other attendants of the monarch are people furnished with long whips, made of hemp, cords, graps, or hair, with a thong or lash 8 or 12 feet in length, without any handle; and whose business it is to run before the procession with strange gestures, in order to clear the way, and to announce his majesty's approach. As the government is despotic, all forts of promotion depend on the king's pleasure; nevertheless, respect is uniformly manifested to the authority of chiefs, and officers of a certain rank must always be charged of a certain class. The king's regular troops, or standing army, are always near his person, and do duty in the interior; while the defence of the frontiers is entrusted to the adjoining inhabitants, who form a sort of militia, and watch over the entrances into the country. The high-cit officers of the state are the "Adigar," or prime ministers, two in number, who share the whole power of the court. These are usually selected from opposite factions, and of different dispositions, to prevent an union which might overthrow the royal power. The adigars are the supreme judges of the realm; before them all causes are brought, and they pronounce final judgment; though from their sentence an appeal, seldom of any avail, lies to the king himself. The distinguishing badge of the adigars consists of a certain number of officers, who compose their train, and who carry a fort of flames, and a feal of hard clay, indicating the king's commission, and never permitting it to come to the knowledge of the command. The embassies to the European government at Caloumba are entreated to the prime minister; and they are also charged with the reception of our ambassadors. Next in rank to the adigars are the "Difuaus," who are the governors of the "cortels," or districts, and also the principal military commanders; they attend the king's peron, collect the revenues, and maintain order and discipline. But though they possess great authority, as well as the other officers of state, none of them are allowed to punish capitally without the cognizance of the king, whose exclusive prerogative it is to pronounce sentence of death. The difuaus, while they retain their office, are allowed by the king a certain portion of land for their services; but under pretence of collecting contributions for their royal master, they are chargeable with grievous oppression. Subordinate to these inferior officers resident in the several districts in which they are appointed, as their superiors generally reside at court and attend the peron of the king. To these again there is another inferior rank of officers, who are employed in the collection of the taxes of confiables and other offices. The whole plan of government forms a regular system of opprobrium, which is severely felt by the lower orders of the people, whose property is wholly at the mercy of the rapacious officers of the court.

The principal revenues of the king arise from presents or contributions brought him by the people, or rather irregularly enforced by his officers, two or three times a year. These contributions consist of money, precious stones, ivory, cloth, corn, fruit, honey, wax, arms, and other articles of their own manufacture, as spears, arrows, pikes, targets, talitop-leaves, &c. The oppression principally experienced by the lower classes of the people is also extended to persons of superior rank. On certain festivals observed in great state, all the "Mahondrews" and principal people are required to attend, and none must approach the royal presence empty-handed. After deposition their presents at the palace-gate they are admitted into the presence of the king, and received according to the value of their offering. Besides these stated modes of extortion, there are others less oppressive. Any person who is known to possess any articles of value is required to impart a portion to the royal treasury; and artills are frequently employed by the king to manufacture for him arms and different articles in silver and gold, altogether at their own expense. All the Canadians are obliged to take arms without diminution at the command of the sovereign. His regular troops, as they are called, may consist of about 15,000 men. Like other despots who are afraid to trust their own subjects, the king always keeps about his person a body of Malabars, Malays, and others, who are not his own natural subjects. In these he reposes his chief confidence, and he employs them as his constant body-guard. Before this corps of foreign guards, who do perpetual duty at the royal palace, about 8,000 of his regular troops and a number of the nobles are quartered in the neighbourhood, ready to be assembled at a moment's notice. The rest of the military force lives scattered through the country. Their pay and subsistence consist of a small allowance of rice and salt, a piece of cloth annually given for their drees, and an exemption from taxes and all other services, and a small piece of ground on which they cultivate for themselves. The usual military punishment is compulsion to level a piece of hill, or clear the channel of a river. For more trivial offence the folders are curtailed of their pay and allowances. Draught and jealousy, the constant attend-ants of arbitrary power, pervade the whole military body-guard. Officers are encourag'd by the king to act as spies against each other, and they are expected to inform whenever possible of each other's movements and secrets, and to prevent them, except at times when public exigency requires it, by being assembled. They are chiefly prevented from forming any intercourse or combination with Europeans; and for this purpose a continued chain of posts and watch-towers is established around all the outskirts of his dominions. This system of vigilance is so strictly observed, that no one is permitted to pass from one district to another without examination and a pass-port, bearing different imprints according to the profession of the bearer. The natives universally travel on foot; riding on horseback being a royal privilege, seldom used by the monarch himself. No horfes indeed are kept in the interior except those belonging to his majesty: nor are any horses reared in the interior. The Canadians have no fixed and established laws; though they boast of an ancient code, which remains in the hands of the king, who is its sole interpreter. His authority supersedes every other decision. The trials of the Canadians are summary; and their punish-ments, unlike the king interposes, immediate. Their capital punishments are always attended with some circumstances of cruelty; such as having the victim prostrated by elephants, pounding him in a large mortar, or impaling him on a flake. Imprisonment is a species of punishment never inflicted on a Canadian; and every species of confinement conveys ideas peculiarly horrible to their imagination. The great safe-guard of justice among the Canadians is the natural mildness and honesty of their dispositions, in which they exceed all other Indians. The Canadians, precluded from intercourse with foreign countries, and proud of immemorial independence, might be supposed to enjoy amidst their native mountains and woods, a life of tranquillity and happiness, not to be found amonst those busy nations, that are inflamed by luxury and agitated by the thirst of gain. But this is far from being the case. The oppression of their governors, the constant dread of Europeans, and the superstitious fears arising from the nature of their climate, by which they are continually haunted, deprive this isolated people of all the enjoyments which seem congenial to their situation. Much of the gloom that overhangs the minds of the Canadians originated with the oppressive exactions and destructive inroads of the Dutch. It is to be hoped, says Captain Percival, that we who are the Canadian's countrymen, by a generous and well regulated pol-icy, will speedily diminish their sources of unhappiness.
CANDY.

Percival's Account of the Island of Ceylon, 4to. 1805. See Ceylon.

Candy, the capital of the king of Candy's dominions and the royal residence, is situated in the district of Tattamun, in the midst of lofty and steep hills covered with thick jungle. The narrow and difficult passades, by which it is approached, are intersected with thick hedges of thorn; and hedges of the same sort are drawn round the hill in the vicinity of Candy, like hedges of circumvallation. The only passage through the hills by gates of the same materials, called by the natives "Carpenters," and so contrived as to be drawn up and let down by ropes. When the Candois are obliged to retreat within these barriers, they cut the ropes, and then it is impossible to force a passage except by burning down the gates, which, from their green flate, and the constant annoyance of the enemy, would prove an enterprise of some time and difficulty. These hedge-rows form the chief fortifications of Candy. The river Mahavonga also nearly surrounds the hill on which it stands: the river is here broad, rocky, and rapid; a very strict guard is kept on it, and every one who passes or repass is closely watched and examined. Although the caravans near the hill of Candy have a rampart or break-work, on which some of their artillery is occasionally mounted, it could make but a feeble reliance to the approach of a regular army; so that Candy is indebted for its principal fortifications to nature. The city itself is a mean and miserable place, surrounded by a mud wall of no strength. Our chief knowledge of this city is derived from the embassy of general Macdowal, deputed to the king of Candy by governor North, in the year 1803, of which captain Percival has given a journal, in an appendix to his account of Ceylon: but the information thus obtained must necessarily be imperfect; as the ambassador and his suite were admitted only by torch-light, and always retired before break of day.

From what they could observe the city consists of a long straggling street built on the declivity of a hill, about two miles long, with lesser streets branching off on both sides: the houses were mean and low, chiefly of mud, but their foundations were raised about 5 feet above the level of the street, so that they appeared lofty to passengers. The reason of this mode of construction is to enable the king to hold his assemblies of the people, and to have his elephant or buffalo fights in the street without interfering with the houses. Some of the houses at the upper end of the street, belonging to the principal inhabitants, are tiled and white-washed. When the king passes along the street, none of the inhabitants are allowed to appear before their houses or in the paths on a level with them, as this would be attended with the heinous indecorum of placing a subject higher than the prince defended of the sun. At the upper end of this street stands the palace, built of a kind of chesam or cement perfectly white; and containing a great number of rooms, the walls of which are painted in a grotesque manner, and covered with inscriptions: in one room is a gigantic figure of Buddha in a sitting posture, with two smaller ones at his feet. The palace is surrounded with high stone walls, consisting of two squares, one within the other. In the inner of these, to which there is access by a large arched gateway, are the royal apartments, where the court is held, and audiences are given. The hall of audience, or state-room, is a long viranda, with alternate arches and pillars along its sides, somewhat resembling the aisle of a church. At the farther end of this hall is placed a kind of platform or throne, covered with a carpet and surrounded with steps, where the king sits in state. His feet, and the lower part of his body are concealed from view by a small partition in front. On occasion of general Macdowal's reception, the courtiers were seen below the arches on each side of the hall, some prostrate, others lying on tables and ended-legged. The king was driven in a poke of how-mulla, embroidered with gold, drawn close in several folds round the waist, and flowing from thence down like a lady's gown. His arms were bare from the elbows downwards. On his fingers were many broad rings set with precious stones of different sorts, and a number of gold chains were suspended around his neck over a flint polished piece of sandal resembling Queen Elizabeth's staff. His head was covered with a turban of muslin spangled with gold, and fastened by a crown of gold, by which he is distinguished from all the other Asiatic princes. Round his waist was a rich sash, from which was suspended a short curved dagger or sabre, with the handle richly ornamented, and the hilt composed of gold filagree-work. During the conference, which lasted three hours, rock-water was frequently sprinkled round from curiously wrought vessels of gold; and perfumes were handed about on savers of gold and silver filagree-work. To one proposal made on this occasion, viz. that leave might be given to make a road, and to open a communication from Trincomalee to Columbo through the territories of the king a little north of Candy, he peremptorily refused to accede; but he expressed his decided averison from any intercourse or connexion existing between his subjects and the Europeans; professing at the same time a desire to live on amicable terms with the British, whose power he acknowledged to be far superior to that of the Dutch. On January 31st, 1803, general Macdowal began his march with a considerable force into the Candois territory, and on the 20th of February, after encountering many difficulties, arrived at Candy. The king and his chief adhirg precipitately withdrew, after having let fire to the palace and the temples. The British troops soon extinguished the fire, and took possession of the city.

Although the Candois soon afterwards appeared in considerable force, they were quickly dispersed after a dreadful slaughter. Before the British general left Candy, he adopted various measures to secure his new conquests. After some time, viz. in June, 1803, when it was thought tranquillity was established, and in the midst of a truce, Candy was attacked by the natives under the command of the first adhirg; and the commanding officer, whose troops were composed of horse and foot, and were composed of horse and foot, was set upon by the natives, and had to make a determined resistance and carry on an engagement to repulse them. The king of Candy and his subjects had then melted away, and the difficulty of evacuating the fort, under a solemn stipulation that the garrison should be allowed to proceed, with arms and ammunition, and without molestation to Trincomalee, and that the sick should also be taken care of. In defiance of this agreement, after the command ing officer left the fort, all the English soldiers who accompanied him were treacherously murdered. Shortly after this massacre, the king of Candy, finding that the British force on the island was weak, determined to attack our forts on the coast; but all his efforts were ineffectual; and the British settlements were soon restored to security. Candy, or Kandi, lies in the centre of the country, 80 miles distant from Columbo, and about 150 miles from Trincomalee. N. lat. 7° 18'. E. long. 80° 46'.

Candy, in speaking of Sugar, denotes a preparation of that substance, made by melting, and crystallizing it six or seven times over, to render it hard and transparent. See SUGAR.

Candy-fat, in Botany. See IBERIS.

CANDYBA, in Ancient Geography, one of the most considerable towns of Aisa Minor in Lycia, which, according to Steph. Byz. derived its name from Candybus, son of Deucalion.

CANDYING, denotes an operation in Pharmacy, as
well as Confectionary: those simples which are preferred in substance by boiling in sugar being said to be candied: though the performance of it is now transferred to the confectioner from the apothecary, to whom it originally belonged.

CANDYS, in Ancient Geography, a town of Asia; in Media, Pтолем. 
CANt, in Brit. See Arundo Bambus, or Bamboo. 
Cane, fig. See Saccharum. 
Cane, in Commerce, the same with reed, called among botanists Arundo, which fire. 
Canales,羌走, are said by Bradley to be joints of the roots of a sort of reed, called cano índices. This plant shoots in joints of about three or four feet long, near the surface of the ground, and at every knot produces great numbers of fibres, by which it receives its nourishment. The joints are made straight by the fire, which occasions those fibres or clouds frequently seen in them. Bradley thinks the cane-tree might be propagated here by planting some of the roots with their knots in artificial bags, &c. 
Canes may be stained like tortoise-shell, by a mixture of aqua fortis and oil of vitriol laid on them at several times over live coals, to cause it to penetrate the deeper, and afterwards giving them a gluts with a little soft wax, and a dry cloth. 
Cane, rattan, are a smaller sort brought from China, Japan, and Sumatra, very tough; which being split, are used for making of cane chairs. They are the produce of a reed called rattang Madoranica minor, or lesser rattan. The specific name is rotang, whence rattan, and in the Malayian language signifies a fluff or walking fl inc. These when dry, being struck against each other, will give fire, and are used accordingly in some places in lieu of flint and steel. Being twitted together they make cordage of them. The Chinese and Japanese vessels are said to have their cables made of them, which are less liable to rot in the water than hemp. Phil. Trans. N° 244, p. 326, and N° 267, p. 717. See Canamy. 

The canes, or canns, in the jurisdiction of Guayaquil in South America, are remarkable for both their length and thickness, and the water contained in their tubes. Their usual length is between 6 and 8 tubes; and the largest do not exceed 6 inches in diameter. The round or side of the tube is about 6 lines in diameter; so that when the cane is opened, it forms a board near 1/2 foot in breadth; and, therefore, it will not appear strange that houses should be constructed of such materials. From the time of their first appearance, till they attain their full perfection, when they are either cut down, or of themselves begin to dry, most of their tubes contain a quantity of water, with this remarkable difference, that at full moon they are entirely, or very nearly, full, and with the decrease of the moon, the water ebbs, till at the conjunction little or none is to be found. During its decrease, the water appears turbid; but about the time of full moon, it is clear as crystal. The water is found to be an excellent preservative against the ill consequence of any bruises; at least it is drunk by all who come from the mountains, where such accidents are unavoidable. The canes, being cut, are left to dry, or, as they say, to be cured; whence they acquire such a degree of strength, that they serve for ratters, beams, floors, or even mats for balzas. Ships which load with cacao are also eiled with them, to preserve the timber from the great heat of that fruit. They are also used as poles for litters, and in a variety of other ways. Juan and De Ulloa's voyage to South America, by Adams, vol. l p. 209. 
Cane, fishing-red. See Reed. 
Cane, Indian. See Cana. 
Cane, in Natural History, a name given by the common people of Ireland to the arbatus, or strawberry-tree. See Arbatus. 
Cane, Cana, a long measure, frequent in Italy, Spain, and the south parts of France; of greater or less length, according to the places where it is used. It is called by the Latins calamus, and in scripture a reed. 
At Naples, the camma is equal to seven feet 3/4 inches, English measure; the canna of Thoulouse, and the Upper Languedoc, is equal to the vara of Arragon, and contains five feet 81 inches; at Montpellier, in Provence, Danphonie, and the Lower Languedoc, to fix English feet 53 inches.

Cane, in Ancient Geography, a port-town of Arabia Felix, attributed by Ptolomy to the Adramytes, who formed a clas of the Sabzans. — Also, a promontory near this town, on the Red Sea.— Also, a promontory of Asia minor, near the Caeus. 
Cane, in Geography, a river of Hindoosan, which runs into the Jumna, 20 miles S.E. of Corah. 
Cane, in Rural Economy, a term sometimes used to signify a hollow place where water runs. It also implies a vault of alder, or other aquatic trees, in a moit boggy situation. 
Canea, in Geography, a maritime town of the island of Candia, or Cete, situate at the eastern extremity of a large bay, on the north side of the island, and supposed to have been built on the site of Cydonia, a flourishing city of ancient Crete, although no vestige of ancient edifices be now perceived. Canea, after refilling the efforts of the Ottoman army consisting of 60,000 men for 50 days, during which siege the Turks are said to have lost 25,000, was compelled to capitulate in the year 1547. Although it is much less extensive than Candia, the capital, it is the most populous and the most trading town of the whole island. In this place are reckoned upwards of 40,000 Turks, 2 or 3 thousand Greeks, 156 Jews, 4 French houses, and some Italian houes, which latter are under the protection of the emperor of Germany, or the republic of Ragusa. The form of its buildings resembles that of the houses of the East; in lieu of roofs, inclined and forming a ridge, they have a flat covering without tiles or flates, and constricting a terrace; mott of them are of brick. They are all level or flat, and the doors, windows, and shutters are made out of the line; some of them are tolerably wide; in the public buildings are fountains that flow with an abundant stream. The town is surrounded by a strong wall and a wide ditch. It has but one gate on the land side. The harbour is defended by batteries in a good condition. To the left, on entering, is seen a jetty parallel to the coast, behind which a considerable number of vessels might anchor if the bottom were cleansed. The largest are obliged to remain near the entrance of the harbour, exposed to the waves of a rough sea when the northerly winds blow with violence. If during these northerly gales, they happen to have run into it, it is not possible for them to get out; but they are obliged to lie for the very narrow mouth of the harbour, where the waves rise in 200 tons burden: the arsena and fine docks which the Venetians had contrived opposite to the jetty are falling into ruins and unfit for use. In the environs of Canea, there are some beautiful plains that are tolerably fertile and almost entirely cultivated; and they prefer wait...
The sandstone of Gavilion, and which have preserved nearly all with its appendages. Candia is about 18 miles W. of Candia. N. lat. 37° 57' 0', E. long. 34° 18'.

CANEHEAD, in Ancient Geography, a town of Asia Minor in Canea, mentioned by Ptolemy, says, that it was also called Cyen.

CANEFIELD, in Geography, a town of North America, in the state of South Carolina; 6 miles N.N.W. of Queenborough.

Sp. C. arb. Chlt. exot. lib. 4. cap. 4. Swartz in Linn. Tranac. vol. i. tab. 8. Woodville Med. Bot. p. 318. tab. 117. (C. perumum, and C. tubis microplus alba. Bauh. p. 309. 2, 3, and 4. Park th. 1391. C. cubana, Johnf. dendr. 165. C. cinnamonica, Pink. phyt. vol. 160. f. 7. C. waterana, Genr. fruct. tab. 77. f. 2.) A stem from 10 to 50 feet high, straight, branched only at the top; bark whitish; branches erect, not spreading. Leaves petioled, alternate, but not regularly, oblong, acuminate, entire, thick, dark green, shining. Flowers in terminal, compound corymb, violet, small, fleshy opening; lobes of the calyx roundish, concave, incumbent, smooth, membranous; petals concave, erect, thick, deciduous. Berry globular, helio, smooth, black. Seed fixed to the central angle of the cells, regularly two in each cell, but one or two cells are generally abortive, and sometimes only one different, of different shapes, according to the number of abortive germs and cells, always black, smooth, and shining. Swartz and Genr. The whole tree is very aromatic, and when it is in blossom perfumes the whole neighbourhood. The flowers dried and softened again in warm water have a fragrant odour, nearly approaching to that of musk. The leaves have a strong smell of laurel. The berries have a faint aromatic taste and smell, and are greedily eaten by the white-billed and black-pate pigeons (Columbia jamais. and leucoph. pl.,) who acquire from them that peculiar flavour which is so much admired. Its bark, which is in taste moderately warm, aromatic, and bitterish, and has an agreeable smell, resembling that of chieves, was formerly a common ingredient in the food and drink of the Caribs, and at present is a necessary addition to the meagre pot of the negroes. It is brought to Europe in long quilts, which are about three quarters of an inch in diameter, somewhat thicker than cinnamon, and both externally and internally of a whiten or light brown colour, with a yellowish hue, and commonly intermixed with thicker pieces, which are probably obtained from the trunk of the tree. Its virtues are extracted most powerfully by proof spirit. It has long furnished the nfc of the Caribb and other persons, with which it was confounded, first by John Bauhin, and afterwards by Linnaeus, who, in the first edition of the Species Plantarum, united the two plants under the name of Laurus waterana, but
but in the ensuing editions made it a distinct genus, and called it *winteraria*. The true codex winteranus brought by captain Winter from the sands of Magellan in the latter end of the 16th century, and described by Clusius, was, in consequence of this mistake, very rare, and imperfectly known in Europe for nearly a century, but has been recently brought again to light by the late Dr. Fothergill, with the assistance of the late Dr. Salmon. See *Wintera aromatica*.

The bark of canella alba, which has been received into the London and Edinburgh Pharmacopoeias, instead of the old bark of Winter, has been supposed to possess considerable medicinal virtues, and to be an useful medicine in the fever, and numerous other complaints; but is now considered merely as an aromatic, and is chiefly employed for the purpose of correcting, and rendering less disagreeable, the more powerful and nauseous drugs. It is, therefore, an ingredient in the Poly. Aloe. Pharm. Lond. and in the Timbura amara, *Vinum amaranium*, *Vinum rhei*, &c. of the Pharm. Edinb. See Swartz's Botanical History of the Canella Alba, in the Transactions of the Lunar Society, vol. i. p. 326. t. 2. p. 318. and Woodville's Medical Botany, vol. ii. p. 318. This tree is too tender to live in England out of a flor. It may be raised from fresh seeds procured from the West Indies, but is not readily propagated either by layers or cuttings.

*Canella*, in *Geography*, formerly called the *Kingdom of Cota*, a large district of the island of Ceylon, containing a great number of cantons, principally occupied by the Dutch, and famous for the quantity of cinnamon, which it produces. It has several towns, forts, and harbours, on the coast. The interior is inhabited by the natives, and it has rich mines of rubies, faphires, topazes, cat's-eyes, and other precious stones.

*Canella Alba*. The canella of the Materia Medica, is the inner bark of the *canella*, (which see) a common tree in the East Indies. This bark is brought over in long quills, much thicker than cinnamon, smooth, and brittle, and of a white or whitish yellow colour. To the taste it is extremely pungent, and somewhat bitter, and is not very grateful. It yields its febile qualities both to water and spirit, and has the common chemical characters of all the aromatic barks. On account of its extreme pungency it is seldom used.

*Canelli*, a town of Padmore, in the county of Afti; 12 miles S.S.E. of Afti.

*Canelos*, a town of Portugal, in the province of Tras-os-Montes; 5 miles N.N.E. of Lamego.

*Kanis*, or *Kaneis*, a name sometimes given to the country of *Africa*, called *Borna*, which see. See also *Kaneis*.

*Canenteos*, or *Caranthus*, *Charentes*, in *Ancient Geography*, a river of Gallia Aquitanica. *Ptolemy*.

*Canopus*, in *Natural History*, a name used by some of the older writers for a species of *fufilium* little known to us in its recent state, but described by *Klein* under the name of the *twinata marina canovences*, and by other of the late authors under that of *polychalumum* and *oribona-alius*.

*Canophorae*, *Kanophora*, from *kanos*, a red, and *phora*, I bear, in *Antiquity*, were two virgin qualities of Athens kept in Minerva’s temple in the Acropolis, who at the fall of the Pantheon, carried baskets upon their heads with something sweet or mysterious therein, and delivered them to the priests. The baskets were usually crowned with flowers, myrtles, &c. The canophore, in these ceremonies, always marched the first, the priest next, and the choir of music followed.

The learned are at variance about the contents of the baskets borne by the canophore. Some will have it, that neither they, nor the priestess herself, knew what was in them. Others conjecture that they contained the things necessary for sacrifice, &c.

There were also canophores in the ceremonies of Cerces and Bacchus. Those in the Bacchanalia carried golden baskets, in which were divers sorts of fruit, &c. Among ancient monuments, we find mention of divers figures of canophore. In that famous cornelian, called Michael Angelo’s ring, there are three canophores with their baskets on their heads.

The appellation *canophore* was also given to virgins at Athens, when becoming marryable, they presented certain baskets full of little curiosities to *Dura*, in order to procure leave to quit her train, and change their state of life.

*Canephoria* was a ceremony, which made part of a feast celebrated by the Athenian virgins on the eve of their marriage day. The canephoria, as practiced at Athens, consisted in this; that the maid, conducted by her father and mother, went to the temple of *Minerva*; carrying with her a basket full of presents, to engage the gods to make the marriage happy; or rather, as the scholiast of *Theocritus* has it, the basket was intended as a kind of honourable amends made to that godde, the protectress of virginity, for abandoning her party; or it was a ceremony to appease her wrath.

2. *C. capitata*. *Lam.* 111. pl. 151. fig. 2. *Leaves lanceolate; flowers terminal, aggregate, involucrated."

*Leaves opposite, nearly sessile; entire. Flowers three or four together; leaves of the involucrum numerous, bristle-shaped. Both species found by *Commeron* in the island of Madagascar.

*Canes*, in *Egypt* and other Eastern countries, a poor sort of buildings for the reception of strangers and travellers. People are accommodated in theem with a roof at a small price, but with no other necessaries; so that, excepting the room, there are no greater accommodations in these houses than in the deserts, but that there is a market near.

*Canes Fenorii*, in *Aifternum*, the Grey-bounds, two new constellations, first discovered by *Hvelbin*, between the tail of the Great Bear, and Boötes’ arm, above the Coma Berenices. The first is called *Afferian*, being that next the Bear’s tail; the other *Carina*. They comprehended 23 stars, of which Tycho only observed two. In the British catalogue they are 25.

*Canescens*, in *Entomology*, a species of *Aptis* mentioned by *Lepelchin* in his travels through Siberia. This insect is hoary, stout incurred, horry, projecting from a conic vehicle: abdomen with obscure blotches. Inhabits near the Calpian sea.
CANESCENS, a species of Cantharis found in Saxony. The thorax is yellow; sternum and elytra obscure cinereous. Schall.

CANESCENS, in Liliobatrach., a species of Chrysophyphus that inhabits South America and India. The tail of this frog is biled; both lower rays of the dorsal fin spines, the third very long; month indented. Gen. Linn. Syll., &c. Figured by Schel. v. 2. pl. 25.

CANESCENS, in Orotoni, a species of Motacilla, that inhabits New Holland, the plumage of which is bronze-brown above, and white beneath; head black; front streaked with white; breast and vent bracted with black; spot on the wings, and edge of the tail-feathers at the base tawny. Called by late writers the Van Diemen's warbler.

CANET, in Geography, a town of France, in the department of the Eastern Pyrenees; 5 miles E. of Perpignan. Also, a town of France, in the department of Haurta; 10 miles S.E. of Lodève.

CANECE, See Cagnate.

CAMESTHMUS, in Ancient Geography, a mountain of Greece in Batavia. Also a place of Greece, in the island of Euboea.

CANEPO, in Geography, a town of the duchy of Mantua, seated on the river Oja; 20 miles W. of Mantua. N. lat. 47° 55'. E. long. 10° 46'.

CANEVAR, Dr., an outline for a poet or musician to colour. The French chiefly use the term in writing words to favourite airs in a ballet; which, after being danced to inflations, is improvised more deeply in the memory of the audience by being sung. The word seems to be used with more propriety when applied to a slow and pathetic air, left by the composer, as a mere sketch for the finger to grace and embellish. See Camarilla.

CANTE, in Geography, a town of Spain, in Arragon, 3 leagues N. of Jaca.

CANGA, called by the Portuguese Canga, and in China Chia, in the Chinese Police, a wooden clog or collar borne on the neck, by way of punishment for divers offences.

The canga is composed of two pieces of wood netched, to receive the criminal's neck, and this frame of wood has also two small holes for the hands of the offender. The load lies on his shoulders, and is more or less heavy according to the quality of his offence. Some cangas weigh 200 pounds; but most of them from 50 to 60 pounds. It is a kind of permanent and ambulatory pillory, which the culprit is sometimes sentenced to wear for weeks or for months. The duration of this punishment for having broken the peace, or disturbed a family, or for being a notorious gambler, is generally three months. Although he is forbidden to look about, or to sit down for a certain space of time either in some public square, or at the gate of a city or a temple, and occasionally to rest under this heavy and degrading burden; yet if the offender is thought by the subordinate officer of the civil magistrate to have reformed too long, he is beaten with a whip made of leather thongs till he sinks. The mandarins condemn to the canga. When the time of his punishment is expired, he is again brought before the mandarin, who exhorts him in a friendly manner to amend, frees him from the canga, and discharges him after he has received twenty heavy blows.

CANGIANI, promontory of, in Ancient Geography. See Cangani.

CANGAREE, in Geography, a river of America, in South Carolina, formed by the union of the Saluda and Tyger: about 5 miles N.W. from Columbia.

CANGE, CHARLES DU FRANCAIS DU, in Biography, an eminent linguist and antiquary, was born in 1610, at Avincs, Vol. VI.

where, after attending the bar for some time at Paris, he devoted himself to the study of the heraldic language, and of ancient and modern history. In 1645, he obtained the post of treasurer of France; and continued at Avincs, editing literary avocations with the function of his office, till a pellicle, which prevailed in his native city, in 1660, obliged him to remove to Paris, where he enjoyed peculiar advantages for the prosecution of his studies. Here he was held in high estimation for his extramural learning. By the modency and diligence with which he always employed himself concerning his own talents and literary performances, and for the coherence and ability, which distinguished his social conversations. After having resided for 50 years, without interruption, a good state of health was restored to him, in 1688, with a retention of sense, which, in a few months, terminated his life. Of his learning, which were numerous, the following are the principal: viz. "History of the Empire of Constantinople under the French Emperors," Paris, 1657, fol. "History of St. Louis, King of France, by the Seur de Jouville, illustrated with new Remarks and historical Illustrations," &c. Paris, 1660, fol. "James Chauvin's six Books of the History of the Affairs of John and Manuel Comnenes, &c. and Lat. with historical and philosophical Notes, &c." Paris, 1670, fol. "A Memoir upon the Plan of a new Collection of the Historians of France," inserted in Le Long's Bibliothèque Historique de la France." "Glottarius ad Scriptores mediae et infima Latinitatis, &c." Paris, 1678, 8 vol. fol.; tantum 1681 and 1708, 3 vol. fol.; reprinted in 1735, by the Benedictines of St. Maur, and augmented with 4 new volumes by the abbe Carpentier. To this work Du Cange owes his chief reputation. It is of singular use to those who study the writings and records of the middle ages, and abounds with many interesting and amusing anecdotes. "Cyrilli Philoxeni, alterannae Veterum, Goglari, Latino-Graecae et Graeco-Latinae," 1679, fol. "Historia Byzantina, duplaci Commentario illustrata, &c." Paris, 1689, fol. containing the genealogies of the emperors of Constantinople, and an accurate description of the state of that city under these emperors. "Joannis Zonariz Annales ab Excido Mundi ad Mortem Alexii Comneni, &c." Paris, 1685, 2 vol. fol. "Glottarius ad Scriptores mediae et infima Graecitatis; accedit Appendix ad Glottariun mediae et infima Latinitatis, unam cum brevi etymologico linguarum Galliae et urtiquo Glottario," Paris, 1668, 2 vol. fol. "Chronicon Paschale a Mundo condito ad Heraclii Imperatoris annum vigintinum," Paris, 1689, fol. Whilst this work was in the press, the learned author died; and it was completed and published by M. Baluze. His MSS., which were numerous, are preserved in the king's library. Gen. Dict. Neuv. Dict. Histoire.

CANGI, CANGI, of CANGI, in Ancient Geography, a people of Britain, concerning whose situation antiquarians have been much perplexed. Camden discovered some traces of them in many different and distant places, as in Somersetshire, Wiltshire, Dorsetshire, and Cheshire; and others have found as plain veliges of them in Devonshire, Dorsetshire, Wiltshire, &c. Mr. Basset, (Gloef. Brit. p. 73, &c.) seems to have discovered the true cause of this perplexity, by observing that the Cangi, or Cangi, were not a distinct nation seated in one particular place, but such of the youth of many different nations as were employed in pallingage, in feeding the flocks and herds of their respective tribes. Almost all the ancient natives of Britain had their Cangi, the keepers of their flocks and herds, who ranged about the country in great numbers, as they were invited by the seacon, and plenty of pasture for their cattle. Hence we find traces of
their name in many different parts of Britain; but chiefly in those parts which were best adapted to pastoral. These Scangi of the different British nations, naturally brave, and rendered still more hardy by their way of life, were constantly armed for the protection of their flocks from wild beasts; and these arms they conveniently employed in the defence of their country and their liberty.

**CANGIAGIO,** or **CANNESIO, LUCA,** called **Luchet-

... to, in *Biography,* one of the most eminent of the Genoese painters, was born at Onglia, near Genoa, in 1527; and, being of a volatile disposition, was laid under restraint by his father, who was his teacher in the art of painting. At the age of 17, he was employed in painting the front of a house in fresco; but whilst he was commencing his work, some Florentine painters who were actually engaged, conceived him to be a mere grinner of colours, and when he took up his pallet and pencils, they wished to prevent his proceeding with it, lest he should spoil the work. However, after a few strokes of his pencil, they were convinced of their mistake, and respected his singular abilities. In the exercise of his art, he was uncommonly expeditious and rapid, and as he worked equally well with both hands, his performances were numerous and speedily executed. Of Cangiagio it is remarked, that he practised three different modes of painting at three different periods of his life. His first manner was gigantic and unnatural, which he corrected, in consequence of the remoteness of his friend Aleff, the celebrated architect, for his belt flyk, in forming which he confused nature with attention, and directed his thoughts in sketches, before he began to paint. His third manner was distinguished by a more rapid execution, to which he recurred in order to make more ample provision for his wife and family. The death of his wife was followed by a violent passion for her father, to whom he committed the care of his children. With a view of obtaining a dispensation from pope Gregory XIII., he took a journey to Rome, in 1576, and enforced his request by presenting two pictures to his holiness. The pope, however, inferred that he should dismiss his father-in-law from his house. After this unsuccessful application, he prosecuted the execution of his profession at or near Genoa, and performed some admirable works in the convent of St. Bartholomew of the Armenians. He was afterwards invited by Philip II. to adorn the Escorial; and he complied with the invitation, in hopes of interting this powerful monarch in favour of his unallowed and disquieting passion. But the king's courtiers deterred him from communicating his request, much as his performances were admired, to a prince so religious. These repeated disappointments preyed upon his mind, and brought on a lingering complaint, which terminated in his death, at the Escorial, in 1585. "A great facility of hand, skill in drawing, especially foreshortened figures, and fertility of invention, were the characteristic excellencies of this painter; but he failed in grace, felection, and the truth of nature." In the royal collection at Paris there are a "Sleeping Cy-
pid," as large as life, and likewise "Judith with her At-
tendant," which do honour to this master. In the Pem-broke collection at Wilton, there is a picture, representing Chrift bearing his crofs, which is ascribed to Cangiagio.

**D'Argenville.** Pilkington.

**CANGIAMILA, FRANCIS, EMMANUEL,** canon of the church of Palermo, and inquisitor of the island of Sicily, where he died, in 1763, published "Embryologia facra, sine de officio saccodum, medicorum, et aliorum circa exter-

... man pavulum in utero exsiliometium sulatum." Palermo, 1761, fol. By the canons of the church of Rome, it has been decreed, that children may be efficaciously baptized before they are born, if the water can be made to touch any part of their bodies, or the membranes in which they are involved; and surgeons are cautioned to see this cer-

... mony performed, whenever, from the difficulty of the labour, the life of the child shall appear to be in danger. On the other hand, they are authorized, that, to open the head of a child before it is certainly known to be dead, with a view of pre-

... verving the life of the mother, is to commit murder, and consequently not to be allowed. An abridged edition of this work was published by the abbe Dinonart, in 1761, and 1766, 12mo. Haller Bib. Nat. Eloy. Dift. Hist.

**CANGIANO,** in *Geography,* a town of Naples in the province of Principato Cita; 27 miles N. of Pulciarfo.

**CANGOXIMA, CANGONUMA, or COGONIMA,** is a fort on the most southern verge of the isle of Japan. It was the first at which the Portuguese landed, and they afterwards chose to make it the centre of their commerce, on account of its advantageous situation and commodious harbour. The entrance into it is, indeed, dangerous by reason of a number of rocks, that lie at some distance from it; on one of which is seated a strong caffle, said to have been built by Ongofchior, the grandfather of the emperor Gon-

... gon, or Gonjin, with a view of securing the city, which is the key of the kingdom of Saxam, and of the whole island. At the entrance of the haven was constructed a square light-

... house, situate on a very high rock, which is visible at sea at the distance of about 20 miles; and at the foot of the rock is a convenient road for shipping. The quay is guarded by a stone dyke, which runs into the sea, and has a stone rampart breast-high, covered with copper. In each of 2 large wings built at one end of it are stationed 500 men, who keep watch night and day, to check the kings of Saxuma, who often revolted in order to avoid paying tribute to the emperors. The town is watered by a river which descends from the mountains into a canal formed for receiving it, and from thence it falls with great rapidity into the sea. On the south side of the river is a custom-house for receiving duty, besides other large and sumptuous magazines belonging to the emperor.

**CANHAR, a river of Hindoostan, which runs into the Soane, 5 miles S.W. of Bidigur.**

**CANI, two small flat islands of Africa, in the Medi-

... reanne, near the coast of Tunis, situated about 4 leagues to the north-west of the cape Pil-leg, and very nearly in the middle way to cape Blanco. These islands seem to oc-

... cupy the situation assigned by Plowemy to his Insula Dra-

... contia. N. lat. 37° 45' E. long. 16° 50'.

**CANI, Graoto del. See Graoto del Cani.**

**CANJA, in Nautical Language, a vessel employed on the Nile, and represented by Mr. Bruce as commodious, fast, and expeditions in fishing. That which he describes (Travels to Africa, Vol. I. p. 43.) was about 400 feet from stem to stern, with two masts, main and foremast, and two mon-

... torous latitude fails, the main-fair-yard being about 200 feet in length; about 30 feet in the beam, and about 90 feet in keel. The keel is not straight, but a portion of a parabola whose curve is almost insensible to the eye, but having this advantageous effect in failing, that as the bed of the Nile, when the water becomes low, is full of sand-banks under water, the keel under the stem, where the curve is greatest, first strikes upon these banks and is fast, but the rest of the vessel is afloat; so that by the help of oars and aid of the stream, furting the falls, you easily get off; whereas, if the keel were straight, and the vessel advanced with the pre-

... fure of its immense main-fall, it must remain immoveable upon the bank, and be wrecked. When this vessel is pro-

... ceeding up the stream, before the wind, the yard and sail are 8 never
This opinion, equally erroneous and superfluous, seems to have originated with the Egyptians, who, observing this rising of the Dog-flair, which usually took place in April and May, about the time of the sun’s arrival at the equinox, when the Nile began to rise, upon the changeful state of which the fertility of their country depended, were induced to pay divine honors to this star. They regarded it not only as an indication of the time of the Nile beginning to rise, but that it was the efficient cause of its overflowing, or of the fertility connected with this circumstance. From the color of the star at the first appearances, they supposed the color of what kind of fevers they were to expect; but when it was of a golden colour, they thought it prognosticated a fruitful year, but if it appeared pale and dim, they regarded it as a harbinger of bad omen, that portended a scarcity. They were of opinion also, that the Dog-flair rising with the sun and moon, and accompanied by the fire of that luminary, was the cause of the extraordinary heat which usually falls in that season, and accordingly that they gave the name of the dog-days to about six or eight weeks of the hottest part of summer. The Greeks, in imitation of the Egyptians, their molitors in solitude and superstition, as well as science, held the same opinion, that the Dog-flair was the cause of that sultry heat so often pernicious to the health and life of man. Homer, (Iliad, i. xxii. v. 30) comparing the flaming of the armour of Achilles, whose fury was so fatal to the Trojans, to the pernicious blaze of the Dog-flair rising at the end of summer, calls it an ill omen, “portending heat intense to wretched mortals;” or as the end of the passage is well expressed by Pope:—

“Thais the red air with fevers, plague, and death.”

When the father of the poets had expressed himself in this manner, it is no wonder that others should speak of the rage of the dog-flair, as some of them do of the fury of the hor, (Hor. I. iii. Od. 9, Virg. Aen. i. x. v. 270.) because a star of the first magnitude, called the Lion’s heart, rising in the time of the dog-days, was also thought to contribute towards the great heat of that season.

Some authors tell us, from Hippocrates and Pliny, that on the day the Caniculae or flars in the morning, the sea boils, wine turns sour, dogs begin to grow mad, the bile incares and irritates, and all animals grow languid; and that the diseases ordinarily occasioned in men by these burning fevers, dysenteries, and phrenises. Although Hippocrates had a sentence or aphorism that seems to forbid the use of purging medicines in the dog-days, we must not conclude from hence that great physician and philosopher to have thought the influence of the Dog-flair considerableness. It is probable, that he only meant to point out the hot time of the year, commonly marked by the rising of the Dog-flair. The Romans sacrificed a brown dog every year to Canicula at its rising, to appease its rage. They supposed Canicula to be the occasion of the sultry weather, usually felt in the dog-days.

As to the dog days attended by some with so much superfluous regard, it is pleasant to observe what variety of opinions have prevailed both among the ancients and moderns about the beginning and the end of them. This variety is, in some instances, owing to the ignorance of the writers, who did not know or consider that the Dog-flair varies in the time of its rising in any one year as the latitude varies, and that it rises later and later every year in all latitudes; so that in time this star, by the same rule, may chance to be charged with bringing frost and snow, when it rises in winter. In an ancient calendar preferred by Belis, the begin-
ning of the dog-days was placed on the 14th of July. In one prefixed to the common prayer, printed in the time of queen Elizabeth, they are Eiad to begin on the 6th of July, and to end on the 5th of September; and this was so fixed from that time till the reformation, when that book was revised, and the dog-days omitted. From that time to the correction of the British calendar, our almanacs had the beginning of the dog-days on the 15th of July, and the end on the 28th of August; but since that correction, the times of the beginning and end have been altered; and the former was placed at the 20th of July, and the latter at the 7th of September. The dog-days have been commonly reckoned for about 40 days, viz. 20 days before, and 20 days after the heliacal rising; and almanac-makers have usually set down the dog-days in their almanacs to the changing time of the star’s rising; and thus they had at length fallen considerably after the hottest season of the year; till of late, a very proper alteration has been introduced into the almanacs, and they have been made to commence with the 3d of July, and to terminate with the 15th of August. The propriety of this alteration will be evident, if we consider, that the ancients meant to express by the dog-days, the hottest time of the year, which is commonly during the month of July, about which month, the Dog-star rose heliacally in the time of the most ancient astronomers, whose observations have been transmitted to us: but the predications of the equinoxes has transferred this heliacal rising of a much later and cooker part of the year; and because Hefiod tells us that the hot time of the year ends on the 30th day after the summer solstice, which brings us to about August 10, or 11, the above-mentioned alteration seems to be not only necessary, but very proper.

Canicular year, denotes the Egyptian natural year, which was computed from one heliacal rising of Canicula to the next. This is also called annus canarius, and annus cynicus; by the Egyptians themselves the Sothic year, from Soth, a denomination given by them to Sirius. Some also call it the heliacal year.

The canicular year consisted ordinarily of 365 days, and every fourth year of 366 days, by which it was accommodated to the civil year. The reason of their choice of Canicula before the other stars, to compute their time by, was not only the superior brightness of that star, but because its heliacal rising was in Egypt a time of singular note, as falling on the greatest augmentation of the Nile, the reputed father of Egypt. Ephraim adds, that from the aspect of Canicula, its habit and colour, the Egyptians drew premonitions concerning the rise of the Nile; and, according to Florus, predicted the future state of the year. So that the first rising of this star was yearly observed with great attention. Bainbrige, Canicul. cap. 4. p. 26.

As the Egyptian year of 365 days was about six hours shorter than the true solar year, the heliacal rising of Sirius gradually advanced, at the rate of nearly one day in the interval of four years; so that in 1461 years, it completed a revolution, by rising on every successive day of the year, and returning to the point originally fixed for the beginning of the first month, called Thoth, or Soth. This period, equal to 1460 Julian years, was termed the great Egyptian year, or “Canicular cycle.” Cenformius (De Dei Nat. c. 18.) informs us, that in the confutation of Antoninus Pius, and Brutus Prefens, A.D. 138, the canicular year was renewed. If we reckon backwards 1460 Julian years, we come to the year B.C. 1322, when the sun was in 14° of Cancer, that is, 14 or 15 days after the summer solstice, which happened on July the 5th. Again, in the beginning of the Nabonassarean era, i. e. B.C. 747, the Thoth, or first day of the Egyptian year, had receded to the 26th of February, from July the 20th, when Sirius had been observed to rise heliacally in Egypt. This interval of 1444 days, multiplied by four, gives 576 years. The canicular year must, consequently, have begun 576 years earlier than the era of Nabonassar, viz. in the year B.C. 1722, or 1323, which nearly corresponds with the former date. In this matter, great accuracy cannot be expected, as the observation of the heliacal rising or setting of a star depends upon the state of the atmosphere, the difference of latitude, the situation of the observer, and other circumstances. Bailly (H. de l’Alphon. i. vi. c. 8.) fixes the date of the establishment of this period in the year B.C. 2752, on the authority of a passage said to have been extracted out of Manetho’s history, which intimates, that the shepherds invaded Egypt in the 700th year of the Sothic cycle; and in a vague tradition, that it commenced when Sirius rose heliacally at the summer solstice. But the grounds of this opinion are such as to entitle it to no great regard.

Caniculatus, in Conology, a species of Mytilus that inhabits New Zealand. The shell is smooth, and brown without, the interior surface tinged with various colours, and the socket of the hinge grooved. Martyn. &c.

Caniculum, or Caniculus, in the Byzantines Antiquities, a golden flannel, or ink veil, decorated with precious stones, wherein was kept the sacred enclymus, or red ink, wherein the emperors signed their decrees, letters, &c. The word is by some derived from canis or caniculus; alluding to the figure of a dog, which it represented; or rather because it was supported by the figures of dogs. Ermanni it is derived from canis, an inkhorn. The caniculum was under the care of a particular officer of state, hence called caniculus or caniculus, who was in great respect. Du Cange will have the caniculus to have been the name with the logotheta.

Canigou, in Geography, an eminence of the Pyrenees, about 1440 French toises.

Canina, a town of European Turkey, in Albania; situate in a district of the same name on the sea-coast, near the gulf of Venice. N. lat. 45° 28'. E. long. 15° 50'.

Canina, in Zoology, a species of Asciata that inhabits the Atlantic and northern seas. It is of an elongated shape, round and faceted, with a red pock. Mull. Zool. Dan. Obf. This is the fac-animals of Decumur and Menula marina of Reel. Bohadi in calls it Tibetan feculentum.

Canis, a species of Boa, defended by Linnæus as having 223 abdominal plates, and 77 caudal scales. This beautiful snake is an inhabitant of South America; where it frequently rolls itself round trees, from whence it can the more readily perceive and dart upon its prey. The usual length of this snake is about four feet, and its thickness is moderate in proportion. Its head is large, and bears such a striking resemblance to that of a dog that Linnæus gave it the specific name of canis, in allusion to that circumstance. The colour of the whole animal on the upper parts is of a fine saxon-green, with several short, undulating, transverse white bars down the back, the edges of which are of a deeper green than the ground-colour of the body: the abdomen is white.

Boddart speaks of a specimen of this boa in which the abdominal plates amounted to 205 instead of 223, at the same time that the sub-caudal scales were, exactly the same in number as Linnæus describes them. That examined by Gronovius differed in both particulars from the Linnæan specimen, having 205 abdominal plates and 79 sub-caudal scales.

Laurenti describes this species under the title of boa thalassa;
affinis: Seba by those of Serpent Bojoli Brasilienis, Tetranchnosth, Theola, and Lithisn Cohe verde.  

There is another kind of snake very closely allied to the above species, that inhabits the East Indies, and is supposed by Gmelin to be a variety only of the same snake. Laurenti calls it Boa aurrantias, and Seba Serpent Bojoli cyano ps, the ground colour is of a fine orange; the dorsal bands pale yellow, edged with red, and the abdomen pale yellow.  

CANINANA, the name of a species of serpent found in America, and classed one of the less poisonous kinds. It grows to about two feet long, and is green on the back, and yellow on the belly. It feeds on eggs and small birds; the natives cut off its head and tail, and cat the body as a delicate dish.  

CANINE, in a general sense something that relates to dogs.  

CANINE appateps, appetutis of fames canina. See .  

CANINE laughter, risus caninus, that wherein the lips are drawn far back, and the mouth much extended.  

CANINE ligament, is that whereby the prepuce of the human penis is fastened to the glans, otherwise called the frenum.  

CANINE madnica, rabies canina. See Hydrophobia.  

CANINE sulphur, a sort of native sulphur, discovered near Reggio, intermixed with earthy or rocky matters; thus called by reason that dogs are so fond of it, as to dig it out of the earth.  

CANINE teeth; canini dentes. See Teeth.  

Canis, in Geography, a town of Africa, in the kingdom of Angola; seated on the river Lualaca, S. lat. 5° 56'. E. long. 17° 38'.  

Canis, Angelo, in Biography, a learned grammarian of the sixteenth century, was born in a small city in Tuscany, called Anglera, or Angolari; and employed himself for several years in teaching the Oriental languages in Venice, Padua, Bologna, Rome, Spain, and France. At Paris he lived for his scholars, Andrew Duddith, an Hungarian, afterwards celebrated for his learning and eruditions. At length he entered into the service of William du Prat, bishop of Clermont; and he died in Avignon in 1557. His "Institutiones Linguae Arabicae inactae Thalmudice, in una cum Athiopicae atque Arabicae Collatione," Paris, 1554, 4to, are much esteemed. His "Gregor Grammar," or "Hellenismus," Paris, 1555, 4to, has been highly commended; and by Tuanqui Faber of Suebur, who prefers Caniinius before all other grammarians, it is denominated "The Treasury of Hellenism." "A Latin Translation of Simplicius's Commentary upon Epictetus's Manual," printed at Venice in 1546, fol, is attributed to this author. Gen. Dict.  

Canis, in Ancient Geography, a country of Rhasia, supposed to be that of the Cretans.  

Canis musculus, in Anatomy, the name for elevator labii superioris, which see.  

Canipolils, in Ancient Geography, the name of an ancient episcopal town of Thrace, mentioned in the acts of the council of Sardica, held in 347.  

Canis, or Cappina, a town of Arabia Felix, seated on the Persian gulf; W. of the mouth of the river Lar. Potemenius.  

Canis, in Zoology, a species of Scoros, that infests the inhabitants of the common dog. This kind is distinguished by having the tail pointed, the head flat, and furnished on each side with a wing-like membrane, and the sphenial vessels curved. Wern. Vorn. Intell. &c.  

Canis, a genus of the Mammalia Fera, distinguished by the following characters: fore teeth, upper six; lateral ones longer, dilated; intermediate ones lobate; lower 4x, lateral ones lobate: milks solitary and incurvated; grinders six, seven, or more than seven.  

This genus comprehends the common dog, familiaris, and its varieties, with the species Lupus, Mexicano, Thamus, Hevia, Canista, aurerus, Mesolomeo, Lycaeon, Vulpes, Alpex, Canis, Canis, Canis, Canis argentarius, virginarius, Pygargus, and Cerulo, which see respectively.  

Case Major, the Great Dog, in Astrology, a constellation of the southern hemisphere below Orion's feet, though forming a separate and well-defined form, whose stars Ptolemy makes 17; Tycho only counted 13: Hevelius's 54 in the Britannic Catalogue; they are 51.  

It is unnecessary to advert to the fables of the Greeks concerning the elevation of the dog to the heavens, as the origin of this constellation, as well as of its other name, Sirius, is more probably to be found in the superstition of the Egyptians; who, as we have already observed, (See Canis Major), carefully watched the rising of this star, and judging by it of the tailing of the Nile, called the star the continual and watch on the year. Hence, according to their mode of hieroglyphic writing, they represented it under the figure of a dog; they also called this star Isis, the same given to their great goddess, and Thoth, the name of the god Mercury, whom for his faith, in the invention of letters, arts, and sciences, they sometimes painted in the form of a dog, or of a man with a dog's head, and worshipped him under the name of "Amonis," which fce. They called the same star "Solis," or "Sithis," which, in the Egyptian language, according to Kircher, signifies holly. Sicor and Sirius are also other names for the Nile, from whence Voilhuis derives Sirius, the Greek name of this star, which was imagined to have such dominion over that river; and also Obiris, the name of one of their principal deities.  

Canis Minor, the Little Dog, a constellation of the northern hemisphere; called also by the Greeks, Procyon, and by the Latins Antennis and Canida. This, as well as the former, is one of the old 48 constellations. According to the fables of the Greeks, it is one of Orion's hounds; but the Egyptians were probably the inventors of this constellation, as well as Canis Major, and they might have given it this figure to express a little dog, or watchful creature, preceding and conducting, as it were, the larger, or rising before it; hence the Latins have denominated it Antennis, which fce. The stars in the constellation Canis Minor are in Ptolemy's Catalogue 2; in Tycho's 5; in Hevelius's 13. In the British Catalogue they are 14, of which the principal is Procyon.  

Canis flumens, or Cyynos flumens, the river of the dog, in Ancient Geography, a river of Arabia Felix, which discharged itself into the Persian gulf; probably the fame with the Lar of Ptolemy.  

Canis Carcarius, in Ichthyology. See Squalus Carcarius.  

Canis Galeus. See Squalus Galeus.  

Canis Vulcanus, in Zoology, a name indiscriminately given by old writers to the vampire and terrane bat, Vespertilio Speratum and Vampyrus. Canis vulcanus was also called vespertilio cauda nullls, both the above being of the tailless kind of bats. Canis vulcanus terranatus orientalis of Seba is the Great Bat. Canis vulcanus maxima aurita in Nova Hispania of the fame writer is the Vampire of Buffon.  

Canis BAY, in Geography, a small fishing town of Scotland, in the county of Caithness, and most northern part of Scotland; 11 miles N. of Wick.  

Canischa, a town of Hungary, taken by the Turks in 1600 and retained by them till the year 1660, when it
was captured by the imperial troops after a blockade of 2 years, and ceded to the emperor by the peace of Carlowitz, 96 miles S. of Vienna.

**CANISIUS, Henry.** in _Biography_, a native of Nim­

guen, who became professor of canon law at Ingolstadt, and

who was so little distinguished for his piety and modestly

for his erudition. He died in 1515. Among his works in

law and antiquities, which are highly esteemed, we may

mention his “Summa Juris Canonici”; “Commentarium

in Regulæ Juris”; “Prefationes academicae de Decinis

containing a collection of curious pieces relating to the

history and chronology of the middle ages, printed by J.

Bañinger, in 7 volumes, 4 vols. fol. Amsterd. 1753, with

learned prefaces and remarks by the editor; and noted, with

**CANISOLA, in Geography,** a town of the island of

Clerfo, in the Adriatic; 32 miles N. of Clerfo.

**CANISTER, Great,** a small island in the bay of Bengal,

near the coast of Siam. N. lat. 12° 58’. E. long. 97°

40’.—Little Canister, another small island in the same bay

and near the same coast; 2 leagues S. from the former.—

**Wolf Canister,** a small island in the same bay, near the same

coast. N. lat. 12° 37’. E. long. 97° 16’.

**CANSY, a town of France,** in the department of the

Channel, and chief place of a canton, in the district of St.

Lo, 4 miles S.W. of St. Lo. The place contains 836,

and the canton 9560 inhabitants; the territory includes 90

kilometres and 12 communes.

**CANITZ, Baron of,** in _Biography_, a German poet and

statesman, was of an ancient and illustrious family in Bran­
denburg, and born at Berlin in 1654. After having com­
pleted his early studies, he travelled to France, Italy, Hol­
lund, and England; and upon his return, he was charged

with important negotiations by Frederic II. He was also

employed by Frederic III. Although he was more exten­

sively known as a politician than a poet, his poems have

been much admired by his countrymen, and they were pub­

lished for the tenth time in 1750, 8vo. Most of them were

of the moral elegiac kind, expressive either of the tenderer

sentiments of conjugal affection, or of such reflections as

naturally occurred to a contemplative and virtuous mind on

the various events of life. Horace is said to have been his

model, and his compositions are written in a pure and deli­

cite style. He was eminently learned and ingenious, virtu­

ous and benevolent. Having attained the office of privy

councillor of state, he employed the influence acquired by

his distinguished character and high station in giving encou­
ragement to literature and the fine arts. The disease which

terminated his life was tedious and lingering, and he observed

the flow but certain approaches of his last enemy with the

calmness and fortitude that became the churlish philos­

opher. When his physicians had pronounced his case to be hopeless,

he ordered a cake to be brought to him, and dictated some poetic meditations on this object in connection with his

own circumstances, which are justly deemed the most beau­
tiful of his productions. He retained his cheerfulness to the

last; and just before his death, desired to be led to the

window, which he opened when, having gazed some

minutes at the rising sun, he exclaimed, “O! if the view

of a part of the creation can be thus beautiful and reviving,

how infinitely delightful must be that of the Creator!” He

spoke, and died, in 1699, at the age of 45. Bildnisse, &c.

or Portraits of celebrated German literati, &c. Berne, 1793.

**CANKER, in Gardening,** a vegetable disease common

in fruit and other trees, produced by a form of ulceration in

the bark arising from bruises, the old or dead wood remain­
ing on the trees, and various other causes. It is observed

by the author of the _Philosophy of Gardening_, that this

disease may be termed _gangrenous vegetable_, and that it is

a phagedenic ulcer of the bark, which is very destructive to

apple-trees and pear-trees, as it spreads round the trunk or

branches, and destroys them. Mr. Knight has observed: “It

to be most frequent and fatal to those trees the fruit of

which has been long in fashion, having been perpetually

propagated for a century or two by grafting; which he

believes to be the continuation of the old tree, though now

nourished by a new flock; and that the canker is thus a disease

of old age like the mortification in the limbs of elderly

people, and arises from the irritability of a part of the system.”

But it seems more probable in the opinion of the first

writer, that “it is an hereditary disease, as the buds of

trees being a lateral progeny, and more exactly resembling

their parents, must be more liable to the diseases gradually

acquired, or increased, by the influence of soil or climate,

and have not the probability of improvement which attends

the progeny of sexual generation. It is nevertheless fre­

quently produced on trees by external violence, as a stroke

with a spade given by a careless labourer who is digging

near them; but this probably may more easily affect the

old grafts above-mentioned. When a definition of the

bark is thus produced by external violence, it may possibly,

he supposes, be cured by the application of a piece of

living bark from a leaf valuable tree bound upon it.”

It is likewise recommended, that “the edges of these

gangreensulcers of the bark should be nicely pared off

with a knife, so as to admit the air and to prevent the

depredations of insects, and the lodgment of mould, which

might promote the purrefaction of the elegant juices, and spread the gangrene. This should be so managed as only to

cut away the dead lips of the wound, but not so as to

injure the living bark. Some thick white paint may then be

smear upon the naked albumen, or sap wood, on a dry day,

which may prevent insects from infiltrating their eggs into it, and producing maggots, which erode and destroy the

wood, and may also prevent the dews and rain from rotting it. The paint should, nevertheless, be so spread as not to

touch the edges of the wound, as it might injure their growth by its poisonous quality. A quarter of an ounce of sublimine of mercury,

“hydrargyrum nitidum” rubbed with about a pound of white

lead-paint renders it more noxious to insects.”

Mr. Forsyth thinks it a mistake that it always depends

upon the nature of the ground, as four clays or flinty

gravels. He contends that it invariably proceeds from the

branches to the roots of the trees, and never in the contrary
direction.

In the case of this disease, when extensive, he advices

the careful paring off with a draw-knife or other convenient

instrument of “all the diseased parts of the bark.” And that

as the inner white bark is frequently infected, this must also

be cut away, till no appearance of infection remains. The

infection in the inner bark appears like dots made with a

pen, all of which must be cut clean out; for if any part of

the canker be left, it will infect the new wood and bark.

Wherever you see gum oozing out, you may rest assured

that the canker is not quite eradicated; which, if suffered to

remain, will spread till the whole tree becomes a mass of

gum and canker, and will be killed in a very short time.

When the trunk is become hollow, cut the loofe rotten part

clean out, till you come to the sound wood, taking care to

round the edges of the hollow part; then apply the com­
position in a liquid state, laying it on with a painter’s

brush wherever the cankered bark has been pared off or

the
the dead wood cut out, till these places are entirely covered with it; when that is done, flake some of the powder of wood ashes and burnt bones over the composition, and pat it gently down with your hand." See Composition.

He contends, "that if the foregoing directions be carefully followed, the canker will be completely eradicated, and the hollow trunk in time be filled up with sound wood. When the wood is much decayed, he thinks it will be absolutely necessary to open the ground, examine the roots, and cut off all the rotten parts. When you have cut off all the rotten and decayed parts below ground, and scraped the hollow clean, make up the root of the composition, mixed with four parts, like what is used for grafting; then fill the hollow part with it to within two inches of the surface of the ground, treading it in with your foot, or prefilling it in with the hand as close as you possibly can, to prevent the wet from penetrating to the roots, and leave the surface of the composition sloping from the tree towards the outside of the border to throw the wet off, which will prevent the fresh part of the root from rotting; then cover the root over with mould level with the rest of the border;" and, "when you have examined all the old wounds, where large limbs have been cut off, you should next examine the old bark; and if you should find the outer of it wrinkled and cracked, pare it off, as it is always, when in that state, very much hurt by the canker. This should be done with the draw-knife, or other sharp instrument; then apply the composition as before directed, which will bring on a fine smooth bark under it. In the succeeding winter or spring, you will see all the plater with the old part of the bark that was left in the hollow parts of the tree, or where old branches had been amputated, peeling off and showing the smooth bark underneath. You should then scrape off, with a wooden or bone knife, what old bark remains in the hollows where the draw-knife could not reach, without cutting too much away. When that is done, mix up some fresh cow-dung with soap-uds and urine, making it very thin, and give the tree a coat of this mixture all over where the bark has been scraped off; the cow-dung will adhere to it, and beat the parts where you were obliged to scrape to the inner bark. This will wash, he says, remain till the fresh bark comes on; then it will be discharged of itself, during the summer, or the next spring, leaving a new fresh bark where the old and canker was taken off. Next spring, if any of the old bark remains, you may repeat the same operation, which will cause all the remaining old bark to slough off like a scab from a wound of a human body. By these means, he contends, that you will keep your trees in a fine flourishing healthy state, and, in general, prevent them from becoming bark-bound. If any of them, notwithstanding, should be bark-bound, you must fear them, by taking a sharp knife, and running the point of it straight down the middle of the limb from top to bottom, taking care to run your knife through the outer bark only; then, with a brush, or your finger, rub in some of the composition, to prevent the incision from bringing on the canker." [1]

This operation will cause the tree to expand the bark and become very flourishing.

And it is advised to remember to cut off all the ends of the small florets where the canker had injured them last year.

Cut off also the old fruit stalks, and all the small dead flubs, which, if left, will never fail to bring on the canker.

Theough, or canker bark, or that side of trees which is next the wall, should be scraped or pared off with a tool made in the form of a fiddle. "It is much," he says, "to be regretted, that fruit-trees in general, throughout this kingdom, are in a mutilated, unfruitful state. After gentlemen have purchased the young trees from nurseries, and planted them in their orchards and gardens, they think, says he, that every thing necessary is done; when, in fact, the greater part of the work is yet to come. In packing a carriage, the items and branches are very frequently bruised; in that case, the injured parts of the bark and wood must be carefully cut out, and the composition immediately applied; this may be done when you lead the trees, which operation should be performed in April, May, or even June, when the buds begin to flower, but by no means cut off any of the shoots, except those that have broken or braided very much. When this is neglected, the canker will follow to the great injury, if not death, of the trees.

"How common, continues he, is it to see, in all parts of the country, great numbers of trees so affected with this disease, as not to produce fruit enough in twelve or fourteen years to pay half the expense attending them; whereas, if they were to be managed according to the foregoing directions, they would more than pay all the expense in three years. It is common, when young trees do not thrive, either to blame the nursery-men for sending bad or diseased trees, or to attribute their withering state to the nature of the soil; whereas the fact is, that this frequently arises from the inattention or mismanagement of the person who plants and superintends them.

"If the injured and diseased parts be not cut out at an early period, the trees will not thrive, but will become cankered and flouted, and cannot be recovered afterwards without a great deal of labour and trouble; whereas, if the directions given for heading trees the first year, and cutting out the diseased parts, be attended to, the trees will flourish and bear large crops of fine and well-flavoured fruit." [2]

Canker, in Surgery, is a popular name for those small eroding ulcers which take place spontaneously in the cheeks, lips, and gums. This troublesome species of sore is probably connected for the most part with a state of debility in the patient; as it is cured by tonic remedies given internally, accompanied with accentual diet and country air. It is also sometimes useful to touch the ulcer with diluted acids, or a strong solution of alum in water.

Canker, in Veterinary Science, a dreadful disease incident to the feet of horses, and not of unfrequent occurrence, being very troublesome to cure, and of unpleasing appearance, exciting the fame fenations in the mind of horror and dislike, as do the loathsome animals whose names have been applied to it; hence the term cancer or canker, the crab, and the French term crapaud or toad, and in more ancient times lupus or the wolf.

We venture, however, to assert, that there is nothing specifically poisonous generated in the fores of this description, as in the human cancer, though it has been so imagined by many; from having ourselves been frequently inoculated with the secretions from these sores, (as have, no doubt, thousands of others,) without, perhaps, an instance of any contagion arising from it; nor in the cure is there any specific necessity, as in the cancerous, rabid, or venereal poisonous ulcers.

It may be defined, perhaps, as a simple ulceration of the corniferous, or horn-bearing parts of the foot, attended with more or less weaknens of the parts in forming horn, and generally of irritation from the horny edges surrounding the wound, nor in the indications of cure is there any specific necessity, as we have before observed; but the greatest diligence and attention are requisite in destroying those causes of irritation, and in procuring and encouraging the natural
n natural growth of the horn over the exposed parts, which, in old cases, is found difficult enough.

In describing the situation and appearance of this disorder, we may observe, that all parts of the foot that are covered with horn may become the seat of this complaint, and its appearance will vary indefinitely, depending upon the greater or less degrees of weakness of the fore, or irritation from the surrounding horn. The most usual appearance, however, is a light, purfy, fungus, easily bleeding when touched, and rising higher than the edges of the surrounding horn, giving out a thin watery discharge, with a disposition in the ulcer to fcarel and run under the contiguous horn, and if not timely checked, it will extend itself over the whole foot, when the hoof falling off the horse is necessarily lost. On the other hand, where the proper means of correcting this ulceration are used, the contiguous horn is removed, the fungus is reduced, the parts become dry, horn again extends itself over the diffused surface, and the foot becomes as perfect as it was before.

The time often required to correct the morbid disposition in the part itself, and afterwards in procuring the natural growth of the horn, is so truly tedious, as in very bad cases, to make the expenses of keep and care more than over-balance the value of the horse, and it would be to the disadvantage of his proprietor to attempt it; in other cases it is so easily and readily disposed of as to be well worth the time and expense of curing.

The narrative of a case or two will be a more instructive way of describing the treatment of this complaint than any exposition in general terms; and for this purpose we shall select a successful and an unsuccessful case, such as they occurred to us; and here let me remark, in doing that justice, we wish to hold an example of to every one in these matters, that among the shoeing smiths there are many who take great pride in the cure of this disorder, and whose practice, pretty much confined to this object, has rendered very expert; and as much depends on the adroit use of the drawing-knife in removing the horn from the ulcerated parts, they would have vastly the advantage over a young practitio-ner in this respect, though in other respects their treatment should be the same, though these have sometimes failed in bad cases, or the long protracted cure has rendered it of no real advantage to the proprietors. The disease, we may observe, is almost always artificially induced, and may be prevented, which is of vastly more advantage to know than the mode of its cure.

The foot of the horse may be considered as partaking somewhat of the nature of a gland, which is giving out and secreting horn, and whose ulceration will be attended with other phenomena than occur in the ulceration of flesh, or parts of the animal structure, and this peculiarity will render a different treatment necessary.

The following is a statement of the treatment of a successful case of this disorder, with some observations as the case proceeds.

A black draft horse that had been under the care of a shoeing-smith about nine or ten months to be cured, without success, was put under our care in a truly deplorable condition. The sole and frog were almost one extended surface of disease, secreting a white curdy fluid, which was poured out in great abundance about the sides of the frog; this fluid was probably formed of the union of lymph, and the vehicle throwing out imperfect horn which became partially diffused in it; the same appears to be secreted in running streams, and if allowed to remain long on the part, becomes highly fetid.

The edges of the horn encircling the fore were found to be detached, undermined, and black within; these were every where removed by thinning away the horn with a sharp drawing-knife, and when pared to the bone, so that the drawing-knife would no longer lay hold of it, a lancet blade made rather stronger than those usually are for bleeding, and stuck in a handle, was used for thinning away the remaining part, and to diffuse small bits of horn in situations where the drawing-knife would not conveniently reach. This particular process was pursued on every side of the foot which was found to extend to the wall of the foot, and took up a considerable time, the effusion of the heel bone being cautiously avoided, as this would flow over and obscure the parts to be cut. The foot was then smeared over with egyptian, or the cupreous acetate, and honey, boiled together, though we found it equally, or superiorly efficacious for this purpose when made of blue vitriol and treacle, at a much less expense, which may be acceptable information to those who may have to use a large quantity of it: over this dressing, pledges of tow dipped in tar and plentifully soaked with it are laid, till they cover it to a considerable depth. A hollow flute having been previously tacked on by a few nails, an iron plate is fastened under it, and this is fastened in by iron splints between it and the flute, and driven moderately tight with a hammer: similar dressings are applied to the heels and sides of the foot if requisite, and then bound on tight by tar cords. These dressings require to be removed every 48 hours, or when the disease is very virulent, every day: if on removing the dressings they appear tolerably free from mojiture, it is a favourable sign. If the foot reeks, and the dressings appear drenched with perspiration, little or no permanent horn will be found to have formed; if, on the contrary, the parts are doing well, the ulcer will appear almost dry, with a brown scale of horn formed upon its surface, which will generally fell off of itself, if not removed, and be cut removed, and this for several succesive times till the parts acquire the requisite strength for supporting the horn that is formed, which should however be kept as thin as possible for a considerable time, that it may not irritate and exfoliate again. The surface that was undermined, and from whence the horn had been recently removed, will be found the next day to have twisted very much into a fort of more healthy fungus, and on the surface of which, horn will begin to form; this being removed, another layer beneath this takes place, and so on till it reaches the natural foot. By this curious process nature seems to acquire room, and avoids that comprefion from which the immediate formation of horn on the ulcer would occasion. The parts of the face that were subject to irritation may be known by the thin discharge, and the yellow sooty bleeding fungus; and the points of horn irritatig them must be carefully removed to a considerable distance.

The first horn that forms, especially of the sole and frog, readily peels off, and exhibits underneath small white fibres, by which it is adherent; the second cast is more firmly adhered; and in recent cases where the powers of the foot are not weakened, will a here and become perfect horn; but in old cases, it is requisite often to remove it, or thin it down with the knife, and to keep it soft and pliant with tar dressings to prevent irritation and exfoliation.

Some, mixed of egyptian, apply dry powdered verdigris to the sole; others, apply gum of mastic; and some touch the surface with lunar caulis; others, again, use dilute nitrous acid, or marine acid; and some are fond of red lead boiled down, and mixed with the egyptian, as making it more drying; these irritating methods, though of good effect at first, may be carried too far, and do mischief, and weaken the parts too much; it is of more consequence to
to carefully remove all external irritation from the surrounding horn, and the employing of uniform, regular, and strong, but not excructive preservative, which, if adjunually followed with the milder application of tar, are equal to the cure of mallscabs, except such as from long dis ease have become too destroyed and weak, as not to be capable of forming, or afterwards holding horn upon them, or, as is sometimes the case, that the coffin-bone has been injured, and an exfoliating portion of it keeps up the fore, in spite of every endeavour to heal it, till this is removed, as we have met with in two instances. This injury of the coffin-bone may arise from a nail driven by accident out of its course into the side of the foot, and which, entering the bone, splinters and destroys a portion of it; or from the remedies used being of too corrosive nature, or too violent pressure, that shall have destroyed the surface of it, which dying, acts as an extraneous body in preventing the parts from healing; or the horse, from flamping violently on the unprotected bone, from pain or otherwise, shall fracture its thin edges, and thus keeping up an irritation which shall defy every attempt of cure till these are removed, each of which we have seen cafes of in the course of our practice; we may just remark, that where there is an exfoliating portion, it is best to remove it as early as possible, without waiting the tedious process of natural exfoliation: the wound thus formed being then of the nature of a fresh wound, will more readily heal, a practice, we believe, first recommended by that truly great character, Mr. John Hunter.

The above remedies also may be occasionally changed for each other with advantage, as the long continued application of one thing occasions it to lose its effect; and one agrees best with one subject, another with another, for which there can be no rule laid down.

By pursing the above means steadily and uniformly for about nine months, the above tedious and expensive cafe was cured, and every part of the foot covered with horn: the horse was then turned to grass to encourage the more rapid growth of the horn. On his return from grass he was put to work, but suddenly died in a few months after of a liver complaint, which afforded an opportunity we had much sought for of examining the condition of the coffin-bone after a long existence of this complaint upon it, and also whether nature would restore the lost foliated substance of the hoof; and on examination, the foliated horn had been in a great measure repaired, and was growing down quite perfect; having covered two-thirds of the inside of the hoof where the canceler had existed, and where it terminated, there was seen a smooth and cartilaginous surface on the inside of the hoof, and a similar one attached to the foot, so that there was laid in contact with each other without lamina.

The fole which is left organized in its structure than the wall of the hoof, had no perceptible difference from the original fole. If the coronary ring and origin of the lamina had been destroyed, we should in that case doubt the possibility of their reproduction; for in this case, the coronary ring had been cautiously preserved. The coffin-bone had suffered greatly by the disease being considerably diminished on the fole on which the fore had existed, and was become very porous, rough, and uneven; on its upper part near the coronary ring, a rough elevation of bone had been thrown out, of the size of a pea, such as is deposited in splinters and spavins, being whiter and of not so dense a texture as the natural bone. The channel of the artery had also a thin white fissure deposit running to the inside of the heels of the coffin bone, even where no fore had existed.

In the course of the treatment of this disease in different subjects, we have had recourse to many different measures for keeping on the dressings to the foot; among others for this purpose we have made a leather boot, lined on its sides, with a wooden sole, defended at bottom by a thin ring of iron; this boot afforded the requisite pressure, but kept the foot, as we found by experience, too hot and moist, so that the horn was no sooner formed than it again exfoliated.

Flannel bandages were found to be subject to the same inconvenience. Shoes made with small hooks to the fides, palling the hands over the coronet, could not be applied for any length of time, from the skin of the coronet ulcerating from the pressure: we found on the whole nothing fails but the application of pledgets of tow dipped in tar and laid round the foot, (when the fides were affected) with tar. An iron clip turned up from the shoe and palling parallel to the hoof was also found convenient when the fore was not extensive.

The last point is generally by far the most difficult to heal on the side of the foot; it will be found in general to be about opposite the circular artery of the coffin-bone, or its foramen: in the sole the most difficult point is the heel, and the junction of the sides of the frog with the sole: to get at these most conveniently, tow rolled up pretty tight between the hands, then immersed in the dressing, and thrust into the cavity, will be found a convenient way of getting at it; another roll being laid over this, and another till we arrive at the level of the sole, when a general pledget is applied over the whole.

At other times we thought it more convenient and advantageous, in sole cafes, to pass the iron plate under the shoe, and then ram it full by pulling in the dressings through the openings of the heels.

If there be much moisture in the dressings, the cafe rarely goes on well. The plentiful ufe of tar seems to have the power of suppressing, in some manner, this transudation, and cannot be too much attended to, as it serves also to keep the wet from it, if the horse be used on the road.

A dry loose place is better in the cure of this complaint for the hoifes, than standing constantly in one position: a stall, where especially if it be in the hind legs, the blood accumulates with too much force from the declivity of the stall, their position being much lower than the rest of the body.

Exercife, if the lameness is not so great as to forbid it, is much to be recommended, and the occasional ufe of phyfic, especially where the hoifes stand still; a rowel also may be had recourse to with advantage, especially if there be any disposition to greafe.

The frog, we have thought, appeared to be weaker in its powers of forming horn than the sole, and this than the wall; and the first horn is more apt to be undermined and exfoliate from this part, though it may appear fair to the eye: cells containing a white semifluid matter alfo arise under it and that of the fole, and are often the attendant of these exfoliations.

The cooler the foot can be kept, the more progress is made in the cure; therefore, much dressing or much covering is not so well, and water, though highly prejudicial if applied for a constancy, yet may be used to wash the foot with, and afterwards being well wiped dry, the dressings are applied, as we have thought, with good effect. In some cafes, where the fungus rises higher than the horn, and it may be an object to take it off, it will be better to attack the fungus by carefully paring it with a knife till blood appears, and then use the dejectives and preservative; at any rate by
this means, lefs of the horn need be removed, as we get at it closer to the fungus than in the other cafe; and it is always the consequence where it can be done, to save all the horn possible, on account of its flow growth.

In deflecting away the offending points of horn, we have found it useful to observe the rule of beginning in the most depending parts of the foot, that if the blood fluts, it shall not obscure the parts you are next to come to, as it would do if you commenced differently. If inadvertently a vifcl is opened that is troublesome, it is most readily stopped by the point of the cautery, without affecting the other part.

A kind of canker that is truly difficult of cure is the following.—A large draft horse that had occasionally been drest by the lumps for more than a twelvemonth, had a canker of the near hind foot, with the following appearances: the frog was large and fleshy, with a smooth red surface that would form a hard ball of horn, loosely attached and quickly exfoliating; the fole every where bare of horn, having threads or fibres of considerable length, and hardened only at their extremity, their roots being imputed with a white milky secretion. After endeavouring intellectually to harden thaficle into horn, we cut them off with a pair of lafifs, and found that we made more progress upon the disorder: the parts, however, were fo weak, that they appeared unable to retain the horn they had formed, and after several exfoliations of this fort, finding that little ground had been made from the vicious difpofition of the animal, probably made fo by the long pain he had been expofed to, and the time it confafed as well as the aifilation it required, we determined to abandon the cafe. Two or three of fuch cafes have we feen, out of about twenty, some of which have been fealy cured in a few weeks.

Having given some account of the difeafe itself, it will now be right to consider what is its caufe, and if it can be prevented, for we fully concur in the words of Vegetius: (lib. 2. c. 58.) "prehensius concilium eft pedum tueri sanitatem quam passionem curare," preventive means are certainly the most wise, and after fuch a description of this disorder, there is no one, we should apprehend, that would not be anxious to avert it. We confider the moft prevailing caufe of this complaint to be the running thurifh, which firt only affects the cleft of the frog, but becoming aggravatd, it gradually undermines the horn of the frog and spreads to its fides, and from thence to the fole, and fo on to the wall and whole foot.

We remember one cafe where it appeared brought on by the graece, the difcharge from which running down upon the foot, at length destroyed the horn, and brought on canker. Shaving the frog too clofe with the buttcrwifs would occasion this part to dry and crack, and wet getting into the cracks, and lodging there, would rot the frog and induce canker. Any wound of the frog or fole not healing kindly at firft by the blood, fuch as a kennel nail wound, or any other defcription of wound, becoming irritated by the surrounding horn, would form a canker; however, these are rare cafes compared with the one we have mentioned, viz. the running thurifh, the common fource of the michief, which is certainly a confeguence of the frog being fqueezed together by the contraction of the heels, and this again arises from the nailing of an iron thoe permanently to the foot, for an account of which, fee articles, Foot of the horses, and Farriery.

Such is the "brief chronicle" of our present experience in this difeafe, which, though avowedly imperfect, will serve as a more fure baif for receiving the facts of future labourers than the hitherto almost ufeful accounts of this terrible dif-order.

Canker is also a difeafe in dogs, which feizes their ears.

Canker, in hawks, breeds in the throat and tongue, occa-fioned by foul feeding. It is cured by washing the mouth with honey and white wine boiled together, then fhewing it with cheriw-powder.

Canker, black, in Entomology and Husbandry, a species of caterpillar, which has been occasionally deftructive, in a very great degree, to the crops of turnips in Norfolk. The farmers in that county, obferving great numbers of yellow flies among the turnips, previously to the appearance of these caterpillars, have been led to conclude, that the canker was the caterpillar flate of the yellow fly; and from their frequent appearance on the eastern face-coal it has been inferred, that they are not natives of this country, but that they come hither across the ocean. Their deftructive ravages, however, have not been confined within a few miles of the eastern coal; but they have extended more or lefs into the centre of the county. From the description which Mr. Marshall has given of them, it appears that they have four wings; that their antenna are clubbed, and about one-third the length of the body, each being composed of nine joints; and that near the point of the tail of the female there is a black speck outwardly fringed with hair, but which, opening longitudinally, appears to be the end of a cafe containing a ring, about one-twentieth of an inch in length, which, on agitation, separates into three one-edged iftruments, with a spiral line or wrinkle winding from the points to the haie, making ten or twelve revolutions, and giving them the appear-ance of being ferrated. By means of these iftruments, the female is supposed to deposite her eggs in the edge of the turnip leaf, or sometimes in the nerves or ribs on its under surface. The caterpillar has twenty feet (fix of its legs being considerably long, and the other fourteen very short); and in its first age is of a jet black, deftitute of hair, but covered with innumerable wrinkles. Having attained its full size, it fixes its hinder parts firmly to the leaf of a turnip, or other substance, and breaking its outer coat or flough near the head, crawls out, leaving the skin fixed to the leaf, &c. The under coat, which now appears, is of a blufh or lead colour. The caterpillar in this flate continues to feed on the turnips for fome days longer; it then altogether defifts from eating, and becomes covered with a dewy moisture which feems to exude from it in great abundance, and which, being of a gluttonous nature, appears to form its chryafis cofit. Mr. Marshall concludes from the genuine characters of the fly, that it is tenthrade of Hill. See Tenthrado and Turnip. Phil. Tranf. vol. 73. p. 227, &c.

CANA, in Betony, (Heb. צנה) Kane, a reed, whence our English word Cane is indi{pensably derived. "Kana" is interpreted in the Greek Lexicon λάνης, a mat, or according to Hefychius, the plant of which mats are made. It is larger than arundo and lefs than calamus,) Linn. Gen. r. Schreb. 1. Wild. 1. Gert. 41. Juff. 63. Vent. 2. 203. (Cannacus, Tourn. 102.) Indian flowering reed, or Indian Scott. Balifher, Fr. Cais and order, monandria monagynia. Nat. Ord. fcitihmone, Linn. canae, Juff. drymyrrhæa, Vent. Gen. Ch. Col. Perianth three-leaved, permanent; leaves lanceolate, erect. Cor. Monopetalous, five-cleft (eight-cleft; Salib.) three outer segments erect, larger than the calyx; three inner segments larger than the outer ones, two erect, one revolute, forming a kind of lip. Stem. Filament referring a petal, two-cleft; upper segment erect, bearing the anther; lower one revolute; anther linear, adhering to the edge of the upper segment of the filament. Phj. Germ. inferior,
Stems di(h« $ may place bling i dry Salisbury •

Leaves flower hot-bed Katu-ala C. p. Gceit. 1 fileui latif. phyllus year, late, come from not fibre long and shorter plant, the inner one longer and narrower, often spreading and narrowed; calyx-leaves unequal, entire, obtuse; tube of the corolla much longer than the calyx, a little recurved; outer border a little longer than the tube, abruptly reflexed, deeply three-cleft; segments unequal, linear-lanceolate, entire, obtuse; inner border longer than the outer one, deeply three-cleft, segments thinner, blunted, much curved at the edges, the outer ones narrow, and nearly closed, the inner ones (segments of the corolla, Linn. Sec.) broad, involute, egg-shaped, emarginated: anther white, adhering to the edge of the inner side of the innominate segment, upright, linear, very remotely pointed, two-celled, opening in front; germ pale-green, outer, minutely tubercled: hyde very pale yellow, linien-egg-shaped, smooth on both sides, flat; Filicis white, slightly pubescent. Pericarp and seeds similar to those of the other species. Salisbury. A native of South Carolina, where it was found by Bartram. It is often mistaken for C. glauca.

PROPAGATION AND CULTURE. All the species are perennial, and with proper management will continue many years; but as young plants always flower better than old roots, it is best to raise them annually from seeds which should be sown in a hot-bed in the spring. When the plants are fit to remove, they should be transplanted into separate small pots, filled with rich kitchen garden earth, and plunged into a moderate hot-bed of tanagers-bark. In warm weather they should be supplied with fresh air every day and frequently watered. As they soon grow large, they should be shifted into larger pots, and part of them plunged into the same hot-bed; the rest may be placed abroad in June in a warm situation with other exotic plants. Those which are placed in the hot-bed will be strong enough to flower well in the flower in the following winter; but those in the open air will not flower before the following summer. In the beginning of October, they must be removed into the floor. The variety $ of C. indica, which is a native of Carolina and some of the other northern states of America, being harder, should be more early enured to the open air, where it may remain till the frosts begin. It should be then removed to the green house, and during the winter should have but little water. In the beginning of May it may be turned out of the pot, and planted in a dry soil on a warm south border, where it will produce flowers annually. Miller.

Canna, in Commerce. See Cane.

Canna, in Ancient Geography, a small town of Asia Minor, in the Eolid: Mel.—Also, a town of Cappadocia, in Lydia. Potency,—Also, a place of Asia, between Cyra and Edeia. Anton. Itin.

CANNABA, a place of Asia, in Syria, upon the route from Nicopolis to Ecdesia. Anton. Itin.

CANNABICH, in Biography, a spirited and masterly composer of symphonies of the Mannheim school, contemporary with Stamitz and Holzblat, about the middle of the last century. He was the most eminent solo player on the violin of his time: and his ballet of the descent of Hercules into the infernal regions, is a most beautiful production.
Cannabis, (corolla, Linn.) Superior, coloured; divided into several, often lis, petal-shaped, generally unequal and irregular segments; with three others exterior and smaller, putting on the appearance of an external calyx, (the proper calyx, Linn.) Stem one; filament inserted into the base of the style, often flat and petal-shaped; anther adhering, simple, or rarely double. Germ inferior; style simple, often thread-shaped; stigma simple or divided. Capsule inferior, three-celled, most frequently three-valved, and many-seeded. Root often tuberos, creeping. Stem herbaceous, covered with the feathering petales. Leaves alternate, feathery, younger ones convolute, fomemany-nerved, others spreading out parallel nerves from each side of a simple midrib. Flowers in fputhes, often growing on a cauline, or radical fpath. The genera figned to this order by Jullieu are catibium, canna, glloba, myrolma, anomum, colus, alpinia, maranta, thalia, curcuma, and kempferia.

Cannabina, in Botany, (foio tripartitum diviio. C. Bbuh. pis. 321.) See Bibles Tripartita. Cannabina, (foliob non diviio, ibid.) See B. Cerrna. Cannabina, (indica. Magn. Hort. 40. tab. 40.) See Versinia Alata. Cannabina, Tourn. Cor. 52. tab. 488. See Datisca Cannabina. Cannabis, (corona, Herod. Dioscor.) It is not mentioned by Theophrastus. Linn. gen. 1115. Schreb. 1532. Cal. perianth five-claret; segment oblong, acuminate obtuse, concave. Cor. none. Stam. filaments five, capillary, very short; anthers oblong, four-cornered. Female. Cal. perianth one-leaved, oblong, acuminate; opening longitudinally on one side, permanent. Cor. none. Pyl. germin very small; flyle two, very long; stigma acute. Pericarp the permanent calyx closely covering the seed. Sood, nut globular, depressed, two-valved. Eff. Ch. Male. Calyx five-claret; corolla none. Female. Calyx one-leaved, entire, opening on one side; corolla none; flyles two; nut two-valved, within the closed calyx. Sp. i. C. fatua. Linn. Sp. Pl. Mil. fig. tab. 77. Bauh. Hift. i. fig. 448. Ger. Eemac. 708. fig. 1. 2. Lam. Ill. Pl. 814. Hemp. Chianvre. Fr. “Leaves opposite.” Root annual. Stem from fix to eight feet high or more, upright, obscurely quadrangular, a little hairy. Leaves petioled, digitate; leaflets five or seven, lanceolate, acuminate, ferrated, outer ones the small. Male flowers in small loose racemes or spikes at the ends of the stem and branches. Female flowers, axillary, solitary, very small. Both kinds sometimes occur on the same plant, but always one of them very few in proportion to the other. All the old authors ignorantly call the male flowers female, and vice versa. It is said by Herodotus to be a native of Scythia. According to Linnaeus it grows wild in the East Indies. Thunberg says it grows here and there in Japan. Genlin found it in Tartary, and Father Hemepin among the Illinois, in North America. From long cultivation it is almost naturalized in the four of France, Italy, etc. An oil is extracted from its seeds. The seeds themselves are thought to be good for poultry, and to cause hens to lay a larger quantity of eggs, but should be given to smaller birds with caution, and milled with other seeds. It has been said, that if bullfiches and goldfiches feed upon them too plentifully, the red and yellow of their plumage is changed to a total blackness. For the propagation and culture of this plant, the various processes which it undergoes in the hands of the manufacturer, and the uses to which it is applied, see Hemp. 2. C. indica. Lam. Encyc. (C. simis exotic, Bauh. piz. 320. C. peregrina, Murif. Hift. iii. p. 433. n. 2. Kalengi-Cansjava, Rhed. Mal. 10. p. 119. tab. 60. Tjern-Cansjava, Ibid. tab. 61. Dakka or Bangua of the Indians. B. With a taller stem. Rumph. Amb. v. p. 208. tab. 77. “Leaves alternate.” Stem nearly cylindrical, smaller, more branched, and harder than that of the preceding species. Leaves all conflantly alternate; leaflets linear-lanceolate, very sharp-pointed; in the male plants five or seven, in the female ones commonly but three, on a petiole; near the top entirely simple. A native of the East Indies. Its hard stem and thin bark render it incapable of being wrought into filaments and fpun like common hemp. It has a strong smell, a little like that of tobacco. The Indians make of its bark and the expressed juice of its leaves and seeds, a liquor which has an intoxicating quality: and if they wish to produce a stronger effect, they either chew or smoke its dried leaves mingled with tobacco. A little nutmeg, cloves, camphor, and opium, mixed with its juice, form the composition which the Indians call majet, and which, according to Clusius, is the same as the malach of the Turks.

Cannabis Spuria, (Riv. Mon. tab. 32.) See Galeopsis Versicolor.

Cannacus. See Cannia.

Cannia, in Ancient Geography, a small town of Italy, in Apulia, feated on the river Aufidus, now called Ofanto. The Latins use the plural appellation for this city, probably from its confiding of distinct parts, built on different eminences. The Greeks, and Polybius in particular, called it Kanoe, in the fingular number. This place has been rendered famous in hisory by the battle fought in its vicinity between the Carthaginians and the Romans, in the year of Rome 538, B. C. 216. For some time previous to this battle, Hannibal, the Carthaginian general, had, by various movements and skirmishes, endeavoured to bring Fabius, the wife and wary Roman dictator, to a decisive contest. He well knew that inaction and delay were the principal evils he had to fear, and the diftreas occasioned by want of provisions and money made him anxious to provoke the Romans to an engagement. Fabius, on the other hand, duly apprized of the situation of his adversary, adopted every prudent meafure for protracting the war, and ruining his enemy by delay. Some trivial succfces which were gained by the Romans in their encounters with the Carthaginians, increased the confidence both of the army and of the people; and forgetting their former defeats, they began to imagine that the enemy maintained his fation in Italy, by the permission, by the timidity, or by the excefsive caution of their leader. Miniusit, the general of the horfe, having also, in the abfence of the dictator, obtained some flight advantage over the foraging parties of Hannibal, the army and the people were confirmed in this opinion, and the reputation of Fabius was greatly funk in their efimation. But as he could not be superfed after the ufual term of his office expired, the Senate and people adopted a meafure, which they hoped would induce him to reign. They raised the general of the horfe to an equal
equal command with the dictator, and left them to adjust their respective pretensions. The Roman dictator, instead of rashly and indignantly withdrawing his services in a moment of danger, continued to serve under this diminution of rank and command, and magnanimously overlooked the inuits with which the people had required the service he was rendering to his country. Mummintius being now associated with the dictator, in order to be free from the restraint of a joint command, and from the wary counsels of his colleague, defined, as the more proper mode of adjusting their pretensions, to divide the army between them. In this new situation he exposed himself and his division, by his intimates, to the danger of being entirely cut off by the enemy; but being relented by Fabius, he acknowledged the favour he had received, and committing himself, with the whole army, to the conduct of his colleague, he left this cautious officer, during the remaining period of their joint command, to pursue the plan which he had formed for the war, and to which, without overbearing interference, he determined to adhere. The people, and the senate, however, were not disposed to acquiesce in what they conceived to be the hazardous and dilatory measures which Fabius was inclined to pursue. Having resolved to augment the army in Italy to eight legions, which, with an equal number of the allies, amounted to 80,000 foot and 7000 horse, which they conceived would be a force more than sufficient to counteract that of the Carthaginians, which consisted of 40,000 foot, and 10,000 horse; they intended, on occasion of the approaching election of consuls, to chuse men, not only of reputed ability, but of decisive and resolute counsels. Accordingly, they elected C. Terentius Varro, supposed to be of a bold and dauntless spirit; and, with a view of tempering his ardour, they joined with him in the command L. Æmilius Paulus, an officer of approved experience, who had formerly obtained a triumph for his victories in Illyricum, and who stood high in the confidence of the senate, as well as in that of the people.

The autumn before the nomination of these officers to the command of the Roman army, Hannibal had surprized the fortresses of Cannae, whether the Roman citizens of that quarter had retired with their effects, and where they had collected considerable magazines and stores. This, among other circumstances, determined the senate to hazard a battle, and to furnish the new consuls with instructions to this effect. These officers, having opened the campaign on the banks of the Aufidus, advanced by mutual concert within six miles of the Carthaginian camp, which covered the town of Cannae. Here they differed in their opinions; and a compromise was made by an agreement, that each of them should alternately take the command for a day. Varro, in opposition to the sentiments of his colleague, proposed to give battle on the plain, and for this purpose, as often as the command devolved upon him, still advanced on the enemy. In order to occupy the passage and both sides of the Aufidus, he encamped in two separate divisions on its opposite banks, having his larger division on the river, opposed to Hannibal's camp. Still taking the opportunity of his turn to command the army, he passes with the larger division to a plain, supposing to be on the left of the Aufidus, where, as the field was too confined to receive the legions in their usual form, he pressed them together, and gave the enemy, if he chose it, an opportunity to engage. For the accommodation of his order to the extent of his ground, he contracted the head, and the intervals of his maniples or columns, making their depth greatly to exceed the front which they turned to the enemy. He placed his cavalry on the flanks, the Roman knights on his right towards the river, and the horsemen of the allies on the left. Varro, having thus arranged his forces, and impelled by vanity, in consequence of having obtained some slight advantages by skirmishes between the light horse, or dispirited by an insult of the Numidians, who had pursued a body of Romans almost to the gates of the camp, determined to bring the contest to a speedy conclusion. Paulus Æmilius disapproved of the place which he had chosen for the scene of battle, but willingly to draw the enemy to a situation, where the infantry, in the number of which they exceeded, might have the greater share in the action, whereas Hannibal's cavalry was in every respect superior to that of the Romans; and remonstrated against the precipitance of his colleague. Paulus Æmilius commanded the right of the Romans, Varro the left, and Servilius Cemenus, the confid of the preceding year, was in the centre. Hannibal, as soon as he saw the movement and disposition of the enemy, hastened to meet them on the plain which they had chosen for the field of action. He likewise passed the Aufidus, and with his left to the river and his front to the south, formed his army up in an equal line with that of the enemy. He placed the Gaulish and Spanish cavalry on his left facing the Roman knights, and the Numidians on his right facing the allies. The flanks of his infantry, on the right and the left, were composed of the African foot, armed in the Roman manner, with the pilum, the heavy buckler, and the stabbing sword. His centre, though opposed to the select portion of the Roman legions, consisted of the Gaulish and the Spanish foot, variously armed and intermixed together. Astitribus commanded the left, Hanno the right, and Hannibal with his brother referred the command of the centre to himself. As the armies formed north and south, even the fun, which rofe soon after they were formed, shone upon the flanks, and was no disadvantage to either of them. Some difficulty has occurred in deciding which way each of these armies was turned; as the expressions of Polybius are said by some to admit of a double meaning. His words are "Βλεπωντος ὁ της ἔν τον Ρωμαίων τάξιν προς μεταβείναι τὸν ἐν τῷ Καρθαγίνιων ἐπὶ τοῦ αὐχένος ἐνεργὴν αἴθανον συμβαινειν γινώσκειν τῷ καθ' ἀυτὸν αναφαίνειν." Spectante meridic Romanorum aequi, Carthaginensium vero septentrionem, ambobus inoffensis contigit efl' ab folis ortu. Livy is charged by Chaupry with having misconstrued the passage of the Greek historian, who, according to his opinion, did not mean, that the Romans foold with their faces to the noon-tide fun; but only that they were drawn up to the south of the enemy. Livy's words are (lib. xxii. 46), "Romani in meridiani, Parni in septentrionem verba." He affirms, moreover, that the topography of the plain, and the course of the river, agree with this explanation; and that if the legions had faced the south, the runaways could not, after the defeat, have reached Canusium and Vcnulia, without passing through the whole victorious army. Salapia, Arpi, and Lucceria, would have been their places of refuge. Sminburne inclines to truft to the explanation of Livy, who was sufficiently acquainted with the Greek language not to mistake the meaning of an author whom he studied and followed to closely; more especially as, according to his ideas, the situation of the ground is in favour of the Roman historian; for exactly in that part of the plain where we know with moral certainty that the main effort of the battle lay, the Aufidus, after running due east for some time, makes a sudden turn to the south, and describes a very large semicircle. The Romans, we are to suppose, fought it at the angle or elbow, and placed their right wing on the banks; while the legions extended themselves
selves due call, till the whole line came to face the north. The Carthaginians crossed in two places within the semi-circle; and were drawn out in a line, that formed the chord of which the river was the arch; and therefore the way to Cannanum was open for the fugitives. Swinburne adds, that the scene of action is marked out to posterity by the name of "Pezzo di Sangue," or field of blood. The peafants, he says, threw us some spurs and heads of lances lately turned up by the plough, and told us, that horse-loads of armour and weapons had been at different times carried away from thence. Livy (I. xxii. 12.) and Plutarch (in Fab. p. 183.) inform us, that Hannibal, who knew how to avail himself of circumstances, as a great captain, forgot nothing that could conduce to the victory. A wind peculiar to that region, called in the country the "Vulturus," blew always at a certain period. He took care to draw up in such a manner, that his army, facing the north, had in its backs, and the enemy, fronting the south, had in its faces; so that he was not in the least injured by it: whereas the Romans, whose eyes it filled with dust, scarcely saw before them. The superiority of numbers was greatly on the side of the Romans; but Hannibal refited his hopes of victory on two circumstances: first, on a motion to be made by his cavalry, if they prevailed on either of the enemy's wings; next, on a position he was to take with his centre, in order to begin the action from thence, to bring the Roman legions into some disorder, and expose them, under that disadvantage, to the attack which he was prepared to make with his veterans on both their flanks. The action accordingly began with a charge of the Gaulish and Spanish horse, who, being superior to the Roman knights, drove them from their ground, forced them into the river, and put the greater part of them to the sword. By this event the flank of the Roman army, which might have been joined to the Aedus, was entirely uncovered. Having performed this service, the victorious cavalry had orders to wheel at full gallop round the rear of their own army, and to join the Numidian horse on their right, who were still engaged with the Roman allies. By this unexpected junction, the left wing of the Roman army was likewise put to flight, and pursued by the African horse; at the same time the Spanish cavalry prepared to attack the Roman infantry, wherever they should be ordered on the flank, or the rear. While these important events took place on the wings, Hannibal caused the Roman legions of the main body, with a singular movement that was made by the Gauls and Spaniards, and with which he proposed to begin the action. These came forward, not in a straight line abreast, but swelling out to a curve in the centre, without disjoining their flanks from the African infantry, who remained firm on their ground. By this motion, they formed a kind of crescent convex to the front. The Roman maniples of the right and the left, fearing by this singular disposition to have no share in the action, hastened to bend their line into a corresponding curve; and, in proportion as they came to clofe with the enemy, charged them with a confident and impetuous courage. The Gauls and Spaniards refited this charge no longer than was necessary to weaken the precipitate ardour with which victorious troops often blindly pursue a flying enemy. And the Roman line being bent, and fronting inwards to the centre of its concave, the legions pursued where the enemy led them. Hurrying from the flanks to share in the victory, they narrowed their space as they advanced, and the men who were accustomed to have a square of six feet clear for wielding their arm, being now pressed together, fo as entirely to prevent the use of their swords, found themselves struggling against each other for space, in an inextricable and hopeless confusion. Hannibal, who had waited for this event, ordered a general charge of his cavalry on the rear of the Roman legions, and at the same time an attack from his African infantry on both their flanks: by these dispositions and joint operations, without any considerate loss to himself, he effected an almost incredible slaughter of his enemies. With the loss of no more than 4,000 Gauls, 1,500 Spaniards and Africans, and 200 horses, he put 70,000 of the Romans to the sword. Polybius says the general loss amounted to more than 70,000. The Carthaginians were so furious against the enemy that they did not cease killing till Hannibal, in the greatest heat of the conflict and slaughter, exclaimed several times, "Hold, soldiers, spare the vanquished." The consul Aemilius Paulus had been wounded in the shock of the cavalry; but when he saw the condition in which the infantry were engaged, he refused to be carried off, and was slain. "I have taken my resolution," said he. "I will expire upon these heaps of my dead soldiers; but do you take care not to lose the time you have for escaping from the enemy, through an useless comparison. Go, and tell the senate from me to fortify Rome, and to make troops to enter it for its defence, before the victor arrives to attack it. Tell Fabius in particular, that I lived and died highly sensible and fully convinced of the wisdom of his counsels." The confusion of the preceding year, with others of the same rank, were likewise killed: of 6000 horses only 70 troopers escaped with Varro. Of the infantry, 3000, or according to other accounts, 4000, fled from the carnage that took place on the field of battle, and 10,000, who had been posted to guard the camp, were taken; others retired to Cannanum. The unfortunate confus with much of the fraggler as joined him in his retreat, took poff at Venaue, and afterwards at Cannanum, where he joined a considerable number of those that had escaped; and with a noble confidence in his own integrity, and in the resources of his country, put himself in a posture to refit the enemy, till he obtained further instructions and reinforcements from Rome. On his return to the city, the senate, confident that he had taken at Cannen by their own instructions, and, that influenced by the motives that animated the whole Roman people, he had disjoined, with a superior army, to fling in face of his enemy, or to refute him battle upon battle, but, on arriving, found that the enemy, after many losses, was in a kind of preceffion to meet him; and overlooking his temerity and misconduct in the action, they attended only to the undaunted aspect which he preferred after his defeat, and returned him thanks for not having despared of the commonwealth. From this time they continued their preparations for war with all the dignity and pride of the most prosperous fortune. They refused to ransom the prisoners who had been taken by the enemy at Cannic, and treated with fallen contempt, rather than severity, those who by an early flight had escaped from the field; and when they were petitioned to employ them again in the war, they replied, "we have no service for men who could leave their fellow-citizens engaged with an enemy." On the part of Hannibal, this victory was complete; but his subsequent inactivity saved Rome and her dominions. Many, and Livy amongst the rest, condemn Hannibal for his delay in improving this signal success, as a capital error. But others, restrained by the authority, or rather the silence of Polybius, have forbore from cenfuring the conduct of the Carthaginian general. He allows, indeed, that the Carthaginians entertained hopes of carrying Rome on the first assault;
affault; but he does not explicitly declare his own opinion concerning the measures which might have been prosecuted in respect to a city very populous, extremely warlike, well fortified, and defended by a garrison of two legions. He does not so much as intimate that such a project was practicable, or that Hannibal was to be blamed for not having attempted it. It should be considered, that after the battle he had not more than 20 or 27 thousand foot, who were in a condition to act; and that number could not suffice either for forming the circumference of a city of such extent as Rome, with a river running through it, or for attacking it in form, without machines and other implements necessary in a siege. The victory at Cannae afforded to Hannibal a very considerable booty: but except men, horses, and a little silver which was principally upon the furniture of the horses, he abandoned all the rest to the soldiers. After the battle of Cannae, Hannibal took up his winter quarters at Capua, which fee. Polyb. iii. 262-267-298. Livy, xxii. 43-44-45-46. Plut. in Fab. 182-183. Rollin's Anc. Hist. vol. i. Rollin's Rom. Hist. vol. iii.

The plains on which the battle of Cannae was fought, have more than once, since the Punic war, afforded a scene of warfare and blood. Mela of Bari, after raking the Standard of revolt against the Greek emperors, and defeating their generals in several engagements, was at last routed here, in 1019, by the catapax Balanus. Out of 250 Norman adventurers, the flower of Mela's army, no more than ten escaped the slaughter of the day. In 1201, the archbishop of Plermo and his rebellious associates, who had taken advantage of the monasticism of Frederick of Swabia, were cut to pieces at Cannae by Walter de Brienne, sent by the pope to defend the young king's dominions. The remaining traces of the town of Cannae are very faint: and coffin of fragments of altars, cornices, gates, walls, vaults, and underground granaries. It was destroyed, as we have already observed, the year before the battle; but being rebuilt, it became an episcopal fee in the infancy of Christianity. It was again reduced in the 6th century; but seems to have fulfilled in an humble state many ages later; for we read of its contending with Barletta for the territory which till that time had been enjoyed in common by them; and in 1264, Charles the first issued an edict for dividing the lands to prevent all future litigation. The prosperity of the towns along the coast, which increased in wealth and population by embarkations for the crusades, and by traffic, accelerated the annihilation of the inland cities; and Cannae was probably abandoned entirely before the end of the 13th century. It is now an incendible place, with a titular ice, in the country of Bari. Swinburne's Travels, etc. vol. i.

CANNAGARA, a town of India, placed by Ptolemy on the other side of the Ganges.

CANNAR, or CANNATUS, a promontory of Africa, in the Mediterranean Sea, in Mauritania Tingitana, according to the Itinerary of Antonine.

