management, the tolls were to cease, and the canal be entirely free.

Ribble River. The direction of this river is nearly east for about 12 miles in the county of Lancaster; the tide flows through its whole length; its objects are the supply and trade of Preston town, and the export of coal brought down by the Douglas river, which joins it near Halideth. Preston is the 37th British town, with a population of 11,887 persons. This river commences with a very wide estuary or mouth in the Irish Sea, but grows very shallow, so as to be fordable at low-water, and terminates at the bridge at Preston, near to the aqueduct bridge, on which the Lancaster canal crosses this river. In September last, (1805) it was proposed to apply for an act for placing buoys, and otherwise improving the navigation of this river.

Ripon Canal. Act 7 Geo. III.—The general direction of this canal is nearly N.W. by a bending course of about 7 miles in the Well, and skirting the North Riding of Yorkshire: its objects are the supply of Ripon, and the export of agricultural products, stone, &c. It is considerably elevated; a Borough-bridge, Ripon, and Aldborough, are considerable towns on or near this canal, which commences in the Terfe river at Milby, near Borough-bridge, and terminates at Ripon.

Rochdale Canal. Acts 34, 40, and 44 of Geo. III. —The general direction of this canal is nearly N.E. by a bending course of 314 miles in the counties of Lancaster and York; it crosses the Grand-ridge by a deep-cutting: its general objects are the communication between Liverpool and Manchester, with Halifax, Wakefield, Hull, &c. the export of coals, paving-flenses, &c. At Piccadilly street in Manchester it is joined by the Manchester Ashton and Oldham canal. Manchester is the 2d British town, with a population of 84,020 persons; Huddersfield is the 44th, with 16,671 persons; Spotland the 55th, with 9,031 persons; and Halifax the 58th, with 8,886 persons. This canal commences in Bridgewater's canal at Castle-Field in Manches-
ter, and terminates in the Calder and Hobbie navigation at the basin, wharves and warehouses at Sowerby bridge: to near Hollingwood chapel there is a branch of 4 of a mile, and another of 3 a mile to School-lane in Caldron near Rochdale. From Bridgewater’s canal to Piccadilly wharf, and the Manchester Africa and Oldham canal, 14 miles, has a rise of 754 feet; thence to the Hollingwood branch, 42 miles, has a rise of 84 feet; thence to Failsworth brook, 22 miles, is level; thence to the Rochdale branch, 43 miles, has a rise of 120 feet; thence along the summit-pound and through the deep-cutting to Travis-mill, 74, is level; thence to the Calder and Hobbie navigation, 11 1/2 miles, has a fall of 275 feet; the Hollingwood and Rochdale branches are level. From near Rochdale to Sowerby-Bridge there are 49 locks, (which are of the same width and length as Bridgewater’s at Runcorn,) more than 60 bridges and 8 aqueducts and large culverts. At Hallin’s mill is a tunnel of 70 yards in length, 17 feet high and 21 feet wide, with a towing-path through it. At Dean-Head, between Littleborough and Todmorden, is a stupendous deep-cutting in hard rock, some of it 90 feet deep. A very large reservoir is made on the west side of the summit, and an 100 horse steam-engine is used to pump the water up to the summit-pound. On a bog on Blackton edge are two other large reservoirs, one of them 14 yards deep. Gauges for regulating the tides of the Roch, Irwell and Irk rivers, so that their surpluses floodwaters are taken for the supply of this canal, were contrived and erected by Mr. John Renais, the engineer. Steam-engines within 20 yards of the canal are allowed to condense by its water. On the 28th of December 1798, the east end of the line from Sowerby bridge to Rochdale was completed; on 9th September 1802, it was continued to Lomelfide wharf; and on 21st December 1804, the whole line was completed and opened to Manchester. This company are to pay a compensation to the duke of Bridgewater for his warehouses at Castle-Field, and to the Calder and Hobbie company for their warehouses at Sowerby bridge. This company were authorized by their first act to raise 391,000l. (the amount of shares 100l. each) and by the last act they were authorized to raise a large sum in addition. The rates of tonnage and wharfage, and the exemptions in the first act, will be found in Phillips’s 4to. History, pages 157 and 159, to 161; also, by the second act, certain additions were made to these tolls. Cuts or rails-ways may be made to any present or future coal-mines near the line. In 1791 a branch from this canal was proposed from near Todmorden (104 feet below the summit-level) to 2 miles beyond Colne, having a tunnel thereon of 1/2 mile in length, about 3 miles N. E. of Todmorden.

**Rother River.** The general direction of this river is nearly N.W. by a crooked course of about 19 miles in the counties of Suffex and Kent; it is but little elevated above the sea in any part; its objects are the import of coal, &c. and the export of oak-timber and agricultural products: near Tenden are considerable towns on or near to this navigation; which commences in the tide-way of the English Channel near Rye old harbour, and terminates at Robertsbridge; it has a branch of about 4 1/2 miles to Winchelsea bridge, and some other navigable branches in the level fens which surround Oxney Island, and adjoin Romney-marsh. The harbour of Rye near the mouth of this river, from its tendency to choke up, formerly employed the abilities of captain John Perry, Mr. John Smeaton, and other eminent engineers; and under the acts of 29 Geo. I. and 1, 37, and 41 of Geo. III. several works have been constructed. Previous to the reign of Edward I., it is said, that the Rother vented its waters into the sea at old Romney harbour, about which time a new channel was cut for it to sea at old Rye-harbour, which for a long time favoured itself out, and was deep enough for the use of large vessels, the tide flowing 24 miles up the river; but failures being afterwards erected in improper situations, and embankments made, which (before 1659) the channel became too shallow for ships, and in 1719 it was rendered quite useless for navigation; soon after 1721, the flue above mentioned were removed, but the evil was become so irreparable, that captain Perry advised, and effected the cutting of an entire new channel of about a mile in length, 150 feet wide at top, and 70 at bottom, since called the new harbour (from the sea, near 2 miles west of the old harbour) into the channel of the Winchelsea river, and through that to the Rother and old harbour at Rye; this new canal (finished 14th July 1762) had about its middle part, a flue fluce of two openings, one for the passage of vessels, and the tide near high-water, 40 feet wide, shut by double gates pointing to Landward, and another of 30 feet wide, closed by 5 draw-gates, to be occasionally opened for fowering the mouth of the new channel or harbour, at which there were two stone piers erected at 120 feet apart. The upland and tide waters continued to have their course to sea by the old channel or harbour, and Mr. Smeaton who was consulted in 1753, confidently foretold, that unless the old channel was closed up near Rye, below the entrance to the new one, so as to turn the upland waters through the new harbour, it would be in time quite filled up, as happened to completely previous to 1757, that an act then passed repealing all the former acts relating to this new harbour, and the tonnage which coasting vessels had paid since it was established, on passing or entering the same, was transferred to Ramsgate harbour, near Stour river, into which such ships are able to run for shelter, in case of a storm coming on. The new Rye-harbour was in consequence blocked up, by a bank below the Winchelsea river, over which the new road between Winchelsea and Rye now passes: soon after this, the Rev. Daniel Pope revived the ideas of Meffrs. Perry and Smeaton, with regard to the entrance of the old harbour, and by the assent of Mr. Souterden, cut a new channel, or sea vent, for the river, about 4 of a mile west of the old harbour’s mouth, and being about 4 of a mile in length, before it interfected the old harbour: at this place Mr. Pope constructed a dam of flaw, faggots, and gravel, which effectually blocked up the old harbour’s entrance, and forced the tide to enter and return, and the river waters to vent themselves through his new cut (as Mr. Smeaton had in vain before recommended to be done with Mr. Perry’s new cut.) After which, Mr. Sutherland constructed a pier-head on the east side, and two jetties on the west side of the present entrance to the harbour, which is now said (see Translations of the Society of Arts, vol. xxii. p. 219) to be capable of admitting ships of 250 and 300 tons burthen at spring tides, which here rise 23 feet, and the ebb tides 14 feet. In December 1799, it was proposed to improve the navigation of this river between Rye and Robertsbridge, to extend the navigation of the Winchelsea branch to Siddlescombe, and to make a new navigable branch from Blackwall to Smallhite near Tenterden. In April 1802, this last branch was proposed to be joined by the intended Medway and Rother canal.

**Sandbach Canal.** In the year 1793, a canal was proposed to be made from the Severn river below Shrewsbury to the Trent and Mersey canal at Sandbach, with a cut to Betley, and another to join the Chester canal near Nantwich. The Tarbridge and Winsford, and the Newport and Stone canals, have
have at different times been proposed through parts of the
same tract of country.

Sankey Canal. Acts 28 of Geo. II. and 1 of Geo. III.
—The general direction of this canal is nearly N.W. by S.
very bending a course, that it exceeds a semi-circle; its length
is 124 miles in the county of Lancaster; it is not very
greatly elevated in any part: its objects are the export of
coals and flates, and the supply and trade of St. Helens
and Newton, and the copper, glass, and other works near
them; near Sankey bridge it connects with, and is crossed by
the fide-cut made in 1784, for avoiding the floodings in the
Mersey between Warrington and Runcorn. Warrington is
the 43th British town, with a population of 15,367 per-
sons; Newton and St. Helens are also considerable towns
near, or on this canal; which commences in the Mersey and
Irwell navigation at Fiddlers-ferry, and terminates near
Sutton, on both sides. Near the mouth of Sankey brook
it has a short cut of about ½ of a mile, forming another
communication with the Mersey river; there is a branch of
about ½ of a mile to Penny bridge, and another of ½ of
a mile to Gerards bridge. From the Mersey to Sutton heath
is a rise of 78 feet, by 8.5 fide-locks, and 2 double
locks of 15 feet rife each. The highest spring tides rife
within about a foot of the level of the water at the first
lock. Vessels deeply laden were generally unable to pass
into or out of the Mersey for two or three days of high
tides before the Mersey cut above mentioned was made.
This canal is 48 feet wide and 57 feet deep in water; it
has 18 bridges, all of which are wooden swing-bridges, even
for the great turnpike road between Manchester and Liver-
pool. Between St. Helens and Sutton heath there is a
short tunnel; the canal is fed by a feeder from Sankeybrook,
and there are provisions for enabling the farmers near this
canal to irrigate therefrom, between the 10th of October
and 1st of May annually. Mr. John Lives was the engi-
neer, and has the honour of completing this, the first English
navigating canal, that was attempted: it was opened between
the Mersey and Gerards bridge in the year 1765. The sum
of money to be raised for the purposes of this canal is not
limited in the acts, as is done in all modern canal acts.
The proprietors are authorized to take 12d. per ton on all goods
which are navigated on any part of their canal, except lime-
flour, and materials and meares, which are charged 6d. per
ton. Typical quantities are: 60 tons of coal, 100 tons of
charcoal or coke, and 200 tons of slaves, are rated as a ton, and a
buffalo of coals is to be measured in a vessel 10½ inches diameter outside, and capable of con-
taining one buffalo and one quarter of water Winchester
measure. In June 1797, a loaded barge was rowed 20 miles
on this canal by a machine worked by a steam-engine on board
of the barge, as before mentioned.

Selby and Leeds. In 1769, Mr. James Bridgley surveyed
the line of a canal from the Ouse river at Selby to the Leeds
and Liverpool canal (near to the termination of the Aire
and Calder navigation) at Leeds: it was proposed to pass
Thorp dam, near to Thorp hall, Hambilton, Hallowham,
Burton-Salmon, (where a tunnel was intended,) near Fair-
burn, Newton, the Fire engines, and cross the Aire river,
by Thrwalt mill, Hunflet, and so on to Leeds, a course of
23 miles in length: the opposition of the Aire and Calder
company, who were in the reign of William III. indulged
with very high rates of tonnage, and some other persons,
proved fatal to this scheme when it came before parliament.

Severn River. Acts 19 Hen. VII., 23 Hen. VIII.
and 12 and 45 of Geo. III. —The general direction of this
noble river is nearly north, by a crooked and bending course
of about 174 miles, skirting the counties of Somerset,
Gloucester, Glamorgan, Monmouth, and Hereford, and
through the counties of Worcester, Salop, and Mont-go-
mary: commencing in the tide way in the Bridft Channel,
at Flat-Holm light-house, and terminating in the Montgo-
mery canal at Wellpool. Its northern end is considerably
elevated: the trade of various kinds is very immense on this
important river, and the many navigations which connect
therewith. At the lower layer it is joined by the Glamor-
ganfuye canal and Cardiff and Moseley-Tyddal railway; at
New Amherst by the Severn railway; at Neth by the
Wye river; (not far from its junction with Monmouths-
shire canal, and a branch of Sibsey railway; at King's Road
by the Bath Avon river; at Beecleby by the Wye river;
at Berks-Pill, Hetch-Crib, and at Gloucester by the Gla-
cester and Berkeley canal; at Framleigh by the Stroudwater
river and canal; at Gloucester, on each side of Alney Isle,
and at Liferham by the Hereford and Gloucester; at Plet-
cher's leap with Cornwall's canal; at Tewshbury by the
Stratford Avon; at Diglis by the Worcestershire and Birming-
am canal; at Shrewsbury by the Ouseford and Stour-
bridge canal; at Stourbridge by the Shropshire and Wor-
derford, and the Lenninger canals; at Coal-port and at Loa-
der-craif near Coalbrook-dale, by the Shropshire canal;
and at Shrewsbury by the W分成 and E111e8e5e8e8 canals. Bristol is the 7th British town
with a population of 68,645 persons; Shrewbury the 36th,
with 14,739 persons; Worcest the 40th, with 11,352 persons;
and Gloucester the 72nd, with 5,759 persons; Cardiff, New-
port, Chepston, Thornbury, Berkley, Newsham, Tewshbury,
Upton, Bewdley, Kidderminster, Bridge-North, Much-
Waxlock and WelfPool, are also considerable towns near to,
or upon this river. The falls which this river has in
particular places have been mentioned in a preceding part
of this article, as also a valuable experience of 11 years
continuance on the floods, droughts, and fruits which
affected its navigation; which is unaffiliated by any locks,
fide-cuts, weirs, or other obstructions, except the towing-paths,
which Mr. William Reynolds began between Coal port and
Coalbrook-dale, in consequence of an act, 12 of Geo. III.,
since renewed, for making a towing-path between Coal-
brook-dale and Bewdley bridge, and levying certain tolls
on goods navigated on that part of the river for defraying
the expenses of such path, which has been since completed;
and in 43 of Geo. III. a similar act for making a towing-
path between Bewdley bridge to the Worcester and Birmingham
canal at Diglis below Worcest, which is, we believe, also
completed. The trade of the middle parts of this river is
carried on by two forts of vessels, viz. barges 40 to 60 feet
long with a single mast and square sail, carrying from 20 to
40 tons, and trows with a main and top-mast about 80 feet
high, and square sails; these are 160 feet long and 16 to 20
feet in width, and carry 40 to 80 tons. Some years ago,
Mr. John Wilkinson introduced some barges made of cast
iron plates for navigating this river. In the 16 Geo. III.,
an act was obtained for erecting a cast-iron bridge of one arch
(the first ever erected: see our article Bridges) over this river
at Bowlsey or Madeley wood near Coalbrook-dale. The high
floods, in 1795, carried away a narrow and inconvenient stone
bridge that was at Buildwas, about 2 miles above Made-
ley wood, and in 1796, a new cast-iron bridge was erected
in its stead, as before desribed: by an act of the 17 Geo. III.,
a new stone bridge was erected over this river at Gloucester,
by which the navigation there was much improved. At
Shrewbury the very long and curving loop of the river is tun-
nelled through by a small arch for conveying water to several
mills at its junction again with the river. In the year 1765,
the Trembridge and Windford canal was proposed to join this
river at Trembridge; in 1785 the Stourbridge and Worce-
ter was proposed to join at Diglis; in 1793, the Sandbach, and
another.
another canal in opposition to the Ellesmere (called, in some maps, the Eastern Grand Trunk,) were proposed to join this river below Shrewsbury. In 1795, the Wellington and Leomin-
fler was intended to join at Wellpool; in 1797, the Bridgel and Gloucester was proposed to join, both at Gloucester and at Worcester, to this river; and, in 1801, the Severn and H'ye rail-way was proposed to join this river at Liddon.

In the year 1801, a line of rail-way was projected from the Severn river at Liddon, across the forest of Dean, connecting with the collieries thereon, and extending to the H'ye river at English Bicknor. At a meeting, on the 14th of June, 1802, the southern part of this design was relinquished, and the Dean-Forest rail-way was proposed in lieu of the other part.

Shannon River, (Ireland). The general direction of this famous river is nearly N. E. by a crooked course of more than 100 miles, between the counties of Kerry, Limerick, Clare, Tipperary, Galway, King's county, Meath, Longford, El-
phin, and Leitrim in Ireland. It commences in the Atlantic Ocean, at Loop-head, and terminates at Carrick on the Shannon, which is 65 miles above Banagher. It is joined by the Grand Canal at Tormainbury, and it also is joined by the Limerick canal. Limerick, Kilahow, Cloonfort, Leitrim, Carr, Longford, Roefcommon, Athlone, Portumney, Ne-
agh, Ailcaton, Clare-Abbey, &c. are considerable towns on or near to this river. About the year 1753, the improvement of the navigation on this river was attempted, by the erection of flues with gates on its stream, for damming up and making fall for the boats to pass through with.

The Irish parliament, at different periods, between 1753 and 1774, granted several sums of the public money, amounting to 39,160l. for the improvement of this navigation. It was not until about March 1804, that the upper part of the navigation on this river was completed.

Shorncliff and Rye Canal. Defence a'et 43 Geo. III. The general direction of this singular canal is nearly S.W. by a bending course of about 18 miles, through Romney marsh in the counties of Kent and Sussex. It is fo nearly level with the sea as to require no locks but the tide-locks at its extremities. Its objects, besides aiding the defence of this part of our coast, is the import of coals and sea-beach for road-making; the export of farming products, and improving the drainage of the marsh: Hythe, Rye, Appledores, and Folkstone are considerable towns near this line; which commences in the tide-way of the English channel at Shorncliff battery near Hythe, and terminates in the tide-way of the Rother river opposite Pleydon Height near Rye. This canal is of width and depth sufficient for vessels of 200 tons to navigate; it has a military road by its side, and is flanked throughout with batteries of great strength. This canal was projected by the royal military engineers, in the autumn of 1804; and in June last (1805) 3000 men were said to be em-
ployed thereon, and before now it is, we believe, completed.

Shrewsbury Canal. Aetz 33 Geo. III. The general direction of this canal is nearly E. by a crooked course of 173 miles in length, in the county of Salop: its easterm end is greatly elevated, and at no great distance from the grand-ridge on its western side; its objects are the export of coals from its easterm end, for the supply of Shrewsbury, and supplying the same with farming products, and the country with lime and manure; at Wombridge it is joined by the Ketley canal. Shrewsbury is the 56th British town, with 14,739 persons. This canal commences in Cuffe Föregete bailon, at the town of Shrewsbury, (near to the Ellesmere canal, with which it may be joined by mutual consent,) and terminates in the Shropshire canal above Wrockend-ridge, and near Oaken-gates. From Shrewsbury to Langdon,

near 12 miles, is level; thence to near Wombridge, 43 miles, is a rise of 70 feet, by locks; thence is an inclined plane of 75 feet rise, and near ¼ of a mile in length, to the Ketley canal; thence (along the part which was purchased by this company of Mr. William Reynolds for 543l. being half of what it cost) to the Shropshire canal, 1½ miles, is level. The locks on this canal are contrived in two divisions by doors, which draw up, out of a recess for them below the locks, so that a long narrow canal boat of the usual construction, or two or four smaller and narrow flat-bottomed boats adapted to the inclined-plane, can pass the same without unnecessary waste of water. Near Atcham is a tunnel of 970 yards in length, and 10 feet wide, which has a towing-path 3½ feet wide through it, constructed of wood, and supported on bearers from the wall, so as not to diminish the water-way. At Long is a long embankment and an aqueduct bridge, or rather trough of cast iron, over the Tern river, 62 yards long, and 16 feet above the level meadows, of which we have already given a description in this article; at Reddington are another embankment and a common aqueduct bridge, 21 feet above the surface of the Roden river, over which the canal passes, and at Pinley there are another embankment and aqueduct of less height and width than the former ones. At Wombridge there is a double inclined-
plane of 323 yards in length, and 75 feet perpendicular rise, one of which, empty or partly laden boats are drawn by the aid of a steam-engine, by the help of a loaded boat at the same time on the other, as we have before described.

Mr. Thomas Telford and Mr. William Reynolds were the engineers employed or consulted on the construction of the works on this canal. In March 1796, the Long aqueduct was finished; and in February 1797, the whole line was completed and opened. This company was authorized to raise 70,000l. the amount of each share being 100l. The rate of tonnage is 2d. per ton per mile on all goods, and 1d. per ton for passing the inclined-plane; manures, except lime, being exempt on the pounds, but not to pass the locks when the water is ¼ an inch under the lock-wards. The profits of this concern are not to exceed 3 per cent. on the capital, after which the toll on boats for passing the plane is to be first lowered or taken off. The act in providing for the purchase of 15 miles of Mr. Reynolds's Ketley canal as above, requires him to pay 2d. per ton per mile afterwards for navigating the same, as above. Less than 8 tons in a boat, except in returning, is to be paid for as such.

Shropshire Canal. Aetz 28 Geo. III. The general direction of this canal, or rather system of water-levels and inclined-planes, is nearly north, about 7½ miles, in the county of Salop: its northern end is greatly elevated, and at no great distance from the grand-ridge on its western side; its objects are the export of coals and iron, and the carrying up of lime-flour. It communicates near Oaken-Gates with the Shrewsbury canal; it has no large town near it. It commences in the Severn river at Coal-Port, (a new town established by the late excellent Mr. William Reynolds, whose rapidly increasing manufactories in the year 1800 employed 400 persons,) and terminates in the Donnington-Wood canal at Donnington-Wood. It has a branch from Southall Bank, which proceeds to Brierly Hill near Coalbrookdale (2½ miles), and thence is continued by an inclined plane and rail-
way below, to the Severn at Loads-Croft, near the Broseley iron bridge. There is also a short rain-way branch to Hor-
Hay iron works. At the Severn at Coal Port (formerly called Sheep-wash Meadow) there is a flood-lock, which rises sufficient to clear the highest floods in the river, parallel to which the canal proceeds on a level, ½ of a mile, to near Hay, where is an inclined plane of 350 yards long and 207 feet
feet perpendicular rise; thence to near Windmill Farm, 1/2 mile, is level canal, where is another inclined plane of 600 yards in length, and 126 feet perpendicular rise; thence to the Briery branch at Southall-Bank, 2/4 miles, is level canal; thence to the Shropshire canal, Oake-Woods, 1/2 mile, is level; thence to near Wrockwardine-Wood, 1/2 mile, is also level: at this place is a third inclined plane, of 320 yards in length and 220 feet perpendicular fall; thence to the Donnington-Wood canal, 100 yards, is level. The boats are shallow, and carry 5 tons. There are no locks on this canal, which is supplied with water by two small referrers which lie above the canal, and two others below its level, the water therefrom being pumped up by the beam engines belonging to the inclined planes; the waters which are lifted from the mines contribute also materially to the supply of the different lengths of canal. The three great inclined planes at Hay, Windmill, and Wrockwardine, have each a short inclined plane descending from their tops into the upper canals, upon which the boats, on a proper wheeled carriage, are dragged by the beam-engines, working the wheels, drums, and ropes, and are, by the alight of another boat, or the operation of a brake-wheel, let easily down the long plane, as has been particularly described already in this article. At Briery-Hill the cranes or iron baulks of lime-rock were drawn up, and the coals in boxes were let down through perpendicular shafts, 120 feet deep, by ropes winding on a drum above; but several years ago this plan was laid aside, and an inclined plane, similar to the three others above, except that it has no beam-engine, has been adopted, as before mentioned. Six boats have been passed down, and as many taken up, the Windmill plane of 600 yards long, in the course of 3 single hours; the beam-engine and 3 men only being employed. It is said that only 3d. is charged for letting down a loaded boat, and empty ones are returned gratis. Mr. William Reynolds and Mr. Henry Williams were the engineers; and the works were completed, and the canal opened in the year 1792; it is said to have cost only 47,500l. The rate of tonnage is 2d. per ton per mile on all goods. In the year 1797, the tolls produced a net profit of 6 per cent. on the capital.

SIRROWY RAILWAY.—Act 42 Geo. III. (for Monmouthshire canal).—The general direction of this railway or tram-road is nearly N.W., for about 28 miles, in the counties of Monmouth, and of Brecknock in South Wales: its northern end is much elevated: its object is the export of coals and iron from the rich mineral country through which it passes: at Court-by-bills farm, and at Rifa, it is joined by railway branches of the Monmouthshire canal. Newport is a considerable town near its southern extremity: it commences at the Uske river, near Pill-Gwenly (opposite the commencement of the Monmouthshire canal), and terminates at Trevil lime-rock quarries, in the parish of Llangumin; and it has a branch to Runney union iron works; the line passing through Sirrowy and Tredegar iron works, and through Tredegar park; it was laid also, that a branch of the railway was to be conducted from near Tredegar park to the meadows near the Severn river, where a new sea-port town, to be called New Amsterdam, was laid out and begun. This company were authorized to raise 45,000l., the amount of their shares being 100l., and they have engaged to pay 110l. annually to the Monmouthshire canal company, on condition of their constructing the first 9 miles of this tram-road nearest to Uske; sir Charles Morgan is to make a mile in length of the same through his park at Tredegar, and receive the tolls thereon; and, Meifrin Samuel Homfray, Richard Fotherghill, Matthew Monkhouse, William Thompson, William Forman, and other iron-masters, are also to contribute particular parts of this concern. It was provided, that if these several parties failed to execute their several parts of the line, previous to Michaelmas day 1803, that the sums for 9 as relates herein, should be void. A new turnpike road is made by the side of the railway for 21 miles: the ascent of the railway is so easy, that one horse can draw 10 tons down the line, and return with the empty trains. A new town was laid out and begun at Tredegar new iron works, near Shrewsbury.

SLEAFORD NAVIGATION. Act 32 Geo. III.—The general direction of this navigation is nearly W., for about 12 miles, in the county of Lincoln; it is but little elevated above the sea, the greater part of it being embanked on both sides through level tanks: its objects are the supply of Sleaford and the surrounding county with coals, deals, &c., and the export of farming produce. Tatterhall and Sleaford are considerable towns near this navigation. It commences in the old Witham river at Chapel-Hill (not far from the commencement of the Horncastle canal), and terminates at the castle-caulway near Sleaford. The locks are 60 feet long, and 15 feet wide in the clear; the width of the canal is 30 feet at top, 18 at bottom, and four feet deep, except the summit pound from Haverhill mill to Sleaford, which is to be 5 feet deep, to make a reserve of water, which is to be supplied from the tanks above the navigation in New Sleaford. This company was authorized to raise 25,000l., the amount of shares 100l. each. The tolls are various for different parts of the line. See Phillips's 440. History, Appendix, p. 26. Lime, marbles, and road-materials pay only half the rates of other articles. The profits of this concern are limited to 2 per cent. and after 100l. is accumulated as a fund for contingencies, the tolls are to be lowered. This company are to join with the Horncastle canal company, in the expense of improving the old Witham river between Lincoln high bridge and the Foss-dyke navigation at Brayford-Meer; in consequence of which only half the usual tolls on the old Witham are to be taken, or goods passing to or from these navigations.

SOMERSETSHIRE COAL CANAL. Acts 34, 36, and 42 Geo. III.—The general direction of this canal is nearly S.W., for about 10 miles, begins a principal branch of 7½ miles nearly parallel thereto, in the county of Somerset: its western ends are considerably elevated: its object is the export of coals from the mines near Mendip hills. Bath is the 12th British town, with a population of 32,000 persons, and Bradford the 7th, with 75,02 persons, which are the only large towns near this canal; which commences in the Kennet and Avon canal, at Monks-lane Coombe, and the main or Dunkerton line of canal terminates at Paulton, but a railway continues it forwards to Tynings; the Radflock line or branch of canal proceeds from the lat at Mitford mill, and terminates at Radflock town: but a railway continues it forwards to Welton colliery; there are also railway branches from this line to Radflock colliery, and to Smallcombe and Clifton collieries: from the main or Dunkerton line, there are railway branches to Mearns, Amelbury's, Britton's, Salisbury's, and Radflock collieries. From the Kennet and Avon canal to Mitford mill is level, thence the main or Dunkerton line rises.
The Cdnhls line runs about
the same height from Misford mill. The boats used are
72 feet long, and 7 feet wide. About July 1796, Mr. Robert
Wheeler began the erection of one of his diving or
cuflin locks at Coombe-Hay, for pafing the boats
through a perpendicular shaft, either in ascending or
descending. In November 1797, this apparatus was in suf-
cient forwardness for the caufen to be funk and raised again
in the shaft; and, in May 1798, a trial was made of this
contrivance, fo successful, that the inventor then offered to
undertake to pafs 1500 tons of goods in 12 hours through
this 45 feet rife or fall, without the loss of any considerable
quantity of water, and with the aflance of only one man.
besides the bargemen, to work the machinery. These fair
prospects were, however, blunted, by the bulging of the walls
of the shaft, as we have already mentioned, in describing
this contrivance; and inclined planes were constructed at
this place for letting down boxes full of coals, the decfent
of which, by means of ropes and wheels, drew up the boxes,
either empty, or in part loaded with other goods; the delay and expeance of this method being highly com-
plained of, about September 1802, a new infubcription
was fet on foot, and encouraged by the Kennet and Avon
and Wilts and Berks companies, for substituting locks, 22 of
which were completed, and opened on the 5th of April last
(1825). Mr. John Rennie, Mr. William Bennet, Mr. Charles
Wedge, and Mr. William Smith were the engineers consult-
ed or employed upon this company, which, in January 1801,
was completed from Dunkerton to several of the coal mines,
and which, (after 4 miles of land carriage,) had the efiet
of lowering coals at Bath from 14d. or 15d. per ewt. to 9d.
or 1Od. This company was authorized to raise 185,000l.,
the amount of shares 100l. each. Before undertaking any
of the rail-way branches to the collieries, this company might
require fecurity from the owners of such collieries, that
the tolls thereon should produce, or be made up, to a certain
rate of inereft on the coat of such branches. The profts
of this concern are not to exceed 10 per cent.; but after
1000l. is accumulated and placed in governinent fecurities, as
a fund for contingencies, the tolls on coals are to be lowered.
Husbandry and pleafure boats 12 feet long and 5 feet wide
may be paffed free on the pounds, or where the water
flows waft over the lock-weirs. A tunnel, 3 of a mile
long, was at firft paffed near Coombe-Hay, but by a fah-
quent alteration of the line this was avoided. The rates of
tonnage in the firft act may be seen in Philip's 4to.
Hilfury, App. p. 16; and 164, including, the tolls on horses,
cattle, sheep, &c. travelling on the rail-ways; by the laf-
tome of the tolls were increased. Dunkerton mill was
purchased by this company, and fleam-engines were erectioned
to pump up water for supplying the upper pounds. In se-
veral places this canal was cut through flrete defpofed to flip,
but by the small tunnels or foughs which Mr. William Smith
conftucted, for draining off the springs, the fame was
prevented. On the 3d of May, 1804, a sudden and great
flood happened, which required, it was said, some of the
banks of this canal to be cut in proper places, to give vent
to the water.

Southampton and Salisbury Canal. Acts 35 and
40 of Geo. III.—The general direftion of this canal
is nearly N.W. for about 17 miles, in two detached lengths, in
the counties of Hants and Wilts; it is not greatly elevated;
is objects are the trade between Southampton and Salibury,
the supply of thefe towns, and the eport of the furnifs
farming products of the intermediate country. This canal
commences in the Itchen river, at Northam near Southampton,
and proceeds along the N. E. shore of Southampton water
to the Alverbay canal at Red-bridge. In the Alverbay canal
(about 31 miles above Red-bridge), near Kimbridg mill,
this canal commences again, and proceeds to the Avon river
at Salisbury, or New Sarum. Southampton is the 63th
British town, with a population of 7,312 persons, and
Salisbury is the 70th, with 7,468 persons; Romsey is
also a confiderable town near this line. The eafier part
of this canal, between Northam and Red-bridge is level,
and but little elevated by its tide-locks, above the tide-way
in Itchen river and Southampton Water; from its flifting along
clofe to the shore of the latter river, it was that that facing
ftrahit Peter Pindar took occasion to burdlefque "Southam-
pton's wife fons." Upon this part of the canal there is a
tunnel of confiderable length clofe to, and indeed under part
of the north end of Salisbury town; confiderable difficulties
feem to have attended the making of this tunnel, owing to
the loofenefs of the foil; and the quick-fands at the foot of
the cliff, by the ifle of Southampton Water, have also proved
a very feros obstacle. An aqueduct is built over Shirley
Brook; springs within 1000 yards of the canal may be
taken for its fuiply, which is alfo to be aided by lame refer-
voirs, which were begun in 1796. This company have been
authorized to raife 96,000l., the amount of each share being
100l. Mr. John Rennie is the engineer; the eafier part
of the canal was begun in 1796, and was laid, in 1803, to
be nearly done, but it is not yet opened. The western part from
the Alverbay canal at Kimbridge was completed to Dene, in
October 1798. Stones are to be erected on the banks of this
canal, at every 3 of a mile distance.

Southampton Water. Acts 12 Henry VII. and 18
Henry VIII.—This noble efuary of the Anton and other
rivers has a N.W. direftion for about 10 miles in Hamp-
shire. The tide flows through its whole length, and through
a branch thereof more than 5 miles in length to near
Botley; Southampton water is navigable for large ships;
it commences in the channel between Hampshire and the
life of Wight at Calshot Canle, and terminates near
Red-bridge where it is joined by the Anton river (formerly
navigable near 6 miles to Romsey), and the Alverbay canal
near one of the terminations of the Southampton and Salis-
bury canal; near Salisbury it is joined by the Itchen river,
(about 2 of a mile from the commencement of the Southampton
and Salisbury canal). In the 4th of Geo. III., an act
passed for enlarging and improving the quay and harbour of
Southampton, by building a pier and other works which
commenced in December 1803, and have since been pro-
ceeding.

Staffordshire and Worcestershire Canal. Acts
6, 12, and 30, of Geo. III.—The general direftion of this
canal (sometimes called the Wolverhampton canal) is nearly
north for 464 miles in the countries of Worcefter and Staf-
ford; its middle part is very confiderably elevated, and it
croffes the grand-ridge without a tunnel; its trade in
the export of coals, pottery-wares, hard-wares, &c. is
immense, befoes the general trade between the Severn, the
Mersey, and Trent, which for a long time passed exclufively
through it. Near to Stourton, and to Stewponey, it is
joined by the Stewbridge canal, and at Alderley or Ather-
ley by the Old Birmingham canal. Wolverhampton is the
3rd British town with 12,565 inhabitants, and Kiddermin-
ster is the 95th with 6,110 persons; Bewdley, Stourbridge,
Penkridge, and Stafford, are also confiderable towns on or
near to this canal; which commences in the Severn river at
Stourport, and terminates in the Trent and Mersey canal at
part Haywood. From the Severn river at Stourport, to
the Stewbridge canal at Stewponey, 1 1-2 miles, is a rife of
1274 feet by 13 locks; thence to Tettenhall, the beginning of
of the summit-pound, 17 miles, is a rise of $166\frac{1}{2}$ feet by 18 locks; thence to the tidal Birmingham canal, 1/2 mile, is level; thence to Street-way, 83 miles, is level to the N. end of the summit-pound; thence to the Trent and Mersey canal at Haywood, 134 miles, is a fall of $100\frac{1}{2}$ feet by 13 locks. This canal is 30 feet wide at top, and 5 feet deep, through the depth of water on the lock-fills is only 4 feet. The locks are 74 feet long and 7 feet wide; and several of them are built of a red kind of free-stone; the boats in general carry 20 tons. At Stourport are two basins belonging to this canal connected with the Severn river by flood-locks to keep the water in them always at one certain height. On this canal are three short tunnels; one is near to Stewponey, the other at Whittington, and the other is an arrowed-way under part of the town of Kidderminster; at which place there is an aqueduct-bridge over the Stour river, another at Prestwood on Woldsey brook, another near Milford on the Sow river, and another at Haywood mill over the Trent river. In Chillingham is a large reservoir, and at Mofley another, whose waters are conveyed to the summit-pound by feeders of considerable length. This company may make branches to any place within 1000 yards of the line by consent of the land-owners. Mr. James Brindley was the engineer to this canal, which he began in September 1766, and finished in 1772. The first lock which this engineer erected was at Crompton, on this canal. This company were authorised to raise 100,000l., the amount of each share being 100l. In September last (1805), the yearly dividend on these was flatted to be 2d. The rates of tonnage are flat (in Mr. John Cary's excellent work with maps, now publishing in numbers, on Inland Navigation,) to be $12d$. per ton (24c. lb.) per mile on all kinds of articles except lime and lime-stone, which pay only $4d.$ per ton; and paving and road materials, and manures for adjoining lands which are to pass toll free on the pound, and through the locks when the water flows over the lock-waers. By the Dudley act (16 Geo. III.), coals brought from that canal and carried on this may be charged $2d.$ per ton per mile, but commissioners may authorise lowering this toll. The usual charge made by bargemen in 1796 for freight (including the company's tonnage) was, for perishable goods $24d.$ per ton per mile, and for heavy unperishable goods 2d. In 1802, a tunnel 5 feet in diameter and 135 feet long, composed of cylinders of calf-iron, was laid under the river Penk near this canal for draining a morass of 500 acres. In the last feftions (45 Geo. III.) application was made by this company for a new act, to raise the tolls in order to make new locks, the old ones in some places being decayed and nearly worn out, and for making some new rail-way branches. The Stour river between Stourport and Stourton, by the side of this canal, was made navigable several years ago, but the works thereon were soon after destroyed by a great flood. In the present month (November 1805), a rail-way branch from Latherford in Sharehill is projected, to Mr. Henry Vernon's collieries in Bultbury.

**Stainton and Keaby Canal.** Acts 33 and 38 of Geo. III. The general direction of this canal is nearly W.; for 15 miles in the counties of Lincoln and York, it has its course through level farms and is but little elevated above the level of the sea; its objects are the import of coals and export of agricultural produce, with a better drainage of the country through which it passes. Thorne is the only considerable town near this line; which commences in the Trent river at Keaby, and terminates in the Don river at Fifihlake near Stainton, having also a branch 1 mile in length which joins the Don river at Hangman-Hill in Thorne; the whole is on one level, having tide or flood-locks at its extremities to regulate its height notwithstanding the variable tides and floods in the adjoining rivers. A reversion of 5 acres is conferred on Thorne Common, and the waste water from this canal is to be discharged into the Trent. In 1762, when Mr. John Smeaton was consulted about the drainage of Pottick Car, a navigable canal through these fens was in contemplation. This company were authorised to raise 54,200l., the amount of shares being 100l. each.

**Stoke River.** The direction of this river (sometimes called the Winfon) is W. for about 83 miles in the county of Norfolk; it is embanked nearly its whole length through the fens, and is but very little above the sea; its objects are the import of coals, deals, &c. and the export of agricultural products. Downham is the only considerable town near it; it commences in the Great Ouse river between Denvers-fluce and Salters-Load, and terminates at Stoke-Ferry near the town of Stoke.

**Stort River.** The general direction of this river is almost N.E. by a bending course of about 13 miles between the counties of Essex and Hertford; its northern extremity is considerably elevated; its objects are the import of coals, deals, &c. and the export of farming products. Hoddleston and Bishopstortford are considerable towns near this river; which commences in the Lea river near Hoddleston, and terminates at Bishopstortford. In 1785, this navigation was proposed to be joined at its northern end by the Bishopstortford and Cambridge, and in 1789, it was intended to join the Bishopstortford and Wilton at the same place.

**Stour River (Chriftchurch.)** The direction of this river is nearly N.W. for about 35 miles in the counties of Hants and Dorset; its northern end is considerably elevated; its objects are the import of coals, deals, &c. and the export of farming products; Chriftchurch, Wimborn-Minster, Blandford-Forum, and Malmesbury-Newton, are considerable towns on this river; which commences in the tide-way in Chriftchurch-bay at Chriftchurch-harbour, and terminates at Stourminster. At Ames-crofs in Shillingbrook-Oxford, it is to be joined by the Dorset and Somerfruit canal. In 1762, Mr. John Smeaton was consulted on the intended improvements in Chriftchurch-harbour; the spring-tides in this harbour flow only 5 to 7 feet, and the neap-tides no more than 4 to 6 feet; and 3 hours after high water there is a second or smaller tide, which flows in the harbour from 8 to 18 inches, being greatest at the neap-tides. In the reign of Charles II., a pier of 256 yards in length, was constructed of lumps of iron-stone out of the loofe sandy-cliff near it, and Mr. Smeaton, in 1704, planned another pier to be built for the better security of this harbour.

**Stour River (Harwich.)** The general direction of this river is nearly W. by a bending course for about 29 miles between the counties of Essex and Suffox; the first 10 miles is a wide effuary through which the tide flows, the western end is not greatly elevated; its objects are the import of coals, deals, &c. and the export of farming products; Harwich, Manningtree, Neword, and Sudbury, are considerable towns on this river; which commences in the Sewmarket and Ipswich navigation (near its junction with the German Ocean) at Harwich, and terminates at Sudbury.

**Stour River (Sandwich.)** Act 7 Henry VII.—The general direction of this river is nearly W. by a crooked course of about 18 miles in the county of Kent, it is but little elevated above the sea in any part; its objects are the supply and trade of Canterbury, and the export of farming products. Canterbury is the 57th British town with a population of 9,000 persons, and Sandwich is the 93d with 6,556 persons. Ramsgate is also a considerable place near to this river; which commences in the English Channel or

Vol. VI.
Downs at Sandwich Haven (1½ mile from Ramsgate-harbour), and terminates at the city of Canterbury; the lower end of this river, for 1½ mile in Pegwell bay, has its course through shifting sands which are dry at low water, and covered at high water; it is therefore unsuited for large vessels to enter, and Ramsgate harbour is the only secure retreat for ships in case of a storm on this part of the coast. The celebrated piers which form this harbour were begun in 1749; the southern pier extends 800 feet eastward into the sea, it then returns northward, forming the front next the Downs, by a polygon of 5 sides, each 430 feet in length; these are joined at their angles by octagons of solid masonry that are 60 feet across; the breadth of the pier at top including the parapet is 26 feet, and the whole is built of hewn Portland and Purbeck stone. The entrance for ships is from the north nearly, and is 200 feet wide; having a light-house with Argand’s reflecting lamp on its west side, and this is connected with the shore by a small, though short pier, as on the southern side. The area of the famous harbour, thus formed in the open sea, is 46 acres, and it is deep enough to receive ships of 4 or 500 tons burthen. A spacious dry-dock for the repair of ships connects with this harbour. In a few years after the piers were completed, this harbour was nearly choked with mud deposited by the tides. Mr. John Sneaton, who was consulted, erected a cross-wall at the uppermost extremity of the harbour with numerous sluices therein, by the drawing of which, after the tide has retired and left this refuervor full of water, the mud has been since effectually cleared out; this excellent engineer also extended the pier 420 feet at the head. Nearly 300 ships have been known at once to assemble in this harbour for shelter on the approach of a storm. An act 5 Geo. III., passed for improving this harbour as above, and by 27 Geo. III. the tonnage charged on vessels passing the English Channel for the support of Rye-harbour, was transferred to this harbour as before mentioned. In the year 1834, the Canterbury and Nethersole canal was intended to join the Stour river at Canterbury; and in 1804, the Medway and Rother canal was proposed to join it near the same place.

Stour River (Stourbridge). Many years ago the Stour river from the Severn at Stour-port to the town of Stourbridge, (passing the town of Kidderminster,) about 14 miles, was made navigable by means of sluices, weirs, and other works; but soon after it happened so sudden and violent a flood as to destroy all these works. The Stafford and Worcester, and the Stourbridge canals, have since fulfilled more effectually the place of this river navigation.

Stourbridge Canal. Acts 16 and 22 of Geo. III. The general direction of this canal is nearly E. by a crooked course of about 5 miles in the county of Stafford; its eastern end is considerably elevated, and extends within about 3 miles of the grand-ridge on its eastern side; its objects are the export of coals, non-clay, &c. and forming part of the communication between the Old Birmingham and the Severn, &c. Stourbridge and Dudley are considerable towns near this line; which commences in the Staffordshire and Worcestershire canal near Stourton and Stourpenny, and terminates in the Dudley canal at Black-Delph; there is a branch of near 1 mile to the town of Stourbridge, and a branch of 2 miles to Penfnett-Chafe refuervor, with a side-branch thereto of near ½ of a mile in Brierly parish. From the Stafford and Worcs- easter canal to near Stewpenny, ½ of a mile, is a rife of 432 feet by 4 locks; thence to the Stourbridge branch, 2 miles, is level; thence to the Lays, ½ mile, has a rife of 148 feet by 16 locks; thence to the Dudley canal, ½ mile, is level; the Penfnett and Brierly branches are level with the last or summit-pound, and the Stourbridge branch is level. The width of this canal is 28 feet, and the depth of water 5 feet. The Penfnett-Chafe or Pen overthrow is 12 acres in extent, for supplying the head-level of this canal. This company were at first authorized to raise 50,000l. in 100l. shares; the last act authorized calling upon the subscribers for 7,500l. more, by which their shares are now increased to 10,128 each. The rates of tonnage will be found in Mr. John Cary’s Inland Navigation, pages 50 and 51. Goods may be navigated on the summit-level toll free; and road-materials and manures for adjoining lands, may also be carried on any of the ponds toll free. Less than 15 tons are not to pass any lock without concert. Side-branches may be made to the adjacent collieries. The Worcestershire and Birmingham company were bound (act 31 Geo. III.) to make up the profits of this concern to ½ per cent on per annum, in case of their canal not reaching the trade-accounts, but on the extention of the Dudley canal to join the Worcutter and Birmingham, the last mentioned company were exonerated therefrom, and the Dudley engaged (33 Geo. III.) to make up the annual dividend on the shares in this concern to 121 each; but not to exceed 31, and this when their own canal yielded a dividend of 5l. per share. The part of this canal below Stourbridge supplies the place of the river Stour navigation, which was directed by floods as above mentioned. In 1786, the Stourbridge and Worcester was proposed to join this canal at Stourbridge; as was also a branch since proposed from the Worcester and Birmingham. Stourbridge and Worcester. In 1786, a canal was proposed, and supported by the late lord Dudley and Ward, from the Severn river at Diglis below Worcester city to the Stourbridge canal at that place, palling Bromigrove; its proposed length was 26 miles with 772 feet of lockage, by 128 locks; some tunnels and other large works were neces- sary; a bill for this canal palled the commons, but was rejected by the house of lords.

Stowmarket and Ipswich Navigation. Acts 33 and 45 Geo. III.—The general direction of this canal is nearly N.W. for 6½ miles in the county of Devon; it is but little elevated; its objects are the import of coals, chiefly sea-fish and lime, as manures, and the export of potters’ clay (used in Staffordshire, Lancashire, &c.), and a peculiar kind of imperfect coal found in small quantities at Bovey-Tracey; Newton-Butt and Chudleigh are con- siderable towns near this canal, which commences in the tide-way in the Teign river at Newton Abbots, and terminates at Bovey-Tracey, with a branch of 2½ miles to the town of Chudleigh. From Newton-Abbots to Newton-Butt, 1 mile, is a rife of 20 feet; thence to Bovey, 5½ miles, is 30 feet rifle; the Chudleigh brand is level. James Templar, Esq., is the sole proprietor of this canal, and Mr. Gray was his engineer. At Teigngrace, and the adjoining parishes, the surplus water of this canal has been applied to the irrigating of the lands below it, a capital improvement, which we are very anxious to see more generally adopted. Stowmarket and Bury Railway. In December, 1802, it was in contemplation to make a rail-way from the Stowmarket and Ipswich navigation at Stowmarket, to the Lark river at Bury St. Edmonds, for the purpose of supplying the latter place, and the intermediate country with coals; (the Lark navigation being often interrupted by droughts in the autumn;) and for the reader export of farming. Stowmarket and Ipswich Navigation. Acts 33 and 45 Geo. III.—The general direction of this navigation (which follows the course of the Orwell river) is nearly N.W. for about 26 miles, in the county of Suffolk, the first 13 miles, to near Ipswich, being a wide channel or estuary, in the tide-way, the remainder is not greatly elevated; its objects are the import of coals, deals, &c. and the export of farming.
farming products; it is joined by the Stear river near Harwich. Ipswich is the 4th British town, with a population of 13,327 persons. Harwich, Needham, and Stowmarket are also considerable towns near this navigation; which commences in the German ocean at Landguard fort, and terminates at the town of Stowmarket. This company were, by an act prior to the above, authorized to raise 150,000l. more than already raised; the last act was for improving the port of Ipswich by deepening the same, so that ships might unload at the wharfs, &c. In December, 1802, it was proposed that the Stowmarket and Bury railway should join this navigation at Stowmarket.

**Stowmarket Canal.** Acts 32, 37, and 39 Geo. III.—The general direction of this canal is nearly N. for 2.1 miles, in the counties of Warwick and Worcesters; it is very considerably elevated, and crosses the grand ridge; its objects are the export of coal, lime, and paving-stones; and as a link in the great chain of canal communication; at Kingwood in Rowington a branch of this canal connects with the Warwick and Birmingham; Stratford upon Avon and Henley are considerable towns on or near this canal, which commences in or near the Avon river at Stratford, and terminates in the Worchester and Birmingham canal at King’s Norton, about 6 miles from Birmingham. From near Hockley there is a branch of 2.4 miles long to Tanworth quarries; from near Lapworth there is another branch of 1.5 miles to the Worchester and Birmingham canal; and from near Wilmcote is a branch of 4 miles to Temple-Grafton lime-works; with a branch of about 1 mile from this cut to Alston-Cantelow. From Stratford to near Copnas-hill, 1.2 mile, is level; thence to Wilmcote, 1 mile, is a rise of 86 feet; thence to Pretonmill, 6 miles, is level; thence to Preton-green, 1.3 mile, is a rise of 76 feet; thence to Lapworth-hall, 1 mile, is level; thence to Hockley Heath, 2.5 miles, is a rise of 147 feet; and thence to the Worchester and Birmingham canal, 10 miles, is level; the Tanworth branch is level, and connects with the summit-pound; the Temple-Grafton cut is level for the first 2.4 miles, and in the next 1.5 mile the rise is 200 feet. Near Milepole hill is a tunnel of 320 yards in length; there are several small aqueduct bridges; and some deep-cutting near Waring’s Green. In May 1766 the summit-level of this canal from the Worchester and Birmingham canal to Hockley-heath was completed and opened. This company was authorized to raise 250,000l. the amount of shares 100l. The rates of tonnage and exemptions are very long; see Phillips’s 410. History, Appendix, p. 111 and 112. At the junction with the Worchester and Birmingham canal; this canal and the Worchester and Birmingham canal cut-off bridges are to be erected, to be shut and locked by either company, when the supplies of the other canal fail in dry seasons; with the Dudley and Worchester and Birmingham canals there are a number of regulations as to tonnage, in the second act above (37 Geo. III.). About the year 1792 the Strapford and Groperley canal was proposed to join this at Stratford.

**Strapford and Groperley.** About the year 1792 a canal was proposed to connect with the Avon river and Strapford canal at Stratford, and proceed to the Oxford canal at Groperley, by a course of about 31 miles in length; this being the southern part of the proposed line between Dudley and Groperley; the northern part thereof being since occupied by the Strapford and the Dudley canals.