CANNARES, Indians of the province of Quito, in Peru. They are well made and very active; they wear their hair long, which they weave and bind about their heads, in form of a crown. Their clothes are made of wool or cotton, and they wear fine-fashioned boots. Their women are handsome and fond of the Spaniards; they generally till and manure the ground, whilst their husbands at home card, spin, and weave wool and cotton. Their country had many rich gold mines, which have been drained by the Spaniards. The land bears good wheat and barley, and has fine vineyards. The magnificent palace of "Theomabamba" was situated in the country of the Canares.

CANNAROLA, in Ornithology, the name applied by Aldrovandus to the babbling warbler, Mopailla Canara of Linnaeus.

CANNAVERAL, Cape, in Geography, the extreme point of rocks on the east side of the peninsula of East Florida, having the Mosquito inlet N. by W. and a large island S. by E. This was the boundary of Carolina by charter of Charles I. N. lat. 28° 55'. W. long. 81° 9'.

CANNAYAH, a village of the north side of Washington island, on the N.W. coast of North America.

CANNEL-COAL. See Coal.

CANNELS, in Zoology, a species of biped reptiles in the arrangement of De la Cépée, in the first volume of his "History of opifarious Quadrupeds and Serpents." The other species of this genus is the heliotopis, described by Pallis in the Petersburg Transactions.

The cancell is an animal lately discovered in Mexico by M. Velazques, and brought into France by the vicomtes de Fontanges. Its whole length is 8½ inches, and its diameter the third of an inch; the abdominal semi-rings are 150, and the tail-rings 45; the thickness of the whole body is nearly equal; the legs, one-third of an inch long, are close to the neck, and the feet each four toes furnished with nails. The cancell seems to have a near resemblance to the amphibious of Linnaeus, and perhaps, when it is better known, it may be found to belong to that genus; though, at the same time, the legs justify the genus as established by the count de la Cépée.

CANNIOQUINS, in Commerce, white cotton cloths brought from the East Indies. They are a proper commodity for trading on the coast of Guinea, particularly about the rivers Senegal and Gambia. These cloths are folded fquare-wise, and are about eight ells long.

Cannes, in Geography, a small town and harbour of France, in the department of the Var, and district of Grasse, which gives name to a bay formed by Cape Garap or Graspe. N. lat. 43° 54'. E. long. 7° 7'.

CANNESI, a town of Louisiana, on the north bank of Red River, a branch of the Mississippi.

CANNETE, a town of Spain, in the province of Cordova; 18 miles E. of Cordova.—Also, a town of Spain, in the province of Seville; 5 leagues S. of Olmo.

CANNETS, Fr. in Heraldry, ducks represented without beaks or feet. Cannets have their heads in profile, and they differ from Allerions, which are always displayed and full-faced, and they have longer and more encircling necks than those of the martlets.

CANNETTE, in Geography. See Cagnete.

CANNIA, a place in the island of Ceylon, about six miles from the fort of Trincomalee on the road to Candy, famous for its springs, the waters of which are reckoned very efficacious in rheumatic complaints. The springs are fixed in number, and of different degrees of heat; they all communicate with one another, and exhibit the same phenomena. Their heat varies from 98° to 106° of Fahrenheit's thermometer, nearly in proportion to their different depths. From an analysis of these waters it appears that they possess few mineral qualities, or perhaps any virtue besides their heat, which is of a temperature not unfavourable for hot bathing. Percival's Ceylon, p. 360.

CANNIBAL, or Canibal, is used by modern writers for anthropophagus, or man-eater, more especially of the West Indies. See Anthropophagi.

In the ancient world, tradition has preferred the memory of barbarous nations of cannibals, who fed on human flesh, and in every part of the new world there were people to whom
whom this custom was familiar. It prevailed in the southern continent in several of the islands (See Caribbean), and in various districts of North America. Even in some parts where the practice has been abolished, it seems formerly to have been so well known, that it is incorporated into the idiom of their language. Among the Iroquois, the phrase by which they express their resolution of making war against an enemy is "Let us go and eat that nation." If they solicit the aid of a neighbouring tribe, they invite it to eat broth made of the flesh of their enemies." Nor was this practice peculiar to rude unpolished tribes: the principle from which it took rise is so deeply rooted in the minds of the Americans, that it inflamed in Mexico, one of the civilized empires of the new world, and relics of it may be discovered among the more mild inhabitants of Peru. It was not scarcity of food, as some authors imagine, and the importunate cravings of hunger, which forced the Americans to these horrid repasts on their fellow-creatures. Human flesh was never used as common food in any country. It was the rancour of revenge that first prompted men to this barbarous action. The fierce tribes seldom devoured any but prisoners taken in war, or such as they regarded as enemies.

This fact is confirmed by two remarkable circumstances, which occurred in the conquest of different provinces. In the expedition of Narvaez into Florida, in 1528, the Spaniards were reduced to such extreme distress by famine, that in order to preserve their own lives, they ate such of their companions as happened to die; this appeared so shocking to the natives, who were accustomed to devour none but prisoners, that it filled them with horror and indignation against the Spaniards. During the siege of Mexico also, though the Mexicans devoured with greediness the Spaniards and Tlapecalans, whom they took prisoners, the utmost rigour of the famine which they suffered could not induce them to touch the dead bodies of their own countrymen. The authorities for these facts are cited in Dr. Robertson's Hist. of America, vol. ii. p. 501. See Anthropphagi. See also the articles America, Anisko, Battia, Suckinam, and New Zealand.

Cannon, or Cannon-flame, a base sort of iron-ore, in the Staffordshire mines, of which the want metal is made.

Cannon, in French canon, from the Italian word canna, which is derivable from the Greek word καννής, signifying the beam of a lieedryard or balance, a reed, cane, rod, or ruler, &c.; or from κάννα, in Latin canna, a cane, reed, fugar-cane, pipe, &c. This word, in its general acceptance, is applied not only to large guns, howitzers, mortars, caronades, &c. and all heavy pieces of ordnance or artillery, but also to the barrels of all smaller fixed fire-arms, such as muskets, carabines, fusces, pistols, &c. whether the bores of the flame be smooth on the inside or rifled. In its more restricted and ordinary acceptance, however, it is made use of to express a large-sized fire-arm, a piece of ordnance or artillery, a warlike engine, machine, or instrument for projecting or throwing balls, bullets, shells, grape-shot, flones, &c. &c. by means of gunpowder. It has a cylindrical bore or tube running lengthwise in the middle of it from the muzzle towards the breech for receiving the charges of powder, shot, shells, &c. After gunpowder began to be applied to military purposes, it supplanted and succeeded the tormenta bellica, or warlike machines of the ancients. The first cannons were called bombardes, from βολής or "a bombo et ardore," on account of the great noise, which the firing of them occasioned; and as they succeeded to these machines, they were employed like them for throwing large stones, and had prodigious calibers. Their forms, as well as the engines and instruments made use of in managing, moving, and conducting them, were only such as the most obvious incidents forward, or the rudest and most uncultivated invention dictated. They usually consisted of bars or pieces of iron fitted, and sometimes folded together lengthwise, and hooped with iron rings. Being long beyond all just or due proportion, they were heavy, clumsy, and in a great degree unmanageable; and as they were used for throwing stones, like the machines they succeeded, they were necessarily of a huge or enormous bore, and could not be fired but at great intervals of time. Such were those with which we are told Hannibal, in his march against the Carthaginians, order a battery of waggons, hooped with iron rings, of a length of 1200 feet. Though some use has been made of guns in Europe upwards of a century before, so little improvement had been made in their construction that they could not be fired above three or four times a day, or discharged often without bursting. And Guicciardini, in the first book of his history, informs us, that so great a portion of time intervened between the different discharges and discharges of one of those ponderous and unwieldy pieces, that the baggage had sufficient time to repair at their leisure the breaches made in their walls by the shock of the huge and enormous stones, that were thrown from them. For a considerable time indeed, after men began to apply gunpowder to military purposes, their guns were very long, heavy, and unmanageable, and of course very unfit for quick or expedient service. Military people at that time poffessed but a small share of learning of any kind, and almost none at all of a mechanical or mathematical nature. What they did professionally in regard to the management of artillery was entirely the effect of practice and a bare repetition of what they saw every day done.

But as mathematical knowledge increased in Europe, that of mechanics gradually advanced, and enabled artists by making both brass and iron cannon of a much smaller bore for receiving iron bullets, and a much greater charge of strong powder in proportion to their calibers, to produce a very material and important change in the construction and fabric of those original pieces. Accordingly this historian, in the same work of his history, informs us, that about 141 years after the first use made of those ponderous and unwieldy pieces by the Venetians, in the war which they carried on against the Genoese in the year 1380, the French were able to procure for the invasion of Italy a great number of brass cannon, mounted on carriages, drawn by horses instead of oxen; and that these pieces could always keep pace with the army.

In enumerating the advantages, which arose from this alteration in the structure and management of artillery, he observes, that the pieces were pointed with incredible quickness and expedition in comparison of those formerly made use of in Italy, were fired at very small intervals of time, and could produce in a few hours an effect, which those others could not have produced in the space of many days. In speaking of these matters he uses the following words:

"Et par uneri con quellerc exercito erano flato condotte per mare a Genova quantità grande d'artiglieria da battere le muraglie et da ufare in campagna, ma di tal forte, giannma non havava veduta Italia le semignanti. Quella pestre trovata molt anni innanzi in Germania fu condotta la prima volta in Italia da Venetiani nella guerra, che circa l'anno della falute 1380 hebbono i Genoeci con loro—il nome delle maggiori era bombarder, le quali, sparando dopo qualunque inventione per tutta Italia s'adoperavano nell' oppugnazioni delle terre, alcune di ferro, alcune di bronzo ma grof-
fistime, in modo che per la machina grande et per l'im- 
pertuta de gli uomini e mala attitudine de gli instrumenti 
tardifarnemente et con grandissima difficilta si conduccevano, 
piantavano alle terre co' medesimi impedimenti e piante 
era dall' un colpo all' altro tanto intervallo che con pec-
colifino frutto, a comparazione di quello che fu fatto in 
molto tempo con facili, dove i defensori de luoghi oppugnati 
havesseno fatto di potere aditoane fare di 
tendere ripari e fortificazioni. Mai Francesi fabbricando 
pruzii molto piu espedienti, nè d'altra che di bronzo, i 
quali chiamavano cannoni, et usando palle di ferro, dove 
prima di pieta e fenza comparazione piu groffle e di pico 
gravissimo s'usavan li conducevano in falle certe irrate 
(non da buoi come in Italia si collumanva) ma da cavalli 
agilita d'umanius e di instrumento deputato a quello fer-
vigio, che quali fumero al pari de gli eserciti cavall Bezina, e 
condotte alle muraglie crano piantate con pretezza incredib-
el, et interponendoli dall' un colpo all' altro piussino-
intervallo di tempo si spoio e con impeto si gagliardo pur 
conveneva, che quello che prima in Italia fare in molti giorn-
i si soleva darlo in possibili loro faccia.

These pieces used generally to throw iron-balls from forty 
to sixty pounds in weight; and this change in the formation 
of artillery has not as yet undergone many material alter-
tions. Lighter guns indeed are now employed than those, 
that were made use of at first; but they have suffered greater 
variations in respect of size than proportion.

When, or by whom, guns were first invented is uncertain, 
since the origin both of them and of gun-powder is involved 
in obscurity; though it is highly probable, that mixtures 
or compositions similar to that of gun-powder were made 
soon after the discovery of salt-petre, because it is difficil 
to conceive how the one discovery could exist long without 
the other.

The great inerca of inflammability, which salt-petre 
gives to igneous or inflammable substances, when mixed 
with them, must soon after it was discovered itself have led 
to such a mixture. For a small part of it being either thrown 
or falling accidentally into any fire must have manifested 
this distinguishing quality in it and its prodigiously explosive 
power when mixed with burning bodies, and have led to the 
idea of rendering inflammable materials violently and ex-
cessively more so than they are naturally, and powerfully 
explosive, by mixing them with salt-petre. If the time 
could, therefore, be ascertained when this substance first 
came to be made use of, conjectures might with some fort 
of certainty, or at least probability, be formed when mix-
tures like the composition of gunpowder were first made 
or invented. Such a discovery or invention, however, might 
long exit before a convenient and advantageous method of 
applying it to military projectiles might be thought of or 
projected.

An opinion has generally prevailed, that salt-petre was first 
discovered either by the Arabsians or the later Greeks, about 
the middle ages of the christian era, when alchemy and che-
metry were much attended to and cultivated by both na-
tions. It is even said that the Arabic name for it is expe-
five of its explosive quality. And if the Greek fire made 
life of by the later Greek emperors possessed this explosive 
property, and produced the effects attributed to it, there 
must have been some salt-petre in its composition.

Whether salt-petre was known to the ancients, seems to 
be a matter of considerable uncertainty. They had, how-
ever, both in Europe and Asia, their fiery tubes or cannon, 
which, being loaded with stones, pitch, and iron balls, were 
exploded with a violent noise, much smoke, and great effect. 
And there are several passages, both in the Greek and Ro-
man writers, which show, that the Greek fire itself was used 
by both nations in their wars, and afford reasons for tracing 
it back to a much earlier date than 660, or the first flight in 
the Hellepont, commanded by Constantine Pagurates 
against the Saracens, and ascribing the invention of it to 
Marcus Grecus or Graces.

The invention of gunpowder is usually, though errone-
ously, ascribed to one Bartholdus Schwartz, who is said to 
have discovered it about the year 1250; and the Venetians 
are commonly supposed to have made the first application of 
it to military purposes in their war against the Genoese 
about the year 1580. Both of these suppositions, however, 
are certainly without foundation. For Roger Bacon, who 
lived almost fifty years before Schwartz, describes a compo-
sition perfectly resembling that of gunpowder; and unques-
tionable proofs can be produced of the use of artillery much 
earlier than the year 1580, even in Europe.

Bacon does not mention this composition as a new one, 
but speaks of it as in common use for destructive fire-works, 
and only proposes to apply a well known one to the defini-
tion of armies by the violent effects of its flame unconfined. 
This is the first well-authenticated hint, that was given in 
Europe of the application of gunpowder to warlike pur-
puses; though the Germans attempt to trace back the in-
vention of cannon as far as 1250, and ascribe it to Albertus 
 Magnus, a Dominican monk.

That gunpowder, however, was both known and made 
use of long before the time, either of Roger Bacon, or Al-
bertus Magnus, is a fact that cannot be denied. This is 
established beyond even the possibility of dispute by the treat-
ise of Marcus Grecus, entitled "Liberignium," which is in 
manuscript in the Royal library at Paris. Doctor Mead 
had the particular also in manuscript, a copy of which is now 
in the possession of the ingenious and learned Dr. Hutton. 
The author of it describes several ways of encountering 
and opposing an enemy by launching fire on him; and among 
other things, gives the following directions. Mix together 
one pound of live sulphur, two of charcoal of willow, and 
fix of salt-petre, reducing them to a very fine powder in a 
marble mortar; then put a certain quantity of this mixture 
into a long, narrow, and well compacted cover, and then 
discharge it into the air. This is exactly the description of 
a rocket. He represents the cover, with which thunder 
is imitated as short, thick, but half-filled, and strongly bound 
with packthread, which is exactly the form of a cracker. 
He then delivers different methods for preparing the match, 
and explains how one square may set fire to another in the 
air by having it inclosed within it. He describes two kinds 
of fire-works, one for flying, and the other for making a 
load report. He directs the cafe, tunica, or cartouches for 
the first to be made long and flender, and the composition 
to be very closely rammed; and the cafe for the second to 
be thick and short, and only about half filled. His com-
position for both is stronger than a great deal of gunpowder 
that is made now. It must, indeed, be acknowledged, that 
he treats as expressively and distinctly of gunpowder and the 
eflect of it, as any person writing on the subject, even if 
pretend poissibly could do. He does not, however, speak of 
man compositions as used in war, which shews at least, that 
they were known before the use of any fort of fire-arms in 
those parts of the world, in which he was acquainted with. 
And as he does not pretend to be the inventor of these rockets 
and crackers, or mention them as things new or even recent, it 
may reasonably be presumed, that they were in use long before 
his time, which is not ascertained to a certainty, though he 
himself have lived as early as at least the eighth century. We 
have reason also to conclude from the authorities of many 
authors,
CANNON.

Cannon were formerly made of a very great length, which rendered them exceedingly heavy, and the use of them very limited and troublesome. There were some of them employed by the Turks, in 1391, at the siege of Konstantinopole then in possession of the Christians, and also in 1452, which threw a weight of 120 lb.; but they could not stand repeated firing. Louis XI. had one called at Tours of the same size, that threw a ball from the Bastille to Charenton. One of these cannon, a very large one, was taken at the siege of Dien, in 1546, by Don John de la Caffre, and is now in the castle of St. Julian de Eva, ten miles from Lisbon. The length of it is twenty feet seven inches; its diameter at the middle is six feet three inches; and it threw 120 lb. weight. It has neither dolphins, rings, nor a button; is of an unusual kind of metal, and has a large Indo-Portuguese inscription on it, which says that it was cast in 1460.

Formerly strange and uncommon names were given to cannon. Thus Louis XII., in 1503, had twelve braze cannon called of an extraordinary size called after the twelve peers of France. The Spaniards and Portuguese named theirs after their saints. The emperor Charles V., when he went against Tunis, had twelve cannon founded, which he called the Twelve Apostles. At Milan there is a seventy pounder called the Pimontelli; and there is one at Bois-le-duc called the Devil. At Dover castle there is a fifty pounder called Queen Elizabeth’s pocket-pistol. There is an eighty pounder in the tower of London brought thither from Edinburgh castle called Mounts-meg. There is also an eighty pounder in the royal arsenal at Berlin called the Thunderer, and one of the same calibre at Malaga called the Terrible. There are two curious sixty pounders in the arsenal at Bremen, called the Messengers of bad news. And lastly there is an uncommon seventy pounder in the castle of St. Angelo at Rome, made of the nails that fastened the copper plates which covered the ancient Pantheon, with this inscription on it: "Ex clasribus trabalibus porticus Agrigippa."

About the beginning of the 15th century, these uncommon names were mostly laid aside, and the following among other more general ones adopted.

The English, however, did not manufacture many of these till towards the end of the 16th century.

Speckles of great guns, as they were first used, and before the casting of them in foundries came into practice, are still to be seen in many parts of Europe, and some of them in the tower, and the warren at Woolwich. Such an instrument or engine of war was first called bombarde, afterwards cannon, and now commonly goes by the name of a piece of ordnance or artillery. The word cannon, however, is still applied to that part of every fire-arm great or small, that receives the powder.

Guns were soon after that incident employed in war. But mortars and great guns were first made use of.

Father Daniel in his Life of Philip, of Valois, produces a proof from the records of the chamber of accounts at Paris, that cannon were used in the year 1332. And Du Cange finds mention made of them in Fruisflart, and other French historians sorne time earlier. In the list of aids raised for the redemption of John king of France, in 1368, mention is made of an officer in the French army under the denomination or appellation of major of the king’s cannon, and of his providing four large cannon for the garrison of Harleur. There was one in the arsenal of Bamberg as early as 1325. The French used them in 1338, for the attack of some castles. But they did not certainly employ them in the field against their fellow creatures near so early as the English, who under Edward III., placed five of them, in 1346, on a small hill near the village of Creffy, which chiefly contributed to decide the celebrated battle of that name. From this circumstance several of the French writers have laid claim to a greater degree of national humility than they allow to the English. One of them, treating of cannon, expresses his sentiments on the subject in the following words: “On ne peut point encore ufe en France, en 1547, de cette arme terrible contre les hommes; les Français s’en eurent bien servi, en 1338, pour l’attaque de quelques chateaux, mais ils regrettent de l’employer contre leurs semblables. Les Anglais moins humains, fans doute zous davantage et s’en fervirent a la célèbre bataille de Creccy, qui eut lieu entre les troupes du roi d’Angleterre Edouard III., qui fut si mechan, si perfide, qui donna tant de fil a retordre a Philippe de Valois, et aux troupes de ce der nier; et ce fut en majeure partie a la frayeur et a la confusion, qu’occasionnerent les canons dont les Anglais se fervoient pour la premiere fois, et qu’ils avoient paide par une colline, proche le village de Creccy, que les Francois durent leur der route.” The English also made use of them the year following, viz. in 1347, at the siege of Calais.

It is generally believed that cannon have been made use of in Europe ever since the year 1338, and that they were employed for naval purposes on the Baltic sea, in 1350. At any rate, it is certain that they were used by the Venetians, in
The French also had anciently the following pieces founded, several of which are to be found in France at this day.

At present cannon take their names from the weights of the balls, which they respectively discharge. Thus a piece that discharges a ball of 24 pounds, is called a 24 pounder; one that takes a ball of 12 pounds, is called a 12 pounder; and so of the rest divided into the following sorts.

Ship-guns, consisting of 42, 36, 24, 18, 12, 9, 6, and 3 pounders.

Garrison guns, consisting of 42, 32, 24, 18, 12, 9, and 6 pounders.

Battering guns, consisting of 24, 18, and 12 pounders, and sometimes though but seldom of 42 pounds.

Field pieces consisting of 12, 9, 6, 3, 2, 1, 1/2, 1, and 1/2 pounders.

The following dimensions, &c. for all sorts of brass and iron cannon were established by the Board of Ordnance in 1764.

The following are the dimensions, &c. established by the Board of Ordnance in 1764 for brass howitzers, which may be regarded as a sort of short cannon, mounted like guns on travelling carriages, and were much later in coming into use than either guns or mortars.

## Brass Howitzers

<table>

<td>4.52</td>
</tr>
</tbody>
</table>

Mortars are also a kind of short cannon of large bores, with chambers, and are made either of brass or iron. The following are the dimensions, &c. of all kinds of brass mortars, whether for land or sea service, as established by the Board of Ordnance in 1764.

## Brass Mortars

The
C A N N O N.

The following table shews, at one view, the lengths and weights of our brass cannon as they stand at present, with their respective calibers, or the diameters of their bores, the diameters of their shot, and of their shot gauges, the quantities of powder employed for proving them respectively, their respective charges for service, for furling with them, and for loading them.

### Brass Guns of Cannon.

The interior parts of a cannon are the following:

a. The bore, which is the interior cavity which receives the powder and shot. 

b. The mouth, which is the entrance of the bore. 

c. The vent, which is in all kinds of firearms is commonly or vulgarly called the touch-hole. It is a small hole, pierced at or near the end of the bore or chamber for priming the piece with powder, or for introducing the tube, in order, when lighted, to set fire to the charge. 

d. The chamber, which is used only in guns of large calibers, is the place where the powder forming the charge is lodged.

The following are tools for loading and firing cannon.

Coins, or wedges, which are laid under the breech of a gun, for the purpose of either elevating or depressing it.

Handspikes, for moving and laying it with.

Ladles, for loading the gun with loose powder.

Rammers, which are cylinders of wood, of the same diameters and axes with the shot. They serve for ramming the wads put upon the powder and shot.

The sponge, which is fixed at the opposite end of the rammer, covered with lambkin. It serves for cleaning out the gun when fired.

Screws, which are used with field-pieces, instead of coins or wedges. The screw serves not only for elevating or depressing the gun, but for keeping it at the same angle of elevation or depression.

Tools necessary for proving cannon are the searchers with a reliever, and the searcher with one point.

The searcher is an iron, hollow at one end to receive a wooden handle, and on the other end has from four to eight bat
CANNON.

Distance from the ogee to the fore part of the aftragal one calibre
Breadth of each of the fillets of the aftragal - 0.25
Breadth of the aftragal, or half round - 0.56
Total breadth of the aftragal and fillets - 1.12
Breadth of each of the fillets at the first and second reinforce ring - 0.25
Breadth of the first and of the second reinforce rings - 1.25
Breadth of the ogee, next to these rings - 1.5
Breadth of the fillets at the muzzle - 0.25

The muzzle ogee in a 12 pounder, and guns of higher calibers is equal to 1.25 inches or 1 ¼ inch. But in a 9 pounder, and guns of smaller calibers, it is only equal to one inch. The chase-gridle and aftragal are equal to one calibier.

The distance from the mouth of the gun to the muzzle aftragal is equal to a diameter of the second reinforce ring, in 18 pounders and guns of higher calibers; but in a 12 pounder, and guns of smaller calibers, it is equal to the diameter of the first reinforce ring.

The rising or swelling of the mouldings at the first and second reinforce is about an eighth part of an inch; and the rising of the base-ring is determined by laying a ruler to the extremities of the first and second reinforce mouldings.

The diameter of the gun, through the swelling of the metal at the muzzle, is always equal to the diameter of the second reinforce ring.

Parts of the Caiseable.

From the hind part of the base ring to the fore part of the fillet next to the button, the distance is equal to three-fourth parts of a calibre. The distance from the fore part of the fillet next to the button to the centre of the button is equal to one calibre. The distance from the hind part of the base ring to the hind part of the fillet, between the two ogees, is a sixth part of the calibre. The diameter of the fillet next to the button is equal to one calibre and a half. The diameter of the neck of the caseable is equal to three fourth parts of a calibre. The diameter of the button is somewhat more than one calibre.

It is proper to observe, that the shell at the vent is three inches broad, and reaches from the base ring to within a quarter of an inch of the vent-aftragal, leaving that space for the sake of turning. And the vent is the fifth part of an inch.

General dimension, according to this construction, for iron guns.

Supposing the calibre of the gun to be divided into 14 equal parts, we shall have,

The thickness of the metal at the vent from the bore 16
The thickness of do. at the end of the first reinforce, equal to - - - - 14.5
The thickness of do. at the beginning of the second reinforce equal to - - - - 13.5
The thickness of do. at the end of the second reinforce equal to - - - - 12.5
The thickness of do. at the beginning of the chase equal to - - - - 11.5
The thickness of do. at the end of the chase or muzzle, equal to - - - - 8

The mouldings, and the rest of the dimensions, are nearly the same as in the bras guns. The diameter of the vent, however, in his iron guns, is one-fourth part of an inch, whereas it is only a fifth part of an inch in his bras cannon.

The length of bras guns, according to him (general Armstrong), are the following:

The
Cannon.

The 32 pounder 10
The 44 pounder 9.5
The 38 pounder 9.5
The 12 pounder 9
The 6 pounder 8
The 3 pounder 7
The 1.5 pounder 6

And, according to him, the length of the iron

32 pounder was 9.5
Of the 44 pounder - 9
Of the 38 pounder - 9
Of the 12 pounder - 8
Of the 6 pounder - 7
Of the 3 pounder - 6
And of the 1.5 pounder - 5.5

General Armstrong, in order to ascertain the fitted and belt lengths for battering pieces, made experiments in 1755 with brass 24 pounders of different lengths, but of nearly the same weight. After a great number of trials and experiments with them, he fixed on nine feet six inches as the belt length for a 24 pounder battering piece, though none of the ranges with one only nine feet long, with the same charge of two-thirds of the weight of the ball, and with the same elevation, were somewhat greater than the greatest of those with one nine feet six inches long.

In the following table are the lengths of the 24 pounders with which he made a multiplicity of experiments, and three of the longest ranges of each, loaded with sixteen pounds of powder.

Now it is obvious that if we even suppose all these pieces to have been bored exactly alike, and their vents to have been placed also exactly alike, with regard to the bottoms of their bore, these experiments are not calculated for determining precisely the belt length of a 24 pounder, either for battering in breach, or for any other service. For these suppositions relative to their respective bores and vents being even granted, no other inference can be drawn from them than this, that nine feet six inches is about the belt length for a 24 pounder, that is to be used with a charge of 16 pounds of powder. But a charge equal to two-thirds of the whole weight of the ball is proproporionately large for any kind of service whatsoever. It does not follow from them that nine feet six inches would have been found the belt for a 24 pounder, had the charge been made use of been one-half, one-third, one-fourth, or even one-fifth part of the weight of the ball, the last of which, if the windage be very small, is sufficient even for battering with.

If a specific charge of powder be fixed on as the fitted for a gun of a given caliber for a given service, the belt way to ascertain the proper length of such a gun, it appears, would be to have one of that caliber cast longer than what is necessary, and then to cut it shorter and shorter, by a few inches at a time, firing it always at the same elevation with the Vol. VI.
It appears from these experiments, that when those eighteen pounders were charged with not pounds of powder, their ranges were generally somewhat greater at the same elevation than they were when loaded with either more or less; and that the fee of the eighteen pounder, nine feet long, exceeded that of the other, eleven feet long, with the same charge of half the weight of the ball.

They have every appearance of having been made with attention and accuracy. But as they were all made with a charge of powder by far too great for any kind of service with an eighteen pounder, no just conclusion can be drawn from them with regard to the ball length for a gun of that caliber. Besides, as there were only two lengths made use of, the only inference one can be justified in deriving from them is, that nine feet is a better length than eleven feet for an eighteen pounder, when fired with nine pounds of power. They have no tendency whatsoever to determine what length is best for a cannon of that caliber, when fired with six, or four, &c. pounds of powder.

Mr. Muller, however, regarded them as perfectly conclusive on this head, from finding that 4160 yards, the greatest range of the piece, nine feet long, at an elevation of 45 degrees, with nine pounds of powder, differed only thirty yards from 4190 yards, the greatest possible range of a gun of that caliber, according to an erroneous theory of his, founded on a misconception of Sir Isaac Newton's meaning, in the second book of his Principia, and expresses himself exultingly in the following words. "Thus we have at last determined that important question in artillery sought for ever since its invention."

This gentleman, after ascertaining that the greatest velocity which a leaden bullet of three quarters of an inch diameter can possibly have is that which, uniformly continued, would carry it through 355 feet per second, animadverts on Mr. Robins's method of determining the velocities of shot in the following words.

"Mr. Robins thinks to prove, in his seventh problem, that the velocity of the foregoing leaden bullet is 1668 feet in a second, which is more than four times greater than that above, and, what is more extraordinary, he pretends to have found the same velocity by experiments. As he seems to build his theory upon Sir Isaac Newton's principles, had he read the 4th proposition, book second, of his Principia, he must have been convinced of his mistake."

This is a heavy charge, and were it well founded, would, in a great measure, invalidate all that Mr. Robins has advanced, in regard to the determination of the first velocities of shot, as this is the only example that Mr. Robins calculates in his seventh proposition from his theory of the elastic force of the fluid generated by the firing of gunpowder, which he compares, in his ninth proposition, with the velocity ascertained by means of his ballistic pendulum, and finds to be almost the same. This is the place that Mr. Muller refers to, when he speaks of Mr. Robins as pretending to have found the same velocity by experiments. It is, moreover, deferving of observation, that Mr. Robins does not speak of this velocity as the greatest that can possibly be communicated to such a ball. For a much greater one undoubtedly may be so communicated. And it cannot with justice be alleged that Mr. Robins built this part at least of his theory on Sir Isaac Newton's principles, as his method of determining the first velocities of bullets is entirely his own. The mistake lies not with Mr. Robins, but with Mr. Muller himself, who could not, when he made the animadversion, have read with proper attention the said 40th proposition of the second book of the Principia, which relates entirely to the defecit of bodies in an infinitely comprized and perfectly fluid medium; whereas as Mr. Robins's calculation just mentioned refers expressly to projectile motion: and that projectile velocity may be much greater than the greatest velocity, by which a body can be conveyed by its comparative weight in such a fluid, is what no person, who has considered the subject with the least attention, will offer to deny. Even Galileo himself, who was the first that studied with any care the motions of projectiles and the nature of resisting mediums, seems to have been sufficiently of this truth. For, in his fourth dialogue, after observing that the heaviest bodies would in time, by descending in the air, acquire a degree of velocity which could not afterwards be increased in the same manner as we see light bodies soon arrive at their greatest velocity possible, he says, "This determine and ultimate velocity may be called the greatest which such a heavy body can naturally obtain in the air. But this velocity I imagine to be much less than that which is given to the same ball flung by fired powder." And he proposes to prove this, by first firing a musket loaded with a leaden ball and a proper charge of powder from a hundred yards high or more against a stone pavement, and then firing the same with a like charge against a stone of the same kind at a few yards distance, and examining which of the balls was most flattened. Every body now knows that this imagination of his was perfectly just.

Sir Isaac Newton begins the said proposition in his second book with a rule for determining the greatest velocity, with which a globe can descend in an infinitely comprized and perfectly fluid medium. His words are the following: "Sit A pondus globi in vacuo, B pondus ejus in medio resistente, D diameter globi, F spatium, quod sit at 4 x D ut densitas globi ad densitatem medi, id eft, ut A ad A - B ; G tempus quo globus pondere B fine resistit caedendo defcribit spatium F ; Et H velocitates, quam globus hoccet fua acquirit. Et eft H velocitates maxima, quacum globus pondere fua B in medio resistit potefc defendere." This, however, is the very rule, as is found by calculation, that Mr. Muller made use of for determining the greatest possible projectile velocity of a bullet of three quarters of an inch diameter, as well as those of larger ones. It is not, therefore, to be wondered at, that he has given a very erroneous table of the greatest possible velocities of shot of different diameters, from three pounds up to forty-eight, and of their greatest ranges.

As twenty-one diameters of an eighteen pounder shot are nearly equal to nine feet, and as nine pounds of powder were a charge equal in weight to half that of the shot, Mr. Muller concluded that guns of all calibers having their lengths and charges respectively proportional to these, would give greater ranges than guns of the same calibers with any other lengths and charges, greater or less, would give, supposing, without sufficient reason for doing so, the greatest velocities to be always proportional to the diameters of the shot.

He accordingly, in his constructions for guns, makes both battering and garrison cannon from eighteen to twenty-one diameters of their shot long respectively.

He allows, however, that though it is of advantage to know the ball length and charge for every piece, the lengths of guns must depend on the services they are intended for. He observes, that ship-guns should, for various reasons, be short and light; that field-pieces, or battalion-guns, should also be short and light, in order to be able to advance or retire as fast as the army; that battering pieces should be long enough to prevent the flame of the powder, when they are repeatedly fired, from damaging much, or destroying very suddenly the fides of the embrasures; and that garrison guns ought to be of the lengths that give the greatest range.
ranges, to oblige the besiegers to break ground at the greater distance, and to reach shipping, &c. from forts near the sea, or navigable rivers, as far off from them as possible.

In his general construction of brass cannon for the land service, he supposes the length of the gun to be twenty-one diameters of the shot from a twenty-four pounder inclusive, downwards, giving, however, the same length to the thirty-two pounder and to the forty-two pounder that he gives to the twenty-four pounder, making thereby the diameter of the first of these about nineteen diameters of the shot, and that of the last about seventeen diameters of the shot and one third.

The Conception is this.

Let the length AB of the piece (see fig. 1.) be twenty-one diameters of its shot; and let the diameter of the shot be divided into twenty-four equal parts, from which all the rest of the dimensions are to be determined. Make the Diameter of the bore equal to 25 such parts.

The distance from A, the hind part of the base-ring, to D, the fore part of the vent-aftragal, is 40 such parts.

The thickens of the metal at the breech and vent are 18.5 such parts.

Then the lines drawn from these points will determine the figure of the gun, which will be therefore from A to D cylindrical, and from thence to the mouth conical.

The centre line of the trunnions crosses the centre line of the bore at right angles, and at the distance of three tenths of the whole length AB of the gun, from the hind part A of the breech; the diameter of each of them is equal to eighteen such parts, and its length is equal to its diameter, exclusive of the projection of the second reinforce ring.

The length EF of the second reinforce is always equal to two-thirds of AE, the length of the first reinforce. The breech AC is equal to sixteen such parts; and the chace-girdle is equal to fourteen. The muzzle HB is equal to a tenth part of the whole length of the gun, which is here equal to 50.4 such parts.

The breadth of the base-ring and ogive next to it are each of them equal to 6 such parts.

The first and second reinforce rings, and the ogive next to them, are each of them equal to 5 such parts.

Each aftragal and fillets are equal to 4 such parts.

The cavetto at the mouth is equal to 2.5 such parts.

And the fillets are each equal to 1 of such parts.

The base-ring projects the metal two such parts, the first and second reinforce rings, about one such part; the fillets of the aftragals, the half of one such part; and the round of each aftragal is described from a centre in the outline of the piece.

There is a circular shoulder about each of the trunnions, of which the diameter exceeds that of either of the trunnions by six such parts, and projects so as to be even with the second reinforce-ring.

As to the calculable (see fig. 2.) the distance from A, the hind part of the base-ring, to C, the centre of the button, is equal to twenty-seven such parts; the radius of the button to N, the breadth of the quarter round to two; the ogive to five, and the fillets each to one. If from C, the centre of the button, right lines be drawn to the extremities E F of the base-ring, and points O O be found in these lines equally distant from the button and the second fillet, arcs described from these points with that distance will determine the

C A, whilst right lines OP parallel to CA, the direction of the axis of the piece, will fix the extremes, or limit the hind part of the second fillet, and C F determines the first.

In order to describe the ogee, join the extremities e, q, of the hind parts of the fillets; through the point q, draw the indefinite right line, q p, parallel to OP produced; bisect the right line e q in the point r, and through the point of bisection r draw a right line making angles with e q equal each to the angle s q l, and meeting q l and O q produced in the points, p, r, respectively. Then arcs described from the points P, r, as centres, with a radius equal to P r, P q or q r, will determine the ogee e q r. The quarter round is determined by so describing an arc from a point r in q p produced, that it shall meet the hind part of the base-ring within one of such parts, as the diameter of the shot contains twenty-four. The breadth of the fillet is equal to six such parts, and the diameter of the vent is a fifth part of an inch.

As to the muzzle (see fig. 3.) take the right line B K, equal to twenty such parts, B L equal to six such parts, and draw P L equal to B P, at right angles to B K. From the point K draw also a right line perpendicular to B K. Then if the right line joining the points L, B, be produced to meet this last-mentioned perpendicular in the point I, an arc is described from this point as a centre, with the radius I L, or I K, will determine the cavetto, or concave quarter, round L K. And if through the point a, at the distance of four such parts from B H, and parallel to the same, the right line a r be drawn, in it take a point r at equal distances from the point L, and the extremity of the hind part of the fillet for describing from as a centre, the quarter round, with this distance as radius.

From this construction, with twenty-one diameters of the shot, for the lengths of brass guns respectively for land service, from a 24 pounder inclusive downwards; and with 14 diameters of the shot for lengths of iron field-pieces respectively, he has given us table of the weights and dimensions of each, which are the following.

<table>

He gives another general construction for brass battering pieces on the supposition that the length, A B (see fig. 1.) of each is only equal to eighteen diameters of its shot, with all the other parts of the construction remaining the same as above.

From this construction he gives another table for brass battering pieces, and compares them with the old, as follows.
CANNON.

Lengths and weights of brass battering pieces.

<table>
<thead>
<tr>

</tbody>
</table>

These calculations are on the supposition that the guns are cylindrical as far as the charges reach, and load trunses conical to the mouth. The centre line of the trunses is also supposed to intersect the longitudinal axis of the bore of each gun at right angles, to prevent it, when fired, from injuring or destroying its carriage, which it would do if the said line be lower.

The quantity and weight of metal in a gun by this calculation he determines in the following manner.

Take the diameter of the gun across the centre of the bore at the muzzle without the mouldings, which is equal to forty-three such parts as the twenty-four, into which the diameter of the shot is supposed to be divided, and the square of it is 1849.

To this he adds the square of sixty-one, the number of such parts in the diameter of the gun at the ventialtage.

To thes he adds the rectangle under these two diameters or 43·× 61 = 2623.

The sum of these three products is 8193.

The third part of this sum is 2731.

Which multiplied by 392, the number of such parts in the length AB as the twenty-four, into which the diameter of the shot is supposed to be divided, gives 1070572.

To this content add the square of the diameter 61 by 263 the number of such parts in the length AD = 48840.

To these two contents add four times the cube of eighteen such parts for the contents of the trunses, castable, and mouldings = 23338.

And the sum will be equal to 1242720.

From this sum of these three contents deduct the square of twenty-five, the number of such parts in the diameter of the bore multiplied by its length 416 in such parts = 260000.

And the remainder will be equal to 982720.

Which content, reduced in the proportion of the area of a circle to the length of its diameter gives 771826 for the number of cubic such parts, as the twenty-four, into which the diameter of the shot is supposed to be divided, that expresses the solid contents of metal in the gun.

But the number of cubic parts in a ball, of which the diameter is equal to twenty-four parts, is about 7238.246, by which, if 771826 be divided, we get 106.21 nearly, which increased in the proportion of the weight of gun metal to that of cast iron, of 8754 to 7435, becomes 125.65 nearly, or 126 in whole numbers nearly.

Whence it is manifest that this construction gives the weight of each gun, equal to about 126 times the weight of its shot supposing the diameter of the bore to be to that of the shot 23 2/3 to 24, a proportion, however, that certainly leaves by far too much weightage. Thus a nine-pounder brass gun by it will weigh 1153 lb. or 72 cwt. and 14 lb.

He then gives a general construction for battering and garrison iron cannon supposing the length AB of each to be equal to twenty-one diameters of its shot.

He supposes the diameter of the shot to be divided into twenty-four equal parts as in the preceding construction, and makes the diameter of the bore equal to twenty-five such parts. He makes the length from A, the hind part of the bafe-ring, to D, the fore part of the ventialtage, equal to forty-eight such parts. He gives a thinnest of the metal at A and D, taken from the bore, equal to twenty-five such parts, or to one diameter of the bore; and he makes its thinnest at B, the mouth of the piece, equal to twelve such parts, or to half the diameter of the shot.

He supposes the centre line of the trunses to intersect the axis of the bore at right angles, at the distance of three-fourths of the whole length of the gun, or nine diameters of the shot from A, the hind part of the breech. He makes the diameter of each of them equal to one diameter of the shot, and the length of each, free from the projection of the second reinforce ring, equal to the same.

By this construction he allows about two hundred weight of metal for every pound of the shot's weight, or makes the weight of each gun equal to about 254 times that of its shot.

And from this proportion is derived the following table for battering and garrison iron-pieces.

<table>
<thead>
<tr>
<th>Caliber.</th>

</tbody>
</table>

The thirty-two pounder is the only gun in this table that is shorter than twenty-one diameters of its shot, being only about nineteen of the same. It is also heavier by two hundred weight, than two-hundred and twenty-four times the weight of its shot. For these deviations, however, from his general rule, he has assigned no reasons. And for them we are inclined to think, that no good ones can be given. We are also of opinion, that a much smaller weight of metal for every pound of the shot's weight would be perfectly sufficient.

In his construction of brass guns for ships, he supposes AB, the length of the piece, to be equal to fifteen times only the diameter of the shot; which diameter he divides, as above, into twenty-four equal parts, making the diameter of the bore equal to twenty-five such parts.

He makes the distance from A, the hind part of the bafe-ring, to D, the fore part of the ventialtage, equal to forty such parts; the breech AC, equal to eighteen, the thinnest of the metal at A, and at D, equal to twenty, and at B, the mouth of the piece, equal to ten. The rest of the con-
construction is the same as above, with this exception, that the diameter, as well as the length of each of the trunnions, is half of being equal to one diameter of the shot, or twenty-four equal parts.

By a similar computation to that made use of above, it appears that this construction allows about one hundred and twenty-four pounds of gunmetal for every pound of the shot's weight, or that the weight of each gun is by it about one hundred and twenty-four times that of its shot, from which proportion, the following table is very nearly framed.

### Brass Ship Guns

<table>

</tbody>
</table>

In his general construction for iron ship-guns, he likewise supposes the length of each piece to be equal to fifteen diameters of its shot; the diameter of the shot to be divided into twenty-four equal parts; the diameter of the bore to be equal to twenty-five such parts; the distance from A, the hind part of the breech, to D, the fore part of the vent, to be equal to forty such parts; the breech to be equal to twenty-four such parts, or to one diameter of the shot; the thickens of the metal in the vent to be equal to one diameter, and at the mouth to half a diameter.

It appears by computation, that the quantity of metal, allowed by this construction, is at the rate of about one hundred and forty pounds, or of one hundred weight and one quarter to every pound weight of the shot; or that each gun is by it about one hundred and forty times as heavy as its shot; from which proportion the following table is derived.

### Field Pieces

</table>

He also gives a construction for iron garrison-pieces, supposing the length of each to be equal to eighteen diameters of its shot, and the rest of the construction to be the same as that for iron ship-guns, allowing thereby about one hundred and seventy-two pounds, and two thirds of a pound of metal to each piece, for every pound of the shot's weight, which proportion produces the dimensions and weights in the following table.

C A N N O N.

Of short Cannon, such as Mortars, Howitzers, and Carro-

Mortars are a sort of cannon with short and large bores, with chambers, and are thought to be the first pieces of artillery that were used, as they were employed to throw balls of red-hot iron and stones long before the invention of shells, which is ascribed to a native of Venlo, who at a festival celebrated in honour of the duke of Cleves, threw a number of them, one of which, falling on a house, set it on fire, which rapidly communicating to other houses, reduced the greatest part of the town to ashes. Mortars which are generally believed to be a German invention, are said to have been actually made use of for military purposes in 1435, when Naples was besieged by Charles the 8th. But whether shells were then thrown out of them is uncertain. It is known, however, to a certainty, that shells were thrown from mortars at the siege of Wachenden, in Gelderland, by the earl of Mansfield, in 1588. Cyprian Lycas wrote upon the method of filling and throwing shells, in his appendix to the colloquies of Tartaglia, printed at London in 1598, in which performance, the method of compounding and throwing carcasses as well as various sorts of fireworks, is also shown.

Mr. Maker, an English engineer, is said to have first taught the French the method of throwing shells, which they practised at the siege of Lamothe in 1634. Mortars, however, have been long made use of, chiefly for throwing hollow balls, called shells, filled with a sufficiency of powder for bursting them, which, falling on any building, or into the works of a fortification, or among troops encamped, forming in order of battle, in column, or landing from vessels or boats, &c. are burst or broken by the force or explosion of the powder in them into a number of pieces or fragments, which, flying in all directions, occasion trepidation and confusion, and are destructive to every thing within their reach. They are also frequently made use of for throwing carcasses, which are a sort of shells with five holes filled with pitch and other combustibles, in order to set fire to buildings. Bullets filled with stones about the size of a man's fist, or of hand-grenades, are sometimes thrown from them during a siege into the covert-way, on the men employed in defending it. The ingenious general DeGouloguins contrived a method of throwing bags from them filled each with from four to six hundred shot of different dimensions. The effect of such an application of them, by pouring down shot somewhat like a shower of hail on spots three hundred feet at least each of them in circumference, must be awful and tremendous to troops moving in column, forming in line of battle, palling a deile, landing, &c. &c.

Mortars are, in this country, commonly distinguished by the diameters of their bores. Thus a thirteen inch mortar, a ten inch mortar, and eight inch mortar, are those which have the diameters of their bores respectively equal to thirteen, ten, and eight inches. These are the three largest sized mortars employed by us for land service. Besides them there are two smaller sized forts of mortars, one of which is called a royal, having the diameter of its bore equal to 5.62 inches, and the other a cohorn, taking its name from its inventor, Mr. Coehorn, the celebrated engineer, and having the diameter of its bore equal to 4.52 inches.

The principal part of a mortar on the outside, (see fig. 4.) are, A the charge, including the muzzle, B the reinforce, C the breech, and D the trunnions. The smaller exterior divisions are, the vent, the dolphins, the vent-arial and fillets, the breech-ring and ogue, the reinforce ring and ogue, the reinforce-arial and fillets, the muzzle arial and fillets, the muzzle-ring and ogue, and the shoulder.

The interior parts are, the chamber which receives the charge of powder, the bore where the shell is lodged, the mouth, and the vent.

The chamber is formed variously by different nations. The Spaniards chiefly use the spheric; the French, the Germans, and the Dutch make use of various forms for it, as the conic, the cylindrie, the bottled or the concave; the Portuguese the parabolic, and the English have usually made it in form of a frustum of a cone. No very satisfactory reasons, however, have been assigned for this variety.

Mortars are made of brass, iron, or steel.

Land-mortars are those that are used in sieges and on other land service mounted on beds. Both their and their beds are transported on truck-carriages. There is also a kind of land-mortal invented by count Buckeburg, which is mounted on a travelling carriage, and may be elevated to any degree at pleasure.

Sea-mortars are those that are made use of for sea-service, such as the bombardment of places by water, &c. As the objects they are fired at and intended to destroy are generally at greater distances from them than those to which land-mortars are required or expected to throw their shells, they are somewhat longer than them and much heavier.

Partridge-mortar is a common mortar surrounded by thirteen other little mortars bored round its circumference in the body of the metal. The large mortar in the centre is loaded with a shell, and the others with grenades. When it is fired by the vent the fire is so communicated at the same time to the small ones, that both the shell and grenades go off at once. The French used them in the war of 1701, at the defence of Bouchain, in 1702, and at the siege of Lille, in 1708.

Hand-mortars were frequently made use of before the invention of coehorns. They were fixed to the ends of flaves about four feet and a half long, of which the other ends were fixed with iron for sticking them in the ground. A bombardier elevated one of them at pleasure with one hand, whilst he fired it with the other.
CANNON.

The dimensions of brass land-mortars now made use of in our service are the following.

Chambers contain powder | - | - | - | - | - |

It is proper to observe, that the extremity of the bore next to the chamber is made round, and formed by an arc, which has its radius equal to that of the bore, and is terminated by the lines that form the chamber. The bottom of the chamber itself is semicircular. And the outside of the metal is determined by a circular arc described from the same centre as the bottom of the chamber, and touching the lines drawn parallel to its sides.

By means of these data, and the foregoing dimensions accurately delivered, such mortars may easily be constructed from the plate which exhibits the form of one.

The following are the dimensions of the sea-mortars that are used at present in our service, (see figs. 5. and 6.), which are of two sizes only, viz. of thirteen inches and ten inches bore.

| The diameter of the bore | 13 | 10 |
| The whole length of the mortar | 63 | 56 |
| The distance from the muzzle to the reinforce | 21 | 20 |
| The length of the reinforce | 18 | 14 |
| The length of the bore | 24 | 30 |
| The length of the chamber | 21 | 15 |
| The greatest diameter of the chamber | 8.5 | 6.6 |
| The least diameter of the chamber | 7 | 6 |
| The breadth of the muzzle-ring | 3 | 2.4 |
| The breadth of the muzzle, oggee, and fillet | 1.9 | 0 |
| From the muzzle to the allragal | 0 | 0.4 |
| The breadth of the allragal | 0 | 1.6 |
| The breadth of the reinforce ring | 1.9 | 0 |
| The breadth of the allragal next to the reinforce-ring | 4.5 | 2.2 |
| The breadth of the chace-ring | 1.5 | 0 |
| The breadth of the chace-oggee | 2.2 | 0 |
| The breadth of the chamber-allragal | 0 | 1.6 |
| The thickness of the metal at the muzzle | 4.7 | 2.8 |

The thickets of the metal at the muzzle-ring | - | - |
| The thickness of the metal near the reinforce | - | - |
| The thickness of the metal at the reinforce | - | - |
| The thickness of the metal behind the reinforce | - | - |
| The length of the trunnion from end to end | - | - |
| Its greatest diameter | - | - |
| Its least diameter | - | - |
| Length or the part diminished at each end | - | - |

The chamber contains powder | - | - |

The thickness of the metal at the muzzle-ring is determined by a circular arc described from the same centre as the bottom of the chamber, and touching the lines drawn parallel to its sides. And in the thirteen-inch mortar it is described from a center about three inches and a half nearer to the end of the mortar than that from which the bottom of its chamber is described. And in both these arcs ought to touch right lines drawn parallel to the sides of the chambers.

The invention of Howitzers is of a much later invention than that of mortars. The Howitzer is, however, one of the most useful pieces of artillery, as it can be employed on most occasions either as a cannon or mortar, and is easily moved by an army from place to place. It has its trunnions nearly in the middle, and is mounted on a carriage like a travelling gun carriage. The ten-inch howitzer is the largest in our service, and is not much made use of. It has been
The dimensions of the eight inch howitzer that we now use. 

The diameter of the bore = 8
The distance from the muzzle to the reinforce =
The length of the reinforce = 18.7
The whole length of the howitzer = 28.4
The length of the bore = 25.9
The length of the chamber = 9.8
The greatest diameter of the chamber = 4.6
The least diameter of the chamber = 4
The breadth of the muzzle ring = 1.25
The distance from the muzzle ring to the atragal = 4.6
The breadth of the atragal = 6.7
The breadth of the ogee before the reinforce = 1.4
The breadth of the ogee behind the reinforce = 0 or it has none.
The breadth of the atragal behind the reinforce =
The breadth of the atragal =
The breadth of the atragal =
The thickest of the metal at the muzzle = 2.25
The thickest of the metal at the muzzle ring =
The thickest of the metal near the reinforce = 3.4
The thickest of the metal at the reinforce = 3.4
The thickest of the metal behind the reinforce = 2.5

The weight of the mortars equal nearly to

Without
Without attempting, as we have already observed, to demonstrate the principles of this general construction, he tells us that he has endeavoured to dilate, distribute, or arrange the metal in such a manner, as to make the relative degrees of strength in the different parts proportional to the forces which act upon them. He thinks the thickness of metal at the chamber sufficient, as it exceeds by two parts the diameter thereof, which is more in proportion than what is ever allowed to any brass gun whatever. He observes that though the mortar on the outside ought to be conical from the chamber to its mouth, to suit the action of the powder, he has, in compliance with common practice, given it a reinforce full sufficient to admit of an ogive.

He tells us he does not pretend to determine the true position of the vent, though he had always found that the nearer it was placed to the bottom of the chamber, the farther the mortar threw the shell with a given charge of powder. As he made these experiments, however, with only a three-inch mortar, he apprehends that no just conclusions can be drawn from them with regard to mortars of a larger size.

He delivers it as his opinion, that the cylindric figure is the best for the chambers of such mortars, observing, that though the bottlenecked or conical chambers, or those which have the smallest entrances, will throw shells farther than any other; yet in those which require but little powder, their entrances would be too narrow, and it would be troublesome to clean them; whereas, when they are cylindrical, they are very nearly as advantageous for throwing shells without being subject to these inconveniences.

He informs us, that lie and general Desaguliers made several experiments with chambers of different forms or figures, which contained the same quantity of powder, and uniformly found, that the cylindric threw the shell farther than any other, of which the entrance was larger, particularly when they were not quite filled; that they also made some experiments with cartridges of common writing paper holding charges of powder only equal respectively to half the content of the chamber, and found that when such a cartridge was so placed in the chamber as to be close to the shell, leaving a vacancy between it and the bottom, it threw the shell nearly twice as far as it did when it touched the bottom of the chamber, and left a vacancy between itself and the shell; that these experiments were repeated several times, and always gave the same result. He also informs us, that on filling the chamber partly with powder and putting a piece of common writing paper upon it, he found that the shell went much farther than the same charge without paper threw it; that they likewise made repeated experiments with a cylindrical chamber, and a conical one of the same length and content, that had its diameter at the bottom equal only to half that at its entrance, and observed, that when these chambers were not quite filled, the cylindric alone uniformly threw the shell much farther than the other did.

The first sort of mortars in this general construction, or those of which the weights are expressed by \( \frac{5}{6} d^3 \), have the same lengths which the land mortars have that we now make use of. The second, or those of which the weights are expressed by \( \frac{2}{3} d^3 \), are of the same lengths with those the French have been in the practice of using. And the third sort, that have their weights denoted by \( \frac{3}{5} d^3 \), are shorter than either. In each of them the chamber is cylindric, and the bottom of it a hemisphere. And the sound part of the mortar is described from the same centre as the bottom of the chamber.

In his general construction for sea mortars, the dimensions are the following. See fig. 9. Our sea mortars, as we have already observed, are of two sizes only, viz. of 15 inches and 10 inches.

Besides these kinds of mortars for throwing shells and carriages, there is another sort of mortar for throwing stones either by the besieged from the body of the place, the outworks, or covert way into the besiegers approaches on the glacis, &c. or by the besiegers into the covert ways as they approach the same. There are no such mortars employed in our service; because hand-grenades, or small shells thrown from a common mortar with small charges of powder, answer the purpose intended much better than stones.

The following, however, are the dimensions of a fifteen-inch stone mortar, supposing the diameter of the bore to be divided into thirty equal parts. See fig. 12.

</tbody>
</table>

The length of the howitzer - - 2.25 d^3
The quantity of powder in lbs. - - d^3 / 1102
The weight of the howitzer - - d^3 / 318

The length of the caissons is equal to 24 such parts, the radius of the button to 8, and the oggee with the fillet included is equal to 4.

It is somewhat surprising that howitzers are not more made use of than they are even in the field. For they may be employed successfully for throwing, not only large shells, but large, solid, or cored shot, either point blank, or with small angles of elevation, and with charges of powder suited to different ranges and grazing distances to the great annoyance of the enemy. They are also much fitter than guns for discharging grapes of small shot and small shells from short distances at close quarters, and are peculiarly calculated for sweeping or scouring the covert way along its several branches with shells fired en ricochet. No earthworks are proof against them when a judicious use is made of them. Even at sieges, when the works have revetements, or demi-revetements of masonry, as soon as the walls which support the earth of the rampart and parapet are
are battered down, there is no speedier or more effectual way of completing the breaches and rendering them practicable than by throwing shells into the earth where it is hard of mastery. For they lodge or bury themselves in it, and burrowing operate as small mines.  

Fig. 11 represents a mortar with a bottled or concave chamber, the diameter, $ab$, of the entrance of which is a third part of the diameter of the bore. The distance from $ab$ to $cd$ drawn parallel and equal to it in the longitudinal section is equal to twenty-six inch parts as those, of which the diameter of the bore contains thirty. The conjugate diameter of the chamber is equal to twenty six parts. The form of the outside of the mortar, where the chamber is, is similar to that of the chamber itself. The thickets of the metal at the chamber is equal to fifteen inch parts, and all the other dimensions are the same as in the first construction for mortars above.  

As the entrance of the chamber has its diameter equal to a third part of the diameter of the bore of the mortar, it is large enough in one of either thirteen or ten inches for admitting a man's hand to clean it without inconvenience, and may therefore be loaded without difficulty.  

Besides these pieces of ordinance, there is another, that is now pretty generally used, and is called a carronade, from a foundry that has for a considerable time been carried on by a company under the name of the Carron company, on the banks of the river Carron in Scotland. The carronade is a gun of a fort intermediate length and weight between the cannon and the howitzer, and not a very short howitzer, as the celebrated Dr. Hutton has inadvertently observed in his Mathematical Dictionary. The first howitzer, propeller, or inventor of it was the present learned and ingenious General Robert Melville, so well known for his talents as a military antiquarian, and the discoverer of the temporary Roman camps in North Britain. He at first suggested that not only solid but shell shot might be thrown from it, and afterwards that it might be employed for throwing carcasses and cored shot. The first gun of this nature was cast and constructed according to his suggestions at Carron in 1779 after a rupture with France, and during the American war. The operation was performed under the directions of that very able founder, Charles Galcoigne Esq., then director of that foundry.  

The diameter of its bore was equal to eight inches, having the same caliber with an eight-inch mortar or howitzer.  

The length of its bore including the chamber was equal to six diameters of the same very nearly, or to six times its caliber or four feet.  

The diameter of its chamber was equal to the caliber of a forty-two pounder gun, and contained five pounds and a half of powder.  

Its weight was nearly equal to that of the navy twelve pounder gun, being equal to 31 cwt.  

The boat was cast in an eight-inch spheric iron mould, and the windage was formed by the retreat or shrinking of the metal of the shot in cooling, which when cold weighed about 68 pounds, or about four pounds less than a solid iron shot or ball eight inches in diameter, which weighs about 72 pounds very nearly. From this circumstance it came to be called a 68 pounder, though its original propoer or inventor gave it the name of a smaller from its effects, particularly when fired with shot at timbers or wooden work. It was at first designed for a ship gun. And there is now in the possession of General Melville a small model of it mounted on its carriage on a small platform, to one end of which is fastened a wooden representation, in miniature, of part of a ship's side, with a port, and the following inscription in brafs, let in on the top thereof.

"Gift of the Carron company to Lieutenant General Melville, inventor of the smaller and better carraonades for solid, chip, shell, and cored shot, &c. first used against French ships in 1779."

In the middle of the lower carriage there is a longitudinal groove, along which the gun on its upper carriage rolls. And when so mounted, it may be pointed in any angle less than forty degrees either to the right or left of this groove. A port or embrasure large enough for a 24 or 32 pounder gun is also sufficiently large for receiving the smaller or 68 pounder carronade.

Several experiments were made with one of this calibar the same year, viz. in 1779, at Carron, in the presence of Sir Adolphus Oughton, K. B. then commander in chief in Scotland, General Melville, and many other officers, some of whom were of the corps of artillery and engineers, with much success, both in regard to the projectile force, with which the shell-shot were thrown, and not only the practicability but also the certainty of their producing powerful effects, by hurling wherever they should penetrate, as perfectly convinced Sir Adolphus and all the rest, that in all the cases, which might be many, by sea as well as by land, for the use of this species of artillery, the introduction of such pieces of ordnance both into his Majesty's naval and military service would be of the greatest utility and advantage. Sir Adolphus thought it therefore his duty to transmit to government a fair and candid report of the experiments he had seen made, and a statement of the advantages which he conceived might be obtained by a judicious and proper use of such guns. It happened, however, that no encouragement was then given to the introduction of this species of cannon, though it was so respectably recommended and approved by intelligent profissional men, because it was regarded as a novelty, an innovation, and a departure from common haxked practice and customs, by which public boards, that are but rarely composed of individuals of the first talents, liberality, and information, are for the most part too studiously governed. The proprietors of the Carron foundry, however, were advised to try whether pieces of smaller dimensions, cast and constructed on the same principle, would not meet with a sufficient sale for private vessels of war, as letters of marque and reprisals, and perhaps for some of the royal frigates. They made the trial, and succeeded. For besides a pretty frequent demand that was made for them during the remainder of that war for the use of the two former descriptions of vessels, on account of the great advantages they were found in practice to possess over common guns of the same weights, and much smaller calibers, there were some of the larger fort or of 8 inches caliber, called carronades by the original propoer, introduced by degrees into the navy.  

Two of the naval officers, who first made use of them on board their ships, were Captain Keith Elphingstone, now Admiral Lord Keith, and Captain Henry Trollope, now Sir Henry Trollope, the latter of whom, in a most remarkable instance, by means of two carronades which he had on board his frigate, beat off several of the enemy's, who were panic-struck on viewing the size of some of the shot he fired into them.

Soon after the commencement of the royal war against France, in which Great Britain engaged early in 1793, carraonades of various dimensions, but few of the larger size, or smallers, improperly called 68 pounders from each of their solid iron-balls, which are not near so fit for sea service as hollow or cored shot of the same diameter, but much lighter, came rapidly into use in our ships of war and other armed vessels, and often proved to be of the greatest utility and adv.
vantage. They have ever since been reckoned so useful, that there is now hardly a ship in our navy or an armed vessel, that is altogether without them.

When the carronades were first introduced, they were meant chiefly for the defence of merchant ships, and were calculated, by their construction, to be of such lengths and weights as might be convenient for the sizes of the vessels that were to carry them, supposing each of them to be loaded with a twelfth part of the weight of the shot, as the service-charge of powder. The Board of Ordnance was pleased to order a number of them for the navy: and their first warrant for about 1500 of them was completed before Mr. Gascoigne was certainly informed that the board had fixed on one-ninth instead of a twelfth part of the weight of the shot as the charge of powder for service. These were therefore reckoned both too light and too short for the navy. And on the Board's afterwards ordering 20 carronades of each of the natures of 12, 18, 24, and 32 pounders, he very naturally took the liberty of adding both to the length and fortifications of each of them, so as to increase its strength and power of resistance to burtiling, in proportion to this perhaps ill-judged addition to the charge of powder, substituting also a screw instead of the quoin or wedge. Forty of them were proved at Woolwich, and were afterwards rejected on account of these very improvements.

The late colonel Frazer, of the engineer corps, made a number of experiments at Leith with a smaller, or 68 pounder carronade, both with its own solid shot and with common eight-inch shells, which were corroded by rust, and, independent of that circumstance, had by far too much windage. And it is worthy of remark, that notwithstanding this, the shells went farther than the solid shot before they met the surface of the earth or of the water, or had their first grazes greater when the gun was fired, either horizontally or point blank, or with any elevation not exceeding two degrees, but that with any elevation from two degrees upwards the solid shot went farther.

The following is an exact statement of experiments made at Languard fort on the 27th and 28th of July, 1780, by order of marquis Townshend, and master-general of the ordnance, and comparative trials with a ten and eight-inch howitzer.

Practice with a 68 pounder carronade, or smaller.

The weight of the piece in cwt. qrs. lb. 29 0 6.

The length of the piece in feet and inches, from the hind part of the base ring to the muzzle, 3 11 1.

The length of the bore, chamber included, 3 11.

The diameter of the bore, 8 inches.

The nature of the rope for breeching, 2 1 inches.

The length of the recoil, in feet and inches, 12 3.

Weight of the solid shot, 68 lb.

Weight of the shell shot, 57 lb.

</table>

A 10 inch brass howitzer, weighing 23 cwt. 3 qrs. and 7 lb. fired horizontally, or point blank, with five pounds of powder, had its first graze at the distance of 172 yards, with one degree of elevation at 250 yards, with two degrees of elevation at 300 yards, and with three degrees of elevation at 414 yards.

When fired horizontally, or point blank, with six pounds of powder, it had its first graze at the distance of 80 yards, with one degree of elevation at 225 yards, with two degrees of elevation at 290 yards, and with three degrees of elevation at 445 yards.

An eight-inch brass howitzer fired horizontally or point blank with two pounds of powder, had its first graze at the distance of 119 yards, with one degree of elevation at 195 yards, with two degrees of elevation at 200 yards, and with three degrees of elevation at 246 yards.

When fired horizontally or point blank with three pounds of powder, it had its first graze at the distance of 125 yards, with one degree of elevation at 208 yards, with two degrees of elevation at 278 yards, and with three degrees of elevation at 336 yards.

The recoil of the ten inch howitzer fired horizontally or point blank was 11 feet with 5 pounds of powder, and 13 2 feet with 6 pounds of powder.

The recoil of the eight-inch howitzer fired horizontally or point blank with 2 pounds of powder was 10 feet, and with 3 pounds of powder 16 feet.

An iron 24 pounder, of the late lord Howe's construction, fired with six pounds of powder and one degree of elevation, had
had its first graze, on a medium of four trials, at the distance of 4713 yards; and with five pounds of powder and the same elevation, on a medium of two trials, at 5075 yards.

A 32 pounder iron gun fired horizontally or point blank with high shot and four pounds of powder, had its first graze at the distance of 200 yards, with the same shot, charge, and one degree of elevation at 405 yards, and with two degrees of elevation at 675 yards.

And the same gun with the same charge, point blank, and the same elevations, but with low shot, gave the first grases at 220, 395, and 665 yards respectively.

These experiments clearly prove the great superiority of the smaller, or 68 pounder cannonade, over not only the eight-inch howitzer of the same bore with it, but also over the ten-inch howitzer, which is the largest in our service, and has its point of failure at 100 to 641 and the diameter thereof to that of the smaller as 10 to 8.

They also shew, that it is nearly on a footing with the common iron 24 and 32 pounder, as to its first grazing distance, which is a material point in sea-service, and has greatly the advantage of them, particularly in close combat, by the size of the holes which its shot make in the side of a ship, and from their likewise passing through the same with less velocity. For a shot, especially if its diameter be but small, that passes very quickly through a ship's side, makes only a clean hole, whereas one of a large diameter, that penetrates it with less celerity, makes a rough and ragged one, by tearing and splintering the planks and timbers. And it is well known that shot fired at sea with a greater elevation than five degrees, are of no use whatever, unless they hit the object they are fired at before they meet the surface of the water, as they never graze or rise again from it when fired with so great an elevation. It may be objected to the use of smallers on board a ship, that their shot are too heavy to be easily handled and put into the gun. This objection holds good against the use of them with their shot in its solid form, which of all others is the most unfit for sea engagements. It vanishes, however, when it is considered that the weight of its shot may be reduced by leaving it hollow, or with a core in the centre, from 68 pounds down to 34 pounds and under, and still retain thickness and strength of metal enough for penetrating the side of any ship whatever. This fact has been established by even the possibility of controversy by some experiments that were made at Woolwich in 1781, in the presence of general Melville who proposed them, and his grace of Richmond, then master-general of the ordnance. For in July that year Mr. Gofeigne sent from Carron to Woolwich for that purpose fix hollow smaller, or 68 pounder cannonade shot, weighing from 55 pounds to 551/2 pounds, six others reduced in weight from 68 to 50 pounds; six others weighing only from 43 to 40 pounds, and six reduced down from 41 to 32 pounds so low as from 43 pounds to 40. The lightest of these were fired into a bulk-head, as thick as the side of a first rate, from a suitable distance. They easily penetrated it, and one of them, after penetrating, striking against an oak poll or fluid, nine inches square, tore, shattered, and splitted it amiss to pieces. The master-general, after viewing its effects, said it would have been a terrible shot against a ship, and very judiciously observed, that as the lightest of these hollow shot were found to answer perfectly, it was unnecessary to try the heavier ones. We are convinced, indeed, that the shot of a smaller, or 68 pounder cannonade might, by means of concentric cavities, be reduced down to the weight of 32 pounds, and still retain strength and thickness of metal sufficient for penetrating the side of any ship. In this state they would be much more easily handled than a common 32 pounder shot, having a larger diameter and a much larger surface. These experiments shew, that they are sufficiently strong for that purpose when brought down to within eight pounds of that weight. And if, in addition to this fact, it be also taken into consideration, that a multitude of experiments made with smallers, or 68 pounder cannonades, concurred in establishing this point, that when fired either point blank or with any elevation not exceeding two degrees, the hollow shot went farther than the solid shot before they met the surface either of the ground or water, it must readily be allowed, that they are peculiarly calculated for naval combats. But were these hollow shot to be fired as shells, with a sufficiency of powder in their cavities for burying them, they would be truly terrible and tremendous to shipping in a sea-fight. It may be alleged, that the enemy would soon also get into the use of them as shells. It is true that after a time he might: but however shall make this use of them in a great naval action, he will certainly derive infinite advantages from it. And we trust our enemies will not be the first to make such an application of this very useful piece of ordnance.

Of the position of the vent in cannon, and other pieces of ordnance.

Also the inflammation of fired gunpowder is almost instantaneous, it is natural to conclude, that the impulsive force of a given charge of it is not, ex parte, sensibly altered by its being fired in any particular part or point of it; and of course, that neither the initial velocity nor range of a ball is sensibly affected by the position of the vent. This is a fact that has been sufficiently established by experiments made at Woolwich, by the learned Dr. Hutton, and several respectable officers of artillery, under the authority and direction of the board of ordnance.

The vent is vulgarly called the touch-hole; and is the narrow cylinder or opening through which fire is conveyed from the outside of the piece to the powder that composes the charge.

Formerly both theorists and practitioners differed widely from one another in regard to the proper position of it. It has been customary to place it from one quarter of an inch to half an inch from the bottom of the chamber or bore, and sometimes a whole inch. An idea prevailed, that if the vent were directly opposite to the middle of the charge, the powder would be inflamed in less time than in any other place, and that the explosion would of consequence produce a greater initial velocity and range. This erroneous conclusion was founded on the supposition that if a tube were filled with powder and lighted in the centre, the powder would be burnt in half the time that it would be lighted at either end, and on inadverted to this circumstance, that the inflammation of fired gunpowder is so nearly instantaneous, that no sensible difference as to the time in which it takes place can arise, from the firing of a charge in the centre in preference to any other part of it. In order to determine this point, Frederic the Great, or the Second, of Prussia, ordered a light three pounder to be cast with three shifting vents, one at the centre of the charge, one at the bottom of the bore, and the other at an equal distance from the bottom and centre one; so that when one was used the other two might be flopped up. The gun weighed 2 cwt. 1 qr. 20 lb. Its length was three feet three inches, and the bottom of the bore, instead of being rounded, was quite flat. It was loaded each time with one quarter of the shot's weight of powder. It was found that when the lowest or bottom-vent was used, the ranges were rather the greatest, and that they were somewhat less as the vent was more and more distant from the bottom. The differences, however, were so small, that they might very easily have been produced by the least inaccuracy in making the experiments, or by the gun's being a little more heated at the time of making
Cannon.

making one than another, and but little reliance can be placed
on them.

On the form or figure of the chamber of a piece of ordnance.

The chamber of a gun, mortar, or howitzer, is the cavity
at the bottom of the bore, that receives the charge of powder,
and communicates with the vent, through which the
fire of the priming is communicated to the same. There
are but few guns that have chambers, except some of the
larger sizes and calibers, as it has been found by experience,
that they have scarce any sensible influence or effect on the
velocity of the shot in small and middle sized ones.

Various have been the opinions of authors and artilleryists
respecting the forms or figures of chambers; and different
nations have had them constructed very differently. The
Spanish have been in the practice of using chiefly the
spherical chamber for their mortars; the French, Germans,
and Dutch, the conic, cylinidrical, and the concave, or
bottled, or the chambre à pois, or pear chamber. The
Portuguese have made use of the parabolic form, which was
first suggested or invented by comte de Lippe Buckeburg.
And the English have been in the habit of making theirs in
the form of a frustum of a cone.

The cylindric chamber is that which is equally large every
where, or has the diameter of its bore in every place or part
of it the same. This is found to be by far the most
commodious form for great guns or cannon of a large caliber,
and is indeed almost the only kind of chamber that is made
use of in such pieces of ordnance.

The spheric, or spheroidal chamber, as its very name im-
paints, is that which is made in the form of a sphere, or bul-
et, or at least very nearly so. This sort of chamber for
guns, or cannon, was invented towards the close of the fe-
venteenth century. The object of this invention was to
throw balls and shot with as much force from short, light
and easily transportable cannon as that with which they
were thrown from the long, cumbersome, and ponderous
pieces then in use. It was found by experience, that the
advantages expected and proposed were obtained by this
alteration in the interior arrangement of the bores of guns,
or by the construction of such pieces. For though they were
made a good deal shorter than those formerly made use of,
and were fired with a smaller quantity of powder, they pro-
duced the same effects. But as it was difficult to wipe, or
clean out the interior cavities of such chambers after the
cannon were fired, some fire frequently remained in them, which sometimes occasioned the loss of arms to the
cannoniers, or the persons who were employed to serve and
manage them. Besides these inconveniences, they were at-
tended with others; for the inflamed powder, before it quitted the chamber, acted in all directions with such force
and impetuosity, that their carriages were soon either
broken or rendered unserviceable. They receded very much
and fired with little certainty. For these reasons, guns
with spheroidal chambers were totally laid aside; and soon of
them as were found in the arsenals and fortresses in France
were cast again into cannon, having cylindric bores every
where equal and alike. The guns commonly made use of
at present have no chambers, except some of the largest
calibers. And even these have their chambers cylindrical.

The very ingenious Mr. Robins in the scholium to the
ninth proposition in his new principles of gunnery affords,
that what some authors have advanced in regard to the ad-
vantages of having particular forms for the chambers of
mortars and cannon, is altogether inconclusive, and founded
on erroneous conceptions of the action of fired gun-powder.
The learned Mr. Euler, however, in his commentary and
remarks on Mr. Robins's treatise, contends for the spheroidal
chamber as the best. He admits that Mr. Robins's con-
clusion would be true did the inflammation of the powder
take place in an infant. He allows, that the force of the
powder on the supposition of its firing instantaneously would
be the same, whatever be the form of the space behind the
flot or shell that contains it, and whether this space be ei-
ther wholly or only partly filled with it. He also allows,
that its impelling power after the ball or shell is once in
motion, will in this case be the same, as well as its first
impulsive force, whatever be the form of the chamber; that if
no better reafon than the increafing of the impelling force
can be allotted for changing the figures of chambers, either
in guns or mortars from all proposi-
tions for altering them, except such as tend to render them
more convenient and commodious, ought to be rejected with-
out further examination.

Leaning, however, towards an opinion of professor Ber-
noulli, that the elastic force of the fluid generated by the
explosion of gunpowder, is nearly ten thousand times greater
than the pressure of the atmofphere, he supposes the in-
flammation of gunpowder to be gradual instead of being al-
moft instantaneous, and therefore concludes, that chambers
may be improved by changing their figures, and that the
spherical form is the best of all, as being capable of holding
the greatest quantity of powder under the fame circum-
ference, as better calculated than any other for keeping the grains
near, or contiguous to one another, and for quickening,
or accelerating the explosion. The experiments which he ap-
peals to, and produces for establishing this hypothesis, are
altogether inconclusive, and must have been conducted with
great inaccuracy, or intention to some circumstances that
were conected with, and influenced them. They were
made in preference of him, Mr. Bernoulli, and several other
members of the academy at St. Petersburg, by general Gun-
ther in 1728. And from two of them he infers, that a ball
fired vertically with eight ounces of powder from a piece,
which had the length of its cylinder equal to 77 English
feet, slipped out of it with three velocities which it affixed
with, fired with the same quantity of powder from the
same piece, when the length of its cylinder was reduced to
six feet, by having one foot and seven-tenths of a foot off
from it. Taking this inference too precipitately for granted,
he observes, by way of proving the great inaccuracy of Mr.
Robins's position, "that all the powder of the charge is
fired and converted into an elastic fluid before the bullet is
famously moved from its place;" that according to this the-
ory, the velocity instead of being thrice as great would have
differed from the other three perceptibly, and therefore
most erroneously concludes, that the greatest part of the
powder must have fired whilst the ball moved through the
half font and a half of the bore of the piece, before it was
reduced in length. Now, the quadruplicate ratio of $7 + \frac{7}{9}$
to 6, or of 77 to 60, is that of $35,153,540.14$ to $12,960,000$,
which is considerably less than the ratio of three to one. Mr.
Euler then makes the velocities of the same, or equal shot
fired with the same charge of powder from bores of the fame
diameter, but of unequal lengths in ratios to one another,
respectively greater than the quadruplicate ratios of these
lengths. We know, however, from experiments made
with incontestable accuracy at Woolwich on Mr. Robins's
plan improved, that these velocities are in ratios somewhat
lefs than the subduplicate ratios of the lengths of the bore,
but in ratios somewhat greater than the subtruplicate ratios
of the same lengths, and nearly indeed in mean or middle
ratios between the two. Mr. Euler's making the ratios of
these velocities ten times as great as they really are, proves
incontrovertibly both his theoretical reafonings, and his ex-
perimen-
experimental inference against the position of the almost in-
flammatious firing of gunpowder, and in support of the hy-
pothesis of its firing gradually in the way he describes, to be
completely erroneous.

The objections he endeavours to draw from rifled pieces
against the truth of Mr. Robinson’s seventh proposition, being
inconsistent with facts and experiments, are likewise fallaci-
ous and inconclusive.

A conical or conical chamber is that which is in the form
of a frustrum of a cone, with its bottom sometimes circular,
but generally hemispherical, or nearly so. We have been
in the habit of using such a form for chambers with the
greatest diameter of each at its mouth, or entrance, contrary
to reason and principles, which point out the advantage and
propriety of having the impulse of the inflammable powder made
on the shell or bullet as near to its axis, or to that of the
bore of the piece as possible.

Count Buckeburg proposed the parabolic form, or that
of a paraboloid, or parabolic conoid, which has been made
use of by the Portuguese as the best, erroneously supposing,
that were the line introduced to the focus, the rays of light
powder would by the nature of the figure be reflected into
parallel directions like the rays of light.

A concave chamber is that which has its mouth or en-
trance narrower than its inside cavity. It may be spheric,
spherical, in the form of a pear, called by the French, one
chambra poire, in the shape of an egg, of a bottle, and a
variety of other forms.

Much more, however, depends on the entrance of the
chamber, than on its form or figure. The entrance ought
to be directly opposite to the middle of the ball, or shell,
and to have no greater width than what is necessary for
cleaning out the chamber, which should contain no more
powder than the greatest charge proper for service, to pre-
vant as much as possible any vacancies being left between it
and the shell or bullet. As the cylindric is the most con-
venient form for being easily cleaned out, it ought to be
preferred to others on account of its simplicity. For, in
most of the affairs of life, and more especially in those of
war, of all things of the same kind, the simplest are the most
commodious.

Of the position of the charge of powder.

Every experiment that has been made respecting the posi-
tion of the charge of powder, proves the advantage of its
lying close to the ball or shell. Among others, the follow-
ing are well deserving of notice.

The ingenious general Deguignies in 1753, and Mr.
Muller, then professor of fortification in the Royal Military
Academy at Woolwich, made a number, repeatedly with a
small mortar, which had several shifting chambers.

Into a narrow cylindric chamber of about four inches
long, and holding about twelve grains of powder, there was
put a thin cartridge filled with six grains. This cartridge
was placed in the chamber in such a manner as to lie close
to the shell, leaving a vacancy or empty space between it
and the bottom of the chamber, and was fired by means of
a quick match, introduced through the vent. A cartridge
of the same size, and containing the same quantity of pow-
der, was then put into the fame chamber, but placed at the
bottom of it, leaving an empty space between the powder
and the shell, and was fired in like manner. Lastly, an
equal cartridge with the fame charge of powder was placed
in the middle of the fame chamber, or equally distant from
the bottom thereof and from the shell, and was fired in the
same way. These experiments were frequently repeated,
and it was found, on every repetition of them, that in the
frill case, the shell was thrown nearly twice as far as in the
second, and that the distance it went to in the third case,
was about an arithmetical mean between its ranges in the
frill and second.

They also found, that when the same quantity of powder
was put loose into the fame mortar, and a piece of writing
paper laid on it, the shell was thrown considerably farther
than it was by the fame charge of loose powder without the
paper.

They likewise found, that three cylindric shifting cham-
bers of different lengths, but holding the same quantity
of powder, produced, when filled, equal ranges, but that
when they were not quite filled, the longest gave the great-
est range.

They also tried some experiments with two chambers in
the form of a frustrum of a cone, one of which had its largest
diameter at the bottom, and the smallest at the entrance,
and the other its smallest diameter at the bottom and the
largest at the entrance, and always found, that the ball of
these with the same charge of powder, threw the shell far-
ther than the second.

General Deguignies also found by experiments, that
grained and mealed powder were about equally strong when
in good order and condition; but on putting a small phial
filled with water into the chamber amongst the powder, he
observed the strength of the charge to be considerably in-
creased.

Of the Windage.

The windage of a gun, mortar, or howitzer, is the dif-
ference between the diameter of the bore and the diameter
of the shot or shell. We have been in the practice and still
are, of making it equal to a twentieth part of the diameter
of the shot in every gun except the carronades. The Dutch
have commonly made their windage nearly the same as ours.
The French have been in the habit of making theirs a twen-
ty-sixth part of the diameter of the shot. And the Prussians
make the diameter of the bore of the gun to the diameter
of the shot as 25 to 24. This is a most convenient proportion.
But it makes the windage much greater than it ought to be.
There seems to be no very good reason, indeed, for making
the windage bear any given or determinate ratio to the di-
iameter of the shot, since if the bores be true, the same wind-
age that answers for a small shot will be sufficient, or nearly
so, for a large one. The smaller the windage, the greater
and truer will be the flight of the shot or shells; for when
it is great, they are apt to injure the bore by bouncing from
side to side, and also, at leaving it, to receive from this kind
of motion a sort of cant or deflection from the line of their
direction. With our present windage for guns, except car-
ronades, from one fourth to one half of the charge is lost
and rendered useless. Short guns, indeed, with small
charges of powder and a very small degree of windage will
be more useful and serviceable than guns twice as long with
double charges of powder and a large windage. We will
not undertake to determine precisely what the windage
ought to be. But we are inclined to think, that if the shot
and shells were cast in models having exactly the diameters
of the bores of the different pieces of ordnances for which they
are intended, the retreat or shrinking of the metal in cooling,
will for both leave a sufficiency of windage. The windage
we have been in the practice of allowing for shells of all
sizes, is a quarter of an inch, which is preposterously large
and beyond all due proportion. Were it reduced even to a
third or fourth part of that quantity it would be insufficient.

In our common 12 pounder, 18 pounder, 24 pounder,
32 pounder, and 42 pounder, there is allowed respecti-
ably a wind-
a windage of 0.22 inches; 0.22 inches; 0.27 inches; 0.305 inches; and 0.534 inches. But in our 12 pounder, 18 pounder, 24 pounder, 32 pounder, and 42 pounder caronades, the windage is only about 0.097 inches; 0.1 inches; 0.123 inches; 0.145 inches; and 0.166 inches respectively, which gives them a great advantage and saves much powder.

Of the casting and boring of cannon.

The casting of a gun in its first and limited sense is, the running of any fort of metal or mixture of metals, of which the gun is intended to consist or be composed, into a mould prepared for receiving the fame, and having its inside of such a shape, as to form the outside of the gun. But the casting of cannon in its more general acceptance, includes every thing, and operation preparatory to, necessary for, and connected with the forming of them, such as the making of the molds, moulds, &c., &c. for all which see the article Foundery.

Cannon, as we have already observed, were originally made of bars of iron fitted together lengthwise, or of sheets of iron rolled up and fastened together, and hooped with iron rings. They were ponderous, clumsy, cumbrous, in a great measure unmanageable, and could not be transported from one place to another with great difficulty and labor. They were chiefly employed for those late flames like the machine of the ancients, which the succeeded by bars cannon, which had much smaller calibers, and threw iron bullets instead of stones, but produced in a few hours greater effects than the others could in many days. These guns were first cast of a mixture of copper and tin, called gun-metal from that circumstance, which continued to be employed for that purpose a long time before cast iron was made use of. In the course of time, however, as the use of artillery became more general, and the number of cannon greatly increased, iron guns were invented by way of lessening the expense. An idea, however, that prevailed of their being very liable to burst when much heated by firing, retarded the general introduction of them into service, and was the cause of their being made much heavier than brass guns of the same calibers. And this apprehension strengthened by some accidents of the kind that took place either through improper management, or the carelessness and unskillfulness of some founders, has militated against the general use of them even down to the present time. When cast, however, with the iron obtained from good virgin ore, which the founders can give any degree of malleability, of which the Carron company and others have afforded many proofs and speciments, they resist bursting as much as brass cannon, and possess great advantages over them, as these are composed of ingredients, that melt with different degrees of heat, and are thereby not only liable to be soon injured when much heated, but also to be rendered in a short time totally unserviceable by quick and continued firing.

Till about 40 years ago, cannons were cast with a cylindrical cavity in each of them, having nearly the same diameter with the intended caliber of the piece, which was afterwards enlarged to the proper size by machines, one of these is represented. See Cannon, fig. 13. Two cast iron bars, A, A, were confined in a vertical position, by being ferreved to the four beams, B, C, D, E; between thefe bars a cast-iron frame, C, was at liberty to slide; to which frame the gun, D, D, was fixed by a band, e, across the base ring, fixed by two screws, another similar band, f, fixed across the chace, and two smaller ones, a, a, ferreved across the trunnions, to prevent the piece from turning round by the action of the drill-bar, E; a tin or copper pan, F, was fixed on the drill-bar for containing the chips of metal separated from the piece by the borer on the top of the drill-bar. After the gun was prepared by boring, by cutting off the cap or piece of metal at the muzzle with a saw, it was brought under the frame, C. The two blocks of pulleys, G G, were unhooked from the frame (which was let down and refixed on the bottom of the bars A, A), let down and fastened to the gun below, by chains, to hoist it up into the frame, C, where it was fixed by the screws; the pulleys were then hooked into the top of the frame, to raise it with the gun, high enough to introduce the borer; the pulleys were afterwards slackened, and the drill-bar, which worked in a socket in the ground, set in motion by horses or otherwise, the gun being kept to the work by its own weight; when the gun was bored far enough, it was prevented from descending any farther by the block, H, which was adjustable by screws, to the proper length of the bore; when the piece was bored, the pulleys were again unfixed to support it, while it was detached from the frame, and afterwards to lower it down.

Owing to the unequal contraction of the metal between the core and the outside of the mould, guns cast hollow were always more or less pouncy, and numberless cavities were formed round the core, some of which were too deep for the chasers, and other parts of the surfaces have occasioned the old method to be laid aside, and guns are now uniformly cast solid. The old machines also, where the gun was fixed, not being found to bore always in the right direction, several new machines have been substituted, some of which are represented in figs. 14, 15, 16, and 17.

Fig. 14, is a machine used at the Carron Iron Works. In this, contrary to the former one, the gun, B, is turned by the shaft, A, moved by a water wheel; the drill-bar, E, is advanced by a weight, C, acting on a bent lever, whose fulcrum is F; when the weight, C, has descended to the floor, or nearly, it must be lifted up, and the point, G, then acting as a fulcrum, the rod, H, will be drawn forwards, one or two teeth of the rack, J, and the weight will be ready to act again as before. The gun, B, is fixed by a square lump cast on the end of the caisable, into a coupling box, and wedged up, and the choice of the gun moves in a collar. The only guns cast at these works are caronades.

In fig. 15, the gun is fixed in the same manner as figs. 14 and 17, except that the box, K, is fixed by ferreves instead of wedges, the drill-bar, E, rests on a block, F, and when it is brought forward by the motion of the carriage, G, moving on wheels, a a, to diminish friction; to the bottom of the carriage, a rack, I, is fixed, working into a pinion, L, the rack is kept to the pinion by a roller, b; on the end of the axis of the pinion a capstan-head is fixed, with mortise-holes in it, to contain one end of an iron bar, d, while the other is loaded with a weight, C, for advancing the borer, and is shifted into a fresh hole as often as the weight descends to the ground.

In the machine, fig. 16, the muzzle of the gun can be elevated or depressed, to suit guns of different bores, by ferreves, e, between the two plates, a b; the plates can also be moved farther from or nearer to the coupling box, by a screw, d, to suit guns of different lengths; the two blocks, F G, between which the rack, I, is fastened, are fixed down to the beams, A, B; the pinion, L, is fastened to the block, M, which can slide between the beams, A, B, and has wheels above and below the beams, to diminish the friction; to this block, the end of the drill-bar, E, is fixed; near the other, it rests on the block, F; on the end of the axis of the pinion is a wheel, f, with teeth parallel to its axis, on the end of which axis the bar, g, is loosely fitted; to the other end of
of the bar the weight, \( c \), is hung; when the weight is down, the bar must be fled along the axis, far enough to be lifted up clear of the teeth, and in to be puffed back into its place again, above the next tooth.

The machine at the Royal Arsenal at Woolwich is shown in fig. 17. The two supports of the gun, A B, are of solid brass, and well polished; the drill-bar, E, slides on a strong table, with the rock, I, at its end, the axis of the pinion, \( o \), is upright, and has a wheel, \( d \), at its top, working into an endless screw, \( c \), which has a wheel, \( f \), upon the end of the spindle, with handles on its circumference, for two men to turn it round by; on one of the spokes, \( g \), a common handle is fixed, to turn the wheel back, for withdrawing the drill-bar; the pinion, endless screw, and wheel, \( d \), are enclosed in a brass box, which supports their axes. We think this machine might be improved, by having the pinion horizontal, and applying a weight to it, as before described in the other machines.

Cannons are always cast with a large cap, or piece of spare metal, at the mouth; in the old guns, which were cast hollow, this piece was cut off by a law; in the solid guns, at the Grafton iron works, it is cut off by a machine, represented in fig. 20. On the lathe for turning the outside of the gun, a cast-iron frame, A A, is fixed, for supporting steadily the chisel, \( b \); between the end of the chisel and the frame, a wedge, \( d \), is put in, which a man continually drives with a hammer, to advance the chisel, and turn a notch in the gun; when it is cut about \( \frac{3}{4} \) inch deep, it is broken off by hammers. We think a screw would be judiciously substituted for the wedge.

After cannons are bored, and their outsides turned, the touch-holes are drilled by instruments, figs. 18 and 19; in fig. 18, A A A is a frame of wood, mounted on wheels, B, at one end, for convenience of moving when it is to be used; the frame is wheeled close to the gun, D, laid on two blocks of wood, F F, high enough to take the wheels off the ground, and prevent its running back; the drill, E, and its bow, G, are then to be fixed, between the place of the touch-hole of the gun and the block, H; which block is advanced by one arm, I, of a bent lever, by means of the weight, C, hung on the other arm, \( d \).

In fig. 19. A is a beam of the building, through which a screw, B, works; the lower end of this screw is hollow for some inches, to receive a small part, \( c \), of the drill, C; on the lower end of the drill a head wheel, \( F \), is fixed, to act as a fly; to the upper part, \( e \), of the drill, the ends of two strong catguts are fastened, and after being twinned round it a few times, the other ends are tied to a handle, F E, at \( e \) and \( f \). To use this machine, a gun is brought and laid under the beam, A, the drill set up with the point, \( e \), in the end of the screw, B, which must be screwed down till the point, \( e \), touches the bottom of the hole in the screw, to prevent the point of the drill from slipping away from the intended touch-hole; the workman must then wind up the cords, by turning the wheel, F; when the handle, E, is in the position of the figure, he must force it down quickly, which will turn the drill round; when the catguts are untwisted, he must let the handle rise, but still hold it, to prevent its turning round with the drill, which will continue to turn by the momentum of the wheel, \( V \), and wind the handle, E, to the fame length as in the figure, but with the cords in a contrary direction. The man must then force the handle down again as before.

Fig. 21. represents the different kinds of borers; A is the borer used for solid guns, and a a section of the same; B and C are different views of the borer for boring hollow guns the first time, and D and E are two different borers for finishing either kind of guns.

The following are the dimensions, both of the iron and brass guns, which the French use at present in their sea and land service, and have made use of ever since their revolution.

Weight of Cannon and Maffelotte

| 5628 lb. | 4111 lb. | 3184 lb. | 2175 lb. | 1808 lb. | 1186 lb. | 590 lb. | 266 lb. |
| 3100 lb. | 2600 lb. | 1800 lb. | 1200 lb. | 1235 lb. | 950 lb.  | 550 lb. | 250 lb. |
Canon a l’Espagnol, or a Spanish cannon, is one, that has a chamber at the bottom of the bore in the form of a sphere or a little flattened.

Canon a la Svedés, or a Swedish cannon, is a piece, that carries a four pound ball, and weighs about 600 lbs.

Canon de Campagne ou de bataille, field or battle-cannon, are pieces that are employed in the field with armies.

The composition and proportions of the ingredients made use of in casting bra's cannon, are nearly the same in the different nations in Europe. Founders have affected to keep this composition a secret: it is, however, well known: and if it were not, it would be a secret not worth keeping. For none of them have been able to find out a composition for such guns, as will enable them to stand quick and continued firing, or a hot engagement, without either melting or becoming useless. They are not so well calculated for severe and hard services as good iron guns, that are both lighter and more transportable.

The common proportion of the copper to the tin in gun-metal, is that of 10 to 12. Some founders put to 240 lbs. of metal for casting 68 lbs. of copper, 52 lbs. of bra's, and 12 lbs. of tin. The Germans put to 400 lbs. of metal for casting, 367 4/12 lbs. of copper, 204 4/12 lbs. of bra's, and 97 7/12 lbs. of tin. Some use 150 lbs. of copper, 6 lbs. of bra's, and 5 lbs. of tin; and others 100 lbs. of copper, 10 lbs. of bra's, and 15 lbs. of tin. In short, different founders are guided in their proportions of these materials, by their own whims and fancies. See Copper.

The French make use of mortars, that have their calibers, or the diameters of their bores, each equal to eight inches, three lines of their measure. These mortars have cylindric chambers, each of which contains 1 4/9 lbs of powder. Such a mortar weighs 550 lbs.

They have also mortars of twelve inches diameter with cylindric chambers, each of which contains five pounds and a half of powder. Such a mortar weighs 1450 lbs.

They have likewise mortars of twelve inches caliber, or diameters with chambers a poire, or pear chambers; each of which holds, in like manner, five pounds and a half of powder. Such a mortar weighs 1700 lbs.

They use also mortars of twelve inches caliber, or diameter with pear chambers, each of which holds twelve pounds of powder. Such a mortar weighs 2250 lbs.

Besides these, they have mortars of ten inches diameter, and some of eighteen inches diameter or caliber.

They likewise use these mortars, or mortars for throwing stones of fifteen inches diameter, with chambers in the form of truncated cones, each of which holds two pounds and a half of powder. Such a mortar weighs 1000 lbs.

Cannon, ships, are stronger in metal than those used by land, on account of the necessity they are often under of being charged with chain-shot. They lie on ship-carriages, having four small wheels, without spokes, with two ropes to flop their running back, and bring them again to their place upon the battery.

Cannon of coufè, or Clear-Cannon, in a galley, is the largest, middlemost, and most effective of the guns placed in the prow, or chase of the vessel, and which delivers its shot over the very item, generally carrying a shot of 33 or 34 pounds weight. It is a long piece, and recoils all along the middle of the galley to the main.

Cannon-mouth of a bit, in the Range, denotes a round, long piece of iron, sometimes composed of two pieces coupled together and bent in the middle. Cannon-months are contrived to keep a horn in subjection, being so ordered that they rise gradually toward the middle and ascend toward the palate, that the void space left underneath may afford a liberty to the tongue. See Bit.

Cannonade. To cannonade any object either by sea or land is to discharge or fire cannon at it. A cannonade may take place between fleets, shipping, armies, &c. It may be made by ships against ships, towns, works, batteries; or by batteries works, towns, against ships, &c. A cannonade may take place between two armies, either occupying field positions, or drawn up in order of battle for the purpose of engaging. An army standing on the defensive may keep up a heavy cannonade on the enemy advancing to attack them. The besiegers may cannonade the works of the beleaguered, and the beleaguered may cannonade the approaches and batteries thrown up by the besiegers.

Cannonier, or Cannonier, a peron who is employed in the management, or in the working and firing of cannon. It is a term sometimes made use of to denote an artillery-man, a gunner, and sometimes an artillery officer. Thus, maître canonnier signifies an officer of artillery, whose duty is to attend to the pointing, loading, and firing of the cannon in his charge.

Cannula, in Surgery, is a hollow instrument, usuall, cylindrical, and made of metal; employed for the transmigration of any fluid out of the body, or for the conveyance of some remedial application to an interior organ. For example, the ancients referred to such an instrument, to defend the adjacent parts, on several occasions, when they applied a hot iron so as to act as a canter, (See Cauter.) and the moderns employ a cannula to draw off pus or dropical accumulation from within a large cavity, (See Dropsey, and Trocar): but the use of a cannula for keeping open deep wounds is very problematical; or rather, it is now generally rejected, as being hurtful in many cases, and needless in all.

Cannula, or Canola, in Ecclesiastical Writers, was a tube of silver, or other metal, wherein were put the relics, which the pope sent as presents to princes, &c.

Canuula, or Canola, was also a sort of fibon, through which they anciently sucked the wine in the eucharist.

Canay, Alonso, in Biography, called the Michael Angelo of Spain, from his excelling in the three arts of painting, sculpture, and architecture, born in 1660 at the city of Grenada. Having studied the principles of architecture under his father, an eminent architect of his native city, he directed his attention to sculpture, as a disciple of Pacheco de Sevilla, and he afterwards applied himself to the art of painting in the academy of Juan de Casillo the painter, in the same city. Besides many fine pieces which he executed for the public edifices of Sevilla, he also practiced sculpture, and made two cyllindrical figures of St. Peter and St. Paul of such peculiar excellence, that the Flemish artists are said to have visited Sevilla in order to have an opportunity of copying them. Claiming noble birth, and possesing a high spirit, his first productions were gratuitous. In consequence of a quarrel with Sebastian de Llanos, an eminent painter, which terminated in a duel, he was obliged to quit Sevilla; and in the suite of the count-duke Olivares, as well as under his protection, he went to Madrid, where he was soon appointed first royal architect, king's painter, and instructor to the prince, Don Balthazar Carles. In this situation he acquired distinguished reputation as an architect, sculptor, and painter. His fame, however, excited jealousy and envy, and he was charged with plagiarism in the composition of his pieces. But another circumstance occurred, which was much more injurious to his prosperity. Upon his returning home one evening, he found his wife murdered and his house pillaged, and
and an Italian journeyman mending. The magistrates, discovering that Cano had been jealous of this Italian, and that he was attached to another woman, charged him with the murder; and he was reduced to the necessity of making a speedy escape. He fled for refuge to Valencia, but was soon betrayed by the practice of his art; and he then sought an asylum in a Carthusian convent near that city; and being deterred from taking the order by the dread of its severities, he returned to Madrid, where he was apprehended and delivered to the torture in order to extort a confession. Having endured the rack without cermiration, he was again taken into favour by the king; and with a view to his future security, he obtained the clerical office of refectori of Grenada. In this situation he enriched the churches of Grenada and Malaga with many paintings and sculptures. But having been refused the payment of two pilloles by a counsellor of Grenada for an image of St. Anthony of Padua, he deftied the faint in pieces on the floor of his academy. This fall of passion induced the chapter of Grenada to suspend him from his function; but he was restored by the king, on the condition of finishing a magnificent crucifix, which the king had bespoke, but which he had long neglected. From this time he led a life of charity and devotion; and when delitute of money, he supplied the wants of a beggar by sketching a drawing upon paper, and directing him how to dispose of it. The violence of his temper was still un subdued; and even in his last moments he could not be prevailed upon to make use of a crucifix which was presented to him for adoration, because it was such a wretched piece of work, that he could not bear the sight of it. Cano died at the age of 75, in the year 1676. Cumberland’s Annals of Eminent Painters in Spain. Gen. Biog.  

Cano, or Canus, John Sebastian del, a native of Biffay, who accompanied Magellan in his voyage through the straits, bearing his name, and who, after his death, took the command and proceeded to the isles of Sunda. Thence doubling the cape of Good Hope, he arrived at Seville in 1522, having performed the voyage round the world in three years and four months. Charles V. gave him for a device a terrestrial globe, with this legend, “Primus me circumdedisti.” i.e. thou first hast surrounded me. Moreri. Gen. Biog.  

Cano, or Canues, Melchior, a Spanish theologian, was a native of Tarazon in the diocese of Toledo. Having studied at Salamanca under Francis Victoria, and entered into the order of St. Dominic, he succeeded his predecessor in the theological chair in 1546. Between Cano and Bartholomew Caranza, archbishop of Toledo, who was also at the same time professor at Salamanca, there subsisted a jealousy, which produced two parties in the university. But Cano was superior to his rival in the powers of his genius and the extent of his learning, as well as in the vivacity of his temper and the readiness of his eloquence. Paul III. deputed him to attend the council of Trent; and in 1552 he was made bishop of the Canary islands. He was distinguished, by the favour of king Philip II. and of his unfortunate son, Don Carlos, and it is laid that he sacrificed the interest of the latter to that of the former. He was also charged with having attempted to pervert the king that he might lawfully make war against any foreign, in the assertion of his own rights; but in advancing this principle, he offended the court of Rome. Such were his ambitious views, that he resigned his bishopric in order to be near the court; but he could not long indulge them, as he died at Toledo in 1560, soon after he was appointed provincial of Castile. His work entitled “Locorum Theologicorum lib. xii.” in which he explains the principles or sources (for that is the sense in which he uses the term loci) whence arguments may be deduced for the confirmation of doctrines and opinions, is highly commended by Du Pin. Whilst he maintains the authority of the church of Rome, and the infallibility of the pope, he introduces many liberal sentiments, and it appears that he gave little credit to the legends and fables of corrupt ages. We have some bold and generous remarks to this purpose, cited by Dr. Jortin, in his Remarks on Ecclesiastical History, vol. ii. p. 316-319. Cano’s Latin style is good. Besides the work already mentioned, he also wrote “On the Sacraments,” and “Six Lectures concerning Penance.” Du Pin. Moreri.  

Cano, or Canus, in Geography. See Ghana.  

Cano, a river of Finland, which falls by Birnborgh.  

Canoa, a town of Japan, in the province of Iwami.  

Canobio, a town of Italy, in the Milanese, on the west side of the lake Maggiori; 13 miles S.E. of Dom. d’Ofcello. N. Lat. 45° 58’. E. long. 8° 47’.  

Canoes Island, an island so called by Mr. Mackenzie in his voyage through the N.W. continent of America; situated in about N. Lat. 53° 31’. W. long. 122° 45’.  

Canoes-ridge, a rugged mountain of America, about 200 miles W. of Philadelphia, forming the eastern boundary of Bald Eagle valley.  

Canoes, in Sea Language, a small vessel used by various inhabitants of the earth for the purpose of fishing, of trading, and travelling along rivers, and of war. Canoes are made of different materials, such as the trunk of a tree, the bark of trees, skins of animals, &c. Canoes used on the American, or other rivers, in confluence of the curved form of their transverse fection, carry their lading higher than square-sectioned boats of similar width; and are therefore capable of conveying large hogheads of tobacco, or of other articles, with safety.  

Canoes of the aborigines of Canada, is made of the bark of the birch; and some are of a size sufficient to contain four or five persons.  

Canoes of the Esquimaux, is made of whalebone, about an inch square; there are not felt like ribs, but are from items to items felt fast to each other with strong sinews, and covered over with sealskins. They are from ten to twenty feet long, and about two feet broad; they are formed like a weaver’s shuttle, sharp at both ends, so that they can be rowed either way. In the middle of the canoe are the ribs, both to keep the sides afloat, and to form the hole in the covering wherein the rower sits. A flat hoop is fitted to this hole, rising about four inches, to which the surrounding skin is sewed. The Indian’s seal-skin jacket, being of a proper length, he can occasionally bend the skirt of it round the outside of this hoop; by which means, he keeps the canoe free from water, and is enabled to procure his game far from the land, or in stormy seas. His paddle is from 20 to 30 feet long, being light, and flat at each end: this serves him to balance and steer his canoe, but particularly to row it, which he does with that incredible celerity, that an English boat with ten oars is not able to keep company with the canoe. The young men in their excursis are taught to over-crest their canoes, and when the bottom is upward, to recover by the dextrous management of their paddle, their former upright position, the men rising again either on the side by which they went down, or on the contrary, as they please. The construction of this extraordinary little vessel, so admirably well adapted to the purposes of its owner, does the greatest credit to the ingenuity of the constructor. There is a canoe of this description in the repository of the Royal Society, and another in the library of the marischal college, Aberdeen.  

Canoes of Davis Straits, is in the form of a barge, seven
or eight feet long, and two in breadth; the materials made use of are plant, bent and interlaced like a hurdle, and covered with the skins of sea dogs, or wolves. This light boat carries only one man, who, seated in a hole formed in the middle of what, from this circumstance, appears to be a deck, is enabled to fill, or to transport himself with facility, and without much apparent danger, from one coast to another.