**Strowwater Canal.** Acts 34 Geo. II. 15 Geo. III. 23 (for Thanes and Severn, and 33 and 37 Geo. III. (for Gloucester and Berkeley).—The general direction of this canal is about E. for 8 miles, (following nearly the course of Strowwater river,) in the county of Gloucester; it is not greatly elevated; its objects are the import of coals, and forming part of the first direct communication between the Seven and Thames and Isis rivers; at Wheatshead, the Gloucester and Berkeley canal crosses and connects herewith. Strond is the 114th British town, with a population of 5427 persons. This canal commences in the Severn river at Flameham, and terminates in the Thames and Severn canal at Wallbridge near Strond; from the Severn to the Thames and Severn, there being a rise of 10 feet; this canal is wide enough for the Severn river boats. The engineers were Mr. Thomas Yorston and Mr. Robert Whitworth. The first of the above acts was for powers to raise 200,000l. in 200l. shares, intending to execute the works under the powers of an act of 3 Geo. II. for improving the Strond canal. However, but several expensive lawsuits put a stop to the works, as we have already mentioned, until the second act was obtained; a double lock of 14 feet rise on this canal had a slipping bank of earth 10 feet high by its side, and gave immediate trouble, to prevent the walls thereof being bulged in, this was at last accomplished by the turning of two dry drains of four feet diameter, between the lock and the bank. In 1802 the dividends on shares in this concern were 6l. each, and their price was about 135l. This canal has no horiz towing-path, but slips are erected thereon, and the barges are hauled by men. Where this canal crosses the Gloucester and Berkeley, lock-gates are to be erected to prevent this canal from losing its water; no dues are to be taken for vessels crossing either of these canals. If, while the Gloucester and Berkeley is cutting, the navigation of this canal is interrupted, five guineas per day are to be paid to this company; vessels passing to or from the Berkeley and Gloucester canal and this, are to pay the same tonnage as to and from the Severn at Flamham. This company are authorized to take 25, 37. per ton for coals which pass through this canal, and on the Thames and Severn canals, but not beyond Binfcomb bridge thereon, and for such coals as pass eallway of Binfcomb bridge, 18. per ton.

**Strawwater River.** The act of 2 Geo. II. passed for making this river navigable between the Severn and the town of Strond, a distance of about 8 miles, as above; but the opposition of the millers and others prevented its being accomplished, until 34 Geo. II. when Mr. Bridge undertook to construct the navigation, without waifs of water or prejudice to the mills, by means of canals to hoist the goods in boxes out of the boats in one pound, and place them in others in the adjoining pounds, as we have before described; but this scheme miscarried, and the projectors were nearly ruined; at length the Strawwater canal was constructed by the side of this river as above.

**Surrey Iron Railway, (Northern part.)** Acts 41 and 45 Geo. III.—This, the first public railway constructed near the metropolis, has about a S.E. direction, for 10 miles, in the county of Surrey: its southern end has a considerable elevation: its objects are the import of coals and manures, and the export of chalk, flint, fire-clay, fullers-earth, and agricultural products. Croydon is the 188th British town, with a population of 573 persons; Wallsworth is also a considerable town on this line; which commences near the tidal-river of the river Thames at Wandelworth, and terminates at the turnpike house S. of Croydon, in the southern part of the Surrey iron-rail-way; at the N.W. extremity of Croydon the line of this rail way is but about 5 miles from the Croydon canal; from Mitcham common a branch goes off for about 1.5 miles to Mr. Shipley’s skinning mill at Carhallow; and, to Meffra. Were and Barfo’s oil-mill, about 4 miles, there is another branch at Garrant-lane. This rail-way has nowhere a greater ascent than about 1 inch in 10 feet; it is double throughout, with numerous crossing places for the carriage out of one road or track into the other,
other; of these we have already given a particular account, as alfo of the contrivances for diflounging the contents of the rail-
way waggons, on fome occasions, into barges lying in the en-
trance bafon at Wandsworth, which is about 4 ft. of mile long,
with a lock next the Thames, and is spacious enough to hold
30 barges or more at once, feveral of which can be along the
wharf to load or unload at the fame time. The width of each
track is about 4 ft. 6 in., the waggons carry about 34 tons each,
and feveral of them are often linked together to be drawn by
one horse. This rail-way crofles the Wandle river twice on
wooden bridges. On the 9th of January, 1802, the entrance
bafon at Wandsworth was opened and opened; in October
of the fame year, the rail-way from the fide thereof crofing
the turnpike road, and extending to Garratt was completed,
and in the courfe of the prefent year it was opened to Croy-
don. The company were, by the firft act, to
raife 50,000l. and a further sum, by the act of the late
fessions, the amount of 100l. Few fubjefts have been
more variably flated than the cofl per mile of this rail-way.
Mr. John Phillips, after noticing in his History the com-
 mencement of this work, adds, that iron rail-ways are made
at an expense of about 300l. per mile. The original estimate
was, we believe, 200l. per mile; at a public meeting at
Gosport, in September 1803, it was flated by fome favour-
ers of the extension of a canal from Croydon to Portsmouth,
that the expenditure on this rail-way had amounted to 64,000l.
per mile; but the advocates for extending this rail-way to
Portsmouth instead of a canal, then contended that the ex-
 pense did not exceed 4,500l. per mile; while Mr. James
Malcolm, in his Agricultural Report on Surrey, juft pub-
lished, after flating the great pains he had been at to come
at the facts, fays, "inland, therefore, of the expense being
200l. per mile, it appears as if it would be 700l.!!" (this
includes all the expenditure of the company). The rates
of tonnage are from 2d. to 6d. per ton, per mile, for dif-
ferent goods; and owners of adjoining lands may use the
rail-way for a drift road. Ten pounds annually are to be paid
to the city of London by this company, for connecting with
the river Thames.

SURREY IRON RAIL-WAY (Southern part). Act 43
Geo. III.—The general direction of this line of rail-way is
nearly S. by a bending course of about 16 miles, in the
county of Surrey; upon the chalk-hills or North Downs,
it is greatly elevated; its objects are the import of coals and
manures, and the export of chalk, lime, fire-flone, free-
flone, flints, fullers'-earth, and agricultural products. Croy-
don is the 10th British town, with a population of 5,743
persons; Ryegate and Godflone are also conderable towns
on or near this line, which commences in the northern part
of the Surrey iron rail-way at Croydon turnpike, near the
fouthern end of that town, and terminates at Godflone,
paffing near to the towns of Mertham and Ryegate in its
courfe. It has a rife or fall of 1 inch in 10 feet, in crofing
the Downs; near to Mertham is a conderable length of
cutting 30 feet deep in fome places, in order to obtain the
proper defcent; at Smitham-bottom is 130 feet high, across a
valley, for the fame purpofe, with a road-arch under it; it
crofles the Croydon and Mertham road in another place by an
arch, and the road is funk conderably in order that the rail-way with its proper
defcent may pass over it. The width of this double rail-way,
including a path on each fide for the carriage drivers is 24
feet. Some of the waggons hereon have their fore-wheels
placed quite forward, and the hind-wheels nearly under the
middle of the waggons, by which means flones, &c. can
easily be shot out of them when required. Near to this
rail-way at Mertham there is a quary of white soft fre-
flone (much similar to the Tottenhoe flone on the Grand-
Junction summitt branch). The fhares in this concern are 100l.
each. In September, 1801, it was in contemplation to make
a branch of this intended rail-way from near Ryegate to the
Arun river at Wilborough green; and another branch or
rather an extension hereof, from near Godflone to the
Oufe upper navigation at Linfield. About the month of
June aft (1802), this rail-way between Croydon and Mer-
tham was opened, and 12 waggons loaded with flone, weighing
32 tons, were drawn with cafe by one horse for 6 miles
down the defect to Croydon-turnpike, in 1 hour and 41
minutes; from which place the fame horse fet off again with
4 other loaded waggons attached, and perons riding on them,
making in the whole more than 55 tons, which it was said
he drew with apparent cafe!

SWANSEA CANAL. Act 34 Geo. III.—The direction of this
canal is about N.N.E. for about 35 miles, by a crooked courfe in
the North Riding of Yorkshire. Its northern end is very con-
derable elevated, and this river is subject to rapid and al-
most uncontrollable floods: its objects are the carriage of
coals, and the export of farming products. Aldborough and
Richmond are conderable towns near, or on this river,
which commences in the Tore river at Myton; and the
navigation was intended to terminate at Richmond. In 1767,
Mr. John Smeeon was consulted on the propriety of moving
Topcliff mill to a new feite, in the design which the pro-
pietors of this navigation had adopted of building new mills
in several places, and on which it has been faid that 30,000l.
was expended, and but a small part of the above line was ren-
dered effectedly navigable. Mr. John Smith jun. was the
ficient engineer. In 1801, the Topcliff and Pierbridge was
propofed to join at Topcliff.

SOUTHSEA CANAL. Act 34 Geo. III.—The direction of this
canal is about N.N.E. for about 13/4 miles in the counties of
Gloufcer and Brecknock, in South Wales. Its northern
end is conderable elevated; its objects are the export of
coals and iron-flone, iron, &c. the carriage of lime to the
intermediate works and country; and copper-ore, to the
works, &c. Swansea is the 99th British town, with 6,099
inhabitants. This canal commences in Swansea harbour,
in South Bay, at the mouth of the Tafe river, and
terminates at Hen-noyadd lime-works: a part of this line
between Llandoor brook and Morris town, 1/4 mile in
length, (called Morris's canal) through the eflate of the
duke of Beaufort, was conctrufed by that nobleman, who
receives the tolls thereof. From near Swansea to Llanfamlet
is a branch of 3 miles in length; and a rail-way branch of
about 2 miles to a large coal mine, where an audit or tunnel
of 3 miles in length has been made under ground, and out of
which 200 tons of coals are daily brought; on an incl-
ined-plane on this branch, near 1 mile in length, the coal-
waggons defcend without horses, regulated by a convoy or
brake, as we have before defcribed, and the empty wag-
nons are drawn up the plane again by horses. From the
tide-way at Swansea to oppofite Pont-ar-Taw, 82 miles, is
a rife of 1,200 feet; or, fince to Pont Gwynawladd, 8 miles,
is a rife of 320 feet; and thence 2 of a mile to Hen-noyadd
is a rife of 31 feet. An act 44 Geo. III. pafl for amending
two former ones, for building piers, and deepening and
improving the harbour of Swansea, under the direction of
captain Joseph Huddart. About the year 1797 the weftern
pier, extending 228 yards into the fea, was completed;
which had the effect of confining the current of the Tafe
river, and deepening the mouth of the harbour 2 feet: in
1802 this pier was extended 57 yards farther out, and in
November 1804 a jetty thereto was completed. In April
aft (1805) a new pier was begun on the eftern fide of the
harbour,
harbour, which is to be extended out and brought round wellwardly, within 70 yards of the other pier, for effectually securing and securing the mouth of the harbour: dry and wet docks are also intended, and by embanking the river, a mill spacious quay is to be formed. From this port, in 1768, only 5,474 ships were loaded; but in 1792, they were increased to 10,000 ships, and in 1803 to no les than 25,900 of 1,734,764 registered tons. Within 2 miles of Swansea, seven large copper-works have of late years been created, for smelting of roasted ore from the Cornish and Anglesea mines, brought in ships, which return laden with coals for working the mine-engines and roasting the ore: the number of iron-furnaces, potteries, and other large works near this place are also considerable. This canal company was authorized to raise 90,000l., the amount of shares paid each; and it was provided in the act, that this canal should be completed in 4 years; several railway branches may be made thereto. The engineer was Mr. Thomas Sheaflys, and the canal was completed and opened in October 1798. The rates of tollage may be seen in Phillips’s 4to. Hillys, Appen. pages 166 and 167. Boats with less than 15 tons, when the water does, and 10 when it does not flow over the lock-weirs, are not to pay or paying for that tollage. In the year 1804, 53,235 tons of coal and culver were brought down this canal for exportation, and the gross tonnage on this canal amounted to 35,90l. In Swansea harbour, the Swansea and Oystermouth railway connects with this canal.

Swansea and Oystermouth Rail-way. Act 44 Geo. III.—The general direction of this railway is nearly S.W. by a bending course, following closely the sea thore, for about 73 miles in length in the county of Glamorgan, in South Wales: its object is the carrying of lime-flour, lime, and coals. Swansea is the 99th British town, with 6,696 inhabitants. This railway connects with the Swansea canal in Swansea harbour, and proceeds thence to the Mumbles lime-flour quarries near Oystermouth. In April last (1805) this railway was nearly completed. There is a light-house on the Mumbles point for the security of ships entering Swansea harbour, which was lately improved.

Tamar Manure Navigation. Act 36 Geo. III.—The general direction of this canal is nearly N.W. for about 22 miles, following the course of the Tamar river, on the southern coast of the counties of Devon and Cornwall. Its northern end is considerately elevated: its objects are the import of coals, and sea-fand and lime as manures; and the export of agricultural products. Launceston is the only considerable town on this line; which commences in the tide-way in the Tamar river at Morwellham quay (the commencement of the Tavistock canal) near Callstock, and terminates at Tamarton bridge in North Tamarton, with a branch to Rich-mill grove in Launceston. The Tamar is to be made navigable as far as Port-pool near Blanch-Down, before the canal commences. The locks are to be either about 5 feet or 9½ feet wide, and 124, 244, or 364 feet long, in order to receive a number of small boats, in length and wide by fde therein, as may be judged best. Inclined planes and railway may be substituted in place of locks on the canal in any part. This company is authorized to raise 121,000l., the amount of each share 50l. A feeder may be taken from the Tamar river, and all springs within 2000 yards of the head level, and within 1000 yards of every other part of the line; 200l. per annum is to be paid by this company to the duchy of Cornwall, for the liberty of making this navigation. We have not been able to learn what progress has yet been made in the cutting of this canal. By the act 14 Geo. III., a canal was intended, but never executed, through this line, and extending to the Irish Channel, called the Bude and Launceston canal.

Tamar River. The general direction of this river is nearly north by a crooked course of about 6 miles, between the counties of Devon and Cornwall; the tide flows through the entire length; Beer-Alston is a considerable town near this navigation; which is the point of the import of coal, flax, aud the export of flax and agricultural products. It commences in Hampshire and terminates in the Tamar Manure navigation and Tavistock canal, at Morwellham quay near Callstock. In the year 1754, an act passed for the Bude and Launceston canal intended to connect with this at Callstock, but it was never carried into execution.

Tarkab Canal. In 1753, Mr. Watt surveyed the isthmus between East and West Tarkab holes, on the west coast of Scotland, for a canal to communicate between Loch Fine and the sound of Jura; the distance of high-water mark in the two lochs he found to be 1 mile, and the height of the ridge between them, 45 feet above high-water at neap tides. Mr. Watt’s different estimates were, for a canal with locks 7 feet deep, 175,888l.; and for one to 10 feet deep and a proportional width, 23,884l. The expenses of a thorough cut without locks, of 12 feet deep at high-water, 73,849l., and for one of 15 feet deep, 120,780l. A very large canal has since been formed about 13 miles north of this, called the Cromer canal, which more effectually answers the purpose of communication between Loch Fine and the sound of Jura.

Tavistock Canal. Act 43 Geo. III.—The general direction of this canal is N.E. for about 44½ miles in the county of Devon; a great part of it is considerately elevated above the level of the sea: its objects are the export of flax, copper-ore, and other minerals, and of agricultural products; the import of coals, lime, and other articles for the supply of Tavistock town and the surrounding country; and to facilitate the working of the mines in Morwellham down: this canal commences in the tide-way in Tamar river (near the commencement of the Tamar Manure navigation) at Morwellham quay new basin, near Callstock, and terminates at the town of Tavistock. From Crebar near the north end of the tunnel, it has a branch of 2 miles to the flate quarries at Mill-hill bridge. From the Tamar river, 4 of a mile is level with high-water at Morwellham quay; thence in ¾ of a mile, is a rife of 237 feet; thence, about 3½ miles to Tavistock is level; the branch is level to New Quarry, about 1½ miles; thence to Mill-hill bridge, ¾ of a mile, is a rife of 10½ feet. The locks upon this canal are to be calculated in length and width for the use of boats of 124 feet long, and 5 feet wide, either finely or several together, as on the Tamar Manure navigation above mentioned: but the company have the power to erect inclined planes for boats, or boxes of goods, instead of locks, if they think fit. Through Morwellham down, which is of hard rock, and supposed to be intersected by several fissures, or loads filled with metallic ores, is to be a tunnel about 2500 yards long, and about 460 feet beneath the highest point of the down in its course: near Crebar is to be an embankment and aqueduct bridge 60 feet high, across the Lumbourn river; which is to have a new course cut for it for a considerable distance near the branch of this canal below New Quarry. This canal is to be fed from the Tavy river at Tavistock, and by any springs or fountains within 5000 yards of the line. Mr. John Taylor is the engineer to this canal and tunnel, which paffis entirely through the etate of the duke of Bedford, who has leade to this company the mines which may be found in the tunnelling, or within certain distances of this canal. In February last (1805)
(1803) about 300 yards in length of the tunnel had been cut, and a known load of copper-ore had been intercalated therein, which gave the bell hopes of discovering other unknown ores, as the work proceeds. This company is authorized to raise 50,000l., and the amount of each share is 50l. The rates of tollage are for lime-flour conveyed through the tunnel, 1s. 3d. per ton; for building-stone, flates, bricks, tiles, clay, sand, earth, dung, ores, iron, and metals (made marketable) conveyed through the tunnel, 2s. per ton; and for coal, coke, culm, lime, timber, bark, corn, grain, and all other goods passing through the tunnel, 1s. per ton; and coals, coke, &c., 1s. 6d. per ton. The last rates are not to be charged on any goods either carried or subsequently removed on any part of this canal, which have before paid the tunnel rates; and ores may be carried to the draffing-floors, or the wattle or rubbish of mines or loads be removed to proper places on any part of this canal or its branches, free of tolls. Besides the above rates, all goods which pass into, or from the Tammar river, and are not loaded at Morwellham quay, are to pay as follows for reimbursing the owner and occupiers thereof, for the loss of wharfage on such goods, viz. slate 3d. per ton, lime-flour 6d. per ton; ores, (made marketable) iron, bricks, tiles, clay, sand, earth, and dung, 6d.; and all other goods 1s. per ton; and over and above this, one penny per ton is to be paid on all goods entering the canal basin at Morwellham. The duke of Bedford may make collateral branches or rail-ways to this canal in any part.

**Tay River.** The general direction of this river is N. E. for about 24½ miles in the county of Devon; the tide from the south coast flows through its whole length: its objects are the import of coals, sea-fand, &c. and the export of flate, copra-ore, &c. It commences in Hamaaze and terminates at Lophill quay.

**Taw River.** The direction of this river, or eurya, is nearly east for about 8 miles on the north-west coast of Devonshire: the tide flows through its whole length: its objects are the supply of Barnapple and the adjacent country with coals and other articles, and the export of farming products. This navigation commences in St. George's Channel, at Biddiford bay, and terminates at the town of Barnapple: near to Appledore the Torridge river joins this navigation.

**Taw River.** The general direction of this river, eur, or eurya, is nearly east for about 26 miles, between Angus and Fife, and in the county of Perth in Scotland. The tide flows through its whole length: its objects are the supply and trade of Dundee and Perth, and the adjacent country. Dundee is the 18th British town, with 26,038 persons, and Perth the 26th, with 14,878 persons. This river commences in the German Ocean, and terminates at Perth Bridge. This bridge, built of stone by Mr. John Mylne, was swept away by a rapid flood in 1621. In 1763, Mr. John Sinnot was consulted on the building of a new bridge; and in 1766 he began one of 7 arches, where the river was 892 feet wide: the depth of the Tay at this bridge is 20 feet; and in dry seasons was only 2 feet, at spring tides 10 feet deep. At Staley, 7 or 8 miles higher up this river, three loughs or tunnels of considerable length (one of them from 12 to 9 feet wide arched with stone) are driven through the hill, which occasions a great loop in the river, by which 24 to 20 feet fall is gained, for a large portion of the stream, to work cotton-mills and other machinery; and running in this subterraneous channel it never freezes.

**The River.** The general direction of this river is nearly S. E. by a crooked course of about 12 miles, between the counties of York and Durham: the first four miles are by a very wide eurya: the tide flows through its whole length: its objects are the trade of Stockton, and the export of agricultural products. Stockton is a considerable town on this river: which commences in the German ocean, at Season Nook, and extends to the town of Stockton. In the present autumn there was an intention of improving this navigation. In 1780, the foundations were laid for an iron-bridge, to be erected under the direction of Mr. Thomas Wilson, over this river at Yarm, a few miles above Stockton, in place of an old stone bridge, which had long obstructed the current, and occasioned the river frequently to overflow its banks. In 1768, the Winstanley and Stockton canal was proposed for extending this navigation westward to the coal district about Winstanley.

**Teign River.** The direction of this river, or eurya, is west for about 4½ miles in the south-eastern coast of Devonshire: the tide flows through its whole length: its objects are the import of Newcastle or Welsh coals, and the export of potters' clay, boxey coal, and agricultural products: it commences in the English Channel, and terminates at Newton-Abbots, at the commencement of the Severn canal, near to Newton-Bullock.

**Ternbridge and Winford.** In 1763, Mr. Whittington proposed a canal from the Severn river at Ternbridge below Shrewsbury, to the Wexor navigation at Winsford, 63½ miles, in the counties of Salop, Stafford, and Chelten, with a branch therefrom, near Bridgewater; 43 miles, to the Trent river at Wilkes-Ferry. At St. Severn to the summit or grand-ridge (requiring 25 feet deep cutting,) below Ofley-Park, 24 miles, is a rise of 176 feet; thence to the Trent branch, (½ mile below Bridgewater,) 7½ miles, is a fall of 54 feet; thence to the summit or grand-ridge again, (requiring 25 feet deep cutting,) in Madeley park, 104 miles, is a rise of 800½ feet; thence to the Wexor navigation, 22½ miles, is a fall of 28½ feet; the branch from Bridgewater to the Trent has a fall of 209½ feet. The course of this canal is by Wansford, Alfort, Crudgington, Chetwin-park, Batchere-Grange, Ecclehall, Standon, Wyburnhur, and Batton, near Nantwich. The branch is conducted by Stafford, Tixall, and thence following within a small distance the course of the Trent river. This canal was proposed to be 27 feet wide at top, 15 at bottom, and 5 feet deep, with a towing path on both sides; the locks 60 feet long and 13 wide, and about 10 feet deep each; the boats of 50 tons burthen: 78 road bridges, and 25 accommodation bridges were thought necessary, and 184 aqueducts and culverts: the estimated expense was 99,500l. The Stafford-shire and Worcestershire and the Trent and Mersey canals, which were adopted in the following year, embrace all the general objects of this canal. The Sandbach, and the Newport and Stone, have since been proposed to occupy parts of the southern end of this line, but, like this, were overruled.

**Thames River, (lower part).** Acts 19, 29, 39, 42, 43, 44, and 45 of Geo. III.—This fine river, by far the most important for trade, not only in Britain but in the whole world, has its career nearly west for about 72 miles between the counties of Kent and Essex, and Surrey and Middlesex. The first 20 miles is by an exceedingly wide eurya: the next 21 miles is full an eurya of considerable width; the remaining 31 miles is crooked, and gradually diminishing: the tide flows very powerfully through its whole length. To enumerate its objects would be to recount almost every species of trade and commerce which is carried on in Europe.
Europe. At Earl Mersey it connects with the Colne river; at Weil Mersey, with Blackwater river; at Foulness east point, with Creoch river; at Whitstable and at Sheerness, with the Medway river; at Gravelend, with the Thames and Medway canal; opposite to Purfleet, with the Darent river, or Dartford creek; at Bow-Creek, with the Lea river; at Blackwall and at Limehouse-hole, with the Isle of Dogs canal, (a new side-cut for shortening the navigation of this river;) at Greenwich-dock, and at Wilkinson's gun wharf, Rochesterhite, with the Grand Surrey canal; and, at Limehouse, with the Limehouse canal. London, the first British town, has a population of 864,945 persons; Greenwich is the 4th; with 14,379 persons; and Woolwich is the 23d, with 9,826 persons. Margate, Feversham, Milton, Queensborough, Sheerness, Leigh, Gravesend, Graves-Thurrock, and Deptford, are also considerable towns on or near this lower part of the Thames river; which commences in the English channel at Earl Nefs near Margate, and terminates in the Thames, middle port, at London-bridge. Large ships of war can come up to Deptford, and merchants' ships of 7 to 800 tons burthen frequently lie at the keys close to London-bridge. The port of London, or part wherein the ships lie, generally called the pool, extends almost 4 miles, nearly to Deptford, in which space more than 1000 vessels have been seen moored at one time! the rapidly increasing trade of this great emporium of commerce, the regulations which have of late been made, for mooring the ships at more convenient distances, for a passage up and down the river, and the contiguity of the East India and East India docks to Blackwall are expected ere long, to extend the tiers of ships as far as that place. It was stated, in the year 1800, that the trade of the port of London had increased in the last, or 18th century, by 6,547 vessels and 1,327,763 tons annually; and that (including repeated voyages,) 13,143 ships and vessels were then employed in this trade, to foreign countries, the colonies, and coal-ships, besides 2288 lighters, barges, and punts, employed in the middle part of the Thames, and on the Lea river, and 3336 of the like kinds of vessels used below bridge, in the lading and discharging of vessels, together with 83 boats, ferries, cutters, and hoy, 3000 watermen's whaleries, 155 baw-bows, and 154 pilot-boats, the total number, (exclusive of ships of war, transports, and navy and victualling and ordnance boats,) being 22,500 vessels of various sizes and dimensions, either trading to, or stationed within the pool or port of London; the total value of the goods imported and exported annually by them exceeding 67,000,000l. The corporation of the city of London, as conservators of the river Thames, and under the special authority of the above acts, are, at this time, carrying on considerable works for the improvement of this river; several mooring chains in the pool have been purchased of Lord Gjydir and others, and a harbour-master, approved by the Trinity-house, is appointed to regulate the mooring and conduct of vessels, agreeable to the 19, 29, and 39 of Geo. III. : one of the largest canals ever attempted has been cut, near 14 miles in length, 112 feet wide at top, and 34 feet deep, across the Isle of Dogs, for shortening the passage of vessels to and from the pool, and to avoid the long circuit by Greenwich and Deptford; Mr. William Jeffery is the engineer, under whom the locks and other works of this canal were successfully conducted and nearly finished, when an unforeseen accident, by the blowing up of the coffer and preventer dams, just as the entrance locks were completed, on the 24th of July last. (1805) prevented this canal from being opened until the 9th of December, when the Dukes of York, Well Indianam, of 500 tons burthen, passed through the same, in presence of the lord mayor and corporation of London. Several large sums of public money have been granted by the above acts out of the consolidated fund; for the repayment of which vessels passing through this canal of 200 tons or upwards are to pay 2d. per ton; those from 100 to 200 tons, 2d. per ton; from 100 to 50 tons, 1d. per ton; 50 to 20 tons, 8d. each, and boats and craft 6d. each. Two or more piers are intended to be built at the entrance, for facilitating the entrance of vessels to this canal. Between this canal and the entrance of the East India docks, there is a large mass of silicious pudding-stone, consisting of clay, shelly particles imbedded in a very hard cement, which lies in the bed of the river, and has proved fatal to several ships, on which account the committee, in September 1792, and on several other occasions, advertised for persons who would undertake to lower this rock 18 feet, its length being about 40, and breadth 30 feet; the newspaper accounts of the Boddington Well Indians having struck on this rock on the 14th of September last appear to be incorrect; the rock being now surounded by pikes and buoms, so that no ship can approach it. In the year 1773, Mr. James Sharp suggested the propriety of floating, or wet-docks, for the loading and unloading of ships in the Isle of Dogs; after much discussion a plan was adopted for this purpose, in the year 1799, called the West India Docks, and Mr. William Jeffery and Mr. Ralph Walter were employed as engineers. On the 12th of July 1800, the first stone of this great undertaking was laid with much ceremony. On the 22d July 1802, an unfortunate accident occurred by the bursting of the coffer-dam at the entrance at Blackwall, but which did not prevent the great or import dock, from being opened for the use of West-India ships on the 31st of September 1802. This fine dock, the largest in Britain, is 2600 feet long, 510 feet wide, covering more than 50 acres of ground; its depth being 29 feet, and it is walled in the most substantial manner, with bricks, and coped with immense blocks of stone. Three flacks of the superb warehouses on the banks of this dock were completed at this time; on the 22d of August 1803, several other warehouses on the N. side of the dock were finished, and declared ready for public use; and, on 5th July last, two warehouses on the south side, and the whole of that quay were completed. The outward-bound dock, 2600 feet long, 400 feet wide, and 29 feet deep, has been rapidly proceeding since the completion of the great dock, and is now almost ready, we believe, for opening. At Blackwall, and at Limehouse-hole, there are spacious entrance basons, connecting by tide-locks with the Thames river; from these entrance basons there are locks into the outward and inward, or export and import docks; these docks are calculated for the accommodation of 300 ships, 12 of which can conveniently enter or go out in one tide: there are to be fix immense ranges of warehouses in the whole, with cellars, cranes, and every possible convenience; the whole is to be surrounded with a wall 30 feet high, and a wet foils 12 feet broad, and 6 deep: for security from fire, no dwelling-houses or work-shops are to be built within or near to the boundary wall; no gunpowder is to be suffered to enter the walls, or any fire, candles, or lamps to be lighted within the same, except the necessary fire-lamps on the quays. The company were at first authorized to raise 600,000l. the amount of shares being 500l. each, which, in 1803, bore a premium of 28l. per cent.: the profit to the subscribers are limited to 10 per cent.: several loans of the public money from the consolidated fund have been made towards completing this design. Mooring-chains are provided in the river opposite the entrance basons, for the use of ships entering these docks, in which all West India goods whatever (except tobacco in some cases,) are to be
the land, and all outward-bound ships for the West-Indies are to load herein, or in the Thames at Blackwall; but the tonnage for the building and maintenance of these docks is, (by 39 Geo. III.) not levied exclusively on the West-India trade, as every vessel both on its inward and outward voyage (except coaling vessels under 45 tons, king's ships, corn, fishing, and passenger vessels, and craft navigating above Gravesend,) is to pay: coaling vessels at the rate of 1d. per register ton; and ships trading to or from ports beyond the seas, and paying higher rates, amounting, in some cases, to 1½d. per ton; i.e. the particulars, as also the rates for wharfage, warehouse-room, cooperage, &c. in the Agricultural Magazine, vol. i. p. 115. Mr. Robert Edington, in his Essay on the Coal Trade, 1803, after estimating 4284 coal-ships to enter the port of London annually from the neighbourhood of Newcastle-upon-Tyne, with 1071 chaldrons each, on the average, (a quantity considerably short of the actual importation, see Monthly Magazine, vol. xvii. p. 99, and vol. xix. p. 99.) objects strongly to the above rate, which annually taxes the coals consumed in London and its vicinity with 4284l. on account of these docks, which they are not allowed to enter. For the general accommodation of ships unloading and loading in the port of London, another dock was, after much dilatoriness, undertaken, in the year following, called the London Docks, (or sometimes the Wapping Docks.) Acts 40, 44, and 45 of Geo. III. Mr. John Rennie and Mr. Alexander were the engineers employed, on the 26th of June 1802, the first stone of these works was laid, by Mr. Edington, the then Engineer; and the work proceeded without any difficulty or impediment, until the great dock, the entrance bason, and several of the warehouses were completed, and opened for use on the 11th of February last (1805). The great dock is about 1260 feet long, and 830 feet wide, and covers about 24 acres of surface: it is 29 feet deep from the top of the walls: but the depth of water is only 23 feet; the walls are of brick, coped with stone, and every part of the work is executed in the most complete and masterly style. On the northern side of the dock there is an open fhed the whole length, for examining and weighing the landing of goods, under cover from the weather, from whence a number of small trucks moving on rail-ways convey them to five immense flacks of warehouses behind them, or the cranes hoist them into carts, as may be wanted. Near the S. E. corner of this dock are two immense warehouses let to government for the storage of tobacco; one of them is 762 feet long, and 160 wide, the other 250 feet long, and 200 feet wide, each being in one single room, without any partitions, and their roofs are laid to exceed 6 acres of flatting: they are but one story high, but have spacious arches vaulted under them of the same extent, for the storage of wine, oil, spirits, &c. Other large ranges of warehouses are to be built, and their fronts have been begun north of the present range of warehouses; the windows and doors of these last being bricked up, serve as a temporary wall to enclose the premises: warehouses are also intended on the west and fourth side, where the temporary fence-wall at present stands. The only entrance at present to this dock, from the Thames, is near to Bell-dock in Wapping, where two maffive piers of stone project into the river, and have a tide-lock between them, and further north is a curious iron double swing-bridge, in the line of Wapping-foott, which we have already described; within this is the entrance bason, of an irregular figure, of about 3 acres extent: this bason is connected with the river at every high-water, by the opening of the gates, which shut again and retain the water at that height: from this bason ships lock up into the great dock, whose surface is kept about 3 feet above the height of ordinary tides, by a powerful frame engine erected on the east side of the entrance bason for that purpose, and the bottom of the dock is about 15 inches above low-water mark in the river. There is designed to be another entrance from the Thames by means of Hermitage-dock, into the great dock at its S. W. corner; and from near the opposite or N. E. corner, provision has been made, and the connection made intended, which is to join it with another large dock, intended to be dug, and connect with the Thames at Shadwell. Notices were given in September last of an application to parliament for further powers, to proceed with the above works. The present dock is capable of accommodating 300 merchant ships, and the entrance bason will hold a vast number of small craft, without impeding the passage of ships to or from the great dock. The whole of the docks or warehouses are, when completed, to be surrounded by a very high wall to prevent depredations or the communication of fire, against the happening of which the same regulations are adopted as at the West-India dock above mentioned. Six large mooring chains are fixed at proper distances from each other in the great dock for ships to moor to, consisting of very large floating blocks of deal timber. This company were authorized by their first act to raise 1,500,000l., the amount of each share being 500l. They were required to purchase the concern of the Shadwell water-works for 50,000l.; and ample provisions are made for compounding the owners of the river-quays, the proprietors of street-cart licences, &c. and full provision is made for the receipts and expenditure of this company, and of the West-India dock company, are to be presented annually to parliament. The tolls or rates payable to this company, by ships which enter their docks, are for British coaling vessels (including colliers) 1s. per ton; five other classes of ships are enumerated, which are to pay from 15d. to 50d. per ton; see Agricultural Magazine, vol. iii. p. 102. For the landing, loading, and housing, and for shipping of goods of every different kind, the same sums respectively are to be taken by this company, as were usually paid at the different quays of the port of London in the year 1798. The whole of the site of these docks was covered either with streets and houses, or with gardens, and which the company had to purchase for immense sums of money. For the particular accommodation of the large ships belonging to the East-India company, a third spacious set of docks has been designed, and in the 43 of Geo. III. an act passed for enabling the company to raise 200,000l. for the purpose of building the East-India Docks, and to purchase the dock belonging to Mr. Perry's mafl-house at Blackwall, for their entrance bason. Mr. Ralph Walker is the engineer; and on the 4th of March last (1805) the first stone of this great undertaking was laid by captain Joseph Huddart, and the works are now proceeding with the utmost expedition: the largest, or import dock, is to cover 18 acres of ground, the export dock is to be 9 acres in content, and the entrance bason about 3 acres: the depth of these docks is to be greater than either the London or the West-India docks; the entrance docks now building are 48 feet wide in the clear, and each gate is to be 27-feet wide. Near to Deptford, Greenwich-Dock has its entrance, by a tide-lock, into the river Thames; this dock is about 900 feet long and 400 feet wide, and was constructed several years ago, for the accommodation of ships employed in the Greenland, or whale fishery, with suitable conveniences at proper distances for melting and refining their oil. It is intended that the Great Survey cannal shall have a cut into, and a paffage for its barges, through this dock: and the same company are now excavating a dock near the termination of their canal, at Wilkinron's gun-wharf, Rotherhithe, which
which seems to be intended to admit small ships from the Thames. At Deptford, Woolwich, and at Sheerness there are spacious dock-yards and naval arsenals on the banks of this river, and others at Chatham, within a few miles of it, on the Medway river. In the year 1825 it was proposed to make a large dock and yard, for repairing second and third rate ships of war, of which Major General Binton laid the foundation, near the east pans on the Isle of Grain, on the Medway side of it; its principal object is for repairing the ships dislodge in the Downs and North Seas. In the year 1826 it was proposed to form a wet dock of about 12 acres extent, connecting with the Thames river, by a Northfleet creek near Gravesend: the site of the old chalk pits is intended to be excavated for this dock, in which the new ships of war built at Deptford, Woolwich, and Chatham are to be received and rigged for sea, instead of sending them to Sheerness; that the site there may be wholly appropriated to the victualing and ordnance department. A pier is now building for the protection of Sheerness harbour, under the authorities of the acts of 41 and 42 Geo. III. At Margate, there was an ancient wooden pier in this river, for the protection of the hogs and vessels trading to that place, but in 27 Geo. III. an act passed for an excellent stone pier, which has since been there erected. The great distance which the inhabitants of Gravesend, and Graves-Thurrock, and all those parts, have to travel (over London bridge) to communicate with each other by land, gave rise, in May 1798, to the proposition by Mr. Ralph Dodd for a tunnel, or road arch, under the Thames, from near Gravesend to Tilbury Fort (see Nicholson's Journal, 40. vol. ii. p. 473); and an act of 40 Geo. III. passed to authorise the raising of 55,000l., in 100l. shares, for the Thames Tunnel, and to levy 28. 6d. on each coach, 4s. on each waggon, 25. on each cart, 15. on each horse, 26. on each foot-paletter, and some other tolls, for passing through this tunnel. Government to pay 100l. annually, in lieu of all tolls, for the passage of troops and of government electors of every kind: Sol. to be paid annually to his majesty, and 30l. to the corporation of Gravesend and Milton, in lieu of the right of ferries, near the intended tunnel, to which they are entitled. Mr. Dodd proposed his arch to be a cylinder of 16 feet diameter in the clear, and estimated that the building might be executed for 10,000l., the length of the tunnel being 600 yards; but it does not appear that at this time, or for more than two years after, any borings had been made, even on the shore of the river where the tunnel was intended, to prove whether the chalk rock, which Mr. D. had calculated upon tunnelling in, existed or not: at length, about September 1802, a bed of chalk, supposed to be the same which appears on the surface at Gravesend, was discovered, by Mr. D.'s borings, at 72 feet beneath the surface, at Tilbury Fort; a steam-engine was thereupon erected, and a perpendicular shaft of 150 feet deep was sunk at Gravesend, all in chalk; when, by one of those unaccountable accidents to which abortive schemes frequently hale, this engine-house took fire, and was burnt down, and shortly after the scheme was given up altogether. In the last session of parliament (45 Geo. III.) an act passed for making other archways under the Thames, for the passage of carriages and foot paletters, between Rotherhithe and Limehouse; and we have since read that Mr. Robert Virtue is the engineer to these Rotherhithe archways, that the foot-way arch is to be made a little to the west of the London Dock entrance, and the carriage-way arch at the present horse-ferry between Limehouse and Rotherhithe. On inquiry, we have been told, that the present scheme is, to sink a shaft on one shore of the Thames, with an engine thereon and pumps, and to continue the same to a sufficient depth, at which to be in the tunnel opposite the shores, round to the opposite face of the river one way, and to part from it in an opposite line, by a regular and proper chain of bridges. We can hardly suppose that this matter has proceeded thus far, without its being attended, by the least inquiry into what is proper on the other side, that there may be an approach to the clay, beneath the alluvial matters, which may be filled up with quaker or other loose fill unanswerable to tunnel through, under the bed of a river: but, if we admit the whole matter to be bold clay under the water way or bed of the river, yet the number of houses which must be pulled down, or enlarged, opposite to the tunnel, in the way of conducting the bridges, in order to bring the archway to the surface on one side of the river, and the inconvenience which that entrance will be from the water-side, are almost insuperable objections to its adoption. We have no doubt of the practicability of forming as many arch-ways under the Thames as may be wanted (if money is not spared, and scientific and proper men are employed on the work), but are of opinion that for such to succeed, the river must be piled off, for shunt lengths at a time, while the necessary excavation is made in the bottom for turning a length of the arch's, and securely covering it with clay or puddle: and after several successive lengths are thus formed, the water and traffic of the river may be admitted over the part which is completed. Very powerful pumping-engines will be necessary, in this or any other way of conducting such a work with the probability of success. The Thames river, below London, is embanked through a great part of its course; the time when these banks were first erected is uncertain, but they appear to be of great antiquity; and during several hours of each tide, the adjoining meadows are 10 feet or more below the level of the water. At Dagenham, about 7 miles below Blackwall, a large breach in one of these banks happened, which captain John Perry succeeded in stopping, after several others had failed in their attempts. On the 5th of August 1776 the plan was first adopted of employing convicts in ballasting, and other works for the improvement of the river Thames, under Mr. Duncan Campbell; these men, properly ironed, are lodged in bukis, or old vessels, off Woolwich, and have principally been employed in enlarging the wharfs at Woolwich Warren, or Royal Arsenal, which work is still proceeding. In the year 1787, and again in 1802, the London Lynn and Norwich (or North London) canal was proposed to join the Thames river at Limehouse. In 1798 a new channel was proposed to be cut for the Thames river straight across the Ile of Dogs, and dams with sluices and locks to be made on the old course of the river, for converting the same, round the island by Deptford and Greenwich, into one vast floating dock for ships! About the same time, the London Docks were in contemplation, and a canal was proposed to extend from them to the Thames river at Blackwall; the Ile of Dogs canal has since been made, and in part answered those purposes. In 1802 the Canterbury and St. Nicholas-Bay canal was proposed to join the Thames at the latter place; and in the same year the London and Waltham-Abbey canal was intended to join at Bell-wharf in Shadwell. The Thames and Medway proprietors pay 15. annually as an acknowledgment to the city of London, as conservators of the Thames river, for the liberty of connecting therewith. 

**Thames River (middle parts).** Acts 14 and 17 Geo. III. The general direction of this part of the Thames river is northeasterly, by a very crooked course of 37 miles between the counties of Surrey and Middlesex; the tide flows through the first 16 1/2 miles thereof to Richmond bridge: its objects are the supply of London, and the immense trade which is carried on.
on with the rivers and canals westward: at Vauxhall creek it is joined by the Grand Surrey canal; at Wandsworth entrance-basin, the Surrey Iron Railway joins; at Brentford Creek the Grand Junction canal joins, and at Ham Hall, near Shepperton, the Wey river joins (2 miles from the junction with the Basingstoke canal). London, the first British town, has 864,355 parsons; Wandsworth, Brentford, Kingston, Chertsey, and Staines are also considerable towns on this part of the Thames navigation; which commences in the Thames lower part at London bridge, and terminates in the Thames and Isis navigation at London-fone, at the extremity of Middlesex county, about 6 miles above Staines bridge; from near Chelsea, Pinmill creek extends for about 6 miles to Chelse waer-work engines. From low-water at Richmond bridge to London-fone, 204 miles, is a rake of 36 feet; see a fiction thereof in Gentleman's Mag. March, 1771, and in Zachary Althwe's Considerations on the Thames River, 1805, wherein it appears, that the navigation heron is in two or three places interrupted by shallows, not exceeding 2 feet 9 inches depth of water in ordinary times. At Laleham, Mr. John Rennie gauged the current of this river, in the dry season of 1794, and found 1155 cubic feet of water per second to be then passing down. The corporation of the city of London, as conservators of the river Thames, and by the 17 of Geo. III. above, were authorized to make any new fide-cut by this part of the river, or to erect any weir quite across the channel of the river; and their exertions for the improvement of this navigation, so much in need of amendment, have been confined to the erecting of jetties and weir-hedges, for contracting the breadth of the stream in many of the shallow places, to the dredging or ballasting of others, to deepen the channel, and to theestablishing of regular fuffices of water, twice a week, or oftener, from the ponds and mill-dams in the upper part of the river, for enabling barges, during the run of such fuffices, to pass the shallow places; except, that they have completed a good horse towing-path through the whole length of this navigation, beginning at Putney bridge, on the south shore of the river: immense sums of money (upwards of 1,400l. per annum) having been expended on the above inefficient measures, and yet the navigation in all dry seasons continues intolerably bad, and also frequently interrupted and rendered dangerous by floods. We are happy to observe, that notices were given in September last (1803) for an act to authorize the making of weirs across the river, and fide-cuts and locks, in the parishes of Laleham, Littleton, Shepperton, Sunbury, Chertsey, and Thorpe. The above act (17 Geo. III.) authorized the city of London to purchase certain local tolls on the navigation between Staines and Richmond, and to levy 4d. per ton per voyage up and down, for the above purposes; they have a commodious barge stationed on the river for the residence of a collector of this toll, and an annual account of all the receipts and disbursements under this act is presented to parliament. The Grand Surrey canal was (by its act 41 Geo. III.) required to pay 2 guineas a year, and a rent of 60l. annually, for the liberty of connecting with this navigation; and the Croydon canal 40l. per annum; the Surrey Iron Railway is to pay 10l. per annum; and the Grand Junction company are to pay 600l. per annum, and a toll of 4d. per ton on all goods which pass into or out of this canal. Among the bridges upon this navigation, London Bridge, at its commencement, built of stone in 1209, comes first to be noticed: the river at this place is about 500 feet wide, the bridge, which is 60 feet high and 74 feet wide, consists of 19 arches, the middle one of which is 72 feet wide, but the next there- to on each side are narrow ones, and no regular order is to be observed in the arrangement of the arches, which are most of them of different widths, under 20 feet; the piers between them are immensely thick, being also surrounded with flarlings or vast frames of piling and cros beams of timber, intended for the protection of the foundations of the bridge: previous to the making of the large lock or centre arch, in 1755 (by the removing of a pier and its flarling, and turning one large arch instead of two) the clear water-way between all the flarlings amounted but to 194 feet, and above the flarlings (which are covered when the tide has risen about two thirds of its usual height) the water-way amounted to only 430 feet, or half the width of the river; a further obstruction also arises from the water-wheels, which are fixed on the upper side of the bridge at both of its ends, opposite to several of the arches, for pumping up water for the supply of the city of London and Borough of Southwark. By these contractions of the water-way, a fall and current is occasioned under this bridge, which, for several hours of each tide is quite tremendous, and proves a most serious obstacle to navigation, as well of danger to the bridge itself. If Mr. John Smeaton's advice had not been quickly followed, in 1756, in returning and throwing in the fones, which had been recently taken up from the old middle pier, together with many cargoes of other large and rough fones, the adjoining flarlings and piers of the great lock would certainly have been undermined and the bridge have fallen: large quantities of chalk and Kentifh rag-llones are now annually brought and deposited within the piling of the flarlings, and between them, at the time they are repaired; a work for ever requiring to be done, in some part or other, of these clumsy obstructions to the waters and to navigation: immensely deep gulphs are formed at each side of the bridge by the pitch or fall of the water, and the full and rubbish excavated therefrom is continually thrown up at a distance, so as to form large banks dry at low-water, in spite of a continual dredging or ballast-heaving, which is reformed for to removing them. These inconveniences, which had been long and loudly complained of, occasioned, about the year 1759, a proposal, for pulling down this bridge, and substituting two stone bridges, with capacious arches: these were to be placed near to each other and to connect at their ends; the centre arch of each was to have a draw-bridge, for admitting ships up the river, as far as Blackfriars bridge; the intention of the two bridges being, that one of the drawbridges might always be shut down for the passage of carriages and persons, while ships might be passing through the other into or out of the bayon between the bridges. Another proposal was, to construct a cast-iron bridge of one single arch of 600 feet span and with 65 feet clear opening above high water; as we have already mentioned; these, and other projects for the same purpohe were minutely and carefully examined by a select committee of the House of Commons, and their reports, together with views of the different proposed bridges, have been since published, and a proposal made for a cast-iron bridge of three arches, resting on stone piers, the centre arch 65 feet high for the passage of ships; in September 1802, the city of London gave notice of their intention to apply for an act of parliament for removing London bridge and building another, but nothing further, we believe, has since been done. Blackfriars Bridge is an elegant stone structure, offering fearely the least impediment to the navigation; it was built in 1779, by Mr. Robert Milne; the river in this place is 935 feet wide, it has 9 large elliptical arches, the centre one 100 feet wide, the others regularly diminishing to the outside ones which are 70 feet each. The whole cost of this bridge, in the 102 years during which it was in hand, was 150,840l. Westminster Bridge was built of stone in the year 1750; the river in this place.
place is 1220 feet wide; there are 17 large, and two small semi-circular arches in this bridge, the central one 76 feet wide, the others diminishing by 4 feet each in width, to the small ones at the sides; the cost of this bridge and its avenues was 380,509l., and it was about 10 years in hand. At Battersea and at Putney there are narrow, low, and inconvenient wooden bridges over this river. On the 4th of June 1783, a hand-made and convenient stone bridge was begun over this river at Kew, and in the year 1774, another stone bridge was begun at Richmond. About the year 1801, a new stone bridge was built over this river at Staines, but it was shortly after obliged to be taken down, owing to a settlement therein; an iron bridge was next constructed, and opened on the 3d of September, 1803, of one arch, with 186 feet span, rising only 16 feet above the stone abutments on which it rested; but this, we are forry to add, has lately suffered the fate of the other, and has necessarily been taken down, a circumstance the more to be regretted, as this was the first cast-iron bridge brought into use in this part of the kingdom. At Walton, there is a curious bridge, consisting of a large wooden opening, and smaller brick arches on each side of it. It may be proper to add, that the intention has very recently been announced, of building a new stone bridge over this river from Vauxhall to Millbank, with a new road over the same from Vauxhall turnpike across Tothill fields to Pimlico. In the year 1770, and again in 1794, the Maidenhead and Iffeworth canal was proposed to join this river at Iffeworth and at Bolton's Lock, or Taplow mill; in 1792, the Hampton Gay and Iffeworth was proposed to join at the latter place; in 1801, the Leatherhead and Thames railway was proposed to join this river at Weymouth, and an extension of the Grand Surrey canal was intended to Kingston; in 1802, a cut from the proposed western branch of the Grand Junction canal was proposed to join at Ham Haw opposite to the Wey river; and, in 1803, the Pershore and London railway was proposed to terminate in Stamford Street, near Blackfriars bridge.