**Canoe of the coast of Guinnea.** It is made by hollowing the trunk of a tree; it is of a long figure, and swins with only a small part of its body above the surface of the water; so that the person who sits behind, and guides the canoe, is frequently half covered with water. The breadth is no more than sufficient to contain one man, and the length for seven or eight. The men are fented on round pieces of wood, and half their bodies are below the gunwale. Each man has an oar of a very hard wood, and all row together, like galley-men, in one concordant motion; or, if an individual pulls too strongly, putting the canoe out of its line, his mistake is so well counteracted by the man that guides in the stern, that the whole seems to fly along the surface of the water, and cannot be run long followed by any European vessel. When, on the other hand, the sea is high, they are unable to steer, the lophines of the waves preventing their answering the helm. When the surf overthrows them, they have the address to turn their canoe in the water, to empty it, and re-embark, without running the smallest danger, swimming all the time like fish. These canoes are generally about sixteen feet long, and one or two broad: there are, however, some much larger, measuring thirty five feet in length, five in breadth, and three in depth; they are flat at the stern, with a rudder and deck; the sails are made of reeds, or of grass. The canoes are not allowed to remain in the water, but are drawn on shore, and placed on four treffles; when dry, two men can carry a canoe on their shoulders. In shaping and hollowing the trunks they have felled, the negroes now make use of the hatchets that are sold to them by the Europeans. They narrow them towards the bottom, and cut each end to a point, giving it a small bend of about a foot long, and of a thicknes adapted to the hand, for the purpose of lifting the canoe.

**Canoe of the Indian and Charibbes.** It is the simple trunk of a tree, hewn on the outside to the defird form, and hollowed within by means of fire. Its size consequently depends upon that of the tree of which it is made. It is rowed with paddles and oars, and sometimes has the affifance of a little sail. The lading is placed at the bottom, but as the canoe is not ballasted, it frequently overfets. The aftermost oars supply the purpofe of a rudder.

**Canoe of Noetka Sound.** The large war canoe is generally finished on the spot where the tree grows of which it is made, and then dragged to the water's side. Some of them have been seen which were fifty three feet in length, and eight feet in breadth. The middle part of these canoes is the broadest, and gradually narrows to a point at each end; but their head or prow is generally much higher than the stern. As their bottoms are rounded, and their sides flan out, they have consequently sufficient bearing, and a considerable degree of flability. They have no fets, but several pieces of wood, about three inches in diameter, are fixed across them to keep their fides firm, and preferf them from being warped. The rowers generally fit on their hams, but sometimes they make use of a kind of small fool, which is a great relief to them. In the art of embarking they are extremely cautious, each man regularly taking the flation to which he has been accustomed. Some of these canoes are polished and painted, or curiously flumbed with human teeth, particularly on the ftern and prow. This is affirmed on the authority of captain Cook, who says that the people of the sea coast adorned their canoes with human teeth. But Mr. Mackenzie (Journal of a Voyage through the N. W. Continent of America, p. 335.) informs us, that he was particular in his inquiries, and that he obtained the most satisfactory proof that captain Cook was mistaken; and that his mistake arose from the great fleremance there is between human teeth and those of the sea otter, with which the gunwale, fore and aft, of a canoe, which he examined, was lined. The fides were sometimes adorned with the figure of a dragon with a long tail, of much the fame form as is seen on the porcelain of China, and in the fanciful paintings of other countries.

**Canoe of Kaffir.** Employed on the lake of Wolda, is rounded at both ends; it is much wider in the middle than at either end, and is worked with a single oar, which is placed at the stern: but all the other canoes of that country terminating sharply both ways, are elevated before as well as behind. They are hardened by means of fire, protected from the weather by paint, and lashed round for the purpofe of giving them additional strength.

**Canoe of Terra del Fuego and the Straight of Magellan.** Is of a peculiar construction. The natives take the bark of the largest trees, and bend it into a shape with so much skill, that the vessels have a resemblance to the gondolas of Venice. For this purpofe they place it on a small piece of wood, as Europeans place a flip on the flocks; and when the bark has taken the gondola form, and the necessity bend, they line the bottom and fides, from one end to the other, with upright pieces of their wood, in the fame manner as the parts or frames of a flip are put together: round the top of the deck another bandage of bark is drawn, in doing which, the utmost care is taken to fen the whole together. These canoes are from ten to sixteen feet in length, and two in breadth; holding with sufficient convenience, seven or eight men, who row fanding, and with extreme celerity. See also the articles BOAT, PROA, &c.

**Canoge, or Canouge, in Geography, a town of Hindoofn, feated on the right bank of the Ganges, near the place where the Calini or Callynuddi river joins its. Its ruins are even now of great extent, and in an early part of the Christian era, it was the capital of Hindoofn, or rather of the principal kingdom along the Ganges, and is possibly the place meant by Phiy for Calinippa. It is at present reduced to the fize of a middling town. It is faid to have been built more than 1000 years before our era; and is mentioned in Tertiffa (320 years B. C.) as the capital of all Hindoofn, under the prece fend of Phoos, or Perus, who fought against Alexander. Canogoe corresponds, with regard to extent and magnificence, to the defcription given of Palibothru, and in some refpects, to the local position alligned to it by Ptolemy and Eratofhenes; but other authorities allign this place to Patna. The Indian histories abound with the accounts of its grandeur, and populousnes. Its walls are faid to have been 300 miles in circumference, and its third emperor, Sinalk, could bring into the field 400 elephants, 100,000 horse, and 400,000 foot. In the fifth century it was found to contain 50,000 shops, in which betel nut was sold, 3000 jewellers, and 60,000 bands of musicians, who paid a tax to government. In the year 1018 it was feized by the Gazan emperors, at which time it gave its name to the kingdom, of which it was the capital. It is distant from Agra 127 miles; from Benares 259; from Bombay 889; from Calcutta by Mauritbad 824, by Birbom 719; from Delhi 234; from Lucknow 75; from Madras 1141; from Nagpoure 486; from Ougne 464; and from Poonah 842. N. lat. 27° 3'. E. long. 80° 13'.

**Canon,**
CANON.

CANON, in Ecclesiastical History, a person who possesses a prebend or revenue allotted for the performance of divine services, in a cathedral, or collegiate church.

Canons are of no great antiquity: Paschier observes, that the name canon was not known before Charlemagne; at least the first we hear of are in Gregory de Tours, who mentions a college of canons, instituted by Baldwin XVI, archbishop of that city, in the time of Clotharius I. The common opinion attributes the institution of this order to Chrodegangus, bishop of Metz, about the middle of the eighth century.

Originally canons were only priests, or inferior ecclesiastics, who lived in community; residing by the cathedral church to fulfill the bishop; depending entirely on his will; supported by the revenues of the bishopric; and living in the same house, as his domestics, or councilors, &c. They even inherited his moveables till the year 817, when this was prohibited by the council of Aix-la-Chapelle, and a new rule substituted in the place of that which had been appointed by Chrodegangus, and which was observed for the most part, in the west till the twelfth century. By degrees these communities of priests, flaking off their dependence, formed separate bodies; whereof the bishops, however, were still heads. In the tenth century there were communities, or congregations of the same kind, established even in cities where there were no bishops; these were called collegiates, and as they used the terms congregation and college indifferently: the name chapter, now given to these bodies, being much more modern. Under the second race of the French kings, the canonical, or collegiate life, had spread itself all over the country; and each cathedral had its chapter, distinct from the rest of the clergy.

They had the same canon from the Greek νόμος, which signifies three different things: a rule, a pension, or fixed revenue to live on, and a catalogue or matricula; all which are applicable to them.

In time, the canons freed themselves from their rules, the observance relaxed, and at length they ceased to live in community; yet they still formed bodies; pretending no other functions besides the celebration of the common office in the church; yet assuming the rights of the rest of the clergy; making themselves as a necessary council of the bishop; taking upon them the administration of a fee during a vacancy, and the election of a bishop to supply it. There are even some chapters exempt from the jurisdiction of the bishop, and owning no head but their dean. After the example of cathedral chapters, collegiate ones also continued to form bodies, after they had abandoned living in community.

Canons are of various kinds; as,

Canons, cardinal, or those attached, and as the Latins call it, incolariato a church, as a priest is to a parish.

Canons, domesticus, were young canons, who not being in orders, had no right in any particular chapter.

Canons, exemptus, were such as, without having any revenue or prebend, had the title and dignities of canons, a voice in the chapter, and a place in the choir, till such time as a prebend should fall.

Canons, foreignus, were such as did not officiate in the canons to which they belonged. To these were opposed manumori canones, or canones relictuarie.

Canons, lay or honorary, are such among the laity, as have been admitted, out of honour and respect, into some chapter of canons.

Canons, regular, are canons that dwell in community; and who, like religious, have, in process of time, to the practice of their rules, added the solemn profession of vows. They are called regularis, to distinguish them from those secular canons who abandon living in community; and at the same time, the observance of the canons made as the rule of the clergy, for the maintenance of the ancient discipline.

The canons fulfilled in their simplicity till the eleventh century, some lay the twelfth century, when some of them, departing from the community, took with them the name of canons, or aephephalous priests, because they declined to live in community with the bishop; and those who were left, then adopted the denomination of canons regular, and adapted most of the professions of the rule of St. Augustine. This order of regular canons of St. Augustine was brought into England by Adelwald, confessor to Henry I, who erected a priory at St Albans, in Yorkshire, and obtained for them the church of Carlisle as exempted, with the privilege of chusing their own bishop. They were originally protected and encouraged by Henry I, who gave them the priory of Dunstable in 1135, and by queen Matilda, who in the following year, gave them the priory of the Holy Trinity in London. It appears, that under the reign of Edward I., they had fifty-three priories.

Canons, tertiaries, those who had only the third part of the revenues of the canonicate.

Canon, in an Ecclesiastical Sense, is a law or rule, either of doctrine or discipline, enacted especially by a council, and confirmed by the authority of the sovereign.

Canons are properly decisions of matters of religion; or regulations of the polity and discipline of a church, made by councils either general, national, or provincial. See Council.

Such are the canons of the council of Nice, or Trent, &c.

See Constitutions.

There have been various collections of the canons of the Eastern councils; but four principal ones, each smaller than the preceding. The first, according to Ufner, A. D. 380, containing only those of the first ecumenical council, and the first provincial ones: they were but 164 in number. To these, Dionysius Exiguus, in the year 520, added the fifty canons of the apostles, and those of the other general councils. The Greek canons in this second collection, end with those of the council of Chaledon; to which are subjoined those of the council of Sardica, and the African councils. The fourth and last collection comes down as low as the second council of Nice; and it is on this that Balsamon and Zonaras have commented. See Hardouin's Acta Conciliorum et Epistolarum decoctals ac Constitutiones Summarum Pontificum, in 11 tomes; commencing with the year 34, and terminating in 1714. ProL Paris, 1715.

Canons, Apollonius, are those which have been usually ascribed to St. Clement, in order to procure for them a high degree of authority. They contain a view of the church government and discipline received among the Greek and oriental Christians in the second and third centuries. Bellarmin, Baronius, &c. will have them to be genuine canons of the apostles. Cotelerius observes, (Jud. de. Canon. Ap. ap. Patr. Ap. 1.) that they cannot be ascribed to the apostles or Clement, because they are not received with other books of Scripture, are not quoted by the writers of the fifth ages, and contain many things not answerable to the apocryphal times. Hincmar, De Marco, Beveridge, &c. take them to be framed by the bishops who were the disciples of the apostles in the end of the second and beginning of the third centuries. Beveridge (Cod. Can. Vindicat. I. c. x. 4.) acknowledges that they are interpolated in several places, though he professes a great veneration for them, and has undertaken to defend them. The bishop ascribes a kind of apolitical authority to the 50th canon, which requires of the bishops and prebendaries that they should make use of a three-fold immersion in baptism, under pain of being deposed. The 55th canon strict-
IV. requires the observation of the quadragesimal fast, under spiritual pangs and penalties; and this, together with other <br>stated fasts, Beveridge supposes to have been apocalyptic <br>imitation. S. Bafnage is of opinion, that they were col-<br>lected by an anonymous writer in the fifth century; but <br>Daille, &c. maintain them to have been forged by some <br>heretic in the sixth century; and S. Bafnage conjectures, <br>that some of them are ancient, and others not older than the <br>seventh century. The 8th canon contains a catalogue of <br>the books of the Old and New Testament; which, from the <br>books of the New Testament, that are enumerated in it, could <br>not have been drawn up till after the third century. The <br>epistle to the Hebrews was rejected, or doubted of by many <br>in the first three centuries, and also in the fourth century; <br>but if this canon had been then in being, and acknowledged <br>as apocalyptic, that epistle would have been received by all. <br>Several of the catholic epistles, that of James, the second <br>of Peter, the second and third of John, and that of Jude, were <br>rejected, or doubted of by many in the early times of Chris-<br>tianity; whereas they would have been received by all, if this <br>canon had been in being, or had been acknowledged to be <br>apocalyptic. This argument is urged by Mill, in his "Pro-<br>logomena," p. 201. Moreover, the Revelation was received <br>by many in the second, and third, and following centuries, <br>which would not have been the case, if there had been a <br>canon composed by the apostles, or Clement their companion, <br>in which all other books of Scripture were distinctly enumer-<br>ated, and that omitted. How, says Baronius to this pur-<br>puse, could so many of the Latin and Greek writers receive the <br>Revelation, which was wanting in an apocalyptic canon? <br>And how could there have been such different opinions about <br>the epistle to the Hebrews, and several of the catholic epis-<br>tles, if they had been made canonical by an apocalyptic de-<br>cree? Besides, the first epistle of Clement was reckoned ca-<br>nonical by very few, if any of the writers of the first three <br>centuries; therefore this pretended apocalyptic canon, which <br>gives it a place among books of sacred Scripture, was not in <br>being; and the second epistle of Clement was not esteemed <br>his in the third century, though the catalogue of this canon <br>includes it. The Greek church allows only 8 of these ca-<br> nons, and the Latins only 50; though there are 84 in the <br>edition given of them in the "Corpus Juris canonici." See <br>Lardner's works, vol. iv. p. 334, and Jortin's Rem. on <br>Eccles. Hist. vol. i. p. 278. &c. Cave, Hist. Lit. vol. i. p. 29. <br>Jones's New and Full Method of settling the Canonical <br>Authority of the New Testament, vol. i. p. 25.<br>Cannon, is also used for the authorized catalogue of the <br>sacred writings. The word is originally Greek, κανον, and <br>signifies a rule or standard, by which other things are to be <br>examined and judged. Accordingly the fame word has been <br>applied to the "tongue of a balance," or that small part, <br>which, by its perpendicularly position, determines the even <br>poize or weight, or, by its inclination either way, the uneven <br>poize of the things which are weighed. To this purpofe is <br>the observation of the ancient school of Aristophanes in <br>Ran. v. 809. Hence it appears, that as the writings of the <br>prophets, apostles, and evangelists contain an authentic ac-<br<count of the revealed will of God, they are the rule of <br>the belief, and practice of those who receive them.<br>Cannon seems also sometimes to be equivalent to a list or ca-<br>logue, in which are inserted those books, that contain the rule <br>of faith. Hence Du Pin, and others, have supped, that thefe <br>books are called canonical, because they are placed in the ca-<br>logue of sacred books. It has been said, however, that the <br>Greek word is never used in this sense, by any prophane writers, <br>nor even among the Chriftians, till the fourth century; be-<br>fore which time the word was certainly applied to the sacred <br>volume. Mr. Whilton (Essay on the Apoftical Conflit, <br>chap. i. § 6.) imagines the canon of Scripture, or the ca-<br>nonical books of the Old and New Testament, to be thefe, <br>and only thefe, which are inserted in the fifth apolo-<br>tical canon, and that they were fo fixed by the ancients only <br>on that account. But as the spuriousness of these pretended <br>apocalyptic canons is very generally allowed, it is needless <br>to refute this opinion. See Apoftical Canons.<br>The use of this appellation, as applicable to the books of <br>Scripture, is undoubtedly very ancient. St. Paul has twice <br>ufed the word canon, or rule. Gal. vi. 16. Philip, iii. 16. And <br>though in these passages he may refer to the doctrine of <br>the gospel in general, or to some particular maxim of it, and not <br>to any books containing the rule of faith, yet his use of the <br>word may have given occasion for fixing that denomination <br>to the books of Scripture. Irenæus, speaking of the Scrip-<br>tures, (Adv. Hæres. i. iv. c. 69.) tells them τοῦ κανόνος τῆς <br>αποστολῆς, i.e. the canon of truth; and here canon is not a <br>catalogue, but the books, or the doctrine contained in the <br>books of Scripture. Clement of Alexandria, (Strom. l. 4. <br>p. 453.) disputing with some heretics of his time, blames <br>them for making use of apocryphal Scriptures, "cheating <br>to follow any thing, rather than the true evangelical <br>canon (or the canon of the gospel)." In another place <br>(Strom. l. vi. p. 676.) he says, "the ecclesiatical canon is <br>the consent and agreement of the law and the prophets with <br>the Testament delivered by the Lord." Eclelus (Hist. <br>Ecclef. l. vi. c. 25.) tells us, that Origen, in his exposition <br>on Matthew, enumerates the books of Scripture according <br>to the canon of the church; i.e. the canon received and es-<br>tablished in the church. Athanasius, in his Enclial epistle, <br>mentions three forts of books, the canonical, which are those <br>now received by us, such as were allowed to be read, and <br>such as are apocryphal, by which he means books forged <br>by heretics. In the Synopsis of Scripture, which some have <br>ascribed to him, but probably not written till 100 years after <br>his time, near the end of the fifth century, there occurs fre-<brquent mention of canonical and uncanonical books. The <br>council of Laodicea, about 325, ordains, that "no books, <br>not canonical, should be read in the church, but only the ca-<br>nonical books of the Old and New Testament." The third <br>council of Carthage, about 397, ordains, "that nothing be-<br>side the canonical Scriptures be read in the church under <br>the name of Divine Scriptures," Epiphanius, Philastrius, Ruf-<br>inus, Jerome, Augustine, Chrysostom, Ildoare of Pelopon, and <br>Leontius of Cappadocia, use the words canon and ca-<br>nonical in the same fene. Hence we may infer, how much <br>the use of these words, canon and canonical, has obtained <br>among Chriftians, to denote those books, which are of the <br>highest authority, and the rule of faith; as opposed to all <br>others whatever, particularly to ecclesiatical, or the writings <br>of orthodox and learned catholicks, and to apocryphal, the <br>productions, chiefly of heretics, which by a fpecious name <br>and title made a pretention to be accounted among sacred <br>books. The mosf common and general division of the ca-<br>nonical books is that of ancient and new, or the Old and <br>New Testament.<br>The canon of the Old Testament is much more easily set-<br>tled than that of the New; because whatever almost may be <br>objeéted against the authority of the preface canon of the <br>former, either in behalf of any books which are not in it, or <br>againif any that are, may be anwered by this fingle confi-<br>deration, viz. that we receive the fame and no other books <br>than fuch as were received by the Jewish church in the time <br>of our Saviour, as is evident from the copies of them proc-<br>ured by the Chriftians, and the catalogues they made of <br>them soon after the deftruction of Jerusalem. Some differ-<br>ence,
C A N O N.

ence, however, has occurred in the mode of their arrangement. Holy Bay (de Bih. Text. Orig. x. c. vi. p. 192.), the notation of the sacred books into the Law, the Prophets, and Hagiography, is of the highest antiquity. The Jews are said by some, but as others think, without sufficient evidence, to have ascribed it to the prophet Ezra. Although the Jewish people have been very uniform in the number of sacred books received by them, they have varied, and have been somewhat arbitrary, in the general denominations and divisions of them. Haean Volfinus suspects that the above mentioned division, was an invention of Aquila, who, in the second century, made a new version of the Jewish scriptures into Greek; whereas, the old partition was that of the Law, the Prophecies, and Psalms. Dr. Lardner offers, that no traces of it appear in the Scriptures of the Old or New Testament, nor in Josephus, nor in Philo, nor in any Christian writers before Epiphanius and Jerom, near the end of the fourth century. Some, indeed, have supposed that this tripartite division is referred to in Luke, xxiv. 42; but other learned and judicious persons, as Le_escen and Wollins, are of opinion that by the "Psalms," in this place we are not to understand the metrical books, or any other general division of the scriptures of the Old Testament, but the book of Psalms. J. F. Buddens. (Hist. Eccl. Vet. Test. tom. posterior, p. 818, 310. Halle Magdeburg. 1719.) cited by Lardner, says it is uncertain when and by whom this partition was first used; and he also shews the impropriety and inconvenience of it, as generally used by the Jews. It does not appear that any notice is taken of it, or regard had to it in Melito, Origen, Cyril, or Athanasius. Among those who have used this partition, there seems to have been a great variety of opinions concerning the books that should be called "Hagiographa." The term has nothing in it appropriate and distinctive; and this may have been the ground of that difference of opinion among those who have used it, concerning the books that should be placed in this class. Every other partition of the sacred books of the Old Testament, with which we are acquainted, seems, in the judgment of Dr. Lardner, to be preferable to this of the Law, Prophets, and Hagiography. Those denominations, which we sometimes meet with in the New Testament, the "Law," or "the Prophets," denoting in general the ancient sacred writings, are very just. The dichotomy, "the Law and the Prophets," to common in the New Testament, is very proper. The tripartite division in Luke, xxiv. and Josephus, "the Law, the Prophets, and Psalms or Hymns," is also very proper. Another partition is that used by Cyril of Jerusalem, viz. legal, historical, metrical, and prophetic, which seems to have been regarded by Athanasius, Origen, and Melito, in their catalogues, appears to Lardner and others the most proper and commodious.

Some have placed the books of the Old Testament from the first to the last, in chronological order. This, however, is a matter of no importance, and might be found inconvenient. But if they are divided into classes, the order of time may be useful. Accordingly, in the first class, must be the five books of Moses; then the historical books, Joshua, Judges with Ruth, Samuel, the Kings, the Chronicles, Ezra, Nehemiah, Esther; next the metrical books, Job, the Psalms, the Proverbs, Ecclesiastes, the Canticles; lastly, the prophetic books, the twelve prophets in one book, each of which might be placed, according to the order of time, Isaiah, Jeremiah, with the Lamentations, Ezekiel, Daniel; or, first of all, the four larger prophets, and then the book of the twelve letter prophets, as they are called: by which we perceive, that the present order of books in our Bibles is, in the main, such as we have reason to be well satisfied with.

The first catalogue of the books of the Old Testament recorded by any Christian writer is that of Melito, Bishop of Sardis, in Lydia, who is placed by Cæsarius of the year 416. He travelled into Palestine on purpose to learn the contents of these books. Epiphanius has preserved his catalogue, and he says, that it is a catalogue of the scriptures of the Old Testament universally acknowledged. It contains the books received by the Jews into their canons; but he does not mention the book of Esther. The order in which he enumerates them is as follows, viz., five books of Moses, Joshua, Judges, Ruth, four books of the Kings, two books of Chronicles, the Psalms of David, the Proverbs of Solomon, the Ecclesiastes, the Canticles, Job, the books of the Prophets, Isaiah, Jeremiah, the Twelve Prophets in one book, Daniel, Ezekiel, Ezra, Origen, about 220, has a catalogue, in which the books occur in the following order, viz., five books of Moses, Joshua, Judges with Ruth, one book; the first and second book of the Kings, called by them Samuel, and reckoned one book; the third and fourth of the Kings, also one book; the first and second of the Remains, in one book; Esdras, first and second, in one book, called by them Ezra; the book of the Psalms; Solomon's Proverbs, Ecclesiastes, Canticles, Isaiah, Jeremiah, Daniel, Ezekiel, Job, Esther. The book of the Twelve Prophets is wanting in our copies. Athanasius, in his Pedale Epistle, and also in the Synopsis, enumerated the books in this order, viz., the five books of Moses; then the historical books, from Joshua to Ezra; then, the books in verse, the Psalms, Proverbs, Ecclesiastes, Canticles, Job; lastly, the Prophets, which are the Twelve Prophets in one book, Isaiah, Jeremiah, Ezekiel, and Daniel. Cyril of Jerusalem, about 354, has a catalogue, in which he utters divisions. The first are the five books of Moses; then the historical books; after them, five books in verse, Job, the Psalms, the Proverbs, Ecclesiastes, the Canticles; and, last of all, five prophetic books, which are the Twelve Prophets, in one book, Isaiah, Jeremiah, Ezekiel, Daniel. Epiphanius, about 368, has three catalogues; in two of which all the books of the Old Testament are enumerated from Genesis to Ezra or Ether, without any partitions. But in the other he divides them, observing, that the books of scripture are comprised in four Pentateuchs, and two over and above the first Pentateuch, or that which is most properly so, containing the five books of the Law: the next contains the five books in verse, the book of Job, the Psalter, the Proverbs of Solomon, the Ecclesiastes, the Canticles; the third Pentateuch contains those called Graphica, by others Hagiographa, which are the book of Joshua, the book of Judges with Ruth, the first and second of the Remains, the first and second of the Kingdoms, and the third and fourth of the Kingdoms: the fourth Pentateuch consists of the Twelve Prophets, in one book, Isaiah, Jeremiah, Ezekiel, Daniel; the two others, over and above the first, are the two books of Ezra, reckoned one book, and Ether. This catalogue is followed by John Damascenus, about the year 380. Jerom, A. D. 393, enumerates 32 books of the old law, according to the number of the Hebrew letters; viz., five books of Moses, Genesis, Exodus, Leviticus, Numbers, and Deuteronomy; eight of the prophets, viz., Joshua, Judges with Ruth, Samuel, Kings, Isaiah, Jeremiah, Ezekiel, and the Twelve Prophets; and nine of the Hagiographa, viz., Job, David or the Psalms, Solomon comprehending three books, i.e., Proverbs, Ecclesiastes, and the Song of Songs; Daniel, Chronicles, Ezra, and Ether. Hence we see, that St.
Jerome’s canon of the Old Testament was that of the Jews. All other books not received by them, he calls Apocryphal. See Apocrypha.

In the catalogue of Rufinus, about the year 397, the books of the Old Testament are enumerated in the following order: viz., in the first place, are the five books of Moses, Genesis, Exodus, Leviticus, Numbers, Deuteronomy. After these are Job, Tobit, Judith, and the four books of the Kings, which the Hebrews reckon two; the book of the Remains, which is called the Chronicler, and two books of Ezra, which by them are reckoned one, and Esther. The prophets are Isaiah, Jeremiah, Ezekiel, and Daniel; and besides, one book of the Twelve Prophets: Job also, and the Psalms of David. Solomon has left three books to the churches, the Proverbs, Ecclesiastes, and the Song of Songs. In the third, otherwise called the sixth, council of Carthage, assembled in 397, it was ordained, that nothing beside the canonical scriptures should be read in the church under the name of Divine Scriptures; and that the canonical scriptures are these, Genesis, Exodus, Leviticus, Numbers, Deuteronomy, Joshua, Judges, Ruth, four books of the Kings, two books of the Remains, Job, Daniel’s Psalter, five books of Solomon, the books of the Twelve Prophets, Isaiah, Jeremiah, Ezekiel, Daniel, Tobit, Judith, Esther, two books of Ezra, and two books of the Maccabees. Upon this canon it has been remarked, that this council was not general, but provincial, or national: that the bishops assembled did not owe much learning or judgment, when they reckon five books of Solomon; that the decree of this council, by placing among canonical scriptures Tobit, Judith, and the two books of the Maccabees, contradicts antiquity, or ought to be explained with a distinction; the word canonical being used laxly, so as to comprehend not only those books which are admitted as the rule of faith, but those also which are esteemed useful, and may be publicly read for the edification of the people: and that this council mentions only two books of Ezra, meaning, probably, the book of Ezra properly so called, and the book of Nehemiah; but nothing is said of the other two, sometimes called the third and fourth books of Ezra. According to Augustine, (De Doctr. Chir. I. ii. c. 8. tom. iii. p. 1. Bened.) about 397, the entire canon of scripture is the following books, which he thus enumerates. There are five of Moses, that is, Genesis, Exodus, Leviticus, Numbers, Deuteronomy; one book of Joshua; one of the Judges; one small book called Ruth, which seems rather to belong to the beginning of the Kingdoms; then the four books of the Kingdoms, and two of the Remains, not following one another, but proceeding, as it were, parallel on the side of each other. These are historical books, which contain a succession of times in the order of events. There are others which do not observe the order of time, and are unconnected together: as Job, Tobit, Esther and Judith, and the two books of the Maccabees, and the two books of Esdras; which let us do more observe the order of a regular succession of things, after that contained in the Kingdoms and Remains. Next are the Prophets, among which is one book of the Psalms of David, and three of Solomon, the Proverbs, the Song of Songs, and Ecclesiastes. For these two books, Wildom and Ecclesiastick, are called Solomon’s for no other reason but because they have a resemblance with his writings; for it is a very general opinion, that they were written by Jefus, the son of Sirach: which books, however, since they are admitted into authority, are to be reckoned among prophetical books. The rest are the books of those who are properly called prophets: as the several books of the twelve prophets, which, being joined together and never separated, are reckoned one book. The names of which prophets are these: Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggni, Zechariah, Malachi. After them are the four prophets of larger volumes: Isaiah, Jeremiah, Daniel, Ezekiel. In these 43 books is comprised all the authority of the Old Testament.

From this extrait it appears, that there was not then any canon of scripture settled by any authority, that was universally acknowledged by Christians. Though there might be decrees of councils relating to this matter, they were not deemed decisive and of authority, everywhere, and by all. But till private and inquisitive Christians had a right to use their own judgment concerning this point. Although Augustine says, that Wildom and Ecclesiastick ought to be reckoned among prophetical books, &c.; yet Rufinus and Jerome, who were a little older, must be allowed to bear a right testimony, and to declare truly what was the sentiment of most Christian churches, when they say, that the Wildom of Solomon, Ecclesiastick, Tobit, Judith, and the Maccabees, were indeed allowed to be publicly read: but that nevertheless they were not canonical, and that “the doctrine of religion may be proved by their authority.” From other passages in the works of Augustine it appears, that he acknowledged only 3 books of Solomon to be his; the Proverbs, Ecclesiastes, and Canticles; and that the Jews have no more of his writings in their canon. With regard to the books of Wildom and Ecclesiastick, he observes, that though they were esteemed by some, on account of some resemblance of style and design, to be Solomon’s, the learned are satisfied they are not his; and that they were chiefly respected by the Western Christians. He particularly owns that the book of Judith was not in the Jewish canon. Augustine, indeed, often quotes those books of the Old Testament which we now generally call apocryphal, as Wildom, Tobit, Ecclesiastick, and the Maccabees; but he frequently uses expressions which shew they were not esteemed the books of the prophets, or of equal authority with the books of the Jewish canon. In his “Retractions” (I. ii. c. 20.) he owns his mistake in quoting the book of Ecclesiastick as prophetic; when it was not certain that it was written by a prophet. He also says in another place, (I. ii. c. 20.) that he had not any proof of some propositions which he had advanced, but from the book of Wildom, which the Jews did not receive as of canonical authority: In another work written about the year 420, he says, “The Jews do not receive the scripture of the Maccabees as they do the Law, and the Prophets, and the Psalms, to which our Lord bears testimony, Luke xxiv. 49, that upon the whole, Augusitine feems not to differ from Jerome and Rufinus. For the testimonies of other ancient writers, Chrysostom, Theodoret, Cosmas of Alexandria, Gregory bishop of Rome, Leon
tius, &c. to the Jewish canon, we will refer to Lardner, ubi infra. In the Stichometry of Nicephorus, patriarch of Constantinople, who flourished in the beginning of the ninth century, we have a catalogue of the books both of the Old and New Testament. The divine scriptures mentioned in this work as received by the church and reckoned canonical, are: Genesis, Exodus, Leviticus, Numbers, Deuteronomy, Joshua, Judges, and Ruth, the first and second books of the Kingdoms, the third and fourth of the Kingdoms, the first and second of the Remains, Ezra, first and second, the book of Psalms, the Proverbs of Solomon, Ecclesiastick, the Song of Songs, Job, Isaiah the prophet, Jeremiah the prophet, Baruch, Ezekiel, Daniel, and the 12 prophets. All together, it is said, the books of the Old Testament are 32. The contradicted books are three books of the Maccabees, the Wildom of Solomon, the Wildom
Wisdom of Jeth, the Son of Sarch, Palms, and Odes of Solomon, Esther, Judith, Sifamam, and Tobit, called also Tobias. The writings of the book of Baruch, among the sacred scriptures of the Old Testament, is the only circumstance in which they catalogue differs from that of the Jews; but this, and the omission of Esther, which was not in all ancient catalogues, may be reckoned things of no great consequence. In the Itchomistry prefixed by Catechum to the apostolical constitutions there are 69 books of the Old and New Testament, among which were placed 5 books only, which we call Solomon's, the Proverbs, Ecclesiastes, and the Canticles: the other two, sometimes ascribed to him, Wisdom and Ecclesiasticus, are placed with those, which are out of the 69, or contradictory books. Among the 69 there is but one book of Ezra, probably meaning our Ezra and Nehemiah; but among the apocryphal is a book called the Revelation of Ezra. The book of Esther is not placed among the 69, but in the second class of such as were reckoned useful. See Bible.

The canonical books of the New Testament, received by christians in this part of the world, are the Four Gospels, the Acts of the Apostles, 14 Epistles of St. Paul, seven catholic Epistles, and the Revelation. Dr. Lardner suggests, that the chief canon of the New Testament, is that which may be collected from Eusebius of Caesarea, and which seems to have been the canon of Rome in his time. The canon should consist of two classes: the first consisting of those books, called παπαργίας, which he affirms we were then universally acknowledged, and had been uniformly received, by all catholic christians; these are the four gospels, the Acts of the Apostles, 13 epistles of St. Paul, one epistle of St. Peter, and one epistle of St. John. These only should be esteemed of the highest authority, from which doctrines of religion may be proved. The second class comprehends those books of which Eusebius speaks, called ἡκάκτων, as contradicted in his time, though well known; concerning which there were doubts, whether they were written by persons whose names they bear, or whether the writers were the Apostles of Christ. These are the epistle to the Hebrews, the epistle of James, the second and third of John, the epistle of Jude, and the Revelation. These should be reckoned doubtful, and contradicted; though many might be of opinion, that there is great reason to believe they genuine. They should be allowed to be publicly read in christian assemblies, for the edification of the people; but not to be alleged, as a deciding, alone, sufficient proof of any doctrine. Eusebius reckons a third class of books of the New Testament, called ἐλθαίς, spurious; but Dr. Lardner observes, that there should be no such third class of sacred books; forasmuch as there appears not any reason from christian antiquity to allow of that character and denomination to any christian writings, beside those above-mentioned. This canon is a good one, because it is short, and contains only those books, which were acknowledged by all in the time of Eusebius, and from the beginning; and seven others, which were then well known, and are next in esteem to those that were universally acknowledged; and were generally received as of more authority than any other controverted writings. Nor is there in them any thing inconsistent with the facts, or the principles delivered in the books, universally acknowledged. Moreover, there may be a great deal of reason to think, that they are the genuine writings of those, to whom they are ascribed, and that the writers were Apostles. No other books, beside those now generally received by us, ought to be esteemed canonical, or books of authority. The books contained in this canon, were written by several persons, in several places, and at different times; and it is, therefore, reasonable to think, that it was formed gradually. At the rise of the christian religion, there were no written fables or accounts of it: nor, indeed, was it so, that any books should be written about it, till there were converts to receive and keep them, and deliver them to others. In process of time, the writings of the apostles and evangelists would be repeatedly received by christian profeters, as the written word of God, or sacred scriptures. Those who received them would embrace the opportunities that occurred of conveying them to others; and those who received them so kindly offered of them persevered by those who delivered them. Before the end of the first century, or, indeed, not very long after the middle of it, it is likely there were collections made of the four gospels, and of most of the other books of the New Testament, which were in the hands of a considerable number of individuals and of churches. From quotations of some and from the writings of Irenaeus, Clement of Alexandria, Tertullian, and other writers of the second century, of Origen in the third, and of Eusebius in the fourth century, it appears, that most of the books, now received by us, and called canonical, were universally acknowledged in their times, and had been so acknowledged by the elders and churches of former times. And as to the rest, now received by us, though they were then doubted of, or controverted by some, they were well known, and approved by many. Athanasius, who lived not long after Eusebius, having flourished from the year 326, and afterwards, received all the same books, which are now received by us, and no others. This has been the prevailing sentiment ever since. This canon was not determined by the authority of councils; but the books of which it consists were known to be the genuine writings of the apostles and evangelists, in the same manner that we know the works of Caesar, Cicero, Virgil, Horace, Tacitus, to be theirs. And the canon has been formed upon the ground of an unanimous, or generally-concurring testimony and tradition.

That the number of books to be received as sacred and canonical has not been determined by the authority of any council or councils, universally acknowledged, is apparent from the different judgments among christians, in several parts of the world, concerning divine books, particularly the Epistle to the Hebrews and the Revelation; which were received by some, rejected, or doubted of by others. This was also the case with respect to some of the catholic epistles. No such authority had settled the canon of the New Testament in the time of Eusebius, because he mentions no such thing. There was no catalogue of the books of Scripture in any canon of the council of Nice, A. D. 325. Augustine, A. D. 397, giving directions to inquisitive persons, how they might determine what books are canonical, and what not, does not refer to the decisions of any councils. Cassiodorus, in the fifth century, has three catalogues, one called Jerome's, another Augustine's, and another that of the ancient version; but without reference to the decree of any council, as decisive. And it seems most probable, that in all times, christian people and churches had a liberty of judging for themselves according to evidence; which evidence, with regard to the genuinenesses of most of the books of the New Testament, has been so clear and manifest, that they have been universally received. The genuinenesses of these books was determined by testimony, or tradition. The first testimony is that of those who were contemporaries with the writers of them; and this testimony has been transmitted by others. That the primitive christians formed their judgment concerning the books of Scripture in this way, appears from their remaining works.
works. Influences to this purpose might be collected from Clement of Alexandria, Tertullian, Origen, Eusebius, Athanasius, Cyril, Rufinus, and Augustine. But, besides observing the testimony of writers in former times, they also criticized the books that were proposed to them; examining their style and contents, and comparing them with those books which had been already received, as genuine, upon the ground of an unanxious testimony, and undoubted tradition. Some indeed have said, that the council of Laodicea, held probably A.D. 256, first settled the canon of the New Testament. But it may be justly said to have been settled before. At least, says Dr. Lardner, there had been long before a general agreement among Christians, what books were canonical and what not. From the decree of the council itself it appears, that there were writings already known by the title of canonical. That council, in its last canon, merely declares, "that private plaus might not to be read in the church, nor any books not canonical, but only the canonical books of the Old and New Testament:" after which follows a catalogue or enumeration of such books, in which are rejected the apocryphal books of the Old Testament, and the Revelation in the New Testament. The 47th canon of the council of Carthage, assembled A.D. 397, ordains, "that nothing besides the canonical Scriptures be read in the church, under the name of divine Scriptures." This council's canon of the New Testament is the same as that now received, without any other later writings as canonical; though from the manner in which the Epistle to the Hebrews is mentioned, there is reason to suspect, that it was not so generally received as the other 39 epistles of St. Paul. "We no where read," says Le Clerc (H. E. ann. 100. num. iii. iv. et ann. 29. num. xxii.) "of a council of the apostles, or of any assembly of the governors of Christian churches, convened to determine by their authority, that such a number of gospels, either more nor fewer, should be received. Nor was there any need of it, since it is well known to all from the concursing testimony of contemporaries, that these gospels are the genuine writings of those whose names they bear; and since it is also manifest that there is in them nothing unworthy of those to whom they are attributed, nor anything at all contrary to the revelation of the Old Testament, nor to right reason. There was no need of a synod of grammarians, to declare what are the works of Cicero or Virgil. In like manner, the authority of the gospels has been established by general and perpetual consent, without any decree of the governors of the church. We may say the fame of the apostolical epistles, which owe all their authority, not to the decisions of any ecclesiastical assembly, but to the concursing testimony of all Christians, and the things themselves which are contained therein." Upon the whole, we may conclude, that the writings of the apostles and evangeliasts are received, as the works of other eminent men of antiquity are, upon the ground of general consent and testimony; nor does the canon of the Scriptures of the New Testament owe its establishment to the decisions of councils, but to the judgment of Christian people in general; and the judgment is right and reasonable. If we refer to the writings of ancient authors, we shall find, that they had the same canon of the New Testament with that which is generally received in our times. Accordingly, the catalogue of canonical books furnished by Origen about A.D. 235; Eusebius, A.D. 315; Athanasius, A.D. 326; Cyril, A.D. 347; (the book of Revelation excepted); Epiphanius, A.D. 370; Basil and Gregory Nazianzen, and Amphilochius, A.D. 370; Gregory Nyffen, A.D. 371; Jerom, A.D. 392; Augustine, A.D. 395; Rufinus, A.D. 397; Innocent I. bishop of Rome, A.D. 402; Ifigene of Pelusium, and Cyril of Alexandria, A.D. 412; Caesian, A.D. 424; Prosper of Aquitaine, and Eusebius, bishop of Lyons, and Sedulius, A.D. 433; Leo, bishop of Rome, and Savilian, prebiter of Marselles, A.D. 440; Dicyclus, falsely called the Areopagite, A.D. 452; Gelabius, bishop of Rome, A.D. 494; Andrew, bishop of Cæsarea, A.D. 570; Faunus, an African bishop, and Aristas, A.D. 540; Caedibarius, A.D. 556; Photius, patriarch of Constantinople, A.D. 838; Oecumenius, A.D. 950; Theophylact, A.D. 1070; (the Revelations excepted); and Nicephorus Callisti, A.D. 1337; agrees with that which is now received among Christians. We learn from Paul Sarpi's history of the council of Trent, that one of the doctrinal articles concerning Sacred Scripture, extracted, or pretended to be extracted out of Luther's works, was this: "that no books should be reckoned a part of the Old Testament besides those received by the Jews; and that out of the New Testament should be excluded the Epistle to the Hebrews, the Epistle of James, the second of Peter, the second and third of John, the Epistle of Jude, and the Revelation." And in that council there were some bishops "who would have had the books of the New Testament divided into two classes; in one of which should be rejected those books only which had been always received without contradiction; and in the other, those which had been rejected by some, or about which at least there had been doubts." Dr. Courayer, in his notes, seems to favour this proposal. See his French translation of the history of the council of Trent, (I. i. c. 43. tom. i. p. 235, and c. 47. p. 240. note 1). Concerning the difference of opinions that have fulfilled among ancient and modern writers, with respect to the authenticity of particular books, their authors, &c. see the titles of those books, Hebrews, Peter, John, James, Jude, and Revelation, or Apocalypse. For the time of writing the several books of the New Testament, and other particulars relating to them, see their respective titles. See also Gospel, Acts, Epistle, and Testament. Those who wish to examine this subject more at large, may consult, besides the well-known writings of Cohn, Richardson, Nye, Jones, Lardner, Michaels, Kennett, &c. "Gerhardi de Madrichi Canon Scriptures faciae ecclesiasticus," Jena, 1725; "Schmidtii Historia antiqua et Vindicatio Canonis Sacri V. et N. T.\" Lipsia, 1775, and "Stodchi Commentatio Historico-critica de Librorum N. T. Canon," Franco. ad Vindrum, 1755. Such persons as are acquainted with German literature will find much new and curious information in Dr. Seemler's "Freie Untersuchung," or Free Inquiry into the Canon, 3 vols. 12mo. Halle, 1771-1773; Weber's "Bezyräge zur Geschichte des Canons," Thibingen, 1791, and in Eichhorn's "Repertorium," vol. v. p. 217. Some of the fathers have distinguished the inspired writings into three classes: proto-canonical, deutero-canonical, and apocryphal; which see respectively. Canon, psephal; a table of the moveable feasts, showing the day of Easter, and the other feasts depending on it, for a cycle of nineteen years. The psephal canon is supposed to be the calculation of Eusebius of Cæsarea, and to have been done by order of the council of Nice. Canon, in Monastic Orders, a book wherein the religious of every convent have a fair transcript of the rules of their order, frequently read among them as their local statutes. This is also called regula, as containing the rule and institution of their order. The canon differs from the missale, martyrologium, and necrologium. Canon, again, is used for the catalogue of saints acknowledged and canonized in the Roman church.
**Canon.**

A canon is also used, by way of excellence, in the Romish church, for the secret words of the mass, from the preface to the **Pater**; in the middle of which the priest consecrates the host. The common opinion is, that the canon of the mass commences with *Te lucis*, &c. The people are to be on their knees, hearing the canon; and are to reverence it to themselves, as not to be heard.

The Latin canon is, *canto fuscum, regula, a rule or law.* In speaking of harmonies, in the division of the monochord, it implies the ratio of sounds, or the proportion of sound to sound, when a string is divided by moveable bridges into harmonic intervals. Hence *Eulcid's celebrated tracts on harmonies, as well as Ptolemy's,* is called *fettu canones,* the section of the canon.

But, in musical composition, a canon is a law given by one part to another, or to several parts. As nothing is more difficult to compose than canons, in no species of composition has exercised ingenuity, meditation, and labour, in more various ways than the construction of canons.

In the unison and octave, they are not only more easy to compose, but are more pleasing to hear; as all other canons are moving in two or three different keys at the same time. But canons that are easy to write, and pleasing to hear, are in no collision among masters and profound contrapuntists. They have no more respect for a canon in the unison and octave, than a geometrical for a four in addition; they regard canons as mathematical problems, of which, if the solution is easy, they are unworthy of notice. They are, in reality, more calculated to exercise intellect, than delight the auditor's ear.

Canons in the 5th or 4th obtain the most reverence; but these furtive imitations have been practised in the 2d, 3d, 6th, and even the 5th. But rigid fugues call these only imitations, as the intervals are not familiar. Canons were the last compositions which masters condescended to publish in score. They were regarded as enigmas, which required the deepest sagacity and science to unfold. All the several parts were written on one staff, frequently without specifying when, where, and in what interval the other parts came in. Sometimes, indeed, the composer was so indulgent as to place this character, $^\dagger$, over the first or second of each of the other parts; but without indicating at what distance from the *proposa* or subject, or whether above or below it. At other times the performers were told what kind of canon it was, and how resolved by a Greek or Latin term; that is, on what found the *risposta* or answer. It was to be made. If in the 4th, 5th, 6th, &c. the words *diatessaron, diapente, diatessaron,* &c. occur. If these terms are used simply and unaccompanied, they generally imply that the answer is made in such interval above; but if some expletive is not added to the interval in which the answer is made, the performer is uncertain whether it is above or below the text or subject proposed.

Padre Martini says (Saggio di Contrappunto) that there are so many canons still preserved of the old ecclesiastical composers, each of which is upon some peculiar construction, that it would require a long treatise even superficially to explain them.

A canon that is written and composed in a mysterious and singular manner, is called the Italian *canons chino*; a canon in score, or clearly explained, *canons operto.* A canon written only on one line, and seemingly in one part or melody, sometimes has its solution pointed out by different clefs and rests at the beginning. In old composers, whether the *risposta* is made above or below the subject, is often determined by the Latin particle, *alter,* or *alt,* or by the Greek *hyper,* or *hypo.* So many of the most ancient canons are,
CANON.

To give a list of the principal writers on fugue and canon would be enumerating all the authors who have written on music from the 17th century to the present. The rules have been varied but little from Pietro Aro's time, though new contrivances and new eminences have been multiplied without end.

Composition in plain and florid counterpoint should be studied, and its rules and exceptions well digested by a musical student, before he attaches himself to fugue and canon, which will make him indifferent about melody, provided, under canonical restrictions, he can make his harmony correct.

All that now remains for us to do, in order to smooth the way in this kind of study when the young composer thinks it expedient to undertake it, is to give a few short specimens of the principal kinds of canon that have been cultivated by great masters of the old school, when nothing else was prized, and all their powers were devoted to that almost exclusively.

No writer has more clearly laid down the rules of fugue and canon than Dr. Pepusch, as no one was more deeply read than he was in all the annals of that kind of lore. Mosquera, Padre Martini, Kirnberger, and subsequent writers, may have somewhat extended and detailed the rules more minutely than the venerable graduate of one of our universities; but as far as he goes, we may safely depend on his doctrines. Concerning canon, his precepts are few and short; but of fugues, both precepts and examples are not only numerous, but luminous and indisputable, which rendered it less necessary to be diffuse on canon, as the laws of fugue are the laws of canon, with respect to bringing in the anwers of the several parts; and all the short examples of fugue in Dr. Pepusch's treatise are almost wholly in canon.

After fully treating of regular fugue, and its laws, he says: "Regular fugues are of two sorts: the one is called by the Italians, *fuga logata,* and the other *fuga fidelis.* The first sort is in English generally called canon, and we may express the other by the name of *free fugue.*"

"A Canon is that sort of fugue in which the several parts strictly contain the same melody from the beginning to the end; or in which the guide and the answers are, throughout the whole composition, exactly alike.

"A Free Fugue is not confined to this obligation; for in that we may introduce various subjects, different from the theme on which the fugue began, and break off also at pleasure; however, every subject introduced is a guide, which must have its answer in the same *falsification* (intervals) as itself; and these *free subjects* must also be very regularly introduced, according to the different keys into which the modulation is brought, and which are proper to the chief key of the composition."

It seems as necessary for the accents of the answers to a canon to fall on the same parts of a bar, as in a fugue; particularly in setting words. Even in Sala's excellent examples of canon, when the subject is led off after a minim rest in one part, and a semibreve rest in the *riffage,* or reply, the melody is so disguised, and there is such confusion, that there is no canon, nor hardly an imitation, discoverable by the ear from the beginning to the end; so that all the pains and ingenuity that have been bestowed on the construction are thrown away; and if there is any melody in the first part, it is totally destroyed by the second. For eminent writers on canon, expressly, see Valentini, Michele, Rocco Rodio, and Bevin.

After all that has been said in this long article, in favour of *Canon* as an ingenious contrivance, and of its utility among the studies of young musicians; we must own that *canons* which have no other merit than the difficulty of their construction and solution, should never see the light, being the mere off-spring of pedantry and dulness; but that such laborious works of this kind as are built on agreeable subjects, and are rich in harmony, may, in society, afford great pleasure to real lovers and judges of music, cannot be denied.

**Canon of Ptolemy**, in Chronology, a canon of the Chaldaean, Persian, Greek, and Roman kings, compiled by Claudius Ptolemaeus, who flourished in Egypt in the reigns of Adrian and Marcus Antoninus, about A.D. 150, from the annals and histories of the several kingdoms to which it relates, and esteemed an invaluable treasure in the science to which it is subservient. It has been preferred in Commentaries of Theon, and published by Overall and Petaurus from two MSS. in the royal library at Paris. In this canon the author computes from the epoch of the Nabonassarian æra, and from that day of the month on which the Egyptian Thoth fell. The years made use of are Egyptian, and consist of 365 days, without intercalulation. In every reign the years are reckoned as complete; and those reigns which are less than a year, are omitted, whether they comprehended a Thoth or not. This defect was, in some degree, supplied by additions to other reigns; yet it appears in history, that a year was now and then superseded. The first part of this canon has been improperly entitled "Ptolemy's Canon of the Kings of the Assyrians and Medes," as it includes none but kings of Chaldaea or Babylon.

**Canon of Ptolemy.**

Playfair's Chronicle, p. 312.

CANON, in Geometry and Algebra, a general rule for the solution of all cases of a like nature with the present inquiry. Thus every letter of an equation is a canon; and, if turned into words becomes a rule to solve a question of the same nature with that proposed.

CANON, natural, of triangles, is a table of sines, tangents, and secants together; so called, because serving principally for the solution of triangles.

CANON, artificial, of triangles, is a table wherein the logarithms of sides and tangents are laid down. See SINE, under which article the method of constructing the natural and artificial canon will be explained. See also GUNTER, Gunter's Line, Scale, and Sector.

CANON Law, a collection of ecclesiastical constitutions, decisions, and maxims, taken partly from Scripture, partly from the decrees of general and provincial councils, and partly from the decrees of the popes and bulls of the holy See, and the reports of the fathers of the primitive fathers, whereby all matters of policy in the Roman church are regulated.

"If the canon law," says Dr. Robertson (Hist. Charles V. vol. i. p. 74, &c. Svo.) "be considered politically, either as a system pursued on purpose to subvert the clergy in usurping powers and jurisdiction, or else repugnant to the nature of their function, than inconsistent with the order of government; or as the chief instrument in establishing the dominion of the popes, which shook the throne, and endangered the liberties of every kingdom in Europe, we must pronounce it one of the most formidable engines ever formed against the happiness of civil society. But if we contemplate it merely as a code of laws respecting the rights and property of individuals, and attend only to the civil effects of its decisions concerning that, we must view it in a different, and a much more favourable light." It is not easy to fix with precision the period at which ecclesiastics first began to claim exemption from civil jurisdiction. In the early and purest ages of the church, they made no pretences to such immunity. The authority of the civil magistrate extended to all persons, and to all cases. But in ages of ignorance and credulity, the ministers of religion became objects of universal reverence. Accordingly we find in Tacitus (de Mor. Germ.) that priests were highly revered by the Germans, and that they presided in the assembly of the people. They alone were permitted to chastise, to bind, and to punish; which they did, not by order of the prince, or of his ministers of justice; but, as by an inspiration of that Deity, who is always present to those who make war. When the barbarians who overran the empire first embraced the Christian faith, they found the clergy in possession of considerable power, and they naturally transferred to these new guides the profound submission and reverence which they had been accustomed to yield to the priests of that religion which they had forsaken. The clergy, whose function was regarded as sacred, availing themselves of the advantage which the superstition and credulity of mankind afforded them, gradually emancipated themselves from subjection to the profane jurisdiction of the city and to civil courts; and extended that indulgence which seems at first to have been merely an act of complaisance, flowing from reverence of their character, into a legal exemption. Hence they proceeded to establish courts, in which every question relating to their own character, their function, or their property, was tried. Upon different pretexts, and by a multiplicity of artifices, they communicated this privilege to so many persons, and extended their jurisdiction to such a variety of causes, that most concerns which gave rise to litigation were drawn under the cognizance of the spiritual courts.

Du Cange, in his Glossary (Voc. Curia Christiianatatis) has collected most of the causes with respect to which the clergy arrogated an exclusive jurisdiction, and refers to the authors, or original papers, which confirm his observations. Gian-Ni, in his Civil History of Naples, (l. xix. § 3.) has ranged these under their proper heads, and scrutinizes the pretensions of the church with so much boldness and confidence. M. Fleury observes, (Hist. Eccl. tom. xix. Disc. Prelim.) that the clergy multiplied, at such a rate, the pretexts for extending the authority of the spiritual courts, that it was in their power to withdraw every person and every cause from the jurisdiction of the civil magistrate. The ambitious project of erecting a spiritual monarchy, superior to all others, even in worldly power, was manifested by the whole conduct of the bishops of Rome, and of the clergy generally, in their relations with them, both before and after the period in which the canon law was perfected. This appears in the canons enacted by their councils for the government of that monarchy; and it was very signally displayed in the canons of the provincial synod, held at Merton in Surrey, A. D. 1258, by Doniface, archbishop of Canterbury. The first canon of that synod forbids archbishops, bishops, and inferior clergy, to appear before civil courts to answer for any part of their conduct which had the most remote relation to church affairs; and threatens the judges, and even the king himself, with the highest censures of the church, if they infringe on such appearance. The second relates to patronages; and the third is against the intrusion of clerks into benefices by a lay power. The fourth makes such regulations concerning excommunication, as rendered that sentence truly terrible. The fifth forbids laymen to imprison clergymen. In the sixth, the church claims a right of judging concerning contracts between a clergyman and a layman. The seventh affords a right of the church to judge and punish Jews. The eighth provides for the perfect security of those criminals who had taken refuge in churches. The ninth, tenth, and eleventh, are designed to prevent all invasions of every kind in the possessions of the church and clergy, which are declared sacred and inviolable. And the two last provide...
The first "Syntagma" of canon law was composed by John the Scholastic, a priest of Antioch, in the sixth century. He is also the author of the "Nomo-Canonon." Both were published at Paris in Juyfelle's "Bibliotheca Juris Canonici," tom. ii. In the ninth century, the celebrated Photius compiled his "Syntagma Canonum," and his "Nomo-Canonon." The former has not been published; but the latter was given with a Latin version and Balfon's commentary, by Juyfelle, at Paris, 1615.

The canon law that obtained throughout the whole of the twelfth century, was the collections of canons, "Codex canonum," compiled by Dionysius Exiguus, in 526, and published by Juyfelle in 1628, and improved by Lidore of Seville, who appropriated them to the discipline of Spain; the capitularies of Charlemagne, and the decrees of the popes, from Siricius to Anastasius. No regard was had to any thing not comprised in these; and the French have since maintained the rights of the Gallican church to confit in their not being obliged to admit any thing else, but to be at liberty to reject all innovations made in the canonical jurisprudence since that compilation, as well as papal decrees before Siricius.

Indeed, between the eighth and eleventh centuries, the canon-law was mixed and confounded with the papal decrees from St. Clement to Siricius; which till then had been unknown: this gave occasion to a new reform, or body of the canon-law, or harmony of discordant canons; which is the collection still extant, under the title of "Concordia Discordantium Canonum," first made by Ivo, in 1144, and perfected in 1154, by Gratian, a Benedictine monk, from texts of Scripture, councils, and sentiments of the fathers, in the several points of ecclesiastical polity; and containing those constitutions which have been denounced, by way of eminence, the Decrees, and forming the first part of the canon-law. These are the most ancient, as they commence from the time of Constantine, the first Christian emperor of Rome, and they reached as low as the time of pope Alexander III. It is now generally known by the name of the "Decretum" of Gratian, which was formed in imitation of
the Pandects of Justinian; and is a confused immemorial
compilation, full of errors and forgeries.

The second part of the canon-law consists of the decrees
of the popes, from the time of pope Alexander III. to pope
Gregory IX., and published, under the auspices of that pope,
by Raymondus Bazenius, about the year 1230, in five
books, entitled "Decretalia Gregorii Nom." 

In 1409, pope Boniface VIII. continued the papal
decrees as far as his time, under the title of "Secundus
Decretalium." To these, pope John XXII. added the "Clement-
ine," or the constitutions of his predecessor Clement V.
approved by the council of Vienne, and full authenticated
about the year 1317. And to all these were afterwards
added twenty constitutions of the said pope John, called
the "Extravagantes," and some other constitutions of his
successors, called "Extravagantes Communes." These are
usually called the DECRETALES.

All these, viz. Gratian’s decrete, Gregory’s decretals, the
sixth decretal, the Clementine constitutions, and the extrava-
gantes of John and his successors, form the "Corpus Juris
Canonicus," or body of the Roman canon-laws, which,
including the comments, make three volumes, in folio; the
rule and measure of church government. As the decrees set
out the origin of the canon law, and the rights, dignities,
and decrees of ecclesiastical persons, with their manner of
election, ordination, &c. so the Decretals contain the law
that is to be used in the ecclesiastical courts; and the first title in
every one of them is the title of the blessed Trinity, and of
the catholic faith, which is followed with constitutions and
customs, judgments and determinations in such matters and
casus as are liable to ecclesiastical cognizance, the lives and
conversion of the clergy, of matrimony and divorces, in-
quisition of criminal matters, purgation, penance, excommuni-
cation, &c. But some of the titles of the canon-law are now
out of use, and belong to the common law; and others are
introduced, such as trials of wills, bastardy, defamation, &c.
Beneath these pontifical collections, which during the times of
popery were received as authentic in this island, as well as in
other parts of Christendom, there is also a kind of national
common-law, composed of "Regatus" and provincial consti-
tutions, and adapted to the exigencies of this church and king-
dom. See Constitutions. At the dawn of the reformation,
in the reign of Henry VII. it was enacted, that the
canon-law should be reviewed; and till that review took
place, such canons, constitutions, ordinances, and synods
provincial as had been made, and were not repugnant to the
law of the land or the king’s prerogatives, should still be used
and executed. The review was proposed again in the reign of
Edward VI. and of Queen Elizabeth; but as it was never
accomplished, the authority of the canon-law in England
depends upon the statute of the 25th Henry VIII. c. 19,
which was repealed indeed by Queen Mary, and again revived
and confirmed by 1 Eliz. c. 1.

As to the constitutions and canons made in the convoca-
tion of the province of Canterbury in 1263, ratified by the
king, and soon after adopted in the province of York; these
never obtained a parliamentary confirmation; and it has been
therefore adjudged upon the principles of law and the consti-
tution, that where they are not merely declaratory of the ancient
 canon-law, but are introductory of new regulations, they do not bind the laity, however the clergy may regard
them. Strang’s Rep. 1672.

Lord Hardwicke cites the opinion of Lord Holt, and de-
clares it is not denied by any one, that it is very plain all the
clergy are bound by the canons, confirmed merely by the
king; but they must be confirmed by the parliament to bind
the laity. 2 Atk. 825.

There are four species of courts, in

which the canon (and civil) laws are permitted, under cer-
tain restrictions, to be used. The courts of the archbishops
and bishops, and their derivative officers; usually called in our
law courts, Chancery, or the ecclesiastical courts. 2. The
military courts, or courts of chivalry. 3. The courts of
Admiralty. 4. The courts of the two universities. Their
reception in general, and the different degrees of their re-
ception in all these courts, are grounded entirely upon cus-

CANONESS, in the Roman Church, a woman who enjoys a prebend, affixed by the foundation, to maids; without their being obliged to renounce the world, or to make any vows. There are few of these, except in Flanders and Germany; they are rather looked upon as a female race and retreat of girls for marriage than an engagement for the service of God.

Canonesses of St. Augustine, or Regular Canonesses, are a kind of religious, who follow the rules of St. Augustine, of which there are various congregations. The order of canonesses was first instituted by Lewis the Meek, in the beginning of the ninth century.

Canonesses, in Modern History, a denomination given in Belgium to the registers of land, and hereditary expanders of the uages of the country. They have every where their officers and deputies, and are not liable to removal; and all papers attested by them are received as authentic and decisive in disputes concerning lands and their boundaries.

Canonheriis, Peter, Andrew, in Biography, the son of a physician of eminence at Genoa, under whom he received the rudiments of his education, which he completed at Parma, where he applied with equal industry to the study of medicine and jurisprudence. In 1604, probably on his being created doctor in philosophy, medicine, and theology, he published at Parma "Conclusiones philosophicae et medicinae," 4to. and the same year "De admirandis Vini Viticulture," 8vo. Antwerp; in 1607, "De Cunivola Doctora Libri quinque," 4to. Florissant. But his principal work is, "In septem Aphorismorum Hippocraticis Libros, medicae, politicae, morales, ac theologice Interpretationes," Ant. 1618, 2 tom. 4to. But the labour of the author has rather obscured, than elucidated the texts he meant to explain. Haller Deh. Med. Eloy. Diet. Hill.

Canonica, in Philosophical History, an appellation given by Epicurus to his doctrine of logic. It was called canonica, as consisting of a few canons, or rules, for directing the understanding in the pursuit and knowledge of truth: and it is represented as a very flight and insufficient logic, by several ancients who put a great value on his ethics and physics. The fables of Epicurus's canonica consists in his doctrine of the criteria of truth. All questions in philosophy are either concerning words or things: concerning words, concerning things, they seek their truth; concerning words, their signification: things are either natural or moral; and the former are either perceived by sense, or by the understanding. Hence, according to Epicurus, arise three criteria of truth, viz.: sense, anticipation or premonition, and passion. The great canon, or principle, of Epicurus's logic is, that the sense is never deceived; and therefore, that every sensation, or perception of an appearance, is true. Stanley's Hill. Phil. p. xiii. p. 35. See Epicurean Philosophy.

Canonica is also used by some ancients to denote the art of music: and it is more particularly used to denote that species of music, which does not determine the intervals of sounds by the ear, but by a canon or fretted chord. See Canon.

Canonical, something that belongs to, or partakes of the nature of a rule or canon: and amounts to much the same with what we otherwise call regular.

Canonical is an appellation more peculiarly given to those writings which have been received as the rule of our faith and practice, and comprehended in the canon or catalogue of the Scriptures. In which sense, canonical stands contradistinguished from apocryphal. Divines generally hold, that those books only of the New Testament are to be accounted canonical, which were either written, or at least approved and authorized by the apostles. Formerly they were not so well distinguished as among us. In the first ages of the church, Dodwell observes the genuine writings of the apostles used to be bound up together with those now called pseudepigraphi, and apocryphal; so that it was not manifested, by any public judgment, which of them was to be preferred to the other; but later times thought fit to make a separation.

The Jews allow of no books for canonical, but those written before or soon after the return from the Babylonish captivity, when the gift of prophecy ceased among them. In determining the question, what books are canonical, and what are apocryphal, some have had recourse to the authority of the church. Accordingly, the papists have generally affirmed, in their controversies with the protestants, that the authority of the Scriptures depends upon, or is derived from the power of the church; or, in other words, that it is in the power of the pope, or council, or both, to determine what books shall be received as canonical. Others are of opinion, that there are innate evidences in the Scriptures themselves, which, applied by the illumination or testimony of the Holy Spirit, are the only true proofs of their being canonical, or the word of God. The insufficiency of these two modes of decision has been examined and evinced by several writers, and particularly Mr. Jones, ubi infra. The principal, and without doubt, most unexceptionable and satisfactory method by which this question can be determined, is tradition, or the well approved testimonies of those who lived in, or near the time when the books supposed to be canonical, were written. To this purpose Mr. Jones alleges, that the several books of the New Testament, at their first writing, were published abroad to the world, and delivered to the first churches in distant countries, for their use; and they who first received them knew them to be the books of the persons under whose names they were published, and could, and did testify to the succeeding ages, what they thus knew of the facts. This testimony of the primitive churches is still faithfully preferred in the writings of the ancient Christians, and is, therefore, not only a good and sufficient, but the principal means by which we know the truth of the fact, viz. that the books were written by such and such men. Besides, the books contain in themselves evidences of their excellency above all others, which should serve to confirm our faith; and, for our farther help, we may hope to obtain the influences of God's Holy Spirit, to clear our judgments, and free us from prejudices, to help us to perceive the former evidences in their due strength, and to impress the things revealed on our minds, as to produce a suitable conduct. Moreover, those books which are mentioned in the catalogues made by the most ancient Christian writers of the sacred and inspired books, are to be esteemed canonical, and those which are not found in any of these catalogues, must be considered as apocryphal. And farther, those books are justly esteemed canonical, which the first writers of Christianity have cited in their writings as Scripture, and those apocryphal which they have not so cited. Besides, those books are canonical, which the primitive Christians read in their churches, or public assemblies, as the Scriptures or word of God. Jones's new and full Method, &c. vol. i. See Canon and Apocryphal.

Canonical, pseuf, or deutero-Canonical. See Canon, and Deutero-Canonical.

Canonical is also an appellation given to those epistles in the New Testament, more frequently called catholic, or general epistles.

Canonical, canonicus, was also an appellation given to all the officers and ministers of a church or monastery, from the
the bishop or abbot to the meanest servant, including priests, monks, virgins, and all who were entered in canon, that is, in the matricula or register of the church.

Canonical benefice, canonici egoi, was an ancient tax, or tribute, imposed on certain provinces, whereby they were obliged to furnish the emperor with so many horses to mount his cavalry.

Canonical benefices, or certain fixed incomes of the day, were certain of the clerics, more especially under the Roman church, to the office of prayer and devotion. Such were matern, salubris, beneficia, benefices, beneficium. In our country the canonical hours are from eight to twelve in the evening, before which marriage cannot legally be performed in any parish church.

Canonical infliction, a regular and legitimate collation to a heretic, agreeable to the rules of the canon law.

Canonical letters, in the Ancient Church, were a sort of testimonials of the orthodox faith, which the bishops and clergy sent each other, to keep up church communion, and distinguish orthodox Christians from Arsy, and other heretics. When they had occasion to travel into other dioceses, or countries, dignitary and recommendatory letters, also letters of peace, &c. were so many species of canonical letters. See DISMISSAL.

Canonical liberty, a freedom to which certain churches are left, being governed by the ancient canons and usages established before the papal hierarchy was carried to its height; such as that which, of later days, the French call the Gallican liberty.

Canonical life, the method or rule of living preferred by the ancient clergy who lived in community. The canonical life was a kind of medium between the monastic and clerical lives.

The orders of monks and clerks were originally distinct; but, in the process of time, pious persons instituted colleges of priests and canons, where clerks, actually engaged in the ministry, or admitted for it, might live under a fixed rule, which, though somewhat more easy than that of the monks, was nevertheless more restrained than the secular. This was called the "canonical life," and those who embraced it, "canons." Authors are not agreed concerning the founder of the canonical life. Some ascribe it to the apostles; others refer it to pope Urban I., about the year 1230, who is said to have ordered bishops to provide each of their clergy as were willing to live in community with necessities out of the revenues of their churches. Most writers ascribe it to St. Augustin, who, having engaged a number of clerks to devote themselves to religion, instituted a monastery within his episcopal palace, where he lived in community with them. Onuphrius Peninus says, that pope Gelasius I., about the year 495, placed six regular canons of St. Augustin in the Lateran church.

Canonical obedience, is that communion which by the ecclesiastical laws the inferior clergy are to pay to their bishops, and religions, to their superiors.

Canonical portion, is the amount of the estate of a person deceased, as the canons allow to the parish church to which he belonged.

Canonical punishments are those which the church may inflict: such are excommunication, degradation, and penance, in Roman catholic countries; also excommunication, alms, whipping, &c.

Canonical purgations were ancient methods of proving innocency by ordeal, purgation, &c. See also CONFIRMATION, Oath, &c.

Canonical fines, in the ancient church, those which were capitul or mortal; such especially were idolatry, adultery, murder, heresy, and schism.

CANONICUM, in a general sense, denotes a tax, or tribute.

CANONICUM is more particularly used in the Greek church, for a tax paid by the clergy to bishop, archbishops, and metropolitans, for their use, and the support of their honours.

CANONICUM also denotes a duty of thirds, paid by the Greek laws to their bishops, or, according to Du Cange, to their priests. The canonicum is assessed according to the number of monks, or clerics, in a place.

The emperor Justinian Canonicus made a constitution for regulating the canonic ton of bishops, which was confirmed by another made in 696, by his nephew Alexius Comnenus. A village containing thirty fires, was to pay for its canonicum, one piece of gold, two of silver, one sheep, six bushels of barley, half a bushel of wheat, six measures of wine, and thirty loaves. Du Cange, Glos. Gr. tom. i. p. 578.

CANONIST, a person skilled in, or who makes profession of, the study and practice of the canon-law.

Canonists and civilians are usually combined in the same persons. And hence the title of dexter juris uritius, or legum doctor, usually expressed in abbreviation, L.L. D. or J.L. D.

CANONUM, in ancient Geography, a place of the isle of Albion, on the route from Venta Lancorum to Londonium, between Cambodunum and Caeranomag, according to Antonine's Itinerary. Mr. Camden has placed this station at Chelmsford, and Dr. Gale hath fixed it at Little Canfield.

CANONIZATION, a declaration of the pope, whereby, after a great deal of solemnity, he enters into the list of saints some person who has lived an exemplary life, and wrought miracles; or, as is often the case, performs some singular service for the church, in which a principal part of this kind of merit consists. See BEATIFICATION.

The word canonization seems to be of later origin than the thing; there being no influence of the use of the word before the twelfth century, whereas St. Ulrichius was canonized in the tenth. The term is formed from canon; because the primitive canonizations were only orders of the popes, or bishops, whereby persons eminent for piety, &c. were inserted in the canon of the mass, that they might be commemorated in the service; because, in those days, the use of martyrologies was unknown in the church. Mabilon distinguishes two kinds of canonization; a general, and particular; the first made by a general council, or a pope; the second, by a bishop, a particular church, or a provincial council. There are instances likewise of canonizations, or at least of something very like them, by abbots.

At first, only martyrs were canonized; but by degrees they came to confessors, &c.

Canonization was anciently confined in infecting the saint's name in the sacred dupplex, or canon of saints; in appointing a proper office for invoking him, and erecting churches under his invocation, with altars for masses to be celebrated on; taking up the body from the place of its first burial, and the like ceremonies: by degrees, other formalities were added; and processions were made with the saint's image in triumph; the day of his death was declared a feast; and to render the thing fill more solemn, Honorius III. in 1225, added several days indulgence to a canonization.

It is a great dispute among the learned, when the right of canonization, which it is owned was anciently common to ordinaries, especially metropolitans and princes, with the pope, became first peculiar to the pope. Some say, Alexander.
The subject of Antwerp, in their Propylæum, affix, it was not established till two or three ages ago; and then by a mere custom, which passed tacitly into a law, which appears not to have been generally received in the tenth and eleventh centuries. This, however, is pretty certain, that it was generally allowed before pope Alexander III., but since his time we read of no faults canonicæd by any but the popes, to whom he is said to have restricted the privilege and cognizance of canonization; and the archbishop of Vienne in France, and his suffragans, acknowledged it in an authentic manner in the year 1271, by a letter written to Gregory IX. deferring him to canonize Stephen, bishop of Die, who died in 1208. "Quia nemo," they say, "quoniam meritorum prærogativa pulest, ab ecclesia Dei pro faciendo habendus, aut venerandus ess, nil prius per sedem apostolicam ejus fæatus fuerit approbatas.

**CANONICAT**, in Geography, a small island of North America, in Newport county, Rhode island, extending south nearly as far as the south end of Rhode island, and north about seven miles, its average breadth being about one mile; the south shore forming the west point of Newport harbour, and the west shore being about three miles from the Narragansett shore. On this point is Jamestown. It was purchased of the Indians in 1657, and in 1678 incorporated by the name of Jamestown. The soil is luxuriant, producing grain and grapes in abundance. Jamestown contains 507 inhabitants, including 16 slaves.

**CANONNIERE** is a small loophole or opening made in a wall, for firing through with a musket or sable. Thus canonniere de retrachements are openings made in the soldiers' huts or cabins, for firing through on the enemy. The word is now in general use, of canonniere being substituted in its stead. The name of canonniere, however, was formerly given to embrasures.

**CANONIER** is also a fort of tent, in which infantry and cavalry lodge on a campaign. One of them, like a hut or cabin, holds seven men. They are of different forts and sizes, according as they are intended for the accommodation of infantry, cavalry, fuitlers, servants, and officers. For a description of their forms or figures, see the article CASTRAMETATION.

**CANONY, or CANONICATE, the benefice filled by a canon. Canonicate is dilLATED from prebend, in that the prebend may fit without the canonicate, whereas the canonicate is imparable from the prebend. It is to the canonicate, not to the prebend, that the right of suffragances, and other privilages, are annexed. See PREBEND.

**CANONSBUY, in Geography, a town of North America, in Washington county, Pennsylvania, pleasantly situated on rising ground, near the north side of the west branch of Chartier's creek. 18 miles S.W. from Pittsburgh, and 9 miles N.E. from Washington. It contains about 100 houses, and two meeting-houses, one belonging to the Presbyterians and the other to the Seceders. Its academy is flourishing, and a charter was lately granted in the formation of the assembly for a college. In its vicinity are several valuable mills.

**CANOPICUM, in Ancient Geography, a town of Africa Propria, situated between the town of Tabraca and the river Bagradas. Pliny says, that it was inhabited by Roman citizens. It is the "Canopica" of Ptolemy.

**CANOPUS, in Astronomy, a bright star of the first magnitude in the rudder of Argo, a constellation of the southern hemisphere. See ARG.

The longitude of Canopus, as given by Halley, for the year 1705, is 10° 52' of Cancer, and its southern latitude, 75° 49'. F. Noel, in 1697, found its right ascension 93° 54', its declination southwards, 52° 29'. F. Tencille, in the beginning of March 1705, observed the declination of canopus 52° 50' 4'. F. Thomas, in January 1682, found the declination 52° 51' 33', its right ascension 95° 32' 20", longitude, 8° 54' 50".

**Cancer, latitude southern 75° 55°**.

**CANAUS, in Ancient Geography, a town of Egypt, seated at the distance of 120 stadia from Alexandria, near the sea, and at the extremity of the western branch of the Nile, hence called "Olbian Canopicum," or the Canopic branch. This branch commences near Ptolemais or Pough, crosses the lake of Behir or Bahira, and falls into the fec near the feet of Canopus. Near its termination is the lake "Madid" or "Maadie," denoting in Arabic "passage," which is the remains of this branch. This lake is, at present, only a saltwater lagoon, which has no communication with the Nile, except at the time of its greatest increase. It is passed on horseback, when the overflowing of the river, or a continual fresh, has not augmented the depth of the water. In other cases it is crossed in a boat, but the pass is very unsafe and incommodious. The mouth of this ancient branch of the Nile is very narrow, and formed by a bank of sand. On the eastern bank stands a large square building, resembling in its construction that of the French factory at Alexandria, and of all the Caravanseries in Egypt. Beyond Maadie towards the site of Canopus, from which the sea forms an immense bight, the sea-shore is so low, that it became necessary to raise ditches or embankments of solid construction and of considerable extent for keeping out the sea, which covered a part of the adjacent ground as long ago as the time of Strabo, and which in bad weather still overflows the dykes, extends as far as the promontory of the prent Aboukir, and inundates a great space of land. Upon these dykes small towers are erected at some distance from each other. The town of Canopus, which is said to have been built by the Laocæmonians, and which is mentioned by several ancient writers, as Pliny, Tacitus, Seneca, and Juvenal, &c. was erected upon a rock, forming a handy road for shipping, and elevated above the reach of inundations. Pliny, who collected the testimonies of antiquity relating to this place, says, that it was formerly an island; and the Periplus of Scylax points out a defect island near the Canopic mouth: the local situation of Canopus renders this account credible. The remains of this ancient city occupy a vast extent of ground, which is strewn with ruins that present many objects of admiration to the curious inquirer. The columns of beautiful granite that are found among these majestic ruins, called by the inhabitants of Aboukir, the city of Pharaoh, are of alluring magnitude, and their capitals are of the finest workmanship; some of these columns were not long ago standing, together with a large arch that formed the entrance to a subterraneous cavern; but they have recently been destroyed by the natives for the sake of the stones, which they employed in their buildings and in repairing the dykes that confine the sea. On the sea-shore are still observable, the foundations of a very large, regular building, in the midst of which is a cavern leading to the sea, where ruins are to be seen at a great distance. Blocks of granite of different forms
forms lie scattered among the ruins of antiquity, and in the midst of these occasionally covered by the sea, which has made considerable encroachments, is a colossal statue of a woman, made of granite, fluted through its whole length, and in some of its parts mutilated, which the people of the country conceive to have been the figure of Pharaoh's daughter. By the side of the statue is a very large sphinx, partly mutilated, the pedestal of which is encircled with hieroglyphics almost effaced. The columns of granite with which this place abounds, are probably parts of the magnificent temple, consecrated to the honour and for the peculiar worship of Serapis. Foreigners from the most distant provinces, but particularly from Alexandria, resorted hither in crowds, attracted rather by the pleasures they might enjoy in the city, than for the purpose of offering sacrifices to the god. The priests were, indeed, consulted as physicians, than as interpreters of the oracle, and they were occupied in reciting the marvellous oracles that were performed here, the honour of which they attributed to Serapis. We need not wonder that this should be a place of great resort, when we consider that the surrounding country, inhabited by the Nile, was clothed with the riches of nature, and that the city afforded all the enjoyments of luxury in the greatest profusion. The attractions of the situation, the beauty of the climate, the delicacy of the table, the general affluence of the people, and, in short, the pleasures of every kind, which seemed to have made this their favourite abode; all concurred to make Canopus the most enchanting retreat, and to render its inhabitants the happiest of all people.

"Felici gens fortunata Canopi,"

says Virgil, Georg. i. iv. But diffusion had here attained its highest pitch; licentiousness knew no bounds. Strabo (i. xvii. vol. ii. p. 1153) informs us, that the canal which passed from Alexandria to Canopus was covered night and day with boats, full of men and women, who sang and danced in the most lewdish manner. To the same purpose Seneca observes, (Epist. 51) that if a page wished for retirement, he would not choose Canopus as a place of retreat. Juvenal, when he is representing in strong terms, the degree in which the manners of the Romans were corrupted, says, that Canopus itself condemned them:

"--- Et moris urbis dammate Canopo."

Upon or near the ruins of ancient Canopus, is built the present Abukir, called by mariners, Bekir, which has a cable built upon the point, a cape which permits a considerable way into the sea. Some shallows stretching out beyond the cape enclose, in a large bay which is here formed by the coast, a small harbour, where vessels lie in safety, at the foot of the castle, in the front of which is a good roadstead; this was the usual anchorage of French frigates, which cruised in these seas. It was also frequented by merchant-ships, when they were obliged, from bad weather, to quit the new and dangerous port of Alexandria; and likewise by the country "germs" when they could not make Alexandria, or clear the "Boghafs" of the Nile at the mouth of the Rosetta branch. In this roadstead the valiant and now (1806), much lamented lord Nelson obtained his glorious victory over the French fleet. See ABUKIR.

CANOPUS, in Pagan Mythology, an Egyptian deity, as some have supposed, whole divinity probably originated in a Greek fable. The Greeks were fond of tracing the arts, sciences, and theological opinions and rites of other nations to a Greek origin. Accordingly they relate, that Menelaus, in his return from Troy, stopped to refit his ships and refresh his crew on the coast of Egypt, near one of the mouths of the Nile; and that, during his stay, Canopus or Canopus, his chief pilot, was bitten by a viper, and fell a victim to this accident. The city of Canopus, they say, was erected over his tomb, and derived its name from him. This etymology of Canopus is mentioned by Strabo, ad supr. But through Herodotus, they say that Menelaus had been in Egypt, and had taken notice of the city called Canopus, he does not see a word of Canopus, or of his death. This Greek fable, however, was repeated in the fourth century by Epiphanius, (Joan. iv. p. 10. edit. Petavius) who has made Canopus a particular deity of the Egyptians. Rufinus also has repeated it. (Hist. Eccles. iv. c. 26.) The Chaldeans, it has been said, who worshipped fire, called their sacred deity through many countries, in order to exvise his power to be superior to that of other deities; and as he obtained a complete victory over all the other gods of wood, bronze, iron, and gold, his dominion was established, or his claim to worship acknowledged. The priests of Canopus, when they heard of this triumph, determined to give their deity an opportunity of contending with that of the Chaldeans. They represented Canopus under the form of vessels pierced with a great number of holes, which were filled with wax, in which they were anointed, to purify the water of the Nile; and having dipped one of these vessels with water, and painted it with different colours, they fitted it to its surface the head of an idol of human shape; and then brought it out to contend with the Chaldean deity. The Chaldeans accordingly kindled a fire all round it; but when the heat had melted the wax, the water gnashed out through the holes, and extinguished the fire; and thus, it is said, Canopus conquered the god of the Chaldeans. As a proof that such an Egyptian deity as Canopus actually existed, it has been alleged, that the geographer, Dionysius Periegetes, calls the city of Canopus, the celebrated temple of Canopus of Amymele:

"Kal tismes pei'tous 'Aymemelis Kanopi."

"There stands Canopus temple known to fame;"

"The pilot, who from fair Amycla came."

This passage, however justly interpreted, affords no evidence that a particular god, called Canopus, had a temple in that city. Homer (Il. B. v. 657.) calls the territory of Pyrrhus "the temple of Ceres," because its fields were very fertile in corn. Thus also Pindar (Pyth. 127.) calls Lybia and the "whole of Egypt," the "fertile temple of this Nile." By a similar metaphor, Dionysius might have called the city of Canopus, which he believed to have derived its name from the Maufoilium of Canopus, "the temple of the pilot of Amymela." The temple of Canopus was that of Serapis; and this deity was worshipped in other countries besides Egypt, under the appellation or distinction of Serapis of Canopus. The singular form under which Serapis was worshipped at Canopus will serve to lead us into an acquaintance with the nature and attributes of this deity, which were different from those of the Serapis or Pluton, brought by the Greeks to Alexandria. This was a bottle, or vessel, as we have above mentioned, made of a very precious clay, which served to filter the water of the Nile, or to render it clear and fit for drinking. The inhabitants of Canopus found this clay in their neighbourhood, and they carried on through Egypt an extensive commerce in these filtering vessels. The medals of Canopus, struck in honour of Adrian, present one of these vases surmounted with a serpent, which was, without doubt, the good genius, αγαθος Διαμουρ. This name of good genius had been given to the branch of the Nile which flowed near Canopus. Hence we may conclude, that the great divinity of the Canopians.
Canopia was the good genius of the Nile, and that it was represented by a floating vessel; but the god of the Nile, which pursued its course in the Canopic branch, was transformed by the Greeks into Serapis. Accordingly they worshiped at Alexandria Serapis-Ptolema, and at Canopus, Serapis of the Nile. Many Egyptian 'vak,' called 'serapiamons,' are preferred in the collections of Antiquities; some of which may reasonably be supposed to represent the Serapis of the Nile.

**CANOPY**, in Architecture and Sculpture, a magnificent kind of decoration, formerly to cover, and crown an altar, throne, tribunal, pulpit, chair, or the like. See BARDACH.

The word is formed from the barbarous Latin canopus, of occasion, a net spread over a bed to keep off the gods, from canus, a net.

Canopics are also borne over the head in processions of state, after the manner of umbrellas.

The canopy of an altar is more peculiarly called Canorus.

The Roman grandees had their canopics, or spread veils, called stufa, over their chairs; the like were also in temples over the statues of the gods. The modern cardinals' still retain the use of canopics. The canopy, as we render Κανοπαίος (Judith xiii. 9.) should, as Dr. Shaw figures (Travels in the Levant, p. 221), rather be called the gnat or misquito net, which is a close curtain of gauze or fine linen, suffed, all over the East, by people of better tattum to keep out the flies.

**CANORASAY**, in Geography, a small island of Scotland, near the north coast of the island of Coll.

**CANOSA**, a town of Italy, in the kingdom of Naples, and country of Bari, destroyed by an earthquake in 1694. It was once episcopal, but the see has been united to the archbishopric of Bari: 31 miles west of Bari. This town occupies part of the site of the ancient Canusium founded by Dionysius, and afterwards a Roman colony, which became one of the most considerable cities in this part of Italy for extent, population, and magnificent buildings. The area of Trajan seems to have been that of its greatest splendour; but it was thus marked as an object alluring to theavarice and fury of the barbarians. Genfrie, Tortola, and Authar-Viri treated it with extreme cruelty. The province to which it belonged was reduced to a deplorable state in 559. No town in Puglia suffered more than Canosa from the outrages of the Saracens; and the measure of its distress was much augmented by the contells between the Greeks and Normans. In 1192, it was aligned, by agreement, to Bohemund, prince of Antioch, who died here in 1191. Under the reign of Ferdinand III. this chief belonged to the Grimaldis; but on their forfeiture, the Alfedetti regained it, and still retain the title of Marquis, though the Capet are the proprietors of the fief. The ancient city stood in a plain between the hills and the river Ofanto, and covered a large tract of ground. Its ancient granary is still attested by many fragments of aqueducts, tombs, amphitheatres, baths, military columns, and two triumphal arches, which seem to have been two city gates. The present town stands above, on the foundation of the old citadel, and is a poor remnant of so great a city, not containing above 300 houses. The church of Sabins, built, as it is said, in the 6th century, has altars and pavements that are rich in marbles, and the fix Verde Antico columns that support its roof are the largest and finest, says Swinburne, which he ever saw of that species of marble. In a small adjoining court, under an octagonal cupola, is the mausoleum of Bohemund, adorned in a minute Gothic style. In 1461, the prince of Taranto, among other acts of barbarity practiced by him at Canosa, broke open this sepulchre, and disturbed the ashes of a hero, who, by his extraordinary military talents, rivalled the fame of his father Gnutcard, and by his victories hoiked the throne of the eastern emperors; and when he was deprived of his Italian inheritance, turned his arms against the Saracens, and formed a new sovereignty for himself in Palestrina. As prince of Antioch, he became one of the foremost captains of the Crusado against the infidels. Swinburne's Travels, vol. ii. p. 321.

**CANOSA,** in Itelhydogy, a name given by Salian, and some other authors to the species of *Shark,* called by modern writers *squalus galbus,* the tope of the Cornish fisherfolk.

**CANOSIA,** in Geography, a town of the province of Saluzzo; 15 miles S. W. of Saluzzo.

**CANOT Cabe,* lies on the salt lake of the island of St. Lucia, in the West Indies, towards the north end of the island. On its south side is a bay of the same name.

**CANOUGE.** See CANOGUE.

**CANOVIO,** a town of European Turkey, in the province of Aragon; 22 miles S. of Durazzo.

**CANOUL,** a town of Hinduooftan, and capital of a circuit, in the country of Hydabad; 95 miles S. W. of Hydabad, and 124 E. of Banderag. N. lat. 16° 10'. E. long. 78° 29.'

**CANSCHWORCE,** L. a town of France, in the department of the Loire, and chief place of a canton, in the district of Marqués. The town contains 2419, and the canton 6470 inhabitants; the territory includes 238 kilometres and 7 communes. It is a place of considerable trade in cattle and woollen stuffs.

**CANQUES,** in Commerce, a sort of cotton cloth made in China; with this cloth they make that first garment next their skin, which is properly their shirt.

**CANSRena,** in Conchology, a species of *Nerita,* that inhabits the Indian, African, and American seas, and of which there are nearly thirty varieties at present ascertainned. It is specifically distinguished by the shell, smooth, with a somewhat pointed spine, and bident, gibbous, umbilicus, Linn.—Obs. There is much reason to believe that some at least of those shells which Gmelin considers as varieties only of his *nerita canrenata,* may prove, on further examination, to be distinct species.

**CANSADO Cabe,* in Geography, is situated three leagues N.N.E. from Cape Blanco, on the coast of Africa.

**CANSCHI,** in Botany, (Rheed. Mal. i. tab. 42. Burm. Ind. 1298.) See *Trevia Napus.*

**CANSCHY,** a large tree in Japan, from which the inhabitants make their paper. See a particular account of the process from the Ephem. N. C. in the Coll. Acad. P. E. tom. iv. p. 144. It is not certainly known, whether it be the paper mulberry, *norus papyrifera,* Linn. *papyris,* Lam. *brassicaeuis,* L'Herit. and Ventenat.

**Gen. Char. Calyx globular-pitcher-shaped, four-toothed. Corolla tube. Stema filamenta four, inserted into the bottom of the calyx; anthers roundish, not extending beyond the calyx. Filiis semina superior, very small, enclosed by four scales; style one; stigma capitata. Peric. berry one-seeded. A shrub. Leaves alternate. Flowers with one bracte, in axillary spikes. Character formed from a dried specimen of Sonnerat's communicated by La March, except the fruit, which is taken from Rhede's figure.

**CANSO. CANOOS.** in Geography, an island, 6
cape, and small fishing-bank on the S.E. coast of Nova Scotia, about 40 leagues E. by N. from Halifax. The island is small, and near the continent, N.E. from Cape Canfo, which is the south-eastermost land of Nova Scotia. Canfo has a good harbour, about three leagues deep. Here are two bays of safe anchorage. Near these, on the continent, is a river, called Salmon river, on account of the great quantity of salmon taken and cured there. This is thought to be the infant fishery of that part of the world. Lime-foun and gypsum are found in the gulf of Canfo, which is a very narrow strait, forming the passage from the Atlantic into the gulf of St. Lawrence, between Cape Breton and Nova Scotia.

Canfo Port, of which the south point is Cape Canfo, is situated in N. lat. 45° 20' 7". W. long. 60° 35'.

Canfo is also a township near the above-named place, in the county of Halifax.

Canstadt, a town of Germany, in the circle of Swabia, and duchy of Wurttemberg, seated on the east bank of the Neckar. In the town is a manufacture of printed linens, and near it are medicinal springs. It is distant three miles N.E. from Stuttgart. N. lat. 48° 51'. E. long. 7° 36'.

Canstein, a town and citadel of Germany, in the circle of the Lower Rhine, and duchy of Westphalia; 6 miles S.E. of Stadsburg.

Canstrisius, an officer in the church of Constan- tinople, whose business is to take care of the patriarch's pontifical vestments, affit in robing him, and during mass to hold the incense-pot, and sprinkle holy water among the people, while the hymn of the Trinity is singing. The word is also written Canstrinus; it is usually derived from Canstrum, a name which some suppose given to the incense-pot, others to the kind of balsam in which the patriarch's vestments were kept. Du-Cange.

Canwa, a river in Geography, a river of Hindoostan, which runs into the sea, 40 miles S.S.W. of Junagur or Chumagur, in the country of Guzerat.

Cant, a quaint, affected manner of speaking, or writing, adapted chiefly to the lower sort. Cant is originally derived from Andrew Cant, a Camero- nian preacher in Scotland, who, by exercise, had obtained the facility of talking in the pulpits in such a tone and dialect as was understood by none but his own congregation; and hence the term is extended to denote all sudden exclamations, and whining tones, especially in praying and preaching. This origin of the word, however, has been disputed, and it has been derived from the Latin cantare, to sing. Others imagine that it is corrupted from quain, of Fr. caint, and Lat. compitus.

Cant, or Canning Language, is also applied to words and phrases affected by particular persons, or professions, for low ends, and not authorized by the established language. Cant is not restrained to the style of gypsies, thieves, and beggars, but poaches a large department in the politer pro- vinces of the English language. An anonymous author has given a canting dictionary, comprehending all the terms used in the several tribes of gypsies, beggars, shoplifters, highwaymen, foot-pads, and other classes of cheats and villains, with a collection of songs in the canting dialect. Lond. 1725, 8vo.

A writer in the Tatler, alligns divers sources of cant-words; as phizz, bippo, mobb, pozz, lamm, &c. Tat. No. 250.

The free language will melt of it come under the denomi- nation of cant; and the like holds of the terms in alchemy, heraldry, not to say in astrology, or even chemistry, pharmacy, &c. In reality the difference between a cant-term, and a technical term it is not easy to assign, unless we choose to refrain the former to words introduced out of folly, affection, or imposition; and the latter to such as are introduced for the sake of clearness, precision, and signifi- cance.

Cant is also used to denote a sale by auction.

The origin of the word, in this sense, is dubious; it may come, according to some, from quantum, how much; according to others, from cantare, to sing, or cry aloud; agreeably to which, we sometimes call it an out-cry.

Canting timber, in ship-building, are those timbers which are flattened near the two ends of a ship. They are so called because their planes are inclined to the middle vertical fe- culation of the ship lengthwise, or plane of elevation, in contradistinction to those whose planes are perpendicular thereto. And this canting, or inclination of any timber is such, that it may stand perpendicular, or nearly so, to that part of the ship's side where the timber is flattened.

Cant is also popularly used for an angle, or corner; and cantpieces are those that are used in the angles of the kites, and hide-trees; or to supply any part that may be fanny or rotten.

Cant, Agent, in Biography, affisted Ruysech, towards the end of his life, in making his anatomical preparations. He was afterwards a pupil to Albinus, and distinguished for his abilities, but died at a very early age. He left a well- furnished library, abounding particularly in works on anatomy. In 1721, he published "Impetus primiti anatomici ex liberis cadaveribus nati," fol. Leid. with six engraved plates representing the muscles of the face, the carotid artery, duum mater, the heart in situ, the stomach, and joint of the knee, in general correctly delineated. Haller Bib. Anat.

Canta, in Geography, a jurisdiction of South America, in the vice-royalty of Peru, and circuit of Lima. It begins at the distance of 5 leagues N.N.E. from Lima, where it terminates in the circado or circuit of that city. Its extent is above 30 leagues, most of which comprehend the first branch of the Cordillera of the Andes, so that the temperature varies in different parts of the country, and is thus beneficial to the fruits of the earth and pastures; and as every species may be appropriated to its suitable degree of heat, the produce is large and very good. The papa is particularly distinguished among the fruits, and the roots find a good market at Lima. The extensive fields of Bamboo, which partly belong to this jurisdiction, though cold from their high situation, afford pasture for innumerable flocks of sheep; they are divided into "Haciendas," or estates belonging to noble families of Lima.

Cantabile, an Ital. adj. implying music fit to be sung; a melody for the voice, not instrumental. A series of measured sounds, of which the cantilena is graceful or pathetic, is said to sing. To be able to play or sing an aria di cantabile, is the highest praise that can be bestowed on a musician. Execution surpasses, and for a certain time amuses; but goes no farther than the ear; but to sing a cantabile with tenderness and expression, is conveying sounds to the heart.

Cantabra, an Ancient Geography, a river of India, reckoned by Pliny among the most considerable which discharged themselves into the Indus.

Cantabri, a people of HISPANIA Citerior, or Hither Spain, or Province Tarraconensis; whose district was bounded on the north by the sea of their name, "Oceanus Cantabrum," now called the bay of Biscay; and extended from the country of the Almorin, on the west, to that of the Vaiconi, on the east. Pliny divides them into four nations, without distinctly naming them. The Cantabrians inhabited
a mountainous country, and were, in their disposition and habits, ferocious and warlike. The women were no less valiant than the men; and devoted themselves to similar employments. Strabo mentions several facts, evincing the facility with which the females delivered themselves of their children, without requiring any temporary confinement, or any intermission of their usual occupations. He also informs us, that they entered the several territories without betraying any concern, and chanted their laments even at the moment of their dying. It was with great difficulty that the Romans subdued this hardy and valiant people. They, as well as the Alturians (see Asturia), defended themselves for a considerable time with invincible firmness and resolution; availing themselves of the places of security and inaccessible retreat which their mountains afforded them. They were, however, at length overpowered, and constrained to submit to the arms of Augustus, about 25 years before Christ. Antiklius, Furinius, and Agrippa were employed in this service; and after having been driven from their towns, and pursued even to their rugged mountains, whilst the Roman fleet harassed their coasts, they were obliged to shelter in mount Medullius, and were so surrounded, that they had no possible means of making their escape. When this stubborn people found themselves thus encompassed, they preferred a voluntary death to surrender and captivity. Molt of them destroyed themselves by the sword, by fire, or by a poison extracted from the yew-tree, or from an herb resembling parsley, which they preferred as a resource against any reverse of fate, because it made them die without pain. Mothers smothered their children, to prevent their falling into the hands of the enemy; and among those who were taken, a young boy was observed, who, having found a sword, killed his brothers, and all his relations, by the order of his father. In like manner, a woman killed all that were prisoners with her. At last, when Augustus had succeeded in subduing them, he determined to soften their ferocity, by compelling them to abandon their mountains; having fold some of the prisoners, he required hostages from those that remained in the country, and fixed their abode in the plains. Inimical of a foreign yoke, they took advantage of the absence of Augustus; they again revolted, and attacked the Roman garrisons with their usual fury. Agrippa was therefore deputed to complete their reduction, but he found the enterprise extremely difficult, so that even the Roman soldiers under his command began to despair of ever accomplishing it. This brave commander, so much was his legions disheartened by the resistance and repulses with which they had to encounter, was under a necessity of recurring to intrigues and merce, and of punishing some of his soldiers with ignominy, before he could induce them to renew their engagement with this formidable enemy. But having at last prevailed upon them to meet the Barbarians in an open field, he so animated them by his example, that, after an obstinate conflict, he obtained a complete victory, and thus terminated this destructive war. Having put to death those who were able to bear arms, and destroyed their cattle and strongholds, and forced those who survived to quit their mountains, and to settle in the plain, he subdued them so effectually, that they never attempted to revolt again, but quietly submitted to the Roman yoke. Strabo, lib. iii. Sueton, in August. The celebrity of the valorous Cantabrians was formerly so great, that most of the provinces of Spain laid claim to the honour of having been comprehended within the limits of ancient Cantabria. Louis XV. created or formed a regiment of this name, the 13th December 1745, which, by an ordinance of the 11th of July 1747, was called Royal Cantabre. Silius Italicus, in his enumeration of the different tribes, people, or nations, whom Hannibal carried with him into Italy, makes the Cantabrians march before all the rest. And Pompey regarded the Cantabrians, and some of the neighbouring people, as the best troops in his army. CANTABRIA, the name of a country on the northern coast of Spain, called by the inhabitants Visca, and by others Bilbao, and comprizing the provinces of Biscay, Alava, and Guipuscoa. See the preceding article. Strabo says, (lib. iii. vol. i. p. 237.) that, according to the report of some writers, the Lacedæmonians had once possessed part of this country, and built in it a city called “Optirellis.” The Goths having invaded Spain, in the 7th century, Lenuigild refuted to subdue that part of it which remained steady attached to the Romans, and turning his arms against the Cantabrians, took and destroyed the city of Cantabria, situated between Logronno and Viana, and the city of Amaya. But there he terminated his career; afraid to run the risk of penetrating farther among the mountains and desiles inhabited by those people, who, in spite of him, continued faithful to the Romans, though they were entirely expelled from Spain.

CANTABRIAN, the ancient language of the northwestern part of Spain, in use before the country was subdued by the Romans. Dr. Wallis seems to make the Cantabrian the ancient language of all Spain: which, according to him, like the Gaulish, gave way to a kind of broken Latin called romanes or romangae: which by degrees was refined into the Celtiberian or preface Spanish. But we can hardly suppose, that so large a country, inhabited by such a variety of people, spoke all the same language. The ancient Cantabrian, in effect, is still found to subsist in the more barren and mountainous parts of the province of Biscay, Alusias, and Naverre, as far as Bayonne, as much as the British do in Wales; but the people only talk it: for writing, they use either the Spanish or French, as they happen to live under the one or the other nation. Some attribute this to a jealousy of foreigners learning the mysteries of their language; others to a poverty of words and expressions. The Cantabrian does not appear to have any affinity with any other known language, abating that some Spanish words have been adopted in it for things whose use the Biscayans were anciently acquainted with. Its pronunciation is not disagreeable.

The Lord's prayer, in the Cantabrian tongue, runs thus: Gure aicro cervean aetnca. fanstica betho bicaicn, otho bethi refana, eguan betho bicoatudrian cerno bekta lrunarron, &c.

CANTABRICA, in Botany (Cl. Hist. 2.49.). See Convolvulus Cantabrica.

CANTABRUM, in Antiquity. Under the Roman emperors, succeeding Constantine, this was a kind of banner, ensign, or standard, differing in this respect from the vexillum, that the latter of these was a large flag, distinguished by its colour, and by a device on it; whereas the former, or cantabrum, was only a small standard and flag, which had also a particular colour, and served for rallying and encouraging the soldiery. For this purpose it is said to have borne on it some words or motto of good omen. Minucius Felix and Tertullian mention it in their apologies, and compare it to a crois.

CANTACUZENUS, JOHANNES, in Biography, emperor of Constatinople and a learned historian, was born of an ancient and noble family at Constantinople, about the year 1205; and having been bred both to literature and to arms, he attained the highest offices of the state, such as preste of the bedchamber under Andronicus the Elder, and the
the dignity of domesic under Andronicus the Younger. Attaching himself to the interest of Andronicus the Younger, in opposition to that of his grandfather Andronicus the Elder, who abdicated the government A.D. 1328, and having contributed to rescue him from the power of his grandfather, he brought him back in triumph to the palace of Constantinople, after six years of civil war. Under his reign Cantacuzene ruled both the emperor and the empire; and it was by his valor and conduct that the isle of Lesbos and the principality of Autria were restored to their ancient allegiance. Although he enjoyed many favourable opportunities for enriching himself by oppression and rapine, his enemies confess that, among the public robbers of the empire, Cantacuzene alone was moderate and abstemious. Nevertheless, his wealth, probably devolved upon him by inheritance, appears from his own account of it to have been prodigious; more especially when we consider that it was partly accumulated in the last period of the empire, and in a land, most probably in Thrace, so repeatedly waited by foreign and domestic hostility. He does not indeed specify the value of his money, plate, and jewels; yet, after several very considerable deductions, his forfeited treasures were sufficient for the equipment of a fleet of 90 galleys. He does not give us either the extent or number of his estates; but his granaries were filled with an incredible store of wheat and barley; and the labour of a thousand yoke of oxen might cultivate, according to the practice of antiquity, about 35,520 acres of arable land. His pastures were stocked with 2500 broad mares, 200 camels, 300 mules, 700 assrs, 5000 horned cattle, 50,000 hogs, and 70,000 sheep. Thus distinguished by rural opulence, he enjoyed, in a very high degree, the favour of his sovereign; and though he declined accepting the honour that was offered him of being his associate in the sovereignty, he was named in the last testament of Andronicus the Younger the guardian of his son John Paleologus, who succeeded his father in the ninth year of his age, A.D. 1341, and the regent of the empire during his minority. This trust he discharged with fidelity, till a regard to his own safety rendered it necessary for him to adopt measures of self-defence. A combination, however, was formed against his regency by the dowager empress, Anne of Savoy, the great duke or admiral Apocaurus, and John of Apri, patriarch of Constantinople. By this powerful confederacy Cantacuzene was assailed at first with clandestine and at length with open arms. During his absence on the public service he was accused of treason; proscribed as an enemy of the church and state; and delivered, with all his adherents, to the frown of justice, the vengeance of the people, and the power of the devil. His fortunes were confiscated, his aged mother was cast into prison, all his past services were buried in oblivion, and he was driven by injustice to perpetrate the crime of which he was accused. As long as the empress and the patriarch affected the appearances of harmony, he repeatedly solicited the permission of retiring to a private, and even a monastic, life; and after he had been declared a public enemy, it was his fervor with to throw himself at the feet of the young emperor, and to receive without a murmur the froward of the executioner. At length he reluctantly adopted the only measure that was likely to avail to his security, which was that of drawing the sword and assuming the imperial title. Accordingly in the strong city of Demotica, his peculiar domain, he assumed the purple, A.D. 1341; maintaining, even in this act of revolt, some shew of loyalty, by cauing to be proclaimed the titles of John Palæologus and Anne of Savoy before his own name and that of his wife Irene. Conflantinople adhered to the young emperor, and the principal cities of Thrace and Macedonia returned their allegiance to Constantinople. His army, which was stationed on the bank of the Menes, for the purpose of intercepting or interfering the capital, was dispersed by treachery or force, and the empress accepted the terms, and embraced the former of the Byzantine court. Cantacuzene, driven by Apocaurus, left the city into the mountains of Serbia, his truly band of followers was diminished to 2,500, and at last to 1,000 men. The "Crab," as depop of the Serbs, regarded him with hostility; but in a state of miserable dependence, he never declined assistance, and was at length defeated without reply, to a new multitude of hopes and fears. A civil war commenced, which, after having raged for many years, terminated in a decisive victory on the part of Cantacuzene, who re-entered Constantinople A.D. 1347. The indefatigable Anne, declared the powers of rebellion, or the hope of relief, was at length compelled to yield to the applications of her friends and enemies; and a treaty was dictated by the emperor, who professed a loyal and zealous attachment to the son of his benefactor. The marriage of his daughter Helen with John Palæologus, to whom he had been for some time engaged, was at length consummated; the hereditary right of the pupil was acknowledged; but the sole administration, during ten years, was vested in the guardian. Thus two emperors and three empresses were seated on the throne; a general amnesty was proclaimed; and the festival of the coronation and nuptials was celebrated with fallacious appearances both of concord and magnificence. The tranquillity of Cantacuzene and of the empire was, however, soon disturbed by suspicions and enmities between the two emperors and their respective adherents, which at length broke out in a civil war, A.D. 1353. Cantacuzene, aided by the Turks, was successful, and the young emperor was compelled to take shelter among the Latins of the isle of Tenedos. The victor, provoked by his insolvency and obstinacy, was induced to associate with himself his son Matthew, whom he invested with the purple, and thus he established the succession in the family of the Cantacuzenes. Palæologus, however, afield by the Genoese, who, by a treaty subscribed by Cantacuzene, A.D. 1352, which formerly banished the Venetians and Catalans, obtained a monopoly of trade, and almost a right of dominion, regained Constantinople, A.D. 1355; and Cantacuzene abdicated his share of the government, and retired to a monastery, where, under the assumed name of Joseph and the habit of a monk, he devoted the residue of his life to literary and theological exercises. His wife Irene also retired to a nunnery, and exchanged her own name for that of Eugenia. If, indeed, he issued from this retreat, it was as the minister of peace, to facilitate the obstinacy and solicit the pardon of his rebellions son. In the retirement of a cloister his active spirit prompted him to engage in a controversy against the Jews and the Mahometans, and he composed four apologies for the Christian religion and four discourses or books, (printed in Greek and Latin at Basle, in 1543, by Bible and Gualtherus, from Greek MSS.,) at the particular request of a prolepte to Christinon, Aechmenides, called also Meteiri, who was assaulted with letters from his friends at Ipahan. Maracci informs us, that, though he had read the Koran, he adopts the vulgar prejudices and fables against Mahomet and his religion. He also, with equal zeal, defended the divine light of mount Thabor; and under the character of emperor and theologian, he professed in the synod of the Greek church, which established, as an article of faith, this uncreated light. See the article Barlaam. In his retirement he also wrote a history of his own times in four books, or at least of those times during which
he was a principal actor, comprehending a period that extends from the revolt of the younger Andronicus, A.D. 1320, to his own abdication of the empire, A.D. 1355, and continued one year beyond the abdication of his son Matthew, A.D. 1357. "In this eloquent work," says Gibbon, "we should vainly seek the sincerity of an hero or a penitent. Retired in a cloister from the vices and passions of the world, he presents not a confession, but an apology, of the life of an ambitious rascalman. Instead of unfolding the true counsels and characters of men, he displays the smooth and spacious surface of events, highly varnished with his own praisés and those of his friends. Their motives are always pure; their ends always legitimate; they confine and rebel without any views of interest; and the violence which they inflict or suffer is celebrated as the spontaneous effect of reason and virtue." Voltaire, however, without hesitation, prefers him to all the Byzantine historians. A Latin translation of this history, from the Greek MS. in the library of the duke of Bavaria, with notes, was published by Pontanus at Ingolstadt in 1633, fol.; and at Paris in 1645, in a splendid edition consisting of 3 volumes, fol. of the Greek from the MS. of M. Seguier, chancellor of France, with Pontanus's Latin versions, and the notes both of Pontanus and Greuter. Some other treatises by Cantacuzene, who assumed the name of Chirilodocus the monk, are extant in MS. in the Vatican, Parisian, Cevenal, and Bodelian libraries. The death of Cantacuzene is placed by respectable authority on the 20th of November 1411. (Du Cange, Fam. Byzant. p. 260.) But if he were of the age of his companion Andronicus the Younger, he must have lived 116 years; a rare instance of longevity, which, in so illiberal a person, would have attracted universal notice. Fahr. Bib. Græc. t. vi. l. v. c. 5. § 12. p. 409; &c. Gibbon's History, &c. vol. vi.

CANTADUANES, in Geography. See CANTADUANES.

CANTE, in Ancient Geography, a people of Britain in that part called Caledonia, who, according to Ptolemy, were feated towards the eastern coast on the north side of the frith of Tayne. Mr. Baxter places them in Breben, which he derives from the Britih words "Pow Chant," signifying, as he says, the country of the Cante.

CANTAL, in Geography, a large and lofty mountain of France, which is said to be 993 toises higher than the level of the sea, and always covered with snow. It is situated in the centre of a department to which it gives name, and which is one of the three formed out of Auvergne and le Velay. This department is bounded on the north by the departments of Upper Loire, Puy de Dôme, and Corrèze; on the east by those of Upper Loire and Lozère; on the south by those of Lozère, Aveyron, and Lot; and on the west by those of Lot and Corrèze. Its superficies is about 3,124,802 acres, or 574,487 hectares; its population consists of about 243,708 persons; and it is divided into four communal districts, viz. Mauriac, Murat, St. Flour, and Aurillac.

CANTALIVER, in Architecture. This term is used by workmen to denote those blocks which are frequently placed, at regular distances, under the eaves of a house, or the upper mouldings of a cornice, which they serve to support or ornament. Cantaliver, therefore, is essentially the same with modillion; but the latter word is confined to the description of regular architecture, while the former has a general and trivial use.

CANTANUS, in Ancient Geography, a town placed by Steph. Byz. in the island of Crete. It was an episcopal seat, and mentioned in the acts of the council of Chalcedon.

CANTAR, or CANTARO, in Commerce, an eastern weight, of different value in different places, equivalent at Acre in Turkey to 603 pounds, at Tunis and Tripoli to 114 pounds.

CANTAR is also an Egyptian weight, which is denominated a quintal, and consists of a hundred, or of an hundred and fifty ratsus, according to the goods they are to weigh.

CANTARA, in Geography, a river of Sicily, anciently called "Taurumius," which runs into the sea; five miles from Agolla.

CANTARE, Ital. to sing. Singing is a faculty that requires the union of so many gifts of nature, and so much adherence from art, that the complete concurrence and union of both rarely happen. The requisites from nature are a voice full, flexible and extensive in compass, well-toned, clear, and interesting; with an ear perfectly correct in time and tune. The acquisitions from art are a good partimento, or delivery of the voice from the chest, free from nasal or guttural defects, a good thake, good taste and expression, with a rapid, distinct, neat, and articulate execution of divisions, and the power of sustaining a long note with readiness, and of augmenting and diminishing its force by the most minute degrees.

The individual in possession of all these requisites, will be regarded as a prodigy! and with health, diligence, and good conduct, may be pronounced heir to a great estate, arising from means the most flattering to self-love, and grateful to a good heart: the power of innocently delighting mankind.

These qualifications the critical and fadidious hearer thinks his due—be it so: but in order to balance the account between the performer and his audience, let us remind the latter of the fair and just claims which every performer possessed of great talents has on the public, but in a particular manner, a finger, who having arrived at thee captivating powers by uneasing study, toil, and experience, is not only entitled to confident remuneration, but to regard and attention from the public, for its own sake: for if by neglect, snore, and mortification, a vocal performer's mind is disquieted, and chert agitated, that ardent desire to please those who seem disposed to be pleased, and those efforts which encouragement alone can illuminate, are chilled and paralyzed, to the great loss of the feeling part of an audience, and disgrace of the humbled performer. From such treatment what can be expected but a cold, inanimate, and lifeless performance, without professional zeal, or the enthusiasm of genius and talents.

Garrick used to say, that applause was an aliment without which he could not live on the stage; and inattention to the part he was representing, he never forgave. He complained to an officer on guard, of a centinel yawning aloof on the stage during his acting one of his best parts; and he never relit till Pinto the first violin, and leader of the band, had quitted his station, after perceiving him fall asleep in the orchestra, in flight of the whole house, while he was acting one of the most imprefve and afflicting scenes in King Lear.

Singing has long been cultivated and cherished in Italy. In the Cortegiano of Castiglione, written at the beginning of the 15th century, we are told of two fingers, whose merit in a totally different style of singing was so equal and so great, that they charmed all hearers. These performers are mentioned to prove, that in all the arts there are various roads that lead to perfection, and different means of delighting mankind. Bidon says the author of that pleasing work, has such force, readiness, and variety of passages, that the souls of all hearers are so excited, inflamed, and ravished, that they seem transported above themselves, and almost
exalted into heaven. Nor does Marchetto Cara less excite the affections by a more tender and touching style, which commiserates and fothers the affections of others, or with sweet, complaining, heart-felt notes, softens, instructs, and penetrates the mind, for sorrow not their own. Toño applies to Fanciulla and Cuzzoni, the two great vocal rivals of his time, those captivating powers by difficult talents.

And we may, perhaps, with equal accuracy and candour affirm, that Such are at present, (1802) the excellencies of the Billington and the Bainti, whom however the one to the other, only proves that the taste of hearers is as various as the style of singing of great performers.

Since the establishment of operas, no professional talents in any of the fine arts have been more celebrated than those of great Italian fingers; who being invited to different states and kingdoms, have an opportunity of extending their fame to every part of Europe; and their talents are as well known at Vienna, Madrid, Peterburgh, Dresden, Berlin, Munich, and London, as in their own country.

We cannot pretend to render this article a complete elementary treatise on singing, and, indeed, as Johnson truly said of books of instruction, "nothing is well made by a receipt!" yet, to trace, and specify a few of the first principles of the art, may be of some use to vocal students out of the reach of better instructions.

For those who seek vocal precepts in books, we recommend the perusal of Toño and Mancini; and as a specimen of the art, we shall present our readers with Tenducci's first injunctions to his scholars. For fagio, or exercises for the voice, those of Leo, on which so many great singers have been formed, are now only useful to the performers of old music; but new melody requires new fagio, to prepare a finger for divotions and graces of the present times. For such, the most modern, and perhaps the best, are those of Apriile, which, however, are now full 30 years old; but many modern melodies have been since produced in the vocal compositions of Paciello, Cimarosa, Sarti, Haydn, and Mozart, as well as refinements in the performance of Paccieretti and Marchefi, with which young scholars should be made acquainted.

The Cyclopaedia, being intended to assist those who study an art or science without a master, we shall present the solitary student in singing with the following instructions drawn up in Italian, as we imagined by the late Signor Tenducci, who brought them to the author of the present article to revise and translate; but on comparing them with the preliminary rules placed at the head of the English edition of Apriile's Modern Italian Method of Singing, under the title of Necessary Rules for Students and Dilettanti of Vocal Music; it appears that the Italian copy of the instructions, brought by Tenducci to be translated, belonged to Apriile, and that the English translation of these rules is literally that with which Tenducci was furnished by himself.

Necessary rules for students and dilettanti of vocal music.

I. The first and most necessary rule in singing, is to keep the voice steady.

II. To form the voice in as pleasing a tone, as is in the power of the scholar.

III. To be exactly in tune; as without a perfect intonation, it is needless to attempt singing.

IV. To vocalize correctly; that is, give as open and clear a sound to the vowels, as the nature of the language, in which the fluent flings, will allow.

V. To articulate perfectly each syllable.

VI. To sing the scale, or gamut frequently; allowing to each found one breve or two semibreves, which must be sung in the same breath; and this must be done, in both, a mezza di voce: that is, by swelling the voice, beginning pianissimo, and increasing gradually to forte, in the first part of the time; and to diminishing gradually to the end of each note, which will be expressed in this way.

Pianissimo --- crescendo (forte) --- diminuendo Piano.

VII. To exercise the voice in sol-fagio every day, with the monosyllables, de, re, mi &c.

VIII. To copy a little music every day, in order to accustom the eye to divide the time into all its proportions.

IX. Never to force the voice, in order to extend its compass in the voce di petto, upwards; but rather cultivate the voce di testa, in which is called solfette. In order to join it well, and imperceptibly, to the voce di petto, for fear of incurring the disagreeable habit of singing in the throat, or through the nose:—unpardonable faults in a finger.

X. In the exercise of singing, never to discover any pain or difficulty, by distortion of the mouth, or grimace of any kind; which will be best avoided by examining the counterpoint in a looking-glass, during the most difficult passages.

XI. It is recommended to sing a little at a time, and often, and if standing, so much the better for the chell.

XII. That scholars should appear at the harpsichord, and to their friends, with a calm and cheerful countenance.

XIII. To rest or take breath between the passages, and in proper time; that is to say, to take it only when the periods, or members of the melody, are ended; which periods, or portions of the air, generally terminate on the accented parts of a bar. And this rule is the more necessary, as by dwelling too long upon the last note of a musical period, the finger loses the opportunity it affords of taking breath, without breaking the passages or even being perceived by the audience.

XIV. That, without the most urgent necessity, of either a long passage, or of an affecting expression, the words must never be broken, or divided.

XV. That a good mezza di voce, or swell of the voice, must always precede the ad libitum pausa — and Cadenza.

XVI. That in pronouncing the words, care must be taken to accord with the sentiment that was intended by the poet.

XVII. That the acute and super-acute sounds must never be forced as to render them similar to shrills.

XVIII. That in singing, the tones of the voice must be united, except in the case of staccato notes.

XIX. That in pronouncing the words, double consonants in the Italian language, must be particularly enforced, and care taken not to make those that are single seem double.

XX. To pronounce the flaccitia with the greatest care and attention, which must generally commence with the highest of the two notes, and diminish with the lowest.

XXI. That the ornaments and embellishments of songs should be derived from the character of the air, and passion of the words.

As Apriile was the real author of these precepts, to whom we did not allow an article when we were at work upon the letter
CANTATA, the title of a short lyric poem, consisting of alternate recitation and air. The word Cantata, according to Du Cange, was used in the church as early as the year 1314, to express what we at present mean by anthem, with which it still synonymous in Germany: being chieflv confined in the Lutheran church to sacred music. The Roman church had many admirable sacred cantatas during the last century, by Carissimi, Graziani, Bodini, and others. And during the present century, Domenico Scarlatti set one at Rome for Christmas Eve, which was performed in the apotolic palace, 1717. Bononcini set another, 1729, for the same occasion and place. The difference at present between sacred cantata and moteti seems to be the recitative.

The secular cantata is a species of composition extremely well suited to the chamber, in which fewer parts, fewer great effects, and less light and shade, are necessary, than in ecclesiastic or dramatic Music; for the performance being in daily life, and the poet and musician without an orchestra or choir to assist in painting the stronger passions, composers aimed, for a long time, at no effects out of the power of a single voice and a single instrument to produce.

Cantatas of considerable length, accompanied by a numerous band, are usually performed in Italy on great occasions of festivity: as the reconciliation of princes after long division, or the arrival of great personages in the capital of a state. Thus, when pope Ganganelli and the king of Portugal were reconciled, in 1750; and soon after, when the Emperor Joseph arrived at Venice, on his first visiting Italy, cantatas were sung at Rome and Venice equal in length to an opera. But these differ essentially from what is usually meant by a cantata or monologue for a single voice, consisting of short recitatives, and two or three airs at most; as they are occasional poems in which several singers are employed; but though in dialogue, they are performed, like oratorios, without change of scene, or action.

As cantatas were first suggested by the musical recitation of the opera in which the chief events were related in recitative; in like manner they received several progressive changes during the 17th century, previous to their perfection. First, they consisted, like opera scener, of little more than recitative; with frequent formal clozes, at which the finger, either accompanied by himself or another performer on a single instrument, was left at liberty to swell his tale and talents.

The next change was in having a single air, generally in triple time, distinct from the recitative, and repeated to different stanzas after each narrative part of the poem, like modern ballad airs. At this time the term da capo not being in use, the air was written over again, as often as it was wanted, sometimes in exactly the same notes, but more frequently, with little changes and embellishments to the same base, and to different stanzas.

Before the invention of recitative, madrigals for voices alone, and afterwards for instruments in unison with the several vocal parts, constituted the chief music that was performed in the chamber, and in private concerts, till folongs, accompanied by a single instrument, were brought into favour by Caccini and his imitators, in Italy and other parts of Europe. See CACCINI.

Adami tells us, page 154, that Giovanni Domenico Piaiachez Romano, admitted into the Pope's chapel 1612, composed several cantatas in a good stile, and in the bel taille of singing, which were printed 1615; and page 195, that the Cavaliere Loredan Vittorio da Spoleto, soprano in the pope's chapel 1632, and one of the first evrati employed in musical dramas on the stage, was a celebrated composer of AIRS, E CANTATA DA Camera.
The first time, however, that we have found the term Cantata, used for a short narrative lyric poem, was in the Madrigale sacro a voce sola del Signor Benedetto Ferrari da Reggio, printed at Venice 1638; which is twenty years more early than the period at which the invention of cantatas is fixed by other writers, who have given the honour to Barbara Strozzi, a Venetian lady, who, in 1653, published vocal compositions, under the title of Cantate, Ariette et Dinti. Ferrari, detto della torre, for his excellent performance on that instrument, was one of the earliest composers of operas for Venice. Of the two full musical dramas that were performed in that city, 1657 and 1658, Ferrari was the poet; but in 1659, he was author both of the words and music of the opera Armida, as he was of several subsequent musical dramas.

Carissimi, Cesti, Longi Rolli, Stradella Lygenzii, Baffani, Alessandro Scarlatti, Gasparini, d'Adlorga, Marcello, Bononcini, Porpora, and Handel, all cultivated cantatas, and added something to the beauty of their construction.

The golden age of Cantatas, in Italy, was the beginning of the 17th century, when they were brought to their greatest degree of perfection, without other accompaniment than a basset viol, and harpsichord, by the genius and abilities of Alessandro Scarlatti, Francesco Gasparini, Giovanni Bononcini, Antonio Lotti, the Baron d'Adlorga, and Benedetto Marcello; and, at a later period in a more elaborate style, with accompaniments, by Nicolo Porpora, and Giovanni Battista Pergolesi, who seem to have been the last eminent composers that cultivated this species of chamber drama, till it was revived by Sarti.

The most voluminous and most original composer of cantatas that has ever existed, in any country to which our inquiries have reached, seems to have been Alessandro Scarlatti. Indeed, this master's genius was truly creative; and we find part of his property among the stolen goods of all the best composers of the first forty or fifty years of the last century.

Pergolesi's cantatas will be considered with his other works, elsewhere.

The French followed the Italian fashion in their rage for cantatas. Their great lyric poet, Baptiste Roufeau, and others, wrote a great number, which were set à la Lutte, and fùg à la François; but having never been heard out of France, nor could the music now be found, we believe, in it, we shall be excused, if we refrain from disturbing the ashes of the dead. There is an excellent critique on Cantatas, particularly those of his own countrymen, by M. Gingucq, in the new Encyclopædia, in which he has treated the subject with much judgment and good taste.

In England, cantatas were published early in the last century, by Handel, Bononcini, Attilio Ariosti, Gasparini, Rolingrave, and Dr. Pepusch; as difficult to find now, perhaps, as those of Clerambart, Montechair, Campora, Monver, and Batillin, in France.

But Cantatas, which were composed with more care, and sung with more taste and science than any other species of vocal music, during the latter end of the 17th century and beginning of the 18th, seem to have been wholly laid aside, after the decease of Pergolesi, till revived by Sarti, who has set, in the manner of cantatas, several of Metastasio's charming little poems, which he calls canzone.

These exquisite compositions were produced by Sarti expressly for the voices of Pacchierotti, Marchesi, and Rubini, and are, in all respects, the most perfect and complete models of chamber music that have ever come to our knowledge.

Indeed, it is to be lamented that a species of composition so admirably calculated for concerts in the cantata, should now be so seldom cultivated; as it contains a college drama entire, having a beginning, a middle, and an end, in which the charms of poetry are united with those of music, and the mood is animated while the ear is gratified. Opera fumas, or single songs, now supply the place of cantatas in all private concerts; but, besides the lady where these songs are taken out of their niche, as they were originally calculated for a numerous orchestra, they can seldom be completely accompanied by a small band.

Cantatilles, French, the diminutive of Cantata. It seems to be equivalent to Canzonetti in Italian, when a few lines of recitative precede a short air.

Cantata Prices, in Middle Age Writings, hired weepers, and wavers at funerals.

Cantay, A small island of the East Indian Ocean, Situate in a gulf formed by the west point of the island of Java.

Cantecroix, A town of Brabant, in a small territory of the same name; 5 miles N.E. from Antwerp.

Canteen, in French Cantine, in the cabaret, tavern, or place in a garrison-town or city, where the garrisons or troops have the privilege of purchasing spirits, wine, and beer at a much cheaper rate than they can buy them at other taverns or public houses. For the most part every citadel, fort, fortress, and castle, has the droit de cantine.

Cantina for Tobacco, in French Cantine du Tabac, by an ordinance of the 30th July, 1722, the king of France established a sufficient number of such cantines for furnishing his troops with the tobacco necessary for their consumption.

Cantina-maker, or Canten keeper, in French Cantiniere, is the person who has charge of the canten, dispenses things in it, and makes the proper, necessary, and authorized distributions in it.

Cantone, a small vessel usually made of tinned plate or wood, in which soldiers, when on their march, or in the field, carry their liquor. The use of wooden cantoes has for some time been general in the British armies. They are made cylindrical, like barrels, 7½ inches diameter, and 4 inches long outside, holding three pints. (See Manufacture of Canteens, Plate I., fig. 1.) Mr. George Smart, a very ingenious mechanic of Ordnance Wharf, Westminster-bridge, who manufactures them in great numbers for government, having adopted and contrived a very complete set of machines for abrading of labour therein, has liberally permitted us to describe and make drawings of this manufacture, which will, we trust, be acceptable to our readers. The wood which Mr. Smart uses, is the belt wainscot, or foreign oak, which is fawed out into boards 3 of an inch thick; these, after being planed, are cut in the direction of the grain, into slips ½ inches broad, and the whole length of the board, by a circular saw called a ripping-saw, similar to that in fig. 2, except that the groove, G, and slider, H 1, are omitted; A is the circular, or wheel-saw, made of steel plate, with fine teeth; on the end of its axis is a pulley, B, turned by a band going round it, and round a large drum under the bench, CC, driven by a horse-wheel. In fig. 3, is shewn the manner of fixing the saw, A, to its spindle, between two pieces of metal, C and D; one of which, C, is part of the spindle, and the other, D, is a moveable one, pushed towards the saw by a nut, E, working on a screw, at the end of the spindle; the plane of the saw in the ripping machine is not fixed exactly at right angles to the bench, CC, but at the proper angle for the fawes of the canteen, which are cut from these slips, when put together to form a cylinder of the true fize. The truth with which these faws cut, being fo great, that the edges
edges do not want planing. D, fig. 2, is the guide for the edge of the board as it is cut, which, for cutting slips of different widths, can be moved nearer to, or farther from the saw, by loosening the thumb-nut, E, the screw from which moves in an opening, F, in the bench, CC, and it is always kept parallel to the plane of the saw, by two equal levers, L, L. A workman takes one of the boards, and puts its edge against the guide, D; when he puts it forward, the saw, A, cuts it along into slips very quick; these slips are delivered to another workman, who uses a saw, called a cross-cutting saw, represented in fig. 2, the guide and saw of which have been described; G, is a grove cut in the bench to receive a slider, H, across one end of which another piece, l, is fixed, having a notch, J, in the underside for the saw to pass through, when it is slid forwards; the end of the slip, K, which is to be cross-cut, is pushed up close to the guide, D, and the piece, l, and slide, H, are pushed towards the saw which cuts it off instantly; the slide is then drawn back, and the slip, K, pushed up to the guide, D, for another length as before. The pieces, which are 4½ inches long, and 1½ inch broad, are for the flames of the canteen. The flames, b, fig. 1, and fig. 6, which have a hole in them for the cork or bung, are first cut out by the flame means as the common flames, but of twice the thickness; the piece, a, b, c, fig. 6, of this is cut out at once, by a machine called a tenoning or rebating machine, shown in fig. 4. A is a bench, in the middle of which is fixed a frame, carrying two circular saws, set at the proper angle to each other, to cut out the piece; D, is an inclined bed, with a groove, G, and slider, H and I, (as before described in fig. 2,) at the bottom of this bed, is fixed a piece of thick iron plate, E, acting as a guide to the saw while it is cutting: near the middle of this bed is the saw, e, the plane of which is parallel to the bed, D: a little farther on the bed is the saw, f, with its axis nearly horizontal; that end of its spindle which carries the saw, is supported by a crooked iron, g, fastened down to the frame by screws, so as to be capable of adjustment; the pulleys, f and g, on the spindles of the saws, are very near to each other, so that the fame band turns them both; it first passes round a large drum, driven by a horse-wheel, under the floor, then comes over a pulley, b, to change its direction; it next passes over the pulley, g, and then f, turning the two saws, (as represented separately in fig. 5,) it afterwards passes over the two pulleys, k and h, to change its direction to the drum again: the piece of wood which receives the saw, l, can be slid in and out of the tube, m, and fixed at any place by a pin, to tighten the band as it stretches: the piece of wood intended for the saw is laid against the croos, I, of the slider, H, and held tight while it is pushed forwards; the saw, e, cuts the plane, a, fig. 6, and as the flame advances, the plane, k, c, is cut by the saw, d, fig. 4. The hole, d, in these flames, for the corks, are bored by the machine represented in fig. 7. A, is a spindle with a pulley, B, on it, turned by a band, going quite round it, and a drum (with a velocity of 1800 revolutions per minute); at the end, a, of this is a male screw to fasten on the common borer, or centre-bit, fig. 8. D and E, fig. 7, are two smooth wooden rails, for a slider, g, to move upon, in the middle of which is fastened a small piece of wood, a, having a hole through it at b, and a shoulder at d; the workman takes one of the flames out of the box, G, and, putting one of its ends against the shoulder, d, of the slider, g, and one of its edges against the bottom board, holds it fast, while he pushes it forward against the borer. When it is necessary to use a different fixed borer, the slides, D and E, and frame, H H H, which holds them, can be raised or lowered, and fixed by two screws, i, j. The common and bung flames thus prepared, are given to a workman who uses tools represented by figs. 10, 11, and 12, Canteen. Plate II. fig. 10, is a thick block of wood, in which is turned a circular groove, a, a, an inch deep, and ½ of an inch wide; it is for fitting the flames in; when the groove is filled with the flames, the workman takes a screw-hoop. fig. 11, which is a thin plate of steel, with a square lump at one end, and another near the other end, to receive a screw, c, to tighten it; the workman puts this hoop over the flames, as seen in fig. 13, and turns the screw, c, until the flames are brought close enough, to drive on the iron truncheon, fig. 12. These cylinders, or canteens, are taken to a workman, who turns them in a lathe, fig. 14, where A is the pulley on the mandril, turned by a band from a large wheel, worked by a man; B is a conical chuck, on the end of the mandril, on which a canteen is driven by a mallet; the lathe is then set to work, and the ends of the flames or chime turned smooth by a tool laid in the notch, a, of the reel, C; another tool like a hook is then used, for cutting the groove on the inside of the flames, for receiving the head. The boards for the heads are first fawn out, as before described, into squares 7½ inches each side, these are cut circular by a lathe, fig. 15: the mandril has a wooden chuck on one end, with four steel points in it; a workman takes one of the square boards, G, and puts it up against the points in the chuck, and to confine it while it is turning, he uses a piece of wood, D, one end, d, of which is placed against the middle of the board, and the other has a small hole in it to receive the point of a screw, F, working in the puppet, E; the lathe is then turned, and the board cut to the proper diameter, by a chisel laid in the notch in the reel, C. The next operation is heading and hooping the canteens, which is done by knocking off one of the true hoops, and putting one of the heads into the groove; the flames are then tightened by the screw hoop, fig. 11, so that the hoop of the canteen may be driven on; the other head is then put in, and the hoop on, in the same manner; and the wires, a, and another not seen, fig. 1, are put in; they are for receiving the belt by which the canteen is carried by the folder. They are, finally, proved, by pouring a small quantity of hot water into them, and filling the cork-hole with a wooden flopper, when they are soaked, and the hot water rarefying the air within, the same will rush out violently, and discover any small leak that it may have. The slips of iron plate for the hoops are cut from large plates of sheet-iron, by the shears, fig. 16. A is the centre of a strong wooden lever eight feet long, which has a steel blade, a, a, two feet long, fixed by three screws to the under side of it; D is a strong bed fixed separately in fig. 17, on the top of which the other blade, b, b, is fixed, by three hooks, c, c, the upright legs of which go through the bed, and are fixed by three nuts; between the back of the blade and these hooks, three wedges, d, d, are put in; by drawing which the blade can always be brought near enough to the other blade, c, a, to cut; C C, are two guides to steady the lever, B; near one end of the blade a piece of iron, c, is fixed on the lever, B, which acts as a stop to the edge of the plate, E, as it is cut; f is another stop for the fame purpose, which slides through a hole in the bed, and is pushed up by a spring, g, under the bed. The plate of iron, E, is pushed forwards from behind by one man, while another is lifting up the lever, B, till it reaches the stops, e, f; the man at the handle then pushes it down, and cuts the length of a hoop at once off the plate, when the lever is down the under side of it pushes down the stop, f, so that the hoop may fall off; when the lever is lifted up to cut another hoop as before. The holes for the rivets of the hoops are next punched by a machine, represented in fig. 18. A is an iron lever, having a punch fixed.
fixed in it at B. under this is fixed a dove-tailed groove, C, to hold a piece of fixed, d, which has several holes of different sizes in it, to suit different punches, any one of which can be brought under the punch, and fixed by the screws, in each side of the groove, C: across the top of the groove, an iron plate, e, is fixed, with a hole in it, for the punch to go through; its use is to prevent the hoop, (which is put under it), after it is punched, from slipping with the punch; D is a screw put into the bench, to prevent the punch from being driven too far into the hole; the boy who works this machine lifts up the lever, A, puts one end of the hoop under the plate, e, and then pushes it down, which makes the hole; he then lifts it up again, and puts the other end under to make the hole in it; till looking the hole before made, over the plate, E, which determines its length.

After the hole is punched, a machine, shown in fig. 19, is used, to cut the ends of the loopholes; A is the lever, and B the cutter fastened to it; C is the other fixed cutter, which can be adjusted by a screw. E, fixed to the bench; F is a guide, between which the lever, A, piles, to keep it steady; the end of the piece of iron for the hoop, is laid by the boy who attends the machine, upon the fixed cutter, C, and the handle is pushed down to cut it off. The hoops are then bent round a block, and riveted in the common way. By these ingenious contrivances, the operations are rendered so simple, that a good workman will head and hoop 200 of the canoes in one day, working 14 hours; and two active men will cut with the shears, (fig. 16,) 63 hoops in a minute; great attention must be paid to keeping the trumph-hoops always of the proper size, as they are apt to expand with continual use, which is the reason of their being so thick, (fig. 15,) and if they are too large, the heads of the canoes will not fit.

CANTIEL, Cantellum, in Ancient English Writers, denotes a custom of selling by the lump, without tale or measure. Spleman derives the word from quadratum, and defines it by over measure, or what is added over and above strict measure. Kennet derives it from the old word cant, a hundred, that is the fable of about a hundred weight; answering to what we now call the taking of a hundred pound on content; as when we take it in a bag, sealed up without telling the price.

CANTIEL, Peter-Joseph, in Biography, was born in the diocese of Rouen, in 1645; and having entered into the society of the Jesuits, passed his days in their college at Paris, where he devoted himself to literature, with an ardour which hastened the termination of his life, in 1684. His principal labours confessed in preparing the Delphine editions of the classics; and he published Jullin and Valerius Maximus, the latter of which he enriched by five dissertations on Roman affairs. He also wrote a treatise "De Romana Republica," printed at Paris, in 1684, 12mo. and esteemed an excellent abridgment of Roman antiquities; also, "Metropolitanarum Urbium Historia Civilis et Ecclesiastica," tom. i. Paris, 1684, 4to. Nouv. Dict. Hiflor.

CANTELEU, in Geography, a town of France, in the department of the Lower Seine, and district of Rouen; one league W. from Rouen.

CANTEMIR, Demetrius, in Biography, prince of Moldavia, and a descendant of a noble Tartarian family, was born in 1673, and educated in part at Constantinople, whether he was lent in his youth as a kind of hostage. Disappointed by the Ottoman Porte in his expectations of succeeding his father, as prince of Moldavia, he conceived a prejudice against the Porte; and though he continued at Constantinople till the year 1712, when the war broke out between the Czar Peter the Great of Russia and the Porte, and was appointed by the latter, governor of Moldavia, he preferred the rank of prince of the country. With this view he violated his fidelity, and entered into an agreement of mutual aid and friendship with the czar. When the Russian arms failed of success, he was obliged to quit the Turkish territories, and to follow his new patron, who recommissioned him with the title of prince of the Russian empire, sovereignty over the Moldavians settled in Rossia, and other considerable appointments. His reference was at Charkof in the Ukraine till 1773, when he removed to Moscow. Here on occasion of his second marriage with a Russian princess in 1779, he showed his heart, and changed his Turkish name for the European. The czar made him a proxy-council; and Tcacovsky accompanied him in his different wars, conducting himself so as to gain general esteem. In 1786, on the ship he was shipwrecked, and lost several papers which he had taken great care and pains in compounding. He died at his estate in the Ukraine in 1793. Cantemir was industrious and learned, and is said to have understood 11 languages. He was the author of several works. His "History of the Growth and Decay of the Ottoman Empire," A.D. 1630 - 1682, written in Latin, and published in an English translation by Thiodal, Lond. 1724, fol. is charged by Gibbon (Hist. vol. xi. p. 434.) with containing strange blunders in oriental history; though he acknowledges the author was conversant with the language, annals, and institutions of the Turks. His "System of the Mahomettan Religion," was written and printed in the Russian language, by order of czar Peter; his moral dialogues entitled "The World and the Soul," were printed in Moldavia in Greek and Moldavian; "The present State of Moldavia," was printed in Latin; his "Musical Airs with Turkish Words," and "An Introduction to Music," in Moldavian. He was also the author of other pieces, which were either lost in his ship-wreck, or still remain in MS. Morei. Gen. Biog.

CANTEMIR, Antiochus, was the son of the preceding, by whom he was carefully educated, and initiated in letters. He was successively ambassador from the Russian court to those of London and Paris; and, in the different revolutions of his own country, he conducted himself with singular prudence. His chief distinction consisted in his having first applied Russian language to the composition of poems of any extent or dignity; and he wrote translations of Anacreon and the epistles of Horace, besides various satires, odes, fables, &c. His fates, like those of Bocion, were a happy mixture of strong sense and poetry, and many of his verses are become proverbial in the Russian language. He also published translations in prose of the "Plurality of Worlds," the "Persian Letters," and "Algarotti's Newtonian Dialogues." He was a member of the academy of Petersburg, and died in 1744. The abbé Guefor wrote his life in French, and translated his fates into that language. He was much inclined, at an early age, to the study of the Scriptures, and printed a "Concordance to the Psalms," in the Russian language. Nouv. Dict. Hist.

CANTER, William, an eminent linguist and philologer, was born at Utrecht of an eminent and respectable family in 1542, and studied first at Louvain, and then at Paris. Being obliged to leave Paris in 1561, on account of the civil wars, he visited several universities in Germany and Italy, and at length settled at Louvain, where he pursued his literary occupations with an affluency and ardour, which terminated his life at an early age in 1575. Thuanus says, that he deferred to be reckoned among the most learned men of his age, and laments his immature death as a great loss to literature. He understood six languages, besides that of his own country, viz. the Latin, Greek, Hebrew, French, etc.
French, Italian, and German. Temperate, and even abstruse in his diet, he was singularly methodical in the distribution of his time for study. He began at seven in the morning, and not sooner, because early rising did not suit his constitution, and required his literary avocations very intensely till half past eleven. He then walked out an hour before dinner, and another hour after he had dined. Having slept an hour upon his couch, he resumed his studies, and prosecuted them without interruption till midnight, devoting the last hours of the day to correspondence with his friends, and other busines that required a deep degree of attention and labour. He had collected, during his short life, a very excellent and curious library, consisting of the best authors in various languages, and a number of Greek MSS., which it was his intention to have published with Latin versions and notes, if his life had been prolonged. The damage which his library sustained from an inundation at Louvain in the winter of 1573, was an affliction, which would have proved fatal to him, if his friends had not affixed him in collecting his scattered books and MSS., and repairing the injury they had sustained. The principal works of Canter are eight books under the title of "Variae Lectiones," containing emendations and explanations of several ancient authors, published at different times, and reprinted in Gruter's Tho- faurus, tom. iii. Latin versions of the "Cæsannia of Ly- cophron," of some "Pythagorean Ethical Fragments of Stobæus," of the "Difficulties of Aristides," and of the "Syn- thesis," &c. Notes on the "Familiar Epistles and Offices of Cicero," various readings on several MSS. of the "Sep- tuagint," editions of "Euripides," of "Aeschylus," of "Sophocles," and of various other authors; and several Latin poems in the Deliciae Poetarum Belgarum. Morei.

Canter, in the Manor, denotes the flow gallop, which is a soft and easy pace in which most people delight. Berenger (Hist. and Art of horsemanship, vol. i. p. 71.) conjectures, that our word canter, expressive of this pace, may owe its derivation to the Latin term "Cantherius," which was the appellation of the horse, that usually performed it. Dr. Johnston, in his Dictionary, calls this pace the Canterbury gallop, and defines it to be the hand gallop of an ambling horse, called a canter, and probably derived from the matters riding to Canterbury on easy ambling horses. "How just the derivation may be," says Berenger, "I will not presume to decide; but the definition must puzzle all who are horsemen, and all who are not." See Cantheri.

CANTERBURY, in Geography, is the capital of the county of Kent, and the metropolitical see of the archbishop, who is primate of all England. The present city occupies a site which, during the Roman colonization of Great Britain, was a military station of that warlike people, and, according to the opinion of many eminent antiquaries, was the Durovernum of Antoninus's Itinerary. Three other principal Roman stations, which Mr. Somner calls Castra Riparenfæ, were connected with this, by three different Roman roads, some traces of which have been discovered. The names of these stations, and their respective distances, are thus given by Antoninus. From Durovernum to ad portum Rutupis (Richborough) 12 miles; to ad portum Dubris (Dover) 14 miles; and to ad portum Lemnianum (Lime) 16 miles. Without entering into the Roman history of this place, it may suffice to remark, that various relics of that people have occasionally been found here. Besides some seats and walls, which appear to have a Roman foundation: from: Masonic pavements, urns, coins, &c. that have been discovered, are evident memorials of that people. In the Saxon heptarchy, Canterbury, or, as they called, Cantwarabrig, was the principal place in the kingdom of Kent, and, during the reign of Ethelbert, was constituted the metropolitical see of all England. This monarch, having given a favourable reception to St. Aulfin, and his forty monks, who landed in the life of Thangest in the year 597, was pleased to affix for their residence that part of the ancient Durov- vernum which is now called "Stable-gate," and which had formerly been a kind of chapel, or oratory for the royal fa- milv, where they had been accustomed to worship, and Sacrifice to their gods. The munioners entered the town in procession, singing a hymn. They were first restricted to the precincts, and, though zealous in their ministerial functions, did not make much progress in converting profesties, till the king assented, and recommended Christianity. This example produced numerous converts; and some monkish chron- iclers do not hesitate to affort, that 10,000 perons of both sexes were baptized in the river Swale in one day. This is too improbable to be credited in the present age. Au- gustin having, however, completely established himself here, dedicated an ancient church to the honour of Christ, and Ethelbert founded an abbey, which was afterwards called St. Augustin's, the site, &c. of which has since been occupied by the bishop's palace. (See Augustin, vol. iii.)

Canterbury is particularly distinguished for its military, as well as ecclesiastical fame. Successively occupied by the Romans, Saxons, Normans, &c. it became the scene of re- peated sieges and battles in the respective wars of each nation. It pofted a castle at the Norman Conquest, as it appears from the Domesday-book that the conqueror ob- tained it in exchange from the archbishop and abbot of St. Augustin's. The outer walls, and walls, appear to have in- cluded an area of about four acres of land. Nearly the whole of this fortress has been destroyed, and its fosses filled up. The walls and gates, which formerly surrounded the city, have nearly suffered the same fate. Some of the latter remain, and parts of the former still retain their original cha- racteristics. The whole extent of the wall measured nearly one mile and three quarters in circumference. Its thick- nesses, on a medium, is about five feet, and at certain intervals were formerly twenty-one fortified towers. Without, there was a deep foss, nearly 150 feet wide, which environed the whole. The different entrances to the city were protec- ted by fix fortified gates, each of which gives name to the respective wards, or parts of the city, wherein they are situa- ted. Besides these, there were some smaller passageways through the walls, called pellens. Wall-gate stands on a bridge, which crosses the river Stour, and is the largest of these structures. It consists of two lofty spacious towers, emar- tled, particolled, and machicolated, and is now used as the city prison. Archbishop Sudbury is said to have built this gateway, and the wall which proceeded from it northward on the bank of the river. Further north, is a small pellern entrance, and near it is a large pile of building, called the Abbots-nunn, the machinery of which was con- structed principally from designs, by that great engineer, the late John Smeaton. The Northgate is very peculiar and remarkable, from having a long narrow church over it, which takes its name from the gate. Next to this, east- ward, was Queeningate, in which part of a Roman arch may yet be discovered on the outside of the wall. Near this is a pellern, which is occasionally opened for the convenience of the deanery, and some of the prebendal houses. Burgate, and St. George's gate, are in the eastern side of the wall. The latter is directly opposite to Wellgate, and is con- structed and fortified in the same manner. In each tower of this gateway is a cillern, from which pipes slided, to convey water to different parts of the city. Besides these, there were nine other gates, which belonged to the cathedral and to the monastery.
monastery. Some of these are distinguished for their architectural ornaments; particularly that of Christ-Church. This, says Mr. Summer, is a very glossy, strong, and beautiful structure, and, according to an inscription on the cornice, was built in the year 1517. The principal front of this building is highly enriched with niches, canopies, shields, and other ornaments. The most considerable building, and greatest ornament of Canterbury, is the cathedral church, dedicated to Christ. This magnificent and spacious edifice displays the various styles of architecture which characterized different ages from the eleventh to the sixteenth century. The Danes besieged this city in 1014, and on the twentieth day of the siege let it on fire, and completely burnt the cathedral. Lecithius, or Agitus, the archbishop who governed the see from 1020 to 1038, refounded, and made considerable progress in rebuilding this structure, which was again burnt in 1067. The present edifice appears to have obtained its foundation from archbishop Lanfranc, who was invited from Normandy by the Conqueror, in 1073. He is said to have completed the building, according to the then prevailing Roman style, in the course of seven years. In consequence of accidents by fire, and the dilapidations of time, different subsequeint archbishops made various alterations, additions, and improvements: but to particularize the whole would exceed our due limits. One or two prominent circumstances must suffice for the present work. Further, and very detailed particulars may be found in Dart's "History of Canterbury Cathedral," and in Goffin's "Walk in, and about Canterbury." In 1330, the new choir, built by archbishop Anselm, was dedicated with great solemnity in the presence of king Henry I. and his queen, David, king of Scotland, and many of the nobility of both kingdoms. On the 26th of December, 1370, archbishop Becket was barbarously murdered at the foot of the altar. He was buried here, where a magnificent shrine was erected to his memory, and the monks having canonized him, his tomb was reforted to by an innumerable concourse of pilgrims from all parts of Christiantized Europe. This circumstance gave more extensive celebrity to Canterbury than any other event, and from that period the place continued to increase in monastic buildings and inhabitants, till Henry VIII. dissolved the bigoted delusion and the religious foundations at once. Erelonus and Stowe have each given a particular description of Becket's shrine, from which it appears that besides a coffin of gold, there were many jewels, &c., employed to decorate the remains of this saint. (See Becket, vol. iv. p. 1.) The present cathedral consists of a nave, aisles, choir, transepts; two towers rising at the west end, one rifting from the centre, some private chapels, or oratories, a chapter-house, cloisters, &c. Some of these buildings display much skill and beauty in their architecture, and some are further ornamented by many ancient and curious monuments. Among the latter may be noticed theoile of Henry IV. and his queen; Edward the black prince; cardinals Chatillon and Pole; archbishops Courtney, Chicheley, Bourchier, Walter, Reynolds, Kemp, Stratford, Peckham, Warham, Langton, and Sudbury; besides many others erected to the memory of eminent and distinguished characters. At a short distance from the city walls, are the remains of St. Augustin's monastery, which was certainly the first Christian establishment in Great Britain. This was burnt in 978, and though at first only a small foundation, soon increased in extent and revenues. Patronized by a king, and under the government of a man like Augustin, it attracted the company and property of numerous devotees from all parts of the converted island; and in proportion as Christiannity was extended, so was the sacred fame of this place propagated.

At the dissolution, Henry VIII. seized the town, and intended to make it a palace for himself. It was afterward granted to cardinal Pole; and in 1573, queen Elizabeth kept her court here in her progress through Kent. The boundary wall included about six acres of land. Some of the remaining buildings are appropriated to a brewery, and its fine entrance gate-way, though still a beautiful object, is gradually crumbling away.

Canterbury formerly contained seventeen churches and parishes within the walls, and three in the suburbs; but of these only fifteen remain. The Jews, Presbyterians, Quakers, Methodists, and Baptists, have each their respective places of worship. Among the buildings we may particularize the following: Having formed both beautiful and curious to entice them to the notice of the inquisitive traveller. St. Martin's church, being composed partly of Roman brick, is considered the most ancient building in the city. St. Dunstan's church is a large, handsome structure. St. Margaret's church contains an ecclesiastical court, where the archbishop, archdeacon, &c. hold their several visitations; and where various causes relating to ecclesiastical affairs are tried. This city is provided with many other public edifices; and its hospitals and other charitable establishments are numerous. Here are two public libraries, a prison for Eait Kent, a free grammar school, a theatre, assembly rooms, and a large guild-hall, which, besides containing several convenient apartments, is embellished with some portraits of persons who were benefactors to the city. The city workhouse was established by act of parliament in 1728. The name of Chancer, and his Canterbury tales, with the Chequer inn, which was at one time occupied by our veteran poet and his fellow-pilgrims, will long be associated in the memory of all lovers of old English poetry.

The corporation of the city consists of a mayor, recorder, twelve aldermen, a chamberlain, town-clerk, twenty-four common council men, and some inferior officers. It sends two members to the imperial parliament, who are elected by the freemen, of whom there are resident, and non-resident, upwards of 1600. An act of parliament for paving, lighting, and watching the city was obtained in 1757, since which time the appearance of Canterbury has been materially improved, and its local advantages greatly augmented. The road-way of all the principal streets is paved with Guernsey pebbles, and the foot-paths with Yorkshire squared stones.

Canterbury is fitted in a fine valley on the banks of the river Stour, which, dividing itself into different channels, thus forms five or six islands, some of which are built on, and are united to other parts of the city by bridges. At the southern side of the walls is an artificial conical eminence, called Dane John Hill, or Dungie-Hill. This mound and its vicinity having been judiciously planted, and laid out in pleasant walks, is thereby rendered a very attractive and delightful promenade to the citizens. The principal manufactories of the city are for worsted, silk, and cotton, and here is a manufactory for blending silk and cotton, or silk and worsted, which is known by the name of Canterbury muslin, or bullis. In the environs of the city are numerous hop plantations. See Kent.

Canterbury being a county in itself, its magistrates have authority to determine all disputes at law between the citizens, and to try capital offences. On these occasions the mayor sits as judge, attended by the recorder, and the bench of aldermen. This city is 55 miles east from London, and has markets on Wednesdays and Saturdays, besides several fairs. The horses in 1800 amounted to 17,000, and the inhabitants to 5000. Goffin's "Walk in and about the City of Canter-
CANTERBURY, or CANTERBRY, in *Ancient Architecture*, rafter, or joints of a house, which reach down from the ridge to the caves.

CANTH, in *Geography*, a town of Silesia, in the principality of Breslau, on the Wilitzer; 12 miles S.W. of Breslau.

CANTHAREE, among the *Anteians*, a kind of candlestick. See Branch.

CANTHARELLUS, in *Botany*, (Jull. 4. Meruliis, Writ.) See Agaricus and Meruliis.

CANTHARELLUS, in *Entomology*, 3 species of Staphylinus, of a black colour, with the wing-cases glaucous, and yellowish at the tip. *Inhabit* Sweden. *Gmelin.*

CANTHARIAS longis, in *Natural History*, a name given by some writers to a follicle substance supposed to resemble a beetle. We sometimes meet with parts of the ichthyoptery or bony parts of fishes, which are ridged longitudinally, much in the manner of the outer wing of some of the beetle tribe; and from their size and shape, which is an oblong, or oval one of the bigness of a common beetle, and sometimes of the largest, and at others of the very smallest kinds; these have been called by some, petrified beetles and cantharia lapisides; others have extended the name to such species of amber as have in them the body or any fragment of the beetle of any species.

CANTHARIDES, in the *Materia Medica*, are beautiful green flies with a golden burnish, found in the south of France, in Spain and Italy, of very important use in the Materia Medica. (For the natural history of this fly, see Meloe Vespicatorius.) The cantharides of Italy are the largest, but the Spanish are accounted the best, and are the most valued, whence the insect is also commonly known by the name of Spanish Fly.

When these flies appear in swarms, they are accompanied by a very distasteful and fetid smell like that of mice, and this effluvium is so powerful, when proceeding from a large swarm, that perforce exposed to it, experience symptoms of strangury, and ador urine, pain in the eyes, and violent itching over the body.

The common way of collecting these insects is, to spread cloths under the trees containing them, to shake them down, and then kill them by putting them on a hair sieve and exposing them to the vapour of boiling vinegar, or elfe (which is the commonest mode) simply to immerse them in vinegar and water. They are then dried thoroughly, either in the sun or in airy chambers, being frequently turned by the hands armed with gloves. They are then well and carefully packed in clove wooden barrels lined on the inside with paper. The insect, when well dried, is so light as to weigh no more, on an average, than about a grain and a half.

Cantharides in this state will keep well for a considerable time, and if in clove vessels, they hardly acquire any smell, but in open vessels and in the damp, they putrify in some degree. They are liable, however, notwithstanding their very corrosive quality, to be attacked by very small worms, which gradually crumble them to powder in every part except the wings. The acid quality, however, is not very materially injured thereby, and remains for a great length of time, though slowly diminishing in intensity.

The singularly acid property of cantharides has led several chemists to endeavour by chemical analysis, to determine in what principle it resided. Thouvenel’s experiments on this subject are of some importance. This chemist found four distinct substances in cantharides, some of which are doublets till further decomposable. After softening them with warm water, he submitted them to strong pressure, which left behind about half the weight of a parenchymatous matter that was not further attended to. Hot water then extracted about 2 of the whole weight of a yellowish red and very bitter substance, which gave an acid by distillation, and melted out a quantity of yellow oil which boiled at top.

This latter concrete by cooling, and has a very acrid taste and the peculiar smell of the insect. Heated with ether, it separates into two distinct conceivably oily matters, that are soluble in either, being green, waxy, and peculiarly acrid, and the other untouched by this menstrum, remaining yellow.

The green oil is about 2 of the whole, and the yellow oil after this has been separated, amounts to about a fifth. All the active medicinal properties have been supposed to reside in these oils, and especially the green. The truth of this supposition is somewhat questionable to the full extent, since this oil is insoluble in water, which liquid certainly extracts some acid properties from the insect, but it is yet highly probable, that it is the most active portion. This concrete oil being very difficult of putrefaction and more of the nature of resin, will also explain why the virtue of the insect remains so active after very long keeping. The whole of the active power of the insect, both which resides in the oil and in the extract, is readily dissolved by alcohol diluted with as much water; and in this way the tincture of cantharides is prepared. Something further, however, may probably be done on this subject by an able chemist who should pursue this research.

Cantharides have a peculiar and somewhat nauseous smell. When taken into the mouth, no taste is at first perceived, but after a while, a senation of burning comes on which is very durable. Taken into the stomach even in the dose of two or three grains, it produces most excruciating pain and sensation of burning, inflaming and excoriating the whole intestinal canal, and producing death with great agony. It also has a peculiar tendency to affect the urinary organs, occasioning very acute pain and burning on passing the water, often attended with blood, and also with strangury, or a painful difficulty of passing it. These affections of the bladder often are felt in a lighter degree after the external use of this insect.

The chief use to which cantharides are applied is, in *Blisters*, as has already been fully described under that article, and need not here be repeated. No other known substance answers the effect so certainly, so extensively, and on the whole, so easily to the patient, and hence this insect is one of the most valuable articles of the materia medica. Much refinement has been attempted in the composition of the different blistering plasters, and many additions have been proposed, but with very dubious advantage. It does not appear that any substance can add to the vesicating power of the fly when fresh and good, and when a diminished effect is wanted, the simplest and surest way is, either to lessen the quantity of the cantharides or the usual time of its application.
The internal use of cantharides is justified by found experience, but on account of its extreme danger, it should be employed with great caution. The minor affection is generally the first and most unmistakable sign of an excessive dose. It is given internally sometimes in drops, and formerly in debility of the urinary and generative organs. Camphor is laid to check the disposition to strangury, but this is most doubtful. Opium is more certainly an useful addition. The dose of the fly in substance is about half a grain, and can seldom be borne oftener than once or at most, twice a day. The use of cantharides is also used internally in doses of from ten to twenty drops. Besides the above-mentioned uses of this medicine, the juice has often been found of singular service joined with decoction of elm-bark or farlaoprinse, in oblique cutaneous diseases. The juice is used externally as a stimulant application.

CANTHARIUM, in Botany, (Rumph. Anth.) See 
Nepenthis Distillatoria.

CANTHARINUS, in Entomology, a species of Cerat 
byx, (Saperda Fabr.) that inhabits Germany. The 
colour is ferruginous: thorax cylindrical, with the antenna and legs black. Fab. Linn. &c.

CANTHARINUS, in Entomology, a species of Cimex. The 
colour of this insect is black: thorax armed with a single tooth, and marked with a white circle: wing-cases cinereous, with four yellow spots: feceal yellow. A native of Denmark. Mull. Zool. Dan.

CANTHARIS, in Entomology, a genus of Coleopterous 
sects distinguished by having the antenna filiform: thorax 
in general margined, and shorter than the head: wing-cases 
flexile: tides of the abdomen edged with folded papillae. Linn. &c.

The species of this genus Gimelin divides into three 
sections, the first containing those which have four hatchet-
shaped feelers; the second, those with filiform feelers, the 
last joint of which is fuscous, (or true Mahachins of Fabricius) and the Lymexylus, or those having the anterior 
feelers projecting, the last joint but one, with a large ovate 
segment, and the last joint ovate and acute. The 
species are these:

Section 1, viridescens, fusca, marginella, media, hae 
matolomia, punctata, dichroma, multicolor, livida, difictata, 
exsula, livida, rugifera, jambe, lateralis, marmagdula, 
biguttata, minima, cardiace, albicans, tellacea, atrum, 
marginea, hisnaculata, pallipes, pallida, ruficollis, flavipes, 
melecanopha, bipunctata, angulata, nigra, pulicaria, car 
nesceina, coccinea, bicolor, bilineata, triuncla, alitci, occu 
latata, collaria, cuprea, argentea, janthina, americana, rubi 
pes, brucuifera, fulva, serrata, tropica, fonchii, capifica, fal 
veola, violacea, viridescens, lepturides, nigripes, melanura, 
hirta, picea, chalybida, tricolor:

Section 2, aerea, bipunctata, hemorroidalis, virid 
ibus, fanguinolenta, cyanus, pedicularia, nemoralis, fuscata, eque 
tris, oecrhus, chrysolomides, ceruscocephala, suecia, 
Herbii, erythroclausa:

Section 3, abbreviata, proboscidea, barbata, navalis, fax 
onica, morio, which respectively.

Obi. The Fabrician genus Cantharis, includes only 
thefe Linnaeian species of the genus that have four hatched-
shaped feelers: Jaws bifid; lip entire; and antenna fili 
form.

CANTHARIUM, in Ancient Geography, the most 
western promontory of the Isle of Samos.

CANTHARUS of a Fountain, among Roman writers, 
denotes the part, or apparatus, out of which the water 
issues.

It was made in divers forms, sometimes in that of a shell, 
at other times in that of an animal, which yielded water 
at its mouth, eyes, and the like.

CANTHARUS, in Embryological Writers, denotes a foun 
tain, or cistern, in the middle of the Town, before the an 
cient churches, wherein persons washed their hands and 
feet before they entered.

CANTHARUS, in Entomology, a species of Skittis. The 
tail is immaculate, and the body bidentate longitudinally 
with yellow. Linn. Arted. &c. Inhabits the Medi 
terranean.

CANTHELEA, or CANTHALIA, in Ancient Geography, 
a maritime town of Africa, in the territory of Carthage, 
in the vicinity of Carthagin. This town is said to have 
received its appellation from the Pagan debt Saturn; for, 
according to Sanchoniatho and Damascius, the word of 
the Phoenician tongue had a particular relation to that deity. 
In confirmation of this opinion it is added, that there was 
a town in that place called "Vicus Saturni," the direct 
or town of Saturn, where Jerome is said to have lodged 
during his exile in Carthia.

CANTHERII, in Antiquity, a general name applied by 
the Romans to horses used on many different occasions, 
but which was always understood to mean "geldings." 
Many unsatisfactory conjectures have been formed concerning 
the etymology of this word. The best explanation, says 
Hieronymus (Hilt. &c. of Horsemanship, p. 71) seems to be 
that which deduces it from the Greek, χανθείον, cantheion, 
which, by no unusual change of one letter for another, may 
be made "cantherion;" signifying, in its original sense, 
a pack-faddle; and as it was usual to calibrate the "can 
therii," or pack-horses, in order to make them gentle and 
quiet, it became a custom to call all calibrated horses, 
"cantherii," though appointed to other services beside that 
of carrying packs or burdens. In process of time, people, 
who, for various reasons, rode on horseback, began to 
use these cantherii, or geldings, for their gentleman's temper, 
to other horses.

CANTHICOLUS, or IRINUS, in Ancient Geography, 
a gulf of India, according to Polteny, into the northern 
part of which the river Indus discharges itself.

CANTHICUS, in Anatomy, a port of the Indian sea, to 
the west of the most western mouth of the River Indus.

CANTHICUS, in Botany, a genus formed by La Mark 
and adopted by Jussieu, for two plants nearly allied to 
Gardenia and Coffea; but flated by La Mark to differ from 
the former in their two-seeded berries, and from the latter, in 
their short flowers and simple stigma. One of them is 
Gardenia spinae of the younger Linneus, G. Dumetorum of 
Willdenow, which for the other, see Webera 
Tetrandra. As La Mark has not infected this genus in his 
Illustrations, he appears to have since formed a different 
judgment concerning it, but as the detail of species in that 
work is not yet complete, it cannot be determined in what 
manner he would now dispose of these two plants. We 
have followed the arrangement of Willdenow.

CANTHUS, in Anatomy, the junction of the superior 
and inferior eyelids. Hence there is an internal and 
an external canthus. These parts are also called the angles 
of the eye; that which is towards the nose being termed 
the inner or greater angle; and that which is towards the 
temple, the outer or lesser angle of the eye.

CANTHUS, in Chemistry, the lip of a vessel; or that part 
of the mouth of a vessel, which is a little hollowed, or de 
pressed, for the easy pouring off a liquor.

Hence, to pour by decantation, is to pour through that 
place.

CANTHUS, in Entomology, a species of Papilio (Dan. 
Fbs.)
that inhabits North America, the wings of which are entire, and fuscous above: anterior pair immaculate: on the upper surface of the posterior ones fix ocular spots. Fabr. &c. Off. This insect is noticed by Lineaus (Annot. Anim.) under the name of Papilio Eurydice, and it is also Papilio Argente of Cramer.

CANTICL. Carmina lefebri. Songs sung through the streets of Florence in the Carnival, by persons in masks, during the time of Lorenzo il Magnifico. These songs, after the manner of the Greek feoda, were applicable to persons of different trades and occupations; among the rest there is one for those who played on the rucbe, the trumpet, and various instruments of music used in the German troops, called by the Italians, Lunci. The first of these songs that were performed in this manner, were set by Arrigo Tudisco, Maestro di Cappella of the church of St. John, and a musician of great eminence, of whose compositions various specimens are preferred by Glorianus. Aut. Francisco Graevi, commonly called, Il Lati, collected and published the words of these songs in 2 vols. Svo., under the title of Tutti i trionfi. Carri, Moscografia a Canti Carmina lefebri andati per Firenze dal tempo del magnifico Lorenzo de' Medici sino al anno 1559. The poetry of these songs is still in great favour with the Florentines.

CANTICLE, a hymn or pious song: as, the Song of Songs, by Solomon. The first and most ancient canticles were composed on occasion of great and memorable events, and should be ranked among the most ancient historical monuments. Canticles were sung in church, and often accompanied with dances, as appears in the sacred writings, where the most considerable composition of this kind is the song of songs, which some authors imagine to be an epithalamium, composed by Solomon on his own nuptials with the daughter of the King of Egypt. But theologians find under this allegory, the union of Christ and the church. M. Caluance saw nothing in the song of songs, but a regular opera: the scenes, recitatives, duets, chorusses, every thing necessary to an opera, according to him, is contained in this canticle, and he doubts not but that it has been represented.

CANTICLES, or the Song of Songs, in Biblical History, a Hebrew mode of expression to denote a song superlatively excellent in file and sentiment. Of this ancient poem, the author is ascertained, by the unanimous voice of antiquity, to have been Solomon; and this tradition is corroborated by many internal marks of authenticity. In the very first verse it is said to belong to Solomon: he is the subject of the piece, and the principal actor in the conduct of it. Allusion is made to the rich furniture of his palace, chap. i. 5.; to the horses and chariots which he purchased of Pharaoh king of Egypt, i. 9. 1 Kings x. 28, 29.; to Amminadab, who was eminent for such chariots, and who married one of Solomon's daughters, vi. 12. 1 Kings iv. 11.; to his building of the temple, under the figure of a palaquin or coach for his bride, iii. 9. 10.; to the materials of which it was formed brought from Lebanon and other hills, iv. 8. In a word, all the leading circumstances of Solomon's life in a religious view appear to be alluded to, or implied in this ancient poem, and therefore render it probable that it was a production of some writer in his age, if not his own composition.

That the Song of Songs, from the most early period, was deemed a sacred book, and ranked with the Hagiographa of the Jews, and thence received among the canonical books of the Old Testament, may be inferred from the following confederations. A translation of it is ascribed to the seventy Jews, who flourished about 300 years before Christ, and which still forms a part of the Alexandrian version. With the same conviction of the sacred character of the work, it was rendered into Greek, in the second century, by Aquila, Symmachus, and Theodotion. Origen, on the authority of the Jews, contemporary with him, and whom he was in the habit of consulting respecting the authority and literal import of their sacred books, inferred it in his Hexapla, and wrote some homilies upon it, explaining its mystical sense, which have in part been translated into Latin by Jerome. That the ancient Jews, without exception, considered it as a production divinely inspired, appears moreover from the allegorical signification annexed to it by the Chaldee paraphrase. Josephus, in his answer to Apion, lib. i. 38, gives a catalogue of the Jewish books, and includes in the third class of such as related to moral instruction the Song of Songs. See Bible and Canon. Eusebius, also, following his footsteps, makes it the fifteenth of that number. See his Ecclef. Hist. lib. vi. cap. 25. From the Jewish synagogues, the book of Canticles was received into the Christian church, without any doubt of its divine authority. This appears from Origen and Eusebius. It is cited by Ignatius, about the beginning of the second century, as a book of authority in the church at Antioch. It is included in the canon of the apostles. See Canon. And in the apostolical constitutions, a passage from the Canticles is quoted. Con. vi. 13. 18. See Constitutions, apoc.

Though the Song of Songs comes down to us recommended by the voice of antiquity, its divine authority has been called in question by many writers in modern days. Wharton thinks it a dissolute love song, composed by Solomon when advanced in years, and degenerate in practice; and that therefore it ought to be excluded from the canon of the sacred books. Taken indeed in its primary and literal sense, it must be considered as describing a royal marriage, and may therefore be denominated an epithalamium or nuptial song. The celebrated Michaelis supposed that the object of it was to teach God's approbation of marriage. But the ideas of Harmer appear much more rational, who, though unwilling to give it the name of epithalamium, thinks it a marriage song to be explained by compositions of a similar nature in eastern countries. "What can be more likely," says he, "to lead us into the literal sense of an ancient nuptial poem than the comparing it with similar modern productions of the East, along with antique Jewish compositions of the same kind?" Boffuet, bishop of Meaux, was of opinion that this song was to be explained by the consideration, that the Jews were wont to celebrate their nuptials for seven days together, distinguished from each other by different solemnities; and this notion has been adopted by the author of "A New Translation of Solomon's Songs, with a Commentary and Annotations." The principal objection to this opinion is, that the conduct of the poem does not admit of such a distribution; and the distinguishing each day by some distinct ceremony is a mere supposition unsupported by fact.

The elegant and learned bishop Lowth devotes two of his Prelections to an examination of this poem, and he determines it, with Boffuet, to be a sacred drama, though deficient in some of the essential requisites of dramatic composition. Sir W. Jones, from his knowledge of Eastern poetry, was led to compare some parts of it with familiar productions among the Arabsians, and delivers it as his opinion, that it is to be classed with the Hebrew idyls. Pocf. Afiat. Con. p. 92. Supported by the high authority of this illustrious scholar, Mr. M. Good, in an elegant metrical version with which he has favoured the public, considers the Song of Songs.
Songs as forming not one continued and individual poem, but a series of poems, each distinct and independent of the other; and he denominates them sacred idylls. "The Song of Songs," he says, "cannot be one connected epithalmion, since the transitions are too abrupt for the wilder flights of the Oriental muse, and evidently imply a variety of openings and transitions; while, as a regular drama, it is deficient in every requisite that could give it such a classification."

In opposition to this it may be remarked, that the subject of the poem, from beginning to end, is the same; the personages, introduced as speakers, are the same; and, though to a modern reader the transitions in many places may seem abrupt, and the thoughts unconnected, the conduct of the piece is not suspended, but carried on under a fable regularly constructed, and terminating in a conclusion interesting and unexpected. The apparent want of connection in the sentiments of an ancient dramatic composition must be manifest; and it is the business of a critic to remove those causses, by pointing out the place of representation; by affixing to the proper characters their respective speeches; by unfolding in the history of the times, the event on which the fable is constructed; by marking the commencement and close of the several acts or stages of the action: in a word, by conveying his own imagination, and that of his reader, to the place of exhibition, and thus calling the eye, as it were, to the affluence of the ear in developing the unity of the subject, and supplying the smoothness of the transitions.

Having thus produced the sentiments of others respecting the nature and object of the Canticles, we shall next briefly state those of an ingenious friend, who considers it, for the reasons which he has adduced, as a parable in the form of a drama.

Firstly, When closely examined, it will appear to possess all the essential qualities of a drama. The marriage of Solomon with the daughter of Pharaoh, (as related 1 Kings i. 1.) a political event which, from the personages concerned in it, would be interesting to the Jewish nation, was, as such, proper to furnish the fable of it. The writer is entirely left behind the curtain, and the whole of the composition is brought forward before the reader in parts between the speakers. The dramatis personae are Solomon, the bride, her attendants, and the virgins of Jerusalem. It should be observed, though the fact has indeed been overlooked by the critics, that all advance is made by the lady herself. She comes to his palace unfetiched, and apparently unfetiched. Finding him not there, she goes in search of him, intreats to be received into his embrace; and when, without denying, he eludes her intreaties, she pursues him in the ardour of her affection almost beyond the bounds of female delicacy and modesty. On the contrary, the royal spouse is cold at heart, and distant, prone to recede, and to intrigue with his favourite concubines, but anxious to conceal his indifference and infidelity under laboured encomiums on the beauty of his spouse. The action is complete, polishing a beginning, a middle, and an end, and compofed of scenes, the shifting of which, if observed by a modern reader as by an ancient spectator, would have preferred the conduct of the piece uniform and condense. The plot, it must be allowed, is very simple, the inconsistencies of it arising only from those unforeseen impediments which were thrown by rival beauties in the way of the royal bride, and which threatened to deprive her of the object of her attachment. The catastrophe is the triumph of honourable love over the allurements of seduction, and the security of virtuous enjoyment over the torments of jealousy and illicit fruition.

Secondly, Considered as a parable, like other parables, while it conveys a literal fenee interesting and appropriate, it conveys likewise a religious lesson of supreme importance. Now the method of deciphering a fable or parable is, not by seeking under the veil of the allegory certain maxims of recondite wisdom, which bear no resemblance to the literal fenee, but by facts generally known and fully understood; nor is the interpretation to be deemed true unless, as in the case of the parable of Naaman or that of the laven, these exhibit an obvious and characteristic analogy between the fimple and the metaphorical accretions. On this principle, it is apprehended that, in the parable of the Canticles, the bride means the Jewish religion, and the royal spouse the Jewish nation, represented under the name and person of their ruler and chief; and the object of it is to delineate, under images borrowed from the communal state, the conduct of the Israelites at large, and that of Solomon in particular, in respect to their knowledge and worship of Jehovah.

In proof of this position, it will be necessary to specify a few leading particulars.

1. The relation subsisting between Jehovah and the Jews, as his chosen people, is usually described, in the Jewish writings, in language expressive of the relation between a husband and the woman who is the object of his peculiar affection and choice. See 1Sa. iv. 5. Jer. iii. 1. Ezek. xvi. xxiii. Hof. i. Mat. ix. 15. xxv. Rev. xix. 7.

2. The description, given in the poem, of the royal bride consuits of those figures and allusions which, in other parts of the Jewish scriptures, are employed to delineate the character of true religion. Thus she is said to be a fountain, to be a garden, to have a vineyard, to be more delicious than wine. See 1Sa. iv. 1. Mark xii. 1. Isa. xii. 2, 3. John iv. 14. vii. 37. Pf. xix. 10.

3. While the royal lover is lavish of his encomiums on the beauty of his bride, he was cold and faithless, and all advance is made by herself. This delineates with exactness the character of the Jews, with respect to their religion. It was bestowed upon them unasked and unforced. While loud in praise of their worship, they were ever prone to the idolatry of their neighbours; and the God they were forfaking ceased not, as it were, to pursue them, and to solicit their return to him. We read of Solomon, (1 Kings i. 1-7.) that the strange women he married were the means of seducing his heart from God; and the bride seems to have been sensible that the virgins, with whom he associated, were the cauue of alienating his affections from her, and the repeatedly intreats them not to far up use assume her beloved.

4. Solomon built a temple in which the knowledge and worship of the true God might be cultivated; and the service of the temple was appointed by the wisdom of heaven to be but an introduction to the more rational service of the Christian church. For this reason, the temple might be considered as the cradle or couch in which the Jewish religion was to be nurtured, and, as it were, to be conveyed home to her parent's house; that house of which God was the owner and author, and of which Christ was the chief corner-stone. Accordingly the royal lover is represented as making a couch for the bride. In this grand palaquin she is conveyed home with her husband; and here she expects to enjoy his undivided attachment, without any apprehension from the seductive arts of her rivals. And it is certain that those of the Jews who passed over from the temple to the Christian church never afterwards relapsed to idolatry, but ever remained faithful to the worship of the true God.

5. The temple being made of the wood of Lebanon, the bridal couch is, for this reason, represented as made of the same timber. Hence with much propriety the royal lover invites his bride to come from Lebanon, and other hills,
whence the materials for the temple were brought; and hence too, with equal propriety, the language in which the husband celebrates the accomplishments of his spouse is copied from that temple which was devoted to her service.

6. When they arrived in the parent's house, the informs her husband, "We have a filer who is little, and hath no bosom." Which means that, when the Jewish temple was exchanged for the church of Christ, Judaism itself pointed out the gospel dispensation, which being in its infancy encumbered with rites and ceremonies, had not yet all its vigour and purity. To the information of the bride respecting the younger sister the king replies, "If she be a wall, we will build for her a palace of silver; and if she be a door, we will enclose her with boards of cedar." Which is to this effect: "If the new religion, the younger sister, be intended as a wall or an additional security of the old; if the religion of the gospel prove an auxiliary to the service of the temple, we Jews will erect for her portion a splendid edifice; we will adopt her as a beautiful appendage of Judaism: but if, on the other hand, she will abolish the Levitical code, and throw open a door to receive the Gentiles to the privileges of the Jews, we will reject her, and endeavour to close up the breach which she has made in our dispensation." The answer of the bride is remarkable: "I am a wall," by which she delicately hints that she was the means of excluding the chosen people of God, and of separating them from the idolatry of their neighbours; but that her younger sister was intended to remove this wall of separation, and to unite the Gentiles with the Jews in the knowledge and worship of the true God."  

7. The gradual expansion of revelation, from the first dawn of it in the garden of Eden till it reached its meridian fulness, in consequence of the death and resurrection of Christ, is thus beautifully portrayed in the character of the bride: "Who is the that looketh forth as the morning, fair as the moon, bright as the sun, and serene as the starry hosts?"

Finally, The royal husband addresses his bride as being at the same time his filer, My filer, my spouse. These two inconstant relations are now easily explained. The father of the husband, the Creator of the Jews, was also the author of their religion. The bridegroom and the bride, being descended from the same great Parent, were also a brother and sister.

The metaphorical sense thus capable of being put upon every part of this poem, justifies the high appellation of The Song of Songs, which has ever been given it. It accounts also for its being regarded, by Jews and Christians, as a sacred composition, and for its reception first into the Jewish, and then into the Christian canon. On its first publication its allegorical import must have been generally understood, and it was natural that, as with the process of time it became unintelligible, it should still retain the high rank and estimation which at first it so justly acquired. It was also equally natural in the first Christian writers, on receiving it into the canon of the Jewish scriptures, but without knowing the true significatior of it, to interpret it as referring to Christ and his church. The interpretation, however, though adopted by most modern divines, has only involved it in mystery, fancy, and absurdity; and the consequence was that its claims to inspiration have been called in question; nor is there any means of restoring it, in the estimation of rational critics, to the sacred writings, but by disclosing the beautiful lesson of religious wisdom concealed under the veil of its allegory. The epitome, respecting the younger brother and filer, demonstrates that its views terminate in the temple service. While, at the same time, the allusion at the close to the rite of the gospel, and the conversion of the Gentiles, which took place so many hundred years after Solomon, proves that the author was actuated by divine inspiration.

CANTICUM, Latin, in Mufe, a motet, anthem, or sacred song.

CANTI, in Ancient Geography, a people of Albion, or Britain, who inhabited that part of the country which from them was called Cantium. See CANTUM.

CANTILENA, in Mufe, an Italian word equivalent to melody, the treble, the principal part of a composition, opposed to the recitavo, or under parts, either in instrumental or vocal music.

CANTILLANA, in Geography, a town of Spain, in the country of Seville, seated on the Guadalquivir; 12 miles N.W. of Carmona.

CANTIMARONS, or CANTIMARONS, a kind of floats or rafts, used by the inhabitants of the coast of Cornwall to go a fishing in, and to trade along the coast. They are made of three or four small canoes, or trunks of trees dug hollow, and tied together with wicker ropes, with a triangular sail in the middle, made of mats. The persons who manage them are abash half in the water, there being only a place in the middle a little raised to hold their merchandise; which last particular is only to be understood of the trading cantimaron, and not of those who go fishing.

CANTING-ARMS, among Heredities, are those arms which express their owner's surname. These answer to what the French call armes portantes; they are a sort of rebukes, and are never prefixed to be noble. See Arms.

CANTING-QUOINS, in Ship Building, the name of canting-quoin. See Cant and Quoin.

CANTIGEBUS, in Ancient Geography, a town of Germany, placed by Ptolemy near the Danube.

CANTUM, as it is called by Caesar and Ptolemy, Cantia of Bede, now Kent, derives its name and that of its inhabitants, most probably, from the British word "Cant," which signifies an angle or corner, and applied to this part of Britain from its form and situation. It is separated from the continent by a narrow sea, called by Solinus "Fretum Gallicum," but by Tacitus and Ammianus Marcellinus "Fretum Oceanum," and "Oceanus Fretalis." The places of Cantium mentioned by the ancients are Durovernum, Durobrigia, Durolenum, Portus Rutupiae, Portus Dubris, Regulbium or Regulium, and Portus Lemanum, now Canterbury, Rochester, Lonham, Richborough, Dover, Reculver, and Leine. Ptolemy reckons Londinum, London, among the cities of the Cantii; but in this particular he was certainly mistaken. This was probably the first district of Britain which received a colony from the continent; and it is no less probable that it had frequently changed its masters, by new colonies, who came over from time to time, and drove the inhabitants farther north. Amidst all its revolutions it retains its appropriate name, and it was transferred to all the successive tribes by which it was inhabited. At the time of the Roman invasion its inhabitants were evidently of Belgic origin, who had arrived at so late a period, that they differed in no respect from their countrymen on the continent. "The inhabitants of Kent (says Caesar, Bell. Gall. i. v. 10.) are the most civilised of all the Britons, and differ but very little in their manners from the Gauls." This resemblance was owing to the proximity of their situation, which, being nearest to the continent, was most frequented by emigrants from thence. It was this situation, also, that exposed them to the first assaults of the Romans. Caesar, in both his expeditions into this island, landed in Kent; and therefore we may conclude, that the Cantii were principally concerned in the vigorous opposition that was made to his landing, and in the several
several skirmishes and battles that were fought against him after his landing; particularly, they made a very bold but unsuccessful attempt upon his naval camp. Their refuils, however, was less vigorous on the next invasion of the Romans, in the reign of Claudius; for we learn from Dio (l. b.) that Anius Plautus, the Roman general in that expedition, traversed their country without losing an enemy; and as they now submitted to the power of Rome without a struggle, so they continued in a state of quiet submission to it to the very last. Cantor, in the most perfect state of the Roman government, formed a part of the province which was called "Flavia Caearia." Henry’s Hist. vol. i. p. 273, 8vo.

CANTO’O denotes a part or division of a poem, referring to what is otherwise called a book. The word is Italian, and properly signifies song. Tasso, Ariosto, and several other Italians, have divided their longer or heroic poems into cantos. In imitation of them Scarron has also divided his Gigantomachia, and Boileau his Lutrin, into chants or songs. The like usage has been adopted by some English writers, as Butler, who has divided his Hudibras, and Dr. Garth his Dipsomancy, into cantos. A translator of part of Virgil’s Aeneid, has even subdivided a book of Virgil into several cantos.

CANTO, Ital. a song, part of a poem. Il canto, in Music, implies the first tole of a vocal composition, in four parts. In a chorus of more than four parts, there is frequently a second canto; as canto zdo. the second treble. Canto fermo, plain chant, canto Gregoriano, the Gregorian chant, or the chant instituted by pope Gregory, written in the Roman mifals, in square black notes, on three or four lines only. Canto figurato, florid counterpoint.

CANTOOCR, in Geography, a town of Pidmont, 23 miles N.N.W. of Turin.

CANTON, Jones, in Biography, an ingenious natural philosopher, was born at Strand in Gloucestershire, July 31, 1713, O. S.; and having, at an early age, made a considerable proficiency in mathematics, under the tuition of a schoolmaster in his native town, he was taken from school to learn the business of his father, which was that of a weaver of broad cloth. This employment, so unfitable to his faculties and views, did not restrain his ardour in the prosecution of science; and his acquaintance with astronomy was at this time so considerable, that by the help of the Caroline tables he computed eclipses of the moon and other celestial phenomena. He also contrived several kinds of dials. In his favourite pursuit he encountered many difficulties and discouragements; but devoting those hours to study, which the family spent in sleep, and reduced to the necessity of secreting a candle for this purpose, he made such progress that he was able to construct, with a common knife, an upright sun-dial of stone, which served to shew not only the hour of the day, but the rising of the sun, his place in the ecliptic, and some other particulars. This dial was placed in the front of his father’s house, and as it excited the admiration of several neighbouring gentlemen, it was the means of introducing him to their acquaintance, and of gaining for him an access to their libraries. In one of these libraries he found Martin’s Philosophical Grammar, in the perusal of which he first acquired his taste for natural philosophy. In another library he met with a pair of globes, the use of which facilitated his solution of various problems. At this time he had the happiness to be introduced to the acquaintance and patronage of the Rev. Dr. Henry Miles, a dissenting minister at Tooting, near London, well skilled in natural knowledge, and a respectable member of the Royal Society. Mr. Canton accompanied Dr. Miles to London, in 1737, and after residing with him for sometime, he articulated himself for five years as an assistent to Mr. Samuel Watkin, master of an academy in Spital-square. Having recommended himself in this subordinate situation, by his ingenuity, application, and good conduct, he was taken into partnership by Mr. Watkin in 1743, and afterwards succeeded him in his school, where he remained till his death. The science of electricity had for some time engaged the attention of Mr. Canton; and after the discovery of the Leyden Philo towards the close of the year 1745, he made it the object of his particular investigation, and in the following year his method of determining the quantity of electricity accumulated in it was communicated by Dr. William Watson to the Royal Society. His mode of doing this, as Dr. Priestley observes, in his "History of Electricity," had a near affinity to the discovery of Dr. Franklin. Towards the close of the year 1749, he assisted his friend Benjamin Robins, Esq. In his experiments for ascertaining the height to which rockets ascend, and the distance at which their light may be seen. In January, 1750, Mr. Canton communicated to the Royal Society his "Method of making artificial magnets, without the use of, and yet far superior to any natural ones." The discovery of this method had been made some time before; but Mr. Canton, from motives of delicacy, with respect to Dr. Gowin Knight, delayed the publication of it, till he was urgent to it by Martin Folkes, Esq. This communication was soon followed in the same year by his being elected a member of the Society, and by his receiving its gold medal. In this year he was also complimented with the degree of Master of Arts, by the University of Aberdeen; and, in 1751, he was chosen one of the council of the Society. On occasion of the change of the style in 1752, he gave to the earl of Macclesfield several memorial canons for finding leap-year, the dominical letter, the epact, &c. which were afterwards published by Dr. Jennings in his "Introduction to the History of the Globe." In 1752, Mr. Canton had the honour of being the first perfon in England, who, by drawing the electric fire from the clouds, during a thunder-storm, verified Dr. Franklin’s hypothesis of the similarity of lighting and electricity. In 1753 his paper, entitled "Electrical Experiments, with an Attempt to account for their several Phenomena," was read at the Royal Society. This paper, as well as another communicated to the Society in 1754, contains some curious facts and discoveries, of which an account will be given in the History of Electricity. Mr. Canton, in 1752, sent to the editor of the Lady’s Diary a solution of the prize question for that year, explaining the phenomenon of the "shooting of stars." The answer was anonymous; but Mr. Thomas Simpson, who then conducted the Diary, sent the prize to Mr. Canton, accompanied with a note informing him that, though he had concealed his name, he knew him to be the author, because no one else could have answered the question. Our author’s next communication to the public was a letter in the Gentleman’s Magazine for September, 1759, on the electrical properties of the Tournaisin, which fee. In the same year the Royal Society received a paper, entitled, "An Attempt to account for the regular diurnal Variation of the horizontal Magnetic Needle, and also for its irregular Variation at the Time of an Aurora Borealis." Mr. Canton’s observations on the transit of Venus were communicated to the Royal Society in November 1761; and in 1762, a letter addressed to him by Dr. Franklin was read, containing remarks on Mr. Delaval’s electrical experiments; in December of the same year his curious paper entitled "Experiments to prove that Water is not incomprehensible" was also communicated to the Society. See Compression. These experiments, as they refuted the famous Florentine experiment, were carefully examined, and the
conclusion deduced from them very cautiously received. They were repeated before a committee of the Society, who professed themselves satisfied with their accuracy and with the facts inferred from them; and in consequence of their report, the council unanimously voted to Mr. Canton the gold medal, which was delivered to him on the 30th of November, 1765. In 1769 our author communicated to the Society, "An easy Method of making a phosphorus, that will imitate and emit Light, like the Bolognian flow, with Experiments and Observations." See PHOSPHORUS. Mr. Canton was one of the committee of the Royal Society, who, in 1768, took into consideration the belt and the most effectual method of fixing electrical conductors to preserve the cathedral of St. Paul's from damage by lightning: and the mode which they recommended has been put into execution. Our author's last paper, addressed to the Royal Society, was read in December 1769, and contained "Experiments to prove that the Luminousness of the Sea arises from the Putrefaction of its animal Substances." Besides the papers above recited, and which have been inserted on account of their peculiar importance and utility, Mr. Canton wrote a number of others, which appeared in several different publications. The compiler of this article had the honour of intimate acquaintance with Mr. Canton for several of the last years of his life; and he can bear testimony from his own observation to the peculiar neatness and elegance of his apparatus, and to the accuracy and address with which he conducted his experiments. He can also testify with gratitude and pleasure to the urbane manners, and to the readiness with which he communicated information to all who wished to receive, and who seemed disposed to derive any advantage from it. His death, of a dropy in the thorax, probably occasioned by his sedentary and flatus habits, at comparatively the early age of 54, in March 1772, was much regretted by all who knew him, not only as it deprived them of an esteemed friend, but as his decease was no inconceivable loss to the interests of science, which he affably cultivated and improved. His wife, whom he married in 1744, and by whom he had several children, survived him. His eldest son, Mr. William Canton, succeeded him in the academy. Bing. Brit.

Canton, in Geography, a quarter of a city, considered as separated and detached from the rest.

The word seems formed from the Italian cantone, a square, flat, or corner flat.

Canton is also more frequently used for a small country, or district, under its separate government. Such are the thirteen Swiss cantons; each of which forms a republic apart; but all are leagued together, and constitute what is called the Helvetic body. See Switzerland.

Canton, in the late organization of the French constitution, denotes a subdivision of a district; as districts are subdivisions of the departments. See Department. Each canton is composed of a certain number of communes (see Communes); and is comprehended within the jurisdiction of a justice of peace. The "assembly of canton" is composed of all the citizens domiciliated within the canton, and who are in consequence upon the communal list of the district. The first consul nominates the president of this assembly, whose functions last five years; and he is affitled by four scrutineers and a secretary. Each assembly of canton divides itself into sections, for the purpose of performing the functions that belong to it; and it proposes two citizens, from whom the first consul chooses the justice of peace of the canton, and also two citizens for every vacant place of deputy. The justices of peace, and their deputies are appointed for ten years. In the cities consisting of 5000 persons the assembly of canton precursor two citizens for each place in the municipal council; and in cities, where are several assemblies of canton, each assembly is empowered in like manner to present two citizens for the same purpose. The members of the municipal councils are taken by each assembly of canton from a list of 500 persons of the first consideration of the canton; and these councils shall be renewed, one by one, every three years. The will of the citizens of the canton, who are continued five years in office, but may be rechosen. The assembly of canton nominates for the electoral college of district the number of members assigned to it, in proportion to the number of citizens of which it is composed; and it nominates to the electoral college of department, from a given list, the number of members assigned to it. The government convenes the assemblies of canton, and fixes the time of their duration, and the object of their meeting.

Canton, or Quang-chou-foo, a city and maritime port of China, and capital of the province of Quang-tong or Canton. The city and the suburbs are situated for the most part on the eastern bank of the Pe-kiang river, which communicates by canals with the neighbouring provinces. The city is composed, as it were, of three different cities, separated by lofty walls, but so connected, that the same gate serves to pass from the one and to enter into the other. These three cities united form a regular square, and the city wall is laid to be about six or seven miles in circumference; though the inclosure is occupied partly by pleasure-grounds and fish-ponds, as well as by private and public buildings. The suburbs are much more extensive. The streets are long and straight, chiefly paved with flat flones, and ornamented at certain intervals with triumphant arches; some of them are covered, and these contain the richest shops. The houes are generally low, consisting only of one story, without windows to the street; but other buildings, inhabited by the most respectable merchants and mandarins, are lofty, spacious, and convenient. Some of these are fitted up in the English manner, with glass windows and fire-grates, the latter of which are found to be useful about the winter solstice. A large garden with pools and parterres surrounds the buildings. On one side of them is a temple; and on the other, a high edifice, the top of which commands a view of the river and shipping, as well as of the city and the country to a considerable distance. Perons of condition are carried in chairs; and few females are seen in the streets. These, however, are continually crowded, especially with persons, who are all loaded, and most of whom have their heads, legs, and feet bare. There is no other convenience in this city for removing goods from one place to another but by means of porters. The quay on which the European factories are built, and which is very extensive, is situated, without the walls of the city, on the left bank of the river, and displays by flags the colours of every nation. These factories compose a long range of buildings, of one story, with several yards. From behind, they form a street, crowded with shops, which are furnished with every kind of merchandise; and the street is closed at the two extremities by barriers, beyond which the Europeans are not to pass. Formerly they went every where, except into the Tartar town, which is contiguous to the Chineese town. The number of strangers to be seen in the suburbs, while their ships are loading and unloading in the river, together with their various languages, dreeses, and characteristic deportment, would give occasion to doubt, if a judgment were to be formed from that part of the town, to what nation it belonged. The town of boats is a league above Canton. They are all in fruit rows, and form streets. Each boat, being tolerably large and covered, affords an habitation to a whole family; who have also a small boat to procure provisions,
The number of inhabitants in the town and suburbs of Canton is estimated at a million and a half; and if we consider the great extent of the city, the vast resort of trading vessels and boats, and the immense number of mechanics, tradesmen, merchants, merchants' clerks, porters, watermen, fishermen, hatmakers, and native Chinese, it will not be thought extravagant. The custom is sometimes composed of 20,000, at other times of 25,000, and even of 35,000 Tartars.

The number of persons, who are obliged to live on the water in boats, and who are prohibited by the express regulation of the law from settling on shore, may amount to 300,000, including the women of the town, who are estimated at 40,000. Canton is not only one of the best and most considerable ports of China, but it is the only one which Europeans are permitted to frequent; it is also the rendezvous of a great proportion of Chinese vessels, trading to Cochinchina, Formosa, Haynan, Siam, Malacca, Achem, Batavia, the Moluccas, Japan, &c.

The great objects of import and export are principally carried on in this city by means of agents belonging to companies in Europe. Such have been, as for G. Stanton observes, (Embassy to China, vol. ii. p. 57.) the profanity, punctuality, and credit of the English East India company in particular, and of their agents, in the estimation of the Chinese merchants, that their goods are always taken, at a quantity and quality, for what they are declared in the invoice; and the bales with their mark pass in trade, without examination, throughout the empire. These agents are divided generally into super-cargoes and writers; and they are allowed a commission on the business which they do, according to their stations in the service. The exports of Canton consist of many articles, but that which is most commended is tea; of which the Europeans and Americans received, in 1795, 5,577,800 lbs., and the English private trade amounted to 23,733,580 lbs. The exports from Canton to India amounted, in 1792, to 330,000, leaving a vast balance in favour of India, which is paid in cash. The articles purchased for India consist chiefly of raw and wrought silk, sugar and sugar-candy, tuseeag, alum, porcelain, camphor, nankeen cloth, quicksilver, and turmeric. In 1792, there were imported into Canton from England, in 16 company's ships, to the amount of near 1,000,000, in lead, tin, woollens, together with furs, and other articles of private trade.

The order for woollens only in the following year was 250,000, higher than the preceding year. The legal trade from the British dependencies in India to Canton, in 1792, amounted to very near the sum of 700,000 l.; besides opium, which is clandestinely imported there, to the amount of about 250,000. The articles legally imported consisted of cotton, silk, pepper, madder-wood, elephants' teeth, and bees' wax. The total imports from foreign European nations to Canton, in 1795, amounted to 200,000; and their exports to upwards of 600,000. Many of the imports were of British manufacture. The Canton artists are uncommonly expert in the imitation of European works. They repair, and even make watches, copy paintings, and colour drawings, with great success. They supply strangers with coarse silk rockings, knit or woven at Canton, though few or none of them are worn by the natives. The toys made at Canton, and known under the name of balancers and tumblers, are partly filled, and their equilibrium sustained, by quicksilver. The lapidaries of Canton, who cut diamonds, use for that purpose adamantine spar. The amalgama of tin and quicksilver is applied, by the artificers in Canton, in making small mirrors, with glass blown upon the spot from broken pieces of that material imported whole from Europe. The spectacles used by the Chinese are formed of crystal, which the Canton artists cut into laminae, with a kind of steel saw, formed by twirling two or more fine iron wires together, and tying them like a bow-string to the extremities of a small flexible bamboo. The siliceous powder of the crystal, procured by sawing, is received into a trough of water; and with that mixture the wire and groove formed in the crystal are often moistened. The powder of the crystal, like that of the diamond, helps to cut and polish itself. Gold leaf is used by the silk and velvet weavers in their tints and embroideries. Tinplate also are made of it at Canton, which, though not worn by the Chinese, are sold in Europe as adornments. Silver is also drawn into threads, like gold, to be used in the silk and cotton manufactures. For the method used at Canton in preparing their white copper or petung, &c. see that article.

By the accurate observations of Mr. Raper, during the year 1774, cited by Kirwan in his "Ephemer," &c. p. 97, the temperature of Canton was 75° 14'; the standard temperature 75° 4'; the greatest heat in January 66° 5', the least 51'; the greatest heat in August 89°, and the least 80°. N. lat. 23° 7' 50". E. long. 113° 2' 15".

Canton, a province of China, of which the above described city is the capital. See Quang-Tong.

Canton, a township of America, in Norfolk county, Massachusetts, incorporated in 1797; being formerly the northern part of Stoughton.

Canton, in Heraldry, is one of the nine honourable ordinaries; being a square portion of the escutcheon parted from the rest.

It has not any fixed proportion; though regularly it should be less than a quarter, it is often only a ninth part, and used as an addition, or difference, frequently to express bailiary. The canton is sometimes placed at the right corner, and sometimes at the left; in which latter case, it is called a canton saffier. For its form, see Plate, Heraldry.

Canton is also used for the spaces left between the branches of a crook or sallier.

To Canton, or dispose of in cantonments, in French cantonnement, in the Military Art, is to distribute troops in towns and villages as contiguous to one another and as nearly in the same line as possible, and in such a manner as to command the avenues to the same, and to front the district of country the enemy is in, or the towns, villages, posts, or positions, he may occupy or poffefs himself of. Troops are sometimes cantonned after the fatigue of a siege, that has been undertaken early in the spring, that they may have some time to reposie and recruit themselves; sometimes in the midst of a fatiguing campaign, for the purpose of rest and refreshment; sometimes towards the close of a campaign, when forage is scanty and the weather tempestuous, till such time as the enemy shall go into winter quarters; and sometimes before the opening of an early campaign for the fake both of subfitude and of convenience to a proper or eligible camp of exercise, which is at all times within reach of their cantonments, and can be protected from them.

The cantonning of troops is also a phrase occasionally, though not very properly, made use of for the disposing or distributing of troops into winter quarters. See the article Quarters. In a garrisoned town or place, where there is not a sufficiency of barracks and cafemats for the troops, different divisions of it are allotted to different regiments for the accommodation of their officers and men. And such an allotment or division of the town, is sometimes called the cantonning of it.

CANTONE, in Commerce, a measure of three gallons, wine-measure, at Alicante.

CANTONED, a word used in Architecture, when the
corner of a building is adorned with a pilaster, an angular column, buffle quoin, or any thing that projects beyond the naked of the wall.

**CANTONED, CANTON'S, or CANTONIZED, in Heraldry,** is when the four cantons, or spaces round a cross, or faltier, are filled up with any pieces.—He bears gules, a cross argent, cantoned with four scallop shells.
The word is also used when there are little pieces in the cantons, or spaces, of any principal figure of an effigio.

Thus the faltier of Lenox is cantoned with four rosettes.

**CANTONING, in Middle Age Writers,** denotes the dividing a thing into hundreds, or filling it by hundred weights, or hundreds in tale.

**CANTONMENTS, in Military Art,** are a fort of transient or temporary quarters for different purposes, but chiefly for the repos of troops. Cantonments differ from quarters in this respect, that the latter are seldom made use of but for a short rest or refreshment to an army that is much fatigued, but continues to do the same fort of duty in them as in the field; whereas in the latter, duty is performed as in garrisoned places.

In quarters of cantonment, the troops ought to be arranged and disposed of nearly in the same manner as in order of battle; viz., with the cavalry on the wings and the infantry in the centre. The cantonments should not be very much scattered or extended. They ought not to exceed ten or twelve leagues in front, or be more than four or five in depth.

Before you take the field, they should be a little contracted, and then divided or disposed of under the command of five or six of the oldest generals. One of these should command the cavalry of the right wing, another that of the left, and the rest the infantry in the centre. By such a division or disposition, all orders from the commander in chief will be the more expeditiously executed, and the troops will with greater ease form their columns when they are going to take the field.

**CANTOR, in Entomology,** a species of Cerambix, found in China. The thorax is unarmed, cineereous, with black dots; wing-cages pale, tetaceous; bidentated at the tip, and cineereous with black spots. Fabricius.—Obf. This is of the middle size, and vitlike.

**CANTORS, Lat., a finger, a chanter.** In the Lutheran church, the cantor is the coryphæus of the psalmody. In most parts of Germany, where the protestant religion is established, each parish has a cantor to teach singing, and to direct the choir.

Though cantor is a general appellation for a singer, it is in a particular manner applied, in this country, to the person who has the direction of singing the psalms and hymns in parish churches. He is precentor, or leader of the plain, which he likewise ends, by singing the last word of every line; so that he may be called the alpha and omega of sacred song.

The cantor, who is likewise frequently schoolmaster, besides having a good voice, should necessarily understand counterpoint; if not in a high degree, at least sufficiently to correct such errors as may have crept into compositions, through the ignorance or carelessness of transcribers. He should likewise be able to make an accurate score, and from the score to figure the bass, in such a manner as to include all the accidents of modulation. "Without these qualifications," says Mr. Walther, in his Musical Lexicon, "as a German organist is not gifted with universal knowledge, no perfect harmony can be hoped."

In the market towns and villages of Thuringia, in Saxony, where two persons are usually employed in a school, he who directs the music in the choir, or leads the psalm or chorus, is called rector or schoolmaster, and the organist is commonly cantor.

**CANTRED, or CANTREE, denotes a district or division of an hundred towns or villages.** The word is British, compounded of cant, hundred, and tre, or tref, town or village.

Wales, with regard to its lesser divisions, seems to have been originally divided into "bôds," "trews," and "caers." The "bôd" is supposed to have been the manor-house of a chiefman on his hill settlement in the country; the lands which he alligned for the maintenance of his dependants in the increasing colony were called a "trew;" and the inclusion of such lands for defence or convenience, formed either of wood or stone, might have been denominated a "caer."

An affenblage of several "bôds," formed a "trew" or township; and a hundred of these "trews" constituted a "cantrew." For the more easy and regular dispatch of business, a "cantrew" was divided into two or more "commots;" each of which consisting of a certain number of "bôds" and "trews" formed a distinct precinct, and was considered as a lordship, possessing a separate court and jurisdiction.

Anglesey, in particular, was divided into three "cantres" or "cantreds," which are each subdivided into fix "commots" or "commotes," each of "commotes" containing about sixty "treves" or townships.

The general partition of Wales into "cantrews" and "commotes" is very ancient. Rowl. Monum. Ant. Eff. § x. p. 110, &c.

CANTU, in Geography, a town of Italy, in the Milanese; 5 miles S.S.E. of Como.

Sp. i. C. perfusilis, Lam. Ill. pl. 105. fig. 1. "Flowers terminal; flaments longer than the corolla; leaves egg-shaped, petiolate, entire, smooth." Willd. A shrub, smooth in all its parts. Branches woody, thick, stiff, marked with scattered tubercles or knots. Leaves an inch and a half long, and near an inch broad; alternate; petioles short, proceeding from the tubercles. Flowers peduncled, in terminal racemes; calyx often three-eleft, and divided more deeply on Pide. Found in Peru by Joseph de Jullieu. 2. C. bustifolia, Lam. Ill. pl. 105. fig. 2. "Flowers terminal; flaments shorter than the corolla; leaves oblong, nearly falcate, entire, pubescent beneath." Willd. A shrub. Branches woody, rather cylindrical, pubescent towards their summit. Leaves small, about six lines long, and little more than two broad, alternate or falcate-lacinate, lanceolate-egg-shaped, entire. Flowers large, peduncled, upright; peduncles and calyx pubescent; corolla tubular, an inch and half long. Found in Peru by Joseph de Jullieu. 3. C. Hoit-zi, Willd. (Hoitzia mexicana; Lam. Eneey. Juss.) "Flowers axillary; flaments longer than the corolla; leaves 8—12—18-veined."
egg-shaped, fleshy, toothed." Willd. Stem a little shrubby; branches slender, cylindrical, pubescent, especially near their summit. Leaves alternate, entire near their base, a little divided underneath. Flowers of a fine red colour, solitary, nearly fleshy, on the upper part of the branches; segments of the calyx acute, bracteate, of a little longer than the calyx, and surrounding it in the form of an exterior calyx, fleshy, toothed, and terminated by a spinous point; tube of the corolla four or five times longer than the calyx, slightly curved. Fruit not known. A native of Mexico. Willdenow justly observes that as it differs from Cantua only in its bractes, it ought not to constitute a distinct genus. 4. C. pinnatifida. "Lam. Ill. (c. coronopifolia, Willd. Po- lemonium rubrum, Linn. Sp. Pl. Iponcra rubra, Syl. veg. Qaimoebil pinnatum erectum, Dill. Eth. tab. 241. f. 53. 57.) "Flowers terminal; flameus the length of the corolla; leaves pinnatifida." Stem somewhat shrubby, upright, not milky. Tube of the calyx short; segment of its border awl-shaped, longer than the tube. Stamens inserted into the middle of the tube of the corolla without valves. A native of fandy foil in Carolina. Four other species are figured by Ruiz and Pavon in the Flora Peruviana, and three more by Cavalliales in his Icones Plantarum. CANTWELL, Andrew, in Biography, born at Tipperary in Ireland, but lived principally in Paris, where he was made doctor in medicine in 1742. The same year he published a translation into French of the account of Mrs. Stephen's medicine for dissolving the stone in the bladder; and in 1756 an account of Dr. Hans Sloane's medicines for diseases of the eyes; also some severe strictures on the practice of propagating the small pox by inoculation; and in the Philosophical Transactions, London, No. 453, an account of a double child, a boy. He died at Paris, July 11, 1764. Haller. Bibl. Anat. Ecol Dict. Hist. CANTY BAY, in Geography, sometimes called New bay, lies on the coast of Java in the East Indies, and is formed by an island of the same name. It furnishes the best accommodation for wooding and watering in their seas. CANTYBRE. See CANTRE. CANYAS, or CANSAS, in Commerce, a coarse sort of linen or hempen cloth, usually woven open, and regularly, in little figures, serving for divers domestic purposes, and especially for the ground of tapestry work and painting. We have divers sorts and denominations of canvas, most of them imported from abroad; as Dutch, Barbars, and Holmi canvas; packing canvases; goutines and spruce canvas; polichov, itching, or Queensborough canvas; working canvas, for botts or cushions, narrow, broad, and brocked. Canvas also is the cloth on which painters usually draw their pictures; the canvas being smoothed over with a flock, then sized, and afterwards whited over, makes what the painters call their primed cloth, on which they draw their first sketches with a coal or chalk, and afterwards finish with colours. Canvas also is a name sometimes given to fail cloth. Canvas-lace, in the Military Art, contain about a cubic foot of earth or sand, with which they are filled. Their use is to raise a parapet in halte, or to repair one when beaten down. See Sacks of earth. Canvas is also used among the French, for the model or first words, whereon an air, or piece of music, is composed, and given to a poet to regulate and finish. The canvas of a long contains certain notes of the composer, which fiew the poet the measure of the verses he is to make. Thus Du Lort says, he has canvas for ten follettens against the Macks. CANUCCIS, in Ancient Geography, the station of a Roman colony in Africa, planted there by Aurelius, about 7 miles W. from Juf; the Guum of Probity, and Gomagus of the Itinerary, and corresponding to the Lucchi of the Agamemnon. See BRASS. CANVEY, in Geography, a small island in the mouth of the Thames, near the coast of Essex, about 5 miles long and 2 wide; high tides often overflow the lowet parts of it. 5 miles N.W. from the North. CANTULA. See CANULA. CANUS, in Zoology, a South American species of Vole, distinguished by having 158 abdominal plates, and 70 caudal scales. Linn. Muf. ad Fr. This name is debited to Boldmatt as being of a hoary colour, with large whitish spots disposed separately, with a fowy white spot between each. The mount is obtuse and rounded; head imbricated with scales. It is conceived that this species ought to be considered as a connecting link between the two genera Bua and Coluber. CANTUSIUM. See CANTUS. CANUTE, termed "The Great," in Biography, king of Denmark and England, succeeded his father Sweyn in the first kingdom, about the year 1014; and commenced his reign with the invasion of England and Norway, both which kingdoms had revolted from his father. England, however, was his principal object; and as the English had recalled Ethelred their king, who had abdicated the throne, he was not unpre- parative that this event might lead to an attempt for rendering him independent of the crown of Denmark. Accordingly he prepared for an invasion of the kingdom, and soon appeared with a fleet off the eastern coast, which he ravaged with merilis fury; putting ashore all the English hostages at Sandwich, after having cut off their hands and noes. His absence, however, had afforded Olaus king of Norway an opportunity of invading his kingdom, and he was under a necessity of returning home in order to check his progress. This enterprise having been completely accomplished, he resumed his attack on England, and made great depredations on the southern coast, where an army was assembled against him, under the command of prince Edmund and duke: Edric, the son-in-law of Ethelred, who was a notor- ious traitor. Edric still continued his perfidious machinations; and after endeavouring in vain to get the prince into his power, he found means to disperse the army; and he then openly defied to Canute with 40 vessels. When prince Edmund, called "the Iron"; succeeded his father Ethelred, he contended gallantly against Canute and his confederates; but after the loss of two battles, occasioned chiefly by the fallacy and treachery of Edric, he was obliged to acquiesce in a treaty, which divided the kingdom between him and Canute. The latter referred to himself the northern division, consisting of Mercia, East Anglia, and Northumberland, which he had entirely subdued; and the southern parts were referred for Edmund. This prince survived the treaty about a month; and his murder, by the accomplices of Edric, made way for the succession of Canute to the crown of England, A.D. 1017. Against his valour and activity and the strong force which he commanded, the two sons of Edmund could make but an ineffectual reftistance; however, Canute, before he feized the dominions of the young princes, summoned a general assembly of the states in order to secure to himself the succession of the kingdom. In order to maintain the unoffended possession of the throne, he gratified some of the nobility with extensive governments and juridiction, and others, on whose fidelity he could not rely, he put to death. Among the latter was the perfidious Edric. His Danish followers were liberally recompened by means of the heavy taxes which were
were laid on the people, and particularly on the inhabitants of London, who were thus retaliated for their affection to Edmund and their reliance to the Danish power in two obstinate sieges. In one of these sieges he diverted the course of the Thames, and thus by a new channel brought his ships above London-bridge. Canute, having by the concurrence of art and power established himself upon the throne, determined, with the fonnded policy, to reconcile his English subjects to the Danish yoke, by the justice and impartiality of his administration. Accordingly, he went back to Denmark as many of his followers as he could spare; he restored the Saxon customs in a general assembly of the states; he made no division between the Danes and English in the distribution of justice; and he took care by a strict execution of law, to protect the lives and property of all his people. In process of time the Danes were gradually incorporated with his new subjects. For the greater security of his government he contrived to remove the two fons of Edmund to Hungary; and, to conciliate the Normans, who cpiioned the case of Alfred and Edward, the sons of Ethelred, he married Emma, the mother of these princes and the sister of Richard, Duke of Normandy.