THAMES AND ISIS NAVIGATION. Act 11, 15, 28, and 35 of Geo. III.—The general direction of this navigation is nearly N. W. by a very serpentine and crooked course of about 110 miles between the counties of Surrey and Berks, and of Bucks, Oxford, and Gloucester: its western end is considerably elevated; its objects are the supply of London and the carriage of goods, and a variety of other articles; near Reading it connects with the Kennet river; at Abingdon, the Wilts and Berks canal joins this navigation: at Badeck's garden in Oxford, this navigation is joined by the Oxford canal, and at Godalming, by the duke of Marlborough's cut from the same canal. Oxford is the chief town, with a population of 11,904 persons, and Reading is the 55th, with 9,742 persons; Staines, Windsor, Maidenhead, Great-Marlow, Henley, Wallingford, Abingdon, and Lechlade, are also considerable towns on this navigation, which commences in the Thames middle part at London-Stone near Staines, and terminates in the Thames and Severn canal at Lechlade. From Staines-Rome to the water above Bolton's Lock, 15½ miles, is a rife of 34 feet: thence to the entrance of the Kennet river 24½ miles, has a rife of 27½ feet, besides the rife at the weirs; thence to the termination of the Thames and beginning of the Isis river, is about 23 miles; thence to the Wilts and Berks canal about 10 miles; thence to the Oxford canal about 8 miles, and thence to Cricklade about 29 miles. The Gentlemen of the counties adjoining this navigation are Commissioners for executing, in different districts, the above acts; they have borrowed 60,832l. and have expended the

fame, over and above the surplus of the toll, in making 24 side-cuts with opening weirs and pound locks, with a horse turning-path, and other works for improving this navigation, which is now accomplished, so that very long and wide barges, drawing 3 feet 6 inches, can go in general past the fame; the rate of turnover is only 4 per cent per mile; and an account of the receipts and expenditure on this concern is annually presented to parliament. In 1766, the receipts amounted to 95,351l. in 1801, to 125,662l. in 1842, to 171,251l. Mr. Lovemy Althuis, an engineer to the said and 3d district of this navigation. In the year 1798, Mr. Bridgestreet prepared a design and model for his Majesty, of a cast-iron bridge, of one arch, proposed to be erected over the Thames at Butet. In the year 1779, the Reading and Maidenhead canal was proposed to join this navigation at Sunning, and at Bolton's lock; in 1832, a western branch of the Grand Junction canal was proposed to join this navigation at Harneyford near Great Marlow, and crossing the same at that place, it was to proceed to join it again near Reading; and in the same year another branch from the Grand Junction, through Abingdon, was proposed to join this navigation near to Abingdon, and to the Wilts and Berks canal.

THAMES AND AVON CANAL. In the reign of Charles II., Mr. Joseph Mason was employed to survey the line for a canal, and a bill was prepared and brought into parliament, from the Thames and Isis navigation at Lechlade, by Cricklade, Malmsbury, Chippenham, and thence by the course of the Avon river to Bath, 40 miles in length; in 1754, this design was again revived, with the idea of employing the folders upon it; and it was flated that a canal 50 feet wide at top, 50 at bottom, and 4 feet deep, might thus be completed for 10,000l. per mile.

THAMES AND MEDWAY CANAL. Act 40 and 44 of Geo. III.—The general direction of this canal is S. E. for 3½ miles in the county of Kent; it is level with the ordinary high tides in the river Thames; its object is for shortening the voyage of barges from Gravesend to Chatham round by the Nore; Chatham is the 40th British town, with a population of 10,055 persons, and Rochester the 90th, with 6,817 persons; Gravesend is also a considerable town near this canal, which commences in the Thames river at Gravesend, and terminates in the Medway river at Nicholl's shipyard in Frensham, with a cut from Whitewall on the line of this canal to the Medway at Strood, opposite to Chatham royal dock-yard. Tide-locks and entrance basins are to be made at each of the three terminations of this canal; Mr. Ralph Dodd was the projector of this canal, on which Mr. John Reenie and Mr. Ralph Walker have since been employed. In December 1801, this canal was completed from Gravesend to Denton. The company were authorized to raise by the first act 60,000l. in 100l. shares, and a further sum by the last act, and they are to pay 1s. annually to the city of London as conservators of the Thames river, for the liberty of connecting therewith, and to the corporation of Rochester, as conservators of the Medway, for the same privilege.

THAMES AND SEVERN CANAL. Act 23, 31, and 36 of Geo. III.—The general direction of this canal is E. S. W., for 30½ miles in the counties of Gloucester and Wilts: it crosses the Grand Ridge by a tunnel; its objects are a communication between the Severn and Thames rivers, the supply of the country through which it passes with coal, deals, &c. and the export of farming products. Stroud is the 114th British town, with a population of 5,422 persons; Minchinhampton, Cirencester, Cricklade, and Lechlade, are also considerable towns on or near to this canal; which com-
mences in the Stroudwater canal at Wallbridge near Stroud, and terminates in the Thames and Its navigation at Lechlade; it has a branch of about 1 mile in length to the town of Cirencester. Proceeding from Cirencester, or Salperton, 21 miles, it is a rise of 243 feet by 26 locks; hence, the summit pound continues through the Tunnel, 15 miles, to near Cirencester and Lechlade; thence, to the Thames and Its navigation, 205 miles, it is a fall of 154 feet by 14 locks. The first 4 miles of this canal from Stoud to Brinkome, port Bandon, is of the same width and depth as the Stroudwater canal, and is navigated by the Stroud boats; the remainder of the line is 4 feet wide at top, 30 at bottom, and 5 feet deep; at Brinkome-port, goods going seaward are removed into barges 80 feet long and 12 feet wide, which carry 70 tons each. The famous tunnel on this canal at Sapperton, is 1,400 yards long, the arch being 25 feet wide in the clear, and 250 feet beneath the highest point of the hill, which proved to be hard rock, much of which required blasting, and some of it was too solid to need any arch of masonry to support it; the other parts are arched above, and have inverted arches in the bottom; the cost of excavating this tunnel, in 1788, amounted to 8 guineas per cubic yard. The summit level of this canal is supplied by a feeder brought through lord Bathurst's gardens. Mr. Robert Whitchurch and Mr. Joseph Cheere, were the engineers. On the 29th of April, 1789, the Sapperton tunnel was finished, and on the 19th of November of the same year, the whole line was completed and opened. We are sorry to have heard it reported, that this canal has been converted through porous gravelly soils, when a lime for the face, equally convenient, might have made the cuttingfail in a clay soil, and that pudding has been in too many instances neglected or has failed, by which the canal is rendered short of water, and the land and mills have been greatly injured: fanciful round buildings like those, were not made in different places on this canal, for the 'refuse of the lock-keepers. This company were authorized to raise 255,000l., the sums being reck. each; there was a provision that 3 per cent. interest should be paid (out of the principal) to the fabricators on their shares, until the canal was completed and opened; we have heard that the present profits are not much above y 1 per cent. No flamps were necessary to the proceedings of this company. The rates of tollage and the regulations thereof with the Stroudwater company, are very long. See Phillips's 420. History, pages 222 to 225. Manures for the adjoining lands are to pass toll free; less than 6 tons not to pass the locks without paying for that weight; 1/2 mile-flows to be erected.

In 1759, this company offered bounties for introducing the coals brought by their canal to the western parts of Oxford and Berk shires. The Gloucester and Berkeley company are to compensate this company, in case the construction or repair of their works interrupts at any time the communication with the Severn. In September 1809, it was intended to make from near logleham a forked branch passing Fairingdon and Highworth, to connect with the Wilts and Berks canal in two places.

THAME'S CANAL. Act 13 Geo. III.—The direction of this canal is nearly N.E. for about 4 of a mile in length, in the Well Riding of Yorkshire; it is considerably elevated, near to Skipton, which is a considerable town; it commences in the Leeds and Liverpool canal, near Skipton, and terminates at Skipton-castle, lime-flone quarries. It was cut at the private expence of the earl of Thame, through whose estate alone it passes, except one clofe; its object is to convey coals to the lime-kilns, and to export lime as a manure and for building.

THAMES AND DUAL NAVIGATION. The general direction of these rivers is east, or nearly 30 miles in the county of Norfolk; they are not greatly elevated above the sea in the immediate places and the importation of coal, deals, &c. and the export of farming products. Yarmouth is the 57th British town, with a population of 13,157 persons; Aylsham is also a considerable town on this navigation, which commences in the Yare river Yarmouth, and terminates at the town of Aylsham; it has branches from near Thurne and Horning, through the fens and broads, to Hickling and Dilham, about 8 and 10 miles in length.

TRENT RIVER. (Lower part.) Act 34 Geo. III.—The general direction of this navigation is nearly S.S.W. by a bending and crooked course of about 115 miles, skirting Yorkshire for a short distance, and through the counties of Lincoln and Nottingham, and between those of Leicester and Derby: it is not greatly elevated in any part: its navigation,
CANAL.

The importance of the navigation which it forms with other rivers or canals: at Kashley it connects with the Grantham and Keighley canal; at Stockham, with the Idle river, and near the same place with the Gildersfield canal; at Tunkley, with the Fijiolle canal; at Gainsley, in South-Mulcham, with the Dee river; at Trent-bridge, near Holme-piepout, with the Grantham canal, and the Nottingham canal; near Sawley, with the LongFramebuffer navigation, or San river, and the Buresly canal. Nottingham is the 17th British town, with a population of 28,901 persons; and Newark is the 17th, with 6,700 persons. Burton upon Strath, Gainsborough, Newark, Southwell, and Bingham, are also considerable towns near this navigation; which commences in the Humber river at Trent-fall, (at the junction of Ouse river, and Market Weighton canal,) and terminates in the Upper Trent river at Sawley-ferry, at the junction of Dr. Sway canal, and the Trent and Mersey canal. It has a whole of 10 miles in length, made in imitation of the above act, for avoiding 21 locks, and 2 bridges, which occur in 15 miles of the river between Trent bridge, at the commencement of the Nottingham canal, and Sawley Ferry, at the commencement of the Trent and Mersey canal. This act has a rise of 20 feet, and it crosses and connects with the Buresly canal near Sawley; it has also a short cut, and lock into the Trent in Beeton. The farther part of this river is through towns, and is embanked on both sides: it is subject to very great floods: the tide flows to Gainsborough, so that small vessels can come up to that place; but between this and Wilden-ferry, a great number of shallows occur, owing, in a great measure, to the too great width of the river: Mr. John Smith, who examined it in 1761, rates, that in several places in the common flat of the river, in dry seasons, there was not above 8 inches depth of water; that at such times, without the aid of sail and pumps, it was impossible to raise a vessel on this river, and the lowest mills upon the Derwent, navigation was impracticable. The 33 of Geo. III. for Grantham canal required the proprietors of this navigation to deepen the bed of their river, so that there shall always be 30 inches deep of water in the drier season; for boats to pass between the Grantham and the Nottingham canals, and by which they may also pass into the Trent canal, for avoiding the shallows above Nottingham. An act was passed a few years ago for building a new bridge over this river at Gainsborough. In 1803 a new bridge was intended at Gunthorpe-ford. In the year 1759 and 1760, several acres of land were gained from the wide muddy banks of this river, by filling up the ditches by means of furze hedges, to check the current, and ensure the abundance of depots for the current, or the current, and ensure the abundance of depots for the current, or the river. 32 Geo. III. 12, the 33 Geo. III. for Derby canal, only left the said state to be changed, to grade well, or only the tributary river, into the river, with every means that will cost £200. 2 Geo. IV. by Grimsby canals, the company are to leave the navigation for 10 years, and 2 Geo. IV. for all other purposes, excepting the road-works and public works, which cost the river, when deposited at above, between the Grantham and Nottingham canals. In 1760, the Buresly and Kings-Bridge, and in 1792, the Trenthouse, and Bridgewater canals were proposed to join this river at Wilkin Ferry, where the Trent and Mersey canal now joins.

TRENT RIVER, (upper part). Acts 6, 10, 15, 16, 22, 25, 29 Geo. III. This general direction of the navigation is in W.S.W. by a crooked course of about 25 miles, in the forest and Staffordshire, and entering Leicestershire: it is not very greatly elevated above the sea, in any part: its objects are the carriage of coals, and the export of lead, gypseous, earthenware, silk, and agricultural produce: it connects at Swatkstone with the Derby canal, and has the Trent and Mersey canal running the whole length almost by its side, and communicating with it at two extremities. Burton-upon-Trent is the only considerable town on this navigation; which commences in the lower Trent navigation at Wilden Ferry (at the commencement of the Derwent river and Trent and Mersey canal), and terminates near Burton, at a branch from the Trent and Mersey canal. The turn of Ocker bridge is the first proprietors of this navigation, and all other persons are restricted from erecting or using wharfs or warehouses on its banks without his special consent. The canal or his lessees are entitled to 3d. per ton, on goods navigated on any part of this navigation; which was fixed, in 1765, to be unimproved, except by the erection of locks at two different mill-wheels, and more than 20 shallows then existed, over which boats could not pass in dry seasons, without the aid of pumps. Strange stories were at that time related of the conduct of these lessees, and incursions were made, that a barge loaded with stones was sunk by design in Kings-mill lock, and which lay there almost 5 years, and obliged all goods to be unloaded into fresh boats at that place! happily the rivalry of the canal by its side, renders such an occurrence hereafter unlikely ever to happen. The bridge over this river at Burton-upon-Trent is said to be the longest in England, being 1,423 feet long, with 34 arches. It may be proper here to remark, that Mr. Scouett, in 1758, recommended the making of a long bridge or water-road adjoining the lower part of this river, between Mulcham and Newark, that should have 500 yards of clear water-way through its arches! In 1763, the Brecon rail-way was proposed to join this navigation at Welton Cliff; in 1769, the Commercial canal, and in 1797, an extension of the Affleby de la Zouch canal was proposed to connect herewith at Burton.

TRENT AND MERSEY CANAL. Acts 6, 15, 16, 25, 29, 32 Geo. III. This canal (sometimes called the Grand Trunk, or the Staffordshire canal,) has its general direction about E.S.E. by a very bending course of 43 miles in the counties of Chelford, Stafford, and Derby: it crosses the grand-river by a tunnel; its objects are the export of coal, salt, pottery-wares, lime, gypseous, Saltland-flutes, agricultural produce, &c. and forming parts of the grand inland communications between Liverpool and Manchester, with Hull, Bristol, and London; at Quarn's wood in Stoke, it connects with the Newcastle-under-Lune canal: at Great Haywood with the Stafford and Worcestershire canal; at Fradley Heath with the detached part of Coventry canal; and at Swatkone it crosses and connects with the Derby canal. Although none of the towns on this long canal appear to have so many as 5,000 inhabitants, yet Northwich,
Northwich, Middlewich, Sandbach, Newcastle-under-line, Stone, Stafford, Rudsey, Lichfield, and Burton-upon-Trent, on or near to the site, are of considerable places.

The commencement of this canal is in Bridgewater's canal at Prenton-brook, and its termination in the Trent lower navigation, at Wilden-ferry near Shardlow, the point of junction of the Trent canal, or side-cut, the upper Trent navigation, and the Derwent river: from Etruria, a principal branch (sometimes called the Caldon canal) proceeds by Froghall to Uttoxeter, by a very bending course of about 28 miles in length; from this, at Froghall in Kinglsey, there is a rail-way branch of 3½ miles to Caldon-low line works, also from Stanley-Mofs in Endon there is a canal branch of about 3½ miles to the town of Leek, and from Shelton, a short cut to Cobridge: from Stoke-upon-Trent there is a rail-way branch to Lane-end; and from Etruria another to Handley green; from Longport to Dale-hall there is a canal branch, and the fame is continued forwards by a rail-way to the potteries at Burslem; there is a cut 1 mile in length to the Trent river near Burton. Near Lane-delph, and in Harc-ecalla there are short cuts or tunnels, extending to the pits or feams of coals. From Bridgewater's canal to Middle-wich, 18 miles, is a level: thence to near Talkl, 11 miles, is a rife of 326 feet by 35 locks; thence along the summit-pound, and through Harc-calla tunnel to the Caldon branch at Etruria, 6 miles, is level; thence to the Stafford and Worcee-fee canal at Great Haywood, 12 miles, is a fall of about 150 feet and 19 locks; thence to the Coventry canal at Fradley Heath, 13 miles, is about 32 feet, and 4 locks; thence to Horninglow wharf, 12 miles, is about 86 feet fall, and 11 locks; thence to the Derby canal at Swarktone, 10 miles, is about 16 feet fall, and 2 locks, and thence to the Trent river at Wilden-ferry, 6 miles, is a fall of about 32 feet, and 4 locks. From the summit level of the line at Etruria to near Bagnal on the Caldon branch, 5½ miles, is a rife of 75 feet, by 7 locks; thence to Stanley-Mofs, 1 mile, is level; thence to Froghall, 93 miles, is a fall of 61 feet, by 9 locks. From Prenton-brook to Middlewich, at the western end, and from Wilden-Ferry to Horninglow near Burton, at the easterne end, the width of the canal at top is 31 feet, at bottom 18, and it is 5½ feet deep; the locks here are 14 feet wide, adapted to river barges of 40 tons burthen; the middle part of the canal, and its branches, are 29 feet broad at top, 16 feet at bottom, and it is 4½ feet deep, the locks being only 7½ feet wide; the boats are 80 feet long, 6 feet wide, and carry 18 to 20 tons of lading. There are 16 public wharfs on this canal with warehouse, cranes, weighing-engines, and other necessary conveniences at each. Over this canal there are 358 road and foot bridges, and under it 3 large aqueducts, and 124 letter ones and culverts. Through Harc-calla Hill is a tunnel of 2888 yards in length, and upwards of 70 yards below the hill; this tunnel intersects, and has 5 crofs branches to, several veins of coals in the hill, and is also famous for being the first public canal-tunnel constructed in England; the driving of this tunnel, in 1767, cost about 500,874d. per yard run; the height of the arch is 12 feet, and its width 9 feet within side.

At Prenton-on-the-hill near Bridgewater's canal is another tunnel of 1241 yards in length; at Barton in Great Bud-worth is another, 572 yards long; at Saltersford, or Salters-field, in the fame parish, is another of 350 yards long, and there is a fifth tunnel at Armitage, or Hermitage, of 130 yards in length; the heights of the fcate tunnels are 171½, and their width 13½ feet. At Monks-bridge there is an embankment 13 feet high of 1½ mile in length, and an aqueduct bridge over the Dove river of 23 arches, from 15 to 12 feet wide each. At Alrewas is an aqueduct over the Trent river, with 6 arches of 21 feet span; and near Middle-wich is another aqueduct over the Dane, with 3 arches of 20 feet span. In the Rudyerd vale, N.W. of Leek, near the grand-ridge, is a resevoir of 150 acres extent, with an artificial head 30 feet in height; from this a feeder conducts its water to the Leek branch, and thence into the summit ponds of the Caldon branch, and of the main line: there are four smaller resevoirs near the summit, which measure together 60 acres; all waters within 5 miles of the line are allowed for the use of this canal. The rail-way branch to Mr. Gilbert's Caldon lime-works, made about the year 1777 or 1778, was composed of cast-iron bars pinned down upon rails of wood fixed across wooden sleepers, as we have before describ'd; it appears to have been set out, before the true principles of this excellent mode of conveyance were so well understood as at present, being very crooked and with frequent variations in the angle of its acent; in the left of the above acts, there is a provision made for varying the line of, and improving this rail-way. It is laid to have coit, at first, about 1750l. per mile; in 1794, one horse, we are told, for 9 months in the year, made in each week three journeys on the one days, and two journeys on the other two days, hauling 3 tons 6 cwt. of lime-floor down each journey, from the quarries at Caldon to Froghall wharf; for forwarding this floor to the canal at Etruria, the company found boats, the largemen found their own horses and boy, towing lines, &c. and delivered the floor at Leek, at the distance be- ing about 161 miles. Mr. James Brindley, Mr. John Smea-ten, and Mr. Hugh Nicolls were the engineers employed or consulted on the works of this canal, which were begun in July 1766; in April, 1773, the line eastward of Harc-calla tunnel was completed, and in May, 1777, the whole line was completed and opened: the Leek branch, the extension of the Caldon branch to Uttoxeter, and the Cobridge branch have been underucken since the year 1775; the Lane-end, Handley-green, and Burslem branches were projected in 1802. The first act above included 6 miles of the west end of Bridgewater's canal, but with a power to affig or make over the same to the duke of Bridgewater, which was accordingly done; the 6th act above affered 11 miles of the Coventry line, between Fradley-heath and Fazeley, to this company, who completed the fame, and then fold it in equal moieties to the Coventry and the Birmingham and Fazeley companies, as before mentioned. This company have been authorized at different times to mile 334.250l. the amount of their shares was 220l. each, until 42 Geo. III., when a division of them was made into 1001. shares. The rates of tonnage are 1½d. per ton per mile, with reasonable wharflage after 24 hours, on all kinds of goods; but paying and road-materials (lime-flores excepted,) and manures pafs toll-free on the pounds and through the locks, when water runs wants over their paddle-wells. The act 33 Geo. III. for Derby Canal, granted some rates to this company on goods crossing this canal or passing out of it into the Trent by the Derby canal; see Phillips's 4to Hist, Appendix, p. 58 and 59. In the years 1760 and 1765, the Wilden and Kings-Bromley, and the Tern-bridge and Windsor canal were propos'd through parts of the tract now occupied by this canal: in 1793, the Sandbach canal was propos'd to join near that place, and the Bredon rail-way was intended to be connected herewith near Welton-chif: in 1796, the Commercial canal was propos'd, to crofs this canal at Horninglow near Burton, and again near Burslem; in 1797, an extension of the Aflow-de-la-Zouch canal to join this at Horninglow was propos'd; the design of the two last proposals was, an extension of the wide canals for 40 ton boats, and with the fame view a plan was, in 1797, mentioned of widening
widening this canal and its locks, bridges, &c. so that wide boats might pass between Bradley-Heath, and the call-end of Harecastle tunnel.

**Tweed River.** This river seems to be navigable but about 1 mile from the sea to Berwick bridge, between Berwick liberty and a detached part of Durham county. Berwick is the 8th British town with a population of 7,187 persons; it has a great trade in salmon, which are caught in great quantities in this river, and 40,000 kits if it have been pickled and sent off from this town in one year; 75 to 80 vessels are employed in fisheries, and the trade of this place connected therewith. At Berwick there is a flood bridge 94 feet long, with 15 arches over this river. At Kelso several miles higher up on this river, a flood bridge was, in 1768, washed away, and a call-iron bridge was proposed to be erected in its stead.

**Tyne River.** Acts 9 and 10 Henry V., 6 and 7 William III., and 41 Geo. III.—The general direction of this river is nearly W.S.W. by a crooked course of about 14 miles between Durham and Northumberland; the tide flows through its whole length; its great object is the export of coals. Newcastle-upon-Tyne is the 10th British town with a population of 36,666 persons, South Shields is the 67th with 8,108 persons, and North Shields the 88th with 7,280 persons; Gateshead is also a considerable town near this river, which commences in the North Sea at Tynemouth, and terminates at Blaydon in Winalton. A very peculiar kind of vessels, as before mentioned, is in use upon this river for carrying coals from the wagggon-roads, or railway's, and flatboats to the ships; these are called keels, and are limited (by 11 and 15 Geo. III.) to 25 tons of laden, or 8 Newcastle chaldrons of coals. From an humane set of Gentlemen refusant upon, and concerned in the trade of this river, originated the idea, and they offered a public reward for the life-boat, which Mr. Greathead brought to perfection, and first tried at the mouth of this river on the 30th of January 1790. (See the article Life-boat.) The coals from the numerous coal-mines near this river were formerly delivered to the colliers or coal-ships lying below Newcastle bridge by means of the keels, but of late years several mines have been opened on both sides of the river, and the railways therefrom are conducted to flatboats or spouts on the quays, by which means the coals are shot at once into the holds of the ships. Wooden railways were, since about the year 1685, in use between the mines and this river; one of them of considerable length, the same being a great means of coals, to ship them to many parts, are usually shipped from this river for London, amounting to 700,000 chaldrons annually: see Edington's Essay, &c. p. 31. On some of these mines, immensely large steam engines are employed; in 1758, a new engine was erected at Walker collory, with a cylinder 74 inches diameter and 10 1/4 feet long, which weighed 6 1/2 tons, and was calculated to lift 500 cwt. of water by each stroke of its pump. There is an ancient stone bridge of 9 arches over this river, which was greatly damaged by a flood in 1771; in the year 1801, it was suggested to remove as many of its piers as would form a 144 feet opening near the north bank, and to construct an iron arch over the same, high enough for the keels to pass without lowering their masts. The conservators of this river, in pursuance of the laws of the above acts, have deepened and improved the same and its quays; in 1801, a new dry, or graving-dock, was opened at South Shields, capable of receiving ships at high tides; in 1828, an act passed for building a new light-house at Tyne mouth with reverberating lamps, instead of a coal fire blown by bellows, before used.

In the year 1796, it was proposed to make a tunnel or coal-arch under the Tyne river from North to South Shields for the passage of carriages and passengers, and the expense thereof was estimated at £6,875. In 1797, the Newcastle and Carlisle canal was proposed to join this river near Newcastle; in 1798, the Newcastle and Haydon bridge, and in or before 1861, the Newcastle and Maryport were also proposed. In 1797, and again in 1802, the Durham and Chester-le-Street canal was proposed to join this river near Gateshead; and in 1803, the Tyne and Berwitt canal was proposed through part of nearly the same tract.

**Tyne and Berwitt Canal.** In 1803, it was proposed to make a canal from the Tyne river, near Gateshead, through Gateshead, Winklum, Lamley, and Birtley townships, to Beamish iron works and coal-mines.

**Ulverstone Canal.** Act 33 Geo. III.—The direction of this short, but large canal, is nearly N.W. for 44 miles in Lancashire; it is level with high-water at ordinary tides, with a sea-lock at its entrance; its object is to admit ships to Ulverstone town. This canal commences at Hammer-fide hill in Morecambe bay in the Irish Sea, and terminates at the new wharf and wharfs at Ulverstone; the canal is 65 feet wide at top, 50 feet at bottom, and 15 feet deep; the lock is 112 feet long; at the lowest ebb tide there is a depth of 9 feet water at the gates, and at spring tides of 20 feet; a public swing-bridge is built at Hammeride. That able engineer, Mr. John Rowie, was employed on this canal, and completed it about July 1797. This company was authorized to raise 7,000l, the amount of their shares being 50l. each. Coals may be brought to this canal from the Lancaster canal, without paying the sea duty; some iron works have been established near Ulverstone since the opening of this canal.

**Uppingham Canal.** In 1793, it was proposed to make a canal from the town of Uppingham in Rutlandshire, to connect with the Leicestershire and Northamptonshire Union canal, and provision is made in its act (53 Geo. III.) for such junctions.

**Uske River.** The direction of this river is nearly N. for about 4 miles in the county of Monmouth; the tide flows through its whole length; its objects are the export of coals, iron, &c. and the trade of Newport; at Pill-Gwenni it connects with the Monmouthshire canal, and with the Sirhevy tram-road; it commences in the Severn river at Nail, and terminates at Newport bridge.

**Wakefield and Hullis.** In September last (1825) notices were given for a railway from the Calder and Hebble navigation at Bottom boat in Wakefield, to Hullet-hall colliers, with branches to Bridal and Smifin bridge in the west riding of Yorkshire.

**Warwick and Birmingham Canal.** Acts 33 and 36 of Geo. III.—The general direction of this canal is nearly N.W. for 25 miles in the counties of Warwick and Worcestershire; it crosses the grand-river without a tunnel; its objects are the supply of Warwick with coals, &c. and forming part of the most direct water communication between Birmingham and London; at Kingwood in Rowington, this canal is joined by a branch from the Stratford canal, Birmingham is the 6th British town with 73,670 persons, and Warwick is the 107th with 5,775 persons, on the line of this canal; which commences in the Warwick and Napton canal in Budbrook parish near Warwick, and terminates in the Digbeth cut of the Birmingham and Fazeley canal at Digbeth near Birmingham; it has a cut of 1/4 of a mile to the
the lev in Salteford in Warwick. From the Warve and Napton canal, about 4 miles, to near Budbrook town, 5 level; thence 24 miles to Hatton, a rise of about 20 locks; thence to the Stratford branch, about 5 miles, is level; thence to Knowle common, about 41 miles, is level; thence to Knowle-wharf, 1 mile, is a fall of about 5 locks; thence to Deritend, about 10 miles, is level; thence to the Digbeth branch of Birmingham and Foxley, 14 mile, is a rise of about 5 locks. At the termination at Digbeth a stop-lock is erected, which the Birmingham and Foxley company may fall upon, whenever the water in this canal is of 6 feet depth at such lock. At Hafcra there is a tunnel of 500 yards in length; at Henwood wharf there is an aqueduct over the Blythe river; near Flint Green another over the Cole river; and near its termination at Digbeth another over the Rsa river. In May 1756, the northern end of the canal for about 9 miles to Henwood quay was completed and opened; and, on the 19th of December 1759, the whole line was completed and opened; and, on the 30th of April 1759, a bank of this canal broke, it was filled, and the flow of the waters did some damage. This company was authorized to raise £85,000, the amount of their shares is 100, each. The rates of tonnage will be found in Mr. John Cary’s Island Navigation, pages 56 and 57; paving stones, road-materials, and marrals for adjoining lands, except lime, are to pass free on the pounds, or through the locks when the lock is open; all boats, not exceeding 5 feet wide, may be used by occupiers of lands; boats less than 100 feet long, or with less than 20 tons of lading, are not to pass the locks without leave. The Birmingham and Foxley company are allowed to take 6s. per ton on all goods which pass from this canal to this, until they have paid off £3,600 of their debt, after which they are to take only 5s.; they are also allowed 3d. per ton on all goods passing from this canal to that.

Warwick and Napton. Act 34 and 36 Geo. III.—The general direction of this canal, (at first called the Warwick and Braumin, is nearly Eas, for about 15 miles, in the county of Warwick: it is considerably elevated, and terminates near to the grand-ridge, on its Weft side: its main object is, the opening of the moat of the line between Birmingham and London. Warwick is the 107th British town, with 5,773 persons; Southam is also a considerable town near to this canal; which commences in the Warwick and Birmingham canal, in Budbrook parth near to Warwick, and terminates in the Oxford canal at Napton on the-hill; near Warwick it crosses the Avon river, on an aqueduct; near Radford and Long-Rington there are smaller aqueducts. This canal is level with the Warwick and Birmingham canal at their junction, and is entitled to the waste water from that canal. This canal was completed on the 15th of December 1759. The company were authorized to raise £150,000; the amount of each share being 1000, but by the last act above, the holders of the original 1000 shares, were authorized to contribute any further sum, and to be entitled to a proportionate dividend, with original shares, on such addition. The tonnage rates are adapted to the principle, of making goods pay a higher rate for short distances; see John Cary’s Island Navigation, pages 59 and 60: paving-stones, road-materials, and marrals for adjoining lands, (except lime,) are to pass free on the pounds and through the locks when the water runs waste thereat. Boats less than 70 feet long, or with less than 20 tons of lading, are not to pass the locks without leave. The Oxford canal company are entitled to a variety of rates on goods passing out of this canal into that, which fee in Cary, as above.

Waveney River. The general direction of this river is nearly S.W. by a bending course of about 23 miles, between the counties of Suffolk and Norfolk; it is not greatly elevated in any part; its objects are the import of coal, deals, &c. and export of agricultural products; Yarmouth is the 28th British town, with a population of 14,855 persons; Becles and Bungay are also considerable towns, on or near this river; which commences in the Tare river at Bawdsey, and terminates at the town of Bungay.

Wear River. Act 31 Geo. II.—The general direction of this river is nearly S.W. for about 16 miles in the county of Durham; it is not greatly elevated in any part; its principal object is the export of coal. Sunderland is the 37th British town, with 12,413 inhabitants; Durham is the 7th, with 7,530 persons; and Bishop Wearmouth is the 97th, with 6,126; Monk’s Wearmouth and Chester-le-Street are also considerable towns, on or near this river; which commences in the River Wear near Sunderland to the north side of the river in Monk-Wearmouth. On the 9th of August 1756, a grand iron bridge of one arch, 236 feet span, and 100 feet high above high-water mark, was completed over this river at Wearmouth near Sunderland, as we have already mentioned in this article, and in our article Bridges. The importance of this bridge, besides its advantage in admitting ships further up the river, will appear from the tolls for passing over it, having been let for the current year at 208l. At the mouth of this river there are two piers for the improvement of Sunderland harbour; in 1762, a new light-house, 70 feet high, was built on the North pier, furnished with reflecting lamps; during tide-time every night, another light is exhibited below the principal one, as a notice to ships of the proper time to enter the harbour. In 1797, and again in 1802, the Durham and Chester-le-Street canal was proposed to join this river near Chedder, and hence extend the navigation to Durham.

Wear River. Acts 7 Geo. I. and 34 Geo. II.—The general direction of this river is nearly S.E. by a crooked course of 20 miles in Cheshire: it is but little elevated in any part; its objects are the import of coal and Cumberland iron-ore, and the export of felt and agricultural products; Frodsham, Northwich, and Middlewich, are considerable towns near this river; which commences in the Mersey and Javel navigation, near Wetton, and terminates at Winsford bridge: the rise is about 433 feet by 10 locks: the boats are from 50 to 100 tons burthen: the trustees for this navigation were authorized to borrow money at 5 per cent. interest, and 50 per cent. for the river: in 1759, the debt amounted to £20,000, borrowed at 5 and 5½ per cent.; this debt has long ago been paid off; and, there being no private interest in the concern, to the amount of 3000l. has been paid in some years, to the county treasurer of Cheshire, to be laid out in amending and repairing the public bridges, and
and in the repair of high-ways leading to the salt-works, agreeable to the directions of the first act. The salt-mines at Northwich are 300 feet deep. In 1663, it was in contemplation to make a cut to this river, from near Frodsham, into the Mersey at Warton or Warton point, for avoiding the bar or flood at the mouth of this river.

**Welland River.** Act 51 Geo. III. - The general direction of this river is nearly N.W. for about 37 miles in the county of Lincoln, and skirting the county of Northampton; it is not much elevated above the sea in any part; its objects are the import of coals, deals, &c. the export of Ketton free-borne, Collywobblers, white flutes, agricultural products, &c.; near Crowland it connects with Cawenham, a branch of the New river. Bolton is the 10th British town with 226 inhabitants; Spalding, Crowland, Market-Deeping, and Stamford, are also towns of some note on this river; which anciently was navigable for considerable vessels, from Fossdyke-wath to Spalding; but owing to the confluent changes, which have been taking place in these surprising fens, and their outfall into the wash, we learn, that in 1678, there was not 6 inches' depth of water at low tide in the channel, 2 miles below Spalding; so that when the commissioners of fens inspected the same, their boat was obliged to be carried in a cart upon the fens for 3 or 4 miles below that town. In 1721, Mr. Nathaniel Kinderly (see his Ancient and Present State, &c. page 83) recommended the cutting of a new channel, from near the mouth of Glen river to Wyberton near Bolton, by which the outfall of this river would be into the channel of the Witham river, instead of Fossdyke-wath. The subsequent contractions of the Welland river, by embankments near its mouth, some what improved the navigation to Spalding, and delayed until the year 1794 the adoption of Mr. Kinderly's proposed cut: in future the commencement of this navigation is to be in the tide-way of the Witham river at Wyberton roads, and it terminates at Stamford bridge. The new cut is to commence near the Ship athoue in Wyberton, where there is to be a sea-fluice against the Witham, for the river and flood waters, with gates pointing to sea and to landwards; the threshold of this sluice is to be one foot below low water mark, and it is to be 50 feet wide in the clear; adjoining to the sluice is to be a tide-lock, for the use of the navigation, 60 feet long, and 8 feet wide, in the clear. From this sea-fluice, the cut is to be continued westward, with a regular gradient in its bottom, to a point below the fall of Velmar's sluice, and is to terminate in the old Welland river, near Hooton's Gibbet: the width of the bottom of this new cut is to be 50 feet, and the sides are to be 2 feet for 1 in height; at the distance of 50 feet from the edge of this cut on the South side, and 30 on the North side, banks 11 feet in height are to be made, to retain the floods and prevent their overflowing the adjoining fens, a precaution which has been adopted through the whole course of the fens. Meffrs. John Hudson, George Maxwell, and Edward Hare, are appointed commissioners for setting out, and employing proper persons to execute the new cuts, sluices, locks, &c. and are to cleanse the channel of the Welland for some distance above the new cut, and erect a sufficient dam across the river below the entrance of the same, at Shepherd's hole, to float the tide waters and turn the land waters through the new cut; the rates of tonnage for navigating of which, will be found in Phillips's 40th History, A. p. page 179. A bridge is to be built over the new cut at Fossdyke Inn: at Crowland, there is a most ancient and curious bridge on this river, springing from three different abutments, and meeting in the middle. See our article Bridge.

In 1797, it was slated that 10,000l. had been vitupered for carrying the above new cut and improvements between; and we hope that in less than three years will be completed. There are 39 miles of canal in the above cut, including the towns and maintaining the work when completed by the subscribers. The greatest part of the course of this navigation from Spalding to near Pilgrim's period, and from Market-Deeping to Stamford, is by gradual cuts, on the north side of the old river, for avoiding its imperfect channel.

**Welford and Longford.** About the year 1704, a canal was proposed from the Montgomery canal and River Burr near Welford, to the Longford canal at Welford; pulling Whipp's-Calle and Ludlow in its course.

**Wey River.** C. The general direction of this river is nearly N.S. for 22 miles in the county of Surrey; it is not greatly elevated; its objects are the import of coal deals, &c., and the export of chalk and agricultural produce; at Weyley near Weybridge, it is joined by the Bifhambridge canal. Godalming, Guildford, and Chertsey, are considerable towns on or near to this navigation; which commences in the Thames river at Ham-Faw near Weybridge, and terminates at the town of Godalming. From the Thames to Guilford bridge, 1 ½ miles, is a rife of 862 feet; in this part the channel of the river was very early improved by slip cuts, and pound-locks, (said to be among the first erected in England, and to have been introduced by Sir Richard Wharton;) from Guildford bridge to Godalming, is a canal 42 miles, with a rife of 345 feet, which is supplied by a feeder from the Wey at Godalming. In 1791, and again in 1803, this navigation was proposed to be joined near Godalming by a canal from the Icking river, (see Portmouth and Croydon.) In 1803, the Grand Surrey was proposed to be extended to this river near Welley, and in 1802, a branch from the Grand Junction canal was intended to connect with this river by means of the Thames at Ham-Faw.

**Wharfe River.** The general direction of this river is nearly N.W. for about 5 miles, between Ainly Liberty and the West Riding of Yorkshire; it is not much elevated above the level of the sea: its objects are the carriage of coals, free-borne, &c. and the export of agricultural productions. Tadcaster and Cawood are considerable towns on or near to this river, which commences in the Osfe river near Cawood, and terminates at the town of Tadcaster.

**Whitby Haven Brooke.** This brook is navigable but a very short distance, in a S.E. direction at its mouth, which is wide, constituting the harbour of Whitby in Cumberland: its chief object is the export of coals, lime, and freestone. This harbour, situate on the Irish sea, has had several acts passed for its improvement, viz. 7 and 10 Anne, 13 Geo. III., 1st, 2nd, 28th, 32d, and 45. Geo. III., and in September last (1805) notices were given for a further application to parliament. Whitby is the 6th British town with 8,743 inhabitants. Mr. John Smaton was consulted in 1763, on the building of a north pier, and extending the southern one with 200 feet of it. In 1796, a violent storm happened, which considerably damaged the quays of this harbour. There are several railway lines from this harbour, to the famous coal-mines in its vicinity. On the 4th of August 1728, the first rail or wagggon-way was opened at this place, leading to Harriithwaite and Woodhouse collieries. In 1802, the Henshaw lime-works were opened. On the 9th of August 1803, the railway, 700 yards in length, passing over Bramley-arch, or Road-bridge, to Howgill and Whingill coal mines, were opened: and in the same year thefe to Brackenhaw- waite mine were opened. On 23rd March last (1825) the William Pit, at 750 yards distance from the north wall of the harbour, was opened. Some of the veins of coal in these pits are 7½ to 12 feet thick, and from the whole of them 500 tons or upwards of coal are raised daily: one of these...
miles extends 1/2 of a mile under the sea, at about 600 feet beneath its bottom; inclined planes, 100 fathoms long, being used, for drawing up boxes of coals and others of water, from the extremities of these workings under the sea, to the bottoms of the shafts; these boxes are drawn up the planes by horse gins; for which purpose, and dragging the coal-waggons to the shafts, 100 horses are constantly employed under ground in these pits. The fire-damp often proves fatal to the men and horses employed in these works.

There is a fine white fine-flint quarry on the west side of the harbour.

Wibby and Dewbury. In 1802, a railway was proposed from the Calder and Hebble navigation at Ravensbridge in Dewbury, to Lowmoor iron-works in Wibby, about 7 miles in length.

Wilden and King's-Bromley. In 1760, the line for a canal was surveyed by Mr. James Bridley and Mr. John Smeaton, from the Trent river at Widken ferry to King's-Bromley near Litchfield, 25 miles, with a rise of 115 feet by 39 locks, with a branch therefrom to Longridge near Burton, 30 miles, with 1662 feet rise, by 28 locks; from which last a level branch was again proposed of 33 miles, to Newcastle-under-line: another branch of 25 miles, to Litchfield mill-pool, 18 feet rise, and 3 locks, and thence 1/2 of a mile farther with 30 feet rise, and 5 locks: another level branch was proposed of 10 miles, to Fazeley near Tamworth, and thence 1/4 of a mile, to the Tame river, 17 feet rise, by 3 locks. This canal was intended to be 24 feet wide, and 24 deep, with fords instead of bridges: the estimate was 100,000l. Mr. Smeaton suggested an extension of this canal, over Harccefell-hill, by deep-cutting, withorefiers and steam-engines, for supplying the summit. The Trent and Mersey, Notts-Corps, and Coventry canals have since accomplished what this scheme had in view.

Wilts and Berks Canal. Acts 35 and 41 Geo. III.

The general direction of this canal is nearly N.E. by a bending course of about 52 miles, in the counties of Wilts and Berks: it crosses the grand ridge at the foot of the chalk-hills without any tunnel: its objects are the import of coals from both its extremities, the export of farming products, &c. Abingdon, Wantage, Swindon, Wotton-Baffet, Chippenham, Calne, Melksham, and Trowbridge, are considerable towns on or near to this canal, which commences in the Kennet and Avon canal at Semington, and terminates in the Thames and Iffy navigation at Abingdon. It has a cut of about 1/4 of a mile to Chippenham, one of about 3 miles to Calne, and another of about 1 mile to Wantage: the summit-level extends from near Wotton-Baffet, to the extremity of Wilts. The locks are calculated for long, narrow boats. On the Calne branch there is a short tunnel, under the road at Cuningham park: and a principal aqueduct-bridge over Broadtown brook near Wotton-Baffet. The rise of the road over the canal bridges is nowhere to exceed 3 inches in a yard; the springs and streams within 2000 yards may be taken; the use of inclined-planes instead of locks is provided for in the act; but they will not be necessary, the canal being generally cut through clayey soils that have plenty of water: half-mile flumes are to be erected on the canal banks. The company have been authorized to raise 311,360l. the amount of shares being 100l. each. The inhabitants of Calne made an offer, in Augull 1799, we are told, to cut the branch to that town, on being allowed the tolls thereon for so doing. In Augull 1799, the western end of the line was completed and filled, and on the 1st May 1801, by the completion of the Aqueduct between the Avon to Semington, the junction was formed, and 22 miles of the line to the aqueduct near Wotton-Baffet; with the Calne and Chippenham branches, have since been used, principally in bringing in Somersetshire coals. In September 1800, two branches of the Thames and Severn canal, by Parlingdon and Highworth, were proposed, to join this canal at Uffington and Shirehampton. In 1802, the Aylebury branch of the Grand Junction canal was proposed to connect with this canal by means of the Iffy river at Abingdon.

Winford and Stockton. In 1708, Mr. James Bridley and Mr. Robert Whitworth surveyed the line for a canal from the Tes or river at Stockton in Durham county; passing Hartburn, Coatham-Neb, Monk-hunter, Oak-tree, Maidendale, Bank-top, Darlington, Cockerton, Lower-Walworth, Long's-croft, Killery, and Stanhope, to Winford; with a branch 1/4 mile from Lower-Walworth to the Tes at Pardon-bridge; another from Darlington, 3 miles to Croft-bridge on the Tes; and another from Coatham-Neb, 2 miles to the Tes at Yarm. The rise from Stockton to Winford is 328 feet. A feeder was to be taken from the Tes river, 3 miles above Winford. The export of coals, lime, and lead, was the object of this proposed canal.

Wibbeach Canal. Act 34 Geo. III.—The direction of this canal is nearly S.E. for 6 miles, in the counties of Cambridgeshire and Norfolk: it is but very little higher than the sea, being embanked through the level fans: its object is a communication between Wibbeach and Lynn, instead of an old part of the Nene river near it, which is almost grown up. Wibbeach is the only considerable town near this canal, which commences in the Nene river at the old sluice in Wibbeach, and terminates in the Nene river again at Outwell (at the commencement of Well-creek, a branch of that river leading to the great Ouse river): it is straight and level, having flood locks at its extremities. This company were authorized to make 20,000l. the amount of each share being 10s. All goods entering or passing out of this canal are to pay 3d. per ton, except government stores and baggage, road-materials, machinery, and materials for the use of the Pen-Corporation; husbandry boats may also be used toll free, but not pass the locks. The commissioners for the Nene navigation are to have 100l. out of these tolls, and the remainder, after paying interest on the debt, is to be applied in the repair and improvement of Well-creek.

Witton (old) River. Act Geo. II.—The general direction of this river is nearly N.W. for about 41 miles in the county of Lincoln; it is but little elevated above the sea in any part: its objects are the import of coals, deals, &c., the export of farming products, and forming part of the inland communication between Lynn and Hull. Liverpool, Manchester, &c. Near Tatterhall it is joined by the Hornsedge navigation; at Chapel-hill by the Steaford navigation and at Wyberton roads the new outlet and navigation of the Welland river are to join this river. Lincoln is the 7th Britifh town, with a population of 7,308 persons, and Bolton is the 102d, with 5,926 persons; Tatterhall is also a considerable town near this river; which commences at the Scap or Sculp in the tide-way of Bolton deeps in the Wash, and terminates in the Fosdyke canal, or new navigation at Brayford Meres. This river below Bolton, about 4 miles, was anciently so deep, and was so much frequented by ships, that in the 6th year of King John, when the merchants of London paid only 8d. as a tax on their lands and goods, Bolton contributed 7s. At a gradual decay and silting up of the channel and harbour took place to such a degree, that when in 1761 Melfs. John Griseley, Langley Edwards, and John Smeaton examined the state of this navigation, and of the quacks used on the lining fans, through which this river is embanked on both sides through nearly its whole length, owing to the long neglect of the banks, which should have confined the returning tide and the land-waters, so as to lower the channel, they reported that 20
ton barges could then nearly reach Bolton, while the navigation above that town was entirely lost, and the ancient channel was in several places entirely grown up and abandoned by the water, in its ordinary state. Mr. Smeaton then recommended the erection of a cau-disque upon this river below Bolton, the fill thereof as low as low-water, with 3 openings, amounting to 50 feet wide; these to be furnished with doors pointing to sea-ward, and draw-gates behind them gauged, or having their tops, two feet below the surface of the lens, for always retaining a proper quantity of water in the river in dry seasons; also a sea-lock at the same place for the navigation, furnished with three pair of gates, two of them pointing to the land and one to the sea; the straightening, enlarging, and deepening of the river above Bolton to 80 feet at top, 50 at bottom, and 10 feet deep, were recommended, and the erection of three pound-locks, furnished with flood-gates or opening-ways adjoining, below Lincoln, and one other inch lock above. The estimate for such works as related to draining, was £8,000, and for the navigation works £7,370. It was remarked that Lincoln high-bridge had but 15 1/2 feet clear width of water-way, above which a hard gravelly place, probably an ancient ford, called Brayford head, covered frequently with only 3 feet of water, acted as a weir for holding up the waters of Brayford mead and the Fosdyke canal. When Mr. Smeaton was afterwards consulted in the year 1782, he objected to a navigation lock which had been in the interim erected below Lincoln town, and recommended the cutting off the communication between Fosdyke canal and Brayford mead, by a pound-lock with gates pointing to the canal, and to deepen this river through and above Lincoln bridge, and to remove Brayford head, so as to lower the water in Brayford mead: the principal wharfs appear to have been since made, and the trade of Lincoln is now carried on upon this mead or water. By the acts of 2 Geo. III. for Howdcroft and Skawford navigation, those companies were required to contribute equally with this company in the expenses of deepening and improving this river through Lincoln high-bridge, and thence to the Fosdyke canal, in the next 7 years; in consequence of which, goods paffing on this river to or from the Fosdyke, or Skawford navigations, are to pay only half the accustomed rates on this river. In 1803 it was in contemplation to further improve the navigation of this river below Lincoln. Much has been written on a prohibition said to exist against the shipping of coals from this river, on account of its preventing a rivalry with Newcastle and Sunderland coals in the London market, by the produce of the Yorkshire, Derby, and Nottingham mines being brought by the Trent, the Fosdyke, and this navigation, to Bolton deep; an expectation not much better founded, we fear, than that the opening of the Skawford canal would have any effect on the London coal-market.

Worcester and Birmingham Canal. Acts 31, 38, and 44 of Geo. III. — The general direction of this canal is nearly N.E. for 29 miles in the counties of Worcester and Warwick; it crosses the grand-ridge by a tunnel; its objects are the export of coals, and a more direct communication between Birmingham and the Severn river; at Selly Oak it is joined by the Dudley canal, and at Kings Norton by the Stratford canal. Birmingham is the 6th British town, with a population of 75,670 persons; Worcester is the 40th, with 11,325 persons; Bromgrove and Droitwich are also considerable towns near this canal; which commences in the Severn river at Diggs just below Worcester, and terminates in the old Birmingham, and the Birmingham and Fosdyke canals, at their junction at Farmers bridge at the upper end of the town of Birmingham. From the Severn to Tardebig, 15 miles, is a jile of 428 feet by 71 locks; thence to the Birmingham canal, 14 miles, is level. The width of the canal at top is 42 feet, and the depth 6 feet; the locks are 30 feet long and 15 feet wide; the boats are of 30 tons burden. At Worcester there is a very fine basin for the canal boats. There are 4 or 5 principal, and several smaller cutlets; the principal tunnel at Well Heath is 2500 yards long, 60 feet high, and 114 feet wide below the arch, the depth of water therein is 75 feet; at Tardigbe is another of 700 yards in length; at Shortford is another of 390 yards in length; at Oddingley one of 120 yards; and, at Edgbaston another of 110 yards in length; four of these tunnels are upon the summit-pound. Near Cotton-Hackett there is an immense piece of deep cutting; in 1754, Mr. Care's machine worked by a horse at length, was used for excavating the soil, instead of wheeling it out in barrows. Where the summit-pound of this canal connects with the Birmingham, the Dudley, and the Stratford canals; four locks are erected, which the several companies may shut and lock up, when the supplies of this or the other canals fail, so as to endanger the lowering of the summit-pound, to obstruct the navigation. Mr. John Smeaton was one of the engineers to this canal, the scheme of which was laid, and a bill was brought into parliament in 1790, but the opposition of interests, and natural difficulties, of this vast undertaking then proved fatal to it; the great anxiety and fatigue which Mr. Smeaton underwent in this arduous undertaking, are thought to have injured his health, and to have shortened the days of that very able and excellent man. In May 1796, the eastern end of this canal, as far as the Stratford canal at Kings-Norton, was completed. The arching of the Well Heath tunnel was begun on the 28th of July 1793, the whole of it was turned by the 25th of February 1797, (1780 yards of it having been completed in the year 1795) and in March 1797, the navigation was extended through it to Hopwood wharf, and in the following year, the same was extended to the western end of the summit-pound at Tardebig. The company were provided by their two first acts to raise £300,000. 18. 12d. their whole shares being made hereby, of the odd value of 138. 17s. 6d. each; these were said to be depreciated in value already by the cost of the work; but in 1802, they had risen to 46l. each. The last act was for raising a further sum of money for completing the very difficult part of the line, and supplying lockage-water, by beam-engines to pump it up from the Severn, by reservoirs, &c. which yet remains to be accomplished. The rates of tonnage owing to the several junctions with neighbouring canals are very complicated; see Cary's Inland Navigation, pages 68 to 70. Two-pence per ton is charged on goods entering the Worcester basin from the Severn river, to be there unloaded. This company guarantees the future profits of the Droitwich company to the extent of 5 per cent. annually on each share, and those of the Stratford company to 9 per cent. on each share: they are also to compensate the water-bailiff of Worcester for his dues on coals sold on the Severn at Worcester; they are also to pay to George Perrot Esq. as owner of the Stratford Avon navigation, 420l. per annum for lots of his tolls on the upper part of that river by the making of this and the Stratford canal, besides making up any deficiency there may hereafter be, in his rents of 1227l. for the tolls on the lower part of that river. About the year 1793, a branch was proposed, it appears, from this canal near Hanbury-Hall to the Droitwich canal at that town.