Canute, having settled his power in England beyond the danger of a revolution, made a voyage to Denmark, for the purpose of refilling the attacks of Oifmund, king of Sweden; and in this expedition he was accompanied by a great body of the English, under the command of the earl Godwin. The earl, by his skill and valour, contributed to the total dilcomfiture of the Swedish army, and so effectually recommended himself to Canute, as not only to obtain his daughter in marriage, but to lay the foundation of that immense fortune which afterwards accrued to his family. Canute, availling himself of this advantage, puffed with such celerity to Schon, that he surprized the enemy, and flew in battle the king of Sweden. In another voyage, which he made afterwards to Denmark, he attacked Norway, and expelling the julf, but unwarily Olau, kept possession of his kingdom till the death of that prince. Canute was now one of the most powerful sovereigns in Europe; extending his empire over Denmark, Norway, and England, and having rendered Sweden tributary. But neither the elevation of his rank, nor the extent of his dominion, could bound the grasp of his capacious and aspiring mind. Experience taught him the unsatisfactory nature of all terrestrial enjoyments; and he began to direct his views towards that future existence, which it is so natural for the human mind, whether fatigued by prosperity or disfigured with adversity, to make the object of its attention. The spirit of the age in which he lived, however, gave a wrong direction to his devotion; and instead of making compilation to those whom he had injured by his former acts of violence, he employed himself entirely in those exercises of piety, which the monks represented as the most meritorious. He built churches, endowed monastery, enriched ecclesiastics, and bestowed revenues for the support of chantries in various places, where he appointed prayers to be said for the souls of those who had there fallen in battle against him. He even undertook a pilgrimage to Rome, where he refided a considerable time, and where he obtained from the pope some privileges for the English schools erected in that capital, and exemptions from those impositions and tolls which the English pilgrims had been accustomed to pay in the countries through which they passed. It is natural to imagine that a sovereign, so prosperous and powerful, should meet with adulation from his courtiers. A singular, but well known, instance of this kind occurs in the calce of Canute. Some of his flatteners, when they were one day expressing their admiration of his grandeur and dominion, said to him, that nothing was beyond the reach of his power: upon which the monarch, it is said, ordered his chair to be set on the sea-shore, while the tide was rising; and as the waters approached, he commanded them to retire, and to obey the voice of him who was lord of the ocean. He feigned to sit some time in expectation of their submition; but when the sea still advanced towards him, and began to wash him with its billows, he turned to his courtiers, and remarked to them, that every creature in the universe was feble and impotent, and that power refided with one being alone, in whose hands were all the elements of nature; who could say to the ocean, "Thus far shalt thou go, and no farther;" and who could level with his nod the most towering piles of human pride and ambition. The only memorable action which Canute performed, after his return from Rome, in 1031, was an expedition against Malcolm, king of Scotland, who had refused to render him homage for the county of Cumberland, which he held as vaffal to the crown of England. Upon his appearing on the frontiers with a formidable army, Mal-colm submitted, and agreed, that his grandson and heir, Duncan, whom he put in possession of Cumberland, should make the submitions required, and that the heirs of Scot-land should always acknowledge themselves vassals to Eng-land for that province. After this enterprize Canute passed four years in peace, and died at Shaftesbury, in 1035; leaving three fons, Sweyn, Harold, and Hardicanute, and appended, by his will, Harold successor to the English crown. Mod. Un. Hist. vol. xxviii. p. 429. Hume's Hist. of Eng-land, vol. i. p. 143-154.

CANUTI Avis, in Ornithology, tringa canutus; our common knot is so called by some old writers.

CANUTUS, in Ornithology, a species of Tringa, known in this country by the name of knot. It is a native of various parts of Europe, and of America. The bill is smooth; legs inclining to ash colour; primary quill feathers ferrated; outermost tail-feathers white, and without spots. F. Suec. Brinnich, &c.

The bill of this bird is dusky ash-colour; irides hazel; lores dusky; eye-brows and band on the wings white; body cinereous above, beneath white; lower wing-coverts tipt with white; chin and breast with minute spots; belly and vent with dusky lines.

Canutz, a species of Tringa, with smooth bill; legs inclining to ash-colour; primary quill feathers ferrated, exter-ior tail feathers white and without spots. F. Suec. Obs. This is the knot of English writers, Canutus of Bril-lon, and Canut of Buffon. Inhabits Europe and America. Length nine inches; flesh excellent.

Cany, in Geography, a town of France, in the depart-ment of the Lower Seine, and chief place of a canton in the district of Yvetot; the place contains 1435, and the canton 12157 inhabitants; the territory includes 1771 kilometres, and 23 communes. The adjacent country produces great quantities of corn and flax. N. lat. 49° 48'. E. long. 1° 32'.

Cany Ford, a river of America, in the state of Tennes-see, which is short and navigable, and runs N. W. into Cumber-land river, W. of the Salt-lick and opposite salt-lick creek, 50 miles in a straight line from Nashville.

Canytis, in Ancient Geography. See Catytis.

Canzone, an Italian lyric poem in regular stanzas, for which Dante has given precepts and established the laws. The canzonet of Petrarch, and the old poets seem to want variety of measure, and to be too long ever to have been intended for music.

Canzonetta, is the diminutive of canzone, a short lyric poem, and always intended for music.
CANZURI, a name given by some authors to a peculiar kind of cannabis more esteemed than any other sort. Some have suspected it thus called from Kunzur or Chuanur, the name of a place where they suppose it to be produced, which forms the more probable opinion, though Scaliger rejects it. See CANDERBURY.

CAO-CHAN, in Geography, a town of Aifa, in the kingdom of Corea; 30 miles E.S.E. of Hettin.

CAO-CHAN-LI, a town of Aifa in Corea; 400 miles E. of Peking.

CAOINAN, the name given to the funeral song of the Irish. Mr. Beauford (Irish Trans. Vol. IV. p. 46, &c.) has presented to the curious a specimen of this song, with the words in Irish and English, set to musical notes, with its full choruses of sighs and groans, and burden of ullala lollal lollal. He has also prefixed a brief account of the modes of lamentation, by bowls, gYeulures, and ceremonies, which have prevailed, and which still, in a degree, prevail in Ireland. He supposes them to have been derived from the prehistoric inhabitants of Ireland, of Celtic race. Thefe, he says, were a timorous and unwarlike race, as their military weapons, and every vellige of their cuumions and manners strongly indicate: their religion also was spiritual and unattended with human blood. Such a religion and such manners imply a susceptibility of tender impressions, and feminine expressions of sorrow. Accordingly, it has been affirmed of the Irish, that to cry was more natural to them than to any other nation, and at length the Irish cry became proverbial. Cambrensis, in the 12th century, informs us, that the Irish then musically expressed their grief, or applied the musical art, in which they are said to have excelled all others, to the orderly celebration of funeral obsequies, by dividing the mourners into two bodies, each alternately finging their part, and the whole, at times, joining in full chorus. This antiphonial finging is said to have been coeval with Christianity in this isle. See AANTHONY. It was then the funeral elegy rofe in poetic numbers, and was fing in poetic accents to the sound of musical instruments. After the body of the deceafed, dressed in grave cloths, and ornamented with flowers, was placed on a bier, or some elevated spot, the relatives and "Keeners" ranged themselves in two divisions, one at the head and the other at the feet of the corpse. The funeral caonian having been previously prepared by the bards and "crooters," the chief bard of the head chorus began, by finging the firft flanza in a low doleful tone, which was softly accompanied by the harp; at the conclusion, the foot feimi-chorus began the lamentation of "ullaloa," from the final note of the preceding flanza, in which they were anfwered by the head feimi-chorus; thefe both united in one general chorus. The chorus of the firft flanza being ended, the chief bard of the foot feimi-chorus fung the fecond flanza, the strains of which was taken from the concluding note of the preceding chorus; which ended, the head feimi-chorus began the fecond "gol" or lamentation, in which they were anfwered by that of the foot, and then, as before, they united in the general full chorus. Thefe alternately were the fong and choruses performed during the night: the genealogy, rank, poftsfeions, virtues, and vices of the dead were reheafed; and various interrogations were addreffed to the deceafed. Each verfe of the Caonian, it is said, conftituted only of four feet, and each foot was common of two syllables; the three firft required no correpdcence, but the fourth was to correpond with the terminations of the other verses. This kind of artificial metre was much cultivated by the Irish bards; but, on the decline of that order, the caonian was allomned by women, and became an extempormeous performance. Each province was supposed to have different caonians, and hence the Munster cry, the Litter cry, &c., are the only distinct imitations of the different choruses of the same caonian, independent of provincial distinctions. As the caonian was long extemporal, and had no genuine established time, each set of "Keeners" varied the melody according to their taste and musical abilities, carefully preferring, however, the subject or burden of the song throughout, both in the vocal and instrumental part; as begun by the leading "Keener." The caonian is at present much neglected; and this ancient custom will probably soon cease; English manners and the English language supplanting that of the aboriginal natives. At the conclusion of the "Keenan," the body was conveyed to the place of interment, attended by the friends and relatives of the deceafed, and accompanied by the cries of women, who at certain intervals sung the "goll" or "ullaloa." In ancient times, after the interment, the favourite bards of the family, seated on the grave or funeral, performed the "comin- thal" or elegy; which they repeated every new and full moon, for the first three months, and afterwards generally once every year, for perfections of dilution. The elegy was more regular than the "keenan," both in respect to its poetical composition and concluding cadence. The families, both in Wales and Ireland, retained this custom to the close of the last century, and it is frequently alluded to in the Irish ballads and pastoral romances.

CAO-LIM, in Geography, a town of Aifa in Corea; 500 miles E.N.E. of Peking. N. lat. 43° 40'. E. long. 122° 5'.—Alio, a town of Chinese Tartary. N. lat. 45°. E. long. 123° 54'.

CAO-MING, a town of China, of the second rank, in the province of Yunnan. N. lat. 25° 22'. E. long. 102° 44'.

CAO-TANG, a town of China, of the second rank, in the province of Chantong; 200 miles S. of Peking. N. lat. 36° 78'. E. long. 115° 54'.

CAO-TECHIN, a town of China, of the third rank, in the province of Pet-cheli; 15 miles E.S.E. from Tchenting.

CAO-Y, a town of China, of the third rank, in the province of Pet-cheli; 30 miles S. of Tching.

CAO-YAM, a town of China, of the third rank, in the province of Pet-cheli; 12 miles S. of Gan.

CAO-YANG, a town of Aifa, in the kingdom of Corea; 7 miles N.W. of King-kitafu.

CAO-YUEN, a town of China, of the third rank, in the province of Chang-tong; 42 miles N.W. of Tchin-tchen.

CAORLO, a town of Italy, on an island of the same name, in the gulf of Venice, near the coast of Friuli; the see of a bishop, suffragan of Venice. N. lat. 43° 54'. E. long. 12° 44'.

CAOUANNA, in Zoology, Caouanne of Ray; oedou varicata, a modern naturalist, and logger-headed turtle of Cateby. The flesh of this species is highly rancid, hard, tough, and frivolous. See TESUDO CEITTTA.

CAOUKE, in the Turkish Drefs, a high fliff turban, worn by the odabachees, or heads of the chambers of janizaries, when they go in procession.

CAOUTCHOU, Elaflu Gum, in ChemistrY. This fingular vegetable substance was firft brought to Europe from South America, about the beginning of the last century. Nothing however was known concerning its natural history till a memoir was presented in 1736 to the French academy by Con- daime, in which it is stated, that there grows in the province of Eimeraldas in Brazil, a tree called by the natives "Hhevé," from
from the bark of which, when wounded, there flows a milky juice, which by exposure to the air, is converted into caoutchouc. Some time after, the same tree was found in Cayenne by M. Freneau; and it appears from later researches, that this singularly elastic substance is procured from at least two trees natives of South America: of these, the one is called by botanists laevis caoutchouc, and the other, jatrophis caoutchouc. The American caoutchouc is usually brought to Europe in the form of globular narrow necked bottles, about a fourth of an inch thick, and capable of holding from half a pint to a quart or more. They are formed upon moulds of unburnt clay, pieces of which are often found adhering to the inside. In its native country it is fabricated by the inhabitants into vessels for containing water and other liquids, and on account of its inflammability, it is used at Cayenne for torches.

In the Atlantic researches is an account by Mr. Howison, surgeon at Pulo Penang, of a substance exhibiting all the properties of caoutchouc, procured from the juice of a climbing plant, the urceola caoutchouc, a native of that small island, and the neighbouring coast of Sumatra. If one of the thicker and elder items of this plant is cut into, a white juice oozes out, of the confession of cream, and thinly pungent to the taste. By exposure for a short time to the air, or fill more expeditiously by the addition of a few drops of acid, a decomposition takes place; the homogeneous thick cream-like juice, separates into a thin whitish liquor, resembling whey, and the caoutchouc concretes into a clot or curd, covered superficially with a thin coating of a butteraceous substance. If the juice as soon as secreted is carefully excluded from the air, it may be preserved for some weeks without any material change, but at length the caoutchouc separates from the watery part in the same manner, though not so perfectly as it does by free exposure to the air. The proportion of caoutchouc contained in the juice by the oldest items, is nearly equal to two thirds of its weight; the juice from the younger trees is much more fluid, and contains a considerably smaller proportion of this substance.

According to the experiments of Mr. Howison, cloth of all kinds may be made impregnable to water by impregnating it with the fresh juice of the urceola; and the pieces thus prepared are most effectually and expeditiously joined together by moistening the edges with the entire juice, or even the more watery part, and then bringing them in contact with each other. Boots, gloves, &c., made of this impervious cloth are preferable even to those formed of pure caoutchouc, as they are more durable and retain their shape better. If a sufficient quantity of this juice could be obtained, it might no doubt be applied to a vast variety of important purposes.

The colour of fresh caoutchouc is yellowish white, but by exposure to the air it becomes of a smoky grey. American caoutchouc, in the flake in which it is brought to Europe, being formed of a multitude of extremely thin layers, each of which is exposed to the air for some time in order to dry before the next is laid on, is of a yellowish smoky colour throughout, but masses of East Indian caoutchouc being formed more expeditiously, are dark-coloured only on the outside; when cut into, they are of a very light brown, which however soon deepens by the action of the air. Caoutchouc is perfectly tasteless, and has little if any smell, except when it is warmed; it then gives out a faint peculiar odour. The elasticity of this substance is very remarkable, and is one of its most characteristic properties. Strips of caoutchouc when softened by immersion for a few minutes in boiling water, may be drawn out to seven or eight times their original length, and will afterwards resume very nearly their former dimensions. During its extension, a very sensible warmth is produced, as may be perceived if the piece is held between the lips; and on the contrary, when it is allowed to contract, a decrease of temperature will immediately take place. By successive extensions and contractions, especially in cold water, its elasticity is much impaired; but if in this state it is immersed for a time in hot water, it absorbs the caloric which it had lost, returns to its original size, and recovers its primitive elasticity. At the temperature of about 40° Fahr. caoutchouc begins to grow rigid; its colour becomes much lighter, and it is nearly opaque, and as the cold increases, it becomes still more stiff and harder. These changes, however, depend merely on temperature, for a piece of hard frozen caoutchouc again resumes its elasticity on being warmed. The fresh cut surfaces of this substance will unite together by simple contact, and by a proper degree of pressure, may be brought to completely in union so as to be no more liable to separate in this part than in any other. Its fp. gr. according to Briffon is 0.935. It undergoes no alteration by the action of the air at the common temperature. When boiled for a long time in water it communicates to this fluid a peculiar smell and flavour, and in so far softened by it, that two pieces thus treated, and afterwards strongly pressed, will form a permanent adhesion to each other.

When heated to a temperature nearly equal to that of melting lead, caoutchouc runs into a black viscid fluid of the consistence of tar, which does not concret on cooling, neither does it dry by long exposure to the air. When held to a candle it readily takes fire, and burns with a copious white flame, and a large quantity of dark coloured smoke, exhalmg at the same time a peculiar, but not unpleasant odour: from its smoke a considerable quantity of very fine lamp-black may be collected. In dry distillation it gives out ammonia and carbonated hydrogen.

Concentrated sulphuric acid, when heated, acts with great energy on caoutchouc, reducing it to a black friable carbonaceous substance, the acid at the same time being in part decomposed, and sulphuric acid being produced. When treated with nitric acid, azotic gas and carbonic and phosphoric acid are detached, caustic acid is left in solution, and the residue is converted into a yellow friable mass. By digestion in oxymuriatic acid the colour of caoutchouc is discharged, it becomes opaque, indurated, and wrinkled, like tanned leather, but appears to undergo no other change. Similar effects are produced, though more slowly, by muriatic acid.

Ammoniacal gas, according to Dr. Thomson, is absorbed by caoutchouc, and converts it into a soft, glutinous, and incalculable substance. The same able chemist also states, that the caustic fixed alkalis are capable of combining with, and dissolving it. Caoutchouc is also soluble with ease at a boiling heat in the expressed vegetable oils, in wax, butter, and animal oil, forming viscous inelastic compounds. Alcohol appears not to have the smallest action on it either cold or hot.

Rectified oil of turpentine, at the common temperature, acts without difficulty on caoutchouc, first rendering it transparent, and embrittling its bulk considerably, and in the course of a few days, effecting a complete solution. This compound is of the consistence of drying oil, and when spread thin on wood, it forms a varnish which however is a long time in becoming quite dry. When mixed with a solution of wax in boiled linseed oil, it composes an elastic varnish which is used for covering balloons.

The only menstrua for this substance, from which it can
can be separated again unaltered, are ether, naphtha, and camphor oil.

The solubility of caoutchouc in ether was first discovered by Martin, a circumstance which from its frequent发生 in the hands of other chemists, was very generally called in question, till Cavalli cleared up the difficulty by showing the necessity of employing warmed ether for this purpose. If rectified sulphur ether is taken in a vessel with pure water, it dissolves about a tenth of its weight of this latter substance, and in this state is capable of effecting a complete and speedy solution of caoutchouc. The solution is of a light brown colour, and when saturated, is considerably vitrified. A drop of it let fall into a cup of water immediately extends itself over the whole surface; and the ether being partly absorbed by the water, and partly evaporated, the water is found covered with an extremely thin film of caoutchouc, posseSSing its elasticity, and all its other characteristic properties. A similar effect takes place when cloth of any kind is soaked in the solution, or any hard surface is inclosed over with it; on exposure to the air the ether is rapidly evaporated, and the caoutchouc which it was combined with is left behind. The affinity of this solution for caoutchouc is very great; if the edges of two pieces of caoutchouc are dipped in it and immediately brought in close contact with each other, as soon as the ether is evaporated, they will be found to be perfectly united. There are two circumstances which must always prevent the extensive use of the etherous solution of caoutchouc, admirably qualified as it is in other respects for many useful purposes; these are, first, its expensiveness, and secondly, the extraordinary rapidity with which the ether evaporates; thus rendering it impossible to lay an even coating of this varnish on any surface, and clogging up the brushes by which it is applied. In order to form tubes or catheters of this substance, the best method is to cut a bottle of caoutchouc in a long fipple, and soak it for half an hour or an hour in ether; by this means it will become soft and tenacious, and if wound destitute on a greased cylinder, bringing the edges in contact with each other at every turn, and giving the whole a moderate and equal pressure by binding it with a tape wound in the same direction as the caoutchouc, a very efficient union will be produced; after a day or two, the tape may be taken off and the cylinder of caoutchouc may be rendered still more perfect by pouring a little of the etherous solution into a glass tube closed at one end, the diameter of which is a little larger than that of the cylinder of caoutchouc; which being introduced into the tube, will force the solution to the top of the vessel. Let the whole of the apparatus be then placed in boiling water; the ether will be evaporated, and a smooth and uniform coating of newly deposited caoutchouc will remain upon the cylinder.

Petroleum when rectified by gentle distillation, affords a colourless liquid not to be distinguished from the purest naphtha, and this, according to Fabbroni, has the property of dissolving one twenty-sixth of its weight of caoutchouc, and of depositing it again unaltered by spontaneous evaporation. It does not appear, however, that this menstruum has been much employed.

The solubility of caoutchouc in caustic oil was first noticed by Dr. Rosburgh. This is an essential oil procured in India, by distillation, from the leaves of the Melocanna cucumis. The solution is very thick and glutinous; and is decomposable by alcohol, this latter uniting with the essential oil and leaving the caoutchouc floating on the liquor in a soft semifluid state. This on being washed with alcohol, and exposed to the air, becomes as firm and elastic as before it was dissolved; while in the intermediate state between fluid and firm, it may be drawn out into long threads, resembling in the pulpit of their forces. The fuses of the tissues of animals, and to extremely elastic. When broken, each end immediately returns to its respective parts. Through these fuses the blood circulates with the finger and thumb is capable of uniting different portions as completely as if they had never been separated, and that without any clamping or locking to the finger.

The use to which caoutchouc has been hitherto applied, are the following. It is chiefly used for rubbing out blacklead-pencil marks from paper, whence it undergoes the Indian rubber; it is of value to the chemist as a means for flexible tubes to gaugemeters and other apparatus; the Surgeon is indebted to it for flexible lyes and catheters; and finally it enters as an essential ingredient into the composition of the bell varnish for balloons.

Caoutchouc Vene in Botany, a species of Uncaria, which see.

CAP, a garment serving to cover the head, and made nearly of its figure.

The era of caps and hats is referred to the year 1429, the first seen in these parts of the world being at the entry of Charles VII. into Rouen; from that time they began, by little and little, to take place of the hoods or chaplets, which had been used till that period. M. le Gendre, lord of, goes farther back; they began, says he, under Charles V. to let fall the angles of the hood upon the shoulders, and to cover the head with a cap, or bonnet: when this cap was of velvet, they called it motte: when of wool, simply motte: the first was laced, the latter had no ornament. Besides two horns, raised to a moderate height, one of which served in covering and uncovering. None but kings, princes, and knights, were allowed the use of the motte.

The cap was the head-dress of the clergy and graduates. Paquier says, that it was anciently a part of the hood worn by the people of the robe; the skirts whereof being cut off, as an incumbrance, left the round cap an easy commodious cover for the head; which round cap being afterwards assumed by the people, those of the gown changed it for a square one, first invented by a Frenchman, called Patrouillet; he adds, that the giving of the cap to the students in the universities, was to denote, that they had acquired full liberty, and were no longer subject to the rod of their superiors; in imitation of the ancient Romans, who gave a pilus, or cap, to their slaves, in the ceremony of making them free: whence the proverb, Pucare feres ad plenum. Hence also on medals, the cap is the symbol of liberty, whom they represent holding a cap in her right hand, by the point. When this cap was exposed to the view of the people, on the top of a spear, as in the case of the conspiracy which had occasioned the death of Caesar, it was intended as a public invitation to the people, to embrace the liberty that was offered to them by the destruction of their tyrant. This thought of the conspirators on occasion of this event, was not new; for Socrates, in his education, when he had professed himself of the Capitol, exacted a cap on the top of a spear, as a token of liberty to all the slaves, who would join with him; and though Marius, in his sixth consulship, destroyed him for that act, by a decree of the senate, yet he himself used the same expedient afterwards to invite the slaves to take arms with him against Sylla, who was marching with his army into the city to attack him. Val. Max. viii. 6.

The Romans were many ages without any regular covering for the head: when either the rain or sun was troublesome, the lappet of the gown was thrown over the head; and hence it is that all the ancient statues appear bareheaded, excepting sometimes a wreath, or the like. And the same usage
usage obtained among the Greeks, where, at least during the heroic age, no caps were known. The torts of caps or covers of the head in use among the Romans on divers occasions, where the *plura*, *pileus*, *cocculus*, *galeus*, and *pallium*, the differences between which are often confounded by ancient as well as modern writers.

The French clergy wear a shallow kind of cap, called the *claret*, which only covers the top of the head, made of lether, linen, worsted, or other stuff. The red cap is a mark of dignity allowed only to those who are raised to the cardinalate. The secular clergy are distinguished by black laiteron caps, the regulars by knelt and wrought ones.

The Chinese have not the use of the hat, like us; but wear a cap of a peculiar structure, which the laws of civility will not allow them to put off; it is different for the different nations of the year; that used in summer, is in form of a cone, ending at top in a point. It is made of a very beautiful kind of mat, much valued in that country, and lined with fatting; to this is added, at top, a large lock of red silk, which falls all round as low as the bottom; so that, in walking, the silk fluctuates regularly on all sides, makes a graceful appearance; sometimes, instead of silk, they use a kind of red hair, the lufro whereof no weather effects. In winter they wear a flat cap, bordered with marllet's, or box's skin; as to the relf, like those for the summer. Nothing can be neater than these caps; they are frequently fold for eight or ten crowns; but they are so short that the ears are exposed.

The cap or bonnet is a mark or ornament of certain characters: thus churchmen, and the members of universities, students in law, plying, and as well as graduates, wear "square caps." In most universities, doctors are distinguished by peculiar caps, given them in alluming the doctorate. Wickliffe calls the canons of his time *birettes*, from their caps. Paquier observes, that in his time, the caps worn by the churchmen, &c. were called "square caps," though, in effect, they were round yellow caps.

The cap is sometimes also used as a mark of infamy: in Italy the Jews are distinguished by a yellow cap; at Lucca by an orange one. In France, those who had been bankrupts were obliged ever after to wear a green cap, to prevent people from being imposed on in any future commerce. By several arrets in 1684, 1652, 1628, 1688, it was decreed, that if they were at any time found without their green cap, their protection should be null, and their creditors empowered to call them into prison: but the practice is not now continued.

Cap of maintenance, or cap of state, one of the regalia or ornaments of state belonging to the kings of England, before whom it was carried at the coronation and other great solemnities; and also of the mayors of several cities in England. It is of crimson velvet faced upermine, with two points turned to the back; and was formerly esteemed a badge and symbol of dignity, and suitable to a prince of the blood, being worn by king Edward III. and succeeding kings of England down to Edward VI.; but of late it hath been granted to private families. It is frequently to be met with above the helmet, instead of a wreath, under gentlemen's crests.

Cap of a gun, is a piece of lead which is put over the touch-hole of a gun, to keep the priming from being wafted or spilt.

Cap, in a ship, is a square piece of timber, put over the head, or upper end of a mast, having a round hole to receive the mast. By these caps, the top-masts, and top-gallant-masts, are, kept steady and firm in the trefiel-trees, where their foot stands; as those of the lower-masts do in their steps.

Or, a cap is a thick block of elm-timber, with two holes perpendicularly to its length and breadth, and parallel to its thicknefs, (the foremost hole being round, and the after one square), used to confine two masts together, when one is erected at the head of the other to lengthen it. The main and foremast caps of large ships are of elm, and made of two pieces coaked or doubled together in the middle; and others are of one solid piece. The main cap, in length, is to be four times the diameter of the top-mast, with the addition of three inches; the breadth is to be twice the diameter, with the addition of two inches; and the depth four-ninths of the breadth. The fore cap, in length, is to be four times the diameter of its top-mast, with the addition of two inches; the breadth twice the diameter, with the addition of one inch; and the depth four-ninths of the breadth. The length of the mizen cap is to be four times the diameter of its top-mast, with the addition of one inch; the breadth, twice the diameter; and the depth four-ninths of the breadth. The caps of yachts and similar vessels have a sheave-hole on each side for the jeers of the lower yards. If the cap is made of two pieces, the thicknefs of the coak is added to one piece. When the coak is adjusted, the two pieces are bolted through with fix bolts, one inch diameter, two at each end, and two in the middle, which are driven from each side alternately and clench on a ring. The holes are let off from the centre of the under-side of the cap at equal distances, and the distance between the holes is to be two-fifths of the diameter of the round hole, and half the tapering of the mast head in its length. The round holes of all caps are leathered and nailed on the upper and lower sides. In order to allow for the shrinking of the caps, the size of the tenon is taken 1½ inch above the flops, and that is let off on the under side of the cap; the caps are also to be raised above a level from the middle-line on the mast ¾ of an inch to a foot in length, in order to allow for their drooping. See MASS, and Plate of Ships.

Cap, is also a semicircular projection from the sides and round the end of a block, above the pin; through which two holes are bored, obliquely from the sides, meeting and forming an angle at the end; through these holes the flirt is passed, to prevent its being chafed. See BLOCK.

To Cap, is said of a ship in the trials of the running or setting of currents.

To Cap a rope, is to cover the end with tarred canvas, which is whipt with twine or spun yarn.

Cap, in Chemistry, signifies the piece which terminates the top of a melting furnace.

Cap, in Geography. See Button Island.

Cap, in Phytology, a name given to the hulk or green succulent coat which covers the upper part of a nut, and connects it with the parent tree. The cap consists of a pillaring and parenchyma derived from the bark, and ramifications from the ligneous body of the branch.

Cap of a mushroom, is the head or superior part expanded over the foot flake, somewhat in manner of a canopy, or umbrella.

Cap, or great Cap, in Surgery, a denomination of a kind of compendious bandage, serving for almost all occasions of the head, being in figure not unlike a helmet. Among chirurgical infirmities we meet with a silver cap, *pilatus argentius*, (though of late also made of wood, or even white wax), perforated at both ends, applied to the paps of nursing women, when ulcerated, for the more commodious giving of suck.

Cap, black, in Ornithology, the pewit, *Tringa parus*.

Cap, black, also the *moluccella atrae-pilla*.

Cap, Neptune's. See Neptune.
C A P

CAP, a pipit, in Fortification. See Bosny à precer.

CAP, merchant, in a trading ship, is the same officer who is called purser on board a man of war. The French call him writer (écritain). He is appointed by the merchant to whom the ship belongs, to take care that nothing be embez- zled or squandered away.

CAPACI, in Geography, a town of Naples, in the province of Casertana; four miles west of Villa. C. PACI, a town of Naples, in the province of Prin- cipato Citra, the seat of a bishop, suffragan of Salerno; five miles north of Agropoli.

CAPACITY, in General Science, an aptitude or disposition to retain or hold any thing.

CAPACITY, in Geometry, denotes the solid content of any body; and "measures of capacity" are our hollow measures for wine, beer, corn, falt, &c.

Capacity, in Law, signifies the ability possessed by an individual, or body politic, to give or take lands, or other things, or to sue actions. Our law allows the king two capacities, a natural and a political: in the first he may pur- chase land to him and his heirs; in the latter, to him and his successors. An alien born hath insufficient capacity to sue in any personal action, and is capable of personal estate; but he is not capable of lands of inheritance. See Alien.

Perfons attained of treason or felony, idiots, imbeciles, in- fants, &c. are not capable of making any deed of gift, grant, or conveyance, unless in some special cases. Co. Litt. 171. 172. See Infant, Idiot, &c. All persons are capable of committing crimes and suffering punishment, on behalf of whom the want or defect of will cannot be le- gally pleaded. There are three cafes in which the will does not join with the act, viz. where there is a defect of under- standing; where there are understanding and will sufficient, but not called forth and exerted by the party possessing them at the time of the action done, as in the case of all offences committed by chance or ignorance; and where the action is constrained by some outward force or violence. Before the cafes comprehended under these particulars, there is one more in which the law supposes an incapacity of doing wrong, from the excellence and perfection of the person: this is the cafe of the king, who, by virtue of his royal pre- rogative, is not under the coercive power of the law; which will not suppoze him capable of committing a folly, much less a crime. Black. Com. b. iv. c. 2.

Capacity, in the Modern Doctrine of Heat, signifies the proportional capability of a given quantity of any substance to absorb and retain caloric; or that disposition or property by which various bodies respectively require more or less of this fluid to superinduce any given temperature in a given mass. See Caloric and Temperature.

That this capacity varies in different bodies, and even in the same substance in different states, may be safely shewn. If the quantities of heat necessary to be added to or taken from bodies, in order to produce equal changes in their temperature, were in all cases proportional to their respective quantities of matter—as if, for example, it would require the same quantity of this fluid to heat a pound of water, a pound of oil, or a pound of mercury twenty degrees; this would, of course, indicate that their capacities were equal: but if, on the contrary, it should be found that the same quantity of caloric applied to these various substances should produce different changes in the temperature of equal quantities, or equal changes in the temperature of different quantities of each, it would follow that their capacities for the fluid must proportionally vary. Let us conceive that having three several pounds of water at the temperature of 110° of Fahrenheit’s thermometer in separate vessels, there be added to the first a quantity of water at 70°, to the second a quantity of water at 150°, and to the third a quantity of water at 90°; and that each of the mixtures be stirred together, and the addition continued, till they have all assumed throughout a common temperature of 70°. Now, as each of the pounds of water has, in this case, been deprived of an equal quantity of caloric, (viz. as much as was necessary to raise its temperature 40°, or from 70° to 110°,) the absolute capacities of the whole of the water, the oil, and the mercury, which have been added, must of course be equal, whatever be the quantity of each; of each of them having absorbed an equal quantity of heat. On comparing the quantities of these latter substances, how- ever, it will be found that we have employed in the experiment about 2 pounds of water at 50°, 4 pounds of oil, and near 60 pounds of mercury, each of which has been heated 20°; so that it requires as much caloric to heat one pound of water 20° as to produce the same effect on two of oil, or thirty of mercury; and their relative capacities are therefore inverely in this proportion.

Nor is it only among substances which essentally differ in their nature that this difference is found: the same body in different states of existence presents us with equal varieties in its capacity. A change in this respect is producible in three ways: by mechanical compression or dilatation, by chemical combination, or by the action of heat itself; of each of which we shall lay a few words.

With regard to the first, the general fact appears to be, that wherever a body is by any means condensed, its capacity becomes diminished; but that where it is dilated or en- larged in its bulk, it is proportionally increased. Thus, if a thermometer be filled up in a receiver, and a quantity of air condensed into it, the mercury will rise; a part of the caloric which is contained in the air being, as it were, squeezed out by its compreffion, and forced into the mercury in the bulk, whose temperature is consequently raised; if, however, on the contrary, the air be rared, the thermo- meter will indicate cold; the capacity of the air in the receiver being increased by its rarefaction, and a portion of the caloric in the continuous bodies consequently absoved, whereby their temperature is lowered and the bulk dimin- ished. It seems probable also that the heat produced by friction or percussion is, in like manner, to be referred to this kind of diminution in the capacity of the subject.

The second mode of changing the capacities of bodies is by their chemical combination; and it is perhaps true, that there is no combination unaccompanied by such a change. In some instances this takes place in a very remarkable degree, and it is from hence that we derive the effects of caloric and frigorilic mixtures. If, for example, a quantity of fulphuric acid, diluted with an equal measure of water, be poured on a quantity of crystals of Glauber’s salt recently powdered, the capacity of the compound is considerably greater than that of its component ingredients, it becomes therefore strongly absorbent of caloric, which it attracts from the bodies in its vicinity, and a quantity of water in a phial placed in the mixture will be soon frozen. The con- verte takes place in the combination of water and sulphuric acid. The capacity of the compound becomes diminished by the mutual attraction of the particles of its ingredients; a portion of the caloric which it contains is therefore ex- tracted, and heat is produced by its emulsion.

The third case of change of capacity, by the action of heat itself, is perhaps the most productive of more important effects in nature than either of the former two. The capacities of all bodies are increased in some proportion to the dilatation of their bulk, and the disaggregation of their constituent particles.
particles as well by the agency of caloric as by any other cause. Hence, when a solid is dissolved, or a liquid resolved into vapour, cold is produced by the augmentation of its capacity; and evapors, when steam is condensed, or congelation takes place, heat is developed by its diminution. Thus, if equal quantities of pounded ice and water, each at 32° of Fahrenheit, be exposed to heat in two similar vessels in a water-bath, the water will be heated to 15° before the ice is all dissolved, the water produced from which will of course still remain at 32°, so that the increase of capacity in the ice, during its solution, is sufficient to enable it to afford, without any elevation of its temperature, such maximum capacity as has raised the temperature of an equal quantity of water 146°; and the like quantity is also again emitted, on its becoming again condensed. If a quantity of water be exposed without agitation to a degree of cold equal to 4° or 5°, it will frequently acquire this temperature without freezing; but as soon as congelation begins, the thermometer will immediately rise to 32°, and the whole will remain at that temperature till all the water is converted into ice. From the quantity of heat which is absorbed by ice during its solution, and the relative capacities of ice and water, which he conjectured from his experiments to be 9 to 10, Dr. Crawford concludes that, as water on freezing appears to give out 146°, and this constitutes 1/20 of all that it contains, it is probable that the temperature of a body which was entirely divided of heat would be 146° below the freezing point, or 148° below the zero of Fahrenheit's thermometer.

This latter change of capacity appears manifestly to be absolutely essential to the well being of the universe, as affording a connate modification of the action of heat and cold, whose effects would otherwise be inordinate. If this did not take place, the whole of a mass of water which was exposed to a temperature above the boiling point would be instantly diffused in vapour with explosion. The fact, however, is, that the capacity of those portions of the liquid which are successively resolved into vapour becomes thereby sufficiently augmented to enable them to absorb the superabundant caloric, as fast as it is communicated; and it is for this reason that boiling water in an open vessel never reaches a higher temperature than 212°. The polar ices would all instantaneously diffuse, whenever the temperature of the circumambient air was above 32°. If it were not that each particle absorbs a quantity of caloric in its solution, and thereby generates a degree of cold which arrests and regulates the progress of the thaw; and the converse of this takes place in congelation, which is in its turn moderated by the heat developed in consequence of the diminution of capacity, which takes place in the water during its transition to a solid state.

CAPALITA, in Geography, a large town of North America, in the province of Guaxaca. The adjacent country abounds with sheep, cattle, and excellent fruit.

CAPAN, in Commerce, an East Indian coin worth 3d. in value.

CAPANABASTIA, in Geography, a town of North America, in the province of Chiapa in Mexico; 70 miles S. E. of Chiapa des Esparagones.

CARACOGO of Buffon, in Ornithology, the hawk-owl of English writers, Strix Hudsonia of Gmelin, and Strix ferrall Hudsonia of Buffon.

CARAISON, or CAPARISON, the covering or elasmonic laid upon a horse; especially aumper or horse of flate.

The word is Spanish, being an augmentative of capa, cape, head.

Anciently the cuparirona were a kind of iron armor, wherewith horses were covered in battle.

CAPASIS, in Geography, small islands near the east coast of Malacca, in the East Indies. N. lat. about 5°. E. long. 103° 30'.

CAPAPS, a kind of head-dress worn by the women of Canda. It is of a fleshed muffin, and is made so as to stand up very high, and extend a great way on the right side. Pococke's Egypt, vol. ii. part ii. p. 10.

CAPE ASTER. See Cineraria Anelloides.

CAPE JASMINE. See Gardenia Florida.

CAPE, in Geography, a head-land; or the extremity of a piece of land, or promontory, running out beyond the reef, into the sea.

CAPE ABACOU, lies near the west end of the south coast of the island of St. Domingo, N. lat. 18° 4'. W. long. 74°.—C. St. Agnes. See St. Agnes.

C. Aqua, a cape of Spain, on the coast of Murcia, in the Mediterranean. N. lat. 37° 32'. W. long. 3° 37'.—C. Audor, of Geer. See Aguer and Geer.

C. Agua, a double point of South America, on the coast of Perú. S. lat. 6° 38'. W. long. 80° 55'.—C. Aguilla. See Aguillar.

C. Alga, a cape of Spain, on the coast of Bifcay, in the Atlantic. N. lat. 45° 32'. W. long. 3° 18'.—C. Albate. See Albate.

C. Albani. See Albania.

C. Algier, a cape on the N. W. coast of the island of Majorca. N. lat. 39° 40'. E. long. 2° 38'.—C. Alice, a cape of Naples, on the E. coast of Calabria Citera, in the gulf of Taranto. N. lat. 39° 30'. E. long. 17° 20'.—C. Amanteo, a cape of St. E. coast of Corfica, and northern part of the entrance into the bay of Bonifacio. See Amone.

C. Ambra. See Ambra.

C. Ammou. See Amoushe.

C. Ancora, a cape on the W. coast of the island of Cabrera, on which are 39° 6'. W. long. 3° 8'.—C. Ancor, or Ancuca, the N. point of the island of Chiloe, in the S. Pacific Ocean. S. lat. 42° W. long. 80°.—C. Anduras. See Anduras.

C. Anduras, Andouil, Ann and Anna. See the Articles.

C. St. Anthony, a cape on the E. coast of Newfoundland. N. lat. 51° W. long. 3° 56'; also, the N. W. point of Staten land, in the straits of Cape Mars. S. lat. 54° 46'. W. long. 63° 45'.—C. Antio, Antongil, Antonio, Apollonio, and Arca. See the respective Articles.

C. Argens, a cape on the E. side of Newfoundland. N. lat. 52° W. long. 5° 15'.—C. Argentar. See Argentar. C. Argentenos, a cape on the southeast coast of Sardinia, 2 miles W. of Argentena. N. lat. 39° 28'. E. long. 8° 36'.—C. Armir, a cape of Naples, on the southern coast of Calabria Ultra. N. lat. 37° 52'. E. long. 16° 1'.—C. Abg une-mon-bas, a cape of Algiers, in the Mediterranean. N. lat. 37° 15'. E. long. 5° 10'.—C. Afirara, the N. W. point of Sardinia. N. lat. 40° 58'. E. long. 8° 13'.—C. Ava, St. Augylina, Baba, Biffa, and Bajador. See the several Articles.

C. Bainetta, a cape on the south west of the island of St. Domingo, near a village of the same name. N. lat. 18° 13'. W. long. 73° 51'.—C. Bajola. See Bajola.

C. Bayona, a cape on the E. coast of Africa. S. lat. 15° 15'. E. long. 39°.—C. Biaum, lies on the coast of Morocco, in the Mediterranean. N. lat. 35° 32'. W. long. 3° 46'.—C. Ballaghian, Ballard, Barba, Bardifan, Barfleur, Barnabaz, St. Barbolone, Baffa, Bussat, Boat's, and
and Beata. See the respective Articles.—C. Bocor, a cape on the coast of Egypt, in the Mediterranean; 4 leagues N. N. E. of Alexandria.—C. Buda, Bedford. See the Articles. C. Bega, a cape of Spain, on the coast of Catalonia, in the Mediterranean. N. lat. 41° 57'. E. long. 28° 19'.—C. Berberia, a cape on the W. coast of the island of Formenca, in the Mediterranean. N. lat. 38° 41'. E. long. 1° 35'.—C. de Berod, a cape on the N. coast of Egypt, in the Mediterranean. N. lat. 31° 29'. E. long. 31° 16'.—C. Bonaparte, a cape on the E. coast of Majorca, N. lat. 39° 35'. E. long. 4° 35'.—C. Bernard, a cape of Egypt on the N. coast, in the Mediterranean. N. lat. 31° 6'. E. long. 33° 43'.—C. Blancas, a cape of South America, on the coast of Terra Firma. N. lat. 10° 28'. W. long. 67° 16'. Also, a cape on the S. coast of the island of Sicily. N. lat. 37° 28'. E. long. 15° 11'.—C. Beja, a cape on the S. coast of the island of Corfu. N. lat. 37° 28'. E. long. 25° 4'.—C. Beja, a cape on the S. W. coast of the island of Cyprus. N. lat. 35° 12'. E. long. 32° 17'.—C. Beja, a cape of Spain, on the coast of Almeria. N. lat. 43° 26'. W. long. 6° 37'.—Also, a cape on the W. coast of the island of Iviaca. N. lat. 39° 2'. E. long. 1° 34'.—Also, a cape on the S. coast of the island of Majorca. N. lat. 39° 22'. E. long. 2° 59'. For other capes of this denomination, see BLANCO.—C. St. Blaise. See BLAISE.—C. St. Blaise, the outermost point of Mollaf bay, in the Cape of Good Hope. S. lat. 34° 10'. E. long. 22° 18'.—C. St. Breas, a cape of America, on the coast of the Ithmus of Darien. N. lat. 8° 36'. W. long. 75° 24'.—C. Blys, a cape on the E. coast of Labrador. N. lat. 53°. W. long. 55° 30'.—C. Bocce, a cape on the W. coast of the island of Sicily. N. lat. 37° 51'. E. long. 12° 43'.—C. Bogeqela, a cape on the south-coast of Africa. 150 miles S. W. of Cape Faralh. N. lat. 14° 15'. E. long. 48° 15'.—C. Boidar and Bon. See the Articles.—C. Banadria, a cape of Africa, on the coast of Barbary, in the Mediterranean. N. lat. 35° 20'. E. long. 23° 14'.—C. Bonaventura, Bonaventure, and Bonavista. See the Articles.—C. Broja, a cape of America, on the N. coast of the Ithmus of Darien. N. lat. 9° 22'. W. long. 8° 10'.—C. Break. See BREAK.—C. Bredanlia, a cape of Scotland, on the W. coast of the island of Rum. —C. CAFE OF GOOD HOPE.

expired after this event, that Van Riebeck, surgeon of a
ship that put into the Cape for the usual purpose, made re-
presentations of the riches of the soil, the mildness of the
climate, the advantages it would give to the Dutch, as a
colony, over other nations, whose ships would all be enabled
to touch there, and, above all, the barrier it would afford
to their Indian dominions; which prevailed on the directors
of the Dutch East India Company to form a regular esta-
blishment at the Cape. Van Riebeck was appointed admiral
of four ships properly equipped for such an expedition,
and, on his arrival at the Cape, governor in chief, with full
power to establish a settlement. He no sooner proposed
than concluded a treaty; and the Dutch took immediate
possession of the Cape, which was surrendered to them
by the natives with great solemnity. Van Riebeck erected a
square fort, containing lodgings, warehouses, and an hos-
pital for the sick, and raised outworks and batteries to
secure their settlements from all attacks. The original inten-
tion of the Dutch seems to have been to limit their posses-
sions to the Cape peninsula, and the two bays that are divided by
the illims; considering it only, as it had hitherto been, a
place forrefreshing and refitting their ships. But the num-
ber of settlers that joined them from time to time, in con-
sequence of the placard which they published for their en-
couragement, made it necessary to cross the illims, and,
by presents and promises, to obtain from the natives the
cession of a tract of land, to which they gave the name of
"Hottentots' Holland." The natives had probably no
idea of resigning, for ever, to a foreign nation, the ground
that was necessary for feeding their own cattle; but con-
ceived it could only be intended for temporary use, and
that, in time, they would depart from the country, as other
Europeans had done for the last century and a half: but,
when they observed them building houses and fortifications,
fowling and planting the ground, and rearing their own
cattle, they began to be jealous of the encroachments of
their new neighbours, and commenced hostilities for the
purpose of expelling them. These hostilities terminated in
the further extension of the Dutch settlement, and in an in-
crease of troops and colonists from Europe. Still, however,
the Dutch East India Company endeavoured to limit the
Cape to the original design of a port for refitting their
ships. They threw every obstacle in the way of its becom-
ing a flourishing settlement; allowed no trade whatsoever
but that which passed through the hands of their own ser-
vants, and made it depend on the governor-general of
Batavia; concluding that the settlers would thus be made
equally submissive to their orders from Europe, and from the
fact of their wealth and influence in the East. A colony,
in such a state, with their declining commerce, entailed
upon them a burden and expense too heavy for them to
bear; and little doubt was entertained of their inclination to
part with it for a moderate sum of money, just before the
French revolution and its destructive consequences unsettled
the affairs of all Europe. Overtures to this effect were
intended to be made by England about the time when the
above unfortunate event took place. It became
wise and necessary, however, to recur to other means for
obtaining possession of this Dutch colony. Accordingly, an
expedition was sent out for this purpose; which was com-
misioned not to act in an hostile manner, but to hold the
Cape in defence and security for, and in the name of, the
prince of Orange, who, having departed from Holland,
unanswerable letters dated from London to this effect. Many
of the colonists had, in the mean while, imbibed French
principles, and became clamorous to declare themselves, by
force public act, a free and independent republic: they pre-
pared to plant the tree of liberty, and established a conven-
tion, whose first object was to make out proscribed lists of
those who were either in favour of death by the guillotine, or
to be banished out of the colony. The property marked
out to be the victims of an unruly rabble were fledged from
among the most worthy people in the settlement, and a great
portion of them were members of the government. The slaves,
whose numbers of grown men are about five to one of male
whites, had also their meetings to decide upon the fate of the
free and independentburghers, when the happy days of
their own emancipation should arrive.

In this state of things the British fleet appeared before the
bay; and it became necessary to commence hostilities. The
rocks of Muizenberg were soon cleared by a few shots from
a man of war, and the regular troops retreated to Wynberg,
a tongue of land projecting from the east side of the Table
mountain, and about eight miles from Cape-town. The
British troops, led on by general Sir James Craig, under the
orders of Sir Alured Clarke, marched to attack the enemy
on their elevated post, and aided by the sailors, soon obliged
them to retreat within their lines. A capitulation was pro-
posed and accepted, in September 1795; and the next day it
was concluded between the two parties. By the 6th article
of the treaty of peace at Amiens in March, 1802, it was stipu-
lated, that the port of the Cape of Good Hope should remain
to the Batavian republic, in full sovereignty, in the same man-
ner as it did previous to the war; but that the ships of every
kind belonging to the other contracting parties should be al-
lowed to enter the said port, and to purchase necessary pro-
visions, without paying any other impost than such as the Ba-
tavian republic demands the ships of its own nation to pay.

In order to form a just idea of the dimensions of the
Cape settlement, we may suppose a straight line to be
drawn from the southern point of the Cape peninsula,
which, however, is not the southermost point of Afri-
can, in the direction of east by north, and this line will inter-
sect the mouth of the Great Firth river (the Rio D'Infante of
the Portuguese), which is now considered as the eastern bound-
ary of the colony. The length of this line is about 580
miles. Again, if from the same point a straight line is
drawn in the direction of north, with a little inclination
westerly, it will fall in with the mouth of the river "Kouffle,"
the northern boundary of the colony, at the distance of about
315 miles. Moreover, if from the mouth of the Great Firth
river, a line drawn in the direction of north-north-west, be
continued to the distance of 225 miles, to a point behind
the Snowy mountains called "Plettenberg's land-mark," and
from thence be continued in a circular sweep inwards to the
mouth of the river "Kouffle" upwards of 500 miles; these
lines will circumferibe the tract of country which constitutes
the colony of the Cape of Good Hope. By reducing this
irregular figure to a parallelogram, it will be found to com-
prehend an area of at least 120,000 square miles; and as the
whole population of whites, blacks, and Hottentots, within
this area, amounts only to about 60,000 persons, every two
square miles may be said to have at least one human creature
allotted to it. But as this desert state of the colony is left
owing to the natural defects of the country, than to the re-
gulations under which it has been governed, the population,
complied with the extent of surface, ought not to be taken
as the test of the intrinsic value of the settlement; since the
population of any country, under a moderate climate, will,
in the natural course of things, always rise to a level with
the means of subsistence. If we estimate the soil of the Cape
by the abundance or scarcity, the luxuriance or poverty, of
the native plants, independently of the clime, it would be
pronounced one of the poorest in the known world; for seven
parts
parts in ten of the above-mentioned surface are, for a great part of the year, and some of them at all times, altogether delirious of verdure. The upper regions of all the chains of mountains are naked masses of sand-flour; the valleys beneath them are clothed with grasses, with thickets, and in some cafes with impenetrable forests. The inferior hills or knolls, whose surfaces are generally composed of loose fragments of sand-flour, as well as the wide sandy plains that connect them, are thinly strewn over with heaths and other flimsy plants, exhibiting to the eye a uniform and dreary appearance. In the lower parts of these plains, where the waters flow into, and filtering through the land, break out in springs upon the surface, vegetation is somewhat more luxuriant. In such situations the farm-houses are generally placed; and the patches of cultivated ground contiguous to them, like the "Oases," in the sandy defects, may be considered as so many verdant islets in the midst of a boundless waste. Of such plains and knolls is the belt of land composed, that lies between the first chain of mountains and the sea-coasts. Soils, in this tract of country, are generally either a stiff clay, impenetrable by the plough till they are soaked by much rain, or light and sandy, tinged with red and abounding with small round quartzite pebbles. A black vegetable mould seldom appears except in patches of garden-ground, vineyards, and orchards that surround the habitations, where, by long culture, manure, and the fertilizing influence of springs or rills of water, the soil is so far mellowed as to admit the spade at all seasons of the year. The extensive plains, known in the colony by the Hottentot name of "Karroo," which are interposed between the great chains of mountains, exhibit a more dismal appearance than the lower plains, which are chequered with patches of cultivated ground; and their hard surfaces of clay, glistering with small crystals of quartz, and condemned to perpetual drought and aridity, are ill adapted to vegetation. The hills that break these barren plains, are chiefly composed of fragments of blue slate, or masses of feldspar, and argillaceous limestone. However, in these Karroo plains, that are tinged with iron, and that are capable of being watered, the soil is extremely productive. In such situations, more especially in the vicinity of the cape, they have the beet grapes, and the beet fruit of every sort. The climate of the Cape is not unfriendly to vegetation; but it is so situated, within the influence of periodical winds, that the rains are very unequal, defending in torrents during the cold season, though hardly a flower fails to refresh the earth in the hot summer months, when the dry south-east winds prevail. These winds blast the foliage, blossom, and fruit of all those trees that are not well sheltered; nor is the human constitution secure against their injurious influence. They relax both the body and mind, and deplete their powers of energy and activity. As a protection from these winds, the colonists who inhabit the nearer side of the first chain of mountains, beyond which their effect does not very sensibly extend, divide that portion of their ground, which is appropriated to fruit groves, vineyards, and gardens, by oak fences; but they leave their corn lands altogether open. Indeed, a cape boor belows no more labour on his farm than is absolutely necessary; and as grain is mostly reaped before the south-east winds are set in, the enclosure of the arable land is omitted. The temperature of the climate at the Cape is remarkably affected by local circumstances. During the winter months, May, June, and July, the mean temperature, according to the statement of Kirwan (Ellis, &c. p. 102), seems to be from 45° to 55°; the heat scarcely exceeds 64°, and seldom falls so low as 34°; in summer the thermometer is generally between 70° and 80°, and sometimes between 80° and 90°; but scarcely ever exceeds 95°; the south-east wind, he adds, is the coldest. Mr. Barrow informs us (ibid infra), that there is a difference of at least from 6 to 10 degrees of Fahrenheit, in the summer months, between Cape Town and Wynberg, within a distance of only about 7 or 8 miles; which arises from the latter place being situated on the windward side of the Table mountain, and the former lying to leeward of it. The variation of climate, to which the Table valley is subject, led a British officer to observe, that those who inhabited it were either in an oven, or at the funnel of a pair of bellows, or under a water-spout. On the Cape side of the mountains the thermometer rarely descends below 40°; but on the elevated Karroo plains, within the mountains, it is generally, in the winter months, below the freezing point by night, and from 70° to 80° in the middle of the day. In order to account for the intense cold of the Karroo plains, Van Humboldt adds the chemical decomposition of the atmospheric air. As fat and clayey earths are strongly disposed to attract the oxygen from the atmosphere, by which the azotic gas is let loose: thin gas entering again in combination with fresh oxygen, of the superincumbent stratum, in an increased proportion, forms nitrice acid, from which salt petre is generated. The consequences of this formation which actually takes place in those plains, must necessarily be a great diminution of temperature.

We may now proceed to observe, that the great scarcity of water in summer is much more unfavourable to an extended cultivation than either the soil or the climate. The torrents of rain that descend for about four months in the year, deluging the whole country, disappear suddenly in the deep channels that intersect the country, and in consequence of their rushing with rapidity and violence into the sea, and leaving the deeply sunken beds of the rivers nearly dry, afford no sufficient supply of water to answer the purposes of irrigation. The periodical rivulets, and the streams that issue from the mountain springs, are either absorbed or evaporated before they arrive at any great distance from their sources; so that in this extensive colony one can scarcely say that there is a single navigable river. The two principal rivers, on the western coast, are the "Berg," or Mountain river, which rises in the mountains that enclose the vale of Drakenstien, and falls into St. Helena bay, and the "Oliphant," or Elephant's river, which, after collecting the streamlets of the first chain of mountains in its northerly course along their feet, empties itself into the Southern Atlantic in S. lat. 31° 30'. Although both these rivers have permanent streams of water, sufficiently deep to be navigable by small craft to the distance of about 20 miles up the country, yet the mouth of the former is choked up with a bed of sand; and across the latter is a reef of rocks. On the south coast of the colony the permanent rivers of any magnitude are the "Broad" river, which is discharged into St. Sebastian's bay; crofted near its mouth by a bar of sand, but navigable within this bar by small craft about 30 miles up the country, in which extent there are scarcely half a dozen farm-houses; and the "Gairnitz" river; the "Knysna," the "Keurboom," the "Camtoos," the "Zwartkops," the "Sunday" and the "Great Fifth" rivers; which see respectively. All these rivers are well stocked with perch, eel, and small turtle, and, to a certain distance from the sea-coast, they abound with almost every kind of sea-fish peculiar to this part of the world. Befide these rivers, the whole slip of land, stretching along the sea-coast, between the entrance of Falbe bay and the Great Fifth river, is inter-sected.
Cape of Good Hope.

fefted by严格的, whole waters are neither absorbed nor evaporated; but they generally run in such deep chasms, that they are of little use towards the promotion of agriculture by the aid of irrigation. In order to account for these deep chasms or cavities, and the general scarcity of springs, notwithstanding the quantity of rain, that falls at the Cape, Mr. Barrow suggests the following considerations. The continued chains of mountains in Southern Africa are composed of sandstone, reposing upon a base of granite. The granite base is sometimes elevated considerably above the general surface of the country, and sometimes its upper part is sunk as far beneath it. In situations where the former circumstance occurs, numerous springs are found, as in the Table mountain, where, on every side, copious streams of pure limpid water, filtered through the immense mass of superincumbent sandstone, glide over the impenetrable surface of granite, and furnish an ample supply to the whole town, the gardens, and the adjacent farms. But in those places where the sandstone continues to descend below the surface, and the upper part of the granite base is sunk beneath the general level of the country, the springs that make their appearance are few and scanty. From these facts it is inferred, that the effluvia or exuviae in the sandstone mountains, being corroded in the lapse of ages, to a greater depth than the openings or conduits, which might, perhaps, at one time have given their waters vent, the springs can no longer find their way upon the surface, but ooze imperceptibly between the granite and the sandstone, below the general level of the country, glide in subterraneous streams to the sea. It is a well known fact, that on almost every part of the isthmus that connects the mountainous peninsula of the Cape to the continent, fresh water may be procured at the depth of 10 or 12 feet below the sandy surface. Other facts of a similar nature serve to evince the erroneousness of the opinion, that has generally prevailed, that the several bays of the colony cannot, without great difficulty, if at all, be supplied with fresh water. This great depth of the commencement of the granite base below the surface may also better account for the most considerable rivers of Africa losing themselves in the sand, before they reach the sea, than by supposing the interior parts of this continent to be lower than the level of the ocean.

Another circumstance that has very much contributed to retard the cultivation of the territories adjoining to the Cape, is the extreme indolence of the colonists. In this fine climate they engage in little or no manual labour. The extent of the forests, beginning at Mossel bay, and running eastward parallel to the sea-coast, is at least 250 English miles, and the breadth from the base of the mountains to the sea is 10, 15, and in some places, 20 miles. Of this tract a great part is composed of large and beautiful plains, intersected by numerous rivers, and abounding in lakes full of excellent fish. The ground is well adapted either to pastoral or tillage, and capable of complete irrigation; but the farmers here, as well as in all other parts of the colony, are, in general, beyond description; the grounds held by each being sufficient for a great number of industrious families. It has been said, that the flip of land between the first chain of mountains and the sea-coast, and from Zavellendam to Algoa bay, if well stocked with inhabitants, so that each would be under a necessity of labouring for a subsistence, would not only be able to furnish a supply of grain for the whole colony, but afford also a surplus for exportation. But though this opinion may not be entirely just, yet Mr. Barrow is confident, that, with the addition of the tract of country between the north range of mountains and the sea-coast, and from St. Helena bay to the Cape, the whole masse of people within the present limits of the colony might be more comfortably subsisted than they now are, and have an abundance of corn, cattle, wine, and other necessaries, over and above, for a garrison of 3,000 men, and for a fleet containing an equal number. But in order to make the country produce this supply, it will be necessary to procure a new face of inhabitants, or to change the nature of the old one.

It is impossible, says this ingenious writer, to convey, by any description, an adequate idea of the condition of the peafantry of the Cape of Good Hope; as it is so inconceivably different from that of the same chiefs in Europe, or indeed in any other part of the world. In the miserable hovels of the Cape boors, fatted beef, or flesh of the larger kinds of game, will be found hanging in the chimney, and the whole, or greater part of a slaughtered sheep may be seen unpended from the roof. A Cape boor never works. His greatest and most pleasing exertion is the killing of game. But in this kind of exercise he manifest no energy or activity, and submits to no fatigue. A Dutch boor never traverses the breadth on foot, but generally fires from the saddle; and even availing the fatigue of carrying his mufket, he is followed by a Hottentot boy, trained to ride or run after him as his armou-r-bearer. It is a mistaken notion, that the peafantry of the Cape are a poor and diffused people, overwhelmed with debt, burdened with taxes, and oppressed by the government in a variety of ways. This will sufficiently appear in the sequel of this article. But they are better fed, more industrious, more ignorant, and more brutal than any set of men, bearing the reputation of being civilized, upon the face of the whole globe. Inflances frequently occur of their savage and inhuman treatment of the Hottentots, whom they retain in a state of connection and dependence, by violence and oppression on one side, and by want of energy and patient suffering on the other. This fanguinary character of many of the African colonists may, perhaps, be owing, in a certain degree, to the circumstance of their having been soldiers in German regiments serving abroad; where the least relaxation from a rigid system of discipline is followed up by the greatest severity of punishment. People of this description, having rifen into influence by the general prosperity that followed the conquest of the settlement, and indulging indolent habits and luxurious living, become no less a curse to their persons than vulgar in their manners. Whilst they pay little attention to domestic and social intercourse, and are in a very culpable degree regardless of character, they are extremely tenacious of their rank. There are, however, many persons in the colony to whom these observations are not applicable; men, whose talents and information, propriety of conduct, and strict integrity, would command respect in any part of the world; but their number is not very considerable. The Malay slaves, in the service of the Dutch, are unaccountably preferred to the Hottentots; though they are generally much inferior to the latter in talents, and much more capricious, cruel, and revengeful. The proportion of slaves to whites, of both sexes and all ages, in the Cape town, is not more than two to one; but that of slave men to white men is near five to one. The field slaves belonging to the farmers are not, however, nearly so well treated as those of the town; yet infinitely better than the Hottentots who are in their employ; the farmer, indeed, having a life-interest in the one, and only 25 years in the other, is a circumstance that may explain the difference of treatment. The one, also, is convertible property, which is not the case with respect to the other. The country slaves, notwithstanding, are ill fed, ill clothed, work
work extremely hard, and are frequently punished with great severity; sometimes with death, when rage overpowers the dictates of prudence and the feelings of compassion.

Mr. Barrow, in the 2d volume of his "Travels in Southern Africa," has lately published, and a very much in detail, the advantages which the Cape of Good Hope possesses, as a military station; as a port and naval station; and as a commercialemporium and territorial acquisition. By a military station Mr. Barrow means, not only a garrison for the defence of the settlement, but likewise a depot, or place suitable for collecting and forming, in as always to have in readiness, a body of troops, either belonging to his majesty's regular regiments, or to the armies of the East India company, fitted and prepared for foreign service, and stationed for the climate either of the East or West Indies. This ingenious writer is of opinion, that the Cape of Good Hope eminently points out such a station. Its geographical position on the globe is such as evidently to recommend it for this purpose. It is situated between the south of Brazil and the north of India, and a direct communication by sea between both is thus formed, which is of great advantage to commerce and the interests of the British empire, as an emporium of Eastern produce; as furnishing articles of export for consumption in Europe and the West Indies; as taking, in exchange, for colonial produce, articles of British growth and manufacture; and as a central depot for the southern whale-fishery. The chief articles of colonial growth and produce confirmed upon the spot, and exported to the East Indies, Europe, and America, may be comprised under the heads of grain and pulse, wine and brandy, wool, hides and skins, whale oil and bone, dried fruits, salt provisions, soap and candles, aloes, ivory, and tobacco. The wheat produced at the Cape is said to be as good and heavy as that of most other parts of the world. A load of this grain consists of ten "muids," or facks, equal to 31 Winchellers bushels; and a "muid," or 3½ Winchellers bushels, usually weighs 120 Dutch pounds, which is equal to 1/414 pounds English. The returns are from 10 to 70, according to the nature of the soil, and the supply of water. Barley, i.e. beer or big, is a productive grain at the Cape, and is only used for feeding horses. Rice is also a thriving grain, and is little used except for cattle in a green state, which is much preferred, and are fit only for horses as green fodder. Peas, beans, and kidney beans, Indian corn or maize, and various kinds of millet, may be supplied to any amount. However, the Cape, in its present state, is not capable of exporting any grain. Wine and brandy may be considered as the staple commodities of the Cape of Good Hope. Ten or twelve different kinds of wine are manufactured at the Cape, having a distinct flavour and quality according to the farms on which they are produced. The best boiled wine that is made at the Cape, is the Madeira, sent to Holland and the Dutch settlements in India, taken by the Americans in exchange for slaves, and purchased by English merchants. See constantia.

The country border falls on the merchants in the town, where it is adulterated in a variety of ways. The pipe is called a "legger," and contains 8 half annas or 90 gallons; each legger paying to government a duty, on entering the town, of 3 rix-dollars. The farmer generally receives from 20 to 30 rix-dollars per legger, which, after adulteration, is sold from 40 to 60, and frequently at the rate of 80 to 100 rix-dollars. Brandy might become a very important commodity as an article of export; but the cultivators of the vine have at present no proper distilling apparatus, nor sufficient knowledge properly to conduct that which they have. It is exported at 80 to 150 rix-dollars per legger, and subject to the same toll, on entering the town, as wines: and both wine and brandy are liable to a further duty of 5 rix-dollars per legger on exportation. The whole export value of wines, including the Conflantia, and the brandy, may amount, one year with another, to about 5,000 rix-dollars, or 10,000l. currency. Wool, which has till a late period been neglected, is likely to become a source of colonial revenue. It is said to have been sold, in its rough state, in the London market at 3s. to 3s. 6d. the pound. It admits of great improvement. The mutton of the Cape sheep is coarse and dull of flavour. Hides and skins, both dried and salted raw, are an increasing article of exportation. The quantity of ox-hides exported may amount to between 2000 and 3000 annually, subject to a duty of 3½d. a piece. Thefe taken off cattle, killed in the country, are used as harness for their waggons, and thongs to supply the place of cordage. The skins of sheep, killed in the country, are converted into facks, and employed as clothing for the slaves and Hottentots. Few are exported. The skins of the wild antelopes and leopard, though brought occasionally to the Cape market, hardly deserve mention as articles of export; for the cape is the name with regard to rich feathers; the annual amount of which is very trifling. The whole value of one year's exportation of this article does not exceed 1000 rix-dollars; of hides and skins of every description not more than 5000 or 6000 rix-dollars. All the whales which have been caught in the bays of the Cape are females of a small size, and yielding from 6 to 10 tons of oil each. The bone is small, and, on that account, of no great value. Under the head of dried fruits, the most important articles are almonds and raisins. The cultivation of vines admits of great improvement; better grapes are not produced in any part of the world than those at the Cape of Good Hope; but neither their wines nor raisins are properly managed. The almonds are, in general, very small, but of good quality; and as the trees thrive well in the dry and warm states, the quantity of these nuts might be produced to an indefinite amount. Before the capture almonds sold from 15. to 15. 6d. the thousand, and raisins from 2d. to 3d. a pound; but their price has since considerably advanced. Dried peaches, apricots, pears, and apples, are not only plentiful, but good of their kind. The whole value of dried fruits, exported in the year 1803, amounted only to 24,42 rix-dollars, subject to a duty on exportation at the rate of 2½ per cent. Salt provisions are susceptible of great improvement by curing them at Algoa bay, and bringing them down in small coasting vessels to the Cape. Salt is spontaneously produced within.
within a few miles of Cape-town, by the evaporation of water in the salt lakes that abound along the west coast of the colony. "Two kinds of fish, the "Hottentot" and the "Snook," are salted and dried in the sun in large quantities, for the use of the agricultural slaves, who eat them by way of the bountiful effects of bullocks' livers and other offal, that constitute a great part of their food. Salt-hutter is a very material article for the consumption of the town, the Garrison, and the navy, and also for exportation. That which comes from the Snowy mountains is accounted the best; but very little of it is good. Soap is manufactured by almost every farmer in the country, and furnishes in some parts the means of procuring cloaths and other necessaries at their annual visit to Cape-town. The unctuous part is chiefly derived from the fat of sheep's tails, and the potatoes or harissa is the fixivated aches procured from a species of fahilia called "Camara," that grows abundantly on those parts of the Karroo, or deserts, that are intersected by periods of dry streams of water. Candles are seldom brought out of the country; but a vegetable wax, collected from the berries of a shrubby plant, the "Myrica Cereifera," plentiful on the dry maryl grounds near the sea-shore, is sometimes sent up to the Cape in large glasses and bottles, and sold from 1s. 6d. to 2s. a pound. The whole quantity exported in the course of 4 years amounted only to 598 lbs., value 63.20 rix-dollars. The hippopotamus, or sea-cow, whose teeth furnished the belt ivory, is no longer within the limits of the colony. The colony is capable of producing great quantities of tobacco; however, very little is exported, though the Cape tobacco is said to be as good, when properly prepared, as that of Virginia. As all grey, old and young, smoke, in the Cape, and as American tobacco generally brings a high price, the consumption of that of native growth is considerable. The inferior sort is used by slaves and Hottentots. The total value of every kind of colonial produce, exported in 4 years, from 1799 to 1802, amounts to 350,925 rix-dollars, or 60,184l. currency. From the above detail it appears, that the Cape of Good Hope is, in its present condition, of very little importance to any nation; confidered with regard to its articles of exportation.

The goods imported from England into the Cape, in 4 years, from 1799 to 1802, consists of woollen cloths, Manchester goods, hooery, haberdashery, and millinery, boots, shoes, and hats, cutlery, iron tools, stationary, bar and hoop iron, smiths' tools, household furniture, paint and oils, earthen ware, naval fles, tongues, hams, cheese, and pickles; and from India and China were imported Bengal, Madras, and Surat piece-goods, tea, coffee, sugar, pepper, spices, and rice. The Americans brought thither lumber, cargoes of deal plank, flares, bark, salt-fish, pitch, turpentine, and the Dunes, Swedes, and Hamburg ship's goods, cargoes of iron, plank, French wines, beer, gin, Seltzer water, coffee, preserve, pickles, &c. in exchange for refreshments, to defray the charges of repairs and other necessaries, or for hard money to carry to India or China. The whole importation into the Cape by British or foreign bottoms, from Europe, Asia, and America, in 4 years, including the value of the prize goods brought in, and of the cates imported in the same period, amounted to 597,745 rix-dollars; or 114,579l. currency.

When the Dutch East India company perceived their settlement extending far beyond the bounds which they had originally preferred, they found it expedient to divide the country into districts, and to place over each a civil magistrate with the title of "Landdrost," who, with his council called "Hemraad," was authorized to settle petty disputes among the farmers, or between them and the native Hottentots, levy fines within a certain sum, collect and apply the parochial assessments, and enforce the orders and regulations of government. The district was divided into a number of subdivisions, over each of which was appointed a "Feldwachtmeester" or country overseer, whose duty was to take cognizance of any abuses committed within his division, and report the same to the landdrost, to adjudge disputes about springs, or water-courses, and to forward the orders of government. The landdrost, however, had only the shadow of authority. The council and the country overseers were the original farmers, and were always more ready to frown and protect their brother homesteads, accused of crimes, than to avail in bringing them to justice. The poor Hottentot had, therefore, little chance of obtaining redress for the wrongs he suffered from the boors. If he espoused their cause, he became unpopular; and the distaste from the capital was a sufficient obstacle to the preferring of complaints before the court of justice at the Cape, which itself had little influence in enforcing its orders in a part of the country distant 5 or 600 miles. Hence it happened that murders and the most atrocious crimes were committed with impunity; and the only punishment was a sentence of outlawry for contempt of court, when the criminal did not appear to the famous, which sentence was little regarded. This extensive settlement is divided into 4 districts; those of the Cape, of Stellenbosch and Drakenstein, of Zweliland, and of Graaf Reynet, which fec respectively.

When the Dutch government obtained, partly by purchase and partly by force, a tract of country from the Hottentots, it made grants of land to the settlers on four different tenures. The most ancient of these is that of "loan" lands, which were granted to the original settlers of certain portions of land to be held on yearly leases, on condition of paying to government an annual rent of 24 rix-dollars. Every farm was to consist of the same quantity, and to be subject to the same rent, without any regard to the quality of the land. This tenure amounted by renewals of the lease, at first made only for one year, to a leasehold in perpetuity. The number of these loan-farms in the four districts amounted in 1798 to 1812, and supposing each farm to consist only of the usual allowance, or a square of 3 miles the side, the quantity of land in all these farms would amount to 10,552,320 acres, and the annual rent they produce is about 44,600 rix-dollars, or about 3 of a farthing per acre. The second tenure was that of "gratuity" lands, which were originally granted in loan; but, on petition of the holders, in consequence of some unfavourable services done to government, they have been converted into a form of annual hold liable to a certain rent, which, like the loan lands, is continued at 24 rix-dollars a year; the number of these estates is 107, which charge rent only at a certain rent, arising from pieces of waste-ground, which, being contiguous or convenient to an estate, have been allowed by government to be occupied by the owners of such estates upon a lease of 15 years, on condition of their paying an annual rent of one shilling per acre. The renewal on this payment is a matter of course. Of
Of such grants there are 35. The fourth tenure is that of "real estates" held in fee simple, and subject to no rent; and they are chiefly situated in the Cape district or its vicinity. There are the choicest patches of land, and have been originally sold or granted to the early settlers in parcels of about 60 morgen, or 120 English acres.

The 2,000 European inhabitants who compose the population of this colony may be divided into four classes; viz. the people of the town, wine-growers, graziers, and farmers, and graziers. The wine-growers, or wine-houses, occupy the hill-houses and the most valuable estates, and are the dependants of the French families who first introduced the vine. These estates are mostly freehold, in extent about 120 English acres, and mostly employed in vineyards and gardens.

They bring their wine to market from September to the new vintage in March; and the deep family roads over the CapePlains require 14 or 16 oxen to draw a log-gan or wine, whose weight is not 2½ tons. The wine brought to market is subject to a tax of 3 rix-dollars for every horse, and the brandy, palling the barrier, pays the same tax. The wine or brandy, confined at home, or held in the country, is free of duty; nor are they subject to any parochial taxes or assessments, a small capitation tax excepted.

The wine-farmers make their excursions in their tent-waggon drawn by six or eight horses. The corn-boors live chiefly in the Cape district, and those parts of Stellenbosch and Drakenstein, that are not more than two or three days' journey from the Cape, and are next in rank to the wine-boors. The grain, which they fell in the country, is subject to no tax or tithe; but a duty, about one tenth of the value, is paid at the barrier for all grain passing towards Cape-Town. Their parochial assessments are the same as those of the wine-boor. The colonists of the Cape are very bad agriculturists, and over their crops more to the goodmen of the soil and favourable climate than to their own skill or industry. Their plough is an unworkable machine drawn by 14 or 16 oxen, which jolt ploughs the surface and does not penetrate the plough soil. Such grounds, when ploughed, are endless more rough than the roughest len-ploughing in England. They rarely give themselves the trouble of manuring, except for barley. For returns of corn they generally reckon upon fifteen-fold, in choice places from 20 to 30, and more where they have the command of water. The grain is not threshed, but trodden out in circular floors by cattle. The annual balance in favour of the farmer is about 141. 13s. 6d. The graziers are those of Graaf Reinet, and other distant parts of the colony. They are the lead advanced in civilization. The hovels in which they reside have seldom more than two apartments, and frequently only one, in which the parents with fix or eight children and the house Hottentots all sleep. Their bedding consists of skins. The walls of their hovels are formed of mud or clay baked in the sun; they are sometimes constructed with fods and poles; and frequently a fort of wattling plastered over with a mixture of earth and cow dung, both within and without; and they are rudely covered with a thatch of reeds, seldom water-proof. As to their clothing, the men generally wear a broad-brimmed hat, a blue shirt, and leather pantaloons, no stockings, but a pair of dried skin shoes. The women have a thick quilted cap that ties with two broad flaps under the chin, and falls behind across the shoulders. They have a short jacket and a petticoat, no stockings, and frequently they use no shoes. The bed for the mother and midwife of the family is an oblong frame of wood, supported on four feet, and reticulated with thongs of buffalo's hide, so as to support a kind of mattress made of skins sewed together, and sometimes stuffed with wool. In winter they use woollen blankets. The bottoms of their cloaks or dresses are set with rows of leather thongs. A large iron pot faces both to boil and broil their meat. They have either been for the table, or knives, forks, or spoons. The house-cow with a large hoop, which he carries in his pocket, for the milk of the family. Their huts and their persons are equally dirty, and their whole appearance betrays an insularity of 1/2, and a low groaning mind. The women are greater drudges than the men, and yet they are not very industrious. Though cut from flax, serge, or all occasions, in lieu of rope, and fines cut from the tendons of wild animals are a substitute for thread. The folds of a "kraal," in which they house their cattle at nights immediately from the doors of their huts; and as they are never cleaned out, they increase the inhabinits of their dwellings. Few of the distant hovels have more than one floor, and many of them none; but the number of Hottentots, in an average, in Graaf Reinet, amounts to 15 to each family; and they are used with the most inexorable indumancy. The produce of the graziers is subject to no kind of colonial tax. They pay only a small parochial assessment proportioned to their flock; for every 100 sheep a florin, or 16d., and for every ox or cow 1d. The condition of the farmers is fuch, that each of them, upon a balance of his income and outgoings, lives annually 931. 16s.

The revenues of the colony are derived from the following sources; viz. land revenue arising from rents (already explained); places for grazing cattle taken by the month, and salt-pana duties on grain, wine, and spirits, levied at the barrier; transfer duty on sale of immovable estates; duty arising from the sale of buildings on loan farms; public vendue duty; fees received in the secretary's office on registering the transfer of property; customs; port fees; postage of letters; seizes, fines, and penalties; licences to retail wine, beer, and spirituous liquors; interest of the capital lent out through the loan-bank; and duty arising from stamped paper. The whole amount of this revenue in 1801 was 92,141. 13s. 4d. This revenue is applied to the payment of salaries on the civil establishment, the expenses of the several departmants, the repairs of government buildings, and the contingencies, and the ordinary expenses of the colony; and during the government of lord Macartney, when the Cape was in the possession of this country, the revenue was more than adequate to the expenditure.

The members of the court of justice at the Cape are chosen out of the burghers of the town. The fiscal, who is the public accuser in criminal matters, and the secretary of the court, are the only persons possessed of legal knowledge. The litigious spirit of the people, encouraged by the attorneys who enter into the profession without any knowledge of the law, multiplies causes; and the expenses of a single suit will sometimes amount to 400 or 500l. Which, though the object of litigation was not worth 100l. The office of fiscal, one of the most important in the colony, consists of the principal and a deputy, a clerk, two bailiffs, two jurors, eight constables, and 19 blacks and Malays, usually called "kaifers." The whole expense to government was under 10,000 rix-dollars; the court of justice and secretary's office amounted to about the same sum; so that the administration of justice cost the government very little. The names of commissions for trying petty suits (not exceeding 45l.) and for matrimonial affairs (or granting licences) consists of a president, vice-president, and four members, whose situations are honorary and biennial. The "weekkammer," or chamber for managing the effects of minors and orphans is one of the original institutions of the colony, and it is managed by a prelent
dent and four members, a secretary and several clerks. For the support of this institution all orphan property, passing through the chamber, suffers a deduction of 7% per cent. upon the capital.

The established religion of the colony is Calvinism, or the reformed church. Other sects are tolerated; the Lutherans have a church; a methodist chapel has been lately built; the Moravians have a church; but the Malay Mislimetans, being refused a church, perform their public service in the home-quarters at the head of the Cape town. The clergy are suitably provided for and generally respected in this country; and they rank next to the president of the court of justice in town, and the landdroths of the country. Besides their clerical duties, they have also the direction of the funds for the relief of the poor, which are raised by weekly donations at church, by legacies, and by the funds which the church demands on the annunciation of false. The amount of the funds belonging to the reformed church in Cape town, in 1798, was 22,168 l. 8s. 6d., and the subsistence granted to the poor was 1112 l. 17s. The funds of the Lutheran church were 14,892 l. 13s. 2d.; and the relief granted to the poor 194 l. 9s. 2d.

Cape ditriv, is the smallest, but the most populous, of the four districts into which the settlement of the Cape of Good Hope is divided. It consists of two parts; one, the peninsula on which the Cape Town is situated; the other, the strip of land extending from the shore of Table Bay to the mouth of the Berg river in St. Helena bay, and separated from Stellenboch and Drakenstein, by the salti lake, Deep river, and Moffel bank river; being about 80 miles from north to south, and 25 from east to west, and containing about 2000 square miles. The Cape peninsula is about 30 miles in length, and 6 in breadth, or 240 square miles. Of the Cape district there is one-fifteenth part of the surface under any kind of tillage. The produce of the Cape peninsula is grapes, with all the European and many of the tropical fruits, vegetables of every description, barley for the use of horses, and a small quantity of choice wine. The other parts of the Cape district furnish wheat, barley, pulse, and wine. The population of this district in 1797 amounted to 18,152 persons, of whom 6261 were Christians, and 11,891 slaves; of the Christians or free people, 718 are of colour, and 1000, nearly, are Europeans. By comparing the average number of deaths with the population, it appears that the mortality in the Cape district is about 2,245 in the hundred. That of the slaves is rather greater, but less, perhaps, than in any other country, where slavery is tolerated. The number of deaths on the average of 8 years, was 250, which is after the rate of 3 in 100. The quantity of land occupied amounted in consequence of a measure taken not very correct to 8018 morgen, or 16,263 acres; of which 500 morgen were employed in vineyards and gardens, and 3589 in grain. Capital crimes in this district are not numerous as might be fancied among such a mixed multitude, the great majority of which have no interest in the public prosperity or tranquility. As to the natural produce of this district, it is of little or no importance, if we except the fisheries. The collecting of shells for lime, and of heaths and other shrubury plants for fuel, furnish constant employment for about 1000 slaves.

It has been generally asserted, that the Cape peninsula was originally separated from the continent of Africa; and this opinion has been founded on a supposed retreat of the sea. Mr. Barrow, on the contrary, apprehends that the sea is gaining upon the land in Southern Africa; and adduces several facts in support of this hypothesis. From all the observations which he had an opportunity of making on the southern coast of Africa he concludes, that the whole of L'Aguilas bank, stretching from Cape Point across the entrance of False Bay to the mouth of Rio Infante or the great Firth river, and to the 37th parallel of southern latitude, has at one time formed a part of the continent. It has been alleged, indeed, in favour of the Cape town, having, at no long interval of time, been covered with the sea, that sea-shells have been found on the land that is accumulated on its surface. In reply to this argument, Mr. Barrow observes, that whole strata of these may be found in the sides of the Lion's Hill, many hundred feet above the level of the sea; and these shells, he adds, have been conveyed to this situation, not by the waves of the ocean, but by birds: and they are frequently found even on the very summit of the Table mountain.

Cape Town, the capital of the colony, is situated on the south-east angle of Table bay. The settlers seem to have chosen this spot for the site of the town for the convenience of water, which rushes in a plentiful stream out of the Table mountain. Saldaunabay would, in other respects, have been more suitable; as Table bay is faulty in every point that constitutes a proper place for the mart of shipping; and is boisterous for four months in the year, as totally to prevent all ships from entering into it. The town is built with great regularity; the streets being all laid out with a line. The houses are generally white-washed, and the doors and windows painted green; they are mostly two stories in height, flat-roofed, with an ornament in the centre of the front, or a kind of pediment; with a raised platform before the door having a hut at each end. It consists of 1145 dwelling-houses, inhabited by about 5500 whites and people of colour, and 9000 blacks. The minute plan of the town also contains all the several departments of government, the clergy, the members of the court of justice, and of the police. The next are a fort of gentry who, having estates in the country, retain the produce of them by means of their slaves: subordinate to these is a number of petty dealers, who call themselves merchants; and lastly, the tradesmen who carry on their several professions by their blacks. Many of the people of colour are fishermen. The salaried of those who are employed in the different departments of government, are so small that most of them are petty merchants. The country boors employ a fort of agents, who keep houfes to lodge their agents when they make their annual visit to the town. These are a kind of Jewish brokers, who subsist by defrauding the simple boors in the disposal of their property, and in the purchase of necessaries for them on their return. The emancipated slaves and people of colour are generally artisans; and many of them support their families by taking fish, of which there are great plenty and variety in Table bay. Upon the whole, the people of the town are an idle diffusate race of men, subsisting chiefly on the labour of their slaves, who are required to bring them certain fum at the end of every week, and what they earn above this sum belongs to themselves, by means of which some of those who are the most industrious have been enabled to purchase their own freedom, and sometimes that of their children. The price of provisions and that of labour bear no proportion. Butchers' meat is about 2d. a pound, and good brown bread, such as the slaves eat, 1d. a pound. A common labouring slave gets from 2s. to 2s. 6d. a day, and a mechanic or artificer 5 and 6 shillings a day. The people of Cape Town are almost all of them petty dealers, and they have a remarkable propensity for public vendues. These vendues are a kind of lottery; in which a man buys in the morning a lot of goods, which he again exposes for sale in the evening, sometimes gaining, and sometimes losing by his bargains.
CAPE OF GOOD HOPE.

Such is the rage for these venuses, that in four incessive months of the year 1831, the amount of property sold by public auction was 1,563,000 rix-dollars, a fund equal to the whole quantity of paper money in circulation, which may be considered as the only money which has of late been circulated in the country. House rent, fuel, and clothing are dear in the Cape-town, and yet there is no city or town in Europe, where the wants of the people are better lodged or better clothed. Fire is less necessary here than in most parts of Europe. During the continuance of the south-east winds, resembling in their effect the south-east Sirocco of Naples, the Cape-town appears to be defetected. Every door and window are closed to keep out the dust and the heat, both of which decrease with the continuance of the gale; the air gradually cools, and every small pebble and particle of dust in the course of 24 hours are carried into the sea. The north-west winds of winter produce a moist and cold feeling, even in Cape-town, where, though the thermometer seldom descends below 46°, and then only about an hour before sun-rise, all the English inhabitants are glad to keep constant fires during the months of July, August, and September. Even in October it is not unusual to observe the fumes of the mountain to the caffward of the Cape illusius buried in flour. The number of marriages in Cape-town considerably surpasses that of the whole colony, for eight years, from 1790 to 1797, inclusively, amounted to 1449; that of christenings to 2139; and that of burials to 1173; so that 1416 was the excess of christenings above burials in that period. The inhabitants of Cape-town are burthened neither with taxes nor affimations. At the first establishment of the colony a kind of capitation tax was levied under the name of "Lion and Tiger money," the produce of which was applied towards destroying beasts of prey; but since these animals have become scarce in the vicinity of the Cape, the name of the affimation is changed, but the fund supplied by it has been appropriated to the repairs of the roads, streets, water-courses, and other public works. Its ordinary amount is about 5000 rix-dollars a year. Another affimation, chargeable on heads of families at the rate of 12.6d. a month, for every house or fire-place, is called "Chimney and hearth money," and amounts to about 5000 rix-dollars yearly. The inhabitants of Cape-town are subject to no taxes nor church-rates; but as the church provides for the poor, every person manumitting a slave pays to it 10l. giving security that such slave shall not become burdenome for a certain number of years. The police of the town is committed to the management of a board, consisting of six bachelors, called the "Burgher Senate." The pleasures of the inhabitants are chiefly of the groffer kind, being those of eating, drinking, and smoking: they have no taste for public amusements, and no exercize but that of dancing. In the whole town there is neither a bookeller's shop, nor a book society. Under the direction of the church is a library, left by an individual, and consisting of many excellent books; but very little used. Books are rarely found in Cape-town to constitute any part of the furniture of a house. Education is so little regarded, that neither government nor the church has been able to raise a sufficient sum for establishing a proper public school in the colony; and few of the natives are in circumstances that allow of their sending their children for education to Europe.

One of the greatest misfortunes in Cape-town is the number of dogs that prowl about the streets, particularly by night, when they quit their dens and lurking places in quict of the offals of butchers' shops. Sometimes the wolves and hyenas defend from their dens in the Table mountain, and dispute the spoil with the dogs; at such times the town re-

C A P

Cape, in Law, a writ judicial, touching plea of lands and tenements; so termed, from the word which carries the chief intention or end of it.

Cape is of two kinds, the magnum and parvum; in which their effect are alike, as to the taking hold of things immovable; though in certain circumstances they differ: 1. In that the capa magnum, or grand cape, is before; and the capa parvum, or petty cape, after appearance. 2. Cape magnum summons the defendant to answer the default; and also over to the demandant: capa parvum only to the default. It is called petty cape, not because of its small force; but because contained in few words.

Cape magnum is thus defined in the old Nat. Brev. 161: "Where a man hath brought a procesc qual relict of a thing that touches plea of land, and the tenant makes default of the day to him given in the original writ; then this writ shall be for the king to take the land into his hands; and if the tenant come not at the day given him by the writ, he loses his land."

Cape parvum, or petty cape, is thus defined, ibid. "Where the tenant is summoned in plea of land, and comes at the summons, and his appearance is recorded; and at the day given him, prays the view; and having it granted, makes default; then shall this writ suffice for the king, &c."

Reg. Jud. fol. 1. 2. Br. ofl. 3. tra. 3. c. i. Hesta. 1. 2. c. 44.

Cape de tumultum, a species of capa magnum, so called from the end to which it tends: it is thus described, "Where I am impleaded of lands, and I vouch to warrant another, against whom the summons ad warrantandum hath been awarded, and he comes not at the day given; then, if the demandant recover against me, I shall have a writ against the voucher; and shall recover so much in value of the lands of the voucher, if he has so much; otherwise, I shall have execution of such lands and tenements as depend to him in fee; or, if he purchase afterwards, I shall have a re-fummons against him; and if he can say nothing, I shall recover the value." Old. Nat. Brev. 161.

Cape du Batardreau, in Fortification, the cap, upper part, or roof of the batardeau constructed on the ditch of a work at the fallant angle of the bailey. There is commonly raised or erected on the middle of it a small tower or turret, six or seven feet, to prevent defilements.

CAPECE, Sebastiano, in Biography, an eminent Latin poet of Italy, who was born of a noble family at Naples towards the beginning of the 16th century, and began his career as professor of jurisprudence in the university of his native city, but afterwards directed his attention to polite literature. His house was the resort of learned men, who produced in 1535 "Commentaries on Virgil," attributed to Donatus. He first attracted notice as a poet by three books in praise of St. John the Baptist, entitled "De Vate maximo." But his fame was chiefly owing to his poem in two books, "De Principiis Rerum," first printed in 1543, and dedicated to pope Paul III.; in consequence of which, Benno and Maunzio did not scruple to compare him, though without sufficient reason, with Lucrètius. This poem, with a translation and learned notes of the abbé Ricas, was reprinted, together with the other poems of Capece, who appears to have been living in 1591, at Venice, in 1734. Gen. Dict. Triebach.

CAPEDUNCULA, in Roman Antiquities, the veilings wherein the sacred fire of Vesta was preferred. See Vestals.

CAPEL, in Geography, a town of Germany in the duchy of Carinthia, on the Fella; 10 miles S. of Volkmarsen.

CAPELAN, in Ichthyology, a name given by writers to a kind of whiting called by the Venetians matlo, and by obsolete authors, stellus or Sinus minimus, and melangus. This is most probably gaudis minutus of the moderns, which Belon calls melangus, and is the smallest of its tribe. The melangus of Geber is certainly too large for the capelan, and appears to be the same with our common whiting, Gobius melanogaster.

CAPELINE, in Military Language, a sort of iron head-piece, or helmet, which the cavalry under John, duke of Burgundy, used to wear.

CAPELINE, in Surgery, a kind of bandage used by the French surgeons in cases of amputations, consisting of a roller with two equal heads.

CAPELL, Edward, in Biography, one of the numerous editors and commentators of Shakespeare, was born in the county of Suffolk, and died in 1781. His edition of Shakespeare, in 1768, was compiled in 20 volumes, small 8vo. with an "Introduction" of singular composition, announcing another work, which was published in 1769, under the title of "Notes and various readings of Shakespeare; together with the Chorals of Shakespeare, or Extracts from divers English books, that were in print in the author's time, evidently flowing from whence his several fables were taken, &c. &c." Mr. Capell was the editor of a volume of ancient poems, called "Prolusions;" and the alteration of "Antony and Cleopatra," as acted at Drury-lane in 1758. See Shakespeare.

CAPELL, in Geography, a town of Germany, in the duchy of Stria; 3 miles N. of Muertzhoflag.

CAPELLA, Matianus, in Biography, an African Latin writer, who flourished about the year 470, and is supposed to have resided at Rome. He is author of a work in nine books, which confines of prose and verse intermixed, upon the seven liberal arts. The title of his work is "De Nuptiis Philologae et Mercanti."

Of all his nine books, no one has been much noticed by the moderns, except the ninth, which treats of music. The few Romans who have read him upon this subject, and the eager desire of classical readers to obtain some knowledge of the means by which the ancients produced, by the power of modulated sounds, those miraculous effects which are recorded, not only by poets, but historians and philosophers, drew particular attention on this part of the work.

The author's plan is the following.

Perfunctory Philosophy and Harmony, or Poetry and Music, under the character of Mercury and Harmonia, he describes their union as a nuptial feast, at which Jupiter and all the heavenly host of Paganism attend; celestials as tertial cultivators of music, Orpheus, Amphion, and Arion, who are admitted among the celestials to partake of the entertainment. And after going over the old ground in relating the wonders which music has performed, in healing diseases, quelling seditions, tempering and bringing to reason the irreligious affections of unruly youth, Harmonia is defined by Apollo and Minerva to unfold the mystery of her art.

We shall not enter on a disquisition concerning the Latinity of this work, which by many critics has been termed barbarous, but confine our reflections to the information which inquirers into the arcana of ancient music are likely to derive from its perusal.

The author explains, by the mouth of Harmonia herself, the Greek scale of tones and femitones, giving Latin translations of the Greek musical terms, proceeding from Prophembanomena, the lowest found in the general system, and mount-
ing up to Hyperborea, ultima excolititation. The next period
of treatment of anomalous: that of modes; of single sounds;
harmonic parts of the syllable; of intervals; genera, keys, tetrachords; of the diapente and diatessaron, or 5th and 4th; of transitions; of melopoeia, rhythm, three kinds—the dae-
tylic, iambic, and sponian; and of six kinds of compound
rhythm.

This ninth book, according to Meibomius, may be re-
garded as divided into two parts: the first containing the
history of music, and its cologium, the second the theory
and precepts of the art itself; and this last is what we shall
chiefly consider, as to its utility. And in mercy to inquirers
after Greek music, or the music of the ancients in general,
we can assure them, that what has been so far sought in
vain among the seven Greek theorists published by Melbo-
mius, in Polyphony, Phutarch, and Boethius, will not be found
in Martius Capella. His definitions are awkward Latin
translations of what may be found not only in Arnulphus
Quintilianus, but in every Greek writer on music. He has
not given us one of the characters of either Greek or Roman
notation; nor is there, either in his encomium or definitions, a
word that encourages a belief that the ancients knew any
thing of simultaneous harmony, or music in parts; or even a
trait of the arrangement of single notes, to enable us to form
any judgment of their melody. The rhythms, of which so
many are mentioned, are thole of verse, which probably were
likewise thole of music.

He was the first from whom we received equivalents in
Latin for the Greek musical technics, and we find in his
poetry many new metres, which we do not recollect to have
seen in any other Roman poet. The learned work of Ca-
pella was first published by Vitalis, in folio, at Venice, in
1490, in a very incorrect state. The corrections of Hugo
Griuus at the age of 14 are among the wonders of literary
history. They were published at Leyden in 1599.

Another Capella, who was a writer of elegy, is com-
memorated by Ovid, "De Ponto."

CAPELLE, in Geography, a town of France, in the
department of the Straits of Calais, and district of Montreuil;
1 league S. of Hesdin.

CAPELLE, la, a town of France, in the department of
Alfue, and chief place of a canton in the district of Vervins;
4 leagues N.E. of Gue. The town contains 1,077, and the
canton 14,697 inhabitants; the territory includes 1873
kilometres and 18 communes.

CAPELLE-MARIN, la, a town of France, in the de-
partment of the Lot, and chief place of a canton in the
district of Figeac; 8 miles N.N.W. of Figeac. The place
contains 1,013, and the canton 12,132 inhabitants; the
territory comprises 215 kilometres and 20 communes.

CAPELEN, a town of Germany, in the duchy of
Sitra; 8 miles W. of Luttchenburg.

CAPELLETTI, a Venetian militia, composed of soldier
that partly were slaves, Dalmatians, Albanians, and Morla-
chians, and were regarded as the choicest and best troops of
the state of Venice. They were much confided in by the
Venetians, and were employed to guard their places of the
greatest importance, and amongst others the palace and place
of St. Mark at Venice.

CAPELLUTIUS, RELAND, in Biography, a distin-
guished physician and philosopher, who flourished in the
latter part of the 15th century, under the pontificate of
Paul II. published in 1490, "Chirurgia," printed at Venice
in folio, and reprinted with additions in 1519 and 1546. It
contains the whole body of surgery, collected principally
from Albuscat, and other Arabian writers. A polished
work of this writer was published at Franckfort in 1642, svo.

reprinted in 1649, 4to, and again in 1682, 8vo; "De Cur-
ratione Peliferorum Apollinarum," a practical work, much

CAPENA, or CAPENCA, Steph. Bye, in Ancient Geography,
a town of Italy in Latium, between the country of the Veii
and the Tiber, according to Livy, who places the wood and
temple of Ptonia within its territory. Virgil also mentions
this city, which was near N. of Rome.

CAPENA was also the name of one of the gates of Rome,
now the gate of St. Schaflhann, S.E. of Rome.

CAPENSIS, in Botany, a species of ANOPLA. The
shell is longitudinally ribbed, slightly truncatetl, with round-
figured, transverse reticulae; flat valve, with a two-lobed rib
beneath. C. C. inhabits the Cape of Good Hope. Shell
sometimes reddish, sometimes white.

CAPENSIS, in Botany, a species of PARELA, (Bombyx) that
inhabits Africa. The wings are pale red; on the anterior
pair two fuscos brevius, the posteriure of which is connected
to a black one.

CAPENSIS, a Linnæan species of Cicindela. This kind
is somewhat bavish, with white wing-cases marked with a
three-branched fuscous line. Inhabits the Cape of Good
Hope, and Calabria.

CAPENSIS, a species of Cerambyx, found at the Cape
of Good Hope. The general colour is black; thorax two-
spined; four rufous bands on the wing-cases; antennæ
moderate.

CAPENSIS, a species of Carabus, described by Thun-
berg as a native of the Cape of Good Hope. This is of a
ferruginous colour, with a black longitudinal line on the
thorax and of the wing-cases.

Observe. The abdomen in some specimens is black; in others
brown.

CAPENSIS, in Ornithology, a species of Alauda, that
inhabits the Cape of Good Hope. The three lateral feathers
of the tail are tipped with white; chin pale yellow, edged
with black; eye-brow yellow; capulark, Lathiam; alauda
capita bupi, Brillaon; and emilis icun ou caladur du
cap de bonne esperance, Buffon. The bill is yellowish brown;
upper part of the body with the tail brown; all the feathers
darker in the middle; chin orange; body beneath ochra-
aceous; legs black; back claw rather hooked.

CAPENSIS, a species of Alfas, of a greyish colour, with
cheestnut-coloured back, and speculum spot on the wing
pale greenish blue, edged with white.

This is the Cape pipon of Lathiam. The length is fifteen
inches; bill red, black at the base; head spotted; legs
reddish; claws black. Inhabits the Cape of Good Hope.

CAPENSIS, a species of Zygophyllum. This has the tail long,
and of a cinereous blue colour; beneath fulvous; head
feathery; bill red. Gmel.

This bird inhabits the Cape of Good Hope. Its length is
fourteen inches. The bill is blackish at the tip; head
grey, inclining to tawny; body above blue green, inclining
to ash on the back; legs and claws red. Brillaon calls it
spifieda capitii bupi spis; and Buffon, marit-poecheur du cap de
bonne esperence.

CAPENSIS, a species of Certhia, that inhabits the Cape
of Good Hope. The colour is fulvous; tail-feathers black-
ith, the exterior ones fringed at the outer edges with white.
Brillaon, &c.

CAPER-bean, in Botany. See Zygoophyllum.
CAPER-bush. See Capparis.
CAPER, or CAPPARUS, in Ancient Geography, a river of
8. Afin,
Afa, in Syria, which flowed between the Lycur and Gorgus, and discharged itself into the Tigris. Pliny.—Allo, a river of Asia Minor, in Phrygia, and in the country of Cilantris. Pliny, says that it washed one of the sides of Laodicea, and Strabo informs us, that it discharged itself into the Meander, near that city.

Caper, in Navigation, a vessel used by the Dutch, for cruizing and taking prizes from the enemy. In which sense caper amounts to the same as we use the word, and is used by the Dutch, for a vessel of small burthen, to be employed in the coasting trade.

CAPERNAUM, in Ancient Geography, a town of Palestine, situate on the north side of the sea of Tiberias, called also the lake of Gennesareth and Sea of Galilee, at some distance west from the mouth of Jordan. Although it stood till the seventh or eighth century, its precise situation is quite lost. According to St. Matthew, (iv. 13,) it was on the borders of Zabulon and Nephtali; and it was celebrated as the place where Christ dwelt after having his family at Nazareth, and where he performed many miracles, which occasioned the woe denounced against its inhabitants for their impiety. Capernaum was also the name of a river and of a mountain in the vicinity of the town. It had also a spring of clear and limpid water, which might probably induce the Jews, after their return from the Babylonish captivity, to build a city near it.

CAPERLANS, in Ecclesiastical History, a congregation of religious in Italy, so called from Peter Caperole their founder, in the 15th century. Caperoles having by his enterprising spirit and influence separated the convents of Brescia, Bergamo, and Cremona, from the province of Milan, a law was sent from the vicar-general and these convents enquifed, which terminated in their favour. In 1475, pope Sixtus IV. erected them into a distinct vicariate under the title of that of Brescia. Caperoles afterwards induced the Doge of Venice to erect this vicariate into a congregation, distinguished by his own name. It still subsists, and comprehends 24 convents, situate in Brescia, Bergamo, and Cremona.

CAPES, of Capez, in Geography. See GAB.

CAPESTANG, a town of France, in the department of Hauralt, and chief place of a canton, in the district of Beziers; 3 leagues N. of Narbonne. The place contains 1,359, and the canton 15,077 inhabitants; the territory comprehends 2,474,000 square kilometres, and 9 communes.

CAPET, Hugh, in Biography, the first king of France of the third race, was the son of duke Hugo, surnamed the Great, who, without wearing the crown, had for the better part of his life held the supreme power in France, and who died A. D. 955, by Hadwiga, or Avoya, of Saxony, daughter to Henry the Fowler, king of Germany, father to the emperor Otto the Great, and to Gerberge queen of France. Dante, in his “Purgatory,” (Canto 29) in order to be revenged on prince Charles of Valois, sprung from this prince, for drawing him from Florence, and confounding his property, when heheaded one of the factions of the city, traduced his family by representing him to be the son of a butcher. This ridiculous calumny has been adopted and circulated by several writers on the authority of Dante. Whereas his father was the son of king Robert, who fixed the Normans in France, brother-in-law to three kings, viz. Rodoiph, Athelstan, and Otto the Great, and defended by his mother from Charlemagne. As to the surname of “Cape,” it was most probably a nick-name, signifying literally “jolterhead,” and metaphorically, a “weak,” or an “obliviate” man. In the bulk of these fables it was applied to Charles the Simple, and, perhaps, in the latter sense, to this prince in his youth. At the death of his father he was 16 years of age, and he was particularly recommended to the care of Richard, duke of Normandy. When the line of Charlemagne, which had possessed the throne between 230 and 240 years, terminated with Lewis V. the last monarch of that line, Hugh Capet, who had served him faithfully during his reign, succeeded him; the crown, as some writers affirm, having been bequeathed to him by Lewis in recompense of his services. However this be, upon the death of the king Hugh Capet took early and effectual measures for securing the throne; as in a few days he caused himself to be proclaimed king at Noyon, and was solemnly crowned at Rheims, by the archbishop of that see, on the 3d of July, A. D. 987. This design was executed without opposition, nor did any person exert himself in behalf of the late king's uncle Charles, the last surviving prince of the race of Charlemagne. On his accession, he added greater strength to the crown than he received from it; since the duked of France, the countries of Paris and Orleans, were in his own hands, and his brother-in-law, the duke of Normandy, was closely attached to his interest. His own queen Adelaide, who is said to have been a princess of high birth and admirable qualities, contributed in no small degree to his security. Having defeated an army raised by William duke of Guienne, in a short but bloody battle near Poitiers, he compelled him to submit; and being a man of good temper and sagacity, as well as of great moderation, he assembled the nobles and proposed to them the association of his son Robert. The proposal being accepted, Robert was crowned with great ceremony on new-year’s day, A. D. 988, at Orleans, by the archbishop of Sens. Having, by this act, secured the crown to his family, he never afterwards wore the royal ornaments, or affected any extraordinary state or magnificence; but administered public affairs with great application, and with such an appearance of modesty, justice, and piety, as recommended him highly to his subjets, and more especially to the clergy, to whom he restored all the abbeys in his possession; and his example was followed by the nobility. In the following year the adherents of Charles of Lorrein, after an unsuccessful contest, did homage to the kings Hugo and Robert. The duke Lorrein remained, as long as he lived, a prisoner at Orleans; and with his son, who enjoyed the duchy of Lorrein, and who died without male issue, A. D. 991, the male line of Charlemagne was entirely extinct. In the sequel of his reign, Hugh Capet strengthened his government by mildness and moderation, and had the singular honour of establishing a new family, and in some measure a new form of administration, without any remarkable circumstances of violence, and without shedding blood. He died on the 24th of October, A. D. 997, in the 57th year of his age, and in the 8th of his reign, leaving his dominions in perfect tranquillity, and his son Robert in the peaceable possession of the crown. His remains were interred in the church of the abbey of St. Denis. The devastations of Hugh Capet governed the kingdom of France, in a direct line from father to son, terminating with Charles IV. surnamed the “Fair,” for eleven generations. There were thirteen monarchs in all, whose reigns together make upwards of 350 years, during which interval they wonderfully extended their authority as well as their dominions; and recovered, either to the crown or to the princes of the royal family, the better part of the ancient kingdom of France. They had also reduced the exorbitant power of the nobility within bounds, and were much less dependent upon the clergy than the monarchs of the second race. Yet, after all, the nation was in low circumstances; the frame of government far from being uniform;
form; and, in short, the seeds of those disorders were very perceptible to discerning persons, which, in the succeeding reign, sprang up and became visible to the whole world in their dismal effects. Gen. Dict. Mod. Un. Hist. vol. xix. and xx.