Wye River. The general direction of this rapid and romantic river is nearly N.W. by a very bending and crooked course of about 85 miles, in the counties of Monmouth and Hereford, and Brecknock, in South Wales, and flowing the
the county of Gloucester: its northern end is considerably elevated: its objects are the carriage of coals, and the export of agricultural products; at Hereford it is approached very near, if not joined, by the Hereford and Gloucester canal. Hereford is the 83rd British town, with a population of 6,828 persons: Chepstow, Colfew, Monmouth, Ross, and Hay are also considerable towns on or near to this river; which commences in the Severn river at Beccles, and terminates at the town of Hay. The tide often rises in the mouth of this river, to the extraordinary height of 40 feet; Chepstow bridge over the same, is of great height above the water at low tide. In 1802, and again in 1804, it was in contemplation to make a horse towing-path by the side of this river, and by deepening the shallows in several places to improve its navigation. In 1802, theDean Forest railway was proposed to join this river at English-Bichnor, we believe; in the same year notices were given, for an intended rail-way from this river at Hereford, to join the same again opposite to Lydbrook; and in March last (1805) another rail-way was proposed from this river to the Monmouthshire canal.

WYRLEY AND ESSENTING CANAL. Acts 32 and 34 Geo. III. The general direction of this canal is nearly S.W. by a very crooked course of 32 miles in the county of Stafford: it is considerably elevated, and terminates at its western end near, or upon the grand-ridge: its object is the export of coals, iron, and lime, which abound in its course: Wolverhampton is the 33rd British town, with a population of 12,556 persons: Lichfield and Walsall are also considerable towns on or near to this canal; which commences in the detached part of the Coventry canal at Huddersford (near to Whittington brook, and the commencement of the Birmingham and Fazeley canal) and terminates in the old Birmingham canal near Wolverhampton: there is a branch of 5½ miles to Hay-head lime-works; another of 2¼ miles to Lordes-Hay coal-pits; another of near 4 miles at Wyrely-bank collieries, with a branch from this last near 1 mile to Ellington new collieries; there is also a branch ¾ a mile to near Walsall town, which terminates within ½ a mile of the branch of the old Birmingham thereto. From the Coventry canal to near Cannock-Heath reservoir, ¼ miles, is a rise of about 246 feet, by 39 locks; thence to the old Birmingham canal, 15½ miles, is level; the Lords-Hay, Hay-head, and Walsall branches are all level with the long pound: the Wyrely branch rises about 36 feet, by 6 locks, in the first ¾ mile, the remainder thereof is level, and therefrom the Ellington branch rises 24 feet, by 4 locks. This canal is 28 feet wide at top, 16 at bottom, and 4½ feet deep. No water is to be taken from the old Birmingham canal, but a lock is erected at that junction, and this canal is to be constantly kept 6 inches higher than that, or all boats are to be flopped, by a man stationed there for that purpose: the surplus water from this is to be vented into the old Birmingham canal. Lichfield water-works pipes were to be carefully guarded in cutting this branch. Branches of 5 miles in length, by may be made to this canal by the owners of the mines, if they waste no water. Mr. William Pitt was the engineer: and the canal and works were long ago completed. The company were authorized to raise 166,000l. the first 35,000l. in 12½l. shares: on the extension of the canal in 1794, the company, were required to purchase the shares of certain discontented proprietors: the new shares are 10l. each. The rates of tonnage will be found in Mr. John Cary’s Inland Navigation, p. 47 and 48. Less than 20 tons in a boat is not to pass the locks without paying for that lading, except empty boats on their return. In 1792, it was proposed to make a branch to Stow-heath, and two others into Ashmore-park.

YELE RIVER. The direction of this river is nearly W. by a landing course of about 22 miles, in the county of Norfolk: it is not much elevated in any part; its objects are the import of coals, salt, &c. and the export of agricultural products: at Yarmouth this river is joined by the Thyon river, and at Burgh by Waveney river. Norwich is the 11th British town, with a population of 36,545 persons, and Yarmouth is the 58th, with 14,845 persons; there are no other considerable towns near this river; which commences in the German Ocean at Gorleston-fort, and terminates at the water-works and mill in Norwich: at Yarmouth there is a draw bridge for admitting mailed vessels above it. The quay of this port is ¼ mile in length, and in some parts 150 yards in breadth: a curious kind of low carriages called Yarmouth-Carts are used for conveying the goods from the quay to the warehouses. In 1824, St. Michael’s Collany bridge over this river in Norwich city was taken down, and a cast-iron bridge erected by Mr. Froult in its stead. In 1785, and again in 1802, the London Lyon and Norwich, or North London canal, was proposed to join this river at Norwich.

YORE RIVER. Act 7 Geo. III.—This river, sometimes called the Ure river, has nearly a N.W. direction for about 5½ miles in the West, and skirtng the North Riding of Yorkshire: its objects are the supply of Borough bridge and Ripon, and the export of agricultural products: at Muxton it is joined by the Swale river. This navigation commences in the Ouse river at Linton, and terminates in the Ripon canal at Milby. From the Ouse to the Ripon canal, is a rise of 11 feet; at Linton river is a lock, and a dam or weir so made up as to allow of 1 inch per mile in this distance, for a steam navigation. Mr. John Smith was the engineer, who in 1767 referred to Mr. John Smeth- ton for his opinion on the height of Linton dam, and other matters relating to the works then going on.

For further illustrative this part of our subject, we intend to give a map of the British islands, sufficiently large to distinguish all the navigable rivers, canals, railways, harbours, &c.: and having adopted a method, by which the inconveniences of large folding-maps will be avoided, and yet perfect facility be given, of reference from any page of the map to the other, this will probably be the first of a series of maps, for describing more particularly than has yet been done, several useful and curious particulars relating to the topography and present state of our own country.

CANAL, Canalus, in Anatomy, is a term applied to several tubular cavities in the bones, and the soft parts of the body.

CANAL of the lower jaw, a considerable excavation under the sockets of the teeth, in which the nutrient vessels and nerve of the teeth are lodged. See SKELETON.

CANAL of Fontana, a small channel in the ligamentum ciliaris, between the flesserotic and choroidal coats of the eye. See EYE, Anatomy of.

CANAL of Petit, Canaliz Petitionis, is formed in the anterior part of the membrane hyaloidea, round the margin of the crystalline lens. See EYE, Anatomy of.

CANAL of the vertebra, a large tube, containing the medulla spinalis, formed in the posterior part of the vertebrae; and extending from the occiput to the sacrum. See SKELETON.

CANAL in Architecture, is applied to the furrows on the face of, or underneath a chimney, sometimes also called porticoes; and fitted up with reeds or flowers; sometimes to those cavities, flattened or winding, made on the caulicules of a capital. See SOFFIT.

CANALS are also used for the flutings of a column or pilaster.

CANAL of the volutes, in the Ionic capital, is the face of the circumvolutions, inclosed by a fillet.
C À N

CANALE, in Geography, the chief town of a county of the same name in the department of Côte, or island of Corsica, and district of Balita, containing 8,977 inhabitants.

CANALES, in Ancient Geography, a place of Italy, in that part of Magna Graeca called Magna Graeca, 30 miles from Lepanto, near the gulf of Caminum. Anton. Itin.

CANALICICUM aurum, or CANAHICUS, that gold which is dug out of mines, or veins under ground.

CANALICULATA, in Conchology, a species of BULLA, described by Linnaeus, the shell of which is cylindrical, and the whirls of the spine ground. Obs. This is brownish or tesselaceous, clouded with a paler colour. Native place unknown.

CANALICULATUS, a species of TURNO found in India. This shell is fulcated, and transversely frilated; colour white, varied with green, and sometimes chequered; whorls of the spine fix, and very convex. Chemnitz, &c.

CANALICULATUS, in Entomology, a species of Cerambyx (Priarus) found in the West Indies, but rarely. The thorax is cremated at the margin; dorsal groove villose and white; antennae short. Fabr. This interesting species is described by Fabricius from a specimen in the museum of Dr. Hunter; another occurs in the cabinet of Mr. Donovan.

CANALICUM, in Ancient Geography, a place of Italy in the Aurelian Way, in the passage from Rome to Arethusa by the Maritime Alps, 12 miles from Vada Sabbatha (Anon. Itin.) it is also called Canadunum, and is marked in the map of M. d'Anville in Liguria, towards the N.W. of Savo.

CANALIS, in Entomology, a species of BRUCHUS, of a small size, that inhabits India. The colour is somewhat ferruginous; wing-cases black at the tip; tail black; central line white. Fabricius.

CANALIS is used by Surgeons for an oblong, concave instrument, in which to put a broken limb, leg, or thigh. It is made either of brass, wood, or earthen ware, sometimes even of hair fitted with linen cloth.

CANALIS arteriosus, in Anatomy, the vessel which joins the trunks of the pulmonary artery and the aorta in the fetus. See Fetus.

CANALIS carotidus, a canal in the petrous portion of the temporal bone, through which the internal carotid artery enters the cavity of the cranium, and a small nerve passes from the sixth pair to the superior cervical ganglion of the great sympathetic nerve. For the description of this canal, see Skeleton.

CANALIS medius, the canal of communication between the third and fourth ventricles of the brain. See Brain, description of.

CANALIS nafalis, the tube which conveys the tears from the lacrimal bag into the nose. See Eye, Anatomy of.

CANALIS natri. See Vagina.

CANALIS testis. See Vagina.

CANALIS transvers, a branch of the umbilical vein, which terminates in one of the hepatic veins in the fetus. See Fetus.

CANALIS Trochanterius, and CANALIS Trochoideus. See Canal, sphyra.

CANALIS, semicircular, of the petrous portion of the temporal bone. See Ear.

CANALUVII Montes, in Ancient Geography, mountains of Macedonia, so called by Polybius, and supposed to be the same with the Canaliac of Livy, and the Canaliacus montes of Ptolomeus and Strabo; situate in the country called Thrace.

CANANDAQH, in Geography, a port town, like, and creek of America, in Ottoman country and state of New York. It is the five town of the county, lying on the north end of the lake of the same name, at its outlet into Canandaga creek. The lake is about 25 miles long, and broad, and conveys its waters in a N.E. and E. course, 35 miles, to Seneca river. This is the site of an ancient Indian town of the same name, and stands on the road from Albany to Niagara, 16 miles. W. of Geneva, and 75 miles S.W. from the city of New York. It is now a flourishing town. By the late census of 1790, there appeared to have been 291 electors in this township.

CANANEA, a small oblong island of Brazil in South America, belonging to the Portuguese, opposite to the mouth of Araraqui river; on the south of which stands the town of Cananea, guarding the entrance of the bay. The island lies about 37 leagues from St. Vincent. S. lat. 25° 10'. W. long. 47° 12'.

CANANGA, in Botany, Jussieu p. 284. Aubl. Guian. tab. 243. Clas. and order, palmata polygyna. Nat. Ord. Annonas. Jull. Eff. Ch. Petals small, germes numerous, capsules or berries egg-shaped, peduncled, one-seeded. Jussieu observes, that the plant for which Aublet formed this genus, is probably a conger of Sonnerat's uvaria longifolia; Ind. p. 233. tab. 131, and also of Aublet's own genus Aberemoa, whose large berries have short partial peduncles. La Mareck has united Aublet's Cananga to the Limnanthes genus uvaria, which he calls in French Cananga, (see Uvaria Monosperma) and has of course also admitted Sonnerat's uvaria longifolia. Aublet's Aberemoa, which was accidentally omitted in its proper place in this work, is considered by La Mareck as a distinct genus nearly allied to uvaria, but not yet fully described, having been seen by Aublet only in fruit. The fruit of Aberemoa is held by Aublet to consist of a roundish head of dry, egg-shaped, one-seeded, one-seeded berries, supported by a common peduncle two or three inches long. It is produced by a tree which is a native of Guiana, the bark of which is blackish; the wood white and hard; and the leaves alternate, simple, about a foot and half long, and five or six inches broad, lanceolate egg-shaped, acuminate, rather thick, firm, pubescent, entire.

CANANI, in Biography. See CANANUS.

CANANO, in Geography, a town of Naples, in the province of Calabria Ultra; 2 miles S.S.E. of Reggio.

CANANOR, a sea-port town of Hindoostan, on the western coast of Malabar. It was taken possess of by the Portuguese towards the close of the 16th century; and about the year 1500, Almeida, the first Portuguese viceroy of India, obtained consent of the king of the country to build a fort, and to secure it with a garrison. From that time it became a large and populous city, inhabited chiefly by Mahometans, and carrying on a very considerable trade. In the year 1665, it was taken by the Dutch, who, considering the convenience and importance of its situation, established a factory there. The adjoining country supplied abundance of rice, sugar, pepper, and other valuable commodities; so that no less than 200 ships arrived annually in this port. However, the Dutch sold it in the year 1770 to the sultan of Anchediva or Angeleva, for the sum of 100,000 rupees. It was taken by the English, under general Abercrombie, on the 17th of December, 1750. Cananor is distant 15 miles N.E. from Tellicherry, and 100 W.S.W. from Serigapatam. N. lat. 11° 55'. E. long. 75° 14'.
CANANUS, John Baptist, in Biography, one of the refiners and improvers of anatomy, was born at Ferrara, in Italy, in the year 1515, where he acquired so much reputation for his skill in medicine, that he was invited to Rome by pope Julius III., who made him architect, and his principal physician. On the death of the pope he returned to Ferrara, and pursued his anatomical researches. He first discovered the valves of the veins, which were afterwards more completely described by Vesalius. The work by which he is known, of which only four complete copies are said to be in existence, is “Museolus Anatomia Corporis Prima,” 1604. printed, Haller thinks, in 1553, no date, or place named. The figures, 37 in number, are neatly engraved on copper. They represent the muscles of the upper extremities. In the preface, he promises a continuation of the work, which he probably did not finish. He died in 1579.

CANAPlES, in Geography, a town of France, in the department of the Somme; 10 miles N. of Amiens.

CANARA, a country of Hindooftan, belonging to the kingdom of Mysore, about 60 leagues in length along the coast of the Indian Sea, and from 10 to 30 broad. Its principal places are Mangalore, Barcore, Onore, and Cavar, which are all respectively. This district is one of the acquisitions gained from Tipoo Sultan in 1790. Canara has a peculiar dialect, which extends as far as Goa.

CANAR-ATAN, or Great Canar, a village dependent on the city of Cuenca, under the jurisdiction of the province of Quito, in Peru. It is remarkable for the riches contained in the adjacent mountains.

CANARD, in Ornithology, among the French, has the same application as duck with us, and annual amongst Latin writers: vide Buffon, and others. In the common phraseology of France, it literally implies the domesticated duck.

CANARDER, Fr. is a term of reproach, when applied to a hauhois player; implying, when his reed fails, that he quacks and cackles like a duck.

CANARDER, in Military Language, denotes to shoot, fire, discharge, or throw any thing at or on an enemy with advantage, or from a covered, secure, and advantageous situation, as out of a small turret, guerite, or centry-box, from behind a hedge, dike, or fence, between pickets or paille-fades, from walls with embrasures or loopholes, &c.

CANARDIERE, a small turret, guerite, or centry-box, sometimes made of wood, and sometimes of stone. Such boxes, or guerites, are occasionally erected or placed at the faintest angles of works as places of shelter for centenels, and for them to fee from under cover. They used formerly to be constructed on carriages for people to shoot, fire, discharge, or throw any thing from, unseen, in un molested security.

CANARIA, in Ancient Geography. See Canary.

CANARIA, in Ornithology, a species of Fringilla, familiar to every one by the title of Canary Finch, or Canary bird. The species is thus defined: bill and body yellowish white, with the quill and tail feathers greenish. Linn. Fr. Suec. &c.

The canary bird in a state of nature is of a plain grey colour, with the down at the base of the feathers black, or blackish; the tail is somewhat forked, and the legs pale. They inhabit chiefly the Canary islands, but are also found in other contiguous places. Forster observed them at Cape Verd, Fayal, and Madeira, where they are said to frequent watery places, abounding most among the fedges on the banks of rivulets.

M. Adamson remarks that the canary bird, which becomes white in France, is at Teneriffe almost as grey as a linen; but the change he supposes is to arise from the coldness of the climate. The colour is also susceptible of considerable variation from the diversity of its food, from captivity, and especially from the intermixtures with other species. So early as the commencement of the last century, Buffon observes, that bird fanciers reckoned in the single species of canary bird no less than nine and twenty varieties, every one of which was so distinct from each other as to be easily pointed out.

It may not prove altogether uninteresting in this place to enumerate the principal varieties of this fancy bird in the natural order through which they may be traced, beginning with those which approach nearest to the primitive species.

Common canary Finch, of a grey colour with the down black, as in the wild bird found in the Canary islands.

Grey canary Finch, with the down and feet white.

Grey canary Finch, with white tail.

Common flaxen canary Finch.

Flaxen canary Finch, with red eyes.

Flaxen canary Finch, with plumage gosled with a golden hue.

Flaxen canary Finch, with the down fair, or unmixed with black.

Flaxen canary Finch, with white tail.

Common yellow canary Finch.

Yellow canary Finch, with the down yellow and unmixed with black.

Yellow canary Finch, with a white tail.

Common agate coloured canary Finch.

Agate coloured canary Finch, with red eyes.

Agate coloured canary Finch, with white tail.

Agate coloured canary Finch, with the down of the same colour.

Common yellow-dun coloured canary Finch.

Yellow-dun coloured canary Finch, with red eyes.

Yellow-dun coloured canary Finch, with plumage gosled with a golden hue.

Yellow-dun coloured canary Finch, with down of the same colour.

White canary Finch, with red eyes.

Common variegated or spangled canary Finch.

Variegated canary Finch with red eyes.

Canary Finch, variegated with fair or flaxen colour.

Canary Finch, variegated with flaxen colour, and having red eyes.

Canary Finch, variegated with black.

Canary Finch, variegated with black and fine yellow, and having red eyes.

Canary Finch, regularly spangled with black and fine yellow.

Crofled canary Finch.

Canary Finch entirely of a full yellow.

Canary Finch of a yellow colour, mixed with brownish grey or greenish; which last, Dr. Latham observes, he has frequently seen in Chinese drawings, but whether they were caged birds or not he was unable to ascerten.

The above-mentioned kinds of canary birds are again subdivided into an amazing number of varieties, some of which are remarkable for beauty, and others are no less esteemed for rarity, or melody of song. All these may, however, be comprehended under two general heads, the variegated kinds, and those with the plumage plain; or, as it seems they are denominated in London by bird fanciers, the spangled.
Canaria.

gold and the gay birds. Writers observe that the white canary finches are never variegated, neither are the citron coloured; but when the latter have attained the age of four or five years, the extremities of the wings and tail become white. The grey are not of an uniform colour, for there are feathers more or less grey intermixed in their plumage, and in many of those birds the grey is lighter or darker, and more or less inclining to brown or black. The agates are of an uniform colour in general, but liable to vary in the intensity of their hues. Those inclining to a cream colour are still more uniform; the yellow is confluent both in the same bird, and in different individuals. In the variegated or spangled birds those that are of a jonquill yellow are tinged with black, and there is generally a spot of black on the head. There are variegated individuals with all the simple colours above-mentioned, though those of the jonquill colour are such as are more commonly variegated with black.

These varieties are not the spontaneous offspring of the common canary finch; but of that bird crossed with the Ventorun, and Gin, or Serin, two species very nearly allied to the canary finch, and both which inhabit the south of Europe. It is by this means, as well as by pairing the canary finch with the goldfinch, linnet, yellow-hammer, chaffinch, and even the domestic sparrow, that so many varieties are produced. The canary bird proves fertile with the fink-kin and goldfinch, but in this case the produce for the most part proves sterile; the pairs succeed best when the hen bird is the canary, and the cock is of the opposite species. Indeed it has been remarked that the male canary bird will not beget with the females of any of the before-mentioned species, and that the cross breed can only be procured by means of the hen canary. The two birds with which the canary intermingles its breed the best, as already stated, are the Serin, or Fringilla Serinum, and Ventorun or Citril, Fringilla Cetinella. The fern is a bird of small size, being rather less than the common linnet. Its upper masdible is brown, the under, whitish: the plumage above, brown, mixed with yellifh green; beneath, greenish yellow, and having the sides marked with longitudinal spots of brown: the wings are marked with a greenish band: quills and tail brown, edged with greenish grey, and the legs brown. This kind is found not only in Italy, but in Greece, in Turkey, Anitlia, Provence, Langtudoe, Catalonia, and probably in all the climates of that temperature. There are, however, certain years in which it is very rare, even in the southern provinces of France. Its song is agreeable and varied, but the song of the female is inferior to that of the male. The citril finch is larger than the ventorun, and has a louder note; it is indeed remarkable for the brightness of its colour, and for the strength and variety of song. The female is somewhat larger than the male, has less of the yellow in its plumage, and does not sing so well, or rather answers him, as it were, by much syllables. It is found in Provence, Dauphiny, Geneva, Switzerland, Germany, Italy, and Spain. In Burgundy it is known by the name of the canary. The plumage on the upper parts is of a yellowish green, spotted, or variegated with brown; beneath greenish yellow: wings dusky and greenish, and the legs flesh colour. We conceive it right to be thus particular in pointing out the characters of the two latter birds, since they have been most commonly confounded as varieties of the canary finch, which alone is found in the Canary islands; and from which they differ specifically, although in general appearance and manners of life they nearly approximate. It is with those two primitive species that the canary bird is commonly crossed with most species, and from the union of which many of the more esteemed varieties of the common canary bird are produced. They are reared chiefly by the Germans and Italians, both of whom are celebrated for their skill in improving the natural notes of the canary bird by tutition. Most of the canary birds, we are told, that are imported from the Tyrol, have been brought up by parents, the progenitors of which were induced by the Nightingale. Our English canary birds have commonly more of the tit-bird note. The principal place for breeding canary birds is Fuhneck and its environs, from whence they are sent to the Levant, and every part of Europe.

Canary birds are bred in large quantities, both for sale and amusement, in England, as well as in Germany, France, and other countries; and in each of these countries they have, by behoving due attention to the subject, very much improved the breed beyond those imported from the Canaries. They are of different colours, yellow, white, buff, grey, and green, with an endless variety of combinations arising from the different shades of colour in the parent birds. Those brought from Germany are generally variegated, or mottled, and are the least valued, because the heat of the flowers, generally used to warm the boxes in that country, renders the birds bred there tender and short-lived; German birds seldom live above two or three years in this country: whereas the canary birds bred in England in the usual way are bred to live eight or ten years. Olina tells us they commonly live 10 or 15 years; Sakele says 18, and we have known individuals that have survived for a still longer term of years.

The cock of the German kind is highly valued for its singing, having a very sweet note, which it continues for some time in one breath without intermission; and raises higher and higher by degrees, with great variety. In this bird the fore part of the head, the throat, the pinion of the wing, and the rump, in the cock bird, are of a brighter yellow than in the hen, which mark will hold good in all the canary birds, of whatever kind they may be. The cock is also bigger than the hen, his carriage more sprightly and majestic, and he is observed frequently to extend his neck and head in a very brilh and lively manner. The hen sings indifferently, in no case indeed as scarcely to deserve the name of singing. Whenever the cock sings, his throat may be seen to swell, and play all the while he is warbling, but in the hen there is no such motion. The Hon. Daines Barrington has written an elaborate treatise upon the notes of singing birds, in which those of the canary bird are treated upon at some length, and which may be confided with much satisfaction by the curious reader. Vide Phil. Trans. v. 67. See Soe of birds.

Among a variety of other farts, there are two kinds of canary birds in particular that are much esteemed among breeders; namely, those birds which are all yellow, and those which are mottled and have a yellow crown; the former, in the breeding style, being called gay birds, and the latter spangled, or fancy birds. The fancy breed are esteemed the strongest, and have the boldest song. Caricots breeders often match a gay with a fancy bird, and then the produce, partaking of both kinds, are called males, being soft irregular birds, and of no value for feathers, though they may prove as good as any for singing. If you propose to breed gay birds, choose the cock and hen of a clear uniform yellow colour, without being spotted with foul feathers; for these indicate that the breed has some time before been crossed. There are several subscription societies in London, which raise annual premiums for those who rear the finest birds, and who have a pattern bird painted, or engraved and coloured, as a standard of perfection, with his various characters explained in technical terms. The principal test of a good fancy bird confidts in his having a clean cap, i.e. the crown of his head defined by a horizontal line at the level of his eyes, and black, is to be of a clean yellow or white, without being broke or spotted.
will be fed with fish feathers, or a single feather of this description is considered as a drawback from his perfection, though the degree of perfection is seldom found. Add to this, that its birds, whether white or yellow, ought to be as clear from yellow or white feathers. The inner is notched on the back, and lighter yellow help on the belly, the handfeemer he will be delighted. These general characters are equally requisite in the hen as in the cock, besides which there is a casual variety in fancy birds, distinguished either as males or females; the males being those whose crown and bellies are of a clean white or pale yellow, and the junks such as have their crown, and belly of a deep yellow. The fine spangled fort, commonly known as French canary birds, and the mealy ones, are the best to breed with for those who are very curious; because a spangled cock with a mealy hen will produce a more regular spangled feather than if the cock and hen were both spangled, as they would then breed too high upon the yellow.

When individuals of an uniform colour are paired together, their young are of the same colour; a cock and hen that are grey generally produce grey birds; but if a male grey is put to a female white, or male white to a female grey, the brood will be more beautiful than the parents; and as the numbers that may be crossed by such combinations are innumerable, we can at all times produce varieties in shade and tint, that have not appeared before. The mixtures that may be made of the spangled birds with those of an uniform colour increase still more the number of combinations that may be produced, and thus varieties in the species may be multiplied without end. It is no more often happens, that without the aid of fancy birds, we have pretty little variegated birds which owe their beauty to the mixture of different colours in their parents or progenitors, some of which either by their father or mother's side may have been variegated.

With regard to the mixture of other species with the canary bird, the following observations have been collected. The birds that come from the junction of the citril, the siskin, and the goldfinch, with a hen canary bird, are generally stronger than those from a cock and hen canary bird. They sing longer; and their voice is more sonorous and strong, but they are taught with difficulty; the greater part always whistle imperfectly, and it is seldom one can be found that is able to repeat a single air correctly, or without muffing.

When we wish to procure birds from a mixture of the goldfinch with a hen canary bird, the former must be two years old, and the latter one; because the canary bird comes sooner to maturity than the goldfinch, and in general they succeed best when they have been bred up together. But this is not absolutely necessary; neither will the hen that has formerly hatched with a cock of its own species always refuse the male of another species, as father Bougot had an opportunity of ascertaining. I happened (says Bougot) to put four male canary birds to eight females of the same species; some bad feeds poisoned three of the males, and all the females lost their first eggs; I resolved to substitute three male goldfinches taken in a trap in place of the three dead canaries, and I put them into the cage about the beginning of May. Towards the end of July I had two nests of mongrels, which succeeded to admiration; and the following year I had three broods with each goldfinch and hen canary bird. These last in general do not breed with the goldfinch till they are a year to four years old, and seldom after, while with their own species they continue to hatch for nine or ten years. The common variegated female alone will breed with the goldfinch beyond her fourth year. A goldfinch must never be let loose in an aviary, for he destroys the net and breaks the eggs of the other birds. Hence we perceive that the hen canary birds, although accustomed to the males of their own species, will yield to the canary of the goldfinch, and will breed with these birds successfully. Their union with thefe is even as fruitful as with their own natural males, since they lay three times in the year with the goldfinch. It is not so in the union of the male linnet with the hen canary bird; there being in that case only one brood, or very seldom two in the course of the year.

The bastard birds, which proceed from the canary, and the siskin, goldfinch, and some others, are by no means inferior, but mongrels that can pair and propagate, not only with the goldfinches or the canary birds indiscriminately, but also among themselves, and produce offspring that can pair and perpetuate their varieties. But it must be owned that the produce of these mongrels is not so certain nor so numerous by any means as in the pure or unmixed species; they seldom hatch more than once in a year, and often lay eggs that are added. Their successful production depends on many little circumstances that cannot be discovered, far less pointed out. It is said, that among the crofs breeds there are always many more males than females. A female canary bird and a goldfinch, paired by Bougot, produced, in the same year, at three hatchings, nineteen eggs that were all fertile; among which there were only three females, the remaining sixteen being all males. When a person wishes to pair the canary bird with the goldfinch, it will be best to take young goldfinches of ten or twelve days old from the nest, and put them into a nest with canaries of the same age. He should feed them together, and leave them in the same cage, allowing the goldfinch to the same food as the canary bird. It is usual to put a cock goldfinch to a hen canary bird, as they pair more easily, and prosper better than the cock canary bird and hen goldfinch. It must, however, be observed, that the brood in the first case is later, because the cock goldfinch and hen canary bird do not pair so quickly as the canary cock. But when the female goldfinch is put to a male canary bird, the pairing takes place much sooner. To succeed, a male canary bird is never to be put into a cage where there are females of its own species, for then he will prefer these to female goldfinches.

The union of the male canary with the female siskin produces exceedingly well. A female siskin, confined in an aviary for nine years, was known to have for the first five years three broods annually, and for the remainder of the time two broods a year, all of which prospered. Linnets and canary birds have been put together, but they seldom breed unless the cock linnet be put with the hen canary bird; the female linnet will not even make a nest, but drops a few eggs in the cage, which are generally added, so that it is needless almost to compel the hen to sit upon them. The chaffinch and yellow hammer are, with great difficulty, made to pair with the canary bird. A female yellow hammer has been left with a male canary for three years, during all which time the female laid only added eggs; and it is just so with the female chaffinch, but the cock chaffinch and yellow hammer with the hen canary bird have produced some fertile eggs.

It follows from hence, and various other facts, that the siskin alone will breed with the canary bird equally well, whether male or female; the hen canary bird produces likewise easily enough with the male goldfinch; not quite so easily with the male linnet; and lastly, that it will breed, though more reluctantly, with the males of the chaffinch, the yellow hammer, and sparrow, while the male canary is incapable of fecundating the females of any of the last, or at least that the latter very rarely succeeds when paired with them.

The dispositions of canary birds are extremely variable. There are some cocks that are always melancholy, and even fallen, sitting seldom, and then in a dimsl strain; they are long in learning, and learn at last, but imperfectly, what you
reaching them, and that which they acquire they very soon forget. They are often as melancholy that their feet and tail are constantly dirty; and they do not please the female, whom they never regard with their song, not even when their young first appear. There are others so wicked that they will kill the hen they are put to, and the only way to tame them is to give them two females, who join for their common defence, and when they have once vanquished by force, the male becomes tame, and they encourage their caprices afterwards by tenderness and love. Some of the males are so ferocious as to break and eat the eggs when the hen has laid them; or, if this unnatural father allows her to hatch them, the young are fearfully excluded from the shell of the egg, then he forces them with his bill, draws them from the nest, and kills them. Others are so wild and ungovernable, that they will neither allow themselves to be touched nor cared for; they must be left at liberty, and cannot be treated like the others; if they are muddied with in the heat they will not breed; their eggs must not be touched, nor taken away; and they will not hatch if they are not suffered to pair or build as they please. And lastly, there are some of an indolent disposition; such, for example, are the grey ones; these never build, and the portion that attends them must make a nest for them. All these tempers are very different, and very different from favourite canary birds that are well-trained: these are always gay, always singing, agreeable, of a happy disposition, and endowed with the best inclinations.

The bad disposition of the canaries frequently proceeds from mismanagement. When they break their eggs and kill their nestlings, they are oftentimes governed by the impulse of impetuous love, and it is to enjoy the female that the male drives her from the nest and destroys the tender objects of her affection. Accordingly, the best means of making such birds hatch is not to put them into different cages. It is better to place them in a room well exposed to the sun; and to the east in winter, where there are many hens and only few cocks, for then they will enjoy themselves more, and multiply better. When a hen fits, the cock finds himself another mate, and does not disturb her. Besides, the cocks have many quarrels among themselves from jealousy; and when they see any one too ardent as to torment the female and attempt to break the eggs, they beat him so severely as to punish him effectually for his temerity.

When the canaries are about to build, they should be furnished with lint, or flares of linen, hair of oxen, moss, and very small and dry straw. Goldfinches and skylins, if put with hen canary birds, when male birds are wanted, prefer small straw and moss, but the canary birds like hair and lint: these should be cut very small, for fear the threads should entangle the feet of the hen, and cause her to pull the eggs from the nest as the rains from it.

For feeding them, you must place in the room a hopper, pierced all round so as to admit their heads, filled with a portion of the following composition: three quarts of rapeseed, two of oats, two of millet, and two of hemp-seed. Every twelve or fourteen days the hopper is to be filled, taking care that the seeds are clean and well winnowed. This food is proper as long as they have only eggs; but the evening before the young are excluded, they must have a dry cake kneaded without fat, which may be left till it be eaten, and then you may give them eggs boiled hard; a single hard egg, if there are but two cocks and two hens, or more, in proportion to the number of birds. They must have no vegetables while breeding, that would weaken the young too much; but, in order to vary their food a little, give them every third day, on a plate instead of the dry cake, a piece of white bread dipped in water, and pressed with the hand; this bread not being such substantial food as the cake will prevent them from growing too fat when hatching. It will likewise be proper to give at the same time some poppy seeds, but only once in two days, for fear of heating them too much: sugar beetens generally produce this effect, which is followed by another still more hurtful; for when they are fed on beets they often lay addition eggs, or bring weak and sickly young. While they have young, it is recommended to boil their rape, to deprive it of its acrimony.

After the eggs are laid, give the canary birds plantain and lettuce seed to purge them. The food of the nestlings, when hatched, must be prepared: it should be a paste composed of boiled rape seed, a yolk of an egg, and crumbs of the cake mixed, and kneaded with a little water, which is to be given to them every two hours. This paste must not be too liquid, and, for fear of its turning sour and injuring the birds, it should be renewed every day till the young can feed themselves.

Canary birds are distinguished by different names, according to their age. Such as are about three years old, are called uncles; those above two, are named cfeijis: those of the first year, under the care of the old ones, are called branchers: those which are new born, and cannot feed themselves, plofles; and such as are brought up by hand, wijings.

The brood of birds in a state of captivity is not so constant, but it is, perhaps, more numerous than it would probably be in a state of native freedom; for there are hens who will hatch four, or even five times a year, laying four, five, or six, and sometimes even seven eggs at a time; in general, they have three broods, and the moult prevents their having more. There are hens, however, that hatch while they moult, provided they begin to fit before that time. Birds of the same nest do not all begin to moult at the same time. The weakest are the first to undergo that change; the strongest are often a month later. The moult of junquin canary birds is more tedious, and generally more fatal than that of the others. The hens of these junquin birds lay only twice, with three eggs each time; the light-coloured ones, both cock and hen, are too delicate, and their brood seldom prospers. The cream-coloured canaries have some repugnance to pairing with one another, and in a large aviary it almost constantly happens, that a cream-coloured male will make choice of a female entirely of another colour. In general the white ones, however, pair, build, and hatch together, and commonly succeed better than when a white one is paired with another of a different colour.

Notwithstanding the difference in the disposition, temperature, and fertility of these birds, the time of incubation is the same in all. They uniformly fit thirteen days, and when it happens a day less or more, it is owing to some accidental circumstance; cold retards the exclusion of the young, and heat accelerates it. Accordingly, it happens sometimes, that the first hatching in April lasts thirteen days and an half, or fourteen days, if the air is at that time cold; on the contrary, the third hatching, which happens during the great heats of July or August, lasts only twelve days and a half. The bad eggs ought to be separated from the good; but in order to know them certainly, you should wait till they have been fat upon for eight or nine days, then take each egg by the two ends for fear of breaking them, and hold them against the sun, or a lighted candle; those which appear clear are to be rejected as it would only fat the hen to no purpose to leave them in the nest. In thus separating the clear eggs from the complement of three, we may select only sufficient to make up two of

Vol. VI.

L 1
them; and the third hen being released from fitting, will proceed to lay again. It is a practice much recommended by bird-fanciers, to take away the eggs as the hen lays them, substituting an ivory one in the place of each, that the whole may be hatched together. When the last egg is laid, the ivory ones are removed, and the others replaced. In general, the time of laying is in the morning, about six o'clock; it is said, when this happens an hour later, it is owing to the hen's being sick; the eggs being thus laid in regular succession, it is easy to take them away the moment they are laid. However this practice is more adapted to our own convenience than to that of the bird, and is contrary to the economy of nature: it causes the mother to part with a great deal of heat unnecessarily, and burdens her at once with five or six young which incommodate her more than they give her pleasure, while when she sees them come successively one after the other, her pleasures are multiplied, and her strength and courage supported; accordingly, some very intelligent bird-fanciers assert, that the natural way has always succeeded better than the above-mentioned practice.

In their native country, canary birds haunt the banks of little rivulets and other watery places; we should not, therefore, suffer them to want water, either to drink or bathe in. As they are natives of a very mild climate, they must be defended from the rigour of winter, although from long habit, they are now so far naturalized to our climate, as to live very well during the winter in a room without fire: some breeders accustom them even to live all the winter in a room with the window or windows open, and only guarded with a net-work to prevent their escape. It is seldom that canary birds brought up in a chamber fall sick before hatching; sometimes a few cocks will over-eat themselves and die; if the hen grows sick while she is fitting, her eggs must be taken away and given to another; for though she should get better soon, she will not return to her nest. The first symptom of fickleness, especially in the cock, is melancholy; whenever he is observed to lose his natural gaiety, he must be put in a separate cage, and placed in the sun in the same room with the hen. If his feathers appear rough, you must look if he has not a pimple on the rump; this the bird sometimes opens with his bill, but if not, it should be pricked with a large needle, and the wound anointed with salves, without mixing any salt with it, which would smart it too much. The most general cause of fickleness is too abundant, or too rich food; when these birds are made to breed in a cage or closet, they often eat too much, or select the succulent food intended for the young, and hence arise the ill-effects of repulsion, or inflammation. By keeping them in a room, this may be in a great measure prevented; because, being among a great number, they hinder one another from eating to excess. A cock who eats for a long time is sure to be beaten by the other males; and the same is the case with the hens; these quarrels give them exercise, temperance, and occupation; and it is chiefly on this account that they are seldom or never sickly in a chamber during the breeding time; it is only after hatching that infirmities and diseases attack them. The greater part of them become afflicted with the pimple before mentioned, and afterwards all of them are subject to moult. Some support this change of slate extremely well, and do not fail to sing a short time every day, but most of them lose their voice, and some even die. When the hens have attained the age of six or seven years, they moult with difficulty, and many of them die. Young canary birds moult early in the year: about six weeks after they are hatched they become melancholy, appear rough, and put their head under the wing. Their down falls in this first moulting, and in the second, the following year, the large feathers, including even those of the wings and tail, fall off. Cold weather is unfavourable to the canaries while moulting, and they would all die at this time, were they not kept in a temperate, or rather in a warm place. The usual time of moulting is about six weeks or two months.

The most fatal, and common disease that the young canary birds are subject to, is what is called the fitchet, in which their bowels tend to the extremity of the body. The intelleves are seen through the skin in a state of inflammation, redness, and distention; the feathers on that part fall off, the bird grows emaciated, gives over eating, though he sit by his meat, and dies in a few days. The cause of this disease is the too great quantity, or succulent quality of the food. All medicines are fruitless; diet alone can save a few out of a number of birds thus affected. They must be put into separate cages, and nothing given to them but water, and lettuce-feed; this food is cooling and purgative, it tempers the ardour that consumes them, and sometimes occasions evacuations that save their lives. In short, we may observe, that this disease proceeds solely from our method of rearing these birds. We ought, therefore, to be particularly cautious of over-feeding them, when we bring them up: boiled rape-feed, a little ground meal without sugar, or biscuit, and in general rather too little than too much food is to be recommended.

When the canary bird utters a faint and frequent cry, which seems to issue from the bottom of his stomack, he is said to be athermic; he is also subject to a sort of extinction of the voice, especially after moulting. The aphthosis is cured by administering plantain meal, and hard biscuit soaked in white wine, and the voice may be restored by giving him for food the yolk of eggs mixed with crumbs of bread, and for his drink, water in which lozenges root has been steeped and steeped, or if boiled in it, so much the better. Canary birds are likewise affected with ulcers in the mouth, which are suppoosed to proceed from a supersumbance of succulent food, as in the former cases: these ulcers commonly occasion an inflammation in the throat, and palate, which can only be cured by administering a cooling diet, and for this purpose nothing can be better than lettuce-feed, with a few seeds of the melon bruised, and infused together in water. The impothesis is another disorder to which the canary birds are liable the most approved medicine for this disorder, we are told, is to anoint the root of the head for two or three days with an ointment made of fresh butter and eapon's grasse melted together. After anointing the head three or four times, it should be examined, to see whether the part of his head affected be soft; and if so, open it gently and let out the matter, which will be like the yolk of an egg. When this is done, anoint the wound, and the bird will soon be cured. Unless this precaution be taken, the canary birds afflicted with this disorder are very apt to fall down suddenly and expire. These birds are also infected with a peculiar sort of loath, and scab, owing to the slovenly manner in which they are kept by some people. Care should be therefore taken to have them always clean, to give them water to bathe in occasionally, to be choice in their food, and never to put them into cages of old wood. Thoe cages it has been recommended, to have made either of walnut-tree, or oak with bars of wire. Cages of the usual cylindrical form are objected to as being improper, since they allow the birds very little place.
little room to walk in, and without this exercise they become melancholy; or at least, lose a considerable share of their natural vivacity: the cages that are constructed of a lengthened form, high, and narrow, are the best adapted to the purpose of breeding and rearing this beautiful song-bird, when the breeder cannot devote a room to that object alone.

CANARIENVOGEL, according to Frisch the canary bird: Fringilla canaria.

CANARIE, Fr. a quick dance in jig time. The word is twice used by Shakespeare,—"Canary to it with your feet."—Love's Labour lost.—"And make you dance canary with spirits fire and motion."—W. Shakespeare.

Meroenne gives a specimen of the kind of movement. He says the caribollies are rapid, and the figure extremely difficult.

Purell has canaries in his museck to Dioclesian. The tune is said to come originally from the Canary islands.

CANARI, in Ancient Geography, a people of Africa, who inhabited the district towards the south-east of Mount Atlas. Pliny mentions them, and says, that they eat the flesh of doves.

It differs from Campanula only in number; a difference which, if allowed to be a sufficient generic distinction, will confer many species from the genera in which they have been very naturally placed, and have long quietly flourished. Linn. Mant. 225. Wild. Mart. Linn. fil. Pl. 259. Bot. Mag. 144. Sp. I. C. caneranulta, (C. caneranula, Linn. Sp. Pl. 239. Tourn. 159. Pink. Alm. tab. 276. fig. 1.) "Stem erect; leaves halbert-shaped, in three or opposite." Root perennial, spindle-shaped. Stem three feet high. Herbageous, erect, rather feble, round, even, notty, branched; branches two or three from each knot; upper ones longer, dichotomous at the end; little branches alternate. Leaves on the stem by threes, or three branches opposite, petioled, unequally toothed, even, veined. Flowers from the forks of the upper branches large, peduncled, drooping; corolla reddish-yellow, or orange, brighter at the bottom, with a yellow eye; each segment marked with three purple branched nerves; anthers yellow. A native of the Canary islands, whence the genus, though not very properly, has derived its name. 2. C. Zanguebar, Lour. Cochinch. 1975. "Stem climbing: leaves halbert-shaped alternate." Stem shrubby, round, even, branched. Leaves heart-halbert-shaped, quite entire, smooth, veined, petioled. Flowers solitary, lateral: corolla pale-colored. Capule somewhat egg-shaped, sharp at the base, fix-nerved, opening at the base, seeds heart-shaped, compressed, surrounded by a turbinate ring, odorous. A native of Zanguebar on the coast of Africa.

Propagation and Culture. The seed species only has been cultivated in Europe. It is propagated by parting the roots, which should be done in July, soon after the plants are decayed. It succeeds well in a light sandy loam, with a fourth part of screened lime-rubbish. The pots should at first be placed in the shade, and unless the season be very dry, should not be watered. About the middle of August they should be placed under the hot-bed frame, and as the nights grow cool, covered with the glass. When the plants appear, the plants should be sometimes, but not often, refreshed with a small quantity of water. About the middle of September they should be removed into a dry airy glass-house, where they may enjoy the free air in fine weather, and yet be screened from cold. They flower from January to March, when they should be frequently watered. In spring, when the flowers begin to decay, the pots should be set abroad in the shade and not watered. Miller.

CANARIUM, from canarius, in Antiquity, a Roman sacrifice, wherein dogs of a red and ruddy colour were sacrificed, for a security of the fruits of the earth against the raging heats and disorders of Sirius in the dog-days.

Gen. Ch. Male. Cal. Perianth two-leaved; leaves egg-shaped, concave, permanent. Cor. Petals three, oblong, resembling the leaves of the calyx. Stam. Filaments five, very short; anthers oblong, the length of the petals.

Sp. 1. C. commune. Linn. Mant. 127. (C. vulgare Rumph. Amb. 2. p. 145. Tab. 47.) B. C. Mehemebenthe, Gart. tab. 102. fig. 1. A robustous lofty tree. Trunk covered with a whitish bark; wood whitish, tolerably solid, but not durable. Leaves alternate, unequally winged; common petals flayed; leaflets nine, large, petioled, oblong, egg-shaped, acuminate, even. Flowers whitish, felvile, slightly variegated panicles, which terminate the branches. Gartner affirms that the commune of Linnaeus, and the mehemebenthe are mere varieties of the same species. He has figured the fruit of mehemebenthe, and given the following description. Drupes superior, berried, acuminate-egg-shaped; skin olive-coloured, thin; pulp small in quantity, full of capillary fibres: shell bony, egg-shaped, either slightly pitted or even, trigonous, three-celled, with three obtuse teeth at the tip, marked with three obscure lines on the sides, and perforated through its whole length with a thread-shaped auxiliary canal. Seeds oblong-egg-shaped, two in each cell, only one of which comes to maturity. The drupe of the other variety is a little larger, and the pulp without fibres. The shell is more sharply triangular, and its sides are perfectly smooth, nearly flat, without the middle raised line. The fertile cell and seed are also larger. In the oldest feeds Gartner never found the kernel rancid, but always fresh, with a flavour resembling that of fresh almonds which, as he observes, is the more remarkable, because the cotyledons, when the integument of the seed is stripped off, seem beaummed with oil, are very slippery, and repel water. A native
A native of the Molucca Isles and New Guinea. The nuts are eaten by the natives either raw, or made into a kind of bread. An oil is also expressed from them which is used at the table. When eaten fresh they are said by Rumphius to bring on dysenteries, and to occasion an oppression of the bowels. 2. C. fimbriatus, or Nanarium. Rumph. amb. 2 tab. 49. Gart. tab. 102. fig. 2. Druef defays, infographic egg-shaped, round, not trigonous, as in the preceding; shell egg-shaped, finely, very thick, obscurely trigonous, marked with three depressed longitudinal lines, to which as many small callous tubercles are joined below the top of the shell; cells three, two of which are often abortive, the third very irregular, and lined with a very thick cartilaginous cutis. See oblong, trigonous, curved in the form of the letter S gibbons in contrary directions near each end. The kernel, on account of its singular form and brittleness, cannot be got out entire, unless the shell be opened carefully from one end to the other. 3. C. decamumnum, Rumph. tab. 55. Gart. tab. 102. fig. 2. Druef the largest of any in the genus; shell oblong-egg-shaped, triangular, thin, thick, with fix teeth at the tips; angles prominent, smooth, longitudinally furrowed; sides pitted with numerous oblong depressions as if they had been eaten by worms; auxiliary canal triangular; cells three, large. Seeds wanting in the specimen examined by Gartner. Professor Martin has represented the taft also as only varieties of C. commune: but it is evident, from Gartner’s descriptions and references to Rumphius, that he judged them to be distinct species.

Loureiro calls this genus Pimelea, on account of its oil, produce, but that name has been given for a similar reason to a very different list of plants, natives of New Holland and New Zealand. See Pimelea. Loureiro has added to the commune of Linnaeus, which he calls Pimelea alba, two other species which he found in Cochin-China and its neighbourhood. 4. C. nigrum. Leaves winged; flowers in lateral racemes; nuts two-celled. An oil is extracted from its kernel, not less agreeable than that of the olive, but heavier on the tumb. 5. C. oleiferum. Rumph. vol. i. tab. 54. Leaves pinnate with four pair of leaflets; peduncles lateral, many flowered; nut one-celled. The drupes are eaten like those of the first species; an oil for the table is likewise procured from them. When the bark is wounded, there exudes a yellowish, odorous, oily resin, similar to copal, which is used to varnish household furniture. The pulp is called Damar or Dammar in the East Indies, and used for the caking of ships, is composed of this resin, mixed with the bark of the bamboo reduced to powder, and a little chalk. It is preferable to all other sublances for this purpose with respect both to its durability and tenacity, and has not the smell of European pitch. Bofc. in Nouv. Dict. The trivial name given by Loureiro to the last species is a bad one, not being at all discriminative.

Canarium, in Conchology, a species of Strombus, found in the seas and great rivers in the southern parts of Asia. This shell is somewhat heart-shaped, with the lip round, short, retuse, and with the spire smooth. Linn. 86c. Length two inches and a half; colour yellow, or brown, with transverse fuscous angulated lines; pillar snowly white. The general contour of the shell remarkably vesticeof.

Canarium of Rumphius is the species of Strombus described by Linnaeus under the name of Giberulus.--Canarium is also the name given by Rumphius to the Linnaeian Strombus uncinus, which see.

Canaria, in Geography, a town of Poland, in the palatinate of Saxony; 16 miles W. of Sandomierz.

Canary, Grand, hill known by the name Canaria, given to it by Pliny and Ptolemy; one of the Canary islands, from which the general appellation is derived; situate between Tenerife on the west, and Forteaventa on the east, about 100 miles N.W. from Cape Bojador on the African coast. N. lat. about 27° 30′. W. long. 13°.

This island is about 100 miles in circumference, and the number of inhabitants amounts to 12,000. Pliny says, that it formerly produced a sort of doles, and pine-apples in great abundance. The soil, though light and sandy, is covered with a rich mould, which produces two harvests in the year. The wheat and other corn are reckoned very good; sugar cane are much cultivated; the vines yield those grapes from which the wine called fack, or canary; and the island abounds with excellent fruits, such as apples, pears, melons, figs, peaches of several kinds, and pluots. It has also plenty of horned cattle, flags, poultry, pigeons, and partridges. Wood is scarce. Filtering-stones constitute an article of traffic from this isle, as well as from Forteaventa. The capital of the island, and also of the Canary islands, is Palma or Canary: the other towns are Galdier, Trachana, and Luz.

Canary, called also Palma, in Latin Civitas Palmarum, and in Spanish Ciudad de Palmas, the capital of the preceding island. Although the governor and the chief people of distinction commonly reside at Tenerife, yet Canary is the see of a bishop, suffragan to the metropolitan of Seville in Spain, who usually resides in this town, and has a tribunal of inquisition. The royal audience, or sovereign council of the Canaries, over which the governor presides, is held in this town, and receives appeals from all the other islands. The revenues of the bishop, amounting to 100,000 a year, are almost entirely distributed in acts of charity through all the islands; and the present bishop (see Emb. to China, vol. i. p. 117.) joins to this humane disposition, the rigour of ecclesiastical discipline, and encourages the observance of ceremonies of piety, by offers of indulgence to those who practice them. This town is seated on the south-west side of the island, at a small distance from the sea. Its climate is temperate; its extent about a league in circumference; its cathedral is magnificent; and its houses, though only one story high, and flat at the top, are generally elegant buildings; it has four convents. The number of inhabitants is estimated at 12,000. N. lat. 25° 10′. W. long. 15° 30′.

Canaries, a clouter or groupe of islands in the Atlantic Ocean, situate about 150 miles to the west of the empire of Morocco in Africa, between N. lat. 27° 15′ and 30°. W. long. 13° and 15° 30'. They are generally sup-posed to have been the home with the Inuits, Bente, or fortunate islands of the ancients, particularly described by Ptolemy and the elder Pliny, and so called on account of the singular temperature of their climate, the fertility of their soil, and the excellence of their cultures. Ptolemy, however, if he meant these islands, has placed them 11° too near the equinoctial, or in the 16th degree of N. latitude, whence some have concluded, that this appellation belonged to the Cape de Verdu islands. But Strabo affirms them a situation which agrees with the observations of modern geographers. Some have derived their name from canis, dog, on account of the number of large dogs which were found on the island Canaria or Canary, two of which were presented to Juba, king of Maturitania. Others derive the origin of the name from the Cannaonites, or Phanicians, who are said to have often sailed from the continent to Carne, supposed to be a contradiction of Canary. The number of the Canary islands has been differently stated, both by ancient and modern geographers. Pliny and Ptolemy reckon fix; Plutarch and others mention only two; modern geographers have generally reckoned 13, exclusive of Madiera, which is at a con-siderable distance to the north: but the inhabited islands have
have been reduced to seven, viz. Palma, Gomera, Teneriffe, Grand Canary, Forteventura, and Lanzarota; for each respectively. To these have been added the following six small islands, viz. Lobos, Roche, Grande, Santa Clara, Arleguana, and Inferior, besides a cluster of rocks, called the Sables, between Madeira and the Canaries. Teneriffe, though not the largest, is probably the most fertile of the Canary islands, and its population amounts to nearly 100,000 persons. That of the Grand Canary has been already stated; that of Palma is estimated at 70,000; of Forteventura at 18,000; of Lanzarota at 8,000; of Gomera at 7,000, and of Teneriffe at 15,000; the total according to this enumeration amounts to 106,000; but others reckon the population of Teneriffe at 60,000, and the whole at 140,000. The air of that island is pure and temperate, and the soil is fertile; the produce is wheat, barley, rice, and oats; the excellent canary wine is obtained chiefly from Teneriffe and Palma: Gomera is noted for figs; and the tree yielding the juice called dragon's blood is not uncommon. Fruits of various kinds are of excellent quality, and are cultivated in great abundance. These islands are well supplied with cattle, such as cows, sheep, goats, and wild affes, which run about in mountains in woods; their pastures are floved with varieties of the feathered kind, of which the canary birds are well known; and the surrounding forests are floked with flocks of fift, particularly fuggroes. All the islands have ditches and washes filled with water at spring-tides, and afterwards evaporated by the heat of the sun, so as to yield a fine sea-salt. Flax, aniefelds, and corriander are cultivated in the different islands. Archil and furnach grow spontaneously. See Archil. Kali is found along the sea-shore, and might afford as good soda as that of Alicant. The cotton shrub and also the fugar-cane are much neglected. Potatoes have within the last 30 or 40 years been introduced in these islands; and at present they constitute almost the chief food of the inhabitants. Wheat and barley are grown in November and December, and usually reapd in April and May. The corn is carelessly raked together, carried home in sacks on the backs of assies, mules, or camels, and then trodden out by cattle, and the grain separated from the chaff by exposing it to the wind. The lands are not rented in the Canaries; the landholder furnishes the seed and implements of husbandry, and receives one half of the produce, besides a certain quntity of wheat for each head of cattle, which he lends to the tenant. Bread is only eaten by the richer inhabitants. The people in general habit much on "goffio," which is only parched grain ground by a little hand-mill, of which every cottage possesses one. Those who use better fare have recourse to salt fish and potatoes. The poor inhabitants of Palma and Gomera are sometimes reduced to the necessity of making cakes of the roots of the "petis aquilina" or male fern, which they dig in the mountains. Lupins are a choice food for cattle; but their flowers are previous fermented in water and boiled with the addition of salt. The capital of the fevea inhabited islands is the town of Palma, or Canary, in the isle of Canary.

History gives no certain information with regard to the original inhabitants of these islands. Some say, that they were exiles from Africa, whom the Romans banished thither, after cutting out their tongues, for having blasphemed their gods. But how perfons, deprived of the organ of speech, could form any language, peculiar to themselves, and transmit it to posterity, it is not easy to conceive; and, therefore, this circumstance attending their origin is probably fabulous. It is said, however, that all the descendants of the ancient inhabitants speak the same language, though diversified into different dialects. Their clothing consisted of hides and fising; and they inhabited caves, and rocks in perfect harmony and union. Their food was the flesh of horded cattle, dogs, and the milk of goats; and they prepared a kind of pudding, or hord, of milk and trituated corn, called "goffio," which is now common under the same name. The first discovery, as well as the original settlement of these islands, is involved in considerable obscurity. It appears, however, that they were imperfectly known to the Spaniards, in consequence of some of their piratical excursions, about the middle of the 14th century. Pope Clement VI. it is said, having preached a sermon to prove that he had the sole right of creating kings and felling kingdoms, exercised the prerogative, Nov. 15th, A.D. 1444., of creating Lewis de la Cerda, deputed from the royal family of Castile, king of the Fortunata islands, supposed to be the Canaries; though the new monarch was unable to discover in what part of the world his new dominions were situated. At length, in 1453, or 1455, or, as others say, 1495, some private adventurers from the coast of Biscay extend the piratical excursions as far as these islands; and John de Bethencourt, a Norman baron, obtained a grant of them from Henry III. of Castile. Bethencourt, with the valour and good fortune which distinguished the adventurers of his country, attempted and effected the conquest, and with the consent of the Spanish court, assumed the title of king of the Canaries; and the possession of them remained for some time in his family, as a fief held of the crown of Castile. In 1431 the grant of them was confirmed to John II. king of Spain, or Castile, by pope Eugenius IV.; and in 1493 Ferdinand and Isabella, king and queen of Spain, being before possessed of four of these islands, conquered the island called Grand Canary; and also the two remaining islands; and by the treaty of peace between Ferdinand, king of Castile, and Alphonso, king of Portugal, it was agreed that these islands should belong to Spain, in lieu of the settlements on the continent of Africa, ceded to Portugal: accordingly, they have all remained in the possession of Spain to this day. Those whom the Spaniards found in possession of these islands they denominated Guanches; and the appellation has been transmitted to their descendants. They are represented as gigantic in stature and barbarous in their manners. They were idolaters and polygamists; and their property was common possession. Ignorant of the use of iron, they cultivated the earth with the horns of bullocks, and sheared their sheep, and swathed themseves, with whitened flints instead of instruments of iron. Although they were denominated barbarous, they were singularly humane, and abhorred the idea of shedding blood. When any one of their princes died, they washed his body, and placing him erect in a cave, they put a sceptre in his hand, with two jars by his side, one filled with milk, the other with wine, as the necessary provision for his journey. When Cadamosto visited the Canaries in 1445, each island was divided into a number of provinces or districts, of which Teneriffe contained nine; but among these little states was overpassed the face of the country with carnage and blood; and yet their military weapons consisted merely of lances and two kinds of lances, one armed with horn, and the other wood hardened and pointed in the fire. For protection against the scorching sun in summer, and against the inclement cold in winter, they anointed their bodies with a mixture of tallow and the juice of certain plants, which tinged their skins with various colours, red, yellow, and green; and both men and women used this extraordinary defence and ornament. Each island and each state had its peculiar form both of religion and government; although within the same society every thing was common; viz. religion, customs, language, manners, and property itself. In Teneriffe there were no less than ten different sects of idola-
ters, some of whom worshipped the sun, and others the moon, and the rest of the heavenly bodies. Although polygamy was allowed, the virgins of the bride rightfully belonged to the chief; and the parties thought themselves highly honoured when he claimed his right. Upon the accession of a new prince, it was the custom to sacrifice a number of young persons of both sexes in honour of him, and in order to procure blessings upon his reign. This was done by precipitating themselves from a steep rock, after the performance of many absurd ceremonies, till they were dashed in pieces by the violence of the fall. The parents of these infatuated victims were distinguished by the favour of the reigning prince. The present Guanches are stout and robust, though inferior in size and strength to their ancestors. Their complexion is tawny, and their noses large and flat. Their genius is lively; they are brave, active, and cunning, and are much addicted to war. Their appetite is singularly voracious; and they live upon grain formed into cakes with milk and honey; and their food is preferred in skin-pouches, which they fasten to their belts and girdles, and in which they likewise bake them in the smoke. Some rigidly abstain from wine and also from animal food. Such are their avarice and activity, that they run up and down mountains, and spring, by means of long poles, from rock to rock with astonishing agility. In all their contests they use stones, and throw them with a force equal to that of a musket-ball. Dr. Sprat (Hist. of the Royal Society, p. 212, &c.) has related a variety of other curious anecdotes concerning this people. The race of the Guanches, however, is now almost extinct. The few who remain in Teneriffe are entitled to some very trifling stipend, as a price of the submition of their ancestors, from the court of Spain, which they punctually, and with some sensations of pride, annually demand. Many of the dead bodies of those Guanches have been found in perfect preservation, in an erect posture, placed against the sides of caves dug into the mountains; the bodies being wrapped round with several folds of goats' skins. The total net revenue of the crown, after defraying the expenses of administration, of all the Canary islands, amounts to about 63,000l. a year. See Teneriffe, &c. 

Canary, an island of the South Pacific Ocean. S. lat. 1° 51' 30'. E. long. from Paris 27° 35'.

Canary bird, in Ornithology, Canary finch. See Canaria Fringilla.

Canary, in Agriculture, a sort of plant cultivated in some of the more southern districts, as Kent, &c. for the small seed which it produces. It is observed, in the Agricultural Survey of that county, "that there are three kinds of tilths for it; namely, summer-fallow, bean-flavell, and clover-lay: the last the writer considers best. If the land is not very rich a coat of rotten dung is frequently spread for it." But whether manured or not, the tillage necessary is to plough the land the first opportunity that offers after wheat sowing is done; and so soon as it is tolerably dry in the spring, furrows should be made, about 11 or 12 inches apart, and the seed sown broad-call about four or five gallons per acre, and well harrowed in. When the blade appears, and the rows are distinct, the intervals are immediately hoed with a Dutch hoe, and afterwards, in May or June, the hoeing is repeated with a common hoe, carefully cutting up every weed, and thinning the plants in the furrows, if they are too thick. It is cut in the harvest, which is always later than any corn crop, with a hook provincially called a twill and a bite, by which it is laid in lumps or wads of about half a sheaf each. The seed clings remarkably to the hull, and in order to detach it the crop must be left a long time on the ground, the reception of moisture sufficient to destroy the texture of the envelope, otherwise it would be hardly possible to thresh out the feed. The wads are turned from time to time, to have the full benefit of the rains and sun, and thereby render them as dry as possible.

It is remarked, that the price of reaping canary in the isle of Thaneet was formerly from 6s to 11 shillings per acre, and the prices of threshing and dressing it five or six shillings the quarter; but at present they are considerably higher. According to the goodomes of the land, and the tillage that has been hallowed upon it, the farmers then expect their returns to be from 25 to 50 buffels per acre, but the common crop is from 30 to 34. It was formerly the practice to sow successive crops on the same land for eight or ten years, but this practice is now justly exploded. It is added, that sowing canary would be a very great improvement to lands which are convenient for water-carriage to London markets, as it is not a crop the farmer ought by no means to depend upon, not only because the return or quantity it yields varies greatly, but also on account of the fluctuation in the price of the feed in the markets. Some advise sowing this crop in drills a foot and a quarter, thinning the plants out afterwards, to 18 to 20 inches apart, and to leave them about two inches dipliant in the rows. Three gallons of feed in this way are sufficient for an acre, where a hopper is made use of to let by a spring as to deliver the feeds at equal distances. It should be sown about the end of February. The chaff of this feed affords a large proportion of good horse-food.

Canary-grass, a sort of grass which can seldom be cultivated with advantage as a meadow or pature grass: but one of the kinds of which is grown in some districts for the feed. See Canary.

Canary-grass, in Botany. See Phalaris Canariensis.

Canary-wheat. See Lichen Recumbens.

CANAS, in Ancient Geography, a town of Asia Minor in Lycia, which was formerly episcopal.

CANAS and Canches, or Tinta, in Geography, a jurisdiction of Peru in South America, in the diocese of Cusco, comminges about 15 or 20 leagues S. of Cusco, and extends about 20 leagues in every direction. The Cordillera divides it into two parts; the highest called Canas, and the lowest Canches. The latter, by reason of the temperature of its air, yields all kinds of grains and fruits; whilst the former affords pasture for very numerous flocks and herds; and in the meadows between the cervices are fed no less than 25 or 30 thousand mules, brought hither from Tucumia to pature. Here is a very great fair for these animals, to which dealers resort from all parts of the diocese. In the part called Canas is the famous silver mine denominated Conono.

CANASERAGA CREEK, a creek of North America, which runs north-westward into Genesive river at Williamsburg, in the late state of New York.

CANASIS, in Ancient Geography, a town of Asia, seated on the coasts of the Erythraean sea, in Carmania, according to the Periplus of Nearchus.

CANASTRON, a promontory of Macedonia, at the extremity of the peninsula of Pallene, between the Thermaic and Oranaic gulfs.

CANATAGUA, a mountainous ridge which passes N. and S. between the provinces of Veragua and Panama, in the Spanish territories of N. America.

CATH. See KENATH.

CATATTE COXONDE, a name given by the Ceylonese to a peculiar kind of cinnamon growing in that island: this is ekeene, the second kind in value, and the name they give it signifies bitter and alfringent cinnamon. The bark of this kind of cinnamon-tree comes off very easily, and is of a very fragrant smell when fresh, but it has a bitter taste. It is not very common in the island, and is not easily dif-
C A N
diligenous on the tree from the cold cinnamon. The trees which yield the eight different kinds of cinnamon, are very various in flavour and virtue, are all so like one another, that it requires a great deal of attention to distinguish them. The root of this kind of cinnamon tree yields a very fine sort of camphor. Phil. Trans. N° 409. See Cinnamon.

CANAVERUS DEMENTIUS, in Biology, a diligenous physician, and voluminous writer in medicine, born at Genoa, in 1559, received his education at Rome, where he became extremely popular as a physician, and acquired a considerable property. He died in 1635: The principal of his works are "De Legum Saevorum Commentaries," Rome 1604, in which he gives the distinguishing characters of the genuine wood; a furious kind having found its way into the shops, and been used in its stead, "Ars Medica." Geno. vol. 1604. This is a reproduction of his account of all the diseases incident to the human frame, with the mode of treating them, taken from the most approved writers, originally printed in 1520 at Venice, here much enlarged and improved. Haller, Bib. Med. Elns. Diet. Hilt.

CANAVEZ, in Geography, a district of Italy, in the principality of Piedmont, of which Ivene is the capital.

CANAVEZ, a town of Portugal, in the province of Entre Duero e Minho; 27 miles E. of Porto.

CANAWISQUE, a western branch of the river Tioga, in America, which rises in Pennsylvania.

CANCALE, a sea-port town of France, in the department of the Ille et Vilaine, and chief place of a canton, in the district of St. Malo; celebrated for oysters: 3 leagues E. of St. Malo. N. lat. 43° 41'. W. long. 9° 31'.

CANCANI, or Cancani, promontory of the, in Ancient Geography, is placed by Ptolemy in the isle of Albion, and is thought to be Brachypit point in Caernarvonshire.

CANCARELLA ASPARAGI of Vailin, in Entomology, synonymous with cryptopodius campefris of Fabricius.

CANCELLER, in Falconry, is a light-flown hawk, in her flocking, turns two or three times upon the wing, to recover herself before the feizes.

CANCELLARIUS, in Antiquity. See Chancellor.

CANCELLATA, in Conchology, a species of Arca, the shell of which is marked with cancellated lines, and bearded; the margin gaping in the middle. Schloet. Inhabits the American ocean.

Obs. In its natural flate this kind is covered with a moist epidermis, or membranaceous coating, beneath which the shell is of a somewhat fusaceous colour, mixed with white, and becket on both sides with four tufts of hair; beaks slightly recurved; posterior depression lanceolate.

CANCELLATA, a species of Nerita, the shell of which is marked with decussating lines and impressed dots; spine lightly elevated; umbilicus gibbous and bifid. This inhabits the coasts of the American islands. Chemnitz.

Obs. This shell is white, and obfoletly spotted, and is sometimes marked with rays or a fulvous band.

CANCELLATA, in Conchology, a species of Cicada, found in Denmark. The colour is yellow, with three dots on the feutal, and tip fusaceous; wings white and reticulated. Mull. Zool. Dan.

CANCELLATA, in Ornithology, a species of Torda, seven inches and an half in length, that inhabits Nativity Island, Luitham calls it the barred phalarope. The upper feathers are brown edged with white; lower ones white with transverse dusky lines; feet pinnaed and dusky.

CANCELLATE, in Botany, open like lattice-work. A term applied to the involucre in atraclis cancellata, to the capsule of the lily, &c.

CANCELLATUM, in Conchology, a species of Bucinum, of a small size, mentioned by Seba. The shell is glabrous, with breaks and lines that variously decussate each other. Native place unknown.

CANCELLUM, a species of Cardium, of small size. This kind is reddish, thin, roundish, with decussating lines. Gaet. &c.

CANCELLI, in Building, lattices, or a sort of windows made with crofs bars of wood or iron, checker-wise.

The term is also applied to the small bars or raft which compass a cut of pulley, a common sort of, or the like.

CANCELLUS, in the Civil Law, an act whereby some former deed is revoked null and void.—This is otherwise called reficlion. The word comes from the Latin cancellum, to encompass, or pile a thing. In the proper sense of the word, to cancel, is to disannul an obligation, by parting the pen from to top to bottom, or across it; which makes a kind of checker lattice, called by the Latin cancellus.

CANCELLING of deeds, letters patent, and wills. See these articles.

CANCELLUS, in Entomology, a Fabrician species of Gammarus (Cancer, Linn.) found in the rivers of Siberia. It is specifically distinguished by having four hand-claws which are deltitude of fangs, and sixteen feet. Pallus describes the same insect under the name of cancellus, but as an oceanus. This crab is of a small size, being very little larger than gammarus lucifus, and has the first pair of antennae incarnated.

CANCELLUS araucanus, Petiver's name of Phalangium reinornae, Linn.

CANCER, the Crab, in Astronomy, one of the twelve signs of the zodiac, and one of the 43 old constellations; ordinarily represented on the globe in form of a crab, and in astronomical books denoted by a figure much resembling that of the number sixty-nine; thus &c. The reason generally assigned for its name, as well as figure, is a supposed resemblance which the sun's motion in this sign bears to that of the crab-fish. As the latter walks backwards, so the former in this part of his course begins to go backwards, or recede from us; though the disposition of stars in this sign is by others supposed to have given the first hint to the representation of a crab. The Greeks pretend that when Hercules was contending with the Libyan hydra, a crab which crawled upon the marsh feized his foot. The hero, however, crushed the reptile to pieces under his heel; but Juno, in gratitude for the offered service, though inconsiderable, advanced the creature to the heavens. The stars in the sign Cancer, Ptolemy makes 13; Tycho 15; Bayer and Hevelius 29; Mr. Flamstead no less than 83. For an estimate of the comparative brightness of several stars in the constellation Cancer by Dr. Heffelch, see Phil. Trans. vol. lxxxvii. p. 311, &c.

CANCER, tropic of, a lesser circle of the sphere parallel to the equator; and passing through the beginning of the sign Cancer. See Tropic.

CANCER, in the Military Art. See Aries.

CANCER, in Surgery, is a disease respecting which the most enlightened and experienced practitioners, for more than two thousand years, have confessed their extreme ignorance; while some of the illiterate and unskilful part of mankind have never ceased to boast of their specific remedies, and still continue to impose on the unfortunate victims of this destrutive malady.

It cannot be at all doubted that numerous cases on record, denominated cancer, and perhaps all those in which cures of this disease are said to have been performed without destroying or removing the part affected, were complaints of a very different nature, and sometimes of an entirely opposite character. A large proportion of the remedies employed by
The ambiguous and undecided state of our knowledge in the diagnostic signs of cancer, has been a most fertile source of error and deception; and, while we remain unfurnished with authentic standards, or established data, by which all observations may be examined, it ought not to excite surprise, if the same name be applied to two complaints, the histories of which are repugnant to each other; or, if opposite modes of treatment be directed for diseases that bear a common appellation. See Mr. Peardon’s “Observations on Cancer,” p. v.

A great deal of commendable pains has been lately taken, by the promoters of two public institutions in London, to investigate the nature and treatment of carcinomatous disorders; but, from the first results of their labours, we scarcely can say that any approaches have yet been made towards the attainment of so desirable an object. One of these gentlemen has shown, with much clearness and acumen, that our best definitions of fibrous and cancer have been very inaccurate and erroneous; whereas another surgeon, of considerable reputation and experience, affirms that “there can be no difference of opinion respecting the nature of the complaint;” and, says he, “the truly fibrous tumour, which is known to be capable of forming the cancerous poison, when allowed to increase in size, has been so often debased, that every surgeon must be enabled from those accounts to pronounce the tumour, when he meets with it, to be of that kind. See Mr. Home’s Observations on Cancer, 8vo. Lond. 1805, p. 156. This author likewise thinks he has proved decidedly, that cancer is not a dis ease which immediately takes place in a healthy part of the body, but one for the production of which it is necessary the part should have undergone some previous change, connected with disease;” whereas Mr. Peardon has adopted the contrary opinion, viz. “that a cancer is always an original disease, and never appears as the sequel of any morbid affection whatever.”

The truth is, we are still in the dark concerning the proximate cause of fibrous and cancer, or the nature of that peculiarity of constitution in different persons and sexes, which predisposes them to this malignant derangement of animal structure. We do not even know precisely in what the cancerous state of an organ consists; and it is yet debated in the medical world, whether or no the disease be local; —although, in our own judgment, the affirmative proposition is always true in the early stages of a cancer.

If we may credit the accounts published by various authors, it appears that there is scarcely any part of the body which is wholly exempted from the attacks of a cancerous affection: but it has been ascertained by reiterated observation, that glandular parts are much more liable to this disease than any other; and it is to a gland only that we are accustomed to apply the term fibrous, which denotes a morbid condition invariably tending to the state of a perfect or genuine cancer.

The name of fibrous has too vaguely and unguardedly been applied to indurated tumours of the non-secretory or absorbent glands, and hence has arisen the epithet of “venereal or fibrous fibrous;” so that patients labouring under such indurations have often been alarmed without any necessity. Indeed, Mr. Peardon says, he “never met with an unequivocal proof of a primary fibrous in an abor

by empirics and purrs for the cure of cancer includes those means which, after long and mature trial, have been rejected as inefficacious by regular surgeons; and, it is well known, that the more innocent (because less active) ointments, and other compositions, now publicly advertised by cancer-curers, are such as no person could have proposed who had the slightest acquaintance with the real forms of this disease.

A true fibrous, before it degenerates into a cancerous form, is hard and unequal on its surface, slightly tactile to the touch, not tending to suppuration, and enlarges very slowly in its commencement; but at length, assuming a more active form, it is surrounded with superficial varicose veins, when it becomes rather painful, and changes the texture of the adjacent cellular membrane or cuticular covering, to which it frequently adheres: the skin, will, in this advanced period, sometimes be discoloured, and puckered or retracted, especially in the female breast; perhaps attended with a degree of softness or fluctuation in some part of the tumour, with shooting pains in its neighbourhood; and at last breaking into a malignant sore, with fungous flesh, and retroverted edges, where it is named an open cancer.

Eroding, forbid, and rebellious ulcers will arise spontaneously in various parts of the body, without being preceded by a fibrous tumour; and, as many of those resemble the cancerated fore, in their general appearance and fatal termination, they have been indiscriminately ranked among cancers, for want of a better classification. See the articles Ulcer, Leprosy, and Elephantiasis.

The fibrous tumour, above described, which has a constant tendency to degenerate into a confirmed cancer, (though not always equally rapid in its progress) will seldom or never yield to diuretic applications; and should therefore be extirpated without delay, if the circumstances of the patient do not otherwise prohibit this operation. The fibrous, on its removal, will exhibit a somewhat different appearance in its structure, according to the progress it has previously made towards maturity. In its early stage, the centre is more dense and semi-cartilaginous than the circumference, the whole being intersected by irregular bands of a ligamentous texture, blended with glandular substance; but as it advances, this central part is less observable, although the intersecting filaments still exist, and an irregular spongy cavity is formed within the tumour, filled with a bloody fluid. Sometimes the mass is composed of several distinct portions, enveloped by the ligamentous bands disposed in concentric circles; and in other cases, there are cysts of various magnitude, in different parts of the tumour, which Dr. Adams believes to be real hidatois, poissified of vitality.

Means have been adopted by several practitioners at different times, to analyze fibrous or cancerous masses; but without affording, hitherto, any satisfactory results. Indeed, the tests to which they have submitted these morbid substances must have entirely decomposed them and altered their nature; so that, probably, we shall not obtain much useful information by having recourse to chemical agents for this purpose.

The chief defiderate in surgical practice, is to discriminate between serofulose indurations and fibrous tumours in the living body; for it is a question, on which the well being of patients must often depend, to determine the precise nature of a disease, before we proceed to active measures. Notwithstanding the apparent confidence with which Mr. Home, in a passage we have quoted, ventures to pronounce respecting the facility of distinguishing and ascertaining a fibrous affection, he, in another part of this book (p. 167.) acknowledges himself to have frequently been mistaken in his diagnosis; and these are his words:

"So much does the same disease differ in its appearances, in different patients, from the endles peculiarities of their constitution, by which every part of their body must be more
Cancer.

more or less influenced, that it is not possible in practice to distinguish, in all cases, between cancerous and tuberculous tumours, after they have advanced to a certain size; and I am ready to confess that, in many instances, I have mistaken the one for the other, and have removed, by operation, tumours which, at the time, had the appearance of being cancerous; and upon examination, after their removal, found them of a tuberculous nature. On the other hand, I have neglected to remove tumours from the circumstances making it probable that they were tuberculous; which afterwards became cancerous, and destroyed the patient.

In all such doubtful cases, it is the safest rule to advise the removal of the tumour, if it be situated fairly for the operation; as it is a much less serious inconvenience to get rid of a diseased tuberculous gland, than to retain a cancerous tumour, which probably might cohabit the patient's life, in the event of its contaminating the adjacent parts by its malignity. There is reason to suspect that many surgeons, who boast of their extraordinary successes in extirpating cancers, have sometimes dissected out tumours which might very innocently have remained: for the surprising durability we find, in the results of the practice of different surgeons, is not capable of being reconciled by any other supposition.

Thus Mr. Nooth affirms "that in 102 firchonous cases, in the early stage of the disease, where he performed the operation, all remained free from any return of the complaint," whereas Dr. Monro's says, "of sixty cancers, which he had extirpated only four remained free of the disease for two years," and these became cancerated afterwards!

This report of the late Dr. Alexander Monro (in Edin. Med. Edi. Vol. 5.) is so very discouraging, that it will not be improper to suppute the failures in those cases arose from some peculiarly untoward circumstances; and yet we have another account, by Mr. J. Hill, of "of less than 88 genuine cancers, all ulcerated except four," being extirpated by himself, and "all the patients but two recovered of the operation." Mr. Hill says, "of the first 45 cases, only one proved unsuccessful; in three more the cancer broke out in different places: and a fifth was threatened with some tumours at a distance from the original cancer: these tumours did not appear until three years after the operation; but the woman was carried off by a fever before they had made any progress. All the rest of the 45 continued found so long as they lived, or are so to this day; one of them survived the operation above 30 years; and 15 are still alive, though the last of them was cured in March 1761.

"Of the next 33, one lived only four months; and, in five more, the cancers broke out after having been once healed.

"The reason why, out of 45 cases, only four or five proved unsuccessful, and fix out of 33, was owing to the following circumstances: the extraordinary successes I met with made cancerous patients flock to me from all corners of the country, several of whom, after delaying till there was little probability of a cure by extirpation or any other means, forced me to perform the operation, contrary both to my judgment and inclination.

"Upon a survey in April 1764, the numbers stood thus:

<table>
<thead>
<tr>
<th>Total cured</th>
<th>63</th>
</tr>
</thead>
<tbody>
<tr>
<td>Of whom, when cured, were aged</td>
<td></td>
</tr>
<tr>
<td>between 70 and 80</td>
<td>15</td>
</tr>
<tr>
<td>70 and 70, 17</td>
<td></td>
</tr>
<tr>
<td>50 and 60, 18</td>
<td></td>
</tr>
<tr>
<td>Below 50, or ages unknown</td>
<td>13</td>
</tr>
</tbody>
</table>

Vol. VI.

"Of the above 63, there were alive in April 1761, 62 and 70. 17 70 and 70, 17 70 and 70, 17 |
| In all | 39 |

"In 28 of the above number, the operation had been performed more than two years before.

"In 11, the operation had been done in the course of the two last years.

"So that, upon the whole, after a course of 50 years practice, 39 of 63 patients were alive and found.

"From the above survey, it appears, that the different patients lived as long after the extirpation of the cancers as, according to the bills of mortality, they would have done, had they never had any cancers, or undergone any operation.

"The remaining 25, which compass the 88, were cured since the year 1764, 82 of whom have been at least two years cured: one or two of these patients were 70 years of age, one 90.

"Mrs. Mundal was 90 when she got a cancer cut off her cheek, 28th June 1768; another appeared upon her forehead in 1770, and was extirpated on the 5th of April that year. After both which recovered; but a tumour appeared below the maxillas, which carried her off in November 1771, above three years after the first excision; that is, when she was 93 years old.

"The tumour therefore at present, July 1779, stands thus:

<table>
<thead>
<tr>
<th>Of 88 cancers extirpated, at least two years ago,</th>
<th>Not cured</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>Broke out afresh</td>
<td>9</td>
</tr>
<tr>
<td>Threatened with a relapse</td>
<td>1</td>
</tr>
</tbody>
</table>

"Which is less than a seventh part of the whole number.

"At this time there are about 50 patients alive and found, whose cancers had been extirpated above two years ago.

"Of five cancerous breasts, only one was ulcerated, which, with one of the occult kind, did not heal; a third relapsed, probably owing to the whole not being fully cut away; the other two are still firm and found in 1772, though one of them was cut October 24th 1764, and the other April 26th 1766." See Mr. Hill's Cares in Surgery, 12mo. Edin. 1772.

This author's experience, we perceive, was by no means so discouraging as that of Dr. Monro, nor was it so completely unavailing as that of Mr. Nooth: but it should be remarked, that Mr. Hill's cases were much worse, and more advanced than those of Mr. Nooth, while the circumstances are not known which occasioned the ill success alluded to by Dr. Monro. Upon the whole then, we think the numerous patients who are afflicted with external cancers need not sit down in despair; as if it were useless to undergo the operation, when performed in due time, and by a skilful surgeon. The refult of our own practice has not been so favourable as that of Mr. Nooth, but has proved at least as successful as Mr. Hill's; and we have no reason to doubt that our contemporaries have been equally happy in their experience after the operation.

To avoid the difficles and pain attendant on such a surgical operation as that of cutting out the part affected, a great variety of means, both external and internal, have been proposed for the cure of cancer; these may be ranked under the several heads of 1. Difficulties.-2. Corrosives.—Mr. M

J. Nar-
CANCER.

3. Narcotics. We could substitute a long list of those remedies from the vegetable, animal, and mineral kingdoms; but since no surgeon of reputation will trust to any of them, after the varied trials which have been so often made, both in this country and upon the continent, we shall not extend the present article by reciting their names and supposed qualities. A few words may, however, be added respecting the most eligible means of palliating symptoms either before the cancer is confirmed, or when it has gone on to a state of ulceration, and cannot be extirpated.

Many hard swellings in the breast, especially those of a pectoral kind, and such as appear after child-beariing, have been mistaken for cancerous tumours; but they may generally be dispelled by the early and repeated application of leeches, bathing with camphorated spirits, soap liniment, hemlock poultices, furminon lotions, or gentle rubbing with mercurial ointment. It has been justly observed by Mr. Home, "that the successes met with in some of these cafes is often productive of material mischief, by inducing the practitioner to be too lenient, and to go on with the use of the same means in other cases, encouraged by his former successes, till the disease has arrived at the state of a true cancer; and therefore has advanced beyond that stage in which it might have been removed by the operation of extirpating the tumour."

It is of great importance, on the one hand, not to alarm our patients prematurely, by giving too hastily and unfavourable an opinion; but, on the other hand, practitioners would do well to weigh all the circumstances which may enable them to decide on the nature of such tumours, and if they are confident of their being carcinomatus, to lose no time in advising the only leap which can be taken for the security of the unfortunate sufferer.

The following are Mr. Hill's rules of determining whether an external swelling be of a cancerous nature or not; viz.

1. When firous tumours are considerably advanced, they are surrounded with large varicose veins, resembling crab's claws, from which resemblance they have got the name of cancers. The absence of these, therefore, is a favourable circumstance, but not to be absolutely depended on.

2. The skin of a cancer, when near bursting, is of a reddish blue, or a blue livid colour, adheres to the under part of the indurated gland, (from which it was originally detached,) and is puckered up into ugly folds, as if leached.

3. On the other hand, the cutis, or skin, when inflamed, is always accompanied with a fever, which keeps parallel with the degree of inflammation. But a cancer is never attended with a high inflammatory fever. It is true, the excessive pain of a cancer sometimes quickens the pulse, but at the same time sinks it.

4. The skin of the inflamed cutis, or phlegmon, instead of being wrinkled or plaic'd, is smooth, red, and stretched, so as sometimes to have a glazed appearance; and, when near bursting, the matter is always found fluctuating below, which seldom happens in cancers. On the contrary, cancers are generally accompanied with a corrodious humour, which abrades the cuticle, till the outer parts are consumed; but no matter is perceived within; whereas, in the cutis, &c. the scar-fim is the last part that gives way, unless it be scal'd or fretted by too hot poultices.

5. The cold scrophulous tumor is in full less danger of being mistaken than the inflammatory kind. For the pain and hardness are not so conspicuous as in the inflammatory tumor; and the matter accumulates for a long time before it bursts. In either kind, if good pus appear, there is no occasion for being afraid of a cancer; and, although the pus should not be of the most laudable kind, but of a whitish fuminous aspect, yet it is never so acid as that which proceeds from a cancer. Nay, even a red, bloody, or fuminous matter, is not of itself a characteristic symptom of a cancer. Excepting the case mentioned above, I have never seen any cancer that contained matter; but I have seen numbers of other ulcers, in bad habits of body, full of bloody ichor."

The hooing cancer-curers of our time have not sufficient knowledge to discriminate between the different kinds of tumours they meet with, and perhaps too little honestly to confess that the cafes in which they have ultimately had some successes were really not cancerous; for such an acknowledgement would annihilate their traffic, and destroy their ill gotten reputation. But our own opportunities have enabled us to affirm, that this mercenary class of practitioners habitually by imposing on the credulous and inexperienced part of mankind, especially the weaker sex, who are tormented by curable disorders, falsely named cancers.

Supposing it to be ascertained that a cancer exists, and it has proceeded to a state of ulceration, not admitting of a surgical operation, the patient should avoid using any means of relief which irritate and give pain; unless it be proposed to destroy the whole by a cautery, which indeed is a far more tedious, uncertain, and tormenting plan of treatment than by cutting out the part.

The topical applications to an open cancer, which have been found most useful to alleviate pain, cleanse the sore, or to correct the fist smell arising from it, are as follow:—
1. Fresh bruised hemlock-leaves.—2. Scraped young carrots.—3. The fermenting poultice.—4. Finely levigated chalk.—5. Powdered charcoal.—6. Carbovnic acid gas.—7. A watery solution of opium.—8. Liquid tar, or tar-water. The internal remedies which have been most beneficial are, 1. Very small and long continued doses of arsenie.—2. Liberal doses of eicuts.—3. The free use of opium.—4. Belladonna.—5. Solarum.—6. Martial flowers.—7. Corroborative sublimates.—8. The juice of civers or goose-grass. But neither the external nor internal remedies, however apparently useful for a time, can be in the least depended on for the cure of a genuine confirmed cancer.

The removal of firous tumours and cancerous excrescences may be effected in various external parts of the body; but no surgeon perhaps could now be found to undertake the excision of any internal organ, for example the uterus. Attempts have been often made by ignorant and bold empirics to destroy a cancerous ulcer of the womb by corrosive injections; but the practice is as cruel as it is absurd, and we have seen the most dreadful consequences from such attempts, without affording the smallest relief to the unhappy patient. Several examples are recorded of the uterus having been excised, and some of these women have survived; but no one that we know of, is related of such an operation being performed for the purpose of extirpating a cancer, although we are aware that it has been lately proposed by a speculatrix writer of Germany. See Med. and Phyf. Journ. vol. xi. p. 34.

The circumstances which indicate the propriety of an operation are these:—1. When the cancer is so situated as not to expanse any large blood-vessels or nerves to be cut during the operation.—2. When the whole of the morbid parts can certainly be removed.—3. When the disease has arisen from some accident, and not spontaneously.—4. When the patient is otherwise healthy.—5. When the cancer has not shewn evident symptoms of considerable malignity during its progress, and does not seem to have involved the adjacent glands or absorbent vessels. The two first of these requisites are not to be dispensed with; for unless we can di-
feet out all the morbid parts, without incurring the danger of dividing important nerves or arteries, this operation must never be attempted.

The mode of operating will vary in different cafes and situations. Some excellent directions are given on this subject by Meffrs. Feeon, Home, Pearon, Bernalen, Rich-ter, Le Duan, Sabatier, and Callifon; which young surgeons should consult, in particular emergencies: the only general rules we can here lay down are,

1. To make the external wound neatly in the direction of the subjacent muscular fibres, and to make it large enough for the removal of all the morbid parts.

2. To sally all the skin which is not diseased, unless there might be too much to heal up nearly.

3. To secure every bleeding vessel, by a ligature, which might hazard a subsequent hemorrhage.

4. To maintain the lips of the wound in close contact, without interposing any dressing or extraneous substance between them.

5. To preserve the parts in an easy and ready position for some days, before they are looked at or opened.

6. To use no other than mild and cooling applications during the cure.

The only point of importance on which we have as yet offered no observations, but which will nevertheless be deemed highly deserving of general attention, is the comparative advantages and disadvantages attending the modes usually employed for the extirpation of cancers.

This is a subject, respecting which, unprofessional readers, especially those who suffer from the complaint, may naturally desire to make up their minds; and, on that account, we shall not hesitate to lay before them the judicious remarks of a late author, who has treated this question very amply. See Home's Observ. pp. 178—189.

"There are two modes by which a cancer may be extirpated; one, is taking out all the parts that are diseased, by a cutting instrument; the other, making use of such applications as will render them dead, and thereby occasion their being thrown off.

The advantages attending the operation by the knife are such as to give it a decided preference in all cancersous diseases. It is the only mode which is capable, in the more advanced state of the disease, of removing the contaminated parts to a great extent; and, in doing it, the surgeon is enabled to take away with precision every part he thinks liable to have been affected. When the operation is over, he can examine the diseased part that has been extirpated, and see whether it is every where surrounded by healthy parts; and, if it is not, by referring it to its natural situation can remove any part which may give him the least cause to suppose that it is contaminated. The skin, after such an operation, is in a loose state, and admits of its edges being brought together, so that the wound may always be much diminished in size; and, in very many instances, the cut edges may be brought together like those of a simple incision.

The operation is only of a few minutes continuance, and the moment it is over, the parts are in a state to commence the process which is necessary for their recovery; and in the course of two or three weeks they are entirely healed, even where the diseased has not been completely removed.

The modes of deadening the diseased part, which have at different times been employed, are three; and as these have sometimes been preferred to the operation by the knife, and some of them are still in use, it becomes necessary to explain in what way they acquired their reputation, and to shew the disadvantages which attend their operation.

"In the earlier times, when the knowledge of cancer was more imperfect than it is at present, an idea was entertained of its growth being similar to that of a vegetable; and it was therefore thought that unless it was taken out by the roots, the diseased was not completely removed. It was then found that very active cauteries were capable of deadening the whole tumour, which is always more or less of an irregular form; and when the diseased part was thus brought away, the projecting portions were considered as the roots of the cancer; and the proving of it being completely eradicated was, that the fore readily admitted of being healed.

Any recurrence of the disease from the contaminated parts, which had not been destroyed, was supposed to arise from the contamination being in a diseased state, and not from any failure of the action of the cauteries; and in this way the original idea of its being a constitutional disease was most probably formed.

"The fact is, that diseased parts have less powers of supporting themselves than healthy ones, and therefore are more readily destroyed: so that a powerful cauterity acts twice the extent, in a diseased part, to what it does in a natural one; and an indolent tumour can have every part of it deadened by means that would only produce a violent inflammation upon the common skin. It was therefore by no means an unfair conclusion, till it was contradicted by experience, that such applications as were capable of deadening every part that was in a diseased state without acting upon the healthy surrounding parts, were to be preferred to the operation by the knife; and it is within my own remembrance, that such an opinion was general in London. Since that time, two things have been ascertained, which prove, that when the tumour has become cancerous, such cauteries are incapable of removing the diseased entirely; the one, that when the poison is once formed, the contamination precedes and extends beyond the diseased alteration of structure; the other, that every thing which irritates the diseased part increases its action, and its power of contamination: and in fact, all regular practitioners have laid aside the arseneal applications to cancerous tumours in the breast, in consequence of finding that the diseased was rarely removed by them.

"They still retain a certain degree of reputation, and are used by several empiemists in London; and cures performed in this way are well authenticated; that is, they succeed when applied to tumours which are yet in a indolent state, if they be diffusely powerful to destroy the whole tumour; and as there is no possibility of ascertaining what the structure of the tumour was, which has been thus destroyed, it is flated by the practitioner to have been an invertebrate cancer, which is attempted to be proved by showing its roots, or the irregularities upon its external surface. But the cauteries, when too weak for the destruction of the diseased part, irritates, and makes it sooner become cancerous. When applied to a cancerous tumour, although strong enough to deaden the whole, it irritates the surrounding parts that have been previously contaminated, and makes them sooner assume the characters of the diseased. This not only happens when cauterities applications are used, but when mortification takes place from any other cause, as in the case flated in a former part of this work.

"This fact of the contaminating power of morbid poisons being increased by any thing that irritates the diseased parts, is not peculiar to cancer. It happens also in the veneral diseased, of which too many instances have come under my own observation.

"I have been, for some years, a favourite practice to attempt the cure of cancers by touching them with cauteries, whilst yet of a small size, and repeating the application till
CANCER.

a found surface is exposed, after the throat has been thrown off, and then to allow it to heal. The effect of this practice is exactly similar to what has been stated. The chancre is cured, but the poison is absorbed, and the constitution contaminated by the disease. But if the chancre be so small, when the caustic is first applied, that the whole ulcer and some of the surrounding parts are deadened completely by one application, the patient will then be perfectly cured of the disease; as there was not time for absorption before the application was made, and its effects were such as to preclude its taking place afterwards. If, on the contrary, the first application only destroys a part of the disease, it irritates the absorbents, and gives them a disposition to take up the poison at an earlier stage than usual. From an experience of this being the case, I have for many years entirely left off the practice of using such modes of treatment, in the early stages of chancres.

"The caustic applications which have been employed for the destruction of cancerous tumours are the following: arsenic, corrosive sublimate, and the actual cautery. As these means are also used for the purpose of removing other tumours, whose structure prevents the knife from being employed, I have had frequent opportunities of making observations on their comparative effects. Indeed the statement contained in the second case which has been mentioned in this volume, explains their different effects upon the same person, so as to afford us the most satisfactory information respecting them.

"The only preparation of arsenic which I have used, is equal parts of the white arsenic and sulphur; these proportions were first recommended to me by Mr. Cline. This acts as a powerful caustic, and appears capable of destroying any tumour which has not acquired the disposition to throw out a fungus. The thongs formed by each application will be very much in proportion to the quantity of the powder applied. By this means I have removed a large tumour in the cheek, which appeared to be taking on the previous flake to becoming a cancer. I have also destroyed a large tumour in the foot. In the last case it certainly affected the constitution, in a manner very similar to what has been already described. In the other, no such effect was produced; so that it would appear that the arsenic is in some cases absorbed more readily than in others.

"The local effect of arsenic is that ofproducing fo violent a degree of inflammation in the part to which it is applied, that mortification ensues. When applied to the flomach, indeed, it destroys the patient before mortification absolutely takes place; and the apparent effects of inflammation upon the part, are not such as would destroy life, were they produced by any other cause. It is to be presumed therefore that the arsenic, taken internally, kills by being absorbed, and producing effects in the circulation incompatible with life. Several instances of patients dying from the effects of arsenic upon the internal coat of the flomach have come under my observation, and specimens of its local effects are preserved among the morbid preparations in the Hunterian Museum.

"Corrosive sublimate acts both locally and constitutionally, as well as arsenic. Its local effects are however less powerful, destroying parts to a less extent, and the constitutional effects from absorption are more like those common to the different preparations of mercury than to those of arsenic.

"The actual cautery is at present almost entirely diffused in surgery, except in cases of dis eased bones, where it is employed to produce death in the part affected, and in that way, put an end to the disease. It is a much milder application than either of the above, gives less pain while acting locally, and produces no constitutional disturbance; and where it is necessary to keep at bay a fungous excrecence, whose growth is not very luxuriant, I should prefer it to the others, from a belief that it does not in the same degree hurry on the diseased action of the tumour. In cases of fungous tumours in the mouth, it is the only means that can be employed; and in an instance of that kind, the diseased was kept under for seven or eight months, by its occasional use, without much pain being produced, or the disease being at all advanced in consequence of the application.

"This account of the effects of caustic applications is given in this place; to show in what they differ from the operation by the knife; and when compared with it, what are the disadvantages, in cases of cancer; although in other tumours, of a less malignant nature, they may be employed with success."

Deferenda relating to Cancer and Syphilis.

The following inquiries were suggested by the perusal of a paper which was printed and distributed in the year 1803, by the medical committee of an institution set on foot for the relief of persons afflicted with cancer. The writer of this article, however, has not thought it necessary to confine himself exactly to the plan which is prescribed in that paper; but has considerably increased the number of queries, with a view to throw readers in general how many difficulties exist on a subject which certain impostors and credulous persons affect to thoroughly understand.

"Query 1. Is there any peculiar habit of body, or mode of living, in either sex, which disposes persons to the formation of cancer, or which enables them to resist its influence?"

2. Is it well known that at certain periods of life, especially in females, this disease is frequent in its appearance: on what physical causes does that liability depend?

3. Are there any means by which the actual formation of a cancer might be prevented, in families where this disease has seemed to be hereditary?

4. Do persons ever suffer in their childhood, or before the time of puberty, from spontaneous attacks of cancer?

5. Does a child become cancerous by sucking a cancerous woman; or could this disease be produced by transferring the virus from one subject to another, in a way of accidental inoculation?

6. Are there any parts of the body exempted from ever assuming this disease; and why do certain organs more frequently become affected than others?

7. Is it clear that the disease called cancer in some brute creatures exactly resembles this complaint in human beings?

8. Has climate or local situation any influence in rendering the human constitution more or less susceptible of cancer?

9. Do the cancers which arise in consequence of particular employments (as chimney-sweeping) at all differ in their nature from those which affect persons under different circumstances?

10. How many kinds or diversities of cancer are there; and do they all, in their several stages, properly come under the same generic appellation?

11. Is there any well marked affinity or relation between cancer and other diseases, in their origin, progress, termination, or difficulty of cure?

12. What are the specific differences between febrirux, carcinomas, lupus, noli me tangere, fungus hematodes, elephantaia, and syphilis?

13. Does the existence of a cancer in any one part of the body afford a presumption that there is a cancerous diathesis, or tendency to a similar morbid alteration of other parts, in the same subject?

14. May
14. May cancer be regarded at any period of its duration, or under any circumstances, merely as a local disorder; i.e. limited to the spot which is visibly affected, and not necessarily contaminating (although tending to contaminate) other organs?

15. Has it been incontrovertibly decided, whether external injuries give rise to cancer in any other way than by resorting to action a disease virtually existing, or at least which was predispited to make its appearance?

16. Does this inherent disposition of dormant cancerous tendency imply a morbid change capable of detection, and of being rendered quiescent by artificial preventive measures?

17. In what sense may it be admitted that cancer, or the carcinomatous distemper, is ever hereditary? And are there any well authenticated facts to support this notion, in any other sense than as children may inherit the same organization or bodily structure which their parents possessed?

18. Is it certainly known and proved that one particular constitution or temperament of body predisposes to this disease?

19. Is the cancerous matter of a volatile and infecting nature, so as to generate this disease in a healthy person, (without real contact) by effusion in the atmosphere exhaled from a cancerous sore; or does it only contaminate by direct absorption of the virus?

20. Can the essential form of any other disease be so changed as to assume a carcinomatous flatte, and finally to degenerate into a cancer?

21. Are there any phlegmatic signs, either local or general, by which we can foretell that more obvious morbid change named cancer; or does there necessarily occur any visible alteration of structure in a part, prior to its being absolutely affected by this disorder?

22. Has a genuine and confirmed cancer been cured by art, without extirpating or destroying the morbid mass?

23. What is the forensic and medical method of eradimating cancers of every description?

CANCER is a Surgical term also applied to a species of hagfish for the head, and divided into several parts, resembling the legs of a crab-fish.

Cancer, in Zoolosy, one of the genera of aquatic infects in the Linnean system. It is also a subdivision or family of the Linnean Cancer moulded into a distinct genus in the Fabrician Entomologia Systematica, and other works of that writer, and a genus of crustaceous animals distinct from infects with Cuvier, La Mare, Latreille, Bosc, and others.

Under the generic title of cancer, Linnaeus compiles all the species of crabs, lobsters, shrimps, hermit or paratitic crabs, and in a word every animal of the true crustaceous kind that appears to have been known to him, with the exception only of the two genera Monoculus and Orlocus, both which are separated by him from cancer.

Linnaeus was induced to consider the cancer, and the two last-mentioned tribes of crustacea, as infects, principally from the circumstance of their being furnished with antennae, pitting articulated limbs or legs, and having the body covered with a solid cud. Being delitute of wings these are referred to the last order of infects Apera, where they follow the genus Scorpio, and precede the two analogous tribes Monoculus and Orlocus. That Linnaeus was not strictly correct in placing the cancer with infects, even according to his own definition of the infect tribe, is evident, but the objections so far as they regarded exterior characters were of little consequence, and after his system had become generally known the cancer were admitted without further inquiry as genuine infects into every entomological cabinet. The French naturalists of the present day do not, however, consider them as infects, but independent of these there are indeed few who, either from accustomled habit, or opinion, founded on the Linnean method, do not regard them as a branch of extermites.