CAPH, a Jewish measure of capacity, estimated by Kim-chi at the 3d part of the log, by Arbrout at the 19th part of the hin, or 32d of the fah, amounting to five-eighths of an English pint. The cap does not occur in Scripture as the name of any measure.

CAPHAR, a toll, or duty, imposed by the Turks on the Christian merchants, who carry or send merchandise from Aleppo to Jerusalem.

The caphars were first settled by the Christians themselves, when masters of the Holy Land, for the support of troops and forces posted in the more difficult passageways, to watch the Arabs, and prevent their pillages. But the Turks, who have continued, and even raised the toll, abuse it; exacting arbitrary sums of the Christian merchants and travellers, on pretence of guarding them from the Arabs: with whom they yet frequently keep an understanding, and even favour their robberies.

CAPHAR, Heb. denoting a field or village, in Ancient Geography, is often used, in composition with other words, to signify a particular town or city. Thus, Caphar-Aria, a village of Palestine, between Jerusalem and Searon:—Caphar-Barica, or Caphar Baruca, a village of palestine, 3 miles from Hebron, in the tribe of Judah, mentioned by Epiphanius and Jerome:—Caphar-Dagon, situated between Dipolis and jamnia:—Caphar-Nimra, a populous town of Palestine, in the land of Ifrad:—Caphar-Neme, a village of Palestine, in Galilee, near Jordan:—Caphar-Ora, a town of Iduma, placed by Ptolomy to the west of Jordan:—Caphar-Saba, the site of Anthipatris, which fee:—Caphar-Samala, a place near Jerusalem:—Caphar-Serek, a town of Palestine, near Eleutheropolis, which existed in the time of Jerome.

CAPHARA, a town of Judah, in the tribe of Benjam. Caphara, a fortified village of Galilee, Josephus.

CAPHARCOTIA, or Capharcotia, a town of Palestine in Galilee, between Scythopolis and Caesarea of Palestine.

CAPHAREUS, a promontory of the island of Eubeas, the doubling of which was reckoned very dangerous, in the infancy of navigation, on account of the rocks and whirlpools on that coast, much spoken of by the ancients. It is now called Capo d'Oro, Capo Chimi, and Capo Figera. On this coast the Grecian fleet was shipwrecked on its return from Troy with Agamemnon. To this purpose Virgil says (A. Encid. l. xvi. v. 260.):—

"Sit triste Minervae
Sidus, et Euboeicae cautes, ultorque Caphareus."

CAPHAS, a mountain of interior Libya, situated in that part of Africa which is about the 15th degree of N. latitude, and 25th degree of E. longitude, whence, according to Ptolomy, the river Daractus arose, supposed by some to be the present Seneal, and from which, it is conjectured, the Levant wind, called the Harmattan, proceeds. See Harmattan.

CAPHESA, or Capsa, a town of Africa, near the source of the river Magrada, surrounded by dactyrs. Ptol. and Strabo.

CAPHÉ, or Caphya, a town of Peloponnesus in Arcadia, N.W. of Orchomenus; it was built by Caphus, and peopled from Attica. In this city were temples of Neptune and Diana. It suffered much from the enterprises of Cleomenes and the Achaean league. Near it was a fountain shaded by a plantain tree of extraordinary beauty, said to have been planted by Menelaus, when he came into Arcadia to raise troops for his Trojan expedition. In the time of Pausanias an antiquity of 1562 years was ascribed to this tree. Thuc. (i. xvi.) says, that it was planted by Agamemnon.

CAPHITOR, an island or district, concerning the situation of which Scripture interpreters have differed. Some have supposed, without sufficient reason, that it was Cappadocia. Others are of opinion, that the island called Caphtor, from which sprung the Capthorim, Cherethites, or Philistines, who are thought of the sale of the fame origin, was the selfie of Crete in the Mediterranean. The able Finche, Dr. Welsby, and others, with greater probability, suppose Caphtor to have been one of the islands formed by the Nile in Egypt, and that it was the same with Capos, which was so situated. To this purpose it is alleged, that the Capthorim, mentioned Gen.x.14 were descendants of Mizraim, the son of Ham, who peopled Egypt; and from them sprung the Philistines.

CAPHURA, the same with Camphor, which fee.

CAPI-AGA, or CAPI-AGAS, a Turkish officer, who is governor of the gates of the seraglio; or grand master of the seraglio. The capi-aga is the first dignity among the white eunuchs: he is always near the person of the grand signior; he introduces ambassadors to their audience: nobody enters, or goes out of the grand signior's apartment, but by his means. His office gives him the privilege of wearing the turban in the seraglio, and of going every where on horseback. He accompanies the grand signior to the apartment of the sultanas, but stops at the door without entering. His appointment is very moderate; the grand signior bears the expence of his table, and allows him at the rate of about sixty French livres per day; but his office brings him in abundance of presents; no affair of consequence coming to the emperor's knowledge, without passing through his hand. The capi-aga cannot be bailwhaw when he quits his post.

CAPIAS, in Law, a writ or process, which is of two sorts; one before judgment, in the court of C. P. called Capias ad respondendum, where an original is found out, &c. to take the defendant and make him answer the plaintiff. The other is a writ of execution after judgment, which is of various kinds; as, Capias ad satisfactendum, Capias pro fine, Capias ulteriorem, &c.

The Capias ad respondendum in C. B. is drawn from the "precipe," which serves both for the "original" and "cipias," and the return of the original is the title of the "cipias." If a "cipias" be special, in cafe, covenant, &c. the cause of action must be recited at large, and the substance of the intended declaration set forth, as also in the original. The "cipias" is a writ commanding the sheriff to take the body of the defendant, if he may be found in his bailwark or county, and to keep him safely, so that he may bring him to court, on the day of the return, to answer to the plaintiff of a plea of debt, trespass, &c. In cases of injury accompanied with force, the law, to punisb the breach of the peace, and to prevent its disturbance for the future, provided a process against the defendant's person, in case he neglected to appear on the process of attachment against his goods, or had no subsistence by which to be attached, subjecting by this writ his body to imprisonment. 3 Rep. 12. But the immunity of the defendant's person, in case of peaceable though fraudulent injuries, producing great contempt of the law in ingent wrong-doers, a "cipias" was also allowed to arrest the person in actions of "account," though no breach of the peace be frustrated, by the flats. of Marlbridge, 2 & Hen. III. 12, and Welf. 3 & 4 Edw. I. c. 13. In actions of "debt" and "definie," by flat. 25 Edw. III. c. 17: and in all actions "on the cafe," by flat. 19 Hen. VII. c. 9.
Before this last statute a practice had been introduced of commencing the suit by bringing an original writ of trespass, "quae clausum frigit," for breaking the plaintiff's close, "vi et armis;" which by the old common law subjected the defendant's person to be arrested by writ of "capias;" and then afterwards, by convirement of the court, the plaintiff might proceed to prosecute for any other lefs forcible injury. This practice (through culum rather than necessity, and for saving some trouble and expense, in fining out a special original, adapted to the particular injury) still continues in almost all cases, except in actions of debt; though now, by virtue of the statute above cited, and others, a "capias" might be had upon almost every plea of complaint. It is now usual in practice, to finely out the "capias" in the first instance, upon the suppos'd return of the sheriff (that the defendant, being summoned or attached, made default, or that he had no substance by which to be attached); especially if it be supposed that the defendant, upon notice of the action, will abscond; and afterwards a fictitious original is drawn up, if the party is called upon to do, with a proper return thereupon, in order to give the proceedings a colour of regularity. When this "capias" is delivered to the sheriff, he by his under-sheriff grants a warrant to his inferior officers, or bailiffs, to execute it upon the defendant. If the sheriff of the county, in which the injury is supposed to be committed, and the action is laid, cannot find the defendant in his jurisdiction, he returns "non est inventus;" whereupon another writ issues, called a "teftatum capiatis," directed to the sheriff of the county where the defendant is supposed to reside, reciting the former writ, and that it is testified "teftatum efi," that the defendant lurks or wanders in his bailiwick, wherefore he is commanded to take him, as in the former "capias." But in a case of this kind also, it is usual, for saving trouble, time, and expense, to make out a "teftatum capiatis" at the first; supposing not only an original, but also a former "capias" to have been granted. This action, being beneficial to all parties, is readily acquiesced in, and is now become the settled practice. But where a defendant absconds, and the plaintiff would proceed to an outlawry against him, an original writ must then be filed out regularly, and after that a "capias." And if the sheriff cannot find the defendant upon the former writ of "capias," and returns "non est inventus," there issues out an "alias" writ, and after that a "pluries," to the same effect as the former; only after these words, "we command you," this clause is inserted, "as we have formerly," or "as we have often commanded you;" "sic aliis, or sic pluries, precipimus." In the King's bench, the bill of Middlesex is a kind of "capias." See Bill of Middlesex.

"A capias" is also used in criminal, as well as in civil, cases. The proper process on an indictment for any petty misdemeanor, or on a penal statute, is a writ of "venire facias," which is in the nature of a summons to cause the party to appear. If by the return to such "venire" it appears, that the party hath lands in the county, whereby he may be detained, then a "diffinis infersus" shall be ifined from time to time till he appears. But if the sheriff returns that he hath no lands in his bailiwick, then (after his non-appearance) a writ of "capias" shall issue, which commands the sheriff to take his body, and have him at the next assizes, and if he cannot be taken upon the first "capias," a second and a third shall issue, called an "alias," and a "pluries capias." But on informations for treason or felony, a "capias" is the first process; and, for treason or homicide, only one shall be allowed to issue, or two in the case of other felonies, by flat. 25 Edw. Ill. c. 14; though the usafe is to issue only one in any felony; the provisions of this statute being in most cases found impracticable. Also, in the case of misdemeanors, it is now the usual practice for any judge of the court of King's-bench, upon certificate of an indictment found, to award a writ of "capias" immediately, in order to bring in the defendant. But in this, and also in civil cases, if he absconds, and it is thought proper to pursue him to outlawry, greater exactness is necessary. Blackft. Com. v. iii. 232, &c. v. iv. p. 318, &c.

"Capias ad satisfaciendum," commonly termed CA. SA., is a writ of execution after judgment; lying where a man recovers in an action personal, as for debt, damage, &c. in which cases, this writ issues to the sheriff, commanding him to take the body of the defendant, whom the debt is recovered; who is to be kept in prison till he make satisfaction.

It is usual to take out this writ, where the defendant hath no lands nor goods, whereof the debt recovered may be leved: and when the body is taken upon a CA. SA., and the writ is returned and filed, it is an absolute and perfect execution against the defendant, and no other execution can be had against his lands and goods. But this is unles the defendant escape, or die in execution, &c. for where a person dies in execution, his lands and goods are liable to satisfy judgment, by flat. 21 Jac. I. c. 24. Rol. Abr. 904. This writ does not lie against any privileged persons, peers, or members of parliament; nor against executors or administrators (except on a "devallavit" returned by the sheriff, 1 Litt. 250; nor against such other persons as could not originally be held to bail. It may be issued out for costs, against a plaintiff as well as a defendant, when judgment is had against him. If the defendant cannot be taken upon a CA. SA. in the county where the act is laid, there may issue a "teftatum" CA. SA. into another county, and so of the other writs.

Capias pro fine. When judgment is given for the plaintiff, it is considered that the defendant be either aimerd, for his wilful delay of justice in not immediately obeying the king's writ by rendering the plaintiff his due; or be taken up, "capiatur" till he pays a fine to the king for the public misdemeanour which is coupled with the private injury, in all cases of force, of falsehood in denying his own deed, or unjustly claiming property in replevin, or of contempt by disobeying the command of the king's writ or the express prohibition of any statute. But now in case of trespass, ejectment, assault, and false imprisonment, it is provided by 5 & 6 W. & M. c. 12., that no writ of "capias" shall issue for this fine, nor any fine be paid; but the plaintiff shall pay 6s. 8d. to the proper officer, and be allowed it against the defendant among his other costs. And, therefore, upon such judgments in the Common Pleas they used to enter that the same was remitted; and now in both courts they take no notice of any fine or "capias" at all. Blackft. tom. v. iii. p. 398.

"Capias ultagatum," a writ which lies against one outlawed upon any action, personal or criminal; by which the sheriff is ordered to apprehend the party outlawed, for not appearing on the exigtent, and keep him in false custody till the day of return; when he is to present him to the court, to be there further dealt with for his contempt: who, in the Common Pleas was formerly to be committed to the Fleet, and to remain there till he had freed out the king's pardon, and appeared to the action. By a special "Capias ultagatum" (against the body, lands, and goods in the same writ) the sheriff is commanded to seize all the defendant's lands, goods, and chattels, for the contempt to the king; and the plaintiff, (after an inquisition taken thereupon, and returned into the exchequer) may have the lands extended, and a grant of the goods, &c. whereby to compel the defendant to appear; when which he doth, if he revere
rever the outlawry, the same shall be restored to him. Old. Nat. Brev. 154. When a person is taken upon a "capitis
nulagatam," the sheriff's to take an attorney's engagement
appearance to appear for him, where special bail is not required;
and his bond with sureties to appear, where it is required.
Capias in Witternam. See Witternam.
Capias conditator ad professicendam, an original writ, which
lies, by the common law, against any officer who has coven-
anted to serve the king in war, and appears not at the time
and place appointed. It is directed to two of the king's serjeants at arms, to arrest and take him wherever he may be found: and to bring him coram comitatu nifi, with a clause of discharge.
Capiatur, judgment quad. See Capias pro fine.
Capibara. See Capybara.
Capiculy, formerly called Janizaries, the first and
best corps or body of the Turkish infantry.
Capidava, in Ancient Geography, a town of Lower
Illyria, between Axiospolis and Carfion. Antonin. Hin.
Capidodius, in Zoology, a name given by Paulus
Javius, and some other obsolete writers, to an animal of the
ceratoe tribe (or fowl as they describe it) distinguished by
having the fowl bending upwards, and armed with broad
furred teeth. The species implied is certainly Delphinus
Orca of Linnæus and later authors.
Capidolia, in Zoology, a synonym of Balea
Musculus.
Capigl, or Capigdi, a porter, or door keeper of the
Turkish Seraglio. There are about five hundred capigis,
or porters, in the Seraglio, divided into two companies;
one consisting of three hundred, under a chief called
Capigii-Baffa, who has a flippend of three ducats per day;
the other consists of two hundred, distinguished by the
name of Buccadigoli, and their chief Buccadiggi-Baffa,
who has two ducats. The capigis have from seven to fifteen
alpers per day: some more, others less. Their business is
to affil the janizaries in the guard of the first and second
gates of the Seraglio; sometimes all together; as when
the Turk holds a general council, receives an embassador,
or goes to the mosque; and sometimes only in part; be-
ing ranged on either side to prevent people entering
with arms, any tumults being made, &c.
The word, in its original, signifies gate.
Capigis-bachi, or Capigis-lachi, a fort of chamber-
buildings belonging to the grand signior whose place is ho-
nourable and lucrative, and who are charged to execute the
orders which they receive from the sultan, e.g. to cut off the
head of a rebel or extortioner, to carry the news of the
appointment to a government, to go and collect the succes-
sions of the great officers of the empire, &c.; their chief, al-
tways taken from this class, is called "Mir-alem." The
Capigis-bachi are sometimes raised to the dignity of pacha
or bakhaw with two tails, and go in that quality to govern
the province which is allotted to them.
Capillaire, a synap made of maiden-hair. See
Adiantum and Asplenium.
Capillament, literally signifies hair, being formed of
the Latin capillus, of caput, q. d. hair of the head. Hence
the word is figuratively applied to several things, which,
on account of their length, or their fineness, resilient hairs: as,
Capillaments of the nerves, the fine fibres, or fila-
ments, whereof the nerves are composed.
Capillament, in Botany, a term used by the old bot-
anists for the filament of the flamen. Bradley terms it to re-

Brain capillaments to the smaller flowers; and stamina (which he corruptly calls apice) to the larger.
Capillament is also applied to the fibrings or threads
about the roots of plants.
Capillaries, a name given by some of the old botanists to the flava, because, according to Mr. Ray, they
strengthen and improve the human hair; or, according
to others, from a curious fancy that they grow from
the earth without flumes, in the same manner as hairs grow
from the human head.
Capillaris, or Capillata, Arbor, an ancient
tree at Rome, on which the veilis virgins, when they had
their office, hung up their hair, and consecrated it to the
gods.
Capillary, of the Latin capilus, a hair, is applied
to several things, to intimate their exceeding smallness, or
fineness, resembling that of a hair.
Capillary is also used by Minerals in speaking of
ores which ramify or shoot out fine branches like threads.
In which sense it amounts to the same with what is otherwise called arborscent and flinted. Woodward speaks of
capillary or arborscent silver and iron; Crew describes a
piece of pure capillary copper from the mine of Heragrant,
the several fings or capilli of which are short, of a reddish
golden colour, growing together almost like those of the
little flume-mofs.
Capillary roots. See Fibrous roots.
Capillary tubes, in Physic, are those which are very
small, or whose canals are so narrow, as by the diminutive
deep of their bores to resemble a hair in diameter. The usual
diameter of capillary tubes is a half, third, or fourth of a
line, or from $\frac{1}{100}$ to $\frac{1}{1000}$ of an inch; though Dr. Hook
assures us he drew tubes in the flame of a lamp much smaller,
and almost as fine as the thread of a cobweb.
The ascent of fluids in tubes of this kind is a pheno-
menon which has been noticed by philosophers, and of which
different accounts have been given. The fact is unquestion-
able; for if one end of a small tube, open at both ends, be
immerged in water, the liquor within the tube will rise to a
feasible height above the external surface; or if two or more
tubes be immergec in the same fluid, e.g. water, one of
them a capillary one, and the other considerably larger, the
water will rise perceptibly much higher in the former than in
the latter; in the reciprocal ratio of the diameters of the
tubes: and the effect is the same in vacuo as in the open air.
The greatest height to which Dr. Hook ever found water
to ascend above the level of the bason, in his very small
capillary tubes, did not exceed 21 inches. See Ascent of
fluids.

For the illustration of this phenomenon, we may observe in
general, that the particles of water and of other fluids mu-
tually attract each other; and that there is also an attraction
between glases and water, &c. which is increased by cold,
and diminished by heat, but which is a capillaries paribus,
proportional to the surface of contact. The mutual attraction
of particles of water is evinced by the globular forms of the
drops of this fluid, by their coalescing when brought near
one another, and by a variety of other phenomena. It is
observed also, that if we breathe on a glas plate, the breath
will adhere to it longer in cold, than in hot weather. If a
drop of water be laid upon glases, the surface most remote
from the glases will retain a convex form, whilst that which
touches it will adapt itself to the surface of the glases, and
adhere to it with a certain degree of force; but if the same
drop be spread over the surface of the glases, it will lose its
convex surface, and adhere to the glases with a greater force.

3 0 2 By
CAPILLARY TUBES.

By this dispersion of its particles they will be removed farther from each other, and their mutual attraction will be diminished; whereas, on the other hand, the attraction between the water and the glass is increased by enlarging the surface of contact. In either of these cases, the water is attracted by the glass only on one side; but if another piece of glass be placed in opposition to the former, and in contact with the film of water, the water will be attracted and retained with a greater force; and if the water be on every side encompassed with glass, or enclosed in a narrow tube, the attraction will become stronger, because the surface of contact in proportion to the quantity of water is thus considerably enlarged. The truth of these observations may be evinced in the following manner. Put water into a glass vessel, (Plate I. Hydrostatics, fig. 1.) and the water near the surface of the glass will ascend, and form a curve, as at A and B; or the same effect will be exhibited at C and D, by dipping part of a piece of glass in the water. In order to explain this effect, let \(A B\), (fig. 2.) represent a section of the surface of a piece of glass, the lower part of which is immersed in the water, B C: and suppose this surface to be divided into a number of indefinitely small parts, \(a, b, c, d, \&c.;\) then the part \(a\), next to the surface of the water, B C, will raise a quantity of water proportional to its attractive force; which quantity is thus brought nearer to the part \(b\) of the glass, and attracted by it, so that another quantity of water takes its place next to \(a\). The first quantity of water being raised to \(b\), is brought nearer to the part \(c\) of the glass, and being attracted by it, is raised to the place \(e\), whilst the first quantity of water \(a\), takes its place, which is succeeded by another quantity of water which rises to the place \(a;\) so of the others. In consequence of this attraction, the water ought to form a film of equal thickness, or the quadrilateral figure, \(g, b, a, s,\) on the whole surface of the glass. But by reason of the mutual attraction of the particles of water towards each other, when the first quantity of water has been raised to the place \(a\), another quantity of water \(s\), is kept suspended by this latter attraction, between the water at \(a\), and that at B C. When the glasses has by its attraction raised the water to \(b,\) the part \(s\) will be extended to \(e,\) because the two quantities of water, \(a\) and \(b,\) can keep suspended a greater portion of water than the single part \(a.\) Thus, the water will ascend along the surface of the glasses, and will remain adhering to it, in such quantity as to form a counterpoise to the attraction of the glass; or, in other words, the preffure of the water thus raised, and the attraction between it and the water, B C, will form by their united actions a counterpoise to the attraction of the glasses. The real ascent of the water, which, in the figure we have referred to, has been enlarged for the better illustration of the subjeét, seldom exceeds \(\frac{1}{2}\)th of an inch, when the glasses is either flat, or not much bent. But this altitude is increased by a variety of circumstances; viz. by the temperature and purity of the water, by the quality of the glases, and chiefly by the polishing and cleanliness of its surface.

In small tubes of different diameters, the perpendicular ascent of water, and of various other fluids, will be in inverse as their respective diameters. Thus, if glas tubes opened at both ends be immersed with their lower apertures in water, (see fig. 3.) the water will instantly rise spontaneously into their cavities; and it has been found to rise higher and with a greater velocity in narrower than in larger tubes, according to the proportion in which the diameters of the larger tubes exceed those of the smaller; and the altitude in a tube of \(\frac{1}{2}\)th part of an inch, (viz. 0.01), in diameter, will be about 5.3 inches. Consequendy, in a tube of 0.02 in diameter, the altitude of the water will be the half of 5.3, viz. 2.65 inches. Also, in a tube whose diameter is 0.1 of an inch, or 12 times 0.01, the altitude of the water will be the 10th part of 5.3, or 0.53 of an inch, &c. Hence it follows, that if we call the diameters of the tubes \(D, d,\) and the altitudes of the water \(A, a,\) we have, \(D : d : a : A,\) and \(A D = ad;\) that is, the product of the diameter by the altitude of the water is always the same, or the constant quantity 0.053 of an inch; for when the diameter is 0.01 of an inch, the water rises to the altitude of 5.3 inches; and 53 x 0.01 is equal to 0.053 = 0.02 x 2.65 = 0.01 x 0.53.

But, therefore, you wish to know how high the water will rise in a tube of a given diameter, it is only necessary to divide 0.053 by the diameter, and the quotient expresses the altitude in inches, very nearly; for allowance must be made for difference of temperature, the nature and cleanliness of the glasses, &c. which influence the altitude. Moreover, since the surface of a cylinder is as the product of the diameter multiplied by the axis, or the altitude, and it has been already shown, that in the part of the tube occupied by the water, the product of the diameter by the altitude is a constant quantity, the surface of the glasses which is in contact with such a pillar of water, is likewise a constant quantity.

Mr. Atwood, in his "Analysis," has given the following method of very accurately determining the diameter of a capillary tube. Put into the tube some mercury, whose weight in grains is \(\omega,\) and let it occupy a length of the tube \(l,\) then, if 136 be the specific gravity of mercury, as it is when in its purest state, that of water being 1, the diameter will be \(\sqrt{\frac{\omega}{l}} \times 0.01923.\) For let \(d\) be the diameter, and the contents of the mercury will be \(d^2 \times \sqrt[3]{7.854} ;\) and as one cubic inch of mercury weighs 3443 grains, we have \(1 \times 3443 = d^2 \times \sqrt[3]{7.854} = \omega;\) hence we shall have \(d^2 \times \sqrt[3]{7.854} = 3443 = \omega = \frac{\omega}{l} \div \sqrt[3]{7.854} ;\) and \(d^2 = \frac{\sqrt[3]{7.854}}{\sqrt[3]{7.854}} = \sqrt[3]{7.854} \div \sqrt[3]{7.854} = \sqrt[3]{7.854} \times 0.01923.\)

Several ingenious persons, who, in examining the phenomena of capillarity, have found that the bulks of the suspended pillars of water are not proportional to the surfaces of glases with which they are in contact, have been embarrassed in explaining them; and for this purpose they have adopted various hypotheses. Some have supposed that the unequal preffure of the air upon the liquor contained in the tube and that in the vessel is the cause of the ascent in the tube. In order to account for this inequality, some have had recourse to the magnitude of the particles of the air and of the ascending fluid; others have conceived, that only an inverted cone of air, touching the surface of the liquor in the tube with its vertex, and having the upper orifice of its tube for its base, could press upon the surface contiguous to its vertex. Dr. Hook supposed that part of the preffure of the air in the tube was taken off by its friction, which he apprehends must necessarily happen against the sides in so narrow a passage, and this hypothesis of Dr. Hook was for a long time very generally received. Those who wish to see his explication of it may find it in the sixth Observation of his "Micrography," or in Cotes's "Hydrostatical and Pneumatical Lectures," (ubi infra.) But since it has
has been observed, that the same effect of liquors in capillary tubes occurs in vacuo as in the open air; this hypothesis of an inequality of pressure has been relinquished; and the solution of the difficulty has been sought for in the mutual attraction of the particles of fluids and the air. Mr. Parkinson, Mr. Hawkisse, and others, have recourse to the attraction of the annulus of the concave surface of the tube. Dr. Jurin (Phil. Trans. N° 255, and N° 373, or Abr. vol. iv. p. 473, &c.) ascribed the suspension of the water to the attraction of the small annular portion, or periphery of the inside of the tube, to which the upper surface of the water is contiguous and adheres; this being the only part of the tube, from which the water must recede upon its subsiding, and consequently, the only one which, by the force of its cohesion and attraction, counteracts the gravity of the water, and opposes its descent. This he shews to be a cause proportional to the effect; because the periphery, and the suspended column, are both in the same proportion as the diameter of the tube. The suspension being thus accounted for, the seemingly spontaneous ascent will be easily solved: for since the water that enters the capillary tube, as soon as its orifice is dipped in it, has its gravity taken off by the attraction of the periphery, with which its upper surface is in contact, it must necessarily rise higher; partly by the preface of the stagnant water, and partly by the attraction of the periphery, immediately above that which is already contiguous to it. Dr. Hamilton (Lect. ii. p. 47, &c.) dissatisfied with the principle adopted by Dr. Jurin and others, supposes that the pillar of water is supported by the attraction of the annulus contiguous to the bottom of the tube. Accordingly, he observes, that when the orifice of a small glass tube, open at both ends, is dipped in water, the small annular surface of glass, on the inside of the tube contiguous to the orifice, will draw up the water lying immediately under it, and every plate of water elevated will raise up that lying above it, until the weight of the column raised counterbalance the force by which this annulus endeavours to draw up more water. The thin plate of water lying over the lowest annulus, and every other plate of the elevated water, must be attracted upwards and downwards with equal forces, because the attracting surfaces above and below it are equal; and therefore the whole column of water, lying above the lowest annulus, being drawn equally in opposite directions, may be considered as unaffected by the attraction of the glass, and must presib with its whole weight on the water retained at the orifice of the tube by the attraction of that lowest annulus, which has no other surface below it to counteract its force. Moreover, when the water has ascended into a small glass tube, open at both ends, take it up, and wiping off the drop hanging at the end of it, invert the tube; the small column of included water, being drawn equally by the glass in opposite directions, will descend by its own gravity, or stop only when it arrives at the lowest orifice. Or, whilst the included column is descending, let the lowest orifice be dipped in water, and taken up, and a small plate of water will be retained at its orifice, and then the included column will be quiescent. Now this column must, by means of the intermediate air, press with its whole weight upon the plate of water at its orifice, which can be retained by no other force than the attraction of the glass annulus, lying just within the orifice of the tube. From hence it appears, says Dr. Hamilton, that this attraction alone is sufficient to sustain, and consequently to raise all the water that rises in glass tubes. Against this reasoning Mr. Parkinson, (ubi infra) has alleged the following experiments. 1. Let a cylindrical glass tube be divided into very small equal annuli, e, f, g, d, c, &c. (fig. 4.) and a be-

ing dipped in water, a thin plate of the fluid will be detached from the mafs, which being now in contact with the second annular surface e, polelles the same power of attraction with a, n, partly at least, be raised by it; and the same will happen with the remaining annuli. And if the efforts of the intermediate annuli should be equal and opposite, which cannot be allowed, yet the superior annulus at g, would be unaffected, and its whole force be transmitted, and it must contribute, at least, towards the support of the column of water. But that each annulus should exert a force in elevating the lamina of fluid contiguous to it, and not contribute towards the support of the fluid thus elevated, is unaccountable; the power of attraction being inherent in the glass, and incapable of it. 2. Let the orifice, F, of the compound tube, EDF, (fig. 5.) be dipped in water; and it will rise to an altitude equal to a b; and if D F be filled, so that the fluid be not in contact with the narrower part, it will subside till its height be equal to a b. But let the tube be filled s, so that the fluid be admitted into the narrower part at D, the height of the column suspended will be equal to a s, though the lowest annulus continues the same. When this tube is inverted, and the orifice, E, dipped in the fluid, it rises to an altitude equal to a s, if the narrower part of the tube be so long; and if E D be less than b s, it rises into the wider tube till its height be equal to b s, the same altitude as if the tubes were cylindrical, and its diameter equal to that of the wider. If these experiments be true, it is clear that the water, rising spontaneously in glass tubes, is neither raised nor supported by the attraction of the lowest annulus.

Others have maintained, and this opinion seems to be the most unexceptionable, that the attraction is proportional to the whole surface of the glass which is in contact with the column of water; for every point or particle of that surface possesses an equal attractive power; and the preface of the suspended water is equivalent to it, or the one is a counterpoise to the other. This influence of glass, and other substances, upon fluids is scarcely perceptible beyond the immediate points of contact; nevertheless, it is clear, that a film of water of a certain thickness must be within the extent of that attractive power all round the inner surface of the tube, as high as the top of the pillar; but the rest of the water, which fills up the cavity of the tube, is attracted to that film, and is kept suspended by it, in consequence of the mutual attraction of the particles of water: yet the whole column is kept up by the attraction of the glass, and is a counterpoise to that force. Let water be kept suspended in the cylindrical glass tube, ABC D, (fig. 6.;) and let the attraction of the glass extend to the lines, E G, F H; and circles of the fluid, whose breadths are m n, r s, &c. will adhere to the surface, and certainly be supported by the immediate attraction of the glass, which is so great, that water suspended in a capillary tube will not evaporate, though exposed to the air for six or seven months: but the intermediate column, E G H F, is only supported by the adhesion of the particles of the fluid to these circles, and to the highest lamina, G H; the attraction of any intermediate lamina, L M, being the same both upwards and downwards; and when the weight of this intermediate column exceeds their accumulated force, it must descend. This seems to be certain, that the shell of particles, C E F D, is sustained by the intermediate action of the glass, which is diffused to the intermediate lamina, n p, q r, &c. by the cohesion of the particles themselves; and in this manner the forces of the opposite points, m q, and r s, conspire, which does not obtain in the forces of the particles upon the outside of the tube; and this seems to be the reason why a column of the fluid is not elevated upon
CAPILLARY TUBES.

By this dispersion of its particles they will be removed farther from each other, and their mutual attraction will be diminished; whereas, on the other hand, the attraction between the water and the glafs is increased by enlarging the surface of contact. In either of these cases, the water is attracted by the glafs only on one side; but if another piece of glafs be placed in opposition to the former, and in contact with the film of water, the water will be attracted and retained with a greater force; and if the water be on every side encompassed with glafs, or enclosed in a narrow tube, the attraction will become stronger, because the surface of contact in proportion to the quantity of water is thus considerably enlarged. The truth of these observations may be evinced in the following manner. Put water into a glafs vessel, (Plate I. Hydrophylax, fig. 1.) and the water near the face of the glafs will ascend, and form a curve, as at A and B; or the same effect will be exhibited at C and D, by dipping part of a piece of glafs in the water. In order to explain this effect, let A B, (fig. 2.) represent a section of the surface of a piece of glafs, the lower part of which is immerfed in the water, BC; and suppose this surface to be divided into a number of indefinitely small parts, a, b, c, d, &c.; then the part a, next to the surface of the water, BC, will raise a quantity of water proportional to its attractive force; which quantity is thus brought nearer to the part b of the glafs, and attracted by it, so that another quantity of water takes its place next to a. The first quantity of water being raised to b, is brought nearer to the part c of the glafs, and being attracted by it, is raised to the place e, whilst the first quantity of water a, takes its place, which is succeeded by another quantity of water which rises to the place a; so of the others. In consequence of this attraction, the water ought to form a film of equal thicknesses, or the quadrilateral figure, g, b, a, s, on the whole surface of the glafs. But by reason of the mutual attraction of the particles of water towards each other, when the first quantity of water has been raised to the place a, another quantity of water s, is kept suspended by this latter attraction, between the water at a, and that at BC. When the glafs has by its attraction raised the water to b, the part s will be extended to t, because the two quantities of water, a and b, can keep suspended a greater portion of water than the single part a. Thus, the water will ascend along the surface of the glafs, and will remain adhering to it, in such quantity as to form a counterpoise to the attraction of the glafs; or, in other words, the preffure of the water thus raised, and the attraction between it and the water, BC, will form by their united actions a counterpoise to the attraction of the glafs. The real ascents of the water, which, in the figure we have referred to, has been enlarged for the better illustration of the subject, seldom exceed about 1/25th of an inch, when the glafs is either flat, or not much bent. But this altitude is increafed by a variety of circumstances; viz. by the temperature and purity of the water, by the quality of the glafs, and chiefly by the polish and cleanliness of its surface.

In small tubes of different diameters, the perpendicular ascent of water, and of various other fluids, will be inversely as their respective diameters. Thus, if glafs tubes opened at both ends be immured with their lower apertures in water, (see fig. 3.) the water will instantly rise spontaneously into their mincy cup, and it has been found to rise higher in a greater velocity in narrower than in larger tubes, according to the proportion in which the diameters of the larger tubes exceed those of the smaller; and the altitude in a tube of about 5 3 inches. Correspondingly, in a tube of 0.02 in diameter, the altitude of the water will be the half of 5.3, viz. 2.65 inches. Also, in a tube whose diameter is 0.1 of an inch, or 100 times 0.01, the altitude of the water will be the 10th part of 5.3, or 0.53 of an inch, &c. Hence it follows, that if we call the diameters of the tubes D, d, and the altitudes of the water A, a, we shall have, D : d :: a : A, and D x A = a : D that is, the product of the diameter by the altitude of the water is always the same, or the constant quantity 0.053 of an inch; for when the diameter is 0.01 of an inch, the water rises to the altitude of 5.3 inches; and 5.3 x 0.01 is equal to 0.053 = 0.02 x 2.65 = 0.01 x 0.53. If, therefore, you wish to know how high the water will rise in a tube of a given diameter, it is only necessary to divide 0.053 by the diameter, and the quotient expresses the altitude in inches, very nearly; for allowance must be made for difference of temperature, the nature and cleanliness of the glafs, &c. which influence the altitude. Moreover, since the surface of a cylinder is as the product of the diameter multiplied by the axis, or the altitude, and it has been already shown, that in the part of the tube occupied by the water, the product of the diameter by the altitude is a constant quantity, the surface of the glafs which is in contact with such a pillar of water, is likewise a constant quantity.

Mr. Atwood, in his "Analysis," has given the following method of very accurately determining the diameter of a capillary tube. Put into the tube some mercury, whose weight in grains is w, and let it occupy a length of the tube l: then, if 13.6 be the specific gravity of mercury, as it is when in its pure flat state, that of water being 1, the diameter will be \[ \sqrt{\frac{w}{l}} \times 0.1923. \] For let d be the diameter, and the contents of the mercury will be \( d^2 \times 7.854 \) and as one cubic inch of mercury weighs 3443 grains, we have \( 1 \times 3443 = d^2 \times 7.854 = w \); hence we shall have \( d^2 = \frac{w}{7.854} = \frac{1}{3443} \). Therefore, \( d = \sqrt{\frac{w}{7.854}} \), and \( d^2 = \sqrt{\frac{1}{3443}} \). And \( \sqrt{\frac{w}{l}} \times \sqrt{\frac{1}{2704.1332}} = \sqrt{\frac{w}{l}} \times \sqrt{\frac{1}{2704.1332}} \times \sqrt{\frac{1}{2704.1332}} = \sqrt{\frac{w}{l}} \times 0.1923. \)

Several ingenious persons, who, in examining the phenomena of capillary attraction, have found that the bulks of the suspended pillars of water are not proportional to the surfaces of glafs with which they are in contact, have been embarrased in explaining them; and for this purpose they have adopted various hypotheses. Some have supposed that the unequal preffure of the air upon the liquor contained in the tube and that in the vessel is the cause of the ascent in the tube. In order to account for this inequality, some have had recourse to the magnitude of the particles of the air and of the ascending fluid; others have conceived, that only an inverted cone of air, touching the surface of the liquor in the tube with its vertex, and having the upper orifice of its tube for its base, could pres upon the surface contiguous to its vertex. Dr. Hook supposed that part of the preffure of the air in the tube was taken off by its friction, which he apprehends must necessarily happen against the sides in so narrow a passage; and this hypothesis of Dr. Hook was for a long time very generally received. Those who wish to see his elusion of it may find it in the 6th Observation of his "Micrography," or in Cotes's Hydrodynamical and Pneumatical Lectures, "ubi infra." But since it has
has been observed, that the same sacci of liquors in capillary tubes occurs in vacuo as in the open air; this hypothesis of an inequality of pressure has been relinquished; and the solution of the difficulty has been sought for in the mutual attraction of the particles of fluids and those of glafs. Mr. HawkbeC, and others, have recourse to the attraction of the annulus of the concave surface of the tube. Dr. Jurin (Phil. Trans. No. 555, and No. 573, or Atr. vol. iv. p. 473, &c.) described the suspension of the water to the attraction of the small annular portion, or periphery of the inside of the tube, to which the upper surface of the water is contiguous and adheres; this being the only part of the tube, from which the water must recede upon its fulfulness, and consequently, the only one which, by the force of its cohesion and attraction, counteracts the gravity of the water, and opposes its descent. This he shews to be a cause proportional to the effect; because the periphery, and the suspended column, are both in the same proportion as the diameter of the tube. The suspension being thus accounted for, the seemingly spontaneus accent will be easily solved: for since the water that enters the capillary tube, as soon as its orifice is dipped in it, has its gravity taken off by the attraction of the periphery, with which its upper surface is in contact, it must necessarily rise higher; partly by the preface of the lagant water, and partly by the attraction of the periphery, immediately above that which is already contiguous to it. Dr. Hamilton, (Lett. ii. p. 47, &c.) dissatisfied with the principle adopted by Dr. Jurin and others, supposes that the pillar of water is supported by the attraction of the annulus contiguous to the bottom of the tube. Accordingly, he observs, that when the orifice of a small glafs tube, open at both ends, is dipped in water, the small annular surface of glafs, on the inside of the tube contiguous to the orifice, will draw up the water lying immediately under it, and every plate of water elevated will raise up that lying above it, until the weight of the column raised counterbalance the force by which this annulus endeavours to draw up more water. The thin plate of water lying over the lowest annulus, and every other plate of the elevated water, must be attracted upwards and downwards with equal forces, because the attracting surfaces above and below it are equal; and therefore the whole column of water, lying above the lowest annulus, being drawn equally in opposite directions, may be considered as unaffected by the attraction of the glafs, and must pres with its whole weight on the water retained at the orifice of the tube by the attraction of that lowest annulus, which has no other surface below it to counteract its force. Moreover, when the water has ascended into a small glafs tube, open at both ends, take it up, and wiping off the dip hanging at the end of it, invert the tube; the small column of included water, being drawn equally by the glafs in opposite directions, will depend by its own gravity, or stop only when it arrives at the lowest orifice. Or, whilst the included column is descending, let the lowest orifice be dipped in water, and taken up, and a small plate of water will be retained at its orifice, and then the included column will be quiescent. Now this column must, by means of the intermediate air, pres with its whole weight upon the plate of water at its orifice, which can be retained by no other force than the attraction of the glafs annulus, lying just within the orifice of the tube. From hence it appears, says Dr. Hamilton, that this attraction alone is sufficient to sustain, and consequently to raise all the water that rises in glafs tubes. Against this reasoning Mr. Parkinson (ubi infra) has alleged the following experiments. 1. Let a cylindrical glafs tube be divided into very small equal annuli, $a, b, c, d, e, &c.$ (fig. 4.) and a be

ing dipped in water, a thin plate of the fluid will be detached from the mafs, which being now in contact with the second annular surface $b$, positfes the same power of attraction with $a$, mainly at least, be raised by it; and the same may be observed in the case of the annuli with the remaining annuli. And if the efforts of the intermediate annuli should be equal and opposite, which cannot be allowed, yet the upper annuli at $g$, would be unaffected, and its whole force remain, and it must contribute, at least, towards the support of the column of water. But that each annulus should exert a force in elevating the lamina of fluid contiguous to it, and not contribute towards the support of the fluid thus elevated, is unaccountable; the power of attraction being inherent in the glafs, and inerasable from it. 2. Let the orifice, $F$, of the compound tube, $E D F$, (fig. 5.) be dipped in water, and it will rise to an altitude equal to $g b$; and if $D F$ be filled, so that the fluid be not in contact with the narrower part, it will subside till its height be equal to $g b$. But let the tube be filled so that the fluid be admitted into the narrower part at $D$, the height of the column suspended will be equal to $a$, though the lowest annulus continues the same. When this tube is inverted, and the orifice, $E$, dipped in the fluid, it rises to an altitude equal to $a$, if the narrower part of the tube be so long; and if $E D$ be less than $b g$, it rises into the wider tube till its height be equal to $b g$, the same altitude as if the tubes were cylindrical, and its diameter equal to that of the wider. If these experiments be true, it is clear that the water, rising spontaneously in glafs tubes, is neither raised nor supported by the attraction of the lowest annulus.

Others have maintained, and this opinion seems to be the most unexceptionable, that the attraction is proportional to the whole surface of the glafs which is in contact with the column of water; for every point or particle of that surface possesses an equal attractive power; and the preface of the suspended water is equivalent to it, or the one is a counterpoise to the other. This influence of glafs, and other substances, upon fluids is scarcely perceptible beyond the intermediate points of contact; nevertheless, it is clear, that a film of water of a certain thickness must be within the extent of that attractive power all round the inner surface of the tube, as high as the top of the pillar; but the rest of the water, which fills up the cavity of the tube, is attracted to that film, and is kept suspended by it, in consequence of the mutual attraction of the particles of water: yet the whole column is kept up by the attraction of the glafs, and is a counterpoise to that force. Let water be kept suspended in the cylindrical glafs tube, $A B C D$, (fig. 6;) and let the attraction of the glafs extend to the lines, $E G, F H$; and circles of the fluid, whose breadths are $m n, r s, &c.$ will adhere to the surface, and certainly be supported by the intermediate attraction of the glafs, which is so great, that water suspended in a capillary tube will not evaporate, though exposed to the air for six or seven months: but the intermediate column, $E G H F$, is only supported by the adhesion of the particles of the fluid to these circles, and to the highest lamina, $G H$; the attraction of any intermediate lamina, $L M$, being the same both upwards and downwards; and when the weight of this intermediate column exceeds their accumulated force, it must descend. This seems to be certain, that the shell of particles, $C E F D$, is sustained by the intermediate attraction of the glafs, which is diffused to the intermediate lamina, $p q, r s, &c.$ by the cohesion of the particles themselves; and in this manner the forces of the opposite points, $m q$, and $r s$, confpire, which does not obtain in the forces of the particles upon the outside of the tube; and this seems to be the reason why a column of the fluid is not elevated upon
CAPILLARY TUBES.

upon the outside, as it is within. Upon the whole it appears, that the pressure of the column of water in the tube is equivalent, or it is a counterpoise, to the attractive force of the surface of the glass, which is in contact with it; and of course it is proportional to that surface. But if we omit the quantity of that counterpoise, or of the pressure of the column of water, we must take into the account not only the quantity, but also the altitude; because, ceteris paribus, fluids prefs in proportion to their perpendicular altitudes; and when the base varies, as in different cylindrical pillars, the preffures are as the products of the quantity of matter by the altitude of each pillar respectively. Therefore the pressure of the pillar of water in a glass tube, which is a counterpoise to the attraction of the glass, is the product of the quantity of water by the altitude; and in cylindrical tubes, this product is always proportional to the surface of glass in contact with water. Having already shown, that this surface is a constant quantity, it follows, that the product of the quantity of water by the altitude of the pillar must likewise be a constant quantity; since it is as the above-mentioned surface. In order to illustrate this by an example; let the inside of the diameter of a tube, B C, (fig. 7.) be double that of the tube, D F; then the pillar of water, E F, will be two inches high when the pillar, A C, is one inch high. Since the contents of cylinders of the same altitude are as the squares of their respective diameters, and their surfaces are as their diameters, it is easily calculated that if the quantity of water in the pillar, E F, weighs two grains, that of A C will weigh four grains; and likewise that the surface of glass in contact with the pillar of water, E F, is equal to the surface of glass which is in contact with the pillar of water, A C; hence it should seem that those equal surfaces ought to keep suspended equal quantities of water; whereas the quantity of water, E F, is the half of the quantity of water, A C; but the height of the pillar of water, E F, is double that of the pillar, A C; and consequently, its pressure, which is equal to the product of the quantity of water by the altitude (viz. two grains by two inches) is equal to the pressure of the column, A C, viz. the product of four grains by one inch.

If a tube confluent of two cylinders, one E F, (fig. 8.) whose diameter is equal to that of the tube, A B, in which the water would rife to the height A B, and the other, a larger part, C D, whose diameter is equal to that of the tube, G H, in which the water would rife to the height G H; and if this compound tube be placed with the narrow aperture in water, as at F, the water will not rife in it higher than the altitude G H, i.e. to the same altitude to which it would rife if the tube were an uniform cylinder of the diameter of the large part. It might, indeed, he expected, that the water would rife higher than D, G; but it must be considered that though the product of the pillar of water, E F, by its altitude is less than a just counterpoise to the attraction of the surface, E F, of the glass; yet the excess of attraction of that surface, instead of aiding to support the water in C E, will operate in a contrary way: that is, if we flate the attraction of the surface, E F, equal to 10, and if the preffure of the pillar of water in it be equal to 8; then the two remaining parts of attractive power will tend to draw the water from the bafoon as much as from the cavity, D E, towards the surface, E F; so that by the addition of the narrow tube, E F, the attraction of the larger part, D I, is diminished; at the same time that the water in it is partially supported by what may be called its perforated bafe, E I.

If a compound tube confluent of a larger part, L N, (fig. 8.) in which the water would rife spontaneously to the altitude, M, and of a narrower part, O K, equal in diameter to the tube, A B, in which the water would rife to the height A B, be filled with water as high as K, and then be placed with the large aperture in water as at N, the whole quantity of water will remain suspended; filling the whole of the large tube and part of the narrow one. The same thing will also take place with a vesel of any shape, as P Q S; provided its upper part be drawn into a narrow cylinder equal in diameter to the tube, A B. In these vesels the water is supported partly by the attraction of cohesion, and partly by the pressure of the atmosphere. That the pressure of the atmosphere contributes in a great degree to this effect is evident, because the water will not rife spontaneoufly into the vesels, O N, P S, to the heights K and P, and also because if these vesels full of water as high as P, K, together with the bafoon, be placed under the receiver of an air-pump, on exhausting the receiver of air or removing the pressure of the atmosphere, the water will descend in them, and will remain in them only as high as it would ascend spontaneoufly. Mr. Cavallo (ubi infra) has illustrated the mode by which water is supported in these vesels; and for this purpose he has calculated, that if the diameter of the aperture, P, be 0.004 of an inch, which will be nearly the case when the perpendicular altitude, P Q, of the water is 1 foot, the whole preffure of the atmosphere on the surface of the water in the tube at P, will be little more than one grain; and as the atmosphere preffures upon that surface with only the 32d part of its entire force, the perpendicular height of the water in the vesel, P Q S, being one foot, the actual preffure of the atmosphere on the surface of the water at P S will be 87/4 of a grain nearly. But this trilling preffure not being sufficient to overcome the attraction between the water and the surface of the tube, P, the water must remain suspended in the vesels, P Q S, or O N. The following experiment corroborates this explanation. Fill the vesels, O N, or P Q S, up to the height, T, by lowering them in the water of the bafoon; and in that situation touch the aperture, O, or P, with a wet finger, so as to introduce a little water into it. Then if the vesel be drawn up, leaving its lower aperture only in the water of the bafoon, the column of water, T N, or T Q, will remain suspended in it, though there be no communication whatever between the water at T, and the water in the capillary aperture.

The altitudes of water, suspended in compound tubes, vary inversely as the diameters of the upper orifices nearly. E.G. In open cylindrical tubes, whose diameters are equal to those of the different parts, A B, and C, (fig. 9.) of the compound tube, A B C, water rifies spontaneously to altitudes equal to g r, and g s, which are inversely as their diameters nearly. Whether the orifice, A or C, be immersed in the fluid, it rifies to the altitude, g r; but if the tube be filled, so that the water may be in contact with the narrow part of the tube, C, the whole column will be suspended, if its altitude does not exceed g t. Again, let a f, and b g, (fig. 10.) be the altitudes of water railed spontaneously in the open cylindrical tubes, E D, and D F, respectively, which are inversely as their diameters. When the wider orifice is immersed, and the tube is filled with water to an altitude less than the length of the wider part, it will subside to a level with the point, g: but if the water be admitted into the narrower tube, the whole column will be suspended if its length does not exceed a f. If the tube be inverted, and the narrower orifice immersed, and water railed into the tube, D F, it immediately sinks, if the altitude of the column exceed b g. Let a d e, (fig. 11.) be a capillary siphon, in whose narrower and wider legs, if sufficiently long, columns of water, whose altitudes are e f, and g b, respectively, and which are inversely as their diameters, may be suspended.
CAPILLARY TUBES.

Fill this fion with water, and hold it in the position of fig. 11; and the fluid will not run out of the orifice, if the liquid be not of such a nature as to form a small angle with the edges of the plate, or the fluid be not of such a nature as to be easily attracted by the edges of the plate. The fluid will flow out of the orifice, if the liquid be not of such a nature as to form a small angle with the edges of the plate, or the fluid be not of such a nature as to be easily attracted by the edges of the plate.

Capillary tubes which naturally discharge water only in separate drops, yield, when electrified, a continued and accelerated stream; and the acceleration is proportional to the smallness of the tube; and the effect of electricity is so considerable as to produce a continued stream from a very small tube, out of which the water had before been able to drop. Priestley's Phil. Electr. 8vo, vol. 1, p. 171.

In connection with the preceding account of capillary tubes we shall here introduce that of contiguous glass plates, between which water rises according to the same law with that of fuch tubes, or in such a manner that the altitudes are inversely as the distances of the plates. E. G. If the glass plates be parallel to each other and placed with their lower edges in water, the water will rise between them, and will remain suspended at a certain height. This height is not so great as that of the water in a glass tube, whose diameter is equal to the distance between the two plates, for an obvious reason; because the water in the tube is surrounded on every side by glass; nevertheless the proportion is the same; i. e. in two or more pairs of glass plates, the altitudes of the water are inversely as the distances of the plates, and the cause of the ascent is the same as in glass tubes. A C D F and B C D E, (fig. 13.) represent two flat glass plates, placed so as to form a small angle, A C B, and immersed with their lower edges in water. The water will rise between them, and remain suspended in the space E F C D E, the outer edge of which, E F C, being a curve called an "hyperbola." One extremity of this curve rises as high as the upper part of the glass plates at C, and the other extremity reaches as far as the edges of the glasses contiguous to the water of the basin at F and E. The water between these plates rises higher near the side, C D; and lower at a distance from it. In short, at any distance from C D, as at a b, c d, e f, the water rises as high as it would rise between parallel plates, whose distance from each other equals the distance between the plates of fig. 15, at any of those particular places. Consequently the altitudes of the water at different distances from C D, are inversely as the distances between the two plates at those places. In fig. 14, which exhibits the same elevation of water with that which is represented in fig. 13, any two, or more, altitudes of water, as a b and c d, are inversely as the distances a b, c d, between the two plates at those places; viz. a b : c d :: d e : b i, (by the similarity of the triangles D b t, D d i) D b : D d i, and this is the known property of the common hyperbola, whose asymptotes are the edge, C D, of the glasses, and the line, D S, where the glass plate intersects the surface of the water in the vessel, G. The water must evidently rise as high as the apex, C, whatever be the altitude of the plates, since the glasses plates come infinitely near each other near the edge, C D. If these plates were bent more or less, then the edge of the water which rises between them would not be an hyperbola, but very according to the curvature of the plates. Let two flat glass plates be disposed, as in fig. 15, so as to form a small angle with each other, as in the former case; and the water will rise between them to a small angle with the horizon, having the edge, B, a little elevated. Let them be separated at C E by the interposition of some thin body, and previously moistened with water; and if a drop of water be introduced between these plates at E C, so as to touch them both, it will move spontaneously towards the upper part of the plates, as far as the edge, A B. The drop of water moves towards the edge, A B, even against the direction of its gravity; because the attraction of the glasses towards the drop is stronger where the plates are closer to each other, as at A, than where they are further apart, as at E; so that the drop at A, is more powerfully attracted towards A, than towards E. If the drop, A B, be gradually raised higher and higher above the horizon, whilst the drop is moving, it will be perceived to move forward and downward towards A B, until at last the gravity of the drop balances the attraction of the glasses, and the water remains at rest. After which, if the edge, A B, be raised still higher, the weight of the drop being greater than the attraction of the glasses, will cause it to descend towards C E.

Phenomena of attraction, similar to those already illustrated in the case of glasses and water, take place between almost every fluid and every solid; even between fluids and solids, or solids and solids. However, a considerable difference results from the different degrees of force with which the particles of each body attract either another, or those of another body. The attraction of water to glafs is greater than the mutual attraction of its own particles; it is also greater than that of any other fluid towards glafs, not excepting even spirituous liquors, which are specifically lighter than water; and hence it is, that water rises higher in capillary tubes than any other liquor. Müschenbrock, Martin, and other writers have given tables of the heights to which different fluids ascend in capillary tubes. It is owing to this capillary attraction, that water rises through the fine veils of wood, and ascends to the tops of the highest trees; that it infuses itself through the pores of certain stones, through sand, sugsar, silt, &c. and that in damp weather, when the air deposits a considerable quantity of water, wood, glue, ropes, linen, paper, parchment, salts, &c. imbibe the water, and are thereby swelled, moistened, softened, and some of them actually dissolved. Hence it is that metals in a fluid state rise and spread themselves between the contiguous surfaces of other metals that are in a solid state; and this is the foundation of the art of fodingerling metals. Hence also mercury infuses itself through the pores of gold and tin; for the particles of mercury attract one another much less than they do those of gold or tin. See Ascent of Fluids. See also Adhesion and Cohesion.

If glafs be applied to any other fluid, whose particles attract each other more strongly than glafs attracts them, all the phenomena of such a fluid in Capillary tubes, and between glafs plates, will be the reverse of those pertaining to water. Quicksilver is such a fluid; and, therefore, if a small globule of quicksilver be laid upon clean paper, and a piece of glafs be brought into contact with it, the mercury will adhere to it, and will be drawn away from the paper; but if, whilst the small globule of quicksilver is thus adhering to the glafs, a large quantity of the same fluid be brought in contact with the small globule, the latter will immediately difengage itself from the glafs, and incorporate with the other matter. We here perceive that a greater degree of attraction subsists between the particles of mercury than between them and glafs, so that it is impossible to spread quicksilver, like water, over the surface of glafs. If quicksilver be put in a glafs, and any wooden or earthen vessel, more than an inch in width, the surface of the quicksilver will be horizontal towards the middle, but convex towards the side. If an iron ball be laid upon the quicksilver, a depression of the quicksilver will be observed all round the ball; if two such balls be placed upon quicksilver, not very far asunder, they will run towards each other; be-
C A P

nate, where the cavities or depressions of the quicksilver are joined either between the ball and the side of the vessel, or between the two balls, there the prejudice of the quicksilver upon the ball, or balls, is diminished by the attraction of the quicksilver below; and of course the balls are impelled that way by the superior prejudice on the opposite sides. If a small tube, (fig. 15) open at both ends, be partly immersed in mercury, the mercury will be found to stand lower within the tube than in the vessel; and this prejudice has been found to be inverts as the diameter of the tubes. Thus, if two tubes are immersed in quicksilver, and the diameter of one is double that of the other, then the difference of perpendicular altitudes between the surface of the quicksilver in the latter tube and in the bason, will be double to the like difference with the former tube. As quicksilver is an opaque body, it will be necessary to hold the tube A B near the side of the vessel, which is supposed to be of glass, in order to render the depression of the quicksilver within the tube perceptible. The same thing takes place between parallel glass plates. If they be immersed in quicksilver, this fluid will stand lower between them than in the other part of the vessel; and the depression is likewise as the distances between the plates. If the plates be situated so as to form a small angle, the quicksilver, rising near the angular edge than at a distance from it, will form a curve, which is an hyperbola, whose asymptotes are the perpendicular edge, or line of the junction of the glasse, and the level of the mercury in the bason. If a glass plate be laid in an horizontal situation, with a pretty large drop of quicksilver near one edge of it, as in fig. 17, which represents a section of it, and another glass plate, A B, be laid so as to form a small angle with it, and at the same time to comprize the drop of quicksilver, the latter will move spontaneously towards O, i.e. towards the aperture of the angle, in order to recover its globular figure. If a tube open at both ends, be having its lower end drawn out into a fine capillary aperture, be filled with quicksilver to the altitude of about an inch or two, no mercury will escape from the lower aperture; but if this lower extremity be suffered to touch other mercury, or if, by breaking off part of the small end, the aperture be enlarged, the quicksilver will readily run out. For other particulars relating to this subject; see the articles to which we have already referred. Mufchenbrock, Introdt. at Phil. Nat. tom. i. c. 20. Gravelfand. l. i. e 5. Helphen, Leift. i. ii. Capillary vesicles, in Anatomy, the most minute and subtle ramifications of the vesicles of animal bodies. Many small vesicles of animal bodies have been discovered by the modern invention of injecting the vesicles of animals with a coloured fluid, which upon cooling grows hard. See Injuncton. Capillary worms, in children, are the same with what are otherwise called crinones, comedones, and dracunculi.

Capillation, or Capillary fractures, according to some writers, is a fracture in the skull, so small that it can scarcely be perceived; but yet it often proves mortal. See Fracture.

Capillitium Veneris, in Physiology, denotes a meteor appearing in the air, in form of fine threads resembling a spider's web. Some think that the capillitium Veneris derives its origin from a cloud, the watery parts of which have been exhaled by the sun's heat, only the earthy and sulphurous parts are left behind, which shoot into this figure. It is sometimes also found hanging about woods and coppices, or even extended on the ground like a fine net, frequently enough mistaken for spiders' webs.

Capillus, See Hair.

Capillus Veneris, in Botany, See Adiantum Capillus Veneris.

Capilupi, Lelio, Camillo, Ippolito, and Julio, in Biography, natives of Mantua and distinquished as modern Latin poets. Lelio, who is said to have died in his native place in 1560, at the age of 62 years, excelled in the composition of cantos, and applied some of the verses of Virgil to a description of the modes of life in monasteries, and of the vernacular clesse. Camillo wrote a book entitled "The Stratagem," in which he gives an account of the massacre at Paris on St. Bartholomew's day: he was not only distinquished as a poet, but employed in several embassies. He died in 1548. Ippolito, the third brother, was born in 1511, occupied several poetical dignities, and whhil he was first secretary and minister at Rome of cardinal Hercules and D. Ferrante Gozzana, wrote letters to both, several of which are extant. The most interesting are those that relate to the war of Parma and Mirandola carried on by pope Julius III., and they display much skill in negotiation and great zeal in the service of his master. In 1560 he was promoted to the bishopric of Fano by Pius IV. and in the following year deputed as his nuncio to Venice. He died at Rome in 1598. Julio, the nephew of the former, is said to have surpassed his uncle Lelio in the composition of cantos. Some have said that Ippolito excelled in fictirical poetry; but others affirm that he, as well as Julio and Camillo, excelled in the elegiac. The "Virgilian canto of the lives of Monks" was printed at Basili in 1525; and Meibomius published "Julii et Lelii Capiluporum patrum Centos Virgiliani, &c." at Helmfpadt, in 4to. 1600. The "Carmina corundem," appeared at Rome, 4to. 1577. The poems of the other brothers are printed in the first volume of the Delicte Poesarum Italorum. Gen. Dict. Tiraabolchi.

Capinero, in Ornithology, one of the synonyms of Motacilla Atricapilla, being the name affinged it by Olina.

Capiplenium, from caput, head, and plerus, full, is used by some authors for a catarh; but more properly, by the Italian physicians, for a continual heaves of the head, frequent at Rome, and almost endemic.

Capiro, in Geography, a mountain of South America, being one of those that surround the harbour of Porto Bello, flanks at the utmost extremity of the harbour in the road to Panama. Its top is always covered with clouds of a density and darknesse seldom seen in those of this atmosphere; and from these, which are called the "Capillo," or cap, has poibably been corruptly formed the name of Monte Capiro. When these clouds thicken, increase in blacknes, and flink below their usual station, it is a sure sign of a tempest. Whereas on the other hand, their clearnes and ascent as certainly indicate the approach of fair weather. These changes are very frequent and very sudden; and the summit of the mountain is seldom observed free from clouds. Hence Capiro is regarded as the barometer of the country, by foctelling every change of weather.

Capisculos, or Capiscolum, in Ecclesiastical Writers, denotes a dignitary in certain cathedrals, who had the superintendence of the choir, or band of music, answer- ing to what in other churches is called chanter or preacher. The word is also written capisculus, and capuscullus, q. d. the head of the school or band of music. The capisculus is also called soiulisus, as having the instruction of the young clerks and choristers, how to perform their duty.

Capiass,
CAPITAM, or the Latin caput, is used on various occasions to express the relation of a head, chief, or principal: thus...

CAPITAM, in Geography, a small place, with a principality, of Naples, in the province of Abbruzzo Ultra.

CAPISTRATUS, in Ichthyology, a species of Caroton, with entire tail; twelve spines in the dorsal fin; body frizzled; and an occelated spot near the tail.

This fish has the head rather large, with eyes of considerable size; a black oval band with white margin; fins yellowish, with branched rays; dorsal and anal fin bordered with brown; and a black band near the caudal fin.

CAPISTRUM, Lat. a bandage used by performers on trumpets and other wind instruments among the ancients, to keep the cheeks and lips firm, and to prevent the distorsion of the countenance. It was called σφέκτα, or τρίφατον, by the Greeks, and is supposed to have been invented by Merytas. It is mentioned in Putharch's Syntagma, in the Scholia of Aristotle, and elsewhere, and may be seen in some ancient sculpture which Bartholomus has had engraved in his treatise De Tribus Veterum... 

CAPISTRUM, in Surgery, a head-flail, or bandage used in case of injuries of the head, especially fractures of the jaw.

CAPITA, or CAPITUM, in Antiquity, denotes a tax among the Romans for the maintenance of the horses in the army, levied according to the number of heads thereof.

CAPITA, distribution by, in the Civil Law, is such a distribution, that every man has an equal share of personal estate, when all the claimants claim in their own rights, as in equal degree of kindred, and not jure representationis, in the right of another person. This mode of distribution is contradistinguished from a distribution per stirpes, which is the only rule of succession according to the common law. Thus, if the next of kin be the intestate's three brothers, A, B, and C; here his effects are divided into three equal portions, and distributed per capita, one to each; but if one of these brothers, A, had been dead, leaving three children, and another...
But if a capital be employed in the improvement of land, in the purchase of useful machines and instruments of trade, or in similar things which yield a profit without changing matters, or circulating any farther; this kind of capital may be called a fixed capital. Every fixed capital is originally derived from, and requires to be continually supported by a circulating capital: nor can the former yield any revenue but by means of the latter. The circulating capital also in its turn requires fresh supplies, without which it would soon cease to exist; and these supplies are principally drawn from three sources, viz. the produce of land, that of mines, and that of fisheries. The cultivation of which requires both a fixed and a circulating capital, and yields a profit, when their natural fertility is equal, proportional to the extent and proper application of the capitals employed about them; or, if the capitals are equal, and equally well applied, proportional to their natural fertility. The intention of the fixed capital is to increase the productive powers of labour, or to enable the same number of labourers to perform a much greater quantity of work. In a great country, the expense of maintaining a fixed capital may be compared to that of repairs in a private estate; and is the necessarily excluded from the next revenue of the society. But the cafe is different with respect to that which maintains the circulating capital. Of the four parts of which this latter capital is composed, viz. money, provisions, materials, and finished work, the last are regularly withdrawn from it, and placed either in the fixed capital of the society, or in their stock referred for immediate consumption. Whatever portion of these consumable goods is not employed in maintaining the former, goes altogether to the latter, and forms a part of the next revenue of the society. In this respect the circulating capital of a society is different from that of an individual; the latter is totally excluded from making any part of his next revenue, which must consist wholly in his profits. But though the circulating capital of every individual makes a part of that of the society to which he belongs, it is not on that account totally excluded from making a part likewise of their next revenue. Although the whole goods in a merchant's warehouse or shop may be so means be placed in his own stock, referred for immediate consumption, they may be so placed in that of other people, who, from a revenue derived from other funds, may regularly replace their value to him, together with its profits, without occasions any diminution either of his capital or of theirs. Money, therefore, is the only part of the circulating capital of a society, of which the maintenance can occasion any diminution in their next revenue. The fixed capital, and that part of the circulating capital which consists in money, so far as they affect the revenue of the society, bear a very great resemblance to one another. See Money. When we compare the quantity of industry which the circulating capital of any society can employ, we must always have regard to those parts of it only, which consist in provisions, materials, and finished work; the other, which consists in money, and which serves only to circulate those three, must always be deducted. Money may be requisite for purchasing the materials and tools of the work, as well as the maintenance of the workmen. But the quantity of industry which the whole capital can employ, is certainly not equal both to the money which purchases, and to the materials, tools, and maintenance, which are purchased with it; but only to one or other of these two values, and to the latter more properly than to the former. Smith's Wealth of Nations, vol. i.

For the extension of capitals by the aid of banks and paper-credit; see Bank and Paper-Money.

CAPITAL, in Money Matters, denotes the sum of money put out to interest. In which sense it amounts to the same with principal, and stands opposed to interest. The borrower may use it either as a capital, yielding a certain annual rent to the lender, or as a stock referred for immediate consumption. If he uses it as a capital, he employs it in the maintenance of productive labourers, who reproduce the value with a profit; in which case he will be able both to restore the capital and pay the interest without alienating or encroaching upon any other source of revenue. But if he uses it as a stock referred for immediate consumption, he acts the part of a prodigal, and dissipates in the maintenance of the idle, what was defined for the support of the industrious; and in this case, he can never restore the capital nor pay the interest, without either alienating or encroaching upon some other source of revenue, such as the property or the rent of land. What the borrower in either of these ways really wants, and what the lender readily supplies him with, is not the money, but the money's worth, or the goods which it can purchase. If he wants it as a stock for immediate consumption, it is those goods only which he can place in that stock. If he wants it as a capital for employing industry, it is from those goods only that the industrious can be furnished with the tools, materials, and maintenance, necessary for carrying on their work. By means of the loan, the lender, as it were, assigns to the borrower his right to a certain portion of the annual produce of the land and labour of the country, to be employed as the borrower pleases. It is the value of that part of the annual produce, which, as soon as it comes from the ground, or from the hands of the productive labourers, is defined not only for replacing a capital, but such a capital as the owner does not care to be at the trouble of employing himself, that regulates the quantity of stock, or of money, which can be lent at interest in any country. As such capitals are commonly lent out and paid back in money, they constitute what is called the monied interest; which fee.

These capitals may be greater in almost any proportion than the amount of the money which serves as the instrument of their conveyance; the same pieces of money successively serving for many different loans, as well as for many different purchases. Hence, a capital lent at interest may, in this manner, be considered as an assignment from the lender to the borrower of a certain considerable portion of the annual produce; upon condition that the borrower in return shall, during the continuance of the loan, annually affsign to the lender a smaller portion, called the interest; and at the end of it, a portion equally considerable with that which had been originally assigned to him, called the repayment. In proportion as the share of the annual produce which, as soon as it comes either from the ground, or from the hands of the productive labourers, is defined for replacing a capital, increases in any country, what is called the "Monied Interest" naturally increases with it. The increase of those particular capitals from which the owners with to derive a revenue, without being at the trouble of employing them themselves, naturally accompanies the general increase of capitals; or, in other words, as stock increases, the quantity of stock to be lent at interest grows gradually greater and greater. As capitals increase in any country, the profits which can be made by employing them necessarily diminish; and it becomes gradually more and more difficult to find within the country a profitable method of employing any new capital. In consequence of this there arises a competition between different capitals; the owner of one endeavouring to get possession of that employment which is occupied by another. The demand for productive labour, by the increase of the funds which are defined for maintaining it, grows every day
day greater and greater; so that labourers easily find employment, while the owners of capitals find it difficult to get labourers to employ. This competition raises the wages of labour, and sinks the profit of stock. But when the profits which can be made by the use of a capital are thus diminished, as it were, at both ends, the price which can be paid for the use of it, that is, the rate of interest, must necessarily be diminished with them. See Interest.

All capitals are defined for the maintenance of productive labour only; and yet the quantity of such labour, produced by equal capitals, varies very much according to the diversity of their employment; which is also the case with respect to the value added by that employment to the annual produce of the land and labour of the country.

A capital may be employed in four different ways; either, first, in procuring the rude produce annually required for the use and consumption of the society; or, secondly, in manufacturing and that rude produce for immediate use and consumption; or, thirdly, in transporting either the rude or manufactured produce from the places where they abound to those where they are wanted; or, lastly, in dividing particular portions of either into such small parcels as suit the occasional demands of those who want them. In the fifth of these ways are employed the capitals of all those who undertake the improvement or cultivation of lands, mines, or fisheries: in the second, those of all smaller manufacturers; in the third, those of all wholesale merchants; and in the fourth, those of all retailers. Each of these methods of employing a capital is essentially necessary either to the existence or extension of the other three, or to the general conveniency of the society. The persons whose capitals are employed in any of these four ways are themselves productive labourers. Equal capitals, however, thus employed, put into motion very different quantities of productive labour, and augment also in very different proportions the value of the annual produce of the land and labour of the society to which they belong. But no equal capital puts into motion a greater quantity of productive labour than that of the farmer; and, of course, the capital employed in agriculture adds a much greater value to the annual produce of the land and labour of the country, and to the real wealth and revenue of its inhabitants. Consequentially, of all the ways in which a capital can be employed, this is by far the most advantageous to the society. The capitals employed in the agriculture and in the retail trade of any community must always reside within that community. Whereas the capital of a wholesale merchant seems to have no fixed or necessary residence anywhere, but may wander about from place to place according as it can either buy cheap or sell dear. The capital of the manufacturer must reside where the manufacture is carried on; but where this shall be is not always necessarily determined. It may frequently be at a great distance from the place where the materials grow; and from that where the complete manufacture is continued. Thus, part of the wool of Spain is manufactured in Great Britain, and some part of that cloth is afterwards sent back to Spain. The same observation applies to the cotton manufacture. Whether the merchant whose capital exports the surplus produce of any society be a native or a foreigner, is of very little importance; but it is of great consequence, that the capital of the manufacturer should reside within the country. It may, however, be very useful to the country, though it should not reside within it. The capitals of the British manufacturers, who work up the hemp and flax annually imported from the coasts of the Baltic, are without doubt very useful to the countries which produce them. The merchants who export the commodities wanted in these countries, in exchange for these materials, replace the capitals of the people who produce them, and thus encourage them to continue the productions, and the British manufacturers replace the capitals of those manufacturers.

When the capital of any country is not sufficient for all the three purposes now noticed, in proportion as a greater share of it is employed in agriculture, the greater will be the quantity of productive labour which it puts into motion within the country, and also the value which its employment adds to the annual produce of the land and labour of the society. After agriculture, the capital employed in manufactures puts into motion the greatest quantity of productive labour, and adds the greatest value to the annual produce. That which is employed in the trade of exportation has the least effect of any of the three. The country, which has no capital sufficient for all these three purposes, has not arrived at that degree of opulence for which it seems naturally designed. But an attempt to accomplish all these three, prematurely, and with an insufficient capital, is certainly not the shortest way for a society, any more than for an individual, to acquire a sufficient one. The capital of all the individuals of a nation has its limits like that of a single individual, and is capable of executing only certain purposes; and it is increased by their continually accumulating and adding to it whatever may be saved out of their revenue: and the revenue of all the inhabitants of the country is necessarily in proportion to the value of the annual produce of their land and labour. The course of human prosperity, indeed, seems scarcely ever to have continued for a long time to enable any great country to acquire capital sufficient for all these three purposes; unless, perhaps, we give credit to the wonderful accounts of the wealth and cultivation of China, of those of ancient Egypt, and of the ancient state of Hindostan. These three countries have been chiefly renowned for their superiority in agriculture and manufactures; nor do they appear to have been eminently for foreign trade. The greater part of the surplus produce of all these countries seems to have been always exported by foreigners, who give in exchange for it something else for which they found a demand there, frequently gold and silver. It is thus that the same capital will in any country put into motion a greater or smaller quantity of productive labour, and add a greater or smaller value to the annual produce of its land and labour, according to the different proportions in which it is employed in agriculture, manufactures, and wholesale trade. See Trade.

The consideration of his own profit is the sole motive which determines the owner of any capital to employ it either in agriculture, in manufactures, or in some particular branch of the wholesale or retail trade; and, therefore, in countries, where agriculture is the most profitable of all employments, the capitals of individuals will naturally be employed in the manner most advantageous to the whole society. The profits of agriculture, however, seem to have no superiority over those of other employments in any part of Europe; infomuch that it would be difficult to produce a single instance, in which a large fortune has been acquired by agriculture, in the same time and from the same capital, which have yielded such a fortune by trade and manufactures, in the whole of Europe during the present century; and therefore agriculture is capable of absorbing a much greater capital than has ever yet been employed in it. Smith's Wealth of Nations, vol. ii. Book ii.

Capital, in Architecture. This term is taken immediately from the Italian word capitello, which is derived from the Latin caput, head. Thus the etymology of this word
word defines its meaning, for the capital is properly the head of a column.

The capitals used in the architecture of the Greeks, though with numberless minute variations of ornaments and proportions, arrange themselves into three general classes, and offer the most obvious distinction between the orders. In this style also it is easy to distinguish between those parts which have their use and origin in the original type of that wooden construction from which Grecian architecture is derived and those which are merely ornaments and accessories. Considering columns in their origin as cylindrical wooden poles, the abacus, which is a square tile or tablet, has an evident use in sheltering and protecting the upper part of the column by its projection, and also in giving a broader base and more convenient form for the placing of the architrave. The abacus therefore may be regarded as the original capital which is most conspicuous in that order which bears the marks of the lightest antiquity, attenuated and altered in succeeding orders and succeeding ages, but never omitted either in the purity of Grecian architecture or its deteriorated imitations.

The Doric order, which prefers more of the primitive type than any other, has a broad and mafly abacus, which with an ovolo and some small fillets, varying in number from three to five, constitutes the whole capital. See Plate XIII. Architecture and Plate 1. fig. 5 and 6.

In the Ionic order we find a very considerable variation; here we have a small and moulded abacus, below which depend two spiral volutes; there is also an echinus and bead, see Plate XXVIII. Architecture. The side of the capital is different as the volutes appear in front, and prevent a pillow or baluster laterally.

The Corinthian is the most richly ornamented of capitals; in this the abacus is hollowed, forming a quadrilateral figure with concave sides, the angles of which are generally truncated, and in the middle of each side there is placed a flower. Below the abacus the capital has the form of a vase or bell which is surmounted with two tiers of leaves. Under each angle of the abacus rises a volute and caulicolli bend under the flowers which occupy the centres of the sides. See Plate XXIX. Architecture.

Such are the general characteristics which are common to all these capitals, but the variations are numerous. The Ionic capital in Grecian examples varies in the more or less flattened form of the ovolo, in a greater or less number of annulets, in the proportions of the parts to one another, and to the column. In the Doric order, composed by modern authors from one or two imperfect Roman authorities, the capital is very different; here we find a feble abacus divided with mouldings; an ovolo and annulets, and below this a necking with an astragal and fillet. See Plate XVI. Architecture. The necking is even sometimes ornamented with husks and rosettes.

The principal variations of the Ionic capital in ancient examples are in the size of the volutes, the form of its curve, and number of revolutions. In the capital of this order, in the temple of Minerva Polias, at Athens, a beautiful and singular instance, we observe an ornamented necking. See Plate 1. Architecture. The circumference of the Ionic capital being dissimilar in front and side, has caused considerable inconvenience in its use. For supposing a quadrangular portico to be erected of this order, the columns in front would all have the volutes outward, and the capitals at the angles would present the baluster side laterally; then either all the columns of the side ranges must have the baluster side outwards to correspond with those at the angles, which would be a singular absurdity, or uniformity must be violated. To remedy this defect, the ancients made the outer volute of the angular capital project diagonally, so as to correspond equally with a volute in front and one on the side. This distorted capital, however, was considered so great a blunder, that most modern architects, when they had occasion to use Ionic columns on plans facing two ways, have adopted the invention of Scamozzi, which consists in projecting all the volutes diagonally, thus forming a capital similar every way, while the abacus has the form of the Corinthian abacus, and like that has a flower in the centre of each side. It is this which is called the modern Ionic capital; an invention which only obviates the difficulty complained of, by spoiling all the capitals, instead of merely those at the angles, for in beauty and elegance these capitals will not bear the smallest comparison with antique examples. This practice was greatly approved at the time, and nearly superseded the ancient method even in circumstances where no accommodation was necessary.

The Corinthian capital varies in the division and form of the leaves; these are directed by Vitruvius to be of the acanthus kind, and thus we find them in the order of the temple of Vesta at Tivoli. The greater number however, both of ancient and modern capitals, are composed of olive leaves, which have three, four, or five folds in each division. The general height too varies from 57 to 77 minutes. Perhaps the most beautiful example extant of a Corinthian capital, is that of the three columns in the Campo Vaccino at Rome, supposed to be the remains of a temple of Jupiter Stator. See Plate XXIX. Architecture.

It remains to speak of the Tuscan capital. There are no well authenticated remains of this order, and the pretensions of Vitruvius on this head are too obscure that the modern compilers of systems of architecture have of course varied exceedingly in their designs, and the order that passes under this name must be regarded rather as a modern than an ancient invention. It has been made to differ from the modern Doric by an air of poverty and rudeness, by the suppression of parts and mouldings. See Plate XIV. Architecture.

The Composite appears never to have been admitted as a separate order by the ancients (see Composite order). It will, however, be necessary to describe what by modern architects has been denominated the Composite capital. This is a combination of Ionic and Corinthian forms; the upper part has the shape of a modern Ionic capital, and the lower part is surmounted with two tiers of acanthus leaves. See Plate XXVII. fig. 4. Architecture. Of this capital there are a few examples at Rome.

From the remains of Egyptian antiquity, it appears, that the architects confined to the severest simplicity in the general forms of their buildings and principles of construction, acknowledged no given rules or orders of architecture for the proportions and ornaments of inferior members. Accordingly we find an infinite variety of capitals, many of them pilling a great richness of decoration and elegance of outline. The ornaments are in general accurate imitations of the natural productions of the country, such as the lotus, the reed, or the palm. In Plate XVI. Architecture, the reader is presented with various fragments of Egyptian architecture. Here fig. 1, is an elegant capital composed of the branches and leaves of the palm and the capsules of its fruit. Fig. 2, is a bundle of tufts of palm flanks, taken in the spring when the branches and leaves are not yet unfolded, and the whole tree refumbles a single flower bud. In fig. 6, we may observe a considerable resemblance to the volutes of the Ionic capital. Fig. 8, is a capital from the temple of Tentyra, composed of the head of Isis and the attributes of this goddess.

2
The temples of the ancient inhabitants of Hindostan, works of dateless antiquity, possess many capitals of extraordinary form and composition. In time of these we find represented the figures of elephants and horses, apparently crouching under the weight of the ceiling. Capitals very similar in ideas to these are also found in the ruins of Pericles, compaids of horses and camels. As Roman architecture sunk into the degraded and barbarous style, known in this country by the name of Saxon and Norman, which was finally superseded by the mode commonly called Gothic, ancient rules were forgotten or delphied. Ornaments were abandoned to the caprice of the carver, and an endless variety of capitals was produced more or less happy according to individual taste or barbarism. Variety indeed forms to have been the governing principle of decoration, and was pursued to an unmeaning excess in contempt of symmetry, propriety, and congruity.

Capital, in Chemistry, signifies the head of an alchimic. Capital, in French capitals, in Fortification, of a work, is an imaginary line dividing that work into two equal and similar parts. Every work in a fortification has its capital. The capital of a balhion, for instance, is the right line drawn from the point or salient angle of it to the middle of the garge, or from the angle of the interior or inward figure, or polygon, to the salient angle of the balhion, or flanked angle. A balhion is said to have a certain number of teffices or factions of capitals, when there are null in the distance from its salient angle to the point where the two semi-gorges meet each other.

The capital of a ravelin or demi-lune is a right line drawn from the re-entering angle of the counter-scarp to the point or to the flanked or salient angle of the ravelin. Capital, of a Lantern, the covering which terminates the lantern of a dome, either in the figure of a bell, as that of the Sorbonne; or of a cupola, or a spiral, as that of the church of Sapienza at Rome. Capital, of a Mill, the covering thereof in form of a cone, which turns vertically on the round tower, in order to expel the falls to the wind.

Capitals, or Capital letters, in Printing, denote large or initial letters, which are used in the titles of books, and on a variety of other occasions. It was formerly the custom to begin every noun with a capital; but the practice, being troublesome, and giving to the writing or printing a confused appearance, has been discontinued. Capitals, however, may very properly commence the first word of every book, chapter, letter, note, or any other piece of writing;—the first word after a period, and, if the two tentences are totally independent, after a note of interrogation or exclamation; but if a number of interrogative or exclamatory sentences are thrown into one general group, or if the confluxion of the latter tentences depends on the former, all of them, except the first, may begin with a small letter:—the appellations of the Deity;—proper names of persons, places, streets, mountains, rivers, ships:—adjectives derived from the proper names of places:—the first word of a quotation, introduced after a colon, or when it is in a direct form; but when a quotation is introduced obliquely after a comma, a capital is unnecessary;—the first word of an example:—every substantive and principal word in the titles of books:—and the first word of every line in poetry. The pronoun I, and the interjection O, are also written in capitals. Other words, before the preceding, may likewise begin with capitals, when they are remarkably emphatical, or the principal subject of the composition. Murray's English Grammar, p. 273, ed. 12.

The ancient MSS. both Greek and Latin, are written wholly in capitals.

In the early days of printing, there were also several editions of books in capital; as of Homer, the Greek Anthology, Aucoumian, &c. Johannes Latunus seems to have brought the ancient practice to give capital in capital.

CAPITALLIS, in Surgery. See Capillunt.

CAPITAN, or CAPTAUN, a forward, vain, impudent braggadocio, who holds of great exploit, whilst he is in reality but shy, timid, and dandified. It is a term sometimes made use of to denote an absolute coward or poltroon.

CAPITANA, or CAPTAINALY, the chief or principal galley of a state, not dignified with the title of a kingdom. The capitana was anciently the denomination of the chief galley of France, which the commander went on board of. But since the supersession of the office of captain general of the galleys in 1669 they have no capitana, but the first galley is called real, and the second patron.

CAPITANATA, in Geography, corrupted from Catapanata, denoting the district under the Catapan, or Greek viceroy, the ancient "Apulia Dauinia," but detached from "Apulia" by captain Baillius Bagiano, or Bagiano, one of its Greek governors, and erected by him into an independent province; one of the 12 provinces of Naples. It is bounded on the north and call by the Adriatic, on the south by the provinces of Bari, Basilicate, and Principato Ultra, and on the west by the Molise and Abruzzo Citt. The country is for the most part level, has few trees and springs; the air is hot, and the soil sandy; nevertheles the land, refreshed by dews, and adjoining the rivers, produces corn, and furnishes pittance for herds of cattle. The springs in the country of Manfredonia, near mount Cargano, the chief mountain of the province, are more plentifully supplied with fresh water. The sides of this mountain afford plantations of oranges; the bogs dug within it are used for building in various parts of the province; and from the top is collected snow, which is of great service in this hot country. Along the coast, which is defended by a number of towers, there are manufactures of salt. Its principal towns are Manfredonia, the capital, Vieglf, Lucera, San Severo, Larino, Troja, Termini, Bo-vino, Voltarara, and Ascoli. The extent of this province comprehends 1,141,622 moggio (5 moggio being equal to 4 English acres), and the number of inhabitants amounts, according to Spinburne, to 491,525.

CAPITANEATE, in a general sense, the name with capitana. Capitanates, in Prussia, are a kind of noble fiefs, or estates, which, besides their revenue, raise their owners to the rank of nobility. They are otherwise called fiefdoms.

CAPITANEI, or CATANEI, in Italy, was a denomination given to all dukes, marquises, and counts, who were called "capitani regis." The name appellation was also given to persons of inferior rank, who were invested with fees, formerly distinguished by the appellation of capitanei regis. Du Cange.

CAPITANEUS, Peter, or Capiteyn, in Biography, born of a noble family at Middleburg in Zealand, in the year 1514, received his education in the universities of Lou-vain and Paris. After taking his degree of doctor, he went to Copenhagen, was made professor in medicine, and first physician to the king, Christian III. ; which offices he appears to have held to the time of his death, which happened in the year 1557, as is seen by a chronogram engraved on his tomb:

"Occubuit fatis CapItaneUs aLta MiCaret, JanI teXta Ubi LUX horaqUe nona fort."
capitaneus, in Ancient Law Writers, denotes a tenant in capite, or chief. See CAPITE

CAPITANEUS Ecclesiae, the same with advocatus, which see Du Cange. Gloss. Lat. tom. i. p. 822.

CAPITANIA, the office or dignity of a captain, and more especially a perpetual feud. See CAPITANATE

CAPITANIA is also a denomination given to the twelve governments established by the Portuguese in Brazil.

CAPITATE, in Botany, the ninth class in Mr. Ray's second method, containing those compound flowers which are united in a roundish form, resembling a head, as the thistle, knapweed, &c. It is also the second division of the twenty-first order in Linnaeus's fragments of a natural method published in the Philosophica Botanica; the first division of the forty-ninth order at the end of the Genera Piantarum, and in the posthumous praelections; and the second division of the first order of the class Syngenesia in his artificial system.

CAPITATE, forming a head; applied particularly to a flower, and to the stigma.

CAPITATION, a tax, or imposition, raised on each person, in consideration of his labour, industry, office, rank, &c. This kind of tribute is very ancient, and answers to what the Greeks called εκ ταξιδεσμων; the Latin, capita, capitatio, and tributum, or tributum capite, or capitare. By this term, taxes on the persons are distinguished from taxes on merchandise, which were called vendigala,quia vendabantur.

Capitation obtained among the Jews. Accordingly Moses ordained (Exod. xxx. 36.), that every Israelite should pay half a shekel "for his soul," or person, as a redemption, "that there might be no plague among the people, when they were numbered." Several interpreters have supposed, that this was intended to take place as often as the people were numbered; and that the evasion of it, when David numbered his subjects, incurred the divine punishment of a pestilence. 2 Sam. xxiv. 1. But it has been more generally maintained, that Moses laid this tax on all the people, payable yearly, for the maintenance of the tabernacle, for the sacrifices, wood, oil, wine, flour, habits, and subsistence of the priests and Levites. In the time of our Saviour, this tribute was punctually paid. See DIDRACHMA.

The rabbins observe that even the priests and Jews in general, except women, children under 3 years of age, and slaves, were liable to pay the half shekel, worth about 15 Sols. The collectors demanded it in the beginning of Nisan, but had no recourse to compulsion till the Rosh Chodesh, when they either confirmed those to pay who had not paid, or took security from them.

The Israelites, on their return from Babylon, paid one-third part of a shekel to the temple; as they were probably, unable, on account of their poverty, to pay a greater sum. Nehem. x. 32. After the destruction of the temple by the Romans, the Jews were compelled to pay the half shekel to the temple of Jupiter Capitolinus, which they had before paid to the temple at Jerusalem. It was levied through all the provinces where any of them were settled, and carried by procurators to Jerusalem. Cicero observes, that Placcus would not suffer that tax, which was collected among the Jews in Italy, to be conveyed thither; and Titus, addressing the Jews, reproached them with ingratitude for employing this tax against their benefactors, and in carrying on the war with the Romans, which the emperors of Rome had, by a particular indulgence, permitted them to levy.

Calmet.

The mode of assessment under the Roman emperors seemed to unite the substance of a land-tax with the forms of a capitation. The returns which were sent of every province or district, expressed the number of tributary subjects, and the amount of the public impositions. The latter of these sums was divided by the former, and the latter, that such a province contained so many "capita," or heads of tribute, and that each head was rated at such a rate, was universally received, not only in the popular, but even in the legal computation. The value of a tributary head must have varied, according to many accidental, or at least fluctuating circumstances; but it is known, that the rapacious ministers of Constantinople had exhausted the wealth of Gaul, by exacting 25 pieces of gold for the annual tribute of every head; which capitation was reduced by the humane policy of his successor to 7 pieces. If we take 16 pieces of gold, or about 9l. sterling, for a kind of moderate proportion between these opposite extremes of extraordinary oppression and of transient indulgence, we shall have probably the common standard of the impositions of Gaul. When we reflect on this subject, it is obvious, that as long as a very unequal division of property must subsist in society, the most numerous part of the community would be deprived of their subsistence by the equal assessment of a tax, from which the sovereign would derive a very trifling revenue. But, whatever might be the theory of the Roman capitation, in the practice this unjust equality was no longer felt, as the tribute was collected on the principle of a real, not of a personal imposition. Several indigent citizens contributed to compose a single head, or share of taxation; while the wealthy provincial, in proportion to his fortune, alone represented several of those imaginary beings. Nevertheless, the difficulty of allowing an annual sum of about 91. sterling, even for the average of the capitation of Gaul, will be more evident by comparing the state of the same country, as it was governed by an absolute monarch of an invidious, wealthy, and affectious people, before the late revolution. The taxes of France, estimated at the annual amount of 18 millions sterling, may be considered as distributed among 24 millions of inhabitants. Seven millions of these, in the capacity of fathers, brothers, or husbands, might discharge the obligations of the remaining multitude of women and children; and yet the equal proportion of each tributary subject would scarcely rise above 5s. of our money, instead of a proportion almost four times as considerable, which was regularly imposed on their Gallic ancestors. The reason of this difference is to be found, not so much in the relative scarcity or plenty of gold and silver, as in the different state of society in ancient Gaul and modern France.

In a country where personal freedom is the privilege of every subject, the whole mass of taxes, whether they are levied on property or on consumption, may be fairly divided among the whole body of the nation. But the far greater part of the lands of ancient Gaul, as well as of the other provinces of the Roman world, were cultivated by flaves, or peasants, whose...
dependent condition was a left rigid servitude. In such a state the poor were maintained at the expense of their masters; and as the rolls of tribute were filled only with the names of those citizens who paid the means of an honourable, or at least of a decent subsistence, the comparative smallness of their number explains and justifies the high rate of their capitation. The population of the territory of the Acldi might probably amount to 800,000 persons; and in the time of Constantine this territory afforded no more than 25,000 heads of capitation, of whom 7600 were discharged by that prince from the intolerable weight of tribute. By a just analogy it may be inferred, that the free and tributary citizens did not surpass the number of half a million; and if their annual payments may be computed at about 40 millions of our money, it would appear, that although the share of each individual was four times as considerable, a fourth part only of the modern taxes of France was levied on the imperial province of Gaul. The exactions of Constantius may be calculated at 7 millions sterling, which were reduced to 2 millions by the humanity or the wisdom of Julian. But as this tax, or capitation, on the proprietors of land, would have furnished a rich and numerous class of free citizens to escape, the emperors, with the view of sharing that species of wealth which is derived from art or labour, and which exists in money or in merchandise, imposed a distinct and personal tribute on the trading part of their subjects. Some exceptions, very strictly confined both in time and place, were allowed to the proprietors who disposed of the produce of their own estates. Some indulgence was granted to the profession of the liberal arts; but every other branch of commercial industry was affected by the severity of the law; nor did the sovereign of the Roman empire, who tolerated the profession, defend it even to share the infamous富裕，of public profiteers. This general tax upon industry was collected every fourth year, and hence called the "Lustral Contribution."

The fatal period was announced by the tears and torments of the citizens, who were often compelled by the impending scourge to embrace the molt abhorred and unnatural methods of procuring the sum at which their property had been affe&ed. Gibbon's Hist. vol. iii. chap. 17.

Capitation taxes, says Dr. Smith, (ubi infra,) if an attempt is made to proportion them to the fortune or revenue of each contributor, become altogether arbitrary. The state of a man's fortune varies from day to day, and without an inquisition more intolerable than any tax, and renewed at least once every year, can only be guessed at. His assessment, therefore, must in most cases depend upon the good or bad humour of his aff-ilers, and must, consequently, be altogether arbitrary and uncertain. Capitation taxes, if they are proportioned not to the supposed fortune, but to the rank of each contributor, become altogether unequal; as the degrees of fortune are frequently unequal in the same degree of rank. Such taxes, therefore, if it is attempted to equalize them, become altogether arbitrary and uncertain; but if it is attempted to render them certain, and not arbitrary, they become altogether unequal. In the different poll-taxes which took place in England, during the reign of William III. the contributors were mostly affe&ed according to their rank, as dukes, marquesses, earls, viscounts, barons, esquires, gentlemen, the old and youngest sons of peers, &c. All shopkeepers and tradesmen worth more than 30l. were subjected to the same assessments, whatever might be the difference in their fortunes. Several of those who in the first poll-tax were rated according to their supposed fortune, were afterwards rated according to their rank. Sergeants, attorneys, and proctors at law, who in the first poll-tax were affe&ed at three shillings in the pound of their supposed income, were afterwards affe&ed as gentlemen. In the capitation tax levied in France, for a long time without interruption, since the beginning of the last century, the highest orders of persons were rated according to their rank by an invariable tariff; the lower orders of people, according to what was supposed to be their fortune, by an assessment that varied from year to year. The officers of the king's court, the judges and other officers in the superior courts of justice, the officers of the troops, &c. were affe&ed in the first manner; the inferior ranks of people in the provinces, were affe&ed in the second.

In England the different poll-taxes never produced the sum which had been expected from them. In France the capitation always produced such a sum. The mild government of England, when it affe&ed the different ranks of people to the poll-tax, contented itself with what that affair happened to produce; and required no compensation for the loss which the state might sustain either by those who could not pay, or by those who would not pay, and who, by the indulgent execution of the law, were not forced to pay. The more severe government of France affe&ed upon each generality a certain sum, which the intendent must find as he could. If any province complained of too high an assessment, it might, in the assessment of next year, obtain an abatement corresponding to the overcharge; but it was required to pay in the mean time. Capitation taxes, as far as they are levied upon the lower ranks of the people, are direct taxes upon the wages of labour, and are attended with all the inconveniences of such taxes. They are levied at little expense; and where they are rigorously exacted, afford a very sure revenue of the state. Hence, in countries where the care, comfort, and security of the inferior ranks of people are not objects of much attention, capitation taxes are very common. It is, however, but a small part of the public revenue, which, in a great empire, has ever been drawn from such taxes: and the greateft sum, which they have ever afforded might always have been found, says Dr. Smith, in some other way much more convenient to the people. Wealth of Nations, vol. iii. b. 5. c. 2.

CAPITATUS, in Jacobology, an obsolete name of that fish most commonly known in England by the name of Miller's thumb, Cottus gobio, and river bull-head of approved authors.

CAPITE, in Law, an ancient tenure, whereby a person held of the king immediately, in right of his crown and dignity, either by knight's service, or fiefage, which fee. This was the most honourable species of tenure; but at the same time it subjected the tenants to greater and more burdensome services than inferior tenures did.

By a statute, 12 Car. II. c. 29, all such tenures by knight's service of the king, or of any other person, knight's services in capite, with all rights, &c. are annulled; and all such tenures are turned into free and common fiefage; so that tenures hereafter to be created by the king are to be in common fiefage only, and not by capite, knight's service, &c.

CAPITE CENSI, in Antiquity, the lowest rank of Roman citizens, who in public taxes were rated the leahl of all, being such as were never worth above 25s. ales.

They were supposed to have been thus called, because they were rather counted and marshalled by their heads than their eftates. Aug. Cell. lib. vii. cap. 13.

The capite cenfs made part of the fifth class of citizens, being below the plebes, who formed the other moiety of that class.

The capite cenfs were not enrolled in the army, as being judged not able to support the expenses of war; for in those days
CAP

days the soldiers maintained themselves. It does not appear that before Caius Marius any of the Roman generals liked the capite ceni in their armies. Sallust, Jug. p. 135.

CAPITELLUM, in Conchology, a species of Voluta with an ovate, rugose, knotty shell, the pillar of which is triplicated.—Murex capitellum of Linnæus. This is about two inches and three quarters in length; colour white, sometimes festooned with fulvous, and marked with decussating ribs. This inhabits the Indian and American coasts.

CAPITO, WOLFGANG-EGBERTUS, in Biographies, an eminent Lutheran divine, was born in 1478 at Hagenuk in Allace, and having studied at Basel, became, in compliance with the desire of his father, a doctor in medicine. He afterwards graduated both in theology and law; and entering in 1520 into the service of cardinal Albert of Brandenburg, elector of Meissen, received from him letters of nobility. After having embraced the opinions of Luther, he formed an intimacy with Bucer and Oeocolampadius, and concurred with them in the establishment of protestantism. He assisted at the council of Marburg in 1529; and after having been twice married died of the plague in 1542. Among the various works which he wrote we may select the following; viz. "Institutionum Hebraicarum lib. ii.;" "Enarrationes in Habacuc et Oseam;" Vita Joannis Oeocolampadis;" "Refusio de Matrimonio, et Jure Magistratus in Religionem." Moreri.

CAPITO, TITINIUS, lived under the emperor Trajan, and is mentioned by Pliny (l. viii. ep. 12) as a writer of no mean character. He described the deaths of illustrious men, among whom were some of his contemporaries, condemned, without doubt, by Domitian.

CAPITO, AETIUS, a celebrated civilian, who adorned the age of Augustus and was distinguished by the favour of his sovereign. He was an opponent of Antilius Laboe, who was more illustrious by his contempt of that favour, and his flero, though harmless opposition to the tyrant of Rome. Their legal studies were influenced by the various colours of their tempers and principles. Laboe was attached to the form of the old republic; his rival embraced the more profitable subsistence of the rising monarchy. Capito, with the tame and submissive disposition of a courtier, seldom presumed to deviate from the sentiments or at least from the words of his predecessors; while the bold republican pursuad his independent ideas without fear of paradox or innovation. Laboe decided according to the letter of the law the same questions which his indulgent competitor resolved with a latitude of equity more suitable to the common sense and feelings of mankind. This opposition of sentiments was propagated in the writings and leonions of the two founders; and the schools of Capito and Laboe maintained their inerelative. The age of Augustus to that of Adrian. The two sects derived their appellations from Sabinius and Procrisus, their most celebrated teachers. Gibbon's Hist. vol. viii. p. 31.

CAPITO, in Ichthyology, an old synonym of the Cichlid, Cyprinus cephalus, which see.

CAPITO is also applied by some of the elder writers to the Mullet, Mugil cephalus, which see.

CAPITO, anadromous, one of the synonyms of Cyprinus Vimba.

CAPITO flavicollaris (Alvovandus) Cyprinus Dobula, Mull. and Gmelin. The true species to which the names Capito caroli, and capito rapae are applied by obsolete writers do not appear to be very clearly ascertained.

CAPITOL, in Antiquity, a famous fort or castle, on the Mons Capitolinus at Rome, wherein was a temple dedicated to Jupiter, hence also denominated Capitolinus, in which the senate annually assembled; and which till serves as the city-hall, or town-horse, for the meeting of the consuls of the Roman people.

It had its name, capitol from caput, a man's head, said to have been found fresh, and yet bleeding, upon digging the foundation of the temple, built in honour of Jupiter. Arrius adds, that the man's name was Telus; whence capitolinus. Others say, that the hill Tarpeius was called capitol, because it was the capital, or chief fortress of Rome.

The first foundations of the Capitol were laid by Tarquin the Elder, in the year of Rome 153, B.C. 671. In consequence of a vow which he had made to Jupiter, Juno, and Minerva, on occasion of his last battle with the Sabines, in which he obtained the victory, he levelled the steep top of the Tarpeian hill, marked out the plan of the temple, which he had promised to erect, and laid the foundation of that glorious structure, which afterwards became the principal place of the Roman worship. Historians have adorned the foundation of this temple with many prodigies, all pointing the future grandeur of the Roman empire. As there were several gods, who had altars on the same hill, and which were to be removed to make room for the new edifice, it was a matter of doubt in what part of the hill the foundations should be dug. The augurs referred to consult each deity one after another, and not to touch their altars before they had given their consent. All the gods agreed that their altars might be removed, except the god Terminus and the goddess Youth, who insisted upon not being displaced; and this circumstance gave the augurs occasion to conjecture, that the bounds of the city and empire should stand for ever, and that Rome should always flourish with youth and vigour. Accordingly the two ditches were enclosed within the walls of the temple. Dionysius Halicarnassensis places this event under Tarquin the Elder, and Livy under Tarquin the Proud. The successor of the former, Servius Tullius, as some have said, raised the walls; and Tarquin the Proud finished it, A.U.C. 221, B. C. 533, having referred for this purpose the tenth of the spoils of Scipia Pomatia, one of the most wealthy cities of the Volsci, and having procured a great number of workmen from Etruria, to begin the undertaking, who were allied in the most laborious part, by his own subjects. But his expulsion from Rome prevented his accomplishing all his purposes. Thus the edifice was not completed and consecrated till the third year after the expulsion of the kings, and establishment of the consuls. The ceremony of the dedication of the temple was performed by the consul Florus, A.U.C. 245; B. C. 528.

The Capitol occupied eight acres of ground; it was 200 feet broad, and about 215 long. It consisted of three parts; a nave, sacred to Jupiter; and two wings, or aisles, to Juno and Minerva. It was adorned from the forum by flairs; Lepidus reckons one hundred in number, because there were to many in the ascent of the Tarpeian rock. The front which looked to the south, facing the hill Palatinius, and the Forum Romanum, and the sides were encompassed with galleries, wherein those, who had the honour of a triumph, entertained the senate at a magnificent banquet, after the performance of sacrifices to the gods. Both inside and outside were enriched with numerous ornaments: the statue of Jupiter, with his golden thunderbolt, his sceptre, and crown, were the most distinguished. The gilding of the whole arch of the temple of Jupiter Capitolinus was undertaken by the Romans, according to Pliny (lib. xxxiii.) after the destruction of Carthage, and if Plutarch (in Oc-
may be credited, it call 12,000 talents. The gates of the temple were of brass, covered with large plates of gold. The inside of the temple and the columns which supported it, were all of marble.

In the same Capitol there were, likewise, a temple to Jupiter the Guardian, and another to Juno; with the mant: and on the descent of the hill was the temple of Concord.