From the earliest times in which mankind appear to have discriminated with tolerable precision the affinity which natural objects bear to each other, and their relative position in the chain of nature, crabs and lobsters were supposed to belong to the invertebrus tribes of animals, and not to infects. But they were incontinent to those minute characters which in the present state of science we are compelled to have recourse to; those animals were tolerably of the same order, and in their ideas made of course parable of the structure of fishes. The Greeks and Romans entertained this notion; they admitted them as a race of creatures strongly allied to fishes, and from being covered with a shell as forming an intermediate link between fishes and the covered or tettaceous mollusca, or what is commonly understood even at this time amongst us by the name of shell fish. In this light only they were viewed by succeeding generations even till the time of Linnaeus, who in his great reform of the animal kingdom thought it necessary to separate them entirely from the covered mollusca, and place them amongst infects.

How far Linnaeus was right in rejecting the established though vulgar notions that had prevailed among mankind for so many ages, remains to be examined. To a curious observer it must appear strange, we had almost said unphilosophical, to be told by those to whom they look up for scientific information, that crabs and lobsters belong to the same class of animated beings as beetles, moths, and butterflies. But we are not to be governed by prejudices, nor by the veneration we are too apt to entertain for the knowledge of past ages in those matters where our own judgment may be employed with equal or greater certainty; they may really have a natural affinity to each other without being obviously so in their external characters. Cestaceous animals are called fishes by the bulk of mankind, though the naturalist is fully satisfied they have scarcely any other relation to fishes than exterior figure, and living in the same element. The opinion also that crabs and lobsters are infects, as Linnaeus describes them, is sanctioned by the authority of so many writers of ability that we cannot be too cautious in venturing to discontinue an opinion so well supported. It is a matter of diffucion that claims the most mature deliberation of the naturalist, and fortunately one that has undergone investigation by men well qualified for the task, or it would be impossible to do it justice within the limits of our present article. The leading particulars may be explained; and if from the result of this it should appear that the crustaceous ought really to be separated from infects, neither the opinion, nor the example of Linnaeus, or his admirers, should deter us from moving them to a more applicable station in the scale of zoology. The question is plain, and resolves itself to this point. Is Linnaeus correct or not in placing the cancer among infects? and if he is wrong in this respect, not the cancer alone, but the monocyclus, and other true crustacea, must be rejected, as well as the cancer genus, to some new order or tribe perfectly distinct from and independent of entomology.

Were it not for the following characters which the crustaceous possess in common with infects; there are circumstances attending them that might at once forbid us to place them where Linnaeus has. Like infects they are furnished with antennae, and with limbs divided into joints, and in these essential particulars approach so near the apertorous order
Cancer.

orderd infects, that it would seem almost as confident to
end the whole apterous order from the systen of ento-
ology as to deprive it of the genus cancer. These reafions
have weight with many, and among others with Fabricius.
This writer, to whose entomological knowledge we ought
not to deny considerable prævice, is a tower of strength on the
Linnaen side of the question; for like Linnaeus he admits the
crustacea as infects, although he invariably rejects the
Linnaen mode of classing them; however therefore he may
differ from Linnaeus in syflematic arrangement, he affords
him countenance in the main material point under immediate
consideration: namely that the crustacea, and of course the
cancer, are genuine infects.—But the arguments on the other
side are also strong, and in the minds of some may be equally
convincing.

It is worthy of remark that our countryman Pennant, a
writer, whose knowledge of entomology was considerably
limited, should be the first among modern writers who pre-
sumed to divide the crabs, lobsters, and marine oniæ from the
infect tribes, after the Linnaean Systema Naturæ had been
early adopted throughout Europe, and that without
having any other motive than a desire to include those
crustacea in his British Zoology. He had but a small ac-
quaintance, as he himself expreſſes it, with infects, and
therefore took the liberty of separating the crustacea from
infects that he might treat of the former of them (Zoothe.
v. 4. Brit. Zool.). Mr. Pennant was not at that time aware
that crustacea might accede to such a separaſſion as he
had bruck out by accident, from a conviction of its being
both natural and juſt; but this has ultimately proved to be
the cafe at leaft to a certain extent.

The idea of crustaceous animals being infects prevailed
among the continental naturalists from the time of Linnaeus
till very lately. Cuvier was perhaps the first who attended
with decisive accuracy to the internal organizations of those
creatures, if we except Zoſfel, whose investigations, though
laborious, were not well directed. (vid. Inſecten-Beſtättigung,
&c.) The reſult of thoſe anatomical obseruations made on
them by Cuvier are intereſſing. They go far to demonſtrate,
or rather they eſeſially prove, that the cruaſſea, and in-
fects are perfectly diftinct from each other. Linnaeus, it
need be fearſely repeated, separated the caceaeous animals,
such as whales, porpoifes, &c. from the fifth tribe, where
they had been previously placed by authors, and to which
they are fo cloſely allied in figure and habiſt, because their
internal organization did not accord with that of fish; and
proved from the reſult of anatomical obseruations, that not-
withstanding their external form they are of the mammalia
tribe, having a heart with two auricles, and two venicles,
body warm, and laſtiferous teats, and for theſe reafons re-
fers them to the fame order as man and quadrupeds whose
internal organization corresponds. The feae arguments will
bear good in this inſance, and if the reaſons of Cuvier are
correct, crabs, and various other cruaſſea are certainly not
infects. Cuvier found the inteıral organization of cruau-
cean animals to be very different from that of infects. In his
"Leçons d'Anatome Comparée," he affirms that cruau-
cean animals breath and reſpire by means of gils in the fame
manner as mollusca, whereas in infects the organs of reſpira-
tion are aſcertainment from the experiments of Reaumur,
Swammerdam, and Malpighi, to be distributed along both
fides of the body; the small lateral spiracles, which we see
one on each side every annulation of the body of an infect
being the openings, through which the air is received into
the tracheal organs; and no ſuch spiracles are found on the
fides of cruauſsea animals. Cuvier likewise found that the
heart of cruauſsea animals ſeemed that of the mollusca,
being muscular, and ſupliefed with veſsels for the circulation
of fluids. La Marec in his "Syste煤ne des animaux fans in-
vertebre" follows Cuvier in a similar train of observation,
and mentions also, that although infects undergo one or
more changes, during which they ſeveral times call their
skin, this never happens after the infect has assumed its lat-
or perfect form (his arachnides, some of the Linnaean infects
of the apterous kinds excepted.) Crabs and other cruaau-
cean, he remarks, do not undergo any ſuch metamorſphoe as in-
fects; the skin or ſhell is of a different nature, being half
calca reous, and is renewed at ſlated periods, or annually,
the old one being thrown off and another growing in its place.
Infects, it is further observed, neither couple nor engender
more than once in their lives, which seems to be the fact with
all (ſome apters excepted); but the cruaauce, on the con-
trey, breed many times in the course of theirs. The cru-
auea, as is particularly noticed by Bole, have many pairs
of jaws, and antenna moſt commonly in greater number than
infects, the latter having never more or less than two, while
the others have almost conflantly four; and the antenna of
the cruauce are also of a very different ſtructure from thoſe of
infects. There are the moft material peculiarities in which
the cruaauce differ from infects, and which we cannot but
allow in our own mind to be ſufficient to justify the removal
of the cruaauæ from under the tribes of entomology.

Firſtly as we admire the merits aloft mentioned of the cruau-
cean, we should not presume to attempt the overthrow of a
part of his systen so confiderable as that under preſent con-
sideration upon trival grounds, but the reaſons against it are
cogent, perhaps unanswerable. We have ever been taught
by Linnaeus himſelf to regard the internal organization of
animals, as an effenſtial and uerifying guide in the natural
distribution of the tribes of zoology; it is by this ſtandard
the merit of his methodical arrangement of this tribe has
been appreciated, and it has fallen to the ground.

The cruaucean tribes, thus ſeparated from entomology,
must constitute a new and diftinct order of animals. Some
difficulty might aſſiſes as to the ſation in the systen to which
they ought to be referred. By placing them as a ſeparate
order immediately after infects, the innovation might create
the leaſt confuſion; but this is even liable to objection.
Cuvier arranges them between the worms and infects, the
worms, in his systen, contrary to that of Linnaeus, occur-
ing firſt. La Marec places them between the mollusca and
the arachnides, a new clas, comprising moft of the Linnaean
insects. (cruaauæ or trachea, the arachnides, which, as the
carcinæ, myrmexes, scorpionæ, and others that have ♂♂♂♂♂♂♂♂♂♂, or lateral ap-
tures communicating with the tracheal organs of reſpiration,
and which engender many times in the course of their lives.
Latreille's Tableau Methodique des Crustacées is placed be-
tween the ameletides (a clas of worms) and the infects, the
latter beginning with the arachnides of La Marec. See article
Crustaceous Animals.

To follow the French naturalists through the maxes of
the various systems propoſed for the arrangement of the crabs
and other crustaceous animals, is not within the compaſs of
our present design. Those naturalists feem only to agree in
the one decided point, that cruaauæ are not infects, each
having in turn rejected the mode of classification adopted by
his predecessor; to that no permanent arrangement has hith-
erto been formed, or perhaps ever may; and to embrace the
whole, full fluctuating even in the unnotated ideas of their
own authors, would only tend to create inexplicable con-
fusion. It will very likely be thought more thanſufficient,
by the faſtidious few, that the Writer of this deſcription has
followed them to far. In proceeding further he conserves the
propriety of forming a new order, as in the preſent state of
things.
things it would be impossible to pursue any of those already adopted. That which he proposes is moulded as nearly as possible to the Linnaean method. So far as the plain and simple rules of subdividing the cancer into families rather than genera, as laid down by Linnaeus, could be conveniently adhered to, his example is followed; the principal deviations are in those influences where alteration has been rendered necessary by the discoveries of recent naturalists in this tribe of animals, and which are of too much consequence to be overlooked.

The last edition of the Linnaean Systema Naturae comprises only a small number of the species of cancer at present known; his genus cancer is divided into several families, in which the whole of his crabs, lobsters, parasitic crabs, &c. are included. The Cancer genus is thus described. Legs eight, (rarely six, or ten) and two chelate hand-claws, or claws furnished with a moveable pincer; feelers six, unequal; eyes two, for the most part placed on peduncles, chelated, and moveable; mandibles horny and thick; lip triple; tail jointed, and unarmed. — The crabs are separated into two principal sections, brachyuran, crabs with short tails, and macruran, crabs with long tails, both of which are again divided into several families.

The crustacea are divided by Fabricius into many genera. The Linnaean cancer form a distinct class called agonata, in the Genera Insectorum of that writer, and comprehended five genera, namely, cancer, pagurus, scyllarus, affinis, and gammarus. His agonata class, in Entomologia Systematica, contains eight genera, crabs, hippa, squilla, and galathea being added to the preceding, besides some other families of crustaceous animals, as limulus, cynmthoza, and monochorus. The same author, in a later work than the foregoing Supplementum Ent. Syll. retains part of the Linnaean cancer together in his new class kieajagnatha, but divides them into many genera, which he names cancer, calappa, cycopede, leucosia, parthenope, inachus, driona, dorippa, orithyia, portunus, mature, hippa, and fymethis; and in his next class excobata includes the remainder of the Linnaean cancer in the genera abunae, scyllarus, palmarus, palamon, alpheus, affinis, peneus, crangon, pagurus, galathea, squilla, polydon, and gammarus. La Marek, it is clear, has derived material assistance from the last mentioned work of Fabricius. The syllera he proposes is very nearly allied to that proposed by Fabricius, as will appear on a cursory view of the following statement of La Marek's genera of crabs.

Crustacea pedestis. * Corps court, ayant une queue une fans feuilles, fans appendices latéraux, et applique sous l'abdomen. Genus crangon, calappa, cycopede, dorippa, portunus, podopthale, mature, porcellane, leucosia, mal, and arthropis. * * Corps oblong, ayant une queue allongée, garnie d'appendices ou de feuilles, ou de crochets. Genus, albunae, hippa, rmine, scyllare, cerevix, pagure, galathea, peneus, crangon, pagurus, squilla, branchiopode. And among his crustaceae feuilles, * Corps couvert de pieces crustaceae nombreuses, sont crevette (or gammarus), and chevreulle (caprella).

Latreille, in his Crustacees Malacostracés, further increases the genera of this natural tribe, constituting altogether thirty-nine genera of those which Linnaeus confines to the single genus cancer.

Several of the above-mentioned recently established genera we conceive it necessary to retain as genera, and others as subdivisions of the cancer family in a more compendious form in the following arrangement.

Crustaceous Animals.

First Order, Caneri Brachyurui, Linn.

Head not distinct from the thorax; body short, having a naked tail, without lateral appendages, or crochets, and folded under the abdomen.

Genus Cancer.

Mouth usually furnished with six feelers; mandibles thick and horny; eyes two, dilated, elongated, movable, and commonly placed on peduncles; antennae four, short, and bilobate, or setaceous, the inner pair (or sometimes both), bifid at the last joint; legs eight or six, and two chelate claws; body somewhat ovate; tail short.

Sub-Section. * Thorax smooth, sides very entire.

Species.

Grapsus. Front retuse, depressed, and armed with four; body variegated. Fabr. &c. — This is a native of the West India islands, where it is not very common. The colour is whitish, variegated, but most elegantly varied with rufous, or red speckled with white, or with minute dotings of red, with a few streaks of the same colour on a white ground, the red specklings pervading the whole upper surface both of the thorax and legs. The hand-claws are comparatively rather small, rough, and of a red colour, bordered with white; body beneath pale. — Cancer tenebricatus, of Haril's Cancer, of which he describes and figures a large and small variety (most likely the two sexes), is certainly a variety of the cancer graphis of Fabricius and Linnaeus.

Mutius. Thorax chevron-brown transversely on the anterior margin. Fabr.— A native of the Mediterranean Sea. The posterior part of the body is truncated; hand-claws smooth; arms denticulated beneath.

Quadratus. Thorax square; sides crenated; hand-claws febril. Bankain cabinet. Fabr. — A native of Jamaica. Size large, exceeding that of cancer uricola; the front inflected, and entire; eyes placed nearly together, and pedunculated; eye lid beneath crenated; thorax acute at the sides; hand-claws short; arms toothed at both sides; hands febril, with elevated dots; legs hairy; appears allied to the acypoda genus.

Kuricola. First joint of the legs spinous; second and third with tufts of hair. Fabr.— Cancer uricola. Linn.

This is the great land-crab of the Bahama islands, the history of which has been so amply detailed by Sloane, Cateby, Seba, and others, that the following particulars, selected chiefly from those authorities, may not prove unacceptable. ** These animals live not only in a kind of orderly society in their retreats in the mountains, but regularly march once a year down to the sea side, in a body of ten millions at a time, as they multiply in great numbers. They withdraw the month of April or May to begin their expedition, and then fall out by thousands from the stumps of hollow trees, which they excavate, from the holes which they dig for themselves under the surface of the earth, clefts of the rocks, and other hiding-places. At that time the whole ground is covered with this band of adventurers; there is no settling down one's foot without treading upon them. The sea is their place of deflation, and to that they direct their march, with the utmost precision. They never turn to the right or left for any obstacles that intervene, if they can possibly pass over them, and even if they meet with a house they will attempt to scale the walls. But though this be the general order of their route, they, upon other occasions, are obliged to conform to the face of the country, and if it is intersected with rivers they are seen to wind along the course of the streams, but if only a small rivulet occurs, they force their passage across it. The preceding sets forward from the mountains with the regularity of an army under the guidance of an experienced commander. They are said to be commonly divided into three battalions, of which the first...
Cancer.

consists of the strongest and boldest males, that, like pioneers, march forward to clear the route, and face the greatest dangers. They are often obliged to halt for want of rain, and to go into the most convenient encampment till the weather changes. The main body of the army is composed of females, which never leave the mountains till the rain is set in for some time, and then descend in regular order, being formed into columns of fifty paces broad, and three miles deep, and so close that they almost cover the ground. Three or four days after this, the rear guard follows, a straggling undisciplined tribe, consisting of males and females, but neither so bold nor so vigorous as the former. The night is the chief time of proceeding, and if it rains by day they do not fail to profit by the occasion; and they continue to move forward in their slow uniform manner. When the sun shines and is hot upon the surface of the ground, they halt, and wait till the cool of the evening. When they are terrified, they march back in a confused disorderly manner, holding up their nippers. They try to intimidate their enemies by clattering their nippers together, as if it were to threaten those that come to disturb them. Their disposition is carnivorous, though they most commonly subsist on vegetables; for if any of them by accident are maimed, in such a manner as to be incapable of proceeding, the rest fall upon and devour it upon the spot, and then pursue their march in the usual manner, sometimes two, or perhaps three months, in this manner, they arrive at their defined spot on the sea-coast, and then proceed to cast their spawn. The eggs are as yet within their bodies, and not excluded and retained, as is usual with animals of this kind, under the tail, for the creature waits for the benefit of sea-water to facilitate their exclusion. For this purpose the crab has no sooner reached the shore than it goes eagerly to the edge of the water, and lets the waves wash over its body two or three times. This has been thought necessary by some to ripen the spawn in the ovaria, as the crab, appearing satisfied with this light bathing, immediately retires, and seeks a lodging on the land. After this, they say, the spawn grows larger, is excluded out of the body, and adheres to the eiliated, or hairs under the tail. This bunch is seen as big as an hen’s eggs, and exactly resembling the roes of herrings. In this state of pregnancy they once more seek the shore for the last time; and flinging off their spawn into the water, leave them to the chance of fortune and accident to bring them to maturity. At this time whole shoals of hungry fishes are at the shore in expectation of this annual supply; the sea to a great distance seems black. At this time and about two thirds of the eggs are immediately devoured by those rapacious invaders. The eggs that escape are hatched under the land; and soon after, millions at a time of the little crabs are seen quitting the shore, and slowly travelling up to the mountains. The old ones, however, are not so active to return; they have become so feeble and lean that they can hardly crawl along, and the flesh at that time changes its colour. The molt of them, therefore, are obliged to continue in the flat parts of the country till they recover, making holes in the earth, which they cover at the mouth with leaves and dirt, so that no air may enter. There they throw off their old shells, which they leave, as it were, quite whole. At that time they are quite naked, and almost without motion, for six days together, when they become so fat as to be delicious food. It is said they have then under their linacous four large white fomes, which gradually decrease in proportion as the shell hardens, and when they come to perfection are not to be found. At that time the animal is seen flowing making its way back; and all this is commonly performed in the space of six weeks. This animal, when possested of its retreats in the mountains, is impregnable, for only subfiding on vegetables it seldom ventures out; and its habitation being in the most inaccessible places, it remains for a great part of the season in perfect security. It is only when impelled by the desire of bringing forth its young, and when compelled to defend into the flat country, that it is taken. At that time the natives wait for their defeat, in eager expectation, and destroy thousands, but disregarding their bodies, they only seek for the small spawn which lies on each side of the formic, within the shell, of about the thickness of a man’s thumb. They are much more valuable on their return, after they have cast their shells, for, being covered with a skin resembling soft parchment, almost every part, except the formic, may be eaten. They are taken in the holes, by feeling for them with an instrument; they are sought after by night, when on their journey, by flambeaux light. The inflant the animal perceives itself attacked, it throws itself on its back, and with its claws pinches most terribly whatever it happens to fall upon. But dextrous crab-catchers take them by the hinder legs in such a manner that the nippers cannot touch them, and thus they throw them into their bags. Sometimes also they are caught when they take refuge in the bottoms of holes in rocks by the sea-side, by chopping a flake to the mouth of the hole, which prevents their getting out; and then, when the tide coming, enters the hole, and the animal is found upon the water retiring, drowned in its retreat.

These crabs are of various colours, some are reddish, varied with black, some yellowish, and others bluish, inclining to blue. Those of a light colour are esteemed most, and when full in flesh are well tasted. In some of the fugar islands they are eaten with apprehension of danger, and form no inconsiderable part of the food of the poor negroes.

Pardius. Thorax oblong, with three teeth in front; eyes large and kidney-shaped. Herbst.

Body size of a small walnut. Colour entirely olivaceous, inclining to fuscous.

Aurantius. Thorax entire at the sides, and retuse before; front truncated and emarginate; hand-claws glabrous; legs compressed. Herbst.

Moderately large; general colour dully orange, or brownish on the thorax; legs paler and more obscure, lal joints furrowed longitudinally.

Corinus. Thorax undulated; hand-claws heart-shaped below, and muricated. Lin.

A large species, being somewhat larger than the ordinary size of our edible, or pound-crab, Cancer pagurus. The prevailing colour of the body tawny-brown, inclining to fuscous; legs pale fuscous, and emarginate at the edges. Inhabitants Surinam.

A small species of crab brought from New Zealand by sir J. Banks. The snout is short and exserted; thorax slightly depressed, and surmounted with a very entire margin; tail conic; legs smooth.

This
This kind has the front inflected and entire; thorax an elevated, acute, and entire margin. Arms large, projecting, and three-spined at the tip; hand-claws large, ovate, smooth, with incurved pincers. Antenna twice the size of the body. Posterior legs filiform, thighs canaliculated.

**HEXAPUS.** Thorax orbiculate and toothed in front; antenna longer than the body. Fabr. Linn. &c.

Body rather larger than a pea; hand-claws large; colour pale tawny. Found in European seas.

**PLATYCHELES.** Thorax smooth, orbicular, very entire; hand-claws flat beneath and ciliated; antenna very long. Herb. Penn. &c.

Herbst describes *Die kreiselförmige*, the name by which he calls this crab, as being rare in Europe. His figure is copied from that in Pennant’s zoology, upon the authority of which he records it as an English species. It occurs chiefly in our country, on the south coast of Anglesea. Muf. Dorow.

**ANATUR.** Thorax smooth, globular, crenated, very entire; hand-claws short, pincers two-edged. Herb. Die calteinenabbare.

**CANCELLUS.** Thorax smooth, crenated; margin of the breast prominently crenated; hand-claws two-edged; arms crenated. Mus. Herb. Linn.

Body roundish, about the size of a horse-bean; hand-claws rather long and linear. Colour pale brownish, dotted with white; claws and legs slightly fereinose.

**HISTRIS.** Thorax slightly orbiculate and smooth, with two teeth on each side; tip between the eyes three-toothed, the middle one largest. Scopoli.

**SCOPOLINUS.** Thorax subrotund, smooth, somewhat convex above; antenna capillaceous. Herb. Nutrix of Scop.

**ANTENNATUS.** Thorax subovate; antennae three times as long; hand-claws wedge-shaped. Forkel.

**PHILEGRUS.** Thorax convex, and fifteen-toothed behind. Linn. This inhabits Asia.

**CASSIDENS.** Head shielded, emarginated; arms with filiform appendages. Forster. Gmel.

**TALICUNA.** Thorax orbicular and very entire; hand-claws municated. This crab is four inches in breadth, fuscous, and becomes red in boiling. Fieh excellent. Inhabits Chili.

**GRANARIUS.** Thorax subovate, smooth, very entire; front cuspitate; eyes cylindrical. Fabr. Slabber.

A minute species of most extraordinary appearance; hardly larger than a grain of wheat. Thorax somewhat ovate, front conflating of a thick obtuse spine, having a smaller one on each side at the base; the large tubular or cylindrical eyes are placed behind them. General colour pale yellowish. Found in the fresh waters of Europe, but rarely.

**MINUTUS.** Thorax smooth, very entire, somewhat square, with the edges rather sharp; legs compressed. Linn. Cancer nutrix of Scopoli. Frequent in deep waters.

**PUSILLUS.** Thorax smooth, square, very entire, with a single tooth on the tarth. Herb. Linn. &c. Inhabits the North Seas, and is greatly allied to minutus, but is not more than one fourth its size, and is therefore extremely small; it is also depressed and of a pale colour.

**Section.** Thorax smooth, and cut at the sides.

**CORALLINUS.** Thorax obovate, one-toothed; front three-toothed. This inhabits India, and exceeds the ordinary size of our largest English crab, cancer pagurus. The thorax is of a fine coral red, variegated with a few whirih

This...
CANCER.

This is a large species, the legs expanding about twelve inches; the thorax is nearly quadrangular, and moderate in size. Colour pale brown.

MARMARIUS. Thorax smooth, with a single lateral tooth, white with rufous spots; front three-lobed; middle one emarginate. Herbf.

Thorax rufous, elegantly characterized with white; legs pale yellow; hand claws with a large rufous spot on each joint.

MACULATUS. Thorax smooth, with a single lateral tooth, yellowish with rufous spots; front three-lobed; middle one emarginate. Herbf.

Except in colour, this differs very little from the preceding, and may possibly be only a variety of it.

AMPHIPRITIE. Thorax tuberculated, with four dilated teeth each side; front two lobed; under surface of the hands and pincers fusceous.

Expands seven inches; general colour fine orange faintly spotted; legs variegated with indented fusceous marks. Perhaps a variety of floridus. Muf. Herbf.

DAINA. Thorax, and upper surface of the hand-claws tuberculated; thorax broad, and narrowing anteriorly; sides crenated with teeth; front with two distinct tubercles.

DORCAS. Thorax rather unequal; front obtuse, and two-lobed; sides compressed, somewhat emarginate, and toothed; hands and legs carinated; pincers black.

Size of the foregoing; thorax blue above; chelate arms and legs tectaceous brown.

METIS. Thorax unequal, with smooth tubercles; front cleft, with two emarginated lobes; margin with five teeth each side. Herbf.

Smaller than C. donee; colour pale; legs and arms moderate. Muf. Donov.

PANOPE. Thorax convex, granulated; front obtuse, with granulated margin, and cleft in the middle; sides four-toothed; pincers of the fore-claws black brown.

Smaller than cancer massae, and somewhat similar in figure; general colour olivaceous; upper surface of the hand-claws granulated and red. Herbf.

TYCHE. Thorax unequal, flat, tuberculated with granules; front advanced, obtusely rounded, and cleft; sides bidentated with two truncated warts; upper surface of the hand-claws tuberculated.

Cancer Tyche. Herbf. Smaller than the last, and of a dirty ash-colour; the tubercles on the hand-claws orange.

ELECTRA. Thorax unequal, and almost flat, tuberculated, and minutely granulated; sides five-toothed; front four-toothed; hand-claws granulated and dentated; pincers rounded, and blackish at the tips. Herbf.

PETRA. Thorax smooth, fusceous, with yellow spots; sides with a single tooth; front three-lobed. Herbf.

PHILE. Thorax smooth, and very glabrous; sides with a single tooth; front three-lobed, the middle one emarginate.

Length two inches; colour dusty olive. Herbf.

OCYRIS. Thorax smooth, somewhat tuberculated, with fusceous ocellate dots; side with a single tooth; front slightly truncated, and furrowed in the middle. Herbf.

CYMODOC. Thorax flat, depressed, nearly square, with a single spine on each side, somewhat truncated in front, and fix-toothed; inner margin of the arm dentated.

CALYPSO. Thorax convex, unequal, tuberculated, and granulated; sides three-toothed; front two-lobed, and granulated; hands granulated, and hispid; legs tectaceous.

EURYNOPE. Thorax flattish, tuberculated, and granulated; four jagged spines on each side; front with many teeth.

Size moderate, colour reddish brown, except on the legs, which are brown faciated with whitish: arms and hands prickly; front of the thorax crenulated, with about thirty teeth. Cancer eurynone. Herbf.

POLYDORA. Thorax unequal, slightly convex, tuberculated, and warted; hands warted; pincers fusceous; legs tuberculated with spines.

PRINCEPS. Thorax elevated in front; sides emarginate; dish streaked transversely with series of fuscous dots; legs banded with purple.

About the middle size; colour ochreous, dotted, and spotted with fuscous. Herbf.

PARVULUS. Thorax three-toothed at each side, and marked with impressed lines above; front entire.

Very small. Inhabits the shores of the American islands.

PAGUS. Thorax with nine obtuse plaits at each side; pincers of the hand-claw black at the tip.

This inhabits most of the rocky shores of England, and other countries of Europe, and is said to be in the highest perfection for the table about Chirillias. The flesh is much esteemed, as being more palatable and wholesome than that of any other kind of crab.

USBECUM-DENTATUS. Thorax nearly smooth, with eleven crenulate teeth at each side; proboscis three-toothed; fingers black at the tip.

A native of America. Thorax rather dilated behind, with crenated or rather ferrated teeth at each side; legs and hand-claws somewhat hairy.

SPINIFRONS. Thorax five-toothed at each side; second and third tooth bifid; front and hands many-splined. Fafr.

AENUS. Thorax very rugged, obtuse, and four-lobed at each side.

Inhabits India. The legs are compressed, varied with grey and rufous; lip doubled, and dotted with black; thighs with a black spot in the middle; hands small.

OCHTODES. Thorax unequal, obtusely toothed at each side; proboscis bifid; hands warty. Herbf.

Nearly the size of Cancer massae; pale flesh colour. Thorax with four, five, or six obtuse teeth at each side; arms and hands of the fore claw tuberculated.

LACTATUS. Thorax with four ferrated lobes at each side; hands ovate and smooth. Herbf.

*** Section. Thorax hairy, or fuscous on the back.

CHIRIS. Thorax hairy, suborbicular unarmed; hands ovate, and mucrinated. Linn. Inhabits the Indian Ocean.

SETOSUS. Hispid; thorax orbiculate, and tuberculated; front bifid and inflected.

Inhabits Chili. Described by Molin.

CRISTATUS. Thorax prickly; proboscis projecting; bifid, and crested; legs prickly. Rumphi.

GERMANUS. Thorax unequal, with a spine on the front, and another above the tail.

Inhabits the German Sea. The body is very minute; front with an ovate plate or lamina between the eyes, terminating in a spine; tail round, and conflating of five globular joints.

AVIRUS. Thorax one-spined in front, with the back sulcated and forth.

A species of small size that inhabits Iceland. Shell with a small
a small erect spine behind the eyes; arms one spined at the base and tip; thumb with a single tooth.

**Cruentatus.** Thorax tuberculated and red; front linear and truncated; Spotted. Includes the Mediterranean; body spotted with white at the tip; hands oblong; smooth, and armed with two teeth, and at the back.

**Hepaticus.** Thorax semi-circular, gibbous, and warly; the margin serrated. Herbill. A native of America and India.

**Scribunus.** Thorax tuberculated and flatish; the margin prickly; hands ended at the inner margin. Described by Herbst as an inhabitant of India.

**Genus Dorippe.**

Antennae four, the exterior ones fuscous, interior palpi-form; thorax somewhat heart shaped and wide at behind; hand-claws two, terminating in pincers; four posterior legs prehensile, and usually folded over the back.

**Lanata.** Thorax heart-shaped, unequal, depressed, hairy, and four-toothed in front; tail with fix teeth at the base.

**Fazincho.** Thorax smooth; margin very entire, with eight teeth in front. Der manis, Herbill. Pale brown, and twice the size of the following.

**Mascarone.** Thorax smooth; margin very entire, with fix teeth in front. Der mascarell, Herbill.

The two last mentioned species have the back of the thorax singularly indented with waved lines, that bear the resemblance of a grotesque human face; colour pale fuscous.

**Frascone.** Thorax tuberculated, entire; anterior part lobed and dentated. Herbill.

Colour brownish; hand-claws and two posterior pair of legs hairy; first joint of the two anterior pair hairy, the rest naked.

**Austua.** Thorax heart-shaped, depressed, and hairy; anterior part four-toothed; tail smooth. Fabr.

**Caliida.** Thorax heart-shaped, depressed, naked; front quadridentated; tail ciliated. Fabr.

**Dromia.** Thorax hairy, five-toothed each side; four posterior legs equal.

**Cancer lanatus.** Rumpf.

**Aegoprola.** Thorax globular, unarmed, and very hairy; pincers naked, and dentated within.

Dromia aegoprola. Fabr. Suppl.

**Artificiosa.** Thorax dawry, depressed, three-toothed at each side; posterior legs large.

Obs. There is reason to apprehend that several species of crabs described on the authority of naturalists in the gen-

**Genus Portunus.**

Antennae four, unequal, small, and jointed; the exterior ones fuscous and longest, interior palpi-form; body large, short, and dentated at the edges. Legs ten, the posterior pair terminated in an ovate plate, or swimmer.

† Division. Thorax bilobed at each side.

**Vigil.** Thorax smooth; arms spinous. This is a native of the Indian Ocean. Size moderate, eyes approximate, and situated upon very long peduncles; anterior tooth on the thorax much longer than the posterior one.
**Truncatus.** Thorax heart-shaped, pubescent, truncated in front, and eight-toothed.

Nearly allied to the two former, but differs in having the thorax broader, truncated in front and all the teeth smaller and more obtuse.

**Fasciatus.** Thorax in front eight-toothed; legs banded with purple, pincers scarlet. Herb. Donov.

**Callianassa.** Thorax fix-toothed; hands spines, and papillou at the angles. Herbil. Colour uniform dirty olivaceous brown.

†††† Division. Thorax with eight teeth on each side. 

**Menestho.** Thorax downy, truncated, and four-toothed in front, posterior lateral tooth large; arms of the fore-claws spines. Herbil.

A large species; thorax above ochraceous brown, legs fame paler.

†††† Division. Thorax with nine teeth on each side.

**Tranquebaricus.** Thorax smooth, with four teeth in front; arm dentated. Fabr.

A native of Tranquebar. This kind is eaten in the East Indies. The thorax is glabrous. Muf. Daldorff.

**Pelagicus.** Thorax smooth; posterior tooth large; hands multangular.

**Sanguinolentus.** Thorax smooth; posterior tooth very large, and three fangainous spots on the thorax. Herbil. Der Blutleech.

Commonly confounded with pelagicus, but certainly a distinct species: it has three red spots on the back of the thorax, and one on each hand, by which it may be readily known. Pelagicus is smaller, the thorax more rounded; posterior spine slender, and outline very diffimilar.

**Defensor.** Thorax smooth; posterior tooth short; front four-toothed, middle ones very short.

**Hastatus.** Thorax rugos; posterior tooth large; front four-toothed; teeth equal.

**Armiger.** Thorax somewhat smooth; posterior tooth large; front five-lobbled; arms dentated on both sides.

**Gladiator.** Thorax downy; posterior tooth large; hands spotted with fangaineous. Daldorff. Inhabits the Asiatic seas.

**Reticulatus.** Yellow reticulated with green; thorax four-toothed in front; posterior lateral, tooth very long.

Cancer reticulatus. Herbil. Above the middle size; prevailing colour yellowish; fore-claws reticulated reddish, fingers red. This is a most elegant species.

**Forceps.** Thorax smooth; posterior lateral tooth largest; fingers very long and filiform. Fabr. &c.

Rather small, and entirely of a pale bluish green colour. Herbil.

**Ponticus.** Thorax rugos; posterior lateral tooth large; hands filiform, fingers short. Fabr.

Smaller than cancer menas; colour pale brown. Muf. Donov.

**Cedonulli.** Thorax smooth, punctured; posterior lateral tooth large; dentated and emarginate, green with yellow spots; hand-claws elongated and multangular. Herbil.

This appears both in size and other particulars to nearly allied to portunus reticulatus, that they may be considered almost as varieties of this same species.

**Hastatoides.** Thorax downy; posterior tooth large, with a single small tooth each side behind. Inhabits the Indian Ocean.

††††† Division. Thorax elong-ovate, with three or more nearly equi-distant spines along each side.

**Marmillaris.** Thorax somewhat aculated and obtuse, with a three-pointed lobe in front; on each side a distinct fuscous mammilated spot. Muf. Donov.

Fabricius constitutes a new genus of this species in his Suppl. Ent. under the name of orithia. It is the only species of this genus known.

* Section. Murita.

Antennae commonly four, the inner pair of four joints, with the last joint bifid, the two exterior short, and scarcely visible; the hand-claws armed with pincers; all the legs terminating in an ovate plate or swimmer.

**Victor.** Thorax dotted all over, lateral margin sub-dentated, the posterior tooth very large.

**Palipes.** Posterior part of the thorax fricated. This inhabits the Indian Sea. Muf. Daldorff.

**Genus Calappa.**

Antennae four, nearly equal; exterior ones setaceous; interior of four joints, the last bifid; body short, enlarged behind; margin much dilated, and concealing the legs when folded; legs eight, terminating in claws; hand-claws two, hands compressed, and armed with pincers.

**Fornicata.** Thorax smooth, crenulated; posterior dilated, angles very entire; hands crenated.

**Tuberculata.** Thorax tuberculated, and many toothed, posterior dilated angle with crenated teeth; hands dentated.

Discovered in the Pacific Ocean. Muf. Bank. Cancer tuberculatus, Fabr. Ent. Syft. The thorax of this species is gibbous, with many tubercles and two impressed lines; snout short, obtuse, and somewhat reflected at the margins; legs simple, fingers fricated, and red at the tip; second joint of the hands tuberculated and acute; hands tuberculated.

**Granulata.** Thorax somewhat smooth and crenated; posterior dilated margin five-toothed; hands crenated.

Cancer granulatus, Linn. Inhabits the Mediterranean. This is a large species, of a pale yellowish, or cream colour, with several oblique roundish tubercles, of a reddish colour, on the fore part of the thorax, and a few on the under side of the hands.

**Marmorata.** Thorax somewhat plated, with three teeth on each side; front crenated and emarginated; arms dilated and toothed at the tip.

**Lophos.** Thorax slightly plated, and crenated on both sides; hind-margin dentated, and six toothed, the posterior angles dilated and five-toothed each.

Cancer lophos, Muf. Herbil. Inhabits the East Indies.

**Cristata.** Thorax slightly plated, and crenated on both sides; hind-margin with seven teeth; dilated posterior angle with three-teeth; hands crenated and toothed. Inhabits China. Muf. Donov.

**Angustata.** Thorax smooth, crenated on both sides with teeth, the posterior one narrow and smooth. Inhabits America. Muf. Lund.

**Gallus.** Anterior half of the thorax tuberculated; both sides crenated and dentated; the posterior dilated angle five-toothed; hands tuberculated above. Herbil.
**Cancer.**

Two or four antennae, small, quadriarticulate, and inserted between the eyes. Body subglobular, more or less convex, and generally inflated; tail naked; legs eight, and all furnished with claws; hand claws two, terminating in pincers.

**Species.**

**Division Ⅱ with ovate hands.**

**Scabiuscula.** Thorax depressed and scabrous, front emarginate.

The body of this species is small, depressed, and rough, with elevated whitish dots. This inhabits India.

**Globosa.** Thorax slightly curved; tail with two tubercles at the base; arms rough. Fabr. A curious species, discovered on the coast of Malabar by Dr. Koenig. Its size is small, figure somewhat globoso; arms rough, hands filiform. Herbist describes it under the name of *Die kugelkrabe*, Cancer globus.

**Crancklarios.** Ovate, very glabrous, or polished; anterior part projecting, and armed with three teeth; hands two-edged and smooth. Linn. *Die Henrichsharkrabe*, *Herbit*.

Body about the size of a small walnut, or rather less, the colour dark brown, slightly tinged with faint red and purpure; the claws are of the same colour, except the pincers, which are pink; legs brownish. This inhabits the shores of Malabar. *Muf. Donov.*

**Porcellus.** Thorax very glabrous, or polished, ovate, obtuse at the anterior part; arms granulated. Fabr. *Die porcellankrabe*, Cancer porcellus, *Herbit*.

This species is about the same size as the preceding, and somewhat resembles it in form, but has the anterior part obtusé, and without teeth; the lateral margins of the thorax are granulated; general colour pale brown, with the two extreme joints of the hand-claws bluish. Inhabits Tranquebar. *Muf. Donov.*

**Pila.** Thorax globose, with a single obtuse elevated tooth in the middle, and the margin crenated with teeth.

Inhabits India. The body is small, globular; front obtusé; hand-claws short and smooth.

**Planeta.** Thorax orbicular and flat; sides bidentated; front with three teeth.

This is a minute species, and inhabits Terra del Fuego.

**Urania.** Globose, highly polished; anterior part projecting and roundish; arms arched, hands smooth. *Herbit*.

An elegant kind of crab, nearly allied to Cancer crani-laris in figure, but above twice the size. The body and hand-claws are olive-sinuous, with some obscure rufous spots: from the tip of the front a broad white stripe descends nearly to the centre of the thorax, where it ends in a broad termination. The pincers of the hand-claws, and all the legs are yellow spotted with ferruginous.

**Division Ⅱ with filiform hands.**

**Punctata.** Thorax ovate, crenated, and three-toothed behind; fingers unarmed.

**Fugax.** Thorax oblong, three-toothed behind; middle tooth longest and recurved; fingers dentated.

Frequently confounded with the preceding species, but is certainly distinct. *Muf. Donov.*

**Nucleus.** Thorax orbicular, with two spines behind; arms granulated.

**Septemspinosa.** Thorax with an elongated and very acute spine on each side; five spines behind.

**Cancer hytrix, Fabr. Ent. Syll.** Inhabits the Indian Ocean.

**Cylindricus.** Thorax with two furrows; sides dilated, cylindrical, and spinous at the tip.

Inhabits Tranquebar. This is of a small size; front obtuse, and grooved in the middle; thorax with two large grooves, and a transverse one on the fore part, all hairy; sides of the thorax whitish, with red dots, rough, and armed at the tip with a strong acute spine; tail whitish, and rough, with two longitudinal grooves in the middle; legs and arms very thin. *Fabr. &c.*

**Eriaceus.** Thorax ovate and very spinous; marginal ones longest and dentated; arms prickly.

Described from the cabinet of Spengler, by Fabricius, as an inhabitant of the Indian Sea.

**Genus Oxyphoe.**

Antennae four (sometimes two), very short, and unequal; peduncles of the eyes lengthened, inserted in a central projection of the head, and extending along the front to the lateral angle of the thorax; body almost square; legs ten, armed with claws, the anterior pair, or arms, terminated in pincers.

**Ceratophthalma.** Thorax dotted; eyes prominent, and terminated in a spine.

Cancer curviro, Linn. Cancer ceratophthalma, Fabr. Ent. Syll. and Pallas, and Cancer curviro of Herbit and Gmelin. This is a species of moderate size, being rather larger than *Mena*; this inhabits the Mediterranean and Indian seas, from whence, about six feet, it comes up the shores, and wanders about the sand, running at intervals with great velocity. The right claw is commonly larger than the other; both are scabrous, as also are the legs, though only in a flight degree. The general colour is brown.

Fabricius supposes the two species, Curviro and Uca, of Linnæus, to be both of this kind, the latter being only an accidental variety, in which the cancer is marked with a rude figure, somewhat resembling the letter H.

**Heterochelos.** Thorax granulated; hand of one arm much larger than the other.

Cancer vocans, Linn. Cancer vocans major, *Herbit*. *O. Heterochelos, La Marc. Inhabits Jamaica, where it con-ceals itself under stones, and when caught, emits a kind of cry. Size of our common crab, Cancer Mena.*

Obs. Herbit has the figure of another species nearly allied to the above; in form the same, but not above one fourth of the size. This is called Cancer vocans major; perhaps the young, or a variety of the preceding, Cancer minor palustris, *Heterochelos* of Plumier. M. S. G.

Colour pale brownish; arms long, and flamed with rufous. *Muf. Donov.*

**Angulatus.** Thorax smooth; oblong, with two spines at the anterior part of the lateral angle. Cancer angulatus Linn. *Ocyphoe bipinosa*, La Marc. *Muf. Donov.*

**Levis.** Thorax smooth, with a single tooth at each side; hand-claws very smooth, right hand longest. Inhabits the Indian Sea. *Daldorff, Fabr. Suppl.*

**Minuta.** Thorax smooth, with a single tooth at each side; hand-claws very smooth and equal. Inhabits the isle of France. *Muf. Daldorff, Fabr. Suppl.*

**Brevis.** Thorax short, plated, with three teeth at each side; hand-claws long. *Herbit, Suppl.*

Moderately
CANCER.

Moderately small, colour in general pale brown. Muf. Donov.

Vocator. Thorax rugose, anterior part fissuous; right hand very large. Herb. Suppl.

Body somewhat gibbous at the sides, and narrowing rather behind; colour of the thorax; left hand-claw, and first joints of the legs dark red, the first variegated with black; large claw, and extreme joints of the legs pale brownish. Muf. Donov.

Genus MAJA.

Antennae four, the interior ones palpiform, exterior fetaeous; body ovate and tubicose, much enlarged behind, and narrowing towards a point in front; legs eight, armed with claws; hand-claws terminated in pincers.

Species.

* Section. Parthenope, Fabr. Arms of the chelate-claws usually very large.

GIRAFFA. Thorax spinous, spines ramose; hand-claws very long and tuberculated beneath. Inhabits the East Indies. Muf. Daldorff.

REGINA. Thorax unequal; margin spinous; hand-claws very long, with spinous angles. An inhabitant of the Indian seas.

LAR. Thorax unequal, four toothed; margin spinous; hand-claws smooth. This is a native of the East Indies. Muf. Daldorff.

ERIOCHELES. Thorax aculeated, hands ventricose, and spinous; fingers tufted with hairs. Cancer Eriocheles of Olivier.

Cancer maja, Linn. Parthenope maja, Fabr. Inhabits the northern parts of Europe, and England. Muf. Donov. Milkaken by Peayatt for Cancer Horridus. This is a large species.

DUBIA. Thorax smooth, three toothed in front; hands compressed, and ciliated; posterior legs very short and dolfal. Inhabits the Indian sea.

MURICATA. Thorax hairy, unequal, with a dorsal line and two dorsal spines on each side; marginal spines four; legs hairy.

CONTRARIUS. Thorax very unequal, tuberculated, and spinous, the front projecting and pointed; hand-claws muri- cated; legs simple, and banded with rufous. Herb. Body three inches in length, hand-claws six inches long and very large; colour pale brown in general, tips of the pincers of the fore-claws black.

ECHINATUS. Thorax heart-shaped, warted, aculeated; arms and hands of the chelate-claws echinated; legs muri- cated. Muf. Donov.

* Section. INACHUS. Fabr. Arms of the chelate-claws usually short or moderate.

HYBRIDA. Thorax hairy, unequal, with a dorsal line, and two dorsal spines; marginal spines four; legs naked at the tip.

INACHUS HYRIDUS. Fabr. Suppl. Very much resembles the foregoing, but is distinct. Inhabits India.

OVIS. Thorax ovate, hairy, with four spines each side.

Cancer hiricus, Herb. Inhabits the East Indies.

HIRUS. Thorax woolly, tuberculated; arms muri- cated; hands smooth.

ARANEUS. Thorax unequal; margin crenated on both sides; anterior part dilated and acute.

Opilio. Thorax prickly; margin three-toothed behind; hands somewhat smooth.

In the cabinet of Prof. Vahl. Inhabits the Mediterranean.

CONSUELA. Thorax covered with prickles; stout long, bidental to five-toothed above; one beneath. Inhabits the Norway seas. Muf. Vahl.

CHIAGRA. Thorax tuberculated, unequal; stout flat, acute; legs tuberculated. Muf. Donov.

ANGUSTATA. Thorax attenuated in front, and smoothish; stout projecting, bearded, and unmarginate at the apex. Inhabits the East Indies. Body minute; thorax smoothish with entire margin; legs spinous; hand-claws short, hands smoothish, the rest spinous.

SCORPIO. Thorax pubescent, with four erect spines; anterior legs very long.

PHALANGIUM. Thorax pubescent, with three acute spines on the anterior part, obtuse tubercles behind; stout bifid.

Common in Northern seas; frequent on the coast of England.

LONGIROSTRA. Thorax prickly, projecting, ascending, stout acute and bifid.

LONGIPES. Thorax prickly; hands ovate and scabrous; posterior legs very long.

Rumpf.

SETICORNIS. Thorax ovate, smooth, stout very long, and frerated on both sides. Herb.

PLANISSIMA. Thorax quite flat, and nearly square, with five teeth on each side, front trifid with spines; inner margin of the thighs, and first joint of the hand-claws dentated. Herb.

HIRTICORNIS. Thorax heart-shaped, unequal, dentated; front with two long, approximate, hirsute spines.

Thorax about the size of a small walnut; legs moderate, chelate; claws nearly the same size as the anterior pair of legs, or rather less; the whole slightly spinous, somewhat hairy, and of a fulvous colour. Muf. Donov.

DAMA. Thorax ovate, and granulated, with seven spines on each side; front with two ramose spines of three branches; arm and joint below the hands of the chelate claws very spinous. Herb.

Length of the body three inches; legs, and chelate claws
claw moderate; thorax brown; hand claws pale brown; legs blackish. Mut. Donov.

CORNUS. Thorax ovate, unequal, with four spines at each side, front four-furled, the interior pair very long. Herbst.

From three to four inches long; hand claws full formed, arms four-touched; thorax pale, oblique; legs darker. Mut. Donov.

SQUINAUD. Thorax obvate, unequal, pricked with lateral spines; front bifurcated; chelate claws moderate and full formed, arm and joint below the hand pricked; legs unarmed. Mut. Donov.

Cancer Squinado. Herbst. Habits European seas, and is a large species.

PHILIPPA. Thorax obvate, granulated, and unequal; snout very large, broad, square, and four-touched in front; hand-claws small and glabrous. Herbst.

Rather small, length one inch and a quarter, colour pale, legs faint yellow, spotted obscurely with reddish.

THALIA. Thorax ovate and granulated; sides spinous; front truncated, with two acute incurvated spines; hand-claws very small.

Length almost two inches; prevailing ferrugineous; hands black or blackish.

CHRYSONIS. Thorax somewhat ovate and tuberculated; anterior part much advanced, and armed with four long curved, horn-like spines.

PLATE. Thorax conic, tuberculated and spinous, with two long spines in front; hand-claws and legs unarmed. Herbst.

This is about an inch and a half in length; thorax pale brown, the two anterior spines approximate at the base, and curving a little to the sides upwards; legs pale fulvous, the first pair longer than the chelate claws.

STYX. Thorax ovate, tuberculated, warty, inout simple, and forck'd at the apex; anterior pair of legs thick, and hispid. Herbst.

Half the size of the former; hand claws very small; colour brown, pale on the thorax.

CANCER. Second Order. Cancrini Marenz. Linn.

Head not distinct from the thorax; thorax oblong, with an elongated tail, furnished with lateral appendages or crochets.

GENUS ASTacus.

Antennae pedunculated, unequal, the exterior ones long and fetcuous, inner pair divided at the extremity; body elongated; legs commonly ten; tail foliaceous.

Species.

Section*. Inner pair of antennae two-claw'd or bifid.

GAMMANUS. Thorax smooth; proboscis toothed at the sides, with a double tooth on each side, at the base; hands smooth.

Cancer gammanus. Linn. A'iacus Marinus. Fabric. This is the common lobster, a species frequent in all the northern parts of Europe. It is most abundant with us in the northern extremity of Scotland, but is far more frequent than ever there on the coast of Norway. In a general point of view we can add little to the history of the lobster beyond what has been already related by Mr. Pennant, upon the authority principally of Mr. Travis of Scarborough, and of which we shall avail ourselves in this place.

The lobster inhabits, says Mr. Pennant, all the rocky shores of our island, but chiefly where there is a depth of water. In Llyn in Carmarthenshire, a certain small bay, nothing different, except in size, borders in the land. In addition to this we must observe that the larger lobsters we have ever seen, I one from the coast of Scotland excepted, were taken in the lobster traps near the front of that part of Carmarthenshire mentioned in Mr. Pennant, and though to very large their flavour was delicious.

Lobsters are brought in vast quantities from the Orkney islands, and many parts of the eastern coast of Scotland to the London markets; (but the metropolis, in which they are chiefly caught, with lobsters at most seasons of the year, from the coast of Norway, and these latter are in more esteem for the table than the Scottish kind). Mr. Pennant mentions in his travels in Scotland, in 1769, that sixty or seventy thousand lobsters are annually brought to London from the neighbourhood of Montrose alone. Lobsters fear thunder, and are apt to call their claws on a great clay; it is said they will do the same on the ringing of a great gun, and that when men of war meet a lobster boat, a jocular threat is used, that if the matter does not fill them good lobsters they will salute him. When irritated, or in heat, the lobsters frequently throw off their claws, and the same happens commonly when those poor animals are plunged into the boiling pot for dressing. When first caught, or taken or entangled only by the claw, they will throw it off with a sudden jerk, and so effect their escape.

The habitation of this species, as Mr. Pennant tells us, is in the clearest water, at the foot of rocks that indwell upon the sea. This has given opportunity of examining more closely into the natural history of the animal than many others, who live in an element that prohibits most of the human researches, and limits the inquiries of the most inquisitive. Lobsters are found on most of the rocky coasts of Great Britain. Some are taken by the hand, but the greater quantity in pots, a fort of trap formed of twigs, and baited with garbage; they are formed like a wire-manufact-trap, so that when the lobsters get in, there is no possibility of returning. These are fastened to a cord sunk into the sea, and their place marked by a buoy. They begin to breed in the spring, and continue breeding most part of the summer. They are highly prolific. Dr. Baker says he has reared 12,444 eggs under the tail of one female, besides those that remained in the body unproduced. The eggs they deposit in the sand, where they are soon hatched. Lobsters change their tails annually like other crustaceous animals. Previous to their putting off their old one they appear fleshy, inoue, and restless. They totally acquire a new coat in a few days after casting off the former one. During the time that they remain defended they seek some very lonely place, for fear of being attacked and devoured by such of their brethren who are not in the same weak situation. The circumstance of the reproduction of the claws in lobsters, though surprising, is sufficiently well known: lobsters, as well as crabs, will renew their claws, if by accident they are torn off, within the space of a few weeks after the mischief has happened. They are very voracious animals, and need on sea-weed, garbage, dead bodies, and similar food.

Mr. Travis communicated some interesting particulars relative to the history of the lobster from a variety of observations made by himself on the coast of Scarborough. Lobsters, he observes, are found in vast numbers, and very fine, upon that coast. The larger ones are in general in their best season from the middle of October till the beginning of May. Many of the small ones, and some few of the larger, are good all the summer. They are, in general, from four to four inches and a half from the tip of the head to the
the end of the back shell. Commonly the pinchers of one of
the lobster's large claws are furnished with knobs, and those
of the other claw serrated; with the former it keeps firm hold
of the flanks of submarine plants, and with the other it cuts
and mines its food very dexterously. The knobbed or numb-claw,
as the fishermen call it, is sometimes on the right, and
sometimes on the left indifferently. It is more
dangerous to be seized by them with the cutting claw than
the other, but in either case the quickest way to get dif-

gaged from the creature is to pluck off its claw: a new
one will be produced in its place, though it will never attain
the size of the former. The female, or hen lobster, does not

call her shell the same year that she deposits its ova, or in
the common phrase, the berry. In the fall when the ova first
appear under her tail, they are very small and extremely black, but
they become in succession almost as large as ripe elder berries
before they are deposited, and turn of a dark brown colour,
especially towards the end of the time of her depositing
them. They continue full, and depositing the ova in con-
stant succession as long as the black substance can be found
in their body, which, when boiled, turns of a beautiful red
colour and is called the coral. Hen lobsters are found in
berry at all times of the year. It is a common mistake that
a berried hen is always in perfection for the table. When
her berries appear large and brownish, she will always be
found exhausted, watery, and poor. Though the ova be
call at all times of the year, they seem only to come to life
during the warm summer months of July and August.

Great numbers of them may then be found under the
appearance of tadpoles swimming about the little pools left by
the tides among the rocks, and may also under their proper
form from half an inch to four inches in length.

In calling their shells, it is hard to conceive how the
lobsters are able to draw the flesh of their large claws out, leav-
ing the shell entire, and attached to their body; in which
state they are constantly found. The fishermen lay the
lobsters pine before calling, till the flesh of its large claw is no
thicker than the quill of a goose, which enables it to draw
its parts through the joints and narrow passage near the
trunk. The new shell is quite membranous at first, but
hardens by degrees. Lobsters only grow in size while their
shells are in their soft state. They are chosen for the table
by their being heavy, in proportion to their size; and by
the hardness of their shells on the sides, which when in
perfection will not yield to moderate pressure. Barnacles
and other small shell-fish adhering to them are esteemed
certain indications of superior goodness. Cock lobsters are
in general better than the hens in winter: they are dif-
tinguished by the narrowness of their tail, and by their
having a strong spine upon the centre of each of the trans-
verse processes beneath the tail, which support the four
middle plates of the tails. The fish of the lobster's claw is
more tender, delicate, and easy of digestion than that of
the tail. The Scarborough fishermen do not take lobsters
in pots as is usual in flint and deep waters; they use a bag-
net fixed to an iron hoop, about two feet in diameter, and
suspended by three lines like a sela. The bait is commonly
fish-guts tied to the bottom and middle of the net. They
can take none in the day-time, except when the water is
thick: they are commonly caught in the night, but even
then it is not possible to take any without the sea, for that lu-
sinous appearance which is supposed to proceed from the
wetness of the shell. In summer the lobsters are found near the
shore, and there to about six fathoms depth of water; and
in winter they are seldom taken in less than twelve or fifteen
fathoms. Like infels, they are much more active and alert in warm weather than in cold. In the water they can
run nimbly upon their legs, or small claws, and if alarmed,
can spring, tail foremost, to a surprising distance as swift as
a bird can fly. The fishermen can see them pass about
thirty feet, and by the swiftness of their motions, suppose
they may go much further. Athenaeus remarks this cir-
cumstance, and says the incertus lobsters will spring with
the alacrity of dolphins. Their eyes are raised upon move-
able hairs, which enables them to see readily every way.

When frightened, they will spring from a considerable dis-
tance to their hold in the rock; and, what is not least fur-
prising than true, will throw themselves into their hold in
that manner, through an entrance barely sufficient for their
bodies to pass: as is frequently seen by the people who en-
due caverns to take them at Fishy bridge. In frothy weather,
if any happen to be found near the shore, they are quite
torpid and support.

Body smooth, pale, and without spots; hands flat, above reddish, beneath yellowish, with a single raised line; legs yellowish. Size of the common shrimp.

Boreas. Thorax prickly, second and third pair of legs filiform. Fabr. Described in Phappe's voyage as an inhabitant of the North Sea. The proboscis is short, depressed, acute, grooved on both sides, with a strong tooth beneath.

Carinatus. Thorax with a dentate keel; proboscis short, recurved, and furnished with three teeth at the tip. The nature of this species is unknown.

Gonocladia. Thorax with a dentate keel; feelers spinous at the tips, body fuscos. Inhabits the Greenland seas. Smallest advanced, with three teeth above and two beneath; external pair of antennae very long, and variegated with red and white; anterior part of the margin of the thorax with three teeth, and back carinated with four; segments of the abdomen ending in a spine each side; middle leaf of the tail with two toothed lines.

Varius. Margin of the thorax with a single tooth; proboscis forked on both sides; body variegated. Described by Fabricius from a specimen taken in the Norway Ocean in the month of August. The external antennae are longer than the body, rufous with white spots. Thorax cylindrical, smooth, with a strong tooth above the eyes. Proboscis projecting, ascending, and forked both above and beneath. Abdomen cincture, with many oblique rufous bands; middle leaf of the tail tubulate; second pair of legs filiform, and longer than the rest.

Section. **Inner pair of antennae three-cleft.**

Jamaicensis. Proboscis forked above, beneath tridentate; arms and hands muriated, pinchers with a strong spine on the inner edge. Sloane, &c. Inhabits Jamaica.

Pennatus. Thorax smooth; proboscis projecting and forked on both sides, beneath smooth; fingers filiform.

This is smaller than the last. Margin of the thorax with a single tooth each side; hands short, ovate with linear acute fingers.

Crangon. Thorax smooth; proboscis short, and very entire; hands with a single movable fang. Inhabit most sandy shores of Europe. With us is known by the name of shrimp. Flesh delicate. This has only six legs; middle leaf of the tail tubulate; colour pale-yellowish, semi-transparent and dotted.

*** Family Palaemon.***

Antennae four; the interior short and bifid; exterior long, simple, with a scale or plate at the first joint of the peduncle.

Tamalus. Hand-claws unequal; the left hand small and filiform. Inhabits the Indian Ocean. Daldorff.

Avarus. Hand-claws unequal; short and subulate. Inhabits India. Daldorff. The inner pair of antennae blue; thorax smooth; snout sharp-pointed; four hand-claws, the anterior ones largest; right hand large and compressed; posterior pair very thin and filiform.

**O.** Tamalus and avarus are perhaps only varieties of the same species.

Rapax. Hand-claws unequal; anterior part of the thorax carinated; snout subulate. Daldorff. A native of the Indian Sea. Thorax smooth and glabrous; four hand-claws, the anterior pair of which has the right hand, sometimes the left hand large.

Malabaricus. Hand-claws unequal; right hand largest; legs filiform.

Inhabits the Indian Sea. Left hand longer than the right; (which is largest), and filiform.

---

**Genus Longimanus.*** Hand-claws advanced, unequal, smooth; front straight, and of the same length as the antennae plates.

Inhabits the East Indies. The thorax is smooth, with two teeth on each side at the anterior part; hands filiform, projecting, smooth, the left one much longer; legs smooth.

**Brevenus.*** Hand-claws of moderate length; shining or pinchers rather short; protum ascending, and longer than the antennae plates.

A native of the East Indies. Muf. Daldorff. Smaller than *Longimanus*; snout compressed, and serrated on both sides; thorax smooth, glabrous, with two teeth on each side of the anterior part; hand-claws filiform, and rather longer than the legs, and smooth.

**Coromandelicus.*** Hand-claws of moderate length; pinchers rather short; front same length as the antennae plates. From the coast of Coromandel. Very similar to the preceding, of which it may be only a variety; it differs principally in the proboscis, being shorter as well as the pinchers.

**Tranquebaricus.*** Hand-claws long and filiform; hands ovate. Inhabits Tranquebar. Daldorff.

Snout ascending, rather longer than the antennae plates, and serrated at the back; hand-claws as long as the body, filiform, very thin and smooth; hands thick; legs filiform and smooth.

**Lar.*** Hand-claws projecting, equal, muriated; snout straight, and length of the antennae scales.

Inhabits India. Fabr. Thorax smooth, with two acute teeth on each side; snout compressed and serrated; legs muriated.

**Serratius.*** Thorax smooth and subcarinated; snout serrated on each side. inhabits the Norway Sea. Vahl.

**Fucorum.*** Thorax smooth; snout ascending, with five teeth at the apex. Lives among fucus. Daldorff.

**Squilla.*** Thorax smooth; proboscis forked above, and three-toothed beneath; margin of the thorax with five teeth. Fabr.

The prawn. Inhabits European seas.

***** Family Alpheus.***

Antennae four; the interior short and bifid; exterior long, simple, with a scale or plate at the first joint of the peduncle.

Tamalus. Hand-claws unequal; the left hand small and filiform. Inhabits the Indian Ocean. Daldorff.

Avarus. Hand-claws unequal; short and subulate. Inhabits India. Daldorff. The inner pair of antennae blue; thorax smooth; snout sharp-pointed; four hand-claws, the anterior ones largest; right hand large and compressed; posterior pair very thin and filiform.

**O.** Tamalus and avarus are perhaps only varieties of the same species.

Rapax. Hand-claws unequal; anterior part of the thorax carinated; snout subulate. Daldorff. A native of the Indian Sea. Thorax smooth and glabrous; four hand-claws, the anterior pair of which has the right hand, sometimes the left hand large.

Malabaricus. Hand-claws unequal; right hand largest; legs filiform.

Inhabits the Indian Sea. Left hand longer than the right; (which is largest), and filiform.
Genus Scyllarus.

Antennæ four, unequal; inner pair rather long, filiform, with the last joint bident; exterior ones depressed, flat, and dilated, and dilated with spines; thorax large, and usually aculeated or rough; body long; tail with swimming appendages; legs ten; no cheliform arms.

Species.

Arctus. Five spines on the anterior part of the thorax; plates of the antenna ciliated and aculeated.

Cancer arctus. Linn. Potitiqueiue. Jonnt. Umiknak. Müller. Urfa cafrata. Belon. and Der Bärenkrebs of Herbst. This is an inhabitant of mott sea. Its size is superior to that of the common lobster. The shells are tuberculated, of a brown colour, and spotted with yellow; legs spotted; thighs spines. Muf. Donov.

Orientalis. Scabrous; anterior part of the thorax at each side armed with three spines; eyes placed close to the foremost one. East Indies. Fabr. Muf. Donov.

The thorax of this species, which is of the middle size, is rough, with three distinct elevated spines down the back; colour pale brown.

Discovered in the South Seas. Its general figure somewhat resembles arctus, but is narrower; the thorax unequal, with crenated margin; claws simple.

Genus Palinurus.

Antennæ four, unequal, pedunculate; peduncle jointed; interior pair short; fctalaceous, bident, and unarmed; exterior very long, fctalaceous, and aculeated, or bifid; body elongated; legs ten, armed with claws dilate of pincers, and tufted with hair at their extremity.

Species.

Polyphas. Thorax very slightly spiny; legs marked with blue. Herbst.

Ornatus. Green, fides spotted with white, abdominal segments smoothish; nearly allied to homerus; shorter antenna, and legs blue, banded with white.

Inhabits the Indian Sea. Fabr. &c. Probably a variety of polyphas, and not sufficiently distinct from the following species, which is also introduced from Fabricius.

Genus Galathea.

Antennæ four, unequal and pedunculate; inner ones short, filiform, of three joints, that at the extremity bident; outer pair fctalaceous and long; body elongated; tail foliaceous; legs usually ten; arms chelate.

Species.

Length from five to seven inches when full grown; colour brown; tips of the pincers of the fore-claws red. Inhabits Europe. Muf. Donov.

Discovered by Mr. Cordiner on the coast of Bamiff, Scotland. Muf. Donov.

Gregaria. Thorax with ciliated plates; snout with three denticles; anterior feelers very long. Fabr.

Much smaller than the two preceding. It is found in the sea round the coast of Patagonia, where it occurs sometimes in such vast shoals that the sea appears perfectly red, that being the prevailing colour of them when alive; it has a brown spot on the back; and the hand-claws are rough, Muf. Bankf.

Amphicrins. Thorax smooth; snout very short and emarginate; middle pair of legs very long.

The body of this kind is small, whitish, subdianous, and dotted with red; thorax unarmet, roundish behind, and broad, and narrowing towards the front; four antennæ fctalaceous, and very long; abdomen of five segments; tail of five leaves, the middle one tongue-shaped.

This kind is highly luminous by night; it inhabits the Atlantic, near the coast of Brasil. Fabr. Muf. Bankf.

Genus Hippa.

Antennæ sometimes two, and pedunculate; commonly four unequal, and fringed with thick hairs; inner pair very short, and bifid; body oblong; tail with small lateral appendages at the joints next the base; legs usually ten, and delicate of pincers.

Species.

Adactyla. Thorax smooth, with very entire margin; tail infeffed, the last joint long, tubulate, and ciliated at each side; hand-claw without fangs. Inhabits the South seas: Bankfian Cab. Cancer Adactyla, Gmel.

Dorsifera. Thorax glabrous, truncated in front, and armed with seven teeth; hand-claws compressed, and furnished with a falcated thumb. Fabr. Cancer dorsifera, Linn.

This kind inhabits the Indian and Southern Oceans. Length of the body and tail about three inches. Thorax smooth, and of a whitish colour, the margins hairy and cre- nated; a small plate ciliated with denticles projects before the front. The outer feelers contain four joints, the first and second of which are long, ciliate, and compressed, and ciliated; tail thin; hand claws rough above, beneath smooth, pincers very short.

The thorax of this species is large, ovate, and rough, with elevated oblong dots, fides crenated; tail very short, infeffed and ciliated; hand-claws incurvated, hands large and rough, with
with two teeth on the superior margin, and five on the lower on: legs eight, compressed, and ciliated, the extreme joint ovate-lanceolate. Fabr. &c.

**Dentata.** Thorax smooth, with five teeth on each side; tarso-spinous. Fabr. Inhabits European seas.

Moderate size; glossy, pale color, with a tooth on each side, behind the eye, three in the middle, and one behind; arms twice the length of the body, and somewhat spinous.

**Scutellata.** Thorax nearly entire and ciliated; hands chelate. Fabr.

Described by Fabricius, from a specimen in the British museum. Native place unknown. It is small, with ovate thorax, rounded in front, and becoming narrower behind; hands smooth.

Gemelin adds to the above species, Cancharius of Linn. and Sinicus of Herbst, but expresses doubt whether they are of this family or genus.

**Cancharius.** has the thorax rugose, oval, hands compressed, and spinous at the margin. Linn. Inhabits South America and India.

**Sinicus.** Thorax somewhat compressed, oval, and spinous; arms and legs spinous. Herbst. A native of China.

* Section Symethis.

**Antenna two, very short, and containing four joints each.**

This species, arranged in the former works of Fabricius in the genus Hippa, forms a new genus, of which it is the only species in Supplementum Ent. Syr. under the name of Symethis, Fabricius having found that instead of four antennae it possesses only two, and those different in structure from Hippa. His genus Symethis is thus defined: antenna due brevissima, quadriarticulata, intra rostrum binae reconditae. Perhaps it ought rather to form a new genus than section of Hippa, in the present arrangement. It is of the middle size; five short and toothed; anterior part of the thorax with unequal impressed dots and obtuse teeth, smooth behind, with lateral rugosities; hands smooth; legs elongated, ciliated, and hooked at the tip. Muf. Spengler.

Obs. Fabricius in Supplementum Ent. refers five of the above described species to his new genus albuna; symmíta, coelitata, dorípes, scabra, and dentata.

**Genus Ranina.**

Antenna four, short; the two inner ones bifid at the extreme joint; body oblong, wedge-shaped, truncated in front; tail large, and ciliated at the edges; legs eight, the four posterior ones terminating in swimmers; hand-claws two, armed with pincers.

Species.

**Serrata.** Cancer raninus, Linn. ? Ranina serrata, La Marech. The thorax of this crab is aculcated, or covered with prickles; color fuscous; hairs that fringe the legs and tail yellowish brown. Inhabits the Indian seas. Rumph. and Herbst.

**Genus Squilla.**

Antenna four, nearly equal, and pedunculate; interior pair rather long and tridactyl, the exterior ones with an oblong plate; thorax long; tail very long, and enlarging towards the posterior extremity; legs fourteen.

Species.

**Maculata.** Hands with a single ten-toothed fang; body very smooth; tail five-toothed on each side. Fabr. Suppl.

**Manus.** Hands with a single six-toothed fang, subulate; tail serrated and spinous. Fabr. Suppl. Cancer manus, Linn.

Inhabits chiefly the Mediterranean and Asiatic seas. Eaten by the Italians and the Chinese. Length about five or six inches.

**Raphidia.** Hands with a single eight-toothed fang; body with two elevated lines on each side.

**Phalangium.** Hands with a single five-toothed fang, the first and third tooth of which are longest; body smooth. Inhabits the East Indian seas. Body smaller than S. manus, smooth, glabrous; tail segment serrated with spines. Muf. Dalldorf.

**Ichnesmon.** Hands with a single four-toothed fang; margin of the tail ciliated, with thick spinous protruberances.

From the East Indies. Muf. Dalldorf. Smaller than S. phalangium; body with three elevated lines on both sides.

**Ciliata.** Hands with a single three-toothed fang; two extreme joints of the abdomen ciliated with spines. Inhabits the Indian seas. Spengler.

**Chiagra.** Hands with a single fang, pubulate, with a rufous protruberance at the base. Fabr. Squilla arenaria of Rumphiuss. This is a native of the South Sea. Muf. Banks.

**Genus Pagurus.**

Antenna four, unequal, the inner ones short and bifid at the summit, the exterior flataceous, and usually longer; body oblong, thorax crufaceous; abdomen vesicular, naked, soft, and furnished at the tip with hooks or claws.

The species of this genus are mostly parasitical, and inhabit the empty cavities of turbinated shells, the animals of which they attack and devour to gain possession of their shell, and it is chiefly on the tesselaceous mollusca, or shell-fish, that they subsist. They change their habitation as they increase in growth, first occupying the shells of the common periwinkle, or trochus, then perhaps a nent as large as a walnut, and after that a whelk. But the paguri of climates warmer than those of Europe are often larger than with us, and require shells of considerable size for their habitation. The tail is naked and tender, being covered only with a skin of very delicate texture, but it is furnished at the extremity with one or two hooks, by means of which it secures itself to the shell which it makes choice of. It is astonishing with what facility those animals crawl both in the water and on the land, bearing at the same time the shell that serves them as a covering on their back. They are indiscriminately called soldier-crabs and hermit-crabs, from the idea of their living in a tent, or retiring into a cell.

Species.

**Latro.** Thorax at the future four-cleft; tail simple and ventricose beneath. Linn. Bouverges, Rochef. &c. A native of the East Indies. Inhabits the holes and cavities of rocks, from whence it wanders abroad in the night-time in search of cocoa nuts, which it procures by climbing up the trees, and throwing them down, then descending after them, and tearing them open with the two fore-claws.
The Indians eat the flesh of this kind of hermit-crab after taking out the entrails, which they think poisonous.

**Miles.** *Parafitic.* Left hand largest, and muricated on each side; legs with very long ferrated claws. Herb. Fabr.

A species of large size. inhabits the East Indies.

**Custos.** *Parafitic.* Left hand-claw largest; hand smooth; legs with very long smooth claws. Fabr.

A native of the East Indies, described in Suppl. Fabr. from the Museum of Dallorff; much resembles Miles, but is different.

**Diaphanus.** *Parafitic.* Depressed; left hand largest and smoothish; joint below dilated on the back. Inhabits the Indian sea.

**Aniculus.** *Parafitic.* Thorax ovate, ciliated at the sides; legs rugged, and hairy. Fabr. Derived from the Bankian cabinet. Inhabits the South Seas.

**Bernhardus.** *Parafitic.* Hand-claws muricated, the right one largest. Linn. An European kind.

**Hungerus.** *Parafitic.* Hands hairy and tipped with black, the right one largest, body banded with red. Herb. Fabr.

A native of India. Smaller than Pagurus Diogenes. Peduncle of the eyes pale with red bands; body smooth; legs and hands hirsute.

**Clypeatus.** *Parafitic.* Thorax smooth, very entire and compressed; left hand largest, and with the legs dotted. Fabr.

Body small, compressed, whitish. Antenna fusous; hands white, with purple dots, and a marginal blue spot. Legs white with innumerable dots and specklings of purple.

**Diogenes.** *Parafitic.* Hands muricated, pubescent; left hand largest. Fabr. Suppl. &c.

Called by Kempfer, Gani na al Koonal, and Medderman of Rumphius. Inhabits American and Indian seas. This, like most of its genus, inhabits empty shells; the general colour is pale tesselaceous or yellowish brown.

**Tubularis.** *Parafitic.* Subcylindrical; shell with excrated dots. Fabr.

Cancer tubularis, Linn. Inhabits the shells of Serpula glomerata in the Mediterranean.

**Oculatus.** *Parafitic.* Hand-claws muricated, equal; peduncles of the eyes as long as the thorax. Fabr.

Found chiefly in the shells of Murex Brandaris. Size of Bernhardus, our common hermit crab. Body entirely ferruginous; peduncles of the eyes advanced or projecting, cylinodrical, with a tooth at the base. Arms with a fanguineous spot on each side; hand-claws rough.

**Alatus.** *Parafitic.* Hands smooth, with three wing-like projections; right hand largest. Fabr. Inhabits Iceland. Dr. Koeng. Rather smaller than Bernhardus; joint below the hands rough; wing-like projections acute.

**Ophthalmicus.** *Parafitic.* Hands equal, muricated; legs faciculated with hairs; eyes clavate. Inhabits the Indian Ocean. Dallorff. Eyes large, and placed on short peduncles, at the base a small acute scale; hands smooth, equal, muricated, with hairs, rufous. Perhaps Cancer Chlamaricus of Herb. 

**Araneiformis.** *Parafitic.* Hands rough; tail callous at the tip, and furnished with a hooked tip. Fabr.

**Scopetarius.** *Parafitic.* Thorax smooth, entire; hands equal, granulated, thighs of the second pair of legs compressed. Herb. Der Mufkettier.

This is about half the size of Pagurus Bernhardus; colour pale brown, with a blue streak down the middle of the two anterior pair of legs, and peduncles of the eyes of the same colour.

**Tympanista.** *Parafitic.* Thorax smooth, very entire; legs fricated; claws marbled. Der Trummelschläger. Herb. Smaller than the foregoing; hands linear.

**Tricus.** *Parafitic.* Thorax smooth, and very entire; left hand-claw largest; hands and legs chefnut, whitish at the tip.

**Excavatus.** *Parafitic.* Right hand largest, with two excavations, and another similar on the movable pincer. Der Aufstehliche. Herb.

**Sclera.** *Parafitic.* Hands muricated, left one largest, whitish; inner sides bearded; eyes obliquely wedged, pedicle compressed. Forfkal, &c.

**Lagopodes.** *Parafitic.* Cincinnus brown; legs rough with hirsutes; left hand largest. Forfkal.

**Dusi.** *Parafitic.* Hands somewhat globular; that on the left side small. Herb. Muf. Donov.

**Canaliculatus.** *Parafitic.* Hands and joint below grooved, with elevated denticulate margin; legs with hairy tufts. Cancer canaliculus. Herb.

**Megasos.** Rufous with roundish white spots; hands and legs spinous, and hirsute. Herb.

A beautiful species, legs and claws vermilion; thorax paler and body inclining to purple, and sprinkled all over with distinct roundish white spots; half segment of the abdomen and base of the tail red, but the tail itself brown and immaculate. Size of a moderately small lobster, or rather less.

**Strigatus.** *Parafitic.* Thorax rather flat, and whitish; hands and legs rufous, with transverse streaks. Herb. Muf. Found in a volute. Smaller than Pagurus Bernhardus.

**Pedunculatus.** *Parafitic.* Thorax flat, depressed; peduncles of the eyes thick; left hand largest, inflated, and muricated. Herb. Muf. Donov.

General colour pale ferruginous; abdomen cinerous, marked with pale, yellowish at the tip; two posterior pair of legs pale.

**Arrosor.** *Parafitic.* Thorax flat; hands and legs with numerous transverse, irregular furrows. Cancer Arrosor, Herb.

**Crustaceous Animals.**

Third order, Crustacea artifices, La Marek.

Heads generally distinct from the thorax; eyes fixed and sessile; body long, and covered with many plates.

**Genus Gammarus.**

Antennae four, very simple and pedunculate; anterior ones short and tubulate; posterior setaceous. Head distinct, body small, oblong, compressed, linear, of many joints. Tail with many riles; legs numerous.

**Species.**

**Ampulla.** Hands without fangs; legs fourteen; posterior thighs compressed and dilated. Inhabits the North Seas. Phipps.

**Caninatus.** Hands without fangs; legs fourteen; back carinated, and spinous. Fabr. Larger than Gammarus Locula; body whitish, somewhat compressed, back carinated; segments somewhat spinous behind. Muf. Brit.

**Nugax.** Hands without fangs; legs fourteen; fix posterior thighs compressed and dilated. Inhabits the North Seas. Phipps Yor.

**Canellus.** Hands without fangs; legs sixteen. Inhabits rivers of Siberia. Onicus cancellus of Pallas.

**Locusta.** Hands four, without fangs; legs fourteen, thighs
CANCER, or Cancer, in Entomology, a species of Cancer (Hippa Fabr.) described by Linnaeus as a native of South America and India, the thorax of which is oval and rugged, with the hand-claws compressed, and spinous at the margin. CANCHE, in Geography, a river of France, which runs into the sea, near Etaples, in the department of the Straits of Calais.

CANCHY, a town of France, in the department of the Somme, 5 miles N. of Abbeville—also called, a town of the department of the Calvados; 10 miles W. of Bayeux.

CANCÓN, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Villeneuve-d'Agon, 2 leagues W. of Montluçon. The place contains 1423, and the canton 3566 inhabitants; the territory includes 1023 kilometres, and 11 communes.

CANCRIFORMIS, in Entomology, a species of Cerambyx, found in South America. The thorax is armed with many teeth; back flat; wing-cases and anterior flanks with a single tooth. Fabricius. Obs. This is cerambyx pulluclus of Drury's illustrations.

CANCRIUS, in Poetry, denote the same with retrograde; which see.

CANCRIUS of Rampart, in Entomology, synonymous with Cancer Cursor. See Cursor.

CANCRIUS, in Entomology, a curious genus of flies, called in England the boat-hall. The structure of its body is very extraordinary, and has been described compared to an inverted boat, wherein its name; it is also gibbous, or swollen; nodules small, placed in a furrow; tongue small; toes divided.

Two species only of this genus have been hitherto discovered, namely, cochlearia and camposphaga, which see.

CANCROPHAGA, a species of Cancro, with a whitish belly. This is the cochlearia fuscus of Brill, the tamara of Maregraves, Ray, &c. and earlier use of Buffon.

CANCZUCI, in Geography, a town of Poland, in the palatinate of Lemberg; 35 miles W. of Lemberg.

CANDA, a town of Italy, belonging to the state of Venice, in the Polesin de Rovigno; 14 miles W.S.W. of Rovigno. Also, a river of England, which runs into the Eden at Carlisle.

CANDABORA, in Ancient Geography, a town of Spain belonging to the Celtiberians. The city.

CANDAHAR, or Kandakar, in Geography, a country of Asia, being part of the ancient Parthus, and situated between the two powerful kingdoms of Hindooostan and Persia, became alternately a province of the Mogul empire and of Persia, till it was again formed into an independent kingdom, as it had formerly been, by Ahmad Shah, one of the Afghan tribe of Abdali, who, from an obscure origin, rose progressively in the service of Nadir Shah, or Kuh Khan, to the rank of an Afghan prince. Nadir stripped him of his country, and compelled him to join his army in 1739. On the death of Nadir, he suddenly appeared among his former subjects, and, in a short time, erected himself as a considerable kingdom in the eastern part of Persia; adding to it most of the Indian provinces ceded by the Mogul to Nadir Shah. He died about the year 1753, and was succeeded by Timur Shah, usually styled king of Candahar, whose subjects, in 1782, are said to have lived under an easy government, considered as an Aryan one. At this time the military force of Candahar was estimated at 200,000 men. His predecessor Ahmad Abdalla had regular infantry, clothed like the Britih: yeomen, and, at one time, made use of the Britih manufactures for this purpose. The trade went by Sind, and up the Indus and its branches, to Cabul, but it has been long at an end. The successor of Timur was Zaman, whose chief subjects are Afghan, or the people of the mountains between Persia and Hindooostan, who may be considered as the founders of the empire; the others are Hindoos, Persians, and a few Tartars. Candahar is bounded on the north by the Gaur and the province of Balk; on the east by Cabul and the river Indus; on the west by Segeltan, and on the south by Arrokage, Mekran, Susee, and Mowlin. Befides Candahar proper, the empire in its greater extent includes Cabulistan, Ghizno, Cahlire, part of Segeltan and part of Choristan. See Cabul. Every part of this mountainous except that which lies towards Persia. The chief city is Candahar.

CANDAHAR, a city of Candahar, the kingdom above-mentioned, is ascribed by M. d'Availle and others to Persia. While the Persians and Mogul empires were severely divided, this was the frontier city and fortress of Hindooostan;
towards Persia, and was esteemed the key of the western provinces of the latter, and not unfrequently changed masters. As Cabul was considered in a political light as the gate of India towards Tartary, Candahar held the same rank with regard to Persia; and hence it has derived its chief importance. Major Rennell has shown that Candahar cannot be the same place, as some have supposed, with the Paromian Alexandria of Alexander. This city, says Turlier, in his "Journey from Bengal to England," comprised within an ordinary fortification of about three miles in circumference, and of a square form, is populous and flourishing; and lying in the great road which connects India with Persia and Tartary, it has been long a diffused mart. It is abundantly supplied with provisions; the fruits are of an excellent quality; and the extensive range of fields occupied by Hindoo traders attests the liberty and protection which they enjoy at Candahar. The tract of territory dependent upon it is said to produce a revenue of 18 lacs of rupees; and from the appearance of all classes of people, the collection seems to be made without any extraordinary rigour. The environs of Candahar occupy an extensive plain, covered with fruit gardens and cultivation, and intermingled with numerous streams of so excellent a quality as to become proverbial; and the climate is happily tempered between the heat of India and the cold of Ghizni. To the west there is a considerable defect, extending nearly to Herat, which renders the passage from Peris to Hindoo and difficult. Between the mountains of Hindoo Khoo, and those of Candahar, the country assumes the form of an extensive valley, from Cabul to the borders of Choristan; and in the tract between Cabul and Candahar, the highest point of elevation of the country is marked by the defile of the waters from it in almost every direction. The distance from Candahar by Cabul to Agraz is 1220 miles; to Benares, 1538; to Calcutta by Morehbad, 2155; by Birboom, 2047; and to Delhi by Cabul, 1071. N. lat. 33°. E. long. 65° 33′.

CANDAIL, a town of Persia, in the province of Melran; 148 miles E. of Kidge.

CANDANA, in Ancient Geography, a town of Asia, in Paphlagonia.

CANDASA, a town of Afa Minor, in Caria. Polybius.

CANDAU, in Geography, a town of the duchy of Comland; 24 miles E. of Goldingen.

CANDAVIA, in Ancient Geography, a county of Macedonia, mentioned by Caesar and also by Seneca, which lay at some distance E. of Dyrrachium. It was bounded towards the east by the Candavian mountains, from which flowed the river Panuas. These are supposed to be the "Cambavi montes" of Livy, and the "Canalivii montes" of Ptolemy.

CANDE', in Geography, a town of France in the department of the Maine and Loire, and chief place of a canton, in the district of Segré, ten miles S.W. of Segré. The place contains 948, and the canton 6,343 inhabitants; the territory includes 285 kilometres and 6 communes.

CANDEISH, a province of the southern part of Hindoostan, in the territory of the Poonah, or western Mahrattas, being one of the three fobahs formed by Acbar in the 16th century out of the conquests in the Deccan. It occupies the space between Malwa on the north, Berar on the east, and Amedangur on the west and south. Its soil is fertile, though mountainous, and it produces more cotton than any other province of Hindoostan. The revenue of this province under Aurungzebe, as stated by Mr. Frazer in his "Life of Nadir Shah," amounted to 112 lacs of rupees. The principal town is Burhanpour, which fee.

Candel, and Candel, in Botany. See Rhizomorph.

Candel, in Geography, a town of France, in the department of the Lower Rhine, and chief place of a canton in the district of Willembourg; the place contains 2366, and the canton 12,444 inhabitants; its territorial extent comprehends 1871 kilometres, and 16 communes.

Caneola, a town of Naples, in the province of Capitanata; two miles S.W. of Alcoth.

Candelabrum, in Architecture. This term, adopted from the Latin, is employed to denote the flanks or supports, in common use among the ancients, to place their lamps upon; or which were hollowed out in the upper part, in the form of a brasier or baloon, for the combustion of inflammable substances.

Candelabra are among the elegant and ornamental remains of antiquity, and curios, as they preserve the remembrance of primitive customs. The most ancient method of illuminating apartments during the night was apparently by burning dry and rufious wood, either in braziers, or more simply, by single branches like flambeaux: the use of oil and of lamps succeeded to these imperfect and inconmodious methods, and candelabra served to support the lamps.

In treating of Candelabra they are to be divided into the two general classes already intimated; those which terminate in braziers constitute the firft, and those which served as lamp stands, the second.

In the first class are comprehended the most remarkable for rize and magnificence; some of which, by their defamation reemble altars, and may even be confounded with them, were employed in temples and private chapels for burning incense. Cicero informs us, that not a house in Sicily was without these sacred utensils, made of silver. Candelabra of this kind are not uncommonly found represented in baffe relieves and on the frizes of temples.

Very large marble candelabra are found at Rome, where, as Winckelmann observes, not one of bronze has been discovered; these from their great size and elevation correspond to the vast halls of Roman edifices, which they illuminated.

The marble candelabra vary greatly in the shape, both of the brasier, and of the body or pillar which supports it; and many of them present models of taste, in form, ornament, and execution. The richest collection of these objects is published in the Museum Vatiiicum: two among these, which were found in the Barberini palace, are distinguished as the most splendid pieces of ornamental workmanship; the base is a triangular altar, having each face ornamented with a figure of a divinity; the shaft is composed of acanthus leaves disposed in tiers in the style of a Corinthian capital, so that one of these candelabra appears, at fiirt sight, a union of three Corinthian capitals placed upon one another; the other, which is the most beautiful, is varied in form by a tuft of acanthus leaves, which fall over like a canopy with a wonderful richness of appearance. The balloon of both is fluted, and by its form and ornaments corresponds with the magnificence of the whole.

Our own country possicles many ancient candelabra, two of admirable workmanship were presented to the Radcliffe library at Oxford, by Sir Roger Newdigate; they were found in the ruins of the emperor Adrian's palace at Tivoli.

Of the candel and clases of candelabra there is a very curious collection in the museum of Portici, which were found in the excavations of Herculanum and Pompeii. They are all of bronze, and were used for domestic purposes. In many of these we find the shaft representing a knotted cane, or a spiny branch, with truncated shoots and leaf stalks. They may be cited as examples of the taste of the ancients, in adapting ornaments to things of common use, to augment their utility, and,
and, at the same time, preserve the type of the objects which give rise to any useful invention. The buds and flowers represent ornament the shafts of the candelabrum, which would otherwise be too plain; they are convenient in affording a firm grasp to the hand, and at the same time they appear to give the history and agreeably recall the simple origin of these utensils. The same art which in stone and marble preferred the original forms of the wooden hut, has perpetuated in bronze the reed or flax, which supporting a tablet, formed the primitive candelabrum.

Among the considerable number of the candelabra in the museum of Portici there are many varieties. Their greatest height is five feet. The shaft of one of these is square, and on the upper part, immediately below the tablet upon which the lamp was placed, is represented a double head, one face of Mercury, and the other of Perseus. The greater number are in the form of a column placed upon a spreading base, composed of three paws, and above the shaft is placed a circular tablet, forming the lamp stand. The ornaments are various; in some the shaft is fluted longitudinally; in others, the fluting are formed spirally; and there is equal diversity in the capitals.

Candelabra of this kind are not employed by any modern European nation: the diffuse of these elegant utensils is owing to the circumstance of candles having superseded lamps.

In Italy the practice of placing round the altar large chandeliers seemed to be an imitation of ancient customs in this respect; the size and the shape even of some of these chandeliers preferre a tolerably just idea of the ancient candelabra, but they differ essentially from those in the socket necessary to receive the candle, and support it in a straight and immovable position, and ill more in the choice of forms and taste of ornament. The smell, or, at least, the moist and builded modern works of this kind, are the chandeliers of St. Peter's, the design of which is attributed to Michael Angelo. Notwithstanding the name of this great artist, the richness of the material, and the beauty of the workmanship, it must be confessed that their form is too much divided, the ornaments are capricious, and their proportion very insufficient for the situation which they occupy.

CANDELARES, in Botany, the sixty-second order in Linnaeus's fragments of a natural method published in the Philosophia Botanica. It consisted of Rhizophora, Minifopos, and Nyfia; but was afterwards abolished by him, and its three genera referred to the Holarceae.

CANDELARIA, in Entomology, a species of FULGORA peculiar to China, that possesses the power of emanating a clear and vivid light from the extremity of its snout in a similar manner to that emitted from the abdominal rings of our common glow-worm (lampyris noctiluca). It is specifically distinguished from the Fulgora, by having the snout ascended: wing-cases green with pale yellow spots; wings yellow, and black at the tip. Linn. Fabr. Donov. Inf. China. See also article Fulgora.

CANDELARO, in Geography, a river of Naples, which runs into the sea, 3 miles S. of Manfredonia.

CANDERN, a town of Germany, in the circle of Suevia, and margraviate of Baden-Dourlach; 11 miles N.E. of Bâle, and 72 of Strasburg.

CANDEROS, in the Materia Medica, a name of an East Indian gum not much known among us, though sometimes imported. It has much the appearance of common amber, only that it wants its yellow colour, being white and pellucid; we sometimes see it turned into toys of various kinds, which are very light, and of a good polish. Garcias and some other authors tell us, that Borneo, and some other places where camphor is produced, have the art of adulterat-
and the safety of the places that are entrusted to them. They also cause justice to be done by the Cadis, and order their sentences to be executed. Each pachalk is divided into a certain number of districts, and each district comprises a certain number of villages, of which some belong to the imperial mosques, and others to the sultan-mother: and the greater number are granted for life to agas, or lords, in consideration of a sum of money paid into the imperial treasury, and an annual quit-rent, which is lodged in the comptoirs of the treasurer of Candia, for the maintenance of the fortresses and the pay of the troops of the country. All land owners pay to the aga, to the mosque, or to the sultan, a certain amount of the produce of their lands; and they are obliged to carry their olives to the mills, which the agas alone have a right to cause to be constructed. Oil pays a tax. The police of the village belongs to the aga, who appoints, for subordinate administration, a foubachi, or subaltern tyrant. More greedy and more untractable than his master. No Greek can marry without the permission of the aga, which is to be purchased at a price; and the aga sometimes appropriates the female who is proposed for marriage to himself; and when he wishes to part with her, he marries her to some Greek inhabitant of the village, who does not refuse her. Married men are not allowed to quit the island, unless they are mariners, or merchants; but bachelors may go to work in the Morea, or elsewhere, upon paying a tax of 60 paras, or two piastres a head before their departure. If a murder happens in a village, or within its territory, and the delinquent be unknown, the aga must pay to the pacha a sum of money, which is levied on all the inhabitants, referring a part for himself. Taxes are arbitrary, and in their amount depend on the population and circumstances of the inhabitants. For the death of a mulufman, the fine is exorbitant, and is almost always attended by the death of several Greeks. The Turkish villages, as well as those of the Greeks, are subject to the police of the aga; but those which belong to mosques or to the sultan-mother, are less oppressed than the others. The Greeks can neither occupy employments proceeding from the government, nor can they be admitted into any corps of troops, unless they have embraced the religion of Mahomet. Thus the island, which long prospered under the laws of Minos, is now governed; and thus the inhabitants of a country where liberty in a manner took its birth, are bent under the yoke of the most ignominious slavery. Among the people, who at this day inhabit the island of Candia, we may reckon Abadiots, Muffulmen by religion, Arabs by origin, and some remains of the Saraccens whose ancestors formerly occupied it. The Abadiots are swarthy, meagre, and of middling stature, and in their disposition mild, fruitful, malicious, and vindictive; they go armed like the Turks, and kill each other on the slightest provocation. They occupy 20 little villages to the south of mount Ida, and form a population of about 4,000 persons. They afford an asylum to the Turks and Greeks who have committed any crimes, whom they themselves kill if they become troublesome. When they have an opportunity, they rob the friars in the Greek monasteries that lie within the reach of their villages. The inhabitants of the high mountains to the south of Candia and Retimo are considered as the real descendants of the ancient Cretans, and are known by the name of "Sphachiots." They are distinguished from the other Greeks by their tall stature, handomie, light of liberty, courage, skill, and above all, by the hatred which they have vowed against the usurpers of their island. These Sphachiots have found means to preserve their laws and their customs under the Romans, the Saracen, the Venetians, and the Turks. Obliged by the Turks to transport, in summer, from the tops of their mountains, the ice necessary for the consumption of the inhabitants of Candia and Retimo, they paid no tax nor import; they had no agas; they never faw among them the agents of the Turkish government; and they formed a republic, in some measure independent, till, in 1769, the Happenings which they enjoyed on their mountains was interrupted by the part they took with the Russians, and the Turks retaliated upon them their revolt by hideous measures that proceeded almost to their utter extirpation. The amount of the population of this island consisting of Greeks and Turks is estimated by Olivier at 24,000.

The climate of Candia has from remote antiquity been deemed singularly healthful, which has been attributed to the abundance of its salutary plants. Hippocrates best his patients thither to breathe the air charged with wholesome vapours. The Turks in the island of Candia, under the happy influence of its climate, have here acquired a taller stature, muscles more prominent and more strongly marked, broader cheek and shoulders, all the proportions which constitute beauty and strength, together with an imposing rep and carriage; although with all these advantages, the freemans of their conntenance gives to their majestic exterior a formidable impression. The Greeks, on the other hand, are of a stature less tall, a corpulence less prominent, a rep less solemn, a make less robust, but more graceful; and they seem to have degenerated under a climate which is natural to them, and in which they are abandoned to slavery, which alike degrades both the form of the body and that of the mind. The same disparity in the exterior attributes of the Turk and the Greek, is also observed among the women of the two nations. The Turkish women are there handomer than in the other parts of the eart; whereas the female Greeks have, generally speaking, fewer charms than they possess in several other countries. The dance of the Greeks of Candia is referred to a very remote antiquity. Homer (II. i. xvin. ub fin. Pope's version.) has described it; and it is the image of the labyrinth of Crete, of which it imitates the windings and turnings. It is serious and grave, though not destitute of simplicity and nobleness. Their songs are slow and languid, and the habit which the Greeks have of singing through the nose renders their songs still more dawling and left sprightly.

With the exception of the leprosy brought to this island from Afa, there are no contagious nor prevailing disorders in Candia.

One of the best cultivated and most productive of the provinces of this island is Kifiasams. To the south of this province is Selino, to the north of these two provinces is Cidonia, and to the south Sphachia. Three leagues from the town of Candia commences the province of Ascorsena, which extends to the south as far as Armires, and to the south as far as the mountains of Sphachia. This province is mountainous, and furnishes abundance of oil, but a small quantity of barley and wheat, and very little wine. It is more peopled by Greeks than by Turks. The province of Retimo is well cultivated and very productive. To the south of this are the two provinces of Asin-Vafali and Amari, furnishing wheat, barley, oil, and some fruits. The former, situated N.W. of the other, supplies also excellent chestnuts. In these provinces the Greeks are more numerous than the Turks. The part of the island that occurs in the north part of the island, after quitting the territory of Retimo, is called Nifo-Petamo. The province of Candia affords very little cotton, but abundance of wheat and barley, and a considerable quantity of raiifs, which last are shipped for the supply of Syria and Egypt. In this territory there are scarcely any olive-trees. The Turks are here as numerous as the Greeks. To the south of Candia lies the province of Meffara, which is reckoned
reckoned the granary of Crete; and to the east of Candia lies the province of Mirabel, to the south of which is the province of Hiera Petra, or Genni-Petra. The province of Setia occupies the whole eastern part of the island. For a more particular account of each of these provinces, see KISSAMOS, SELINO, &c.

Notwithstanding the various alimentary productions furnished by this island, the Greeks live through the whole year on barley bread, salted olives, and wild plants. The more delicate articles of sufficiency they fell in order to discharge the taxes, or to pay the too frequent extortions of their agas. Mutton and pork are everywhere excellent and cheap. Lambs and kids are always to be obtained in the three principal towns during several months of the year. The argali and wild goats are plentiful on the mountains. Beef is scarce, and the ox is little used but in rural labour. Poultry may be procured with ease, and at a cheap rate. Turkeys are sold at a very moderate price; and the island abounds with a great variety of birds fit for food, as the quail, turtle, ring-dove, loriot, roller, thrush, and fig-peckers. The woodcock passes the winter in this island, and the blackbird remains all the year. In spring and summer, larks, ortolans, and many small birds supply the place of birds of passage. The hare and partridge are very common. There are few countries in the Levant that afford a greater variety of useful and interesting vegetables than the island of Crete. Agriculture is subject to many discouragements and restraints in the island of Candia; and industry is checked by the oppression and rapine of the agas, pachas, and janizaries. Such is more especially the case in the villages and territories belonging to the Greeks. The Turks are less oppressed; and the Sphachiot, more sure of enjoying the fruits of his labour, exerts a greater degree of energy and activity. Public granaries are very common near the principal towns; they were probably constructed in the time of the Venetians, and consist of large square pits in masonry, coated with a cement capable of securing from moisture the grain contained in them. The opening is narrow, and carefully closed. As the island does not grow a sufficient quantity of corn for the supply of its inhabitants, a large quantity is annually imported from Volos, Salonica, the Morea, Syria, and Egypt. Wine is made only in a few districts; in others, the inhabitants prefer carrying their grapes to the town, or drying them for trade. The mulberry-tree vegetates very well in Candia, and silkworms thrive wonderfully; and yet the silk used in their manufacture is brought from Syria. Some cloths, in silk and cotton, and in silk and flax, are manufactured and consumed in the country. Flax, though tolerably plentiful, is not cultivated in sufficient quantity for the use of the inhabitants; a great deal is drawn from Egypt. Cotton is little cultivated; that which is consumed being brought from Smyrna and the environs of Ephesus. Sefamum is cultivated for the purpose of mixing its seed with bread, in order to give it flavour. One of the productions of Candia, which has preferred its ancient reputation, is wine, which, in some districts, is still delicious. It is well known, that Homer has praised the wine of Crete, and that Jupiter drank no other nectar during his stay in this island. The malvasy, which is made in the environs of mount Ida, is much esteemed; but all the Cadian wines must be drank with caution, as they are of a fiery quality, and apt to fly quickly to the head and to make the nerves. In several places forells of pines, cedars, and firs cover the declivity of the mountains, and crown the summit of the hills; and afford, by their straight and tall items, as well as by the resin which exudes from them, abundant resources for nautical purposes. On the mountains in the vicinity of Canea, and at the foot of mount Ida, grows a species of rock rose, (Cistus laurifolius, Linn.), which yields lauracum, or baldacum, serving for perfumes and the preparation of certain drugs. The horses of Candia, the race of which originally came from Barbary, have much degenerated in form and beauty. Nevertheless, none can be compared to them for strength and impleness of limbs, and for being sure-footed. The dogs of the island were formerly reckoned, on account of their fleetness and agility, the best in Greece, next to those of Lacedemonia. But, under the Turks, their race is degenerated. The dogs of Candia are a new species of large greyhounds, or courting dogs, which, with a little attention, might be handfome animals and very serviceable. The stray dogs and straying these animals are neglected. It is said that in Candia to carnivorous and venomous animals exists; and it is certain that if such quadrupeds once inhabited this island, their races have entirely disappeared. But the ancients have blazoned exaggeration with their accounts, when they assert that birds of prey would not flourish here. It was also alleged, without foundation, that the island of Candia was exempt from serpents, and other venomous animals. Pliny, however, has made an exception in favour of the phosphorus, or tarantula. Belon has observed, that three species of serpents were known here; and Sumini says, that there exists a species of spider as dangerous as the tarantula, which lives in subterranean retreats, and is of the species of the mason, or mining spider, circumstantially described by Latreille in the " Mem. de la Societe d'Hist. Nat." Whether the gecko (Lacerta gecko, Linn.) be found on this island is not absolutely certain; but it is not improbable, as it is met with in other countries of the coast, in the vicinity of the island of Candia, and particularly in Barbary and Egypt. The hydrophobia is said to have occasionally, though seldom, made its appearance in Candia; and Dapper mentions that this island has been frequently afflicted by mad dogs. The remedy purchased by the king of Prussia, and published in 1777, is known there. The insect that furnished this specific, which the Candians employed from time immemorial as a sovereign antidote to madness, is the melos, or oil-beetle, (Meloe prolarabaeus, Linn.) the larvae of which bear the name of "May-worms." In Candia it is reduced to powder, which the patient swallowed; and it is said to be of so active a nature, as to occasion convulsions, pains in the bowels, inflammations, agony, bleedings to the nose, bloody urine, and even death, when taken in too large a dose. Such dangerous means of cure have been wisely relinquished by modern practitioners. The multiplication of bees is a branch of rural industry, which is encouraged in this island. The ancients indeed feigned that Jupiter had been fed on the honey obtained from the bees of mount Ida.