The Capitol was burnt in the time of Sulla (A. u. C. 675. B. C. 84,) by the negligence of those who kept it. He undertook to rebuild it, but did not live to see it finished, which he intended in his last illness "as the only thing wanting (fays Tacitus, Hist. iii. 72) to complete his felicity." By his death that charge fell to Q. Lucinius Catulus, as being consul at the time, B. C. 70, who dedicated it with great pomp and solemnity, and had the honour to have his name inscribed on the front. It was burnt again in the reign of Titus, A. D. 83, and rebuilt by Domitian with a magnificent: The building which he undertook to rebuild it, but did not live to see it finished, which he intended in his last illness "as the only thing wanting (fays Tacitus, Hist. iii. 72) to complete his felicity." By his death that charge fell to Q. Lucinius Catulus, as being consul at the time, B. C. 70, who dedicated it with great pomp and solemnity, and had the honour to have his name inscribed on the front. It was burnt again in the reign of Titus, A. D. 83, and rebuilt by Domitian with a magnificent palace. The roof of it is flat, and adorned with many statues of illustrious persons among the Romans. In the new building refides the senate of Rome, who daily administer justice there; and in the wings are the apartments of the conscriptors of the city. There is also room enough for keeping antiquities and other curiosities which the traveller of taste has always admired. The "Camera apostolica," or apostolic chamber, has now usurped the rights of the famous "Senatus Populusque Romanus." In the front of this building is a high tower, with the statue of religion erected on the top of it. The double flight of steps at the entrance of this palace is the work of Michael Angelo, who likewise adorned the front with a superb fountain, and two statues representing the Nile and the Danube in a reclining posture. In the centre is a porphyry statue of Rome, in the habit of Minerva, and the usual symbols of the helmet and spear, but fitting. This is a piece of great antiquity, and much admired by connoisseurs. The large hall, where the court of justice is held by the senators, was formerly adorned with several pictures, representing the achievements of the kings of the Romans; but none of them now remain; Clement X1. having, in 1712, supplied their places with a great number of designs, exhibiting the life of pope Pius V. and his caonization. Under the "Corps de Logis" is the capital prifon. In the apartments of the conservators, in the left wing, are two celebrated statues of Julius Caesar and Augustus, both antiques and of white marble. The former, as sovereign of the world, holds a globe in his hand; the latter, a roll or book of a ship, alluding to his victories over Mark Antony and Cleopatra. Near these statues are to be seen two feet and a hand of oriental marble, being part of a colossus or statue of Apollo, which was 30 ells in height, and sent by Marcus Lucullus from Apollonia to Rome, where it was placed on the Capitoline mount. Opposite to this statue of the Capitol are also another large head and hand of brais, supposed to have been longed to a colossus of Commodus or Domitian. Near the inscription on Agrippina's monument is an admirable an cient groups, representing a lion tearing to pieces a bull; but the head is much damaged by time. Thiscolossus piece was found on the banks of the Tibor, near the O'ara gate, in the time of Paul III. Here is also a remarkable piece of architecture, in which five pieces of sculpture are joined, which had originally no connection, and were dug up in different places. In the centre, and elevated above the rest, sits Rome triumphant, in white marble, with a poniard in her left, and a bunch of palms in her right hand; and on the front of the statue, on which she sits, is a woman in tears, representing Decius, or some other conquered province. On each side of this statue is the column of a barbarian prince in a kind of black marble, called 'hedera.' Their rank may be known by their diamonds. The workmanship is exquisite; but it is not known who they are.

Here is also the marble sarcophagus of the emperor Alexander Severus and his mother Julia Mamaea, found on Monte del Grano, near Leptis, and brought hither. It is six feet long, and six broad. Not far from this is a marble column with a statue of Constantine the great, which shews that the art of sculpture was upon the decline, though these two are good pieces, as is also a pedestal of Baccus. Near it are still a very remarkable antique, viz. the "columna rostrata," which is of Parian marble; erected in the year of Rome 494, in honour of the confidatus Caius Duilius, on account of a naval victory, which he obtained over the Carthaginians. Near it is a baso-relievo, representing Curtius leaping into the abyss. At the first landing place are seen two antique fountains; and a little farther, four admirable baso-relievi, representing the triumph of Marcus Aurelius and Lucius Verus, which belonged to their triumphal arch in the Circus. Before the entrance of the great hall is a large statue, 65 feet long, cut in white marble; the head of every fifth of this species, exceeding that measure, being due to the conservators of the city. On the left hand are the Fafni confulares, down to the time of the emperor Pertinax, engraved on marble; and above these is a baso-relievo of the wolf suckling Romulus and Remus. Further in are the names of the modern conservators. In the first hall are some passages of the Roman history, painted by Gioseppi d'Arpino; as, the rape of the Sabines, the combat between the Horatii and Curatii, Romulus and Remus sucking the wolf, and the building of the city of Rome, &c. &c. But the most admired of all is the victory of Tullus Hostilius over the Veii and the Fidenates. There are various other marble statues and paintings in the different apartments, which it would exceed our limits to mention, but which must be highly gratifying to the curious.

From several remains of ancient walls, it is conjectured by some, that the temple of Jupiter Capitolinus stood on the ground which is at present inclosed in the court of the Caffarelli palace. The famous Tarpeian rock is now almost covered with buildings; but it is evident that anciently the rock must have been much steeper, or a wall must have been erected upon it, from which malefactors were thrown down headlong. That the height or depth of it has not undergone any considerable alteration may be concluded from Severus's triumphal arch at the foot of the Capitoline-hill, which, with the amphitheatre in its neighbourhood, is not above two or three feet below the present surface of the ground. See Keyser's Travels, vol. ii.

Anciently, the name capital was likewise applied to all the principal temples, in most of the colonies throughout the Roman empire: as, at Conflantinople, Jerusalem, Carthage, Ravenna, Carpea, &c.

CAPITOLIA, or ELEA CAPITOLIA, in Ancient Geography, a name given to Jerusalem in the time of Ptolemy.
CAPITOLIA, a town of Asia in Calohipia, N. of Adria, according to Ptolemy; between Adria and Gadara, according to the table of Ptolemy; and in Antonine's route from Seriana to Scythopolis, between Neva and Gadara.

CAPITOLINE Games, Ludi Capitolini, were annual games, or contests, instituted by Camillus, in honour of Jupiter Capitolinus; and in commemoration of the Capitol's not being surplundered by the Gauls.

Plutarch tells us, that a part of the ceremony consisted in the public criers putting up the Horatians to sale by auction; they also took an old man, tying a golden bull to his neck, such as were worn by their children, and exposed him to the public derision. Feltus says, they drizzled him in a praetexta, and hung a bull at his neck; not as accounting him a child, but because this was an ornament of the kings of Hetruria.

There was also another kind of capitaline games, called agones capitoline, instituted by Domitian, A. U. C. 839, A. D. 86, and celebrated each fifth year; wherein there were rewards and crowns, or garlands of oak-leaves, bellowed on the victorious poets, and put on their heads by the emperor himself. As the manner and plan of the capitaline games were taken more from the Greeks; than from the Romans, Domitian preferred in them, dressed after the Greek fashion, and wearing a crown of gold, in which were set the images of Jupiter, Juno, and Minerva. He was attended by the priest of Juno, and the college of priests, which he himself had instituted in honour of the Flavian family; all dressed like himself, except that they wore an image of the emperor in their crowns. If the crowns were given to superior merit, the exclusion of Statius, (Capitolia non tene fuscida lyra, Silv. I. iii. v. 31.) may do honour to the games of the Capitol; however, though he could not obtain the prize at these games, he was crowned three times at those of Minerva, in honour of whom Domitian celebrated a feast every year, in his house at Alba, with great pomp and magnificence. Thrice games, which were not abolished in the 4th century, became so celebrated, that the manner of accounting time by lutes, which had obtained till then, was changed; and they began to count by capitaline games, as the Greeks did by olympiads. The feast was not for poets alone, but also for athletes, orators, historians, comedians, musicians, &c.

CAPITOLINE Marbles. See Fasti.

CAPITOLINI, in Roman Antiquity, a college of men residing in the capital and arch, to whom was committed the care of celebrating the capitaline games.

CAPITOLINUS, Julius, in Biography, a Latin historian, flourished at the close of the third, and beginning of the fourth century, and wrote the lives of the emperors Antoninus Pius, Verus, Albinus, Macrinus, the two Maximens, and the three Gordians. These are extant, but some other of his compositions are lost. His matter is chiefly copièd from Herodian, and he is deemed neither a pure nor an exact writer. Voi. Hiit. Latin.

CAPITOL, or Capit, an appellation given to the chief magistrates of Toulouse, who have the administration of justice and policy both civil and mercantile in the city.

The capitouls at Toulouse are much the fame with the echevins at Paris, and the consuls, bailiffs, burgour-masters, mayors, and aldermen, &c. in other cities. In ancient acts they are called consulis capitularum, or capitini, and their body capitulum. From this last come the words capitularis and capitulis. The appellative capitilis arose hence, that they have the charge and custody of the town-house, which was anciently called capitul.
tion of government. When they felt the weight of any grievance, they had a right to petition the sovereign for redress. One of these petitions is still extant: it is addressed to Claveraguin, A.D. 803, and expressed in such terms as could have been used only by men conscious of liberty, and of the extensive privileges which they possessed. They concluded with requiring him to grant their demand, if he wished that they should any longer continue faithful subjects to him. This great monarch made no remonstrance, but signed his willingness to comply; and feasible that he himself did not possess legislative authority, he promised to lay the matter before the next general assembly, that such things as were of common concern to all might be then considered and established by common consent. Capital. tom. i. p. 495—499. As the people by their petitions brought matters to be propounded in the general assembly, we learn from another capitular, the form in which they were approved there, and enacted as laws. The propositions were read aloud, and then the people were required to declare whether they assented to them or not. They signified their assent by exclaiming three times, "we are satisfied," and then the capitular was confirmed by the subscription of the monarch, the clergy, and the chief men of the laity. Capital. tom. i. p. 617; A.D. 822. From a capitular of Carolus Calvus, A.D. 874, it seems probable, that the sovereign could not refuse his assent to what was proposed and established by his subjects in the general assembly. Tit. ix. § 6. Capital. vol. ii. p. 47.

Some distinguish the capitulars from laws; and yet, they were only supplements to laws.—They had their name, capitulars, from their being divided into capitula, chapters or sections. In these capitulars did the whole French jurisprudence anciently consist. In course of time, the name was changed for that of ordinances.

The weaknesses of the greater part of the monarchs of the second race, and the disorder into which the nation was thrown by the depredations of the Normans, encouraged the barons to usurp an independent power formerly unknown in France. The political union of the kingdom was at an end, its ancient constitution was disdolved, and only a feudal relation subsisted between the king and his vassals. The regal jurisdiction extended no farther than the domains of the crown. Under the last kings of the second race, they were reduced almost to nothing. Under the first kings of the third race, they comprehended little more than the patrimonial estate of Hugh Capet, which he annexed to the crown. All these circumstances rendered it easy for the barons to usurp the rights of royalty within their own territories. Hence, the capitulars became no less obsolet than the ancient laws: local customs were everywhere introduced, and became the sole rule by which all civil transaotions were conducted, and all causes were tried. The wonderful ignorance which became general in France, during the 9th and 10th centuries, contributed to the introduction of customary law. Few persons, except ecclesiastics, could read; and as it was not possible for them to have recourse to written laws, either as their guide in business, or their rule in administering justice; the customary law universally prevailed.

Another circumstance that greatly contributed to the disuse of the capitulars, as well as of the Salic and Roman laws, was the great extent given at this time to judiciary combats. During this period, the general assembly of the nation seems not to have been called, nor to have once exerted its legislative authority. Local customs regulated and decided every thing. The last of the capitulars collected by M. Baluze, was written in the year 921, by Charles the Simple. One hundred and thirty years elapsed from that period to the publication of the first ordinance of the kings of the third race, contained in the great collection of M. L orois: and the first ordinances, which appear to be an act of legislation, extending to the whole kingdom, in that of Philip Augustus, A.D. 1195; and the ordinances previous to this reign, contain regulations, the authority of which did not extend beyond the king's domains. See Oeuvres. Baron Montefi quo observes, (Sp. of Laws, vol. ii. p. 272) that there were several sets of capitulars. Some had relation to political government, others to economical, and others to ecclesiastical policy, and some few to civil government. Those of the last species were added to the civil law, that is, to the personal laws of each nation; for which reason, it is said in the capitulars, that there is nothing stipulated therein contrary to the Roman law. In reality, those capitulars that regarded economical, ecclesiastical, or political government, had no relation to that law; and those concerning civil government had reference only to the laws of the barbarous people, which were explained, amended, enlarged, and retrenched. But the addition of these capitulars to the personal law, occasioned, as Montefiquito conceives, the neglect of the very body of the capitulars themselves: as in times of ignorance, the abridgment of a work often causes the loss of the work itself. Ansegile is said to have made the first collection of regulations contained in the capitulars of Charlemagne and Louis le Debonnaire; which collection is divided into four books, and has been approved by Louis le Debonnaire, and Charles the Bald. After him, Benoît collected, about the year 845, the capitulars of these two emperors, omitted by Ansegile, and annexed them to the capitulars of Caroloman and Pepin. This collection is divided into three books, which comprehend, with the four preceding, the seven books of the capitulars of the French kings: the first part of these were published by du Tillet in 1548, and the whole collection of seven books by M. M. Pithou, Father Sirmond has published some capitulars of Charles the Bald; and at length, M. Baluze printed a complete edition of the capitulars in 2 vols. fol. at Paris in 1677. This contains the capitulars of the French kings, and the collections of Ansegile and Benoît, together with some other pieces.

The bishops also in the 8th and following centuries gave the name of capitula and capitulars to the regulations which they enacted in their synodal assemblies, with regard to ecclesiastical discipline, deducing them from the canons of councils, and the works of the fathers. These regulations had the force of laws only in the diocese of the prelate who published them, unless they were approved by a council, or the metropolitan; in which case, they were observed through the whole province. Of this kind are the collections of Martin, archbishop of Braga, in the year 515; those of pope Adrian I., given to Angilram, or Enguerran, bishop of Metz, in 785; those of Thidolfa, bishop of Orleans, in 767; those of Hincema, archbishop of Rheims, in 874; those of Herard, archbishop of Tours, in 878; and those of Ifase, bishop of Langres. Doujat, Hift. du Droit canon. Baluze, Pref ad Capit. M. du Pin, Ecol. Ant. of the 8th century.

CAPITULATION, in Military Language, a particular convention, agreement, compact, or treaty between two powers. Thus, one power makes a capitulation with another to furnish him with troops on condition of subsistence, pay, and certain privileges, or for other military succours or affinities. A corps or body of troops confined to surrender themselves makes a capitulation with that which forces it to do so. A governor or commandant of a place besieged enters into a capitulation with the general of the
CAPITULATION.

befiegling army when he is under the necessity of delivering it up.

The surrender of a place by capitulation is justifiable and honourable, or otherwise, in proportion to the ability, skill, perseverance, and valor, with which it has been defended.

Many governors trembling too much to their courage and the vigour of their arms are negligent in making themselves acquainted with, and practising the means of enabling them to defend the places entrusted to their care as long and obstinately as possible; and, to the bell advantage. This knowledge, however, is of the first importance, and highly efficacious. They think they shall and discharge their duty sufficiently if they expose their own lives on all occasions, either offering themselves or fought for. The examples of several places, which, though taken through want of good conduct, have neverthless been defended with a considerable degree of valour and valor, are apt to lead them into this error. But they would have no reason to dread the blame that might attach to their surrender sooner than they ought, were they to add to their valor that knowledge of defence, which they but too often neglect to acquire.

They believe, that when their outworks are taken, and the miner is attached to the body of the place, or at the mift, if the bastion be at all opened, or a breach made in it, they may surrender and capitulate with honour after appearing sword in hand on the top of the breach at the head of a battalion, that does not fight but only faces the fire of the cannon and mufquetry of the attack, and then retires from the breach behind some trifling and weak retranchment, that appears to have been made more for the capitulation of the troops than for the defence of the place. Such prompt capitulations are sometimes occa- sioned and brought about by the reasonings and importunity of the other officers, who urged by self-interest with to preserve the little baggage and effects that belong to them, and preferring the preservation of them to their real glory, persuade the governor, who for particular reasons of his own wishes also perhaps to be per- suaded, that he may capitulate with honour; that it is much better to secure by a voluntary treaty the liberty of the inhabitants and to march out drums beating, colours flying, arms loaded, balle en bocche to reload them with, matches lighted, and with some pieces of cannon, their baggage and effects, than to await an approaching extremity and to run the risk of being ilomed or having the place carried by force. They represent to him, that one part of the soldiers are wounded, that others are sick, and that those, who are still in a condition for service, are disheartened and disheartened; that their long watchings, their severe fatigues and sufferings, well entitle them to his most fervent attention to their safety and preservation. By urging these and many such other bad reasons, they endeavour to make him form the resolution, which he has himself perhaps already taken, of capitulating, and of which he is probably well pleased in his own mind; that they have made him the overtaker or pro- posal, since, after some formalities, he concludes with them on surrendering up the place; as if a bastion, that is not perhaps bared or stripped of its revetment in more than one spot, furnished a free and easy entrance to the enemy, or as if the flate to which the place belongs had gone to the ex- pense of erecting the works and reveting the ramparts for no other purpose than that of procuring such a capitulation, as troops often make in small and bad redoubts, and some- times in the open field. Such conduct is base and di- nornourable, and such ideas are grafted on ignorance of the proper method of defending works by means of retran- chments one after another, which is not only possible but practicable; and every governor or commandant, that understands and does his duty, will put in practice.

Many and numerous, indeed, are the contrivances for ren- dering the defence of a fortified place long and ruinous to the besiegers, if the governor and other officers of it were better instructed in their duty than they commonly are, and would sacrifice their interest to their glory and the good of their country. The governor or commandant of such a place, besides doing the utmost in his power to have it at all times supplied with a sufficiency of troops, provisions, artil- lery, ammunition, medicines, and every thing else, that is necessary for the support and comfort of the garrison in order to enable him to defend it properly and stand a siege, he should before it is invested or even expected to be besieged, take care that there are no ditches, fences, buildings, or any thing else within cannon-shot of the glacs or covert way, that can serve to cover the enemy from his view, or shelter them in opening their trenches. He should have every ditch filled up, every fence and tree cut down, and even every little eminence or riling ground within that dis- tance levelled if possible. Many of the governors, however, and principal officers of such places act in time of peace as if they supposed they were never to be invested, and totally neglect their environs. They permit the inhabitants to make gardens, to furround these with ditches and fences, to plant trees, and even to erect buildings within cannon-shot of their works; and the moment an enemy appears before the fame they are often so ignorant of their duty as to attempt to cannonade him and to throw their shot at him as great a distance as they are able, as if they wished to facilitate his enterprise or to aid and affiit him in the execution of his de- sign by pointing out to him the very ground where he ought to form his encampment, and the distance at which he should open his trenches and commence the attack. The besieged, however, remaining quiet instead of pursuing such injudicious conduct, is usually attended with one or other of the two following advantageous circumstances; namely, that the besiegers fix their camp either too near to the place, or farther from it than is necessary. If it be too far off, the line of cir- cumvallation becomes too extensive, and is of course less calculated than it otherwise might be for preventing succors from getting into the place. And if, on the other hand, it be too near, the besiegers after some days when the cannon of the place begin to fire on them will be obliged to move it farther off; by which means the line of circumvallation must be commenced anew, and their time and labour will be lost, which, at the beginning of a siege, is all that the besieged can expect or desire.

As it is customary for the enemy a day or two after the opening of the trenches and sometimes on the very same day to advance in order to reconnoitre the places most con- ventient or commodious for the attack, and this reconno- trying is often performed by the general of the besieging army himself, that he may know what resolution to take re- specting it; the governor or commandant of the place should take particular care that none of his people are made priso- ners. For even the most ignorant of them might furnish useful intelligence to the enemy.

When the besieging army is weak he may send out a large body of troops to keep them at a distance by means of muf- quetry. But when it is strong, he should not leave without the place, but a small number of cavalry or infantry, with direc- tions by a feigned retreat to draw the enemy into a situa- tion that will expose them to the fire of the works if they at- tempt to approach and charge them.

The governor or commandant of a fortified place should know how to counteract and prostrate the operations of the besiegers.
CAPITULATION.

befiegers by means of counter-approaches, by forties or fallies, by mines, &c.; all which he ought to make use of and put in practice, disputing every inch of ground, as well as various contrivances for rendering breaches impracticable after they appear to be practicable to the enemy, before he seriously thinks of capitulating. Before the place, intrusted to his care, is actually attacked, he should frequently weigh and ponder in his own mind every possible or practicable method of attacking it, that he can imagine or conceive, and then endeavour to find out as many different sorts of defence for countering and prolonging them. Such mental reflection and examination would render it almost impossible for any occurrence to take place during a siege, that he had not already thought of, or that did not at least bear some resemblance to what he had thought of, and, would enable him to draw from this likeness or similitude prompt resources and expedients.

The articles of capitulation are proposed by the governor or commandant of the place besieged, who receives hostages for the safety and security of those, whom he sends to the general of the enemy. It is customary to give hostages of equal rank reciprocally.

The stipulation of the articles proposed, the alteration, modification, or refusal of some of them, is governed by a variety of considerations depending on the views and knowledge or information of the general, who conducts the siege.

When the articles are signed, the besiegers take possession of some poll, or of a front attacked, according as it is agreed on.

When the time arrives, at which the garrison is to march out, it is usual to introduce into the place by way of honour and distinction the oldest corps of the army of the besiegers, which occupies polls for guarding it; and after the besieged have left it, those corps are marched into it, that are intended to garrison it.

The examination of the artillery, ammunition, flores, and provisos, that ought to remain in the place agreeably to the capitulation, precedes the going out of the garrison which is always done in concert by the officers of artillery, flore-keepers, and commissaries, who exchange signed accounts, or statements and discharges, from which the general gives orders for providing the place with what is wanted.

The troops, that march out, receive an escort sufficient for conducting them safe to the place appointed by the capitulation; an article, which of all others is in general most religiously observed.

After the marching out of the garrison, the first object of attention is the leveling and destruction of the works that were erected or thrown up for the attack of the place, and the repairing of all those, that were injured or damaged by the same. The besieging army, indeed, ought not to quit their lines after the place capitulates till they have filled them up, and either removed their heavy artillery into the place, or sent it elsewhere with whatever is not necessary for its defence. Then they may leave them either for the repose and refreshment of the troops fatigued with the siege, or for the convenience of subsistence, or to execute the remaining part of the plan of the campaign.

When the governor or commandant of a fortified place, after having made every practicable preparation for, and exhausting all his means of defence, is reduced to the necessity of capitulating, in order to obtain as favourable conditions as he possibly can both for his garrison and for the inhabitants, he orders one or more drummers to repair to that part of the rampart, which is next to the attack, and to give notice to the besiegers, by beating the chamade, that he has some proposals to make. For the same purpose one or more white flags are set up on the rampart, and one of them remains either on it or on the breach during the negotiation. The same formality is observed, when after a violent attack a submission of arms is demanded, either for the purpose of burying the dead or for carrying off the wounded.

After the beating of the chamade, the governor or commandant sends some officers of distinction to the commandant in chief of the besiegers to deliver to him the conditions on which he proposes to surrender up the garrison, the city, or fort. As a security, however, for the officers sent from the garrison, the besiegers send an equal number generally of the same rank into the place. When the governor's proposals are not satisfactory to the general of the besieging army, he on his part prefers the conditions, on which he expects it to surrender, commonly threatening to allow the governor no terms whatsoever in case he do not accede to those preferred within a certain time, or before such or such a work shall be finished. If the besieged find the terms or conditions inflected on by the besiegers to be too hard or rigorous, the officers sent to them return to the besieging army, and those sent by them return into the garrison. The drummers are directed to beat their drums upon the rampart, that every one may have timely notice to retire before hostilities re-commence, which they do very soon afterwards. During the negotiation or submission of arms no work ought to be erected or even repaired, either by the besieged or the besiegers. It is necessary, however, to be on the watch at that time as much as at any other, and strictly to guard every point liable to be attacked, to prevent any surprises by foragiers, which are regarded as warrantable and lawful.

But if the terms or conditions of the capitulation be agreed on, the governor or commandant sends two or three of his principal officers into the camp, and the besieging general sends the same number of officers of equal rank into the place, as a security for its accomplishment. When the besieged have performed every thing agreeably to the compact or treaty, their hostages are sent back to them, as are those of the besiegers as soon as the terms, they agreed to, are complied with.

The terms or conditions of a capitulation vary with circumstances and situations; but they are generally to the following purport.

1. The garrison shall march out through the breach with their arms, baggage, horses, drums beating, matches lighted at both ends, bulles en boisse, colours flying, a certain number of pieces of cannon and mortars, with their appurtenances, spare carriages, ammunition for a certain number of charges; to be conducted in safety by the shortest road, or by a specific route, to the nearest town or place belonging to the besieged, and if the distance be so great as to require a march of several days, to be provided with provisions and lodgings during that time.

2. That one of the gates shall be delivered up to the besiegers the evening of the day on which the capitulation or convention is signed, or at a certain hour next day, and that the garrison shall march out a day or two after, according to agreement.

3. The besieged shall furnish a certain number of covered waggons, which are not to be searched, besides others for carrying the wounded and sick that are in a condition to be transported, and in general all the carriages and horses necessary for removing the garrison's baggage, and the artillery allowed by the capitulation.

4. That the sick and wounded who cannot be removed or carried off, and are obliged to be left behind in the place, shall
shall have free liberty to go away, with every thing that belongs to them, when they are in a condition to do so; and they shall in the mean time be furnished with lodgings, and with provisions, goods, or otherwise, and have every sort of medical aid or assistance that can well be afforded to them.

3. That the inhabitants shall exercise their religion according to their accustomed forms of worship, without hindrance or molestation.

4. That the inhabitants, both of the place and its dependencies, shall be maintained in all their rights, privileges, and prerogatives.

5. That the citizens who choose to leave the place shall have free liberty to go whether they please with their effects; and such of the inhabitants as have drawn a partiality to the besieged, or affihed them during the siege, shall not be molested on that account.

6. All the remaining powder and ammunition shall be delivered up to the besiegers, and the loaded mines shall be blown and pointed out to them.

7. All the prisoners made on both sides during the siege shall be released.

A garrison should have a sufficiency of provisions and ammunition to last for three days to entitle them to a convention or capitulation. But if they have not near so much of either, at the signing of the capitulation, they cannot in justice be afterwards regarded as prisoners of war, because the besieged were not at the time acquainted with the circumstances.

If the besiegers will not agree to any other stipulation than the besieged's being made prisoners of war, and the garrison is not in a condition to hold out any longer, it is generally endeavored to render the conditions as little burdensome and rigorous as possible; such, for instance, as the following:

1. That the governor or commandant, and the principal officers, shall keep their swords, pistols, baggage, &c.

2. That the subalterns shall keep their swords and baggage.

3. That the common men shall not be ridden or dispersed about from their regiments.

4. That the garrison shall be conducted by the shortest road to a certain place, and there remain prisoners of war.

5. That the principal officers shall have leave for a few days to go where they please to settle their affairs.

6. When the garrison quits the place, no attempts shall be made to debuff the soldiers, or to encourage them to desert from their regiments.

When the capitulation is settled and signed, an officer of artillery from the besiegers comes into the place, who, with an officer of artillery from the garrison, takes an inventory of all the ordnance and ammunition in it; and commissaries, in like manner, take an account of all the provisions.

The besieged may destroy magazines before, but not after they have made any provision for a capitulation.

When the day arrives on which the garrison is to leave the place, the army of the besiegers is put under arms, and ranged in two files, between which the garrison marches. The general and the principal officers head the two files, to see the garrison done before them.

The governor or commandant marches at the head, followed by the principal officers, who make the garrison march in as good order as possible. The least regiments are common in the van and in the rear, and the others, with the baggage, in the centre. When there are any horse or cavalry, they are also divided into three bodies, to march as the van, centre, and rear. Small detachments of horse and foot are made to march at the sides of the baggage, to prevent it from being rifled.

The artillery allowed by the capitulation march after the first battalion.

When the garrison arrives at the place agreed on, the governor gives up the hostages of the besiegers to the escort; and when the escort reaches the army, the hostages left by the besieged for the security of the escort, carriages, and other things allowed to them, are released.

When the garrison are made prisoners of war, they are in like manner escorted to the place agreed on.

Every thing stipulated or agreed upon in a capitulation should be held sacred and inviolable, and ought to be religiously observed. For when the king grants and signs a capitulation by his general, he acts in the same capacity as when he enters into and concludes a treaty of peace by his ambassador; in either case he acts as the procurator or agent of the community at large, as the constitutional representative of parliament and the nation, and every such act of his is equally binding on both. It is evident that parliament thought fit when it passed the act that established the church of Rome at Quebec and in Canada, and was convinced that it could not constitutionally violate the stipulations made in favour of that religion in the capitulation entered into by general Amherst and the marquis de Vaudreuil.

When the surrendering place or city has a citadel, it should be stipulated that the garrison shall have a certain time allowed them for retiring into the citadel with what they want; that the sick and wounded, who are not in a situation to be removed, shall remain in their lodgings in the place till they are cured or get well, when they are to be furnished with carriages and passports to retire to some place agreed on; that none are to be admitted into the citadel that cannot be useful in assisting to defend it; and that the besieged shall not erect any work or works whatsoever for the purpose of carrying on approaches against the same during the time prescribed.

If the operations, either of the besieged or besiegers, be carried on in conjunction with confederates or allies, stipulations ought to be made on and in their behalf; and if they be principals as well as the besieged, they should be parties to the capitulation.

If the place be a maritime town, with a harbour or harbours, and shipping in them, belonging either to the besieged or to their allies, or other nations, terms or conditions respecting those should be expressly inserted in the body of the treaty or convention.

If the besieged be in a place that is situated in a country distant from their own, to which they cannot return but by water, and have no other strong hold in that country for them to retire to, they should take care to have it stipulated in the capitulation that the besieged shall furnish them with transports, provisions, and a sufficient convey, and carry them to the nearest port or ports in their own country.

As the capitulation agreed to and signed by lord Keith, lord Hutchison, Hullem capitain pouch, and general M'nest, at Alexandria the 30th August 1801, comprises as great a diversity of the foregoing specified conditions or stipulations as any other that we know of, we will conclude this article by inferring it as a very good specimen, form, or model.
CAPITULATION.

Articles of the Capitulation signed by Abdallah Jacques Fran
cois Menou, General in Chief of the French Army now in
Alexandria, to the Generals commanding the Land and Sea
Forces of His Britannic Majesty, and of the Sublime Porte,
forming the Blockade of Alexandria, dated the 12th Fructi
tor, Fourth Nine of the French Republic, (30th of August,
1801.)

Art. 1. From the present date to the 30th Fructidor
(17th of September, 1801), there shall be a continuation
of the truce and suspension of arms between the French ar
my, and the combined armies of his Britannic majesty and
of the Sublime Porte, upon the same conditions with those
which actually subsist, with the exception of a regulation
at to be amicably settled between the respective generals of
the two armies, for establishing a new line of advanced
posts, in order to remove all pretext of hostility between the
troops.

Answer. Refused.

Art. 2. In case no adequate succour should arrive to the
French army before the day mentioned in the preceding ar
ticle, that army shall evacuate the forts and entrenched
camps of Alexandria upon the following conditions.

Answer. Refused.

Art. 3. The French army shall retire, on the first com
plementary day of the French era, into the city of Alexan
dria, and forts adjacent, and shall deliver up to the allied
powers the entrenched camp in front of the lines of the
Arabs, the Fort le Ture, and the Fort du Vivier, together
with their artillery and ammunition.

Answer. In forty-eight hours after the signing of the capitulation, namely, on the 2d of September, at noon, the
entrenched camp, the Fort Ture, and that of du Vivier, shall be deliver up to the allied powers. The ammunition
and artillery of these forts shall be also delivered up. The
French troops shall evacuate the city, forts, and dependen
cies of Alexandria ten days after signing the capitulation, or
at the time of their embarkation.

Art. 4. All individuals, constituting a part of the French
army, or attached to it by any relations, civil or military,
the auxiliary troops of every nation, country, or religion,
of whatever powers they may have been subjects before
the arrival of the French, shall preserve their property of
every description, their effects, papers, &c. &c. which shall
not be subject to any examination.

Answer. Granted; provided that nothing be carried
away belonging to the government of the French republic;
but only the effects, baggage, and other articles belonging
to the French and auxiliary soldiers who have served during
six months in the army of the republic; the same is to be
understood of all the individuals attached to the French ar
my; by civil or military capacities, of whatever nation,
country, or religion they may be.

Art. 5. The French forces, the auxiliary troops, and
all the individuals described in the preceding article, shall
be embarked in the ports of Alexandria, between the 5th
and the 12th of Vendemiaire, year ten of the republic, at
the latest (27th of September to the 3d of October, 1801),
together with their arms, flores, baggage, effects, and prop
erty of all kinds, official papers, and deposits, one field
piece to each battalion and squadron, with ammunition, &c.
&c. the whole to be conveyed to one of the ports of the
French republic in the Mediterranean, to be determined by
the general in chief of the French army.

Answer. The French forces, the auxiliary troops, and
all the individuals described in the 4th article, shall be em
barked in the ports of Alexandria (unless after an amicable
convention it should be found more expeditions to embark
a part of them at Aboukir), as soon as vessels can be pre
pared, the allied powers at the same time engaging that the
embarkation shall take place, if possible, ten days after the
capitulation shall be signed; they shall receive all the bu
tons, arms, baggage, &c. that shall not be prisoners of war, and shall moreover take with them
ten pieces of cannon, from four to eight pounders, with ten
rounds of shot to each gun; they shall be conveyed to a
French port in the Mediterranean.

Art. 6. The French ships of war, with their full com
plement, and all merchant ships, to whatever nation or in
dividuals they may belong, either of those nations at war with
the allied powers, or thole that are the property of owners
or merchants, who were subjects of the allied powers before
the arrival of the French, shall depart with the French ar
my, in order that those that are ships of war may be restored
to the French government, and the merchant ships to their
owners, or to their assigns.

Answer. Refused. All vessels shall be delivered up as
they are.

Art. 7. Every single ship that, from the present day to
the 30th Fructidor, shall arrive from the French republic,
or any of her allies, into the ports or roads of Alexandria,
shall be comprehended in this capitulation. Every ship of
war or commerce, belonging to France, or to the allies of
the Republic, that shall arrive in the port or road of Alex
andria within the twenty days immediately following the
evacuation of that place, shall not be considered as lawful
price, but shall be let at liberty, with her equipage and
cargo, and be furnished with a passport from the allied
powers.

Answer. Refused.

Art. 8. The French and auxiliary troops, the civil and
military agents, attached to the army, and all other indivi
duals described in the preceding articles, shall be embarked
on board some French or other vessels, actually in the ports
of Alexandria, as shall be in a condition to go to sea, or
on board those of his Britannic majesty, and of the Sublime
Porte, within the time fixed by the 5th article.

Art. 9. Commissioners shall be named by each party to
regulate the number of vessels to be employed, the number
of men to be embarked upon them, and generally to pro
vide for all the difficulties that may arise in carrying into
execution the present capitulation. Those commissioners
shall agree upon the different positions which shall be taken
by the ships now in the port of Alexandria, and those which
shall be furnished by the allied powers, so that by a well-regu
lated arrangement, every occasion of difference between
the crews of the several nations may be avoided.

Answer. All these details will be regulated by the Eng
lish admiral, and by an officer of the French navy, named
by the general in chief.

Art. 10. Merchants and owners of ships, of whatever
nation or religion they may be, and also the inhabitants of
Egypt, and of every other country, who may at the present
time be in Alexandria, whether Syrians, Copts, Greeks,
Arabs, Jews, &c. and who shall be desirous of following
the French army, shall be embarked with, and enjoy the
same advantage with that army; they shall be at liberty to
remove their property of all kinds, and to leave power for
the dispositions of what they may not be able to take away.
All arrangements, all sales, all stipulations, whether of com
merce or of any other nature made by them, shall be strictly
carried into effect after their departure, and be maintained
by the generals of his Britannic majesty, and of the Sub
lime Porte. Those who may prefer remaining in Egypt a
 certain
C A P I T U L A T I O N.

Article 1. The individuals composing the Institute of Egypt, and the commission of arts, shall carry with them all the papers, plans, memoirs, collections of natural history, and all the monuments of art and antiquity, collected by them in Egypt.

Article 16. The member of the Institute may carry with them all the instruments of arts and sciences, which they have brought from France; but the Arabian manuscripts, the flatlets, and other collections which have been made for the French republic, shall be considered as public property, and subject to the disposal of the generals of the combined army.

General Hope having declared, in consequence of some observations of the commander in chief of the French army, that he could make no alteration in this article, it has been agreed that a reference thereupon should be made to the commander in chief of the combined army.

Article 17. The vessels which shall be employed in conveying the French and auxiliary army, as well as the different persons who shall accompany it, shall be escorted by ships of war belonging to the allied powers, who formally engage that they shall not in any manner be molested during their voyage; the safety of such of these vessels as may be separated by furs of weather, or other accidents, shall be guaranteed by the generals of the allied powers; the vessels conveying the French army shall not, under any pretence, touch at any other than the French coast, except in case of absolute necessity.

Article 18. The commander in chief of the French army entering into a reciprocal engagement that none of these vessels shall be molested during their stay in France, or on their return; he equally engaging that they shall be furnished with every thing which may be necessary, according to the constant practice of European powers.

Article 19. Commissioners shall be named to receive the artillery of the place and of the forts, stores, magazines, plans, and other articles that the French leave to the allied powers; and lifts and inventories shall be made out, signed by the commissaries of the different powers, according to the forts and magazines shall be given up to the allied powers.

Article 20. A passport shall be granted to a French armed vessel, in order to convey to Toulon, immediately after the camps and forts before-mentioned shall be given up, officers charged by the commander in chief to carry to his government the present capitulation.

Article 21. On giving up the camps and forts mentioned in the preceding articles, hostages shall be given on both sides, in order to guarantee the execution of the present treaty. They shall be chosen from among the officers of rank in the respective armies: namely, four from the French army, two from the British troops, and two from the troops of the Sublime Porte. The four French hostages shall be embarked on board the English ship, commanding the squadron; and the four British and Turkish hostages on board.
board one of the vessels which shall carry the commander in chief, or the lieutenant general. They shall all be reciprocally delivered up on their arrival in France.

Answer. There shall be placed in the hands of the commander in chief of the French army, four officers of rank as hostages: namely, one officer of the navy, one officer of the British army, and two officers of the Turkish army. The commander in chief shall, in like manner, place in the hands of the commander in chief of the British army four officers of rank. The hostages shall be restored on both sides at the period of the embarkation.

Art. 22. If any difficulties should arise during the execution of the present capitulation, they shall be amicably settled by the commissaries of the armies.

Answer. Granted.

(Signed) Keith, Admiral.
J. Hely Hutchinson, Lieutenant General, Commander in Chief.
Hussim, Captain Pacha.
Abdoullah Jacques Francois Menou, General in Chief of the French Army.
James Kempt, Lieutenant Colonel and Secretary.

Capitulation denotes also a kind of treaty, pacta conventa, or original contract, drawn up by the electors, in the name of the princes and states of the empire, before the election of an emperor; which the emperor is to ratify before his coronation; and to observe inviolably in the course of his reign. The imperial capitulations have only been obtained since the time of Charles V., before which time the ordinary constitutions of the empire were in lieu of these capitulations. They were occasioned by the jealousy the German princes had entertained of the too great power of the emperor. Frederic, duke of Saxony, furnamed the Wife, posset for the author of the imperial capitulation; who, declining the empire, which was offered him after the death of Maximilian, advised the electors to choose Charles V. under such conditions as might secure the liberty of the empire. The design of the capitulation is, on the one hand, to prevent the emperor from abusing his power to the oppression of the people; and, on the other, to prevent the people from breaking in on the just rights of the emperor. And the principal points which the emperor undertakes to observe are the defence of the church and empire, an observance of the fundamental laws of the empire, and a maintenance and preservation of the rights, privileges, and immunities of the electors, princes, and other states of the empire, specified in the capitulation. The imperial capitulations are considered as fundamental laws of the empire; and though the drawing up, presenting, procuring the signature, and taking care of the execution of them, be committed to the electors, they are reputed the act of the states of the empire.

The king of the Romans also, when elected, signs the emperor's capitulation, as being in right of such election to succeed to the empire after the death of the emperor.

Capitulum, in Anatomy, a little head, especially of a bone, answering to the Greek condylos.

Capitulum, in Botany, the head, or compound flower of any plant; being composed of many leaves and threads or flamina, closely connected in a globe, circular or dishous figure; as the flowers of bluebottles, scabious, carduus, &c.

Capitulum, in Ancient Geography, a town of Italy, situated in the mountains above Prenele, in the country of the Hernie, according to Strabo. Pliny calls it "Capitulum Hernicum," and Frontinus "Capitulum," and says that it received a colony contrary to the law of Sulla.

Capitulum, in the Ancient Military Art, was a transverse beam, wherein were houses through which passed the wings whereby the axes of large engines, as ballista, catapult, and scorpion, were played or worked. Virro de Archib. lib. i. cap. i.

Capitulum, in Ecclesiastical Writers, denoted part of a chapter of the Bible read and explained.

In which sense they read, "he shall go in such a letter." Afterwards the place of apartment where such theological exercises were performed, was denominated domus capitulii.

Capitularia, in Ancient Geography, a town of Thrace, situated in the country of mount Rhodope. Procopius.

Capivaccio,槄cki, in Medical Biography, a native of Padua, where he arrived at the highest honours of his profession. In what year he was born is not known, but probably about 1575. In 1552, having passed through the usual degrees, he was made professer in medicine, an office he continued to hold with credit upwards, of 30 years, his lectures being always numerously attended. He was also in great request as a practitioner, and particularly famed for his skill in curing the loco venereum, by which he is said to have amased a very large property. This accounts for his refusing to remove to Pisa, though invited thither by the offer of a large salary by the grand duke of Tuscany. He wrote on every branch of medicine; and, as most of his works passed through several editions, we may suppose not unskilfully, though they are now generally superceded by newer opinions. He died in 1580. The titles of the principal of his works are, "De Lue Venerea Aeratea," "Sipir," 1595, Franc. 1594, 8vo. He first began the cure with giving the decoction of guaiacum and farfutar; thence not succeeding, he had recourse to mercurial injection.

"Methodus Practicae Medicinae, omnium Corporis Humani Curavit, Signa, et Curationes exuibus," Ven. 1591, fol. "Methodis Anatomicis, quae Aures Confessandi," edited by Teucer, with a dissertation in praise of anatomy. A compendium, containing descriptions of all the parts of the body, taken from Galen. Venet. 1593. Also, "De Factus Formationes, De Signis Virginitatis, De Urinis," &c. Thele, with several other smaller pieces, were collected and published together under the title of "Opera Omnium," fol. Venet. 1597, reprinted 1601-3, 6, and 17. Aflur De Morbi Ven. Douglas Bib. and Haller Bib. Med. Anat. et Chirurg. A malignant and fatal fever raging at Venice in 1576, Capivaccio was sent for to give his assistance in repressing it. But his endeavours not proving successful, and having unfortunately on his arrival declared the fever not to be contagious, he was sent away in disgrace. More than 100,000 of the inhabitants are said to have been swept off by the fever.

Capivard, in Zoology. See Capbara.

Capiv. See Balsam.

Capneleon, from καπνόν, smoke, and οίλον, oil, among Ancient Naturalists, denotes a species of seed, which flows spontaneously, being warmer, thinner, and more fluid than all other sorts of oils, so as nearly to approach the nature of oil, and evaporating plentifully on being exposed to the fire: whence the denomination, which imports as much as smoking oil. It is sometimes also called pflanthas, or flower of pitch.

Capnia, in Botany, from καπνόν, from, a genus formed by Venentus for the umbilicated lichens of Linneus.

Capnicyn, in Antiquity, chimney-money, or a tax which
which the Roman emperors levied for smoke, and which of consequence was due from all, even the poor, who kept a fire. This was first invented by Nicopolius.

CAPNIO, in Biography. See REUCHLIN.

CAPNISTON, among Ancient Plaetesians, denotes oil whose fumes, rendered aromatic by burning spices, are conveyed to a part affected.

CAPNITIS, or CAPNITAS Tepis, in the Natural History of the Ancients, the name of a species of chalcodony, of a brownish ground, clouded with a large tint of blackish, looking like a column of smoke. The ancients also called our common chalcodony a Jasper, not allotting any peculiar generic name to these milky stones; and the name they gave this species very happily expressed its character, because it looks exactly as if obscured, by a cloud of thick smoke. It is very common in the East Indies, and is sometimes found in Germany and France, but is seldom worked into any thing better than knife-hafts. See Chalcodony.

CAPNOIDES, in Botany. (Tourn. and Gartn.) See Fumaria, Capnoides, and Lutea.

CAPNOMANCY, a kind of divination by means of smoke, used by the ancients in their sacrifices. The word comes from capno, smoke, and maneo, divination. The general rule was, when the smoke was thin and light, a bad omen; if the contrary, it was an ill one.

There was also another species of capnomancy, consisting in the observation of the smoke rising from poppy and jellimin-seeds cast upon light coals.

CAPNOPHILLUM, in Botany, a genus formed by Gartnner for the Conium Africanum of Linnaeus, with the following character. Unbel compound, consisting of few rays; lateral rays of the partial unbel bars; central one: very short, fertile. Inclosed; very short, each consisting of about three leaves. Coarilla irregular. Fruit nearly.seffile; ridges mucronated with tubercles. See Conium Africanum.

CAPNOS, (Lobel.) See Fumaria officinalis, and Spicata.

CAPO, in Ichthyology, a name given by Paulus Jovius and some others to the fish called ececyx by the ancient Greeks, and cuculus by the Latin writers. It is presumed to be a species of trigla, most likely the modern trigla gurnardus; or, perhaps, applied indiscriminately to that species, and trigla lyra.

CAPA, Ital. the head, or beginning of any production. In vocal music, particularly in opera longa of two strains, da capo, at the end of the second strain, is an injunction to return to the beginning of the air or movement, or any part of it where this character of reference $\gamma$, can be discovered, and pursue its course as far as this sign $\gamma$, which is placed over the finale note. See Signo and Carson.

CAPO-BIANCO, in Geography, a canton of the department of the Golo, or life of Corfica, containing 6147 inhabitants.

CAPO d'Ialria, a sea-port town of Ialria, belonging to the state of Venice, the seat of a bishop, suffragan of Udina, situated in the gulf of Trieste, in an unhealthy district, near salt marshes; 7 miles S. of Trieste. N. lat. 45° 43'. E. long. 14°.

CAPOC, in Commerce, a sort of cotton, so fine and so short, that it cannot be spun. It is used in the East Indies to line palanquins, to make beds, mattresses, cushions, pillows, &c.

CAPOETAS, in Ichthyology, a species of Cyprinus, inhabiting the Cyprian Sea, and in winter migrating up the rivers. The anal fin has nine rays, the third ray of the dorsal and anal being the longest, and serrated downwards; and it has two cirri. Gmelin.

COPOLETTO, a town and port of Afa, in Georgia, seated on the Black Sea.

COPOLINIERI, a small town of the island of Elba, near the coast of Tuscany.

COPOLETTO, in Geography, a river of North America, in the province of Guaxaca, which runs into the Pacific Ocean, in miles N. E. of Tangolotargo.

COPPOLINI, in Botany, Mexicanum Hendrues, seu Copoletta daiti. Indicus. It is a tree of moderate bigness, with leaves like thofe of an almond, or our country cherry tree. The flowers hang down in bunches, which are succeeded by fruit resembling our cherries. It blossoms in the spring, and bears fruit almost the summer; it requires a temperate climate, and grows in gardens and fields in Mexico, as well spontaneously as by cultivation.

The juice of the young buds mollifies the tongue when pressed by heat. A decoction of the bark being exposed to the sun for fifteen days, and the weight of a dram of it taken, cures the dysentery. The powder helps inflammations.

In times of dearth, they make bread and drink of the fruit; but it affords an aliment inclining to melancholy, giving a rankness to the breath, and making the teeth black. There are three species of this tree, which differ only in fruit; but all of them hang in clusters.

CAPON, in Rural Economy, a cockerel, which has been culivated as soon as by the hen, or as soon as he begins to crow. Capons are useful to head chickens, ducklings, young turkeys, pheasants, or partridges, as they do it better than hens, and at the same time defend them better from birds of prey, and, from the largeness of their bones, they can cover a greater number of them, and much more completely. See Poultry.

CAPON'S Tail-grafs. See Festuca.

CAPONIER, or French Caponiere, or Caponiere, a sort of double covert-way, with a parapet on each side, sloping, and terminating in the form of a glacis. All communications of this sort and form, between either the body of the place and the outworks, or between the faltant angles of the covert-way, and either arrows or other works at the faltant angles of the glacis, or between the faltant angles of the covert way, and detached redoubts, or works advanced to some distance beyond the glacis, for the purpose of occupying particular spots of ground, to prevent an enemy's getting possession of them, may with propriety be, and sometimes are, called caponiers.

When the communication is directly opposite to the middle of the curtain, and extends from the tenailles across a dry ditch to the re-entering angle of the counter-scarp, or of the ravelin, it is from twelve to fifteen feet wide, has a banquette on each side, as also a parapet, which terminates in the ditch in a gentle slope, in the form of a glacis, at the distance of ten or twelve fathoms from its interior side. The inside of it is excavated from two to four feet below the level of the ditch, and the parapet is raised from three to five feet above the same level. It serves as a safe passage for the troops from the body of the place to the counter-scarp and outworks. Such caponiers are frequently made in dry ditches, even when there are no tenailles opposite to the curtains.

The principal use of such caponiers is to defend, directly, the passage of the ditch opposite to the faces of the bastions, and to afford the soldiers a secure communication between the body of the place and the outworks. To prevent their being seen, as they are quitting or leaving them, the re-entering angles of the counter-scarp are often partly cut off by right lines parallel to the curtains and excavations, or lodgments.
ments are made in those places, sometimes in one form and sometimes in another.

When such a communication is made between a salient angle of the covert-way and a work on one at the foot of the glacis, it is commonly from twenty to thirty feet wide, and has a traverse at its entrance, about eighteen feet thick, with a passage fix or eight feet wide round it.

When such a communication is made from a salient angle of the covert-way to a detached redoubt, or other work, advanced beyond the foot of the glacis, it is usually from thirty to thirty-fix feet wide; and when it is of any considerable length, has commonly two traverses, one at its entrance, and the other in the middle, or about half way between the work and the foot of the glacis.

It was the custom formerly to cover the exponier with thick planks, and a quantity of earth upon them, and to open small embouchures or loopholes in each parapet, for firing through on the enemy. But the smoke of the powder occasioned great annoyance and inconvenience to the men in it. It is, therefore, customary now to cover them, during a siege, only with hurdles or blinds, sufficiently to secure the men employed in defending them against flurces, which the enemy may throw into the ditch to make them abandon it. The same nuisance and inconvenience from smoke would be found to arise from the making use of fire-arms in such esquemeted galleries, with loop-holes in the counter-scarp, as those in some of the works at Portsmouth. Other arms or offensive weapons than fire-arms might, undoubtedly, be made use of in them, with much less inconvenience than miltets, and at the same time with greater effect and certainty, at so short a distance as the width of the ditch. See Fortification, § 18.

COPARALE, in Biography, an Italian performer on the violoncello, who came into England about the year 1733, and was much admired for the full and sweet tone which he drew from his instrument; which was his principal merit: for he was no deep musician, nor had he a poetical hand; yet he was always heard with great partiality by the public, and Handel frequently composed songs expressly to display his intelligible talent of tone.

COPARALI, Cesar, an Italian poet, was born at Perugia, in 1530, and having been successively employed in the service of several cardinals, died in 1631, at the fest of his patron Alcman, marquis of Carzano. As a poet in the benvilence, or burlesque style, he excelled all of those who wrote in the same style, particularly in decency of subject and imagery. His most popular piece was a satire on courts and courtiers, exposing to ridicule and contempt those who flunk into servility and wretchedness by aspiring to fortunes in an attendance on the great. He wrote also some poems of the romantic class, as his "Life of Meisson," left unfinished, and two comedies, viz. "La Scirocco," and "La Rinnettet? published at Venice in 1657. A collection of his poems, with the observations of his son, Charles, was published at Venice, in 1656 and 1662. Tribofchi, Morer. Gen. Biog.

COPARNACK, in Geography, a town and castle of Hungary, in Scelavonia.

COPAT, at Piequet, is when one of the gamellers wiss all the cards, in which case he gains forty points.

COPATO-TASTO, in Music, in high slits on the violoncello, is fluctuating the strings, by making the thumb of the left hand serve as a nut on the finger-board; by which means the four fingers can play as many passages without altering the position of the hand, as in its natural position, without shifting.

CAPOTENA, or Capotana, in Ancient Geography, a town of Abis, placed by Ptolomy in Asia.

CAPOTES, a mountain in Attica, in which, according to Plio, was one of the sources of the Euphrates.

CAP-PIGULDIA, the Capitula Edita of Ptolemy, the Ancient Provinces of Strabo, and the Parthianian Provinces of Ptolemy, a large upper map of land, drawing it in a great way into the sea, on the western coast of the ancient Buzianum, or Tanis. Upon the point of this promontory are the ruins of the city that was lost to those by Juliae, where is built a high round watch-tower. Two more of the like kind occur between this place and Syene; which are necessary guides to mariners in approaching this low and dangerous coast. To the S.E. of Capoula are the tombs and contiguous hills of the "Querables," the ancient "Carina," and "Circumus," at the diligence of five leagues. At these islands Stabo and other ancient geographers fix the beginning of the latter Syria; though Dr. W. is of opinion, it should rather commence at Capoula. N. lat. 3° 37'. E. long. 11° 25'.

COPOLI, or Capoli, one of the smaller Philippine islands, lying a little south of Laco, and three leagues in compass; the soil is fertile, agreeable, and commodious for the Indians, who live after the manner of the Bajazees.

CAPPONZVAR, a small but strong town of Hungary, seated on the river Capov.

CAPPAR, in Ichthyology, a species of Scena, having double scales on the sides of the head. Found in the Mediterranean.

CAPPADOCE, in Commerce, a sort of silk flock, taken from the upper part of the silk worm, and after the silk flock has been wound off. It is also called iasfu and cardufa, because flight fluffs under those names are made of it.

CAPPADOCIA, in Ancient Geography and History, was known to the ancients by the name of Syra or Alisyr, and borrowed the name of Cappodocia, according to Piny (l. iv. c. 3.) from the river Cappadox, or according to Herodian (apud Stephan.) from Cappadocus, the founder of this kingdom. In ancient times, this kingdom comprehended the whole of that country, which lies between mount Taurus and the Euxine sea; and was divided by the Parthians into two great provinces; and by the Macedonians, under the successions of Alexander and his two kingdoms; the one called "Cappodoci ad Taurus," and "Cappodocia Magna," the other "Cappodoci ad Pontum," and commonly "Pontus," which bee.

Cappadocia Magna, or "Cappadocia" properly so called, lay between the 18th and 41st degrees of north latitude; bounded on the north and Pontus, from which it was separated by a long chain of mountains, bearing towards the west the appellations of Lithus and Ophlinus, and towards the east the town of Parahie; on the south, by Lycaonia, and part of Armenia Minor; or, according to M. d'Anville, by mount Taurus, which separated it from Comagena and Cilicia; on the west, by Galatia and Phrygia; and on the east, by the Euphrates, and part of Armenia Minor, or, if it be made to comprise this latter province, it is almost wholly bounded by the Euphrates, which separated it from Sophene. In the time of Archelaus, Cappadocia was divided into ten prefectures, five of which lay near mount Taurus, viz. Melitena, Caramian, Cilicia, Tauris, and Hauritus; and the other five comprehended the remaining part of the kingdom, of the situation and principal towns of which Strabo has given no information. According to Ptolemy Cappadocia, to which he also annexes Pontus, was bounded on the west by Galatia; on the south by Cilicia, and part of Syria towards the Amanus; on the east by Armenia Major and
the Embrates; and on the north by that part of the Euxine sea, which extended from Amisos in Galatia to the branch of the Amusus that bounded the country on the east. The emperor Valens divided Cappadocia into two provinces, viz. Cappadocia Prima and Cappadocia Secunda, of which latter Tyana was the metropolis. The metropolis of Cappadocia, in ancient times, was Mazaica or Edhassa, called afterwards Caferara, which five. Its other cities of note were Comana, Nyfia, Nazianzum, Anablas, Dioscera, Faustipolice, Cabitira, and Sartrum, which five respectively. The principal rivers of this country were the Meias, the Halys, and the Sarus.

Whatever may have been the national character of the Cappadocians at an early period and under their first sovereigns, they were in the time of the Romans reputed lefievous, lewd, and addicted to all manner of vice; and they were deemed so infamous among other nations, that a wicked and impious man was emphatically called a "Cappadocian." The following very ancient Greek epigram, applied to the Cappadocians, is recorded by Constantine Porphyrogenitus:

"Каppаdοκοιν το ἱερόν κατά δειπνό, ἀλλὰ καὶ ἀφιείς, ἔκαθεν ὁ ἱερέας τοις καὶ νυσίν ἑλώνων."

"Cappadocam aequando vipsa mala momordit, fed et ipfa Mortua eel gultato fanguine virulentu."

It was a nation so fervile, says Strabo (l. xii. p. 372.) that when the Romans offered them their freedom to live by their own laws, they said they could not endure liberty. Cicero says of them, that they were "De Grege Venalium," whence it is inferred, that this country furnished a great number of slaves; see also Perius Sat. vi. sub fin Horat. Ep. vi. l. i. v. 59. This national character, however, underwent an important change after the introduction of Christianity; for we find among the natives of Cappadocia Gregory Thaumaturgus, Bashi the Great, and Gregory of Nazianzum.

The religion of the ancient Cappadocians was much the same with that of the Persians. At Comana they had a rich and flately temple, consecrated to Bellona, whose priests and attendants of both sexes amounted, in Strabo's time, to more than 6000. On festivals they had exhibitions of battles, in which the priests and their attendants cut and wounded each other in a transport of enthusiastic fury. They had also several other magnificent temples of Apollo, Catoeus, and of Jupiter, in the province of Marimena, which last had 5000 religious votaries. The chief priest, next in rank to that of Comana, had, as Strabo says (l. xii. p. 372.), a yearly revenue of 15 talents. Diana Perica was worshipped in the city of Callaballa, where women, devoted to the worship of this goddess, are said to have trodden bare-footed on burning coals, without injury. The commerce of the Cappadocians in mules and horses, produced in their country, was very considerable. The horses that were bred on the plains, which stretched from the foot of mount Argeus to the banks of the Sarus, were renowned above all others in the ancient world, for their majestic shape and incomparable swiftnees. Cappadocia abounded also with mines of silver, iron, and alum, and afforded alabaster, crystal, and Jasper, and probably supplied the neighbouring countries with these commodities.

It has been thought by those who have made researches into the history of ancient nations, that Cappadocia was peopled by the descendants of Togarmah, the youngest son of Gomer. In the time of Cornes the metropolis of Cappadocia formed a part of the kingdom of Lydia; and after the defeat of this prince, it became subject to the Persians, to whom the Cappadocians paid an annual tribute, as Strabo says (l. xii. p. 370.), of 1500 horses, 2000 mules, and 50,000 sheep. The most ancient king of Cappadocia, recorded in history, is Pharnaces, a noble Persian, who, having laved Cyrus from a ravenous lion, that pursued him while he was hunting, was rewarded with his father Artaxerxes, and the kingdom of Cappadocia. This country was afterwards subjugated by the Macedonians, and changed into a province; but it was restored to its former name by Ariarathes III., who, having cleared the general slaughter of the royal family by Pericles in the time of his father Ariarathes II., fled into Armenia; and availing himself of the civil divisions that took place among the Macedonians, recovered his patternal kingdom, and transmitted it to his posterity. After a succession of 10 princes, Archelaus, though not related either to the family of the Persians or that of Arishzaranes, which had possessed the sovereignty, was placed on the throne of Cappadocia by Mark Antony, to whom he continued faithful till after the battle of Actium. But having offended Tiberius by paying him no respect, during his retirement at Rhodes, he was enticed to Rome by letters from Livius, who, without discarding her son's retentment, promised him his pardon, on condition of his coming to implore it in person. Archelaus obeyed the summons; but was received by the emperor with contempt and indignation, and afterwards accused as a criminal in the senate. Although the crimes alleged against him were mere fictitious, he was so charged at being treated like a malefactor, that he is said by some to have soon died of grief, or, as others say (Tacit. Annal. lib. 1.), he laid violent hands on himself. Upon his death, the kingdom of Cappadocia was reduced to a Roman province, and governed by those of the equestrian order. Germensicus, A. D. 18, regulated the affairs both of Cappadocia and Commagena, and appointed two of his friends to the government of these provinces. In the year 73, Vespasian sent troops into Cappadocia and attacked the government of that province to the rank of confucl, instead of the order of knights. In this state Cappadocia continued till the erection of the new empire of Trebizon, with which it fell into the hands of the Turks; by whom the whole province, with the addition of Pontus, is now called Amasia, after the name of that city, where the begleber of Anatolia resides. See Amasia.

CAPPODAX, a river of Asia, which has its source in mount Amius, and discharges itself into the Euphrates S. E. of Samosara.—Also, a river of Asia which bounded the Cappadocians on the fide of Galatia, and commencing to the eall of Saounda falls into the Halys at Alpona. See Cappadocia.

CAPPGUM, a town of Spain placed by Pline in Bética.

CAPPIANUS, in Conchology, the name by which some old writers distinguished the sea- worm, or taleaceous mollusca, called by recent authors Teredo navalis. This is also known by the name of ship-worm, being that particular speccies which bores into the bottoms of ships, and to obviate the pernicious effects of which they are now generally fetched with copper from the keel to a little above the water's edge.

CAPAREA, in Ancient Geography, a town of Asia, situate in a plain of Syria, S. E. of Apamea.

CAPPARIDES, or Cappaedae, in Botany, the fourth order of the thirteenth class of Jullius's natural orders, and the eighth order of the thirteenth class in the arrangement of Ventenat; with the following characters. Caryx either many-seeded, or one-seeded divided into tegmen. Petals four or five, often alternating with the divisions of the calyx. Stamina seldom of a definite number. Germ simple, often flari-
tate or pedicelled; fleshy or pedicelled, sometimes flameniferous and glandular at its base; fleshy, or rarely one; ligula simple. Fruits many-seeded, either a fruitlet or a berry, one-celled (rarely many-celled). Seeds often kidney-shaped, either hedged in the pulp of the fruit, or allied to lateral receptacles. Perifertm none, though the interior coat of the seed is sometimes flaky and swollen so as to appear like a perifertm. Euboea seminiferum: radicle curved upon the lobes which are oblong-cylindrical, and applied one to the other. See Ventenat Pl. 15. fig. 3. Stem almost always a shrub or tree, rarely herbaceous. Leaves alternate, simple, entire, rarely ternate or digitate, proceeding from naked, scale-like buds; sometimes with two stipules, the same or glands at their base. Its genera, according to Jullien, are cleome, cadaba, capparis, fodies, cratae, morilina, and durio; the following are added as nearly allied, margarita, norraete, rafen, drofe, and paraffina. Ventenat describes under this order only cleome, capparis, cratae, and morilina; refere and paraffina as nearly allied. CAPPARIS, (Capparis, Theophrast, Dioscorides: derivation uncertain. Some suppose it originally Arabic.) Linn. Gen. 543. Schreb. 846. Willd. 1260. Joff. 243. Vent. 2, 123. Tourn. 155. Clufs and order, polyandra monographia. Not. Ord. patuminae. Linn. capparides, Joff. Gen. Ch. Cal. Perianth four-leaved or four-cleft, leathery; leaves or segments egg-shaped, concave, gibbous, caducous. Pet. four, obtuse, spreading, generally large. Stam. Filaments generally numerous, thread-shaped, spreading; anthers oblong, verifoliate, inclin'd. Fil. Germ pedicelled; frule; nigula obtusa. Peric. Berry, capsule or silique, fleshy, various in shape, one-celled, pedicelled. Seeds generally numerous, kidney-shaped.

Eff. Ch. Calyx four-leaved or four-cleft; leathery. Petals four, filaments long. Pericarp fleshy, one-celled, pedicelled. Obf. C. cantonicus is a five-leaved calyx and five petals.

* With fleshy stipules.

above; scaly-silvery beneath." Young branches, petioles, peduncles, and calyces covered, like hippocr rhinodoids, with ferruginous scales. **Leaves** alternate, petioled, acute, smooth above, but not shining like those of *C. breynia*; covered beneath with small, silvery, roundish scales, having a ferruginous dot in the middle; from three to four inches long, and scarcely an inch broad. **Flowers** rather small, terminal, several together, on short peduncles. *Siliques* five or six inches long, cylindric, a little swollen by the seeds, and of a reddish colour. A native of the Antilles, and described from a dried specimen in the herbarium of Jussieu. 34. *C. adoratiflora*, Willd. 21. Jacq. Hort. Schreb. 1. p. 57. tab. 110. "Peduncles many-flowered; leaves oblong-lanceolate, dotted with scales beneath." **Leaves** attenuated and rounded at the base, acute at the summit. **Fruits** the size of those of the common myrtle. **Petals** violet. **Stamens** a little longer than the corolla. The specific character as given by Willdenow is not sufficiently discriminative. 35. *C. longifolia*, Willd. 16. Mart. 20. Swartz Prod. 81. Pluk. phyt. tab. 327. fig. 6. "Inflorescence unknown; leaves linear-lanceolate, with mealy dots underneath." A native of Jamaica. 36. *C. jamaicensis*, Willd. 20. Lam. 22. Jacq. Amer. 160. tab. 101. "Peduncles many-flowered; leaves oblong, obtuse, marginate, downy beneath; corolla semi-crept, or bell-shaped." A shrub about six feet high, upright, branched, bushy; old branches smooth, blackish; young ones downy, ash-coloured. **Leaves** alternate, petioled, leathery, two inches long. *Flowers* yellowish white, fragrant; peduncles downy, terminal, and axillary. A native of Jamaica. 37. *C. cynophallophora*, Linn. Sp. Pl. 5, and C. flexuosa, Sp. Pl. 9. Willd. 23. Mart. 8. Lam. 13. Jacq. Amer. 138. tab. 98. C. arborefescens, frutic longifolium, Plun. Sp. 7. ic. 73. fig. 1. (Cynophallophorus, Pluk. 126. tab. 172. fig. 4. morifolia flexuosa, Aman. Acad. 5. p. 398. *Breynia folis oblongis obtusis, Browne Jam. 246. tab. 27. fig. 1. Acaecia affinis, silique tereti vetriculosa interiore tunica mucosa miniata, Sloane Jam. 1338. hift. 2. p. 59.) "Peduncles many-flowered, terminal; leaves elliptical, obtuse, smooth; glands axillar; fruit cylindrical, swollen by the seeds." Willd. A shrub twelve feet high in a good soil. **Branches** long, weak, pendant, or supported by the neighbouring shrubs. **Leaves** about three inches long, alternate, smooth, veined, on short peduncles. **Flowers** white, large, very fragrant; flowers often four inches long. **Silique** about six inches long, as thick as the human finger, opening longitudinally by two valves. **Seeds** kidty-shaped, very white, bedded in the bright scarlet fleshy, or pulp of the valves. A native of the West Indies, sent to Mr. Miller from Carthageana. Willdenow makes the flexuosa of *Linnaeus* a variety; but according to Martyn, it has been determined from an imperfect specimen in the Linnean herbarium, to be in no wise different from *C. cynophallophora*. 38. *C. verrucosa*, Willd. 22. Lam. 24. Jacq. Amer. 157. tab. 29. "Peduncles many-flowered; leaves oblong, acute, glabrous on both sides; fruit warty." Habit of the preceding. **Axillary** glands none. *Flowers* white, very open, with little smell; nectariferous glands flat, umbilicated; flowers an inch long, not much longer than the corolla. **Silique** oblong, round, green, shining, entirely covered with warts, two-valved, about an inch and half long; pulp white. Jacq. A native of thistles about Carthageana. 39. *C. frondifosa*, Linn. Sp. Plant. p. 1674. Willd. 17. Mart. 5. Lam. 12. Jacq. Amer. 162. tab. 104. "Peduncles in umbels; leaves crowded on all sides." A shrub commonly about seven feet high, but in thick shady woods not less than twenty; branches few. **Leaves** varying in size, the largest near a foot long, broad-lanceolate, acuminate, smooth, nerved, veined. **Flowers** an inch in diameter, greenish, or purple, falcate; common peduncle round, shining, erect, terminal. **Fruit** cylindrical, an inch and half long, shining, dark purple; fleshy whitish. A native of South America. 40. *C. granulata*, Linn. Supp. 263. Willd. 19. Mart. 15. Lam. 11. "Corymbs terminal; leaves egg-shaped, acute, smooth; fruit globular." A large hoary tree. **Leaves** alternate, entire, veined. **Flowers** pale yellow, in terminal corymbs, which are finally elongated into racemes. **Fruit** large. A native of the island of Ceylon. 41. *C. magnifica*, Mart. 16. Loureiro Cochin. 331. "Corymbs terminal; leaves ternate, lanceolate." A middling sized tree. **Branches** spreading. **Leaves** entire, smooth. **Flowers** large, white; calyx wheel-shaped; segments lanceolate, flat, interrupted; petals broad-egg-shaped, sharp at both ends, many-nerved, veined, spreading, equal, with long claws; filaments twenty-four, very long; anthers three-celled, oblong, recurved; germ rondh, pedicelled; style short. Berry two inches long, round, fleshy, eatable, dotted, rough, one-celled. **Seeds** numerous, kidney shaped, bedded in the fleshy, or pulp. A native of Cochinchina, much resembling *C. grandis*, and differing from it chiefly in its ternate leaves. 42. *C. oblongifolia*, Lam. 29. Forlk. Ægyp. p. 99. "Leaves oval-oblong, obfute, but ending in a sharp pointed tooth, perennial." 43. *C. mitribidactis*, Lam. 30. Forlk. Ægyp. 99. "Leaves alternate, pendulous, linear-lanceolate." Obf. The fruit of this remarkable genus merits a more accurate investigation. Authors are not agreed what it should be called in several of the species, and feem to have given it a name rather from its external form, than from a proper regard to its internal structure.

**Propagation and Culture.**—These plants can be raised in England only from seeds, which should be brought over in the capsules wrapt up in well-dried tobacco leaves to preserve them from insects. As they germinate immediately when fresh, it is not easy to get them dry to Europe; on that account they are scarce in our stoves, although many of them were cultivated by Miller. The seeds should be sown in small pots, filled with light sandy earth, and plunged into a hot-bed of tanners-bark; and should be allowed only a small quantity of water. They will frequently remain in the ground a whole year before they vegetate, and therefore require protection in winter. In the spring following, the pots must be plunged into a fresh hot-bed, and when the plants are come up, should have much air and little water. When large enough to remove, they should be transplanted finely into separate pots. In autumn they must be taken into the flove, and plunged into the hot-bed, where they should constantly remain, and be treated like other plants from the same countries, but should never have much water. Miller.

**Capparis Morifolia**, (Swartz.) See Morisonia.

**Capparis Fabago**, (Dodoens.) portulace folio, (Bauh. pin.) See Zygophyllum Fabago.

**Cappel, Lewis**, in *Biography*, an eminent French Protestant divine and Scripture critic, was born at Sedan in 1687; and becoming minister and Hebrew professor at Sauur, he disdissed himself in the controversy concerning the antiquity of the Hebrew vowel-points. His elaborate work, entitled "Arcanum punctuationsis revelationis," Leyd. 1624, contains strong arguments to prove that the points were not used by the original Hebrew writers, but were added to the text by the Mafortes. He also maintains, that the characters of the Hebrew text were those used by the Chaldeans after the Babylonish captivity, and that before that period the Jews always employed the Samaritan character. The members of the reformed and Lutheran churches
churches were alarmed by this hypothesis, conceiving that it tended to diminish the authority of Scripture, and to reduce it to a level with tradition. The Roman Catholics, on the other hand, eagerly adopted it. It is affirmed, however, that the leaders of the reformation, Luther, Zwingle, and Calvin, were of the same opinion, and the hypothesis is now very generally received. Cappel, unmindful of opposition, pursued his plan, and in his famous work, entitled "Critica Sacra," fol. Paris, 1650, produced a number of various readings, and a list of the errors of抄写ists in the Bible, accompanied with critical remarks. See PUBLISHERS.

The printing of this work was delayed for 10 years, by the opposition it met with at Geneva, Sedan, and Saumur; till at length a son of Cappel, who was a convert to popery, obtained permission by the intercess of fathers Patai, Morin, and Merienne, to print it at Paris. It was warmly attacked by John Buxtorf, in his "Anticriticus," and by other divines; but Grotius, in a letter to the author, expressed his approbation of the work. Cappel likewise published "Sacred Chronology," Paris, 1655, which is printed by Wolton in the Preliminary to his Polyglott. After his death were published his "Commentaries, theological and critical, on the Old Testament," together with the defence of his "Aretium," at Amsterdam, 1689, fol. This learned writer died at Saumur in 1658. Moret, Molinie, E. H. vol. v. p. 377, &c.

CAPPET, in Geography, a place of Switzerland, in the canton of Zurich, where, on account of a religious dispute, a battle was fought between the Catholics and Protestants, in 1551, in which Zwingle, the reformer, lost his life; 9 miles S. of Zurich.

CAPPET, or Waldkapel, a town of Germany, in the circle of the Upper Rhine, and principality of the Upper Hesse, 22 miles S.E. of Caffel.

CAPPET, or Kappel, a small but neat town of Denmark, in the duchy of Sleswic, on the east coast; 16 miles N.E. of Sleswic. It contains about 550 inhabitants, who are industrious, and carry on some trade, exporting bacon, cheese, butter, eggs, and other commodities to Copenhagen, and supplying the interior parts of the province with coffee, sugar, spices, and other foreign merchandise. The environs of Cappel are very pleasant, being grounds gently rising, sprinkled with much wood, and commanding fine views of the bay. N. lat. 54° 44'. E. long. 10°.

CAPPELLA, Ital. a chapel. This substantive is rendered a musical term on many occasions, as manifesto di cappella, a chapel master, or the director and composer of a chapel establishment, a chorister. A cappella, music in a chapel or church style. But the title of manifesto di cappella is not confined to ecclesiastical composers and masters of a choir, but is extended to composers of an opera, and to composers in general. Nor does cappella always imply that a prince or nobleman who retains a band of vocal and instrumental performers in his service, has choral duty daily performed in his chapel; but that he has a band for his evening or occasional concerts, in his palace or mansion; as was the case with the duke of Chandos, at Cannons, in the beginning of the last century.

CAPPELLINE, in Heraldry, a mantling, or a sort of covering or hood, represented entire; not cut, and hanging back over the neck of the wearer. See Mantling.

CAPPELLO, Bernardo, in Biography, a celebrated Italian poet, was born at Venice about the beginning of the 16th century, and imbibed from Bembo, with whom he was intimate, the principles of Italian poetry. To his judgment, however, Bembo submitted his own poems. Cappello, in consequence of an opinion maintained by him in the Senate,

Vol. VI.
to the city. This happened about the year 1770. He was author of several abridgments, metaphysical works, feinting the humour of the time; but what alone seems deserving notice, is his account of a fatal epidemic prevailing in the island of Sicily, during the years 1771 and 2. " De Morti Epidemo qui miserrime Siciliam despossebat, Anno M.DCCCLXXI triduoque 1772, Caufis, Symptomatibus, et Curatione," McLeans, 159., 4to. Halket Bib. Med. Lloy, Dict. Hist.

CAPPRA, in Geography, a small Greek island, N.W. of the isle of Staeo, inhabited only by goats; its wine imports.

CAPPRA, in Zoology, a genus of the Mammalia class in the order Pecora.

The quadrupeds of this tribe have the horns hollow, turning upwards, and bent back, compressed, and rough: from teeth in the lower jaw eight: canine teeth none: chin bearded.

There are the goats of English writers, including our common goat, and its numerous varieties. The species of this genus already ascertained are few, amounting only to two, or three at the utmost, if the domesticated goat, Capra hircus, be considered as the genuine offspring of either of those species known in the state of nature at this time. It is thought by many, and the opinion is highly probable, that our common goat originated from the Capra alpine, Capra aegagrus, or perhaps from the fore goat, Capra ibex, of Linnæus. We can lay but little as to the third species that might have been the parent stock of our present race of domestic goats, the Capra canescens of Gildedenflein described in the Transactions of the Russian Academy for the year 1779; because it appears rather doubtful whether we ought to admit it as a species altogether different from capra aegagrus, or not.

In the twelfth edition of the Systema Naturae, the capra genus will be found far more extensive; Linnaeus having classified several animals of the antelope tribe as species of this genus. The Swedish naturalist was unquestionably justified in this respect, both by his own opinion, and by the example of ancient writers which scarcely an exception from the time of Pliny. They had, for instance, uniformly considered the chamois as appertaining to the race of goats; it was their repica, and even to this day it passes under the trivial name of the chamois goat, though in the systematic writings of modern zoologists it chiefly in the genus antelope. That the natural generic distinctions, if they may be so expressed, observable between the goat and the antelope tribes did not strike the mind of Linnaeus may be preferred as evident; there was but an inconsiderable number (about six species) of the antelope known in his time, and those he placed without hesitation with the goats in his genus capra.

The observations of later naturalists prove sufficiently that Linnaeus might have separated the goats from the antelopes with much propriety: were we to disturb the truth of this assertion, the writings of Pallas, of Schreber, Erxleben, Gilldenflein, Pennant, and Sommii mult siletc every doubt. Grubin, the editor of the last edition of the Systema Naturae, has availed himself of these recent authorities, the antelopes are separated from the goats under the generic name of antelope; the goats retaining the original appellation of capra.

A principal distinction between the two genera consists in the structure of the horns, those of the antelope being round and nearly cylindrical, and either twisted spirally, or annulated: the teeth are exactly the same in both; but the chin of the goat is bearded, while that of the antelope is not. A further very striking difference between the goat and the antelope is observable in the general figure of these animals. The goat is robust, strong, vigorous, petulant, and...
and feale; the antelope is of a graceful form: its limbs long and slender; its disposition timid, harmless, active, and watchful; and in the chase, when pursued on the open plains, its course incomparably more fleet than that of the goat.

Besides, therefore, the peculiar structure of the horns, and other characteristic particulars laid down by systematic writers, the manners and habits of life sufficiently prove that a line of separation ought to be drawn between the antelope and the goat. Mr. Pennant in his preface to the Synopsis of Quadrupeds treats of this subject at some length; his remarks are useful, and although they relate more immediately to the antelope than the goat, the leading points of his argument may be properly noticed in this place. The antelopes (says this author), two or three species excepted, inhabit the hottest parts of the globe; or at least, those parts of the temperate zone that lie near the tropics as to form a doubtful climate. None, therefore, except the saiga, and the chamois, are to be met with in Europe; and notwithstanding the warmth of South America is suited to their nature, not a single species has yet been discovered in any part of the new world. Their proper climates seem, therefore, to be those of Asia and Africa, where the species are very numerous. As there appears a general agreement in the nature of the species that form this great genus, it will prevent needless repetition to observe, that the antelopes are animals generally of a most elegant and active make; of a velvet and timid disposition; extremely watchful; of great swiftness; remarkably light and agile; and most of their movements so light, so elastic, as to make the spectator with astonishment.

Antelopes generally reside in hilly countries, though some inhabit plains; they often browse like the goat, and feed on the tender shoots of trees, which gives their flesh an excellent flavour. This is to be understood of those which are taken in the chase; for those which are fattened in houses are far less delicious. The flesh of some species is said to taste of musk, which perhaps depends on the qualities of the plants they feed upon. This principle (says Pennant) was thought necessary, to point out the difference in nature between the antelope and the goat kind, with which most systematic writers have classed the antelopes: but the antelope forms an intermediate genus, a link between the goat, and the deer; agreeing with the former in the texture of the horns which have a core in them and are never call; and with the latter in elegance and swiftness.

From the tenor of the preceding observations it will be perceived that the late Sir and well-informed zoologists consider it as a decided point that the antelopes and the goats ought to be separated, and we shall therefore speak of the species of Capra as they stand independent of the genus antelope.

**Capra ibex.** Horns on the upper surface knotty, and bending over the back: throat bearded. Brill, reg. an. — Lisa.

Steinbock is the familiar title, by which this animal is better known than any other. The name is derived from the German *stein* and *bock*, or buck of the rock, conveying at once an idea of the animal, and the situations in which it delights, and is commonly found. The French name bouquetin is of German origin, and in England the species is better known by the name of steinbock, than that of ibex goat, as it is called by Pennant. In its general appearance it resembles the common goat, but it is considerably larger, more vigorous, and more active. The colour is a deep brown or greyish brown; much paler, or steel in females, and on the inside of the horns; the outside of the horns are dark, or blackish on the lower part; but it is marked with a distinct black line. The body is of a fine, thick, flat and compressed; the ears are small, but full of fire and expression. The horns in the male are extremely large, measuring from two to three feet in length, and weighing eight or ten pounds; they are of a dark blackish colour, and are marked on the upper surface with transverse prominent terebentes, which it is reported indicate by their number the age of the animal, one additional being formed every year. These horns are thick at the base; and sometimes become so prodigiously large as to extend the whole length of the body. The female is smaller than the male; her horns are smaller in proportion, less distinctly marked with semicircular protuberances, and much weaker than those of the male. The legs are short, but the males are very short, and the hoofs short. The tail is small and of a blackish colour. The young steinbocks are of an ash-coloured grey.

The ibex is found in several parts of Europe and Asia; and it is said on all the great chains of mountains in the northern parts of the ancient hemisphere; upon the Alps, the Pyrenees, the Apennines, and Tyrol. In Asia it occurs on the summits of the chain of mountains extended from Taurus, and continued between Eastern Tartary and Siberia. It also inhabits the tract beyond the Lena, and is said by Vercy to be a native of the mountains of Kamtschatka. In Arabia it is not uncommon, and in the high mountains of the island of Crete it appears to be abundant.

In its general habits or manners this animal resembles the common goat, but possesses every attribute of strength and activity in a degree proportioned to its natural state of wildness. It inhabits the most inaccessible places among rocks and precipices in the hill regions of the mountains, where it finds all that is necessary for its frugal subsistence in the midst of solitude and security. Somnial observed them on many of the loftier elevations of the mountains in the island of Candia, and several other islands in the same sea, and beyond the upper half of Mount Olympus he found there were hardly any quadrupeds to be seen, except a few bears, and the bouquetin, or mountain-goat, capra ibex, who appeared to be sole masters of this solitary waste of nature.

The chase of the steinbock, like that of the chamois, is both difficult and perilous. When it retreats among the crouches and precipices it is impossible to pursue the animal in safety; the chase is then left to the dogs who are taught to hunt them over the most tremendous pales of the mountains amid ice and snow, where many of the dogs are sometimes lost in the vain attempt to follow or overcome their game. But should the mountain hunter once get sight of the steinbock at a distance from his dogs and within the range of his rifle piece he instantly takes an aim, and seldom fails to wound or kill the animal at the first fire. It is in this manner they hunt both the steinbock and the chamois on the Tyrolese mountains. The flesh of the young ibex is said to be in esteem as an article of food; that of the old ones is also eaten, and its fleece and skin employed for various purposes. We may further add that this is the animal whose whole blood was formerly considered as a valuable article in the materia medica, being celebrated for its supposed power of relieving pleuritic and many other complaints. Of its wonderful virtues in this way much has been related in the works of Gofner and Aldrovandus. Its period of gestation is five months as in the common goat.
Capra. "The origin of the domestic goat (says Mr. Pennant in his British Zoology) is the ibex, or wild goat, a species now found only in the Alps, and in Crete." The facts already related in the history of capra ibex clearly prove the writer to be mistaken in affording it to be found only in the Alps and in Crete; the observation is merely introduced to show that he believes the ibex to be the parent stock from which the domestic goat originated.

To ascertain the point in a satisfactory manner is perhaps impossible; we must allow our opinions to fluctuate, between probabilities and conclusions without concurring in our own minds the chance of arriving, with any absolute shrewdness, of the truth. Pallas allows that capra ibex may have been the original from which the domestic goat is derived, at the same time that he is inclined to think with equal probability it may have derived its origin from capra aggrus, the caucasian ibex of Pennant. The latter notion seems most prevalent; Cuvier adopts it; and we are led to think on a point: to ambiguous, not entirely without reason.

Buffon considers the capra ibex, the chamois antelope, and the domestic goat, as one and the same species. He speaks of it as likely that the male ibex coupling with the female chamois may have given rise to the present domestic race of goats.—"There are many cases (says this lively writer in another place) in which we cannot distinguish characters, nor pronounce on differences with certainty; there are others in which we are obliged to suspend our judgment and opinions; and in a great number of others we have not the slightest ray of light to direct us; for independent of the uncertainty arising from the contrariety of affections relative to recorded facts: independent of the doubts resulting from the insufficiency of those who have endeavoured to observe nature, the greatest obstacle to the advancement of knowledge is our ignorance of a great number of effects which time has not disclosed to us."—"We are ignorant whether the chamois goat be any thing more than the common goat in a wild state, or whether an intermixture would not form an intermediate race."—The naturalists of France, though proud of their immortal Buffon, cannot accede to his insufficient flight of his imagination. Sonnini, the editor of the last edition of his works, speaks of it as erroneous. Another French writer was more explicit: "It is absurd (he thinks) to suppose with Buffon that our race of domestic goats were produced from an intermediate breed between the bouquetin (capra ibex) and the chamois; an inspection of the exterior characters, and the internal organization of the three animals, to say nothing of their manners of life, seems to destroy all ideas of their being specifically the same." That the present race of goats cannot be the direct offspring of the cros breed between the ibex and the chamois, as Buffon thought, seems unquestionable; yet we think it pretty certain, from the evidence above adduced, that they may be the descendants of capra ibex, or bouquetin, and in that case that the dimmitude between the internal organization of the capra ibex and that of the common goat cannot be very apparent as our author pretends. This is an interesting point for the comparative anatomist to determine. An account was published in the French Journal de Phys, for October 1786, to prove that the capra ibex sometimes couples with the domestic goat, and produces mongrels. The fact was ascertained by M. Berthoud van-Berchem who saw an instance of it in the Valais, where the inhabitants rear numerous herds of tame goats, and the bouquetin is found in a state of nature among the mountains. It was long before well known that the goat will couple with sheep, the hybrid produce of which differs very little from the natural offspring.
CAPRA.

offspring of the ewe and ram, except in having a hairy instead of woolly fleece. We have yet to learn that an intermixture of the goat and sheep may be productive of a breed of fertile males, as Buffon seems to think very possible.

The history of the common goat has been very amply treated on by many writers, so that we can do little more than repeat the observations of others in this place.

The goat, in its domestic state, is found in almost every part of the globe, bearing the extremes of heat and cold, and differing in form according to various circumstances. It appears to have been originally confined to the old world, from whence it was transported to America. P. Browne seems to intimate that it is an aborigine of the island of Jamaica; but this is improbable; it is believed on very sufficient authority that it was entirely unknown to the Americans till after the discovery of America, when it was introduced by the Europeans.

This animal, observes Buffon, is superior to the sheep both in sentiment and dexterity. He approaches man spontaneously, and is easily familiarized; he is capable of curiously, and capable of a considerable degree of attachment; he is stronger, lighter, more agile, and less timid than the sheep; he is a spirited, capricious, wandering, wanton animal. It is with much difficulty that he can be confined, and he loves to retire into solitude, and to climb, stand, and even sleep on rugged and lofty eminences; he is robust, and capably nourished, for he eats almost every herb, and is injured by very few; his bodily temperament, which in all animals has a great influence on the natural disposition, is not essentially different from that of the sheep. These two animals, whose internal organization is almost entirely similar, are nourished, grow, and multiply in the same manner; and their diseasedsf are the same, excepting a few to which the goat is not subject. The goat fears not, like the sheep, too great degree of heat; he cheerfully expels himself to the sun, and sleeps under its mol hottest rays without being affected with the vertigo, or any other inconvenience; he is not afraid of rain or storms; but he appears to feel the effects of severe cold. The incongruity of his disposition is marked by the irregularity of his actions. He walks, hops, short, runs, leaps, approaches, or retires, hews, or conceals himself, or flies off as if accelerated by mere caprice, and without any other cause than that which arises from an eccentric vivacity of temper; the suppleness of his organs, and the strength and nervousness of his frame, are hardly sufficient to support the pertinacity and rapidity of his natural movements.

When penned along with sheep, goats always take the lead of the flock. They love to feed separately on the tops of hills, and prefer the most elevated and rugged parts of mountains. They find sufficient nourishment in healthy, barren, and uncultivated grounds. They do infinite mischief when permitted to go among corn, vines, copes, or young plantations; for they eat with avidity the tender bark, and young shoots of trees, which generally proves fatal to their growth. They carefully avoid moist ground, marshy meadows, and rich pastures. They are seldom reared in plain countries, where they never thrive well, and where their flesh is always bad.

The male goat is capable of engaging when he is a year old, and the female at seven months. But as the fruits of their early coupling are generally weak and defective, they are commonly restrained till they are eighteen months, or two years old. The he-goat is handsome, vigorous, and ardent, and one is sufficient to accompany an hundred and fifty females for the space of two or three months; but his ardour, which soon consumes him, does not last more than three or four years, and by the age of five or six, he becomes nearly enervated. In the selection of a he-goat for propagation, attention should be paid to his strength and age; he should be large, and about two years old; his neck short and flutiey; his head florid; his ears pendulous; his thighs thick; his limbs firm; his hair black, thick, and soft; and his beard long and bushy. The choice of the females is a matter of consequence, observing only, that those with large bodies, thick thighs, who walk light, have large udders, and soft bushy hair, are the most preferable. They are in season from September to the end of November, though they will couple and produce young at all times. The smell of the goat is highly unpleasant, that of the male especially. During the months of September and October, the whole atmosphere around them is filled with their strong disagreeable odour, and which, though as disagreeing as affecting us, in the idea of some naturalists, may perhaps be conducive to the prevention of many distempers, and to cure those of a nervous and hysterical kind. Horses are supposed to be much refreshed with it, on which account, many people keep he-goats in their stables or stables.

The female produces one kid, sometimes two, very rarely three, and never more than four: she carries her young five months, bringing them forth about April; and is in condition to breed from the age of seven months till she is seven years old. The he-goat, as before said, will propagate as long, if proper care be taken of him, but other-wise becomes useless two or three years sooner. He is then sent to fatten among the common herd. The strong smell of the goat does not proceed, it is said, from his flesh, but his skin. These animals are seldom permitted to grow old, or perhaps they might live eleven or twelve years; but it is usual to fatten and kill them as soon as they cease to multiply, because the older they are the worse is their flesh. The goats are animals that cost very little for their food, and in cold, mountainous countries are attended with considerable advantage: their flesh, tallow, hair, and skin, are all valuable commodities. Their milk is said to be more wholesome and better than that of the sheep; it is used in medicine, curiously calied, and makes very good cheese. The females, says Buffon, will allow themselves to be painful by infants, to whom their milk affords very excellent nourishment. "Like the cow and sheep, (continues this writer) they are affected by the weather, and also by the bird called in France l'angouleme, (the goat-fucker,) which fattens to their uses during the night, and, as some say, makes them lose their milk for ever after." It may be almost superfluous to point out the absurdity of this whimsical idea, founded, as we must believe, on the grossest prejudices of rustic ignorance; this notion is certainly entertained among the lower classes of peasantry, both in our own country and in France. It is a matter of surprise to many, that Sonnini in his edition of Buffon's works, has not endeavored to correct this error, or explain it to our satisfaction. The renderings with which the female goat will allow herself to be foolish by other animals, is indeed well known. Of this; Sonnini has given a very striking instance; he assures us that in the year 1788, he saw a foal which had lost its mother, nourished by a goat, which during the process, was placed on a barrel, in order that the foal might suck with the greater convenience. The foal followed its nurse to pillage, as it would its parent, and was attended with the greatest care by the goat, which always called it back by her bleatings when it wandered to any distance from her.

The colour of the goat is various, being either black, brown, white, or spotted. Those of Wales Mr. Pennant thinks far superior in size, strength, and fineness of the hair,
CAPRA.

to those of other mountainous countries: the goats of France, and the Alps, being generally short-horned, reddish, and small-horned; while the horns of the Cambrian kind have been seen three feet two inches long, and branching three feet further between the tips. "The fact of the goat is in great esteem, as well as the hair. Many of the inhabitants of the mountains breed cattle, and keep their animals to glean the reed on which they drive them in October, for the sake of the hair, either by flooding them with bullets, or running them down with dogs, like deer. The goats killed for this purpose are about four or five years old. Their fact will make candles, far superior in whiteness and goodness to those made from that of the sheep or the ox, and accordingly brings a much greater price in the market: nor are the horns without their use: the country people making of them excellent handles for tucks, and prokaries. The skin is peculiarly well adapted for the glove manufacture, especially that of the kid: abroad it is dressed and made into flockings, beds-tucks, bolster, bed hangings, frills, and even shirts. In the army it carries the foot-soldier's provisions. As it takes a dye better than any other skin, it was formerly much used for hangings in the houses of people of fortune, being susceptible of the richest colours; and when flowered and ornamented with gold and silver, became an elegant and superb furniture."

The fleece is of great use to the inhabitants of the country, where it refines, and affords them a cheap and plentiful provision in the winter months, when the kids are brought to market. The haunches of the goat are frequently fatted and dried, and supply all the uses of bacon: this, the natives is called eelb yr euden, or hung venison."

The meat of a fleshy goat of six or seven years old (which is called bfr.), is reckoned the best: being generally very sweet and fat. This makes an excellent patty; goes under the name of rock venison, and is little inferior to that of the deer. Thus nature provides even on the tops of high craggv mountains, not only necessaries, but delicacies for the inhabitants."

The above passages are selected from Pennant's description of the Cambrian goats, as they contain much useful information. It should, however, be mentioned, that those observations were written above thirty years ago, and are not in every particular applicable to the present state of things in Wales, where English manners, and English husbandry are making rapid innovations. The goat is an animal, we may strictly say from our own very recent observations, but sparingly cultivated at this time in the principality. The culture of this useful animal has been on the decline for the last twenty years, and is now almost wholly confined to the mountainous parts of Caernarvonshire: a small breed of sheep that thrive admirably well on the mountains, where goats were formerly kept, have superseded them: the rearing of cattle, and especially sheep, is considered more beneficial and respectable by the modern Welsh farmer. We have observed goats in greater numbers among the tremendous cliffs that overlook the paws of Pont-Aberglaslyn, than in any other parts of North Wales. In South Wales the goat is seldom seen.

The skin of the goat is readily converted into parchment, and it is also frequently used by the leather dressers for making what is termed Morocco leather: the best skins for this purpose are those of the Côrific breed of goats. The manufacturer, we also learn, can imitate the chamois leather so exactly with the skin of the goat, that the difference is scarcely to be discerned.

CAPRA Angora. γ. Body covered with very long, pendent, spirally curled hair.

CAPRA Angora. β. Chèvre d'Angora, Buff, &c.—Armenian, Penn, &c.

The Angora goat is in general of a beautiful milk-white colour, with short legs, and black spreading spiral twisted horns. The hair on the whole body is deposited in long pendant spiral ridges if it is even a pendent, and the horns of the female, instead of curling inward, as the male, turn outwardward, and are much shorter in proportion.

In its native country the animal is highly valued, and with sufficient reason, for it is a source of riches to its cultivators; the small, and most costly rubies of the highest classes in Turkey being fabricated of its silky fleece: the price it bears is very great. Most of the European nations have agents for purchasing the valuable wool of this animal, which the Turks, it is reported, will not allow to be sent out of their empire in a raw state, but in the form of thread; a multitude of the poorer orders obtaining a livelihood by spinning it. The most considerable manufacture of carders, fabricated with this wool in Europe, appears to be that of Lille and Amiens, in France. In order to preserve this beautiful hair in good condition, the goat-herds of Angora are peculiarly careful of their flocks, washing and combing them with the greatest diligence; and it is said that a change of pasture frequently makes them lose their beauty; this variety being naturally confined to narrow bounds, and produced only in the tract surrounding the towns of Angora and Beilbazar, two places situated in a small district of Asia Minor, not far from Smyrna, and remarkable for producing a peculiar race of sheep, cats, and rabbits, as well as goats, with hair of uncommon length and fineness.

CAPRA Mambria. γ. Horns recumbent; cars pendulous; chin bearded.

CAPRA Mambria, Linn.—Capra Syriaca, Driff.—Graffen mit kragendem Ohren, Runolff.—Chèvre Mambrie, ou chèvre du Levant, Buff.—Syrian goat, Penn.

This variety of goat takes its name of Mambria from a particular mountain, called Mambre, or Mambra, situated in the middle part of Palæstine, near the river Hebron, where they abound. The variety is common in many parts of the Eil, and is principally distinguished by the great length of the cars, which are pendulous, and sometimes reach so low as to inconvenience the animal while feeding. It is reported by travellers, that the owners of these animals, on such occasions, cut off one of their cars that they may feed with greater ease. This, however, is denied by Sonini and other French writers, who assure us that the cars of this goat never reach so low as the ground, and are never cut off. Its general colour is reddish, with short blackish horns. This is the common goat of Aleppo, the inhabitants of which are supplied with milk. The fame is the caique at Cairo, where these goats are driven in small flocks every morning through the different quarters of the city, and every one fees taken from them the quantity of milk they want.

CAPRA Dermo. γ. Horns small, deformed, and closely incumbent to the skull.

CAPRA depurata. Linn.—Capra porra Americana, &c., Driff.—Bouc d'Afrique, Buff. &c.—African goat, Penn.

This is a small variety, or dwarf kind of goat, found in some parts of Africa. The French call the male bouc d'Afrique, and the female, la chèvre naïve. This kind has rough, hair, and extremely short horns, which are very thick, triangular, and lie close to the head; in the female they are still shorter. Dr. Shaw observes, that Linnaeus seems to have entertained an erroneous idea relative to the native country of this variety, and to have suppos’d it an American animal. We may add, that although the animal was originally a native of Africa, it has been long since transported
Abalilus waged war against Perseus. Such was, he tells us, seen at the mouth of Augustus.; another on the tragedy of Sophocles; and at the death of Herakles.

CAPRA Rufostris, 6. Horns erect, and received at the tips.

Hex parvum Americanus, Brist. — Bene de Judá, Chiôro de Judá, Brist. — Whistle goat, Penn.

Herds of this species of goat, are cultivated in most parts of Upper Egypt. This is a dwarf variety, found in various parts of Africa. It is said to be also very common in Guiana and Angola. The flesh is considered an excellent food.

There is a variety of this kind with longer horns; the hair is long and silky, and the whole animal bears some resemblance to a small Aegypt goat. Buffon describes it as being considerably larger than the other, measuring two feet nine inches in length; while the other was only twenty-four inches long. Buff. Suppl. pl. 13.

CAPRA Capricorni, 6. Horns short, turned forwards at the tips, and annulated at the sides.

Ia capricornis, Buff. — Capricorn goat, Penn. — Capricorn goat.

A variety described by Buffon from a skeleton with the horns, preferred in the king's cabinet at Paris. The animal is supposed to be a native of Africa. In the form and proportion of the bones, Buffon tells us it bears a perfect resemblance to the domestic he-goat; and the figure of the under jaw is the same as that of the wild goat; but that it differs from both in the horns; those of the wild goat having prominent tubercles or knobs; and two longitudinal ridges, between which there is a well marked anterior face: those of the common goat have but one ridge, and no tubercles. The horns of the capricorn have but one ridge, and no anterior face; and though they want the tubercles, they have rugosities which are larger than those of the male domestic goat. Those differences, adds Buffon, seem to indicate an intermediate race between the wild and domestic goat; and, besides, the horns of the capricorn are short and crooked at the point, like those of the chamois; and at the same time are compressed and ringed; and hence, they seem to partake of at once the he goat, the wild goat, and the chamois. This variety appears to be feebly known, except from the description of it given us by Buffon.

CAPRA COTTA, in Geography, an inaccessible town of Naples, in the county of Molfet, seated on an eminence; 13 miles N.W. of Molfet.

CAPRA Saliens, or CAPRA Salinares, in Meteorology, a fiery meteor, or exhalation, which sometimes appears in the atmosphere, and is not fired in a straight line, but with inflexions, and windings in and out, resembling the caperings of a goat. The capre saliantes are not so called from their figure, which is various, sometimes round, sometimes long, but, from their moving by jerks, somewhat like the leaps of that animal; and from the little augments of fire which hang at, and sometimes fall from, them, which antiquity has been pleased to fancy like the beards or locks of a goat's hair. Ariostello distinguishes the capra from the trs, in that the latter proceeds with an uniform motion, the former with an irregular one, and as it were by jumps. Ariost. Met. lib. i. cap. 5. Mem. Ac. Infer. tom. vi. p. 95.

The capra seem to be very low, yet sometimes fly so high, that meteorologists have placed them in the upper region, though not so constantly, but they are sometimes found in the middle region. Of globular capra we have divers instances, in ancient as well as modern naturalists. Such was the flame said by Seneca to have been seen in form of a huge ball, about the biga of the moon, when Paulus

8
five flames. See Xyaresia. 2. C. crasifera, Linn. Mant. p. 87. Mart. 3. (Carus, Rumph. Amb. v. p. 491. tab. 170. fig. 3. C. Capraria uniforma. Brum. Fl. Ind. p. 153. tab. 14. fgr. 3.) Leaves opposite, egg-shaped, feecloped, on very short pedicels. Stems herbaceous, much-branched, four or five feet high. Leaves opposite, rather acute. Flowers axillary and terminal; peduncles simple, longer than the leaves. Linn. says that it resembles his caprarias gracilis, but that the leaves are more egg-shaped and petioled. Willdenow has omitted it. 3. C. lucida, Willd. 2. Mart. 6. Hort. Kew. ii. p. 353. "Leaves opposite, oblong, acute, sharply and minutely serrated, even; pedicels winged; peduncles three-flowered." Whole plant smooth. Stems quadrangular, biennial. Leaves an inch and half long; pedicels half an inch. Flowers axillary, a little longer than the pedicels; exterior pedicels sometimes three flowered; bracts awl-shaped, the length of the pedicels; segments of the calyx awl-shaped, three lines in length; corolla suffrutescent; tube cylindrical, pale purple, a little longer than the calyx, gibbous on the outside at the base, a little bent above, then erect, a little elongated on the outside; border horn-yal; segments egg-shaped, obtuse, equal, reddish purple, with a dark purple spot near the throat; throat hairy; anthers oblong, compressed; germ roundish; style shorter than the calyx; stigma large, convex, oblique. Hort. Kew. Willdenow observes that the fruit is a two-celled berry, as it probably is in all the Cape species, since they agree with it in the habit of the flower; and that, therefore, they may not improperly form a distinct genus. A native of the Cape of Good Hope: observed by Maillon. Introduced at Kew, in 1774. It flowers in April and May. 4. C. lanceolata, Linn. jun. Supp. 284. Willd. 3. Mart. 5. Hort. Kew. ii. p. 354. "Leaves opposite, lanceolate, entire; racemes compound, terminal." Stem shrubby. Root twossed long and more, acute, thick. Flowers in a terminal panicle, composed of short racemes. Found at the Cape of Good Hope by Thunberg and Maillon. Introduced in 1774. 5. C. semitellata, Willd. 4. Vahl. Ecol. ii. p. 47*. "Leaves lanceolate, serrated outwards; peduncles sometimes many-flowered." Stem herbaceous, erect, round below, angular above, intermixed with short hairs. Leaves two or three inches long, alternate, thick-fleshed, spreading, narrowing at the base into the petiole, acute, smooth on both sides, serrated from the tip to the middle, then entire. Flowers axillary, and terminal; peduncles scarcely half an inch long, pubescent, from one to four flowered; pedicels alternate, approximate, very short; bracte one at the base of each pedicel, linear-lanceolate, a little longer than the pedicel; segments of the calyx awl-shaped; corolla longer than the calyx, hairy at the bottom; segments five, linear-oblong; stigma capitate. Capsule oblong, a little longer than the calyx, two-furrowed, two-valved, splitting into two. Seeds numerous, very small, affixed to a linear, long receptacle. Vahl. A native of St. Martha, in America. 6. C. undulata, Linn. jun. Supp. 284. Willd. 5. Mart. 5. Hort. Kew. ii. p. 354. L'Herit. Sert. Ang. p. 21. "Leaves opposite, oblong-egg-shaped, entire, waved; upper ones somewhat heart-shaped, in whorls; racemes resembling spikes." Stem shrubby. Found at the Cape of Good Hope by Thunberg and Maillon. Introduced in 1774. 7. C. hastata, Willd. 6. Mart. 7. Hort. Kew. ii. p. 354. "Pubescent; leaves opposite, or in threes, egg-shaped, ferrated, petioled; peduncles axillary, shorter than the petiole." Root annual. Found in the East Indies by Dr. I. G. Koening. Introduced in 1781, by Sir Joseph Banks.

Propagation and Culture. The first species is propagated by seeds, which must be sown upon a hot-bed in the spring, and to bring them forward should be afterwards planted upon another hot bed. About the middle or end of June they may be transplanted either into pots of rich earth, or into a warm border, where they will ripen their seeds in autumn in the open air. The Cape species may be increased by cuttings, and are less tender. Martyr's Miller.

Caparia Gratiosioides, (Linn.) See Lindernia pyxidaria.

Caparia Durianifolia, (Linn.) See Staphyloct durianifolia.

Caparies. (Gra. Virg.) See Lecnea minor.

Caparia, in Geography, one of the Trench islands, in the Adriatic, about 4 leagues from the coast of Italy; very small, and uninhabited. "N. lat. 42° 16'. E. long. 13° 36'."

Capraienses, in Ancient Geography, an appellation given to mountains of Africa, in Maurania, which were inaccessible, and also to the inhabitants of these mountains.

Caprasia, a town of Italy, in Britton. — Allo, the name given by Pliny to one of the mouths of the river Eridanus, or the Po.

Caprata, in Ornithology, a species of Motacilla, of a black colour, with the rump, vent, and spot on the wing-coverts white.

Caprea, in Zoology. See Capreolus and Cervus.

Capreolus, in Ancient Geography. See Capri.

Capreolus, in Ectology, a species of Palaegae, (Cochen.) The wings flexuose, cinceres, with three oblique white streaks, and two lagnata. Inhabits Germany. Larva naked, green, and feeds on the willow.

Caprellus, that species of Aphis, that infests foxis caprea. This is small, of a greenish colour, with pointed abdomen; and the eyes, antennae, and tips of the legs black. Fabr. &c.

Capreolate Plants, in Botany. See Capreolus.

Capreolus, in the Ancient Architecture, a sort of rafters or timbers serving to sustain the cantier, either in buildings, or machines. They were thus called, not, as Philander imagines, from their resemblance to the capreola, or tendrils of vines, but from the affinity of their form and office to wild goats; as these butt and repel things with their horns, so do the former oppose their heads or horns to the weight of the cantier.

Capreolus, in Botany, a term used by the old botanists for a tendril, or caliper, called by Linnaeus circulus.