The only articles of exportation from this island are, oil, soap, wax, honey, cheese, raisins, almonds, walnuts, cheunfts, St. John's bread, linseed, and liquorice-root. The imports supplied by the French consist of woolen cloths, laces, and fluffs, of Lyons, imperial ferges of Nîmes, small flot, tin, iron, steel, coffee, sugar, nutmegs, cloves, indigo, cochineal, paper, and various articles of hard-ware. Venice and Trieste supply glass-ware, hard-ware, and, particularly, planks for making soap-cafes; and Caramania, or Greece, furnishes almost all the wood necessary for the soap-houses. The islanders themselves carry on some trade: from Salonica they draw corn, cotton, tobacco, and iron; from Constantinople, Buria fluffs, Angora chafés, shoes, handkerchiefs, and copper utensils. At Smyrna they take hides, Turkey leather or Morocco, cotton, quilted coverlets, English shalows, and some French goods. At Gaia they purchase for their soap-houses at Aleppo, silk fluffs; and they purchase on the coast of Syria corn and silk. Egypt supplies them with corn and rice, flax, linen.
lacen-cloths, and after. Derma and Bengazi, on the coast of Africa, lend butter known under the name of Manteign, which is a mixture of butter and mutton-fish, used by the orientals in their ragouts and panty. Tunis and Tripoli exchange their crops and their corn for soap and liquors. The wool is coarse and short, and wholly consumed in the country. The hone is a well known article of commerce from Candia and Stancho.

The north coast of this island has the greatest number of harbours and roadsteads; in which are many excellent anchorages; but the south coast affords few places where a ship can rest in safety. The rivers of the island are principally torrents swelled in winter by the rains, and in spring by the melting of the snow; but they have a considerable number of springs, which the inhabitants use for the watering of their lands. During the three summer months, the excessive heat of the sun is constantly tempered every day, from eight or nine in the morning till the evening, by the rapid current of air which prevails from North to South on the northern coast of the island. This refreshing wind, called "enbat," takes its course, and is modified through the Levant, according to the direction of the coasts and the extent of sea which lies before them. In the island of Candia winter is, properly speaking, no more than a rainy season, during which the sky is more charged with clouds, and the heat less powerful, but never such as to make it necessary to have recourse to artificial warmth. However, in this season the mountains are covered with snow, and in some places it remains till the month of June.

Sorini's Travels in Greece, p. 209, 8c. Olivier's Travels in the Ottoman Empire, vol. ii. p. 100, 8c.

CANDIA, the Khondak of the Arabs, derived from chandax or candax, is a maritime town of the island above described, and, though less populous and commercial than Canea, reckoned its capital. Some geographers have supposed that its site is that of the ancient Cyzum; others suppose it to have been Mauum, and others again refer it to Heraulca. Olivier places Cyzum 4 leagues to the west, and Mauum 2 leagues to the east, and Heraulca 4 or 5 leagues to the east; and Candia he imagines to have been part Panormii, which lay, according to Ptolemy, between Cyzum and Heraulca. Candia is situated on a pleasant plain, intersected by beautiful hills, which share its fertility, and the ground on which it stands is supported towards the sea by a strong wall built on rocks, which affords an agreeable walk. The approaches of the place are defended by fort with several pieces of cannon, and it is guarded on the land side by walls of a solid construction, a good ditch, and some advanced works. The form of the town, consisting of straight streets and regular squares, and the substantial construction of the buildings, indicate that it is not the work of the Turks, but that it owes its existence to the Venetians; at the same time its present late announces the dreadful ravages of war, and the lover harrow of want, so that the houses constructed by them have disappeared. Here are still to be seen ruins which are the remains of the memorable siege which it sustained for twenty-four years, from 1646 to 1670, against the Ottoman forces. The decline of its commerce has changed its flourishing state and considerably reduced the number of its inhabitants, many of whom are removed to Canea, together with the foreign merchants. Although it is still the seat of the general government of the island, its population is disproportioned to its extent. It now contains scarcely 10 or 1200 Turks, 2 or 300 Greeks, and about 65 Jews. The Greeks, who inhabited it before it became subject to the Turks, followed the Venetians at the time of its capture, and made their escape into the country: nor have they returned to settle in a town, where their existence is incessantly threatened by the Janizaries, and their fortune frequently invaded by the Pachias. The handomest churches damaged by the above-mentioned siege have been repaired and converted into mosques; but the fortifications have been carefully preserved. To the south-west of Candia, the first chain of mount Ida rises in the form of a pyramid, and seems at a distance as a land-mark to navigators, who wish to anchor in the harbour of that town. The harbour is defended from the north wind by rocks, on which has been built a strong jetty parallel to the coast: it is very secure; and might contain from 30 to 40 merchant-vessels, if it were kept in proper order. But the Turks have suffered it to be choked up, so that there are no more than eight or nine feet of water in the infide of the harbour, and about 15 at its entrance. It affords accommodation only to a few small barns of the country: and merchant-vessels can only enter it in ballast, or with a fourth of their lading. To this and other circumstances it is owing that the trade of Candia is almost annihilated. Navigators who frequent the harbour of Candia have been furnished by a long series of observations with means of ascertaining the state of the atmosphere in the open sea, from the foal inspection of the chain of mountains which encircles the town to the south. When the cloud is collected in heaps above the most prominent of these hills, which bears the name of "Calepo," the weather is bad in the offing, and the wind almost always to the northward; navigators then take care not to quit the harbour. If, on the contrary, the ridge of the mountain is clear and free from vapours, they are certain of finding, without, the wind moderate and favourable for failing out of the gulf, and getting clear of the coast.

The environs of Candia present a few fertile plains that are cultivated, and some rising grounds susceptible of cultivation. At a little distance to the south is seen the insulatd pyramidal mountain already mentioned, at the foot of which is a passage to the ruins of Gortynia, and its labyrinth: to the Europeans this mountain is known by the name of Jupiter's mountain. To the south-west, mount Ida, covered with snow almost all the year, throws out on one side some branches towards the town; and, on the other, runs to join the mountains of Sphachia, covered in like manner with snow during eight or nine months. In this town there are 25 soap-houses, which employ the greater part of the oils of the island, and are situated in the east part of the island. Candia forms one of the three pachalkias of the island. See CANDIA. N. lat. 35° 10', E. long. 25° 18'.

CANDIA, a town of Italy, in the Milanese; 12 miles W. of Verceil.

CANDIA, a township of America in Rockingham county, New Hampshire, N. of Cheffer; about 36 miles W. of Portsmouth; incorporated in 1757, and containing 1040 inhabitants.

CANDIDA, in Conchology, a species of Arca, the shell of which is pellucid, rhomboid, produced in front, truncated behind, and decussated with lirae; beaks remote; posterior margin gaping, the opening ovate and ciliated. Chemnitz, &c. A native of the American and African shores. This kind is white, somewhat granulated, and covered with a blackish subfuscous epidermis.

CANDIDA, in Zoology, a species of Actinia, described by Muller as a native of the northern seas of Europe. This is smooth, with a rugose aperture, the tentacula reeling bristles, and dilated at the margin.

CANDIDATE, a person who sets up for some post or place, either of honour or profit. The word is formed of candida, white; on account of a white shining garment, toga candida, in which those who
aspired to preferments in ancient Rome were habituated, at the time of their appearing for the fame, especially at the public assemblies, in order to distinguish them from the crowd. The white gown worn by candidates was knotted and imitated, but was there any close garment under it, which some interpreters do as well as desire to avoid any suspicion people might have of bribery; though Plutarch rather thinks it done to gain the affections of the people, by being in such an humble garb; or else that such as had received wounds in the service of their country, might more easily exhibit those tokens of their courage and fidelity. The Roman candidates usually declared their pretensions a year before the time of election, which was spent in making interest and gaining friends. Various arts of popularity were practiced for this purpose, and frequent circuits made round the city, and visits and compliments to all sorts of persons, the proceeds of which formed what was called ambitus.

CANDIDATE OF BAPTISM, in the Ancient Church, was called catechumen.

CANDIDATES in the College of Physicians, London, is the order of members, out of whom the fellows are chosen. The candidates must be natives of England, doctors of physic, admitted to the degrees in our own universities, and ought to have practiced physic four years before they are admitted into the order. The number of candidates is never to exceed twelve. See College.

CANDIDATE, in Academic Orders or Degrees, denotes a person to whom, after full examination, and the performance of the degree exercise, licence is granted to take up the highest or doctoral dignity when he pleases. See Degree, Doctor, Licentiate, &c.

CANDIDATI PRINCIPI, were those who were recommended to any offices by the emperors. The candidatus principi was also an office in the court of the emperor of Constantinople, answering to a secretary of state among us.

The candidatus principi was denoted Quaestor principi, or Augustus.

CANDIDATI MILITIS. Among the Romans, these were soldiers distinguished by their figure, stature, and valor in combat. They were placed near the emperor, who was an eye-witness of their exploits. They served him as his bodyguards to protect and defend him. It is said that Gordian the younger first instituted them as well as the Protectors and Scholares; which articles see.

CANDIDUM, in Conchology, a species of Buccinum, described by Martini. This shell is oblong, turbinate, solid, smooth, and white. Country uncertain.

CANDIDUM, promontorium, in Ancient Geography, Botet-Abecho, a promontory of Africa, N. W. of that of Apollo; mentioned by Livy, Pliny, and Mela.

CANDIDUS, in Entomology, a species of Cerambyx, (Saperda, Fabr.) Colour white; thorax and body fuscous, with two white stripes. Fabriucus. The country of this insect is unknown.

CANDIL, in Commerce, an East Indian weight equal to 540 pounds avoirdupois.

CANDIPATNA, in Ancient Geography, a town of India, on this side of the Ganges, in the country of the Avantras, according to Ptolemy.

CANDIL, a cotton or hemp wick, loosely twisted, and covered with tallow, wax, or spermaceti, in a cylindrical figure; which, being lighted at the end, serves to illuminate a place in the absence of the sun.

The word candle comes from candela, and that from candor, of candle, I burn: whence also the middle age Greek candle.
CANDLES.

second time, then a third as before; only for the third lay they are immersed but twice, in all the rest thrice. The operation is repeated more or less times, according to the intended thickness of the candles. With the half dip they neck them; i.e., plunge them below that part of the wick where the other lays ended. Such as we have above described under be the laborious method of making common candles; but within 15 or 20 years past, when an invention was introduced which served very much to diminish the labour and to facilitate the operation. This method of making dipped candles, as now practiced by the manufacturers in London, is as follows: The wicks are prepared as above, and hung at equal distances upon the bosses; and when five or of these are filled, they are put into holes in two pieces of wood, C, D, (fig. 2); thus forming a frame full of wicks. The vessel, A, (fig. 1) is then filled with melted tallow. This vessel is made of lead, and has a hole, B, under it for receiving a shaving-dish to keep the tallow warm; and on each side of the vessel are two leaves, C, D, for catching the droppings of the candles as they are dipped; over the vessel is suspended from the ceiling a framed lever, K, K, with two arched heads, L, L, at each end, in order to give a vertical motion to the scale, I, and frame, EFH, the two crofts pieces, E, F, of which are for the leaves, C, D, of fig. 2, to rest upon. The dipper then lays hold of the upper bar at G and H, and gently pulls down the wicks into the melted tallow, and keeps them down till he finds, that by the tallow adhering to them, they are heavier than the weight in the scale I, previously adjusted to the proper weight. The frame of candles is then removed and hung up to cool, which takes some days, according to the flat of the weather. When they are quite stiff, they are dipped again with a heavier weight in the scale I, and this operation is continued, till they are of the proper size. The workman, by means of this simple contrivance, has only to guide the bosses and candles, and not to support the weight of them as in the old method.

It must be observed, that during the operation the tallow is stirred from time to time, and the stock supplied with fresh tallow. When the candles are finished, their peaked ends, or bottoms, are taken off; not with any cutting instrument, but by pulling them over a kind of flat bronze plate, heated to a proper pitch by fire underneath, which melts down as much as is requisite.

CANDLES, method of making mould. These candles are made in moulds of different materials; that generally used is pewter. Each candle has its mould, consisting of three pieces, the neck, shaft, and foot: the shaft is a hollow pewter cylinder, B, (fig. 6) having the end a somewhat smaller than the other, so that the candle may slide out easily, of the diameter and length of the candle proposed; at the extremity of this is the neck, A, which is a little metallic cavity, in form of a dome, having a moulding within, and pierced in the middle, with a hole big enough for the wick to pass through. At the other extremity is the foot, in form of a little tunnel, through which the liquid tallow runs into the mould. The neck is folded to the shaft, but the foot is moveable, being applied when the wick is to be put in, and taken off again when the candle is cold. A little beneath the place where the foot is applied to the shaft, is a kind of flaring of metal, which serves to support that part of the mould, and to prevent the shaft from entering too deep in the table to be mentioned hereafter. Lastly, in the hook of the foot, is a leaf of the same metal, folded within side, which, advancing into the centre, serves to keep up the wick; which is here hooked on, precisely in the middle of the mould. The wick is introduced into the shaft of the mould by a piece of wire, which being thrust through the aperture of the hook, till it come out at the neck; the wick is tied to it; so that in drawing it back, the wick comes along with it, leaving only enough a-top for the neck; the other end is fastened to the hook, which thus keeps it perpendicular, EE (fig. 5). Ten or fifteen of these moulds, in this condition, are laid in a frame pierced full of holes, the diameter of each being about an inch, by a screw at the top of each mould, which attaches them to the upper board B of the frame. This board has three upright sides and one sloping, which forms a small cistern for the tallow. When every mould in the frame has been provided with a wick, two wires, cc, (fig. 5) are passed through the two ends of the cistern at the top of the frame, and the loops of the several wicks. The ends of the wicks which hang out of the mould are pulled tight, their tops are put over the centers of the moulds, and the friction of the mould keeps them in this position. These moulds are filled with tallow out of a cistern, A (fig. 4.) the outside of which is wood, and lined with lead; within which is another cistern of lead for containing the melted tallow, prepared as above, with about two inches space between them all round to be filled with hot water for keeping the tallow warm. In the bottom of the vessel are three small shuttles, B, C, D, communicating with the inner vessel, and serving to fill the moulds, EE, before described. After the frame is filled and the tallow has acquired its due confluence, the two wires, cc, are withdrawn, and the loose tallow in the cistern at the top of the frame forced out; they are set out in the open air to cool, and when thoroughly cold, the candles are pulled out of the mould by a bolt pin through the loops of the wicks where the wires, cc, passed before.

Those who aim at perfection in their work, bleach or whiten their candles, by softening them on rods or broaches, and hanging them out to the dew, and earliest rays of the sun, for eight or ten days: care being taken to screen them in the day-time from the too intense heat of the sun, and in the night from rain, by waxed cloths. Tallow-chandlers make other candles, which are intended to burn during the night without the necessity of being faulched. The wick of these has been usually made of split rushes; but of late, very small cotton wicks have been substituted for the rush; these are much more easily lighted, are less liable to go out, and, on account of the smallness of the cotton wick, they do not require the aid of faulchers. The price of candles used formerly to be regulated by the masters and wardens of the tallow chandlers' company, who were accustomed to meet at their hall every month for the purpose; but now the price of every article belonging to the trade is fixed at the weekly markets.

CANDLES, wax, manner of making with the ladle. The wicks being twisted, and cut off at the proper length, a dozen of them are tied by the neck, at equal distances, round an iron circle, suspended directly over a large bason of copper tinned, and full of melted wax: a large ladle full of this wax is poured gently, by inclination, on the tops of the wicks, one after another; so that running down, the whole
whole wick is thus covered; the surplus returning into the bason, where it is kept warm by a pan of coals underneath it. They thus continue to pour on the wax, till the candle arrive at its defined size: still observing, that the three纤ile ladles be poured on at the top of the wick, the fourth at the height of \( \frac{3}{4} \), the fifth at \( \frac{4}{5} \), and the sixth at \( \frac{5}{6} \); by which means the candle arrives at its pyramidal form. The candles are then taken down hot, and laid aside of each other, in a feather-bed folded in two, to preserve their warmth, and keep the wax soft: they are then taken and rolled, one by one, on an even table, usually of walnut-tree, with a long square infusion of box, smooth at the bottom. The candle being thus rolled and smoothed, its big end is cut off, and a conical hole is made in it.

_Candles, wax, manner of making by the hand._ The wick being dipped, as in the former, they begin to soften the wax, by working it several times in hot water, contained in a bras caldron, timmed, very narrow and deep. A piece of the wax is then taken out, and dipped by little and little, around the wick, which is hung on a hook in the wall, by the extremity opposite to the neck; so that they begin with the big end, dissimulating still, as they decrease towards the neck. In other respects, the method is the same here as in the former cafe: only that they are not laid in the bed, but are rolled on the table, just as they are formed. It must be observed, however, that in the former cafe, water is always used to moisten the several instruments, to prevent the wax from flicking; and in the latter, lard, or oil of olives, for the hands, table, &c.

_Candles, wax cylindrical_, are made either with the ladle, or drawn. The first kind are made of several threads of cotton, loosely spun, and twisted together, covered with the ladle, and rolled, as the conical ones, but not pierced.

_Candles, wax, drawn_, are so called, because actually drawn, in the manner of wire, by means of two large rollers, or cylinders of wood, turned by a handle, which turning backwards and forwards several times, pa$s the wick through melted wax, contained in a bras bason; and at the same time through the holes of an instrument, like that used for drawing wire, fastened at one side of the bason: so that, by little and little, the candle acquires any bulk, at pleasure, according to the different holes of the instrument through which it pases; by this method, may four or five hundred ells at length be drawn, running. The invention of this was brought from Venice by Pierre Blef-mare of Paris, about the middle of the 17th century.

The ascent of the tallow up the wick in a burning candle, may be resolved into the same principle of filtration, or attraction, as that of water up a heap of ashes, or even up a capillary tube. The wick of a candle is but slightly twilled, that all its hairs may be easily come at; which being very small, soon take the flame: and the flame by its heat rarefyng the air, and dissipating the tallow underneath, makes the globules thereof ascend into the rarefied spaces of the wick, and thefe, with the air about it, prove food for the flame.

A patent was granted in 1799, to Mr. William Bolts of London, for new modes of improving the form, quality, and use of candles. The most material alteration in Mr. Bolts's invention from the common method of making candles, consists in having the greater part of the wick by rendering it moveable; and for this purpose it is kept constantly foaking in the tallow as it melts, so that the cotton is consumed very slowly as in lamps fed with oil. The patentee employs two methods for accomplishing this object; one is that of making candles entirely solid, without any wick passing through them; and applying the wick, which is very flart, upon the top of the solid candle, where it burns like that of a lamp; the heat which it affords when first lighted being sufficient to furnish the first supply of melted tallow, and to continue it as long as any part of the candle remains unconsumed. In order to keep the wick constantly applied, it is fastened to a small projecting spring, into which it is firmly fixed; and the surface of the candle is always kept in contact with the wick, either by causing the wick to pass round the candle like a collar, which moving freely on the candle, will sink in proportion as this is consumed, or by making the wick immovable, and putting a spiral spring at the bottom of the candlestick, which constantly protrudes the candle upwards against the wick in proportion as the tallow is consumed. His second method of constructing the candles is that of forming them in the usual shape, but with a perforation through their whole length; and the wick in this case is a small tuft of cotton, which is put into the opening at the top of the hollow candle, and to its lower part is attached a thread which pases down through the perforation to the bottom of the candle, where it penetrates the candlestick, and is wound round a key or pivot, and by turning this pivot, the wick that is attached to the upper part of the thread will be pulled down in proportion as the candle consumes. This method prevents the gathering of candles, as all the tallow that is melted is readily absorbed by the wick.

By a small variation in the form of the candle, it may be made to serve the purpose of an Argand's lamp; for which end it is compos'd of a hollow cylinder of tallow, including another cylinder also perforated; and the wick, which is of a circular form, is here placed between the inner and outer cylinders. In all these cases, the wick is compos'd of thread, placed longitudinally, and not twilled, as is the case with the common wicks, which undoubtedly afflicts the capillary attraction of the melted tallow. These wicks have also the advantage of not requiring to be snuffed, for removing the carbonaceous matter which escapes unconsumed from the tallow. Another advantage attending these detached wicks, is the case with which their bulk may be proportioned to that of the candle, and to the fulness of the material of which it is compos'd. The patentee also proposes another improvement, which is that of subjceting the melted tallow or other material to a considerable preasure, during the act of cooling; which is done by means of a condensing machine, prefeeding the surface of the liquid substance, and then giving it a greater degree of firmness and solidity when cold. The patentee has likewise described, and illustrated by a drawing, the contrivance which he has adopted for casting the hollow cylindrical candles. For a detail of other circumstances that occur in his patent, we refer to his specification in the Repertory, vol. xii. p. 368.

_Candles, laws relating to._ Every maker of candles for sale, other than wax candles, shall take out an annual licence at 11. 24 Geo. III. c. 42, 43 Geo. III. c. 69. And every person making wax or spermaceti candles shall take out a licence at 1l., and for dealing in, or selling such candles shall pay 10s. 6d., and renew the same annually, under a penalty of 20l. 24 Geo. III. c. 36, 43 Geo. III. c. 69. But no person who hath paid such licence duty for making, shall be obliged to take out a licence for selling also, during the same year. 24 Geo. III. c. 41. By 24 Geo. III. c. 74, no person, residing within the limits of the head-office, shall be permitted to make candles, unless he occupy a tenement of 10l. a year, affixed in his own name, and for which he pays the parish rates; and elsewhere, unless he be affixed and pay to church and poor. By 43 Geo. III. c. 69, in lieu of any fulfilling duties of excise, the following duties are imposed; viz. for every pound avoirdupois of candles, except those of wax.
CANDLES.

Wax and spermaceti, made in Great Britain, 1d.; and for every pound of wax or spermaceti candles so made, 3/-.

All places for making or keeping of candles, and of materials for the same, and furnaces, moulds, &c. for melting such materials, are forbidden to be used without notice previously given in writing at the next office of excise, under a penalty of 50l., and forfeiture of all candles and materials, furnace, &c. which have not been entered, 8 Ann. c. 7.

And by 11 Geo. c. 30, makers of candles who make use of such places or utensils without entry incur a forfeiture of 100l.

Officers shall be permitted, at all times by day, and also in the night with a constable, to enter the house, melting-house, &c. of a maker of candles, and to take an account of the quantity, when all chafes, &c. shall be opened; and the penalty of obstructing or molesting such officer is 100l.; or if candles, &c. be found in unenterted places, the offender shall be convicted in the penalty of 100l. 11 Geo. c. 31; see also 24 Geo. III. c. 11, and 27 Geo. III. c. 31.

Any maker of candles shall give notice in writing to the proper officer of his intention to begin a course of dipping and preparing for the same, with a declaration of the time when he intends to commence his operation, and a specification of the number of sticks, moulds, &c. which he proposes to use, under a penalty of 50l. 10 Ann. c. 26. 11 Geo. c. 30. 24 Geo. III. c. 11. Such notice shall be given, within the limits of the head-office, 6 hours, within any city or market town, 12 hours, and elsewhere 24 hours, before he shall begin, on pain of forfeiting 50l. 25 Geo. III. c. 74.

If he does not begin and proceed at the time mentioned, or within 3 hours next after such notice shall be void. Having begun, he shall continue working without interruption, till the whole course is finished, on pain of forfeiting 20l. 26 Geo. III. c. 77.

Every candle maker shall provide sufficient locks and fastenings to every furnace, copper, mould, &c. to be secured by the officer, when they are not used; and he shall give notice in writing to the said officer, 6 hours before the time when he wishes to use them, within the limits of the chief office, 12 hours in any market town, and 24 hours elsewhere; any offence against the provisions of this act inures a penalty of 100l. 27 Geo. III. c. 31.

The officer shall charge for materials that are misfiling, after he has taken account of the same; and obstruction incurs a forfeiture of 20l. Candles that are spoilt in making shall be defaced by the officer, and he shall make allowance for the duty. No maker of candles shall, on pain of 20l., remove candles before they are surveyed; and those that have not been surveyed are to be kept separate from the others, on pain of 5l. 8 Ann. c. 9.

On suspicion, that candles are privately made, or concealed to evade the duty, the ground of which has been flatted on oath before two commissioners or one justice residing near the place, the officer may be empowered by special warrant, granted by such justices or commissioners, to enter the place suspected, and to seize as forfeited all candles that are found, and all materials for making them; and the person so offending, or obstructing the officer, shall forfeit 100l. 5 Geo. III. c. 43. 27 Geo. II. c. 24. If any candle-maker shall mingle candles not weighed by the officer with those that have been weighed, or remove any before weighing, or conceal any candles or materials, he shall forfeit 100l. 11 Geo. c. 31.

Any person who is found afflicting in privately making candles shall forfeit 20l.; and every person making candles shall once in every week enter the same in writing at the next excise-office, with their weight, number, &c. and quantity; on pain for every neglect of entry to forfeit 20l.; and in one week, after entry, he shall clear off the duties, on pain of double duty, nor shall he carry out candles till the duty hath been paid, on pain of double value.

25 Geo. III. c. 74. Persons buying, receiving, or having in their possession candles, not charged with the duty, shall forfeit the same, and treble value. 25 Geo. III. c. 77.

Nor shall any person expose to sale any candles, unless in his public shop or warehouse, public fair or market, on pain of 5l. 8 Ann. c. 9. No candles shall be imported, otherwise than in some package containing at least 22lb. of neat candles, on pain of being forfeited and forfeiting, and the master of the vessel shall forfeit 50l. 25 Geo. II. c. 21. 42 Geo. II. c. 93.

And no candles imported other-wise than according to 23 Geo. II. c. 21, shall be entered for exportation. 42 Geo. III. c. 93. All wax candles feized on importation or otherwise, and condemned for non-payment of the duties, shall be rendered unfit for use, 23 Geo. III. c. 36.

Candles for which the duty hath been paid may be exported, with a draw-back of the duty, 8 Ann. c. 9. 43 Geo. III. c. 69. If any maker of candles shall obstruct any officer in the execution of the powers given him by any act for securing the duties on candles, he shall for every such offence forfeit 100l. 24 Geo. III. c. 11.

Every maker shall keep full scales and weights, and permit and afford the officer in the use of them, on pain of 10l. 8 Ann. c. 9; and if he use scales and weights that are insufficient, he shall forfeit 100l. 10 Geo. III. c. 44; and by 28 Geo. III. c. 37, the same shall be forfeited, and may be seized by any officer of excise. Obstruction of the officer in weighing or the hindrance of his taking a full account of stock, subjects to a forfeiture of 100l. 26 Geo. III. c. 77.

CANDLES. Observations on the manufacture, comparative value, and use of different. The Roman candles were at first little strings dipped in pitch, or surrounded with wax; though afterwards they made them of the papyrus, covered likewise with wax; and sometimes also of rushes, by stripping off the outer rind, and only retaining the pith. For religious offices, wax candles were used; for vulgar uses, those of tallow. Serv. ad. Æn. i. lib. v. 731. Phil. Nat. Hist. i. xviii. c. 37. Lord Bacon propounds candles of divers compositions and ingredients, and also of different sorts of wicks; with experiments on the degrees of duration, and light of each. Good housewives are said to bury their candles in flour or bran, which, it is said, increases their durability, almost one half. Some speak of perpetual candles made of Salamander wood. Bac. Nat. Hist. Cent. 4. c. 369, and Cent. 8. c. 744.

The two substances most commonly used in the manufacture of candles are wax and tallow. Wax owes its whiteness, and the greater facility it acquires, to an absorption of the vital part of the atmosphere; and in this circumstance it seems principally to differ from tallow, or concrete oil. But as wax is already combined with a portion of vital air or oxygen, it does not burn with so luminous a flame as tallow oil. But it possesses a very great advantage in the fabrication of candles, arising from its freezing point being placed at a considerably higher temperature than that of the other substance. Tallow melts at the 52d. degree of Fahrenheit's thermometer; spermaceti at the 133d. degree; and bleached wax at 155°. Hence it will not be difficult to explain the chief advantage of wax candles compared with those of tallow. Oils, it should be considered, do not take fire, unless they be previously volatilized by heat; and this is effected by means of the wick of a candle, or lamp. The oil rises between the fibres of the wick by the capillary attraction. Heat, being applied to the extremity of the wick, volatilizes and sets fire to a portion of the oil. While this is dissipated by combustion, another portion passes along the fibres, or supplies its place by becoming heated and burned likewise. In this way a constant combustion is maintained. A candle, however,
C A N D L E S.

ever, differs from a lamp in one very essential circumstance; viz., that the oil, or tallow, is liquefied only as it comes to be in the vicinity of the combustion; and this fluid is retained in the hollow of the part, which is still concrete, and forms a kind of cup. The wick, therefore, should not, on this account, be too thin; because if it were, the candle, it would not carry off the fluid as fast as it becomes fused; and the confinement would be, that it would run down the sides of the candle; and as this inconvenience arises from the fusibility of the oil, it is plain that a more fusible candle will require a larger wick; or that the wick of a wax candle may be made thinner than that of one of tallow. The flame of a tallow candle will of course be yellow, smoky, and obscure, except for a short time after wicking. When a candle with a thick wick is first lighted, and the wick snuffed short, the flame is perfect and luminous, unless its diameter be very great; in which last case, there is an opaque part in the middle, where the combustion is impeded for want of air. As the wick becomes longer, the internal between its upper extremity, and the apex of the flame is diminished; and consequently the oil, which much furnishes light, is burnt at a greater speed of ignition to pass through, leaving completely burned, and puffs off partly in smoke. This evil increases, until at length the upper extremity of the wick projects beyond the flame and forms a support for an accumulation of foot which is afforded by the imperfect combustion, and which retains its figure, until, by the descent of the flame, the external air can have access to the upper extremity. But in this case, the requisite combustion which must snuff it, is not effected; for the portion of oil emitted by the long wick is not only too large to be perfectly burned, but also carries off much of the heat of the flame, while it assumes the elastic state. By this diminished combustion, and increased efflux of half-decomposed oil, a portion of coal or dust is deposited on the upper part of the wick, which gradually accumulates, and at length affumes the appearance of a fungus. The candle does not then give more than one-tenth of the light which the due combustion of its materials would produce; and, on this account, tallow candles require continued snuffing. But if we direct our attention to a wax candle, we find that as its wick lengthens, the light indeed becomes less. The wick, however, being thin and flexible, does not long occupy its place in the centre of the flame; neither does it, even in that situation, enlarge the diameter of the flame, so as to prevent the access of air to its internal part. When its length is too great for the vertical position, it bends on one side; and its extremity, coming in contact with air, is burned to ashes; excepting such a portion as is defended by the continual efflux of melted wax, which is volatilized, and completely burned, by the surrounding flame. Hence it appears, that the difficult fusibility of wax renders it practicable to burn a large quantity of fluid by means of a small wick; and that this small wick, by turning on one side in consequence of its flexibility, performs the operation of snuffing upon itself, in a much more accurate manner than it can ever be performed mechanically. From the above statement it appears, that the important object to society of rendering tallow candles equal to those of wax, does not at all depend on the combusibility of the respective materials, but upon a mechanical advantage in the cup, which is afforded by the interior degree of fusibility in the wax: and that, in order to obtain this valuable object, one of the following effects must be produced: either the tallow must be burned in a lamp, to avoid the gradual progression of the flame along the wick; or some means must be devised to enable the candle to snuff itself, as the wax candle does; or the tallow itself must be rendered less fusible by some chemical procures. With a view to the last of these objects, a cylindrical piece of tallow was inserted into a metallic tube, the upper aperture of which was partly closed by a ring, and the central part occupied by a metallic piece merely reflecting that part of the common lamp which carried the wick. This piece was provided with a short wick. The cylinder of tallow was supported beneath in such a manner that the metallic tube and other part of this lamp were left to hold with their whole weight upon the tallow at the ring or contraction of the upper aperture. In this situation the lamp was lighted, and it burned for a considerable time with a bright clean flame, more uniformly intense than that of a candle, and superior to the ordinary flame of a lamp in its colour and the perfect absence of soot. After some minutes it began to decay, and soon afterwards went out. Upon examination it was found, that the metallic piece which covered the wick had sufficed a sufficient quantity of tallow for the supply during the combustion; that part of this tallow had flowed beneath the ring, and to other remote parts of the apparatus, beyond the influence of the flame; in consequence of which, the tube and the cylinder of tallow were filled together, and the expected progression of suflower prevented. In every lamp for burning candle oil, it seems probable, says Mr. Nicholison (ubri infra) that the materials ought to be so disposed as to descend to the flame upon the principle of the fountain reservoir. Although this construction failed, a contrivance of a similar nature would be of very great public utility. With regard to the second object above specified, Mr. Nicholison is led by various considerations to imagine, that the spontaneous snuffing of candles made of tallow or other fusible materials, will scarcely be effected but by the discovery of some material for the wick, which shall be voluminous enough to absorb the tallow, and at the same time sufficiently flexible to bend on one side. The most promising speculation respecting this most useful article, seems to regard the cup which contains the melted tallow. This is apt to break down by fusion, and thus to suffer its fluid contents to escape. The Chinese have a kind of candle about half an inch in diameter, which, in the harbour of Canton, is called a "lobshock." The wick is of cotton, wrapped round a small stick or match of the bamboo cane. The body of the candle is white tallow; but the external part to the thickness of about one-thirtieth of an inch consists of a waxy matter coloured red; this covering gives a considerable degree of fusibility to the candle and prevents its guttering, because it is less fusible than the tallow itself. The wick in the middle might probably be of advantage in throwing up a little carbon in the flame than would have been conveyed by a wick of cotton sufficiently stout to have occupied its place unsupported in the axis of the candle. Mr. Nicholison says that he formerly made a candle in imitation of the "lobshock." For this purpose he adapted the wick in the usual pewter mould; he then poured in wax, which was immediately afterwards poured out; the film of wax, adhering to the inner surface of the mould, soon became cool; and the candle was completed by filling the mould with tallow. When it was drawn out, it was found to be cracked longitudinally on its surface, which it attributed to the contraction of the wax, by cooling, being greater than that of the tallow; or it might have been owing to the too sudden cooling of the wax before the tallow was poured in. The experiment was not repeated. After all, the most decisive remedy for the imperfection of this chesepet, and in other respects best material for candles, would undoubtedly be a diminution of its fusibility: with this view Mr. Nicholison made some experiments. The object is, in a commercial view, entitled to affectionate and extensive investigation. Chlorides in general, supposing the hardness or less fusibility of wax to arise from oxygen
The Chincote obtain from the tallow tree (Crotton foliiforum, Linn.) a kind of vegetable fat, with which they make a considerable proportion of their candles; which are firmer than those of tallow, and free from all offensive odour; but they are not equal to those of wax, or spermacetia. Cheap candles are also made of tallow, and even of grease of too little consistence to be used, without the contrivance of being coated with the finer substance of the tallow tree or of wax. The surface of these candles is sometimes painted red. Their wicks are made of different materials. For their lamps, they use the amianthus, which burns without being consumable in fire, or the artemisia, and cardus marcus, with which tinder is also made; but for candles, they use a light inflammable wood, in the lower extremity of which is pierced a small tube to receive an iron pin, which is fixed on the flat top of the candlestick, and thus supports the candle, without the necessity of a socket. The candle-makers at Munich have for several years past prepared tallow candles with wooden wicks, which afford about the fame quantity of light as a wax candle, burn also with great steadiness and uniformity, and never crack or run. These wicks are formed of very thin slips of wood, bound round to a considerable thickness with very fine spun cotton, but such that the size of the wick does not much exceed that of the wick of a common candle. The candle-makers either purchase or prepare for themselves these slips of wood, which are somewhat square and not completely rounded, and are made of pine, willow, and other kinds of wood, but more commonly of fir. Some take shoots of the pine-tree a year old, or common fir twigs of the same age, scrape off the bark, and reduce them to the size of a small straw; they then rub over these rods with wax or tallow, till they are covered with a thin coating of either of these substances; after which they roll them on a smooth table in a very fine carded cotton, drawn out to about the length of the rod or candle-mould. After this preparation the wick will have acquired the size of the barrel of a small quill; and the more accurately the size of the wick is adapted to that of the candle-mould, so much the clearer and longer will the candle burn. These wicks are then placed very exactly in the middle of the mould, and retained in that position; and good fresh tallow, previously melted with a little water, is then poured round them; but old and rancid tallow will not run if the wicks be properly made. These candles not only burn longer than the common ones, but they do not flare, and they are less prejudicial to the eyes of those who are accustomed to read or write at night. They must be infused with a pair of sharp scissors, and in doing this care must be taken not to damage or break the wick.

It has been suggested by Dr. Franklin, that the flame of two candles joined gives a much stronger light than both of them separate. Probably the union of the two flames produces a greater degree of heat, by which the vapour is attenuated, and the particles of which light consists more copiously emitted. Priestley’s Hist. of Vision, &c. p. 807. For a comparison of the light of a candle with that of a lamp, see Lamp. For the method of estimating the intensity of candle-light, &c. see Light and Photometer.

Dr. Ingenhousz has described in the Philosophical Transactions (vol. 68.) a method of lighting a candle by a small electrical spark. For this purpose he uses a small phial, having 8 to 10 inches of metallic coating, or even less, charged with electricity; and the operation may be performed at any time of the night by a person, who has an electrical machine in his room. “When I have occasion to light a candle,” says he, “I charge a small coated phial, whose knob is bent downwards, so as to hang a little over the body of the phial; then I wrap some loose cotton over the extremity of a long brass pin or a wire, so as to stick moderately fast to its substance. I next roll this extremity of the pin wrapped up with cotton into fine powders of resin, which I always keep in readiness upon the table for this purpose, either in a wide-mouthed phial or in a loose powder; this being done, I apply the extremity of the pin or wire to the external coating of the charged phial, and bring as quickly as possible the other extremity wrapped round with cotton to the knob; the powder of resin takes fire and communicates its flame to the cotton, and both together burn long enough to light a candle. As I do not want more than half a minute to light my candle in this way, I find it a readier method than kindling it by a flint and steel, or calling a venter. I have found, that powder of white or yellow resin lights easier than that of brown. The “farina lycopodi” may be used for the same purpose; but it is not so good as the powder of resin, because it does not take fire quite so readily, requiring a stronger spark not to miss; besides, it is soon burnt away. By dipping the cotton in oil of turpentine, the flame effect may be as readily obtained, if you take a jar somewhat greater in size. This oil will inflame so much the reader if you draw a few fine particles of brafs upon it. The pin dull is the bell for this purpose; but as this oil is scattered about by the explosion, and when kindled fills the room with much more smoke than the powder of resin, I prefer the last.”

For the method of lighting candles by phosphoric tapers or matches, see Phosphorus.

Candle, a term sometimes used in Medicine and Surgery. Thus, medicinal candles, candela feminales, are compositions of odoriferous, aromatic, and inflammable matters, as benzoin, floroxan, olibanum, turpentine, and the like, mixed up with a third or more of the charcoal of willow or lime-tree, reduced to a proper consistence with mucilage of tragacanth, and formed into masses in shape of candles. The effusus and odours of these candles, when burnt, are supposed to be salutary to the breath, &c. For candles in surgery; see Bougie.

Candle, corpi, canus, corpis, in Welsh, a name given to a light or flame, resembling that of a candle, which, according to an opinion very commonly received in the diocese of St. David’s in South Wales, proceeds from the house, and even sometimes from the bed, where a sick person lies a short time before his death, and pursues its way to the church where the corpse is to be interred, precisely in the same track which the corpse is afterwards to follow.

Candle, fade or aflaion by inch of. See Inch of Candle. There is also a kind of excommunication by inch of candle; wherein the time a lighted candle continues burning is allowed the sinner to come to repentance; but after which he remains excommunicated to all intents and purposes.

Candleberry tree, in Botany, see Myrica Cerifera. For the wax of this tree, see Wax.

Candle bombs, denote small glass bubbles, with a neck of slender bore about an inch long, through which a small quantity of water is introduced, and the orifice is then closed up. When this flask is applied to the wick of a burning candle, the flame soon rarefies the water into steam, the elasticity of which breaks the glass with a loud explosion.

Candle, philosophical, or candle of the chemists, as it is sometimes called, consists of a bladder having its orifice furnished with a tube of metal some inches in length, and capable of being adapted to the neck of a bottle, containing a composition formed in the proportion of 3 ounces of oil or spirit of vitriol, and 12 ounces of common water, to which, when
CANDLES, rubb. are made of the pith of a fort of mihes, peeled or flipped of the skin, except on one side, and dipped in melted grane. These are used among the poor in some parts of Great Britain.

Candlewood, slips of pine about the thickness of the finger used in New England, and other colonies, to burn instead of candles, giving a very good light.

The French inhabitants of the island of Tortuga use slips of yellow funal wood for the same purpose, and under the same denomination of bois de chandelle, which yields a clear flame, though of a green colour. The nations of Othakitee use, as a substitute for candles, the kernels of an oily nut annexed, one above another, to a skewer that passeth through them; the nuts answer the purpose of tallow, and the skewer that of a wick.

CANDLEMAS, a feast of the church, held on the 2d of February, in memory of the Purification of the Blessed Virgin. It takes its name either from the number of lighted candles used by the Romish church, in the processions of this day; or because, before maids, the church consecrated candles for the whole year. This ceremony was prohibited in England, by an order of the council in 1548.

Candlemas is also called, in ancient writers, Hypapante; and among the moderns, the Purification.

Some will have this feast to have been instituted by pope Gelasius, in lieu of the heathen Lupercalia; and that procession was thereon made with lighted candles round the fields and grounds, by way of exorcism. Hence Bede says, it is happy for the church to have changed the habitations of the heathens, held in the month of February, around the fall of the procession with hallowed candles, in remembrance of that divine light whereby Christ illuminateth the world, whereas he was stydol by Simeon, a light to lighten the Gentiles. Others ascribe the origin of candles to pope Vigilius, in the year 536, and suppute it instituted for the feast of Proserpine, held with burning tapers by the heathens in the beginning of February. In Scotland, candlemas is one of the four terms of the year. See Term.

In England, this is no day in court, for the judges do not sit; and it is the grand day in that term of all the ins of court, in which the judges anciently observed many ceremonies, and the socities seemed to vie with each other in sumptuous entertainments, accompanied with music and all kinds of diversions.

Candlemas lies, in Geography, two islands in the South Pacific Ocean, discovered by captain Cook in 1775. S. lat. 57° 10'. W. long. 27° 13'.

Candlemas Shows lie about 2° of latitude due N. of Port Prinfin (which see), and were discovered, named, and mapped by Mendana, in 1568.

Candlestick, a household utensil, contrived to hold one or more lighted candles. Larger and more stately candlesticks, contrived for holding a great number of candles, are called branches, and girandoles; and when made of brass, lusters.

In the year 1800, Mr. Raybould, of London, obtained a patent for candelllicks on a new principle, which will also and firmly hold candles of various sizes. The candelllick of his invention is a hollow paper of metal or brass; the candle is fixed into a socket composed of a broad circular base, formed of two half cylinders cut down perpendicularly, and fixed in the same fland, so as to form a complete candle when joined together. Their approach to each other is regulated by a screw, so that they may be placed upon a candle of any size, and will hold it firmly. This candle slides up and down the candlestick by means of a small knob which is fixed to the socket containing the candle, and projects on the outside through a longitudinal slit in the candlestick from the top to the bottom. The candle socket is kept up to any height by a spring which projects from its lower part, and presses on the outside of the hollow pillar, which forms the rim of the candlestick. Fig. 7 Plate of Candlesticks, represents one of Mr. Eardall's patent candlesticks; it is calculated to let the candle at any height as it is consumed, to accomplish this the upper part A slides into that of B, and the part B slides up and down in that of C. In order that these slides may keep in the place they are fastened with 4 screws, fig. 7, unscrewed, and is represented separately in fig. 8.

To the bottom of the rim is soldered a copper cylinder, which goes with inside of the tube c; in three or four places on this cylinder an oblong piece of the metal E is cut out, except at the upper end; it is then bent inwards, to give it a sufficient spring against the sliders A, B, to ready it: this contrivance is the same as is used in sliding telescope tubes. Figs. 9, 10, 11, and 12, represent different contrivances for making the nozzle of the candlestick fit different fixed candles; in fig. 9, the two leaves A, B, which compose the nozzle, are fixed to the part c, as to have a tendency to spring from each other; but they can be brought together to fit the candle, by sliding the ring D upwards. In fig. 10, the two pieces of iron plate A, B, are inclosed in a common vessel, and are riveted to it at c; they may be closhed by the screw D, and their own elasticity opens them when the screw is slackened. In fig. 11, the size of the nozzle A is diminished by three segments of a circle a b, and another not seen, which, when the rim B, on the outside, is turned one way, they move into, and diminish the size of the nozzle A; but when it is turned the other, they draw back flush with the inside of the tube E. This is effected by the mechanism, represented in fig. 12, where A, B, C, C, are the segments moving on centres; on the inside of the rim B, C, are three knobs b, b, b, which, when they are moved round one way, press on the projections a, b, c, on the long end of the segments, and move the n into the cavity A; but when turned the other, they press on the knobs on the short end of the segments, and draw them back.

The golden candlestick was the richest utensil in the Jewish tabernacle. It was made of solid gold, and weighted a talent; and, according to Cumberland, the value of it, exclusive of the workmanship, was 5770 pounds. It contained seven lights, six branching out in three parts on each side of the upright stem, and one on the top of it. Each branch was adorned with cups, knobs, and flowers, alternate and equidistant; and on the top of each was fixed a lamp, in form of an almond, which might be put on or taken off occasionally; and in these were put the oil and the wick, or the cotton, which was drawn in and out by tongs or pliers; under them were flnudflicks for receiving the sparks, or refuse of the oil that fell from the lamps. This candlestick was placed in the antichamber of the temple, on the south side, and served to illuminate the altar of incense, and the tabernacle of the shew-bread; and it was the burden of the priest to light the lamps every evening, at the time of incense, and to extinguish them at the same time.

CANDY.

ubomunding with springs, which excellently adapt them to the cultivation of rice and the rearing of cattle. The humidity of the climate, after the rainy season, counteracts these advantages. The principal difference between the climate of the interior and that of the coast is occasioned by the flagrant of the atmosphere in the former. The depth of the valleys and the thickness of the woods concur in preventing the free circulation of the air; so that the night is constantly attended with very cold damp, which are succeeded by days equally anxious on account of their hot and sultry vapours. Hence it happens, that an European on coming to the interior is very subject to the chill or scuffle fever; a disease resembling our ague and intermittent fever, accompanied with a violent dyshyentery, which never leaves the person attacked till he removes to the sea-coast, where the climate is more cool and refreshing in the day, and more free from the cold and damp of the night. The country of Candy can never derive any improvement from internal navigation; as the several large rivers that intersect it are renders, during the rainy season, so rapid and impetuous by the torrents which fall into them from the surrounding hills, that no boat can venture upon them, while in the opposite they are almost completely dried up. Its largest rivers are the Mahawonu and Mahondu, which feed. The rainy season varies in different parts of the interior. The S.W. quarter is subject to the influence of the equinoctial monsoons, while the N.E. is but slightly touched by those from the opposite quarter. The high range of mountains that enrols the country of Candy divides the island into two different climates; so that there has been a continued drought on one side of them for years, while it has rained on the other without intermission. The eastern parts are less subject to the influence of the monsoons than those to the west, and consequently much less drenched with rains. Among the mountains of the interior, the feasons do not exactly correspond to either of the monsoons; and among them it rains incessantly in March and April, at which period it is dry in the low lands.

The disposition and character of the Canadins derive their call from their situation. Although they are subject to complete despotism, they are proud of being free from a foreign yoke, and of being the slaves only of their own race. They are in their air and affect grave and learned, and regard with contempt the Cingalese in their servility, as a mean despicable race, who better their natural rights for peace and protection. Nevertheless, they are more cautious and polite, and at the same time more crafty and treacherous than their countrymen of the low-lands.

They are also more athletic, and being accustomed from their infancy to bear arms, and to watch the different posts where danger is apprehended, they acquire a military air, which distinguishes them from the Cingalese. Their horses are also neater and better built. The dress of the higher order of the Canadins consists of several folds of cotton cloth, or calico, drawn close round their waist; while another piece, after being wrapped round the body, is tucked up at the back by one end, and by the other drawn together between the legs, or hanging down straight to the ankles; their arms, shoulders, and chest are bare. On their heads they wear a hat of straw, broad and flat at the top, narrow towards the lower part, and covered with "cojoes," a species of leaf-like mane of rice. Over their shoulder, or round their waist, they wear a belt, to which a dagger or short hanger is frequently added. Between them they wear a cap, which holds batik, odalas, and tobacco; and they are commonly attended by a boy, with an ivory or tortoiseshell box filled with these articles. They constantly use an umbrella of talipot-leaf when they walk abroad in the day.

They all wear rings on their fingers; some are polished by royal and petty from among them in trade. The chief distinction, with regard to dress, between the ruler of the Canadins and the Cingalese, consists in the form of the cap, and the manner of their dress. So that the want of the former. The dress of the latter is in only much more elaborate than the Cingalese. The Canadins are more in respect to the countrymen and women.

The women are generally dressed in the same manner as the men, with the exception of the head-dress, which is much more elaborate. The Canadins are distributed into different classes, according to their respective professions. The high cast comprehends the nobles, who never communicate their blood by intermarriage with persons of inferior rank. This class is known by the name of "Hindustani." The next rank includes all, as painters, sculptors, carpenters, and goldsmiths. Their dress is the same with that of the Hindustani, but they are not permitted to eat with the nobles, or to mix in their society. Those who are employed in the lower occupations, as they are dressers, or barbers, potters, weavers, etc., form a third cast, with which the common labourer ranks. The fourth cast includes the peasants and labourers of all descriptions, who either cultivate the land for themselves, or are forced to work for others. All these four casts continue unmixed; the son pursuing the profession of his father from generation to generation. Besides these castes, there is in Canadins, as well as in other parts of India, another wretched cast, called the "scavengers," who by any crime or neglect of superflitious rites have, according to the decree of the priests, forfeited their cast, and are condemned to infamy, pertaining to themselves, and entailed on their descendants through all generations. None of any other cast will intermarry with them; they are not allowed to exercise any trade or profession, nor to hold intercourse but with such as themselves; and if they accidentally touch any thing, it is reckoned polluted and accursed. Not allowed to work, they are reduced to the necessity of begging for their subsistence. These unhappy people are obliged to pay the heaviest of the Canadins as much reverence as common suffrage ordains the latter to pay to their sovereign.

The government of Candy is an absolute despotism, and resistance to the will of the king is attended with certain and immediate destruction. Nevertheless, the Canadins hold in veneration fundamental laws of remote antiquity, the violation of which renders the sovereign amenable to the justice of his country as well as the meanest subject. By these fundamental laws the monarchy is elective, and the people may sit aside the next branch of the royal family, and elect the more distant, or even a stranger; though the throne has been in general, for many ages, possessed by the ancient Canadin royal family, which is now very nearly extinct. The king of Canadins yields no eastern prince in the number and extravagance of his titles, which it is needless to recount. They claim, however, from his subjects corresponding reverence. No one dares approach him without professing himself three times before the throne, and at each act of prostration repeating his titles. Persons of the highest rank are prohibited from coughing or spitting in his presence, and every one must abstain before him avoidable sneeze. For profanity, however, is always attended by a number of punishments on inferior instruments, such as tom-toms, or drums of various sorts, still and trumpets, clarinets, pipes, flageolets, a sort of bag-pipes, and pieces of brahs and iron jangled by way of triangles. Among