Capreolus, in the Ancient Hyphenary, a kind of iron hook or instrument with two forks or tongs, wherewith to stir and move the ground.

Capeolus, in Zoology, a species of Cervus, the foe of English writers. See Cervus.

Capri, in Geography, an old name of the Mediterranean, about three Italian miles from the coast of Naples, about eight miles in circumference. Although it is so mountainous that its coasts are almost inaccessible, some parts of it are very fertile; and it abounds so much with various birds of passage, and more especially with quails, that the greatest part of the bishop's income arises from the taking of these and the hunting of other game. Hence this island has been called the "biloporic of quails." Swinburne, (Travels, vol. iii. p. 7) informs us, that even in bad years the number of quails caught in this island amounts to
amounts to 12,000; and that in good years it exceeds 60,000. On the eastern summit of Capri are cliffs of stupendous altitude that overhang the channel, which separates this island from Capo Campanella, anciently called "promontorium Athenium, or Minervae." The island of Capri or Caprace is famous in history as a place often visited by the emperor Augustus both for health and recreation; and as the retreat of Tiberius, A. D. 27, where he abandoned himself to indolence, intemperance, and the most infamous debauchery. In this retired abode he spent a great part of ten years, secluded from the world, and wallowing in brutal debaucheries, the detail of which has been transmitted to us by many authors of unquestionable credit, although some of the practices which they recite seem to be incompatible with his advanced age and complicated infirmities; however, the obscene sculptures and medals, which have been dug up in almost every corner of the island, sufficiently prove that the charge against him is well founded. On the site of his summer palace now stands the hermitage of Santa Maria, commanding a most enchanting prospect. Tiberius, in order to vary his pleasures, and to enjoy the advantages as well as to avoid the inconveniences of each revolving season, built twelve villas in different situations, dedicated to the twelve greater gods, of some of which the ruins are still to be seen. At Santa Maria are extensive vaults and reservoirs, and on an adjoining brow are the remains of a light-house; two broken columns indicate the entrance of the principal court. At the palace of La Marina, Tiberius had a winter residence; where columns and other fragments of architecture scattered on the fards remain as memorials of its splendour. A semicircular recess of neat work, the "opus reticulatum" of Vitruvius, raised against the cliff, seems to have been a part of the theatre; and the conduit that supplied the palace with water still exists. The ruins stretch far into the sea, which has now submerged the territory from which it had formerly been expelled by terraces and piers. Here the soil is richly vegetative, and composed of diverse layers; a deep stratum of good mould covers a yellow hole, under which lies a stone exactly similar to the tufs of the volcanic hills round Naples. The palace was built with this stone, but in the abutments and back walls are inserted large pieces of lava in a rough flake of terracotta, like that of the crust of Vesuvian flaxes when cooled; yet the upper rocks of Capri are universally calcareous, and homogenous with the tufs of the Sorrentine mountains, of which they appear to have been a part till split asunder, and cast off by an earthquake that buried the intermediate grounds in the sea. These lower tracts in Capri have probably been thrown up by fire in the midst of lime-stone mountains, in the same manner as the plan of Sorrento. According to Dion Cassius, this island was wild and barren before the Greeks took it under their protection; at this day a large portion of its surface is uncultivated and impracticable; but every spot that will admit the hoe is industriously tilled, and richly laden with the choicest productions of agriculture. The odium attached to the memory of Tiberius proved fatal to his favourite abode. Scarcely was his death proclaimed at Rome, ere the senate issued orders for the demolition of every fabrick he had raised on the island, which, by way of punishment, was thereto forward defined to be a state-prison. The wine andol of Cumaeans were banished to its inhospitable rocks, which were soon filled with their blood. In the middle ages Capri became an appendage of the Amalfian republic, and, after the downfall of that state, belonged to the duchy of Naples. About a mile from the fourth side of this island are two or three pointed rocks, the "Scopoli Sirenae," mentioned by Virgil and Ovid in their description of Aeneas's voyage.

"This island," says Swinburne, "reminds us a variety of hazards and advantages, that it was not the fitter to me, who dwell on our unthrifty countrymen restored a man of an intrepid philosophical cast, to have been hai with a scene for meditation and bodily enjoyment; the temple of the air and the excellence of the fruits would secure his health; and the delightful scenery round him would dispel hia cares, and give an even cheerftul flow to his spirits."

Capri, a town of the island above described, seated in a narrow, low, but delightful and fertile spot of land, between two rugged eminences, which form the extremities of the island, and appearing at a distance by its cupolas and buildings to be a considerable place, but on a nearer approach dwindling to a village. It is the seat of a bishop, hifignam of Amala. It is 17 miles S. of Naples. N. lat. 30° 34'. E. long. 15° 38'.

CAPRI, in Ancient Geography, a part of Macedon, which, according to Mela, lay between mount Athens and the river Styron.

CAPRIANUS Muns, a mountain of Sicily, in the vicinity of the town of Hecalea.

CAPRIATA, Pier Giovanni, in Biographia, an historian of Genoa, who flourished in the 17th century. His Italian history comprehends the transactions that occurred in Italy during his own time, which he has related with clearness, and with facility traced to their causes; maintaining at the same time, as he says, a perfect impartiality between the powers of France and Spain, that were concerned in them. The two first parts of this history were published by Capriata in his life-time, from 1613 to 1644; and the third part, extending to 1660, was published by his son after his death. The whole has been translated into English. Gen. Dict.

CAPRICCIO, It. a musical term for a wild, irregular movement, but full of fire and fancy. It is generally intended to display execution in the performance of new and ingenious passages, with the freedom of an extemporaneous flight. During the last century, the caprice of Vivadi, Veracini, and Locatelli, were in high favour.

CAPRICE is applied, in Architecture, to an edifice of a singular tablet, and deviating much from the common rule of building.

CAPRICERVA, in Zoology, one of the synonyms of antelope cervicapra; which see.

CAPRICKE, in Geography, a town of France, in the department of Essaut, and chief place of a canton, in the district of L'Ecluse. The place contains 3239, and the canton 15,429 inhabitants. The territory comprehends 125 kilomètres and 8 communes.

CAPRICORN, the Goat, in Astronomy, a southern constellation and the tenth sign of the zodiac, from which also the tenth part of the ecliptic takes the same denomination. This was one of the 48 constellations received from the Egyptians by the Greeks.

The character whereby Capricorn is represented in astro-nomical writing, is \( \frac{\lambda}{2} \) or \( \frac{\lambda}{2} \), of which the other is an imitation. The former is a kind of resemblance of the crooked horns of t'goat, and the latter of the animal itself.

As to the figure of this constellation, the Greeks pretend that Pan, in order to avoid the terrible giant Typhon, threw himself into the Nile, and was changed into this figure; and that, in commemoration of this exploit, Jupiter took it up into heaven. But it is more probable, as Macrobius observes, that the Egyptians marked the portion of the heavens appropriated
priated to this sign, where the sun begins to ascend towards the north, with the figure of a goat, which is an animal that delights in climbing the sides of mountains.

The ancients accounted Capricorn the tenth sign, and when the sun arrived there, it made the winter solstice, with regard to our hemisphere; but the stars having advanced a whole sign towards the call, Capricorn is now rather the eleventh sign; and it is at the sun's entry into Sagittary, that the solstice happens: though the ancient manner of speaking is still retained.

The stars in the constellation of Capricorn, in Ptolemy's and Tycho's Catalogue, are 28; in that of Hevelius 29; though it is to be observed, one of those in the tail, of the sixth magnitude, marked in Tycho's book the twenty-seventh, was lost in Hevelius's time. Mr. Flamlleet, in the British Catalogue, enumerates 51 stars in this sign.

It is represented on ancient monuments, medals, &c. as having the fore-part of a goat, and the hind-part of a fish; which is the form of an ag(g)ia; and sometimes, simply, under the form of a goat.

For Dr. Heber's account of the latitude and magnitude of the stars in Capricorn, see Phil. Trans. vol. ixxvi. p. 199. 217. vol. lxxxvii. p. 259.

Capricorn, tropic of, a lesser circle of the sphere, parallel to the equator; passing through the beginning of Capricorn, and determining the winter solstice, or the point of the sun's greatest south declination. See Tropic.

Capricorn beche, in Entomology, the trivial English name of Cerambyx longimanus, which bee.

Capricorn-goat, in Zoology. See Capra Capricornus.

CAPRICORNE, the same given by Buffon, and other French writers, to Cattus capricornus, which bee.

CAPRICORNUS, a variety of the goat, Capra aegagrus, with short horns, that turn forward at the apex, and are annulated at the sides. See Capra.

Capricornus niger cornutus, Muf. Petrop. 672, is Cerambyx latius of Linnaeus.

Capricornus ruficus of Petiver, the insect called by modern entomologists Cerambyx editus.

M. Tournefort affirms us, that this method is still practised every year in most of the Grecian islands; and he admired the patience of those who spend above two months in carrying the flies from one fig-tree to another. Caprification is formed from caprificus, the wild fig tree, from whose fruits the insects are produced, which are the chief instruments of caprification. This tree bears three different species of fruit, called furnites, cratirites, and orni, which answer no other purpose but that of facilitating the above operation. The furnites appear in August, and contain little worms, hatched from eggs deposited by flies; in October and November, these worms become flies, which pierce the second figs called cratirites, which do not appear till the end of September: these figs continue to the month of May following, and furnish a lodgment for the eggs of the second class of flies. In May, the third species of figs, called ornis, appear; and when they are grown to a certain size and begin to open at the eye, they are pierced by the flies produced by the cratirites, or winter-figs. When the worms bred in these spring figs are transformed into flies, which happens in the months of May or July, the peafants gather them, and transport them to the garden fig-trees. The success of the caprification depends on this circumstance, and therefore they visit their wild fig-trees and their garden fig-trees every morning, to examine the eye of the fig; by which they judge when the flies are about to infuse from the wild figs, and when they may be applied to as to pierce the garden figs. They are then deposited on such trees as are fit to receive them, and take care that the fruit by the eye, where they lay eggs, the worms of which cause the garden-figs to attain their proper degree of bigness and maturity. The consequence of this operation is, that garden fig-figs, which would scarcely yield twenty-five pounds of ripe figs, and fit for drying, yield two hundred and eighty pounds.

As to the manner whereby the puncture of the flies contributes to the maturation of the fruit, possibly it may be by lacerrating the vessels, and extravagating the nutritive juice when they deposit their eggs; with the egg they may also convey some liquor which gently ferments with the juice of the fig, and softens its pulp. Even the Provence and Paris figs ripen much sooner by wounding their buds with a straw or feather dipped in oil-olive; plums and pears also wounded by insects are found to ripen the soonest, and in these the pulp about the wound is more exquisite than the rest. Mem. Acad. Science, ann. i. 705. p. 447. fqq.

Olivier, in "Nouveau Dictionnaire d'Histoire Naturelle," speaks of this practice as merely the effect of a vulgar error manifested by its high antiquity, and affirms that, after a long reflection in the islands of the Archipelago, he is convinced of its fruitfulness. Caprification, he observes, is unknown in many countries of the East, has not been adopted in France, Italy, or Spain, and has lately been discontinued in several islands of the Archipelago, where it was formerly in use, and yet, nevertheless, good figs are produced in all those countries. The assemblance of the Cynips, or fig-fly, he alleges, cannot be necessary to render the young gums fertile, since each fig contains near its eye a sufficient number of male flowers to impregnate all the female ones within its cavity; and that if it were necessary, the pollen of the wild fig tree, which is supposed to be conveyed by the fly to the germs of the cultivated kind, could not fecundate, at the same time, those which have attained to a considerable size, and those which have but just, or have not yet appeared, and which do not ripen till two months afterwards. In answer to the latter part of the objection, it may, however, be remarked, that Tournefort particularly mentions the strict attention paid by the Greek peafants to the exact time when the orn of the wild should be placed upon the garden fig tree, and that every part of the crop must be supposed to have the needful supply at its proper season. We may also add, that the reasoning employed by Olivier does not at all apply to Tournefort's conjecture concerning the proximate ends of the effect produced. The proper question to be considered is not whether the fig can produce fertile seed without the aid of the fly; of that no well-informed naturalist will entertain a doubt; but whether the fruit of the cultivated tree is increased in size, and heightened in flavour, by the operation. But still it may be asked, why does not the puncture made by the fly occasion a similar extravagation of the nutritious juice of the wild fig, or convey to it the same fermenting liquor, and thus improve its native qualities? The subject, it must be acknowledged, is attended with difficulties which have not yet received a satisfactory solution. But it is surely an unwarrantable degree of scepticism, on account of the same, to discredit the relations of able observers, founded on the experience of ages. Olivier refers to some interesting and instructive
instructive memoirs published by Bernard on this subject, which we have not at present an opportunity to consult.

Caprifolium is also applied, in a less proper sense, to the art of propagating the palm-tree. Act. Edin. Linn. 1721, p. 84.

CAPRIFICUS, in Botany, the name of the wild fig-tree.

CAPRIFOLIUM, a third order of the eleventh class of Jussieu's natural system. It has the following characters: Calyx one-leaved, superior, often divided, or bracteated at its base. Corolla generally monopetalous, either regular or irregular; in a few instances polypetalous, petals united by a broad base. Stamens of a definite number, often five; in the monopetalous genera always inserted into the corolla, and alternating with its segments; in the polypetalous ones sometimes placed upon the pistil, alternating with the petals, and sometimes fixed to the middle of each petal. Gyno inferior; style generally single, sometimes none; stigma single, or rarely three. Fruit, either a berry, or a one or many-celled capsule; each cell with one or many seeds. Corolla of the feed in a large upper cavity of the leaf, solid perisperm. Stem either a shrub or a tree; rarely herbaceous. Leaves in mull, opposite; in a few, alternate; Bipinnate alone.

It is divided into four sections: 1. Calyx calycis, or bracteated; style single; corolla monopetalous. Linnæus, trioleæ, ovidea, sylphoricarpos, dievrella, xylócorus, and caprifoliöm. 2. Calyx calycis or bracteated; style single; corolla polypetalous. Linnæus, vicium, rhézhophora. 3. Calyx bracteated; style none; stigmas three; corolla monopetalous. Viburnum, hortensia, fimbriatus. 4. Calyx simple; style single; corolla polypetalous. Cornus, he-dra.

CAPRIFOLIACEÆ, the third order of the eleventh class of Ventenat's natural system, with the same characters, divisions, and genera, as the Caprifolia of Jussieu, except that ovidea and Hortensia are omitted. The plants of this family are generally reckoned astringent.

CAPRIFOLIUM, a name given by the old botanists to several plants which Linnæus afterwards placed in his genus Lonicera. Tournefort confined the term to such species as have their flowers in heads, with an irregular two-lipped corolla. Jussieu and Ventenat extend it to all that have flowers in heads, or in axillary, single-flowered whorls, including those with a corolla nearly regular, the Periclymena of Tournefort. Gertner seems to have comprehended under his Caprifolium, the whole Linnæan genus Lonicera, having restored the latter name to the Laronthus of Linnæus, some of whose species had been called Lonicera by Pl minim and others. The name, it may be allowed, was changed by Linnæus without sufficient reason; but Gertner has in fact only increased the confusion, in attempting to remove it.

CAPRIGLLIA, in Geography, a town of Naples, in the province of Benevento, 13 miles S. of Benevento.

CAPRIMA, in Ancient Geography, a small town of Asia Minor, placed by Diótorus Siculus in Caria.

CAPRIMULGUS, in Ornithology, a genus of the order Passeres, the goat-peeker of the English, and Pengouwelet of French authors. The character of the genus consists in having the bill slightly curved, very small, subulate, and depressed at the base; mouth extremely large, and fringed at the sides with a series of bristles; ears ample; tongue short and very entire; tail not forked, and containing ten feathers; legs short; middle claw with a broad ferrated edge. Thus far we follow Gmelin, but we have, to observe, that, although this definition of the Caprimulgus genus is applicable to most of the species, there are some with which it will not agree. In Caprimulgus grandis and jamaicensis, for example, the claw of the middle toe is not ferrated, and it is supposed there are other species described, on the testimony of former authors, that are distinct of this Gmelinian character. Gmelin confounds with Latham in considering the entire figure of the tail as an essential character of the genus, but there are species known that have the tail banded, and others that contain white feathers in the tail instead of toes, which latter is considered by both those writers as an essential criterion, among others, of the Caprimulgus genus. The species defined are 21 in number.

CAPRIMALUS gemonis, the grand goat-peeker of Latham. B渐an, Gonomous Maximus, Ray. I. grand spume, and Gouar, vol. de Géographie de Buffon. This is particularly distinguished by being of a blackish colour, variegated with white and yellow; beneath white and black; area of the eyes yellowish; legs white. Lath. Ind. Orn. Blackish, varied with rose-coloured spots and streaks; middle claw not ferrated. Gmelin.

This gigantic species of goat-peeker was supposed to be the largest of its race till the recent discovery of Caprimulgus megacephalus in the Australasian regions, and was therefore named specifically grandis. It is nearly the height of a small yard, measuring 2½ inches in length. The bill, which is three inches long, is covered near the tip with hairs, that completely conceal the mouth. The plumage is blackish, varied principally with whitish and cream-coloured spots and marks on the upper parts of the body. The wings are brown on the outer edge; feathery feathers chiefly white; quills deep brown, slightly barred with white on each side, and the shafts black. The wings reach almost to the end of the tail, which is 1½ inches in length, rounded at the extremity, and of a brown colour, with seven or eight narrow dotted bars of white. Its legs are brown, and covered near the toes with feathers; middle claw not ferrated. Inhabits Cambodia, where it is said to secrete itself within the hollow of some decayed tree in the day-time, especially such as stand near the water. Willoughby's figure of the great ibijou is copied from one given by Mecgrave, that is not very remarkable for its accuracy, both a crested and being erroneously represented on its head. There is a specimen of this bird in the Leverian museum.

CAPRIMALUS megacephalus of Latham, Pengouenlet megacephale of Vielot. A species superior in size to Caprimulgus grandis, lately discovered in New South Wales. The length of this bird is 25 inches. General plumage blackish brown, variegated and streaked with yellowish and dull white; breast dirty-ferruginous; belly black; wings and tail spotted, and banded alternately with black and whitish. The head and neck appear of a large size from the abundance of feathers with which those parts are covered. The bill remarkably stronger than any other of the goat-peeker tribe, its colour pale brown, and fringed at the base with a series of feathers, much longer than the rest, that stand nearly erect, and form a kind of crest. The legs are yellowish.

CAPRIMALUS jamaicensis, the Jamaica goat-peeker. The plumage of this species is ferruginous, streaked with black: wings variegated with white; quill-feathers brown, with white spots; tail barred with black. Lath. Ind. Orn. Caprimulgus jamaicensis, Gmel. Gatera queens, Ray, Buffon, &c. and Mountain owl of Brown.

This kind, though inferior in size to the former species of goat-peeker, is a large bird, being about a foot and a half in length. Shaw describes it in his history of Jamaica, but mistakes it for a kind of wood owl, and Brown has fallen into a similar error. The bill is of a black colour, and much bent downwards at the tip, corresponding in this particular with the
the lower mandible, which is also bent in the same direction, and close exactly together when the mouth is shut; the nostrils are covered with feathers. The irides are reddish-yellow, and the eyes are surrounded with a disk of feathers not unlike those of the owl tribe, and which appear to have deceived both Sloane and Brown. The upper parts of the head, neck, and body are composed of a mixture of ferruginous and black, streaked longitudinally; the wing-coverts are parti-colored, of a deep call, and partly ferruginous and fuscous varied, and irregularly dotted with blackish, and forms of the inner ones with a mixture of white. The quills are of a deep black brown, marked on the outer edge with eight or nine white spots. Its tail is seven inches long, cinereous, dotted with black, and crossed with seven or eight bars of black brown. The legs rather large, feathered to the toes, and armed with black claws, the one middle of which, as in the former bird, is not ferrated. This species, as its name implies, is a native of Jamaica, where it is reported to be uncommon; it inhabits woods, and feeds principally on insects.

**Caprimulgus griseus, grey goat-fucker.** General color grey; wings black, with pale grey lines; tail brownish grey with fuscous lines. Gmel.

A species thirteen inches in length, that inhabits Cayenne; the bill is of a brown colour above and yellow beneath; tail five inches in length, and scarcely extending beyond the length of the wings when the bird is at rest. Buffon, who describes this species, calls it *Penguenevent gris.*

**Caprimulgus corniculatus, Carolina goat-fucker of Catteby,** a kind distinguished by having the upper part of the plumage waved with grey and blackish; beneath reddish-grey, with small blackish lines; three exterior tail-feathers white on the inner edge. Ind. Occ. "Supra linea transferens amphisis alternis atris et griseis variis, subitus ex rufo griseo lineis nigricantibus longitudinalibus, cauda griseo atrato cancellata." Gmel. We have adopted Dr. Latham's specific character of this bird, in preference to that of Gmelin, as being more expressive. The species inhabits Virginia and Carolina, and, like the rest of the goat-fuckers, appears only on the wing in the evening, or when the sky is obscured with heavy clouds preceding rain. The North Americans, it appears from Brown and other writers, call it the rain-bird, in allusion to the latter circumstance. It is the short-winged goat-fucker of the Arctic Zoology.

This does not exceed the common European goat-fucker in point of size. The bill is dull; upper parts of the head, neck, and body transversely variegated with zig-zag alternate lines of dusky-brown and grey; the crown has also some spots of the latter colour, and on the wings are both spots and longitudinal yellowish and dusky flecks. The sides of the head, and all the under parts, are rufous-grey, marked with longitudinal blackish lines; the gape of the mouth along the jaw on each side is white, and beneath this are a few yellowish spots; quills barred with dusky and grey, and spotted on the outer webs with yellow; on the inner web of the three first is a large white spot. The tail is four inches long, of a grey colour, with dusky bands and lines; legs brown, claws black, the middle one ferrated. This bird is said to lay its eggs on the ground, and it appears they very much resemble those of the lapwing.

**Caprimulgus Guianensis, the Guiana goat-fucker.** Colour tawny, streaked and spotted with rufous; beneath the throat a white lunar band. *Le monteveyau de la Guiane, et Terre-cbovre roux de la Guiane de Buffon.*

This kind, which inhabits Guiana, is nine inches in length. The bill is about three quarters of an inch in length, and is beset with bristles. The general colour of the plumage full.

vous, with an irregular mixture of rufous throughout; on the top of the head, and hind part of the neck the flecks are longitudinal, but on the upper part of the back oblique, as well as mixed with spots of an irregular shape on the ruff of the upper parts. Beneath, the plumage much resembles that above, but the spots or markings are most placed in a transverse direction. From the gape arises a white band, a light rufous-bar along the jaw and under the throat. The quill-feathers are black, the first five or six, marked with a white spot. Tail three inches long, and extending an inch beyond the wings when they are closed. This bird, we are informed, is frequently observed to repeat the three syllables *mont-ray-au* very distinctly, when flying abroad at twilight in search of prey.

**Caprimulgus rufus, the rufous goat-fucker, the engoulevent roux de Cayenne of Buffon, and Crapeaud solvant, ou Terre claire de Cayenne, Pl. Enl.** The species is distinguished by being of a rufous colour, varied with black in longitudinal flecks; wings, and lower part of the body fuscated with blackish; quill-feathers varied with rufous and black, in alternate fringes.

Somewhat larger than the foregoing species, being ten inches and a half in length. It inhabits Cayenne. The bill is of a pale brown colour; the irides yellow; and the plumage varied as before described, with rufous, black, and a few white spots. The throat is marked transversely with lines; the lower part of the body is also lined, but the lines increase in breadth as they pass backwards, the upper part of the belly is blackish, the lower rufous. The tail is banded with black, and exceeds the wings by half an inch. The legs are flesh colour.

**Caprimulgus Europeaus, the European goat-fucker.** The colour black, varied with cinereous, fuscous, ferruginous, and white; beneath rufous-white, with fuscous bands. "Niger, cinereo, fusco, ferrugineo et alba varius, narium tubis obsoletis." Linn. Fm. Suec. *Nocturnal goat-fucker,* Pennant.

The European goat-fucker, as it generally called, is a native of Asia and Africa, as well as Europe. Its length is ten inches and a half. The plumage is of a deep blackish colour, beautifully speckled and diversified with spots of grey, ferruginous, and white. The tail is four inches long; the legs short, rough, or scaly, and feathered much below the knee; the toes connected together on each side by a flight membrane, and the middle claw ferrated. The plumage of the male is brighter than that of the female, and it is best known by having an oval white spot on the inner webs of the three exterior quill feathers, and another at the tip of the outer feathers of the tail.

A variety of this species is reported to have been brought from China by Sonnerat. This was rather larger, and the colours somewhat darker, than in our common kind; the feathers of the wings were black, marked with yellow spots, each inclining a black dot in the centre; and the whole were so dimphosed, that, at the first glance, the wings appeared to be marked transversely with seven alternate bands of yellow, and the like number of black ones.

Fern owl, chun-hawk, dorr-hawk, and night-jarr are the most familiar provincial names of this common goat-fucker in various parts of England. Latham calls it the European goat-fucker, this being the only bird of its genus that is found in Europe. It commonly arrives in England the latter end of May, and remains in the southern parts of the island till about the end of September. In its passage from the eastward, it visits Malta, and the south of Europe, a month sooner than England; and it is seldom earlier than November.
CAPRIMULGUS.

November. Some French authors assure us, that several birds of this species have been shot in the woods of Volges in the middle of winter, but such occurrences are very rare. The species has been recently observed in Siberia and Kamtschatka, where it lives not only in forests but also in open countries, where it finds rocks, or high banks, for shelter. With us it lives in woods, and feeds on insects, which it collects on the wings, in the dusk of the evening and morning, like the owl, and remains secreted, like that nocturnal bird, in the hollow of a tree, or some dark recesses, during the daytime. By chance, however, it has been noticed on the wing in the daytime when disturbed in very gloomy weather. It is a great destroyer of the cockchafer-beetle, many of which, with other insects, are usually discovered in its stomach on digestion. The note of this bird is singular, resembling the noise of a large spinning-wheel, or as some liken it to that of the letter K frequently repeated, and which is said to emit only when perched on the branch of a tree, with its head hanging down in the dusk of the evening. Besides this, it has a sharp squeak, which is supposed to be its call of love, as the male is observed to utter it when its partner of the female makes its manner of perching is curious, for it almost constantly places itself longitudinally upon the branch, instead of across, like other birds. The goatucker was accused by the ancients, and many of the elder writers, of fouling the teats of goats, and it is from this vulgar prejudice its popular name of goatucker is derived; this absurd notion, though countennanced by Buffon, is jutly exploded by all modern authors. The female makes no nest, but lays her eggs upon the bare ground, or loose crags, without any apparent care; they are usually two in number, of a white colour, and blotched with bluish brown.

CAPRIMULGUS Virginianus, Virginian goatucker. Colour brown, varied with grey and reddish; beneath reddish-white, transversely streaked; chin with a triangular white spot; area of the eyes and neck above spotted with orange.

This is smaller than the European goatucker, its usual length being eight inches, but those the myosibos-hoock of Hudson's bay, described on the authority of Mr. Hutchins by Latham, in his Supplement, prove to be the same bird as is generally suspected, it sometimes attains to the length of nine inches and a half. All the upper parts of the body are of a dull brown, transversely variegated and blended with rufous brown, and an intermixture of ash-colour, with a slight proportion of grey on the wings; the neck and sides of the neck, and the sides of the head, are a rufous brown, variegated spot, spotted with orange at the under part. The quills are dusky, the first five marked with a white spot about the middle; tail marked similar, the two outer feathers with a spot of white near the extremity; legs flesh-colour, middle claw ferrated.

During the summer, this bird inhabits Virginia, where it first arrives about the middle of April, and frequents the mountainous parts, but will frequently approach the housetops in the evening, when it commonly settles on a rail or pole, and cries for several times together very loud, somewhat like the word whip-poor-will, or whip poor-will, pronouncing the frict and laft syllables loud and clear. The noise of this bird, which is both loud and disagreeable, continues oftentimes the whole night, and it not unfrequently happens that four or five birds of this fame species keep in company, and cry in concert together. They subbit chiefly on insects. The eggs are of a greenish colour, with dusky spots and streaks. Kalm speaks of the flees of this bird as an article of food.

Linnaeus appears to have confused this as a variety of the common or European goatucker, Caprimulgus Europæus. Both Catesby and Buffon call it whip-poor-will, in allusion to its note; it is the long-winged goatucker of the Arctic Zoology, and Virginia goatucker of Latham.

CAPRIMULGUS vitatus, striped goatucker, and frangovent a bandeir noible of Vielott. A new species recently discovered in New Holland, where the English settlers call it the mosquito hawk. This bird is about nine or ten inches in length; the upper part of the head and neck are black, with a stripe of the same colour running, in the form of a crescent, behind the eyes. The black stripe on the upper part of the neck descends on each side to about the middle; where it divides into two distinct branches. Those parts of the head where the black does not appear is of a pale carnation or flesh colour. The upper portion of the neck, with the body beneath, are of a somewhat similar colour, but more inclining to ferruginous. Under the eyes, sides of the neck, and upper part of the wings are marked with spots and transversal lines; back and wing-coverts obtuse blue, speckled with black; quills blackish, spotted and edged with rufus-colour; tail-feathers dark brown spotted with ferruginous, and slightly forked; bill large, and of a black colour; legs reddish-flesh colour.

CAPRIMULGUS albicollis, white-throated goatucker of Latham. The plumage is rufous brown, varied with white and blackish streaks; beneath brownish with black lines; a triangular white spot on the throat; tail somewhat cuneated.

Length ten inches and a quarter; bill brown with the tip black, and the nostrils rather prominent; head streaked with black, upper parts of the body the same, but more obscure; the scapulars, and most of the outer wing covers have a black band near the end, and the tips yellowish buff-colour; latter quills spotted with rufous cream-colour on the outer web, the greater dusky black, and crossed about the middle with a white bar; tail somewhat wedge-formed, the third feather white, second white within and black without, the outermost with a white spot near the base; legs brown; middle toe very long; and greatly ferrated. Described by Dr. Latham, from a specimen in the collection of general Davies, that is suppos'd to have come from Cayenne.

CAPRIMULGUS femitoratus, white-collared goatucker of Latham, is described on the authority of Buffon, who calls it le petit engoulvent de Cayenne; Gmelin calls it femitoratus. This bird is blackish, varied with rufous and grey, with a white muzzle on the lower part of the collar. Length eight inches, and inhabits Cayenne.

CAPRIMULGUS Brocilatus, Brocilian goatucker. Plumage yellowish black, varied with white specks; beneath varied with black and white; area of the eye yellowish white.

Size of a swallow. Bill and eyes blackish; wings and tail even; legs white, the middle claw ferrated at the outer edge; tail expanded. This, as the name implies, inhabits Brazil.

CAPRIMULGUS acutus, blear-tailed goatucker, and l'engoulvent ocurgenne de la Guiana of Buffon. This kind is readily distinguished by the pointed tips of the tail-feathers from the rest of the species in the same tribe; the plumage is blackish, faciliated above with grey, and beneath with rufous; head and collar reddish brown. It inhabits Guiana, and is about seven inches and a half in length. The shafts of all the tail-feathers are bare of webs at the tips; bill and legs black.

CAPRIMULGUS Cayennensis, Cayenne, or white-necked goatucker. Plumage rufous and grey, varied with black undulated lines; throat and stripe on the wing white; temples rufous, with five black streaks. Caprimulgus cayanus, Latham.

Described
Described on the authority of Buffon, who calls it the *Pensoulevent de Cayenne*, as being seven inches and a half in length. Bill black, iridescent yellow; head and neck tinged with rufous; lower part of the belly spotted with black; two middle feathers of the tail grey, crossed with five or six blackish bands; the rest black, bordered with white; legs yellow brown. This bird inhabits Cayenne, where it is found in the plantations, and when on the wing is said to utter a weak cry, which has been compared to that of the toad, and it has also another note that somewhat resembles the barking of a dog. It is not a timorous bird by any means, neither is it a race species.

**Caprimulgus Americanus**, American goat-fucker, distinguished specifically, according to Gmelin, by having the nostrils very prominent and cylindrical. The plumage is variegated with black, grey, and ochreous brown.

This is a Linnaean species, *Caprimulgus Americanus* of that name. Ray calls it the small woodowl, as does his wife School, in his History of Jamaica; it is *Pensoulevent de Bayonne*, ou le balzar of Buffon, and other French authors. This bird is seven inches in length; the bill black, and becet with bristles; the nostrils projecting about one-eighth of an inch; legs and claws grey. Like the rest of its tribe, this kind feeds on insects. It is found in various parts of America.

**Caprimulgus Nova Hollandia**, crested goat-fucker of Philip's Voyage to Bany bay. This is of a brown colour, clouded with black and white, and white beneath; neck and breast with dull rufous bands; eret on the front and face are brown. Inhabit New Holland, and is rather smaller than the European goat-fucker. The length is nine inches and a half. Its bill is black, cape wide, and yellowish within; behind the base of the upper mandible arise a crest of twelve bristles, which are thinly bearded at the sides; quill-feathers brown, the five or six exterior ones with whitish spots on the outer side; tail rounded, fuscois, with twelve whitish bands clouded with blackish; legs rather long and yellow.

**Caprimulgus Apaticus**, Asiatic goat-fucker, or Bombay goat-fucker of Latham. Plumage pale-ash, clouded with black and ferruginous; breast banded with cinereous; crown with a blackish streak, and a pale spot on the jaws and chin.

This species was first described by Dr. Latham, from a specimen in the possession of Sir Joseph Banks, in the Supplement to his Synopsis of Birds. It is, he says, the fize of the Virginia goat-fucker: length eight inches and a half. Bill dusky; general colour of the plumage not unlike that of the Siberian owl, being a beautiful mixture of pale ash colour, mottled with dusky down the middle of the crown; on each side of the under jaw is a pale streak; and on the throat a whitish spot; the breast crooked with numerous cinereous bars; between the legs pale rufous; the quills are dusky, barred with rufous; the first short; four of the greater quills have a spot of white on the inner web; the tail marked the same, but the two middle tail-feathers are likewise mottled, as the back; the outer ones on each side have the ends white for about an inch, but the white extends higher up on the outer webs; the middle toe is greatly pectinated. Inhabits Bombay. Latham.

It seems this bird has been also discovered in Africa by le Vaillant, who names it *Pensoulevent mufcien*, in compliment to its note, which he observes is both piercing and melodious, contrary to what has been advanced by an English writer (Dr. Latham), who affirms that its note is horrible. It has the same manners of life as the European goat-fucker.

**Caprimulgus Indicus**, Indian goat-fucker. Colour pale ash, transversely licated with black; cheeks, breast, and wings spotted with ferruginous; tail-feathers bluish, licated with black, the exterior one varied with ferruginous and black.

Latham describes this species, in his Supplement of Birds, as a native of India, on the authority of lady Impey, without mentioning its size. Another account is given of it by Vielot, a French naturalist, under the name of *Pensoulevent du Capri*, raye de noir, but which is a literal French translation of the following description. "Crowns and back whitish-sable colour, elegantly marked with minute dusky lines; cheeks, breast, wing-coverts, and secondaries beautifully marked in the same manner with lines and large spots of rufut; prime quills dusky; middle feathers of the tail light ash, crossed with a few black bars; outermost feathers rufous and black."

**Caprimulgus torquatus**, gold-collared goat-fucker. This is an inhabitant of Brazil, and is about the size of the common lark. The plumage is cinereous-brown, varied with whitish and dull yellowish spots; on the hind a golden ring; two middle tail-feathers longest.

Though the body of this bird is scarcely larger than a lark, its length of wings and tail is considerable. The upper mandible of the bill is hooked, and becet at the base with ten or twelve thick bristles; eyes black, head large, flat, and broad. The two middle tail-feathers are eight inches in length, but the rest are shorter; legs dusky, with black claws, the middle one of which is forked. This is called by Buffon Tenthèbre du Brésil; and *Le petit entellévent tacheté de Cayenne* by Vielot.

**Caprimulgus longipennis**, Lema goat-fucker of Shaw, Nat. Muf., a native of Sierra Leon. Size of a Martin. The plumage is grey, variegated; wings spotted with rufous and black; on each shoulder a long naked-shafted feather.

Vielot describes this curious bird under the title of *Pensoulevent de Léone*, after Dr. Latham, who very lately published an account of it, in which he names it *Caprimulgus macrourouspus*. The French author, Vielot, gives it as a new species, on the authority of Latham; from which we may presume he was either not aware of its having been previously described by Dr. Shaw, as above mentioned, or did not think proper to acknowledge the circumstance.

**Caprioles**, derived from capræolus, a diminutive of capra, goat, in Horsemanship, are leaps which a horse makes in one and the same place, without advancing forwards; and that in such manner that when he is in the air, at the height of his leap, he yeers or strikes out with his hind-legs as near and even together, and as far out as he can stretch them; in which action, he clacks, or makes a noise with them.

The capriole is the most violent of all the high-raised airs: there are several kinds of caprioles; as a right capriole, back capriole, side capriole, broken capriole, the open capriole, &c.

To make this air perfect, the horse should raise his fore parts and his hinder to an equal height; and when he strikes out behind, his croupe should be on a level with his withers. In rising, and in coming down, his head and mouth should be quite ready and firm; and he should present his fore head quite flat; when he rises, his fore-legs should be bent under him a good deal, and equally. When he strikes out with his hinder legs, he ought to do it nervously, and with all his force; and his two feet should be even, of an equal height, and their action the same: lazily, the horse should, at every leap, fall a foot and a half, or the space of two foot distant from the spot from which he rose. In order to make caprioles, it is not absolutely necessary that a horse should pass through cavorts and saltati; because some horses are naturally
rally more light and active in their loins than in their legs, and
which are brought to leap with more difficulty, than to the
other airs in which their strength must be much more united,
and their disposition attended to; but nevertheless it is cer-
tain, that if the horse is brought to rise by degrees, and is
worked in the intermediate airs, before he undertakes the
caprioles, he will not weaken and drain himself to much, and
will be sooner confirmed in his lefions, than one which begins
to at once with the caprioles. The motions of a horse, when
he makes a perfect capriole, have an effect directly opposite
to that of piafades and curvettes. These two airs are proper
to affaire the head of the horse, and to make it light, and
this by so much the more as the principal action depends
upon the haunches, and a moderate appuy of the mouth;
but caprioles are apt to give too great an appuy, because
of the horse, when he makes the strength of his air, that is,
when he strikes out as he is coming to the ground, is
toally supported by the hand; therefore, before he is
put to leap, he ought to have a perfect appuy, and his
shoulders should at least be raised and lightened, by having
made pèfades; and he should be without fear, anger, or any
kind of uncinelles, because, by leaping, he acquires a know-
ledge of his own strength and power, and he may apply it
to bad purposes, to free himself from obedience, and to in-
dulge his caprice and ill humour. Some horses have a dis-
position to this air, and sufficient strength to go through it;
but their mouths are so delicate, fragile, and averse
from the hand, that you cannot support them without
hindering them from advancing; hence it follows, that their
action before is cold and slow, and never sufficiently
high, and they cannot be carried forward when they raise
their croupe, and strike out; and it is impossible to keep them
firm as they come down. To remedy this, begin their
leisson upon the trot, and prefer them in it so slowly, as to
make them often go into the gallop; observe a medium, in
order to vary their strength and vigour, that they may fur-
nish as many leaps as are requisite to the perfection of the air.
Pursue the same course with a horse that is too strong, and
who retains and avails himself of the strength of his back, so
as not to make his leaps freely and readily; by this means
you will abate his superfluous vigour, which serves only to
disfigure and make him troublesome. It is often to fulfill a
horse that is light in the hand by means of the trot, before
you teach him to leap; but a contrary method must be ob-
served with those which are heavy and clumsy, or that pull
upon the hand. Gallop and trot them; and this exercise
will take away all fear of the aids and corrections, and the
following day they will present themselves more freely and
willingly. Instead of trying to correct the horse, which
pulls upon the hand, compel him to make some caprioles
with his face to the wall, and keep him up to it closer, or
farther off, as you find him heavy, or endeavouring to force
the hand; and by this method you will constrain him to
shorten his leaps, and to be more attentive to his buttocks.
If he abandons himself, or bears too hard upon the hand,
hold him firm at the end of his leap, and in the instant when
his feet are coming to the ground, yield your hand immedi-
ately to him, and he will abandon himself much less upon
the bit. If he retains himself, and hangs back, eating your
hand to him will not alone be sufficient; but to make him
advance, you must push him to his bit, by aiding him brisk-
ly, and in time, with your legs.

To dre the horse to the caprioles, the pillars may be em-
ployed, or they may be dispensed with. When the pillars
are employed, tie them to them, make him keep up to his bit pro-
perly, or what is called "fill up the cords," and endeavour,
by little and little, to make him rise before, taking care to
make him bend his knees, and gather up his legs, as much
as you possibly can. For this purpose, use your switch
briskly; for if you can teach him to bend his legs well, his
manage will be much more beautiful, and he will be much
lighter in the hand. When the fore part has been thus
gained, put him in the pillars again; shortening the cords,
in order to make him raise his croupe from the ground, and
yerk out equally, and, at the same time, with both his hinder
legs, which he must be taught to do, by attacking and
hooking him upon the croupe with the switch or chambriers.
When he is able to rise before and fall out behind, let him
be taught to unite these two times, and perform them to-
gether. Let him then be mounted, and always in the
pillars; and let the rider support him in the hand, and put
him to make one or two leaps, without leaning upon the
cords of the cavelon, in order that he may learn to take a just
appuy, and to feel it. As soon as he begins to know and
obey the hand, he should be aided gently with the calves of
the legs, should be supported, and you should "pinch" him
delicately and finely with both spurs. If he answers once
or twice to these aids, without losing his temper, or being
angry, you will have great reason to expect that he will
soon furnish his lepws equally and jolly, with respect to the
hand and heel. When he has been so far advanced by means
of the pillars, walk him straight forward a certain space; and
if he does not offer to rise of himself, try to make him. If
he himself takes the right time, seize the moment, avail
yourself of it, and let him make two, three, or four capri-
oles, or one or two, as you may judge it necessary. By
letting him thus walk calmly and quietly, in a short time he
will, of himself, begin to make caprioles straight forward; but
in case he should discover any signs of resistance to the hand
or heel, or the other aids, recourse should be had immedi-
ately to the cavelon and pillars. The method, now de-
dcribed, of adjutting and dressing a horse for caprioles, by
means of the pillars, is very dangerous in itself, and capable
of spoiling and making a horse become desperate and ungo-
vernable, unless it be practiced by persons of consummate skill
and experience.

Mr. Beringer prefers the following method, which, though
more difficult and painful to the horse, is better and more
sure. Having well exercised the horse in "pèfades," walk
him straight forward, keeping him "together," and support-
ing him so as to hold and tie him firmly; and, if need be, let
not go so as to flop him entirely. After this, strike him gently
with the end of the switch upon his croupe and buttecks,
and continue to do it till he lifts up his croupe and kicks.
Then care for him, and let him walk some pèfades, and then
attack him again, not minding to make him rise before, nor
hindering him from it, if he offers to do. Remember to
encourage and coax him every time that he answers to the
aids, and obeys. When he is thus acquainted with the aid
of the switch, let him make pèfades of a moderate height,
straight forward, and at the second or third, attack him behind
with your switch, to make him lath out. If he obeys, make
him rise "before" again in the minute that his hinder legs
come to the ground, in order to make him raise two or
three pèfades, to work his haunches. After this, coax and
care for him without letting him rise from the place, if his
appuy be firm and good; and in case it is hard, make him
go backwards, or if it is light and jolly, let him advance
quietly and slowly. To enable him to make his leaps jolly,
and to know the exact time of making them, no attention
should be given to the number of pèfades he makes before
or after his leap, but at the moment when you feel him pre-
pared, and which is in the pèfade, aid him briskly behind;
letting him, in the beginning, not rise to high "before,"
when
when you intend he should yerk out behind, as he would, were he only to make a pafade, that to his croupe may be more at liberty, and he may yerk out with more grace. In proportion as his croupe becomes light and active, you may raise his fore-part higher and higher, and support it while in the air, till he makes his leaps true, and in just proportion. When these lefions have been sufficiently practised, you may retrench by degrees the number of the pafades, which separated and divided the leaps. You may now demand of him two leaps together; and from thefe you may come, with patience and diftention, to three, or from three to four leaps; and, lastly, to as many as he can fuffer in the fame air and with equal strength. Remember always to make him trifle upon his launches; and this is the only fair way of preventing all the diforders horse may be guilty of from impatience and fear. Some horse will leap very high, and with great agility ftrait forwards, which, when put to leap upon the voltes, usually lofe their natural grace and beauty, for want of strength and not being equal to the lafit, in which all their motions are forced and conftrain'd. If a horse has a firm appree and strength fufficient to fupport this air upon the voltes, begin by making him know the space and roundness of the voltes to each hand; let him walk round it in a flow and diftinct pace, keeping his croupe very much prefied and confined upon the line of the voltes, which ought to be much larger for this air than for "croupades" and "balotades." When this is done, make him fieve, and let him make one or two croupes, followed by as many pe- fades; then walk him two or three steps upon the fame line; then raise him again, supporting him more and more, and keeping him even upon the line of the voltes, fo that it may be exactly round, and confining his croupe with your outward leg. If this lefion be given with judgment, your horse will soon make all the "voltes" in the fame air; and to make him fuffer a second, as soon as he has clofèd and finifhed the firft, raise him again, and without letting him fleep, get from him as many leaps as you can, working him always upon the voltes, in which he walks and leaps alternately, till he clofes and ends it with the fame vigour and resolution as he did the firft. Aid always with the outward rein, other upon the voltes, or when you leap ftrait forward, you will narrow and confine the fore-parts, and enlarge the hinder parts, by which means the croupe will not be preffed, but free and uncontrain'd. See Cures and Voltes. The refult way to fucceed, when you undertake to ftrain a horse to croupes, is to arm yourfelf with an invincible patience, and to prefer for this purpofe fuch horses as have a difposition, are active flight, and have a clear finely strength, to fuch as are endowed with greater strength and force; for their feet never leap regularly, and are fit for nothing but to break their riders' backs, and make them fpite blood, by their irregular, violent, and unexpected motions. Berenger's Hi.b. Art. of Horsemanhip, vol. ii. ch. 20.

CAPRONEZA, a small town of Hungary, in Selav- nia; 12 miles from the Save.

CAPRONE, in Geography, one of the Greek iflands N.W. of Samos, larger than Capra, and near it. See Cepha.
which have now acquired the solidity and firmness of a rock. The walls of the town were rebuilt by the inhabitants since their first demolition; but were afterwards destroyed by Jacob Almanzar, who went a governor and troops into the province. In Murum's time Capsa was very populous, abounding with many monasteries and other structures of superlative and regular workmanship; but it is now occupied by an indigent people, fleeced and oppressed by the Turco-Tatar government. It is built on a rising ground, and near it are plantations of olives, olives, pittachios, and other fruit trees, beyond which, occupying a small extent, is an interchange only of barren hills and valleys. The water which refreshes these plantations arises from two fountains; one within the citadel, the other in the centre of the city. The latter, supplied by Dr. Shaw to have been the "Jugus Aquae" of Sallust (Bell. Ingr. § 94), and the "Fairmaid of Elphis" (Geogr. Nub. p. 86) was formerly covered with a cupola. It is full walled round, and discharges itself into a large basin, formed originally for a bath. This fountain and the other before they leave the city, and form a pretty large brook, which, from the quantity of the water, and the rapidity of the stream, might continue its course to a great distance, were it not confinedly employed and inhabited in the uses above-mentioned. The climate and inhabitants of Capsa are unhealthy. Both men and women dress handsomely, except their feet, which they cover with coarse shoes of braving workmanship, and made of the rough skins of wild beasts, equally inconvenient and unworning.

The authors of the Modern Universal History (vol. xiv. p. 281, 8vo.) say, that its most probable situation is in N. lat. 33° 15'; and E. long. 69° 3'; 30 leagues from Teufena.

Capsa, in Geography, a town of European Turkey, in Romania.

Capsarius, from caspa,atchel, in Antiquity, a servant who attended the Roman youth to school, carrying aatchel with their books in it, sometimes also called librarius.

Capsarius was also an attendant at the baths, who took charge of the vestments of those by whom they were frequented. The Caspari, it should seem, at least in the latter days of the empire, had an officer particularly placed over them for the summary administration of justice. Dig. lib. i. tit. 15. § 3. Adverius capbarios quoque, qui mercer ferva in balneis veliftimina infcribatur. Judex coz. custodiscnti: ut fi quid in fervandis vestimentis fraudulentem, ipse cognoscat.

Capsarius, from caps, chast, among the Roman Rankers, was he who had the care of the money chest. or coffer.

Capschak, or Kispechak, in Geography, a considerable country of Tartary, which extends to Europe and Asia, between the Jieck and the Nieper. It is the country from which the Cossacks sprang. It abounds in grain and cattle; it is subject to a khan and several other princes. The people are warriors. Its capital is Stari.

Capsella, in Botany, a name given by Celsippinus to thalpia burra pafioris of Linnaeus, proposed by Juifieu, and received by Ventenat as a distinct genus, because it differs from the other species of thalpia, in having a triangular, or rather inversely heart-shaped, fiddle without a border.

Gen. Ch. Cal. perianth one leafed, five-leafed, or five-toothed, cere, permanent. Cer. monopetalous, wheel-shaped; tube very short; border five-leafed, spreading, plated; segments oblong, converging. Ff. germ egg-shaped; style thread-shaped, longer than the flowers; stigma obtuse. Peric. a dry berry, of different shapes, two or three-celled, hollow, coloured; receptacle adhering to the partition, dry. Seeds numerous, kidney-shaped, compressed.

Eff. Ch. Corolla wheel-shaped. Barry dry. Seeds compressed. Neatly allied to folium, but differs from it in having a dry, not pulpous pericarp, in the pungent, burning taste of its seeds; and in its general habit, which is so much alike in all the species, that it is not easy to give them decisive specific characters. The great variety that is found in the form and colour of the fruit increases the difficulty, and makes it almost impossible to determine, in many cases, which are the distinct species, and which are only varieties. Linnaeus, in his Species Plantarum, acknowledged only two species, one annual, the other shrubby, with a variety distinguished by its small, red, conical fruit. This variety he made a distinct species in his first Miseria and Systema Naturae, and added another with a somewhat shrubby, quadrangular stem. The old botanists mention many kinds. Miller has ten species, besides varieties; but several of his species are now effaced only varieties. Six of them are herbaceous and annual; at least, as he found by experience, they are such in our climate; their stems decaying soon after the fruit is ripe; but it may be doubted whether those that are in our native climates, may not become annual under our artificial treatment. In the enumeration of species, we shall take La Marek and Poiret for our guide.

Sp. 1. C. annuum, Linn. Sp. Pl. Gerat. tab. 132. fig. 2. Woodville Med. Bot. tab. 144. (Piper Indicum volatissimum, Bauh. Pin. 182. Valla-capo-Moago, Heed. Mal. ii. tab. 35.) "Stem herbaceous; peduncles solitary; fruit oblong." Root fibrons. Stem one to five feet high, nearly simple, round, a little frayed, smooth. Leaves egg-shaped, acuminate, entire, petiolar, placed in no regular order; petioles long, flexible, generally smooth, but sometimes, as well as the stem, a little pubescent. Flowers white, lateral; peduncles long. Fruit smooth and shining, very variable in its form and colour; in some inflames long, straight, acute; in others short, thick, obtuse, and even coniculate at its summit; in some red; in others yellow; and sometimes both colours on the same plant; in some, according to Miller, upright; in others pendant, which has induced us to omit the word pendant, inserted by La Marek in the specific character, although those plants in Miller's possession, which had upright fruit, may possibly belong to one of the following species. A native of the East and West Indies. 2. C. fruticosus, Linn. Sp. Pl. Lam. iii. tab. 110. fig. 2. (C. brasiliannum, Clus. Exot. 240. fig. 2. C. indicum, Rumph. Amb. tab. 38. fig. 5.) C. filica oliviformi, Tourn. Infl. 185.) "Stem shrubby; leaves lanceolate; fruit oblong; solitary, rather erect." Stem a little rough, rather nearly round, and like the other parts of the plants, a little pubescent; branches numerous, fluff, angular. Leaves alternate, or two together, or opposite to the young branches, lanceolate-egg-shaped, or acuminate, with yellowish nerves underneath, on short petioles. Flowers small, white, or yellow, placed a little above the axis of the leaves; peduncle long, almost straight, thread-shaped, thickened at the top when the fruit ripens, as in all the other species; calyx almost truncate, with five very short teeth; segments of the corolla almost lanceolate, acute, spreading. Fruit oblong, obtuse,
obtuse, the form and size of a small olive, reddish yellow.  A native of the Indies, and the Isle of Ceylon. 3. C. coriif-
forme, Lam. Illuf. Wild. (Piper filicuca parva, J. Bauh. ii. p. 544, Icon.) "Stem inclining to shrubby; fruit nearly glo-
ular, solitary, erect.  Nearly allied to the preceding.  Stem smooth, a little quadrangular, branched.  Leaves scat-
ttered, smooth, lanceolate, acuminate.  Flowers yellowish white, on long peduncles; calyx short, bell-shaped, trun-
cate, very lightly toothed.  Fruit about the size of a cherry, red or yellow.  A native of Brazil. 4. C. bacatum, bird-
pepper, Lam. Mant. (C. fruticosum, l. Sp. Pl.) C. fructu-
imino, Brown. Jam. 1776.  C. minus fruictum var. Sloane
Jam. 1780.  C. microcarpum, Lam. Mill. n. 105.  "Stem inclining to shrubby, even; peduncles often in pairs; fruit very small."  Stem striated, roundish, almost smooth; branches divaricated, zigzag.  Leaves alternate, peti- 
oled, almost heart-shaped, acuminate, tender, smooth, 
erved beneath.  Flowers often in pairs, very small, yellow-
ish white; peduncles unequal, united at their base, frigate, 
ubcent, calyx short, nearly smooth, with five awl-shaped 
teeth; segments of the corolla short, obtuse.  Fruit glo-
bular, a little oval, scarcely larger than a pea, smooth, red 
or yellowish; peduncle flat; Miller's minimum has leaves a little rounded at their summit, not acuminate.  A 
native of the Indies. 5. C. fruticosum, Lam. Mant. (C. fruc-
tulum longo, per fumum tragoenon, Tour. Inf. p. 152. C. te-
ragonum, Mill. n. 57) "Stem inclining to shrubby; fruit 
erect, thickened, somewhat heart-shaped."  Stem fairly pubes-
cent, angular, compressed towards the summit.  Leaves 
tender, alternate, lanceolate-egg-shaped, acute, fearcely-long-
er than the petiole.  Flowers almost axillary, solitary; 
peduncles straight.  Fruit bright red, globular, sometimes a 
little angular, emarginate, nearly the size of an orange; 
peduncles a little curved.  A native of the Indies. 6. C. 
inclining to shrubby; peduncles either falcate or er in pairs; 
fruit conical, very small, pendulous."  Stem smooth, trafted; 
branches numerous, zigzag, divaricated, angular.  Leaves 
egg-shaped, rather large, sharply acuminate; petioles a little 
pubescent, flender.  Flowers yellowish white, either four or 
five together, or in pairs; peduncles an inch long, curved 
early the top; segments of the corolla obtuse.  Fruit small, 
egg-shaped, terminated by the permanent petiol, yellowish.  A 
native of China. 7. C. conicum, Lam. Illuf. (C. conoides, 
Mill.) "Stem inclining to shrubby; fruit egg-shaped-coni-
cal, erect."  Distinguished from some of the preceding 
chiefly by its fruit, which is about half an inch long, bright 
red, a little belllying at its base, narrowed at the summit into 
an obtuse cone, and generally flanding upright on a curved 
Ilfuif. "Stem inclining to shrubby, zigzag; little branches 
and petioles hairy; fruit egg-shaped, pendulous, three-cell-
led."  Stem nearly quadrangular, pubescent.  Leaves ten-
der, egg-shaped, acute, smooth.  Flowers small, white, 
foliar, or several together; divisions of the corolla short, 
acute.  Fruit yellow, oblong, of a moderate size.  Found 
in the East Indies by Sonnerat.  All the species of capsicum have the same general quali-
ties, which are tenible in every part of the plant.  The 
fruit is much used for culinary purposes in its native coun-
tries, and has long since been introduced into Europe as a 
popular ingredient in soups and high-seasoned dishes.  Its 
taste is extremely acrimonious, and leaves a durable frena-
tion of heat on the palate.  When taken in small quantities 
it is a grateful stimulant; but if used to excess, it has a 
painful effect, and seems to fet the mouth on fire.  In hot 
climes, where only it is indigenous, a liberal use of it is 
found to be salutary in lengthening the rosmach, affil-
gislation, and correcting that putrefactive colililation of the 
humours which those climates have a tendency to produce.  The 
fusser kinds of the fruit are most in request.  The 
fruit of capsicum baccatum in particular, gathered when 
ripe, dried in the sun, and then pounded and mixed with salt, 
is keptfloat in bottles, and known in the West Indies 
by the name of Cayenne pepper.  Pepper-pot, according to 
Miller, is an old name of the same species, or of any sort of it 
which he calls minimum.  For this purpose the ripe fruit is 
first dried in the sun, then put into an earthen or stone pot, 
with a layer of flour between each layer of fruit, and baked 
in an oven till it is perfectly dried.  It is then cleaned from 
the flour, and beaten or ground to fine powder.  To every 
bottle of this powder, a pound of wheaf flour is added, and 
the mixture made into small cakes with leaven; these are 
baked, cut into small pieces, and baked again till they are 
as hard as biscuit, then beaten into powder and sifted. 
The result is the well known Cayenne pepper.  Capsicum gro-
sum is most proper for pickling, the skin being more leath-
er and tender than in the other species.  The fruit should 
be gathered before it comes to its full size, should be cut down 
onto one side to get out the seeds, and soaked two or three 
days in salt and water.  After it is well drained, it should 
be covered with boiling vinegar, and closely stopped down 
for two months.  It should finally be boiled in vinegar 
to make it green, and will want no addition of spice.  It 
the ripe fruit of any of the species be thrown into the fire, it 
produces a noilome vapour which occasions vehement 
feezing and coughing, and sometimes vomiting.  The powder 
taken up the nose will cause violent and dangerous fits of sneezing. 
Cayenne pepper, though its powerful properties have been 
so long known, has but lately been introduced as a medicine. 
It is now used both externally and internally to promote ex-
citement, where the bodily organs are languid and torpid, 
and according to Dr. Woodville, as an aromatic of the most 
aerid and stimulating kind, may certainly be found efficacious 
in some paralytic and gouty cauces.  The French authors of 
Demonstrations de Botanique, flate it to be a powerful 
romachic, and affert that six grains in powder mixed with 
honey, taken every morning, is a true specie for hypochon- 
drial disorders, and those head-aches which proceed from 
a relaxed stomach.  It has been successfully exhibited in 
cynanche maligna, and in what Dr. Mackitrick calls ca-
bexia Africana, which he considers as the most frequent 
and fatal predisposition to disease among negroes.  The 
dope de direct is from fix to eight grains.  Bergius gave 
the feeds of capucism with great luccces in inveterate inter-
mittents.

The annual capucism, which is the most hardy, is culti-
vated in Spain, Portugal, and the south of France, in the 
open air, for the sake of its fruit, which, particularly in 
Languedoc and Provence, is eaten green by the peasants at 
their breakfast, and preferred to onions or garlic.  In that 
state it is also pickled and used instead of capers.  The 
ripe fruit is employed in various articles of cookery.  In Eng-
land the different species are cultivated chiefly for ornamental, 
and their beauty depends in a great degree on the various 
and brilliant colours of the ripe fruit, which, intermixed with 
the green leaves and white flowers, all flourishing at the same 
time, makes a pleasing appearance in the garden, or the 
borders of the flower garden.  The harder annual 
species or varieties are propagated by seeds, which must be 
planted upon a hot-bed in the spring, and when the plants have 
six leaves, they should be transplanted into another hot bed 
at the distance of four or five inches from each other, and 
in warm weather should be allowed a good deal of fresh air. 
Towards the end of May, they should be hardened by 
degrees to bear the open air, and in June may be transplanted 
into
into borders of rich earth. They will flower about the end of June, and will ripen their fruit in autumn. The perennial shrubby forts, after they have been brought forward in the hot-bed, as before directed for the annual ones, should be planted singly in pots filled with rich earth, and plunged into a very moderate hot-bed, under a deep frame, where they may have room to advance. In the day-time, in warm weather, they should have plenty of air, but must be covered with glases every night, and should be frequently watered. On the first approach of frost, they must be removed into the house, where they may have a temperate warmth. The fruit will continue in beauty most part of the winter.

CAPSIZE, to, in Naval Language, to upset, or turn over any thing.

CAP SQUARE, in Artillery, a strong plate, generally of iron, which goes over the trunnion hole in each cheek of a gun-carriage, and is there curved or bent upwards into an arc, sometimes of about 120°, but generally into a semicircular one nearly so as to form with the said hole, (that is sometimes let down into the cheek about two thirds of the diameter of the trunnion, but most commonly so as to have its centre about a quarter of an inch only below the upper surface of the cheek) a circle capable of receiving the same. It is fastened to the plate-plate by a hinge in the joint-bolt, by means of which, it is raised up or let down when wanted. The cap-squares, when fastened down by means of the eye-bolts, or fore locks and keys, keep the trunnions in their holes and the guns on their carriages. There are two of them on every gun-carriage, viz. one on each cheek.

CAPSTAN, a large maffy column shaped like a truncated cone, and paffing perpendicularly through the deck of a ship, and turned by levers, or bars, which paff through holes pierced in its upper extremity; serving, by means of a cable which winds round the barrel, to draw up burdens fastened to the end of the cable. By the capstan veifels are drawn ashore, and hoifed up to be refitted; anchors weighed, and fials hoifed, cargoes discharged or taken in, &c.

The word is alfo written capfion, capfion, and even capfow. It is formed from the French cabfian, which signifies the fame.

The power of the capitan is reducible to that of the axis in perifcope.

The common moveable captan is exhibited in Plate III. Mechanics, fig. 15. A is the shaft, into the top of which four hand-pikes, B, C, D, E, are put, for the men to turn by: this shaft paffes through a collar at G, and works in a hole in the piece H; at F the rope is paffed twice round the barrel, and to keep it from flipping when the barrel is turned, a man conftantly pulls at the end or part J: this machine is prevented from moving by flakes, K, K, driven into the ground. Sometimes, instead of using the common barrel, A, F, fig. 15, a double one, fig. 16, is used. A, B are the two barrels, the one A being smaller than the other; CC is the running rope, one end of which is fannened to the barrel B, and the other to the barrel A; in fuch a manner, that when the shaft is turned, by means of the bar, CD, one barrel will wind on the rope, and the other will wind it off; the middle of the rope goes round a pulley, D, which is hooked to the great rope E. When the machine is turned, so that the great barrel B winds on the rope C, and the little one A at the fame time winds it off, it is plain that the great one takes up more rope than the other can fupply, and it will therefore draw forwards the rope E; and if the two barrels are nearly of a size, the pulley D will advance very slowly, and with proportionally great power.

CAP This capitan might eafily be converted into a crane, or windlafs, for raising weights, merely by giving the compound barrel, AB, an horizontal position, and habilitating a winch instead of the bar, CD. See CRANE. Dr. Robi- fon ascribes the invention of this kind of capitan to a man miftaken but ingenious country tradefman. Encyclop. Brit. Suppl. art. Machinery, vol. xx. p. 107. It appears, how- ever, says Mr. Brewler, in his late edition of ‘Fergon’s Lectures on select Subjects,’ (vol. ii. p. 377.) to be the in- vention of the celebrated George Eckhardt, and likewife of Mr. Robert McKeon of Philadelphia, fon to the present governor of Pennsylvania.

Fig. 17 represents the capitan used at the London docks for handling the ships in and out of the entrance-locks. AB is a caif-iron shaft, the lower end B of which works in a hole or focket in the bottom of a well; at A it moves in a collar in a caif-iron plate fixed over the top of the well, and which acts as a cover thereto: by having these two centres at a confiderable distance from each other, the capitan works very freely. At the upper end of this shaft is a caif iron wheel, E, whose four fpoke are hollow to receive the hand-pikes by which it is turned; F is the conical barrel on which the rope is wound.

There are commonly two capitans in a ship of war; the main-capitan placed behind the main-mall, flanding on the frift deck, and reaching four or five feet above the forecastle: this is alfo called the double-capitan, because it has two drum-heads, and serves two decks for drawing of anchors; and because its force may be doubled by applying hands on each deck. It has bars, whelps, &c. for turning and flogging it. See Plate III. Mechanics, fig. 18. The other is the jejee-capitan, or little-capitan: this stands on the second deck, between the main-mall and the mizen: its use is, chiefly, to have upon the jejee-rope, or to have upon the vol, to hold off by when the anchor is weighed; and on other occasions where a lefs force is required, than to weight the anchors, &c. See fig. 19.

The French call that an English capitan where there are only half-bars used: and which, for that reafon, is only half perforated: this is thicker than the others.

There is also a flying capitan, which may be moved from place to place.

The parts of a capitan are, the foot d, which is the lowest part, the spindle f, the smallest part of which turns round in an iron locket, called the faucer, the whelps, b, a fort of brackets set into the body of the capitan clofe under the bars, and reaching downwards from the lower part of the drum-head to the deck; the barrel A, the main body of the whole; the drum-head c, which is a broad cylindrical piece of wood fixed above the barrel and whelps, in which are holes for the bars to be put into; the bars, which are small pieces of timber by which the men heave; the pins, as e, which are little bolfs of iron, thrust perpendicularly through the holes of the drum-head, and through a correpodent hole in the end of the bar, made to receive them when the bars are fixed; the paws, which are pieces of iron bolted to one end of the beams of the deck, close to the body of the capitan, but fo as that it have liberty to turn about every way; and againft them do the whelps of the capitan bear; fo as that by them the capitan may be flogged from turning back. There are also hanging paws, as g, s, fig. 18, which reach from the deck above to the drum-head im- mediately beneath it; and lastly, the twifter, which is a rope paffed horizontally through holes in the outer ends of the bars and drawn tight, defigned to keep the men steady whilst they work, and to afford room for a greater number to work at once.
An important improvement has lately been proposed to the capitan by capts. Hamilton of the royal navy, which is that of reducing the number of whelps from six to five, making the lower part more obtuse, and filling it up circular by the chocks, and also making the upper part more perpendicular in the sides, and open, the whelps being a portion of a circle.

Several improvements in the structure of the capitan were proposed to the Academy of Sciences at Paris, in consequence of the prize offered by the Academy from the year 1739 to 1741. Seven memoirs on this subject were published in the 5th volume of the prize pieces, forming a detail of 206 pages in 4to. The last improvement was suggested by Stephen-Charles de la Lande, formerly professor of mathematics in the military school. A report on this subject was made to the "Bureau de Confutation" in 1754. The method which he proposes for obviating the inconvenience to which the common capitan is subject, when different round of rope are called about the barrel, by means of a screw or spiral wheel round the capitan, is particularly described in the supplement to Montucla's "Histoire de Mathematiques," vol. iv. p. 585—588.

In fig. 20, are shewn Mr. Plucknett's patent additions to a capitan, which save the time and trouble of forging the melfinger, or rope, by which the cable is hanked in. A is a double circular inclined plane, cut in the deck under the capitan. B, C, D, are lifters of caplan, shown in fig. 21, having a broad flat head, a, and a square bar, b, with a wheel, c, in the bottom of it, which runs on the inclined plane, A, the square part, b, fig. 2, works through the pawl-wheel, E, fig. 20. When the capitan is turned, the lifters running on the inclined plane below, will move up and down; and when the rope has wound itself down to the bottom of the capitan, they will pull it up again, as shewn at B and C, fig. 20. These capitans are now in use in many ships of war, as well as merchant-men, and answer the purpose very well.

The terms belonging to the use of the capitan are, rig the capitan, i.e. fix the bars in their respective holes, thrusting in the pins in order to confine them; hoist the capitan, i.e. go round with it heaving on the bars; surge the capitan; and come up capitan, that is, slacken and let go the cable which you have by; in a like sense they also say, launch out the capitan; pass the capitan, or fix the paws to prevent it from receding during any interval or panic in heaving.

capstan-bars, the pieces of wood employed in heaving round the capitan.

capsula, or capsella, denotes a bag, pouch, or receptacle of divers kinds of things.

The word is a diminutive of the Latin capsula, literally signifying a little box, or cuse; particularly a bag, or fatchel, wherein boys carry their books, &c. to school.

capsula, in chemistry, is a cæthath vessel, in form of a pan; wherein things are frequently placed, that are to undergo very violent operations of the fire.

capsula gentle, in anatomy, is the anterior or right margin of the ileer omentum, (omentum minus the gastro-hepaticum) which contains several vesicles and nerves belonging to the liver and gall-bladder, connected and surrounded by cellular and adipose substance. For a further account of this part, see liver and peritoneum.

capsula communis of the vena portarum, is a covering of firm and compact cellular sub stance, surrounding the trunk of the vena portarum, and attending its ramifications throughout the liver, where it includes also the concomitant branches of the hepatic artery and ductus hepaticus. See liver.

capsula atrabilis, or renales, the glandular bodies which are situated above the kidneys, and which are also described under the names of glandula renales, or suprarenal, and renes succenturiatus. See kidney.

capsula, in botany, (capsula, Lat. a little box) according to Linnaeus is a hollow pericarp, or feed-veil, which opens spontaneously in a determinate manner, but differently in different plants, to afford a pallage for the ripened seeds. Gartner in his excellent work, "De Fructibus et Seminibus Plantarum," uses the term in a more extensive sense, and states that it is to be a dry conceptacle, either membranous, coriaceous, or woody, sometimes without valves, but much more oftenly opening by the means of valves, which differ from each other in number, situation, and figure. He divides it into four species; utricule, famara, follicle, and capsule in the flexilefse sense of the word. To pass over the evident want of logical precision in giving the same name to a whole, and to one of its parts in contradiction to the rest, the first two, not opening spontaneously, may be much more advantageously considered as distinct kinds of pericarp. See those words. The follicle of Gartner corresponds with that of Linnaeus in his Systema Naturae, and practical works. He had called it conceptacle in the Philosophia Botanica, and uniformly separates it from the capsule; but as it possesses all the characters expressed in his definition of a capsule, it would doubtless be more proper to treat it as a particular modification of that kind of feed-veil. See follicule.

capsules differ from each other with respect to their number, the confidence of their outward covering, their external form, their interval division, and their mode of dehiscence, or opening.

1. With respect to their number, they are either single, as in lycnthus, pappar, and the greatest number of plants; or more than one in the same simple flower; either completely separate from each other, as in paeonia, calthia, and sedum; or more or less united, towards the bottom, as in dicetamus, nearly in their whole length as in heliphylla, or fill more intimately as in those which are called coccaces, or grained. The last are described by Linnaeus and most other botanists as consisting of only one capsule; but since each of the cocc or grains has the same mode of dehiscence as occurs in paeonia, dicetamus, and others which are universally deemed polyclapular, it seems more consonant with nature to consider them as diltinct. Those of coccaces are generally paid by Gartner to separate spontaneously from each other in a flate of maturity. It must be acknowledged, however, that when the various capsules of this kind are compared together, they are found gradually to recede from the polyclapular character, till at length they are so closely united, that it is not easy to draw a precise line of distinction between them and those which are strictly one.

2. With respect to the confidence of their outward covering, they are membranous, as in ocallis; coriaceous, or resembling leather, as in acelus; fliehy, or succulent, as in postederea; or woody, as in bankia and cedrela.

3. With respect to their external form, by far the greater number of capsules are roundish, or egg-shaped; but they are sometimes globular, as in centunculus and buttoria; cyllindrical, as in diastitus; inverely heart-shaped, as in venoica; angular, as in cympanula; trigonoous, or three-sided, as in polemonium; folio fided, as in parnassia; five-sided, as in laium; three-furred, as in canna; three-lobed, as in cecus; and so forming gradually to the compound capsule, which
which is dillious, or two-grained, as in mercurialis; three-grained, as in euphorbia; five-grained, as in avena.

4. With respect to their internal division, they confist of one or more cells, (loculiamenta.) When there are two or more cells, the substance by which they are separated is called the delignification, or partition, and the central column, the columnella. See these words. Some of the cells frequently become absorbive as the fruit ripens, and sometimes entirely disappear. The only method of determining their natural number with certainty is, to make a transverse section of the germ at an earlier period of the flower.

5. With respect to their mode of dehiscence, or opening, they are one, two, three, four, five, or many-valved. A capsule is said to be one-valved when it does not separate into distinct parts. Capsules of this kind open in various ways.

1. With lateral holes; about the middle, as in mottled species of campanula; near the base, as in trachelium; and near the summit, as in papaver.

2. With a single longitudinal slit, or chink, (rima); extending but a little below the summit, as in lythrum; to the middle, as in colchicum; and from the top almost to the bottom, as in butomus, caltha, and many others. This slit is generally on the inner or concave side; but is found on the outer or convex one in magnolia, agleia, and a few more.

3. With a short transverse slit on the summit, as in oldenlandia and bodyssey. With an entire round hole at the summit, as in lathyrus and roella; or with three, as in antirrhinum orontium. With short teeth in ceratium; or with deeper divisions, but not so low as the middle (bifarium, &c. dehiscens), as in dianthus and agrostemma. If the divisions descend to the middle of the capsule, it is said to be semi-valved; and if still lower down, whether they reach the base or not, it is called by Linnaeus two or more-valved, according to their number; two-valved, as in cirsium; three-valved, as in cirsus and epilobium; four-valved, as in parasium; five-valved, as in drosera, &c. Gärtner calls every longitudinal division a valve, although it be only a minute tooth, which seems preferable to the arbitrary distinction made by Linnaeus, without any essential difference; but it would, as we conceive, be still better to give that name only to such as extend to the base of the capsule. They open either from the top, as in epilobium, and most other genera; or from the base, as in cirsium. Gärtner adds, that this difference is of no importance: but however inconsiderable it may appear in the eye of the physiologist, it ought by no means to be passed over in silence by the discriminative and arranging botanist.

Capsules are more than one-valved: 1. When they split longitudinally from the summit, or the base, into two or more divisions: 2. When they split longitudinally with more than one chink, leaving the summit and the base entire, as in oxalis, xeris, and many of the orchideae: 3. When they divide transversely into two segments, appearing as if they had been cut round, (circumciss) about the middle, as in angustata; near the summit, as in hylocamus; or a little above the base, as in trianthema.

Capsule of the crystalline lens, in Anatomy, a production of the membranes hyaloidae, which surround the crystalline humour, and remain in its situation. See Eye, Anatomy of.

Capsulate Plants, Capsulate plants, are such as have a tetrapetalous regular flower, consisting of four distinct petals in each flower, and which bear their seeds in short capsule: by which they are distinguished from the filguea, which have their seeds in long cacte, or pods.

Captain, in French, capitaine. This word, in its ordinary acceptation, signifies an officer who commands a company, whether it be a troop of cavalry or a company of infantry or artillery. This word had formerly a much more general meaning than it has at present. For it denoted the commander in chief of an army or body of troops. And in this sense we still make use of it when we say, that Anleen, Anbhal, Scipio, Caesar, Turenne, Condé, Marlborough, Eugene, &c. were great captains. It was the name first given to the chief, head, or commander of a troop, company, or any other body of men by land or sea.

A captain used to be a very considerable officer, and had the command of a thousand, sometimes of four thousand, and sometimes of a greater number of men.

From the time of Leon XII. to that of Henry TV., persons most distinguished for their conduct in the French armies were called captains.

In the legions of six thousand men each, that were instituted by Francis I., every captain commanded one thousand men, who were divided into ten centuries, commanded each by an officer who had not the name of captain, but that of centenier or centurion.

There have been infinities in France of officers commanding corps from four to six thousand men under the sole title of captain. But these large bodies to commanded were composed of strangers or foreigners, as Scots, Germans, Swiss, Italians, whom gentlemen of these nations brought into the service of the French kings, a practice that continued even under Louis XIV.

In the most remote times of the ancient French militia, the name of captain was not given to their officers except the generals. Those, who commanded under the dukes and counts were the viguers and the ecuensiers, during the first and second races of their kings.

But when their sovereigns, besides employing the troops of their vassals, gave commissions to certain seniores to raise companies of gens d'armes, these seigneurs took the title of captain in the sense annexed to it at present. In the business of war, this appellation indeed has always denoted a commandant or chief of troops or soldiers. In the old French romances that of chevalier, which comes from the word cheif or chief, is sometimes made use of. And captain comes from caput, which also signifies chief.

The rank of captain, in the ordinary acceptation of the word is between that of a major and that of a lieutenant. A captain commandant is he who commands in chief a company, or has the chief command of a company.

In every nation almost, and in every service, there are captains of different denominations by the addition of other words expressive of the functions or duties of those, on whom the compounded appellations are belloved.

We for instance make use of the compound term Captain General. By the constitution the king is captain general, or generalissimo of all the forces in his united kingdoms of Great Britain and Ireland and their dependencies. The term comprehends the first military rank, power, and authority in the realm. In 1750 his majesty was pleased to delegate this rank with the powers and authorities annexed to it to his royal highness the duke of York.

Captain Lieutenant. This compound term in our service denotes the commanding officer of the colonel's troop or company in every regiment, when the colonel is either absent or gives up the command of it to him. By an order in 1750 this officer takes rank as a full captain, and by a late regulation he succeeds to the first vacant troop or company, the price of a captain-lieutenant and of a company being now the same. The title of captain-lieutenant is still made use of in foreign countries.

A captain reformed is one, who on a reduction of the army
At the termination of a war and the re-establishment of peace,
looses his company but retains his rank and pay, whether he
be on duty or not.

A captain on half pay is one who loses his company on a
reduction of an army and retires on half pay, until seniority
or a call for his services, puts him again on duty and full
pay.

A captain en second, or second captain, is one, whose com-
pany has been broken up, and who is joined to another to
serve under the captain of it, during whose absence, through
sicknecf or otherwise, he commands.

The French, by annexing others to the word captain,
multiplied the compound denominations of this title to a
great degree. Of these the following are the principal:

Captain general.
Capitaite lieutenant.
Capitaine en second.
Capitaines des postes.
Capitaines réformé.
Capitains conducteur général d’artillerie.
Capitaines des guides.
Capitaines des charrois.
Capitaines général des charrois de l’artillerie.
Capitaines général des vivres.
Capitaines des ordres.
Capitaines des ouvriers.
Capitaine conducteur d’artillerie.
Capitaine de mines.
Capitaine en pied.
Capitaine en pied sur un vaisseau de guerre.
Capitaine de port.
Capitaine d’armes.
Capitaines des gardes du corps du roi.
Capitaines des cent gardes Suisses du roi.
Capitaine des gardes de la porte du roi.
Capitaines des gardes de la prévôté de l’hôtel du roi.
Capitaine des gendarmes de la garde du roi.
Capitaines des chevaux legers de la garde du roi.
Capitaines aux gardes Françaises.
Capitaines en second aux gardes Françaises.
Capitaines aux gardes Suisses.
Capitaines dans la gendarmerie de France.
Capitaines des gardes du corps du Moniteur frère du roi.
Capitaines des Suisses de la garde ordinaire du corps de
Moniteur frère du roi.
Capitaines des gardes du corps de Monseigneur le comte
d’Artois frère du roi.
Capitaines des Suisses de la garde ordinaire de Monseigneur
le comte d’Artois frère du roi.
Capitaines commandants d’infanterie Française.
Capitaines commandants des grenadiers.
Capitaines commandants de chasseurs.
Capitaines a la suite des régiments de l’infanterie.
Capitaines a la suite de l’infanterie.
Capitaines a la suite des places.
Capitaines dans le regiment Suisses.
Capitaines commandants dans les regiments Allemands.
Capitaines commandants dans les regiments Irlandais.
Capitaines commandants dans les regiments Italiens.
Capitaines commandants dans les regiments Corse.
Capitaines des grenadiers royaux.
Capitaines dans les regiments provinciaux d’artillerie.
Capitaines dans les regiments provinciaux d’état major.
Capitaines dans les bataillons d’état major.
Capitaines commandants dans la cavalerie.
Capitaines a la suite d’un regiment de cavalerie.
Capitaines a la suite de la cavalerie.

Capitaines de cavalerie a la suite des places.
Capitaines commandants de carabiniers.
Capitaines attachés au corps des carabiniers.
Capitaines commandants de chevaux legers.
Capitaines commandants de houffards.
Capitaines a la suite d’un régiment.
Capitaines commandants de dragons.
Capitaines de dragons a la suite d’un regiment.
Capitaines a la suite des dragons.
Capitaines de dragons a la suite des places.
Capitaines commandants de chasseurs a cheval.
Capitaines dans le corps du génie.
Capitaine commandant la compagnie des cadets gentils
hommes dans l’ecole militaire.

There are also captains of several different denominations
in their corps of artillery.

Since the revolution in France some of these denominations
have ceased, and some of them have been changed into
others. It is not therefore our intention to give a de-
scription of each of them. We will only take notice of
some of the principal ones, and then speak of the know-
ledge and qualifications which captains ought to pos-
sess.

The title of captain general, or capitaine général, is very
ancient in France, and conferred an almost unlimited com-
mand on the person who possessed it, in the district where
he commanded. But it never corresponded to that of gene-
ral-in-chief or extended to the whole French army, but in the
case of the duke of Savoy in 1635, in the time of Louis XIII.
This title was revived by cardinal Mazarin in 1676 in fa-
vor of the marquis of Cafllement and the marquis d’Ussel-
elles, but not with such extensive powers. For they were
under the orders of the marshal of France, and it only in
fact gave the command of all lieutenant generals. It was
also conferred on others, as Mefieurs de Crequi, d’Humieres,
de Bellefons, and de Gadagni. But it did not continue long in existence. The count de Télèf also had the title of
captain general in Italy in 1702.

In Spain the rank of a captain general corresponds with
that of a marshal of France, who has the command of an
army.

Capitaine conducteur general d’artillerie, or captain-con-
ductor general of artillery, is the person who commands all
the captain conductors of artillery. He has charge of the
equipages and takes care that they are properly arranged
and march according to the orders of the general officer
of artillery, which are transmitted to him by the com-
mandants of the equipages of artillery.

Capitaine general des charrois de l’artillerie, the captain
general of artillery-carrages, or the captain general of the
carriage of artillery. This person ought always to be a
man of much experience as well as of a naturally good
and correct understanding with a clear arrangement of ideas.
He has the command and direction of the whole carriage of
the artillery.

Capitaine des guides, or captain of the guides, is the
person charged with the assembling, shooing, forming and
furnishing of guides. He ought to understand different
languages, and particularly that of the country, in which
the army is carrying on its operations. He should be active,
vigilant, and intelligent, practised in interrogating the guides
he assembles, expert in discovering which of them are best ac-
quainted with such or such a district or tract of country,
in which of them he can place most confidence, and who
amongst them are fittest to be employed as spies. As the
army advances he distinguishes those that are found to be ufeless
and chooses others. He furnishes some of them on foot and
fome
CAPTAIN.

Some mounted, and for this purpose procures both provisions and forage with forage from places in the neighbourhood of the army.

He encamps near the general's quarters, and when the general moves on to one or reconnosse in the field, he accompanies him with the most intelligent of the guides.

Of the knowledge which it is necessary for captains to possess.

That an officer of this rank ought to be well acquainted with every thing necessary for the proper discharge of the duties incident to his command or situation either in peace or war, in garrison or in the field, is a position, too obvious to be disputed, and requires no proof.

A captain then ought to understand the languages most generally spoken in Europe, and particularly that of the country with which the nation he belongs to is most frequently at war.

He should be acquainted with geography in general, and more especially with that of the country or countries in which his nation is carrying on war. He should know the directions and extent of the principal hills and mountains in them, the courses of the principal rivers, their depth and fording places, how far they are navigable by small vessels, by row-boats, or by canoes, the situations of the principal roads, bridges, dikes, fortified places, &c. &c. in them.

He ought to be well versed in history, particularly that of his own country; and should not only be acquainted with the best and most faithful accounts or narratives of battles, both ancient and modern, but ought to examine attentively and minutely the circumstances mentioned as attending each of them, and contributing chiefly to its failure or success. Such a course of study and reflection will soon enable him to acquire a knowledge of military management, resources, and expedients, greatly beyond that which his own experience might ever afford him. When placed in an unusual or trying situation, he will find in it something familiar or unlike to what he had before read or thought of, which resemblance or difsimilitude will immediately suggest to him expedients, and means of extricating himself from difficulties. It is by such a judicious, careful, and attentive perusal of history that both the ablest generals and statesmen have been formed.

For no man's experience alone, without the aid of study and reflection, is sufficient to make a man eminent in any profession.

A captain ought to be well acquainted, not only with the tactics, the manœuvres, the rules, and military regulations in the service of his own country, but also with the different branches of the art of war; and to extend his ideas and knowledge beyond the parade or a review. Regulations, in time of peace, deliver general principles; but they do not point out the happy application of them; which on service depends on the judicious regulations of military maxims by circumstances. He ought to understand what sort of works are best adapted to any particular situation or position; their form and disposition; the manner of tracing or constructing them; the materials necessary for reveting them; the tools and utensils wanted for erecting them; and in short every branch of knowledge requisite for securing or fortifying any given position properly. He should likewise understand the method of increasing the strength of any post by means of inundations, mines, palisades, abatis, advanced works, lines of counter-approach, &c. &c. He should know well how to defend an open city, town or village, a house, a church, an old castle, a church-yard, a barn, a farm-house, a block-house, a parapet, or defile, a dike, a ravine, the pailleage of a river, a ford, a wood, &c.

A captain ought also to make himself well acquainted with the business and duty of an officer commanding an advanced guard, an outpost, a foraging party, and every other sort of detachment.

A captain should likewise understand mathematics to at least a certain extent or degree. He should know the use of mathematical instruments and possess a sufficient knowledge of geometry for surveying and the measurement of heights and distances. He ought also to understand algebra, as far, at least, as quadratic equations.

A captain should also know how to sketch ground expeditiously, and to represent properly on paper the relative situations of hills, rising grounds, towns, villages, ravines, highways, and other roads, as well as the relative heights nearly of the different positions. But a knowledge that is merely confined to this, though it be necessary as an elementary part of instruction, is of but little value, and is calculated for rendering an officer vain and conceited, and for making him supposable that he knows every thing, whilst in reality he knows scarce anything that he ought to know. He should be able to determine precisely whether one position be preferable to another, either for the reception of troops, or for the purposes of defence. He should know how to combine artillery, houses, churches, church yards, dikes, fences, copes, woods, high-ways, &c. with field-works. He ought to understand the best methods of constructing such works, as well as the proper application of artillery to the attack and defence of field-positions. The doctrine of positions, and the combinations of attack and defence, form indeed the sublimest part of the art of war.

A captain, and indeed every other officer of engineers, ought to be thoroughly acquainted with fortification, the principles of construction both regular and irregular, of the attack and defence both of fortified places and field-positions, the theory of revetments and demi-revetments, the construction of batteries, &c. &c. independently of what they should know in common with other officers.

A captain, or other officer of artillery, exclusive of what he ought to know in common with the rest of the army, should be thoroughly acquainted with a variety of things peculiar to the service of his own corps. He should understand, as well as any engineer whatever, the construction of batteries; the situations and services to which different forts of ordnance are best adapted; in what circumstances it is better to make use of shells and hollow shot, than solid ones, and of howitzers and mortars, than cannon; the preparing and making up of ammunition; the charges best fitted to various services and situations; the practice of firing en richelet; the windage fit for different sorts and pieces of ordnance; the theory of projectiles both in vacuo and in the air; the construction of guns and gun-carrriages; &c. &c.

As to the physical qualities or qualifications of captains, they ought to possess good constitutions, and to be capable of enduring the continuance of fatigue, which is of the first consequence on actual service. Troops without these qualities, let their arms and drabs be ever so favourable for expedition, cannot make long and rapid marches, or perform their movements with celerity, which, ceteris paribus, will always ensure success to the army, that possess it in the greatest degree. He should also possess courage, or personal bravery, as well as coolness or steadiness in every situation. He ought likewise to enjoy distinct vision to prevent confusion and mistakes. For though Hannibal both fought and won some great and important battles after he lost the sight of one eye, every officer is not in point of talents, constancy, and abilities, an Hannibal.

As to his moral qualities, he ought to be honourable, just, temperate, free from drunkenness, gambling, and every
every other species of debauchery and dissipation, exempla-
ry in his conduct, conciliating in his manners, not given
to quarrelling, attentive to the comfort of his soldiers, obe-
cient and respectful to his superiors, mild and humane to-
wards his inferiors, a preserver of strict discipline, and at
the same time an enemy to severe and ignominious punish-
ments.

CAPTAI; BASHAW, signifies the Turkish high-admiral. See
Bashaw.

He possesses the third office in the empire, and is invested
with the same power at sea that the vizir has on shore.
Soliman II. instituted this office in favour of the famous
Barbarossa; with absolute authority over the officers of
marine and arsenal, whom he may punish, cashier, or put
to death, as soon as he is without the Dardanelles.

He commands in chief in all the maritime countries, cities,
cities, castles, &c. and at Constantinople is the first magistrate
of police in the villages on the side of the Porte, and the canal
of the Black Sea. The mask of his authority is a large
Indian cane, which he carries in his hand, both in the arsenal
and in the army.

The captain-bashaw enjoys two sorts of revenues; the one
fixed and the other casual. The first arises from a captation
of the islands of the Archipelago, and certain governments
in Nalolia and Gallipoli. The latter confis in the pay of
the men who die during the campaign; in the fifth of all
prizes made by the begrs, in the profits accruing from the
labour of the slaves, whom he hires as rowers to the grand
fiongion; and in the contribution he exacts in all places where
he passes.

CAPTAIN REZI, or CAPITAN REZI, an appellation given by
the Turks to the grand pilot, answering to pilot royal among
the French.

CAPTAIN, a title given to persons commanding ships of
war, carrying 20 guns or upwards. The commanders of
ships in the service of the East India company are also fyled
captains; and the same title has defended, very improperly,
to the masters of other vessels.

The charge of a captain in his majesty's navy is very com-
prehensive, inasmuch as he is not only answerable for any bad
conduct in the military government, navigation, and equip-
ment of the ship he commands, but also for any neglect of
duty, or ill management, in his inferior officers, whose several
charges he is appointed to superintend and regulate. On
his first receiving information of the condition and quality
of the ship he is appointed to command, he must attend her
constantly, and hasten the necessary preparations to fit her
for sea. So strict, indeed, are the injunctions laid on him by
the lord high admiral, or commissioners of the admiralty,
that he is forbid to lie out of his ship, from his arrival on
board till the day of his discharge, unless by particular leave
from the admiralty, or his commander in chief. He is en-
joined to shew a laudable example of honour and virtue to
the officers and men, and to discomfit all disolute, immoral,
and disorderly practices, and such as are contrary to the rules
discipline and subordination, as well as to correct those who are guilty of such offences as are punis-
able according to the usage of the sea. He is ordered par-
ticularly to survey all military stores which are sent on board,
and to return whatever is deemed unfit for service. His
diligence and application are required to procure his comple-
ment of men, observing carefully to enter only such as are
fit for the necessary duty, that the government may not be
put to improper expense. When his ship is fully manned, he is
expected to keep the established number of men complete,
and superintend the master himself; if there is no clerk of
the check at the port. When his ship is employed on a cruising
station, he is expected to keep the sea the whole length
of time previously appointed; but if he is compelled, by some
unexpected accident, to return to port sooner than the
limited time, he ought to be very cautious in the choice of
a good situation for anchoring, ordering the master, or other
careful officer, to sound and discover the depths of water and
dangers of the craft. Previous to any possibility of an
engagement with the enemy, he is to quarter the officers and
men to the necessary stations, according to their office and
abilities, and to exercise them in the management of the
artillery, that they may be more expert in the time of battle.

His station, during the time of an engagement, is on the
quarter-deck; at which time he is expected to take all op-
portunities of annoying his enemy, and improving every ad-

vantage over him, to exhibit an example of courage and for-
titude to his officers and crew, and to place his ship opposite
to his adversary, in such a situation, as that every cannon shall
do effectual execution. At the time of his arrival in port,
after his return from abroad, he is to assemble his officers,
draw up a detail of the observations that have been made
during the voyage, of the qualities of the ships, as to their
trim, ballast, flowage, manner of fURLsing, for the information
and direction of those who may succeed him in the command;
and this account is to be signed by himself and officers,
and to be returned to the resident commissioner of the navy at
the port where the ship is discharged, and to transact a du-
plicate of the same to the navy board.

The pay of captains in the royal navy was formerly very
small; this defect was, however, made up by indulging them
in many privileges not now allowed; as plundering of prizes,
taking convoy-monies, and even carrying merchant goods,
plate, &c. King James II. taking this last privilege away,
in heu thereof granted them an annual allowance of table-
monies, almost equal to their whole former pay. But this
not taking place, by reason of the abdication, king Wil-
liam III. in 1695 ordered the pay of captains to be doubled.
but the fund for this failing at the peace of Ryewick, a new
establishment was made in 1700, whereby nearly one-third
was retrenched from the sea-pay, and that of a line rate
was fixed at 11. of a second rate at 16s. and a third rate at
3s. 6d. of a fourth rate at 10s. of a fifth rate at 8s. and of a
sixth rate at 6s. per day.

Captains of prize ships, after three years from the date of
their first commission, rank as colonels in the army.
Admirals' ships, and those of the first rate, in the French
navy, have two captains, two lieutenants, and two en-
signs.

CAPTAIN, or more properly, master, of a merchant ship.
is the person who has the direction of the ship, crew, and
fading. &c. The proprietor of the vessel appoints the master, and
the master engages his mate, crew, and pilots, &c. though,
when the proprietor and master reside in or near the same
place, they generally act in concert together. In the Med-
iteranean the master is called the patron, or patron.

CAPTAIN, a title in the royal navy, given to those persons
who have the charge or command of a gun, of the tops,
&c.

CAPTAINS OF PORT, in the French Marine Affairs, officers
established in some considerable sea-ports where there are
 arsenals. To them belong the command of the guard of
the place, the watching of the sea, and the care and custody
of the vessels brought into port.

There are such captains at Toulon, Rochfort, Breiten,
Havre, Dunkirk, and Port Lewis. They are to take care of
mooring the king's ships, and oblige all to give the due
salutes.

CAPTAIN'S CLERK, a person employed by the captain to
keep
keep his accounts, &c. His pay is the same as that of a middling man. The captain is answerable for the faults of his clerk; nor can he receive his wages without proper certificates, and must make good all damages sustained by his neglect or irregularity. By a recent regulation, no person can be a purer unless he has served two years as captain's clerk.

CAPTAINRY, capitainerie, in the French Law, denotes the government or command of a royal palace, and the land dependent thereon. The name is also applied to the officer of captains of places or places; such are the capitaneys of Fontainebleau, the wood of Boulogne, &c.

CAPITAINS, in Geography, a town of France, in the department of the Gironde, and chief place of a canton in the district of Bazas; 3 leagues S. of Bazas. The place contains 3,015, inhabitants; the territory comprehends 364 square kilometres and 6 comunies.

CAPTIVE, in Law, is that part of a legal instrument, as a "commisson," "indictment," &c., which shews where, when, and by what authority, it is taken; found, or executed. Thus, when a commission is executed, the commissioners subscribe their names to a certificate, declaring when and where the commission was executed. The caption usually commences with these words, 

Viretur jussum commisssionem istam, &c. or, 

Exeito fius commissarum partem in quibus jubes annuvit, &c. or Capt. &cogn., &c. &c. or Capt. &cogn., &c. Capit. &cogn., &c. Captains of this kind relate chiefly to three sorts of business; to commit a man or to take fines of lands, to take answerers in chancery, and depositions of witnesses. These captions, and the executions of the commissions, must now be in English, by 1 Geo. II. cap. 26.

The word Captive, is also used, vulgarly, for an arrest.

CAPTIONS, in Scots Law, a writ issuing under his majesty's signet, in his majesty's name, obtained at the instance of a creditor in a civil debt, commanding messengers at arms, and other officers of the law, to apprehend and imprison the person of the debtor until he pay the debt. — Also, the name of a writ issued by the court of septon against the agents of the court, to return papers belonging to processes or lawsuits, or otherwise to go to prison.

CAPTIVE, a slave, or person taken by the enemy in war, or by a pirate or corsair. See Slave.

Captive, captivi, among the Romans, differed from dedicati, as the former were taken by force, whereas the latter surrendered themselves.

By the Lex Cornelia, a Roman citizen taken captive, in case he returned, was regarded as having never been taken; if he died in captivity, he was regarded as dead; he was taken in the former case he recovered all his rights, and even the dominion over his children; in the latter his son became free at the time of his father's detention. Justin, Inst. lib. i. tit. xii. § 5.

Formerly captives in war became the slaves of those who took them; and though flavry, such as obtained among the ancients, be now abolished, some shadow of it still subsists in respect of prisoners of war, who are regarded as the property of their captors, and have no right to liberty, but by concession from them, or till their ransom is paid. Negro servants likewise, who are purchased when captives, continue in some degree the property of the masters who buy them, though the property (if it indeed continues) confid.rather in the perpetual service than in the body or person of the captive. Blackl. Com. vol. ii. p. 409. See Negro and Slave.

The Romans used their captives with great severity; their necks were exposed to the soldiers to be trampled on, and their performances afterwards sold by public auction. Captives Vol. VI.

were frequently burnt in the funeral piles of the captive warriors, as a sacrifice to the infernal gods. See Burns. Those of royal or noble blood had their heads severed, and their hair sent to Rome, to serve as decorations in female toys, &c. They were led in triumph laden with chains through Rome, in the emperor's train, as far as the foot of the Capitolium mount, for they were not permitted to ascend the sacred hill, but carried them captive. Those of the prime quality were honoured with gold chains on their hands as well as feet, and golden cushions on their seats. If they made their escape, or fled themselves to avoid the ignominy of being led in triumph, their names or effigies were frequently carved on their places. "CAPTIVITY is used in &c. to denote the punishment inflicted by Providence on the Jews, for their idolatry and wickedness. Their full captivity in Egypt, from which they were rescued by Moses, should be considered rather as the result of providential intervention than as a penal evil. See Egypt.

The frequent captivities of the Jewish people may be regarded as chastisements of Providence for their lapses into idolatry, and as means of reclaiming them to the acknowledgment and worship of the true God. The scripture history informs us of six captivities, which took place during the government by Judges. The first was that under Channa-Rahathaim, king of Mesopotamia, and continued eight years, from the year B.C. 1291 to 1283, when they were delivered by Othniel, the son of Kenaz, Caleb's younger brother. The second was that under Elon, king of Moab, and lasted 18 years, v. 2, from the year B.C. 1232 to 1214. From this they were rescued by Ehud, and the eastern part of the country of Israel, after having been emancipated from the yoke of Moab, had rest 80 years. However, in the mean while, the Philistines invaded the western parts, and were recalled by Shunamm (Judg. iii. 31.) This is reckoned the third captivity. The fourth was that of the northern tribes by Jabin, king of Hazor, from which they were delivered by Deborah and Barak, in the year B.C. 1285; after which period the northern part of the territory of Israel had rest 40 years. (Judg. iv. 1, 2.) The fifth captivity, comprehending north and south Israel, was that under the Midianites, which lasted seven years, from the year B.C. 1245 to 1238; and from this the instrument of their deliverance was Gideon. (Judg. vi. 1.) Their sixth captivity was that under the Ammonites and Philistines. While Jair was judge over north and east Israel (B.C. 1175), those districts were in bondage to the Ammonites 18 years (Judg. x. 2); and at the same time with Jair, Eli began to judge south and west Israel 40 years, (1 Sam. iv. 18.), during which whole period that part of Israel was oppressed by the Philistines. (Judg. xii. 1.) In the first of these 40 years of Eli, which was also the first year of Jair, Samson was probably born; and he lived 40 years, judging west Israel (while Eli also was judge there, and while that part of the country was under the Philistines) 20 years. (Judg. xv. 20.) North and east Israel were delivered from the Ammonites, after an oppression of 22, or 23 complete years, in the year B.C. 1152. (Judg. x. 3.) The oppression of the Philistines continued during the judicatories of Ibzan, Elon, Abdon, Eli, Samson, and Samuel. Ibzan preceded over north and east Israel five or six complete years, from the year B.C. 1147 to 1140. (Judg. xi. 7.), when he was succeeded by Elon. About the fifth year of Elon (B.C. 1153), Samuel was publicly known to be a prophet. (1 Sam. iii. 11.) About the seventh year of Elon (B.C. 1143), Samson pulled down the temple (Judg. xv. 20.,) and destroyed a great number of the Philistines. Uther thinks that this calamity might encourage the
the faith and well Israelites to give them battle. (1 Sam. iv. 1.) Elon was succeeded in the judicature of north and east Israel by Abdon, B.C. 1130; and Abdon by Samuel, B.C. 1122, who was now judge over north and east Israel, as he had been before over south and west Israel. (1 Sam. viii. 15, 16, 17.)

However, the most signal captivities which these people experienced, were those of Israel and Judah, under the sovereignty of these kingdoms, after they were separated B.C. 975, denominated the Assyrian and Babylonian.

The Assyrian captivity, which comprehended that of the ten tribes, commenced in the reign of Pekah, king of Israel, B.C. 792, when Tiglath-Pilezer, king of Assyria, took several cities of Israel, and carried away captives, principally from the tribes of Reuben, Gad, and the half tribe of Manasseh. (1 Chron. vi. 26. 2 Kings, xv. 29.) In the fifth year of Hezekiah, king of Judah, and ninth year of Hoshea, king of Israel, B.C. 731, Shalmanezer, king of Assyria, took and destroyed Samaria, after a siege of three years, transplanted those of the ten tribes, that had been spared by his father, Tiglath-Pilezer, to Niniveh, and provinces beyond the Euphrates, and thus dispersed them among the Gentiles. (2 Kings, xviii. 10, 11.) Moreover, in the 22d year of Manasseh, king of Judah, B.C. 676, Eshahaddon or Assar-ducus, king of Assyria and Babylon, made the last deportation of the Israelites, and planted others in their stead; and in the same expedition, probably, took Manasseh captive, and carried him to Babylon. (2 Kings, xxv. 2. 2 Chron. xxxiii. 11. Ezra, iv. 2.)

The Assyrian captivity of the ten tribes of Israel, sometimes denominated Ephraim, from the chief of them, was predicted by Isaiah (see chap. vii. 8.) in the first year of Ahaz, king of Judah, B.C. 742. "Within three years and five years," says the prophet, "shall Ephraim be broken, that it be not a people." This period has very well puzzled the scripture critics. If this prophecy was delivered in the first year of Ahaz, and Shalmanezer took Samaria, and carried away Israel (Ephraim) into Assyria, in the fifth year of Hezekiah, we shall only have an interval of 24 or 25 years. For the solution of this difficulty, the learned Vigny supposes that the text is corrupted, and that instead of 66 (ע"ש"ע) and 5, it was originally written 26 (ע"ש"ע) and 5. This conjecture would appear much more probable, if it could be proved, that it had ever been usual to write the numbers or dates of years partly in words at length, and partly in numerical letters. But it is not necessary to recur to this expedient. For if we compute, from the first of Ahaz, 25 years in the reigns of Ahaz, Hezekiah, and Manasseh, they will terminate about the 2d year of Manasseh, when the captivity of the Israelites was completed by Eshahaddon.

It has been generally supposed, that the greater part of the ten tribes was lost in this captivity, which put a period to the kingdom of Israel. It is certain, that immediately upon their deportation, they were placed in Assyria and Media; and if they subfitted any where, it is natural to imagine, that they might be found there in the greatest number. But authors have generally sought for them elsewhere. Accordingly, the visionary writer of the second book of Esdras (xvi. 35, 36.) affirms, that they adopted a resolution of retiring from the Gentiles, and of emigrating into a country which had never been inhabited; that the Euphrates was miraculously divided for their passage; and that after pursuing their journey for a year and a half, they arrived at the country, Araxath; a country the situation of which has not been duly ascertained. See Araphians. Benjamin Tudela, a Jew of the 12th century, has assigned them a large and spacious country, with fine cities, in a situation that is altogether unknown. Eldad, another Jew of the 13th century, has placed them in Ethiopia, and hath made the Saracens and 25 kingdoms tributary to them. Another Jewish writer, Perilof of Ferrara, who lived in the 14th century, has allotted to them kingdoms in a country called Pericha, molested by unknown mountains, and bounded by Assyria, and likewise in the deserts of Arabia, and even in the South Indies. Manasseh, a modern of the 17th century, and others, have asserted, that they passed into Tartary, and expelled the Scythians; and other again from Tartary have conveyed them to America. Most of these accounts are unfounded conjectures, and some of them are manifest forgeries of the Jews to aggravate their own r"ation. However, some respectable modern writers imagine, that they have found existing traces of them in the northern parts of India, particularly among the Afghanians. The difficulty of ascertaining the habitations of the ten tribes, has induced others, among whom we may reckon Calmet, to maintain, that they returned into their own country, with the other two tribes, after the Babylonian captivity. To this purpose it is alleged, that their return was predicted. See Hoesa, xi. 11. Aqss, ix. 14. Obadiah, 18. 20. Iliam, xi. 13. 14. Ezekiel, xxxvii. 16. Jerem. xxxvi. 7, 8, 9, 10, 17. 20. xvi. 17. xlix. 2. &c. Zech. ix. 13. 6. 10. Micah, ii, 12. Besides, in the historical books of scripture, we cannot refer to the apocryphal book of Tobit, Israelites, as well as those of Judah and Benjamin, are reported to have returned from the captivity. When Ezra numbered those that were returned from the captivity, he only inquired whether they were of the race of Israel; and at the first pasover, then celebrated in the temple, there was a sacrifice of 12 he-goats for the whole house of Israel, according to the number of the tribes." Ezra, vi. 16. 17. viii. 35. Under the Maccabees, and in the time of our Saviour, Palestine was peopled with Israelites of all the tribes, without discrimination. However, as the decree of Cyrus extended to "all the people of God" (Ezra, i. 3.), and that of Artaxerxes to "all the people of Israel" (vii. 13.), there can be no doubt that many of the Israelites availed themselves of these decrees, and returned with Zechariah and Ezra to their own cities; nevertheless, the main body of the ten tribes remained behind. Accordingly, Ezra, upon whose authority we may depend, informs us, that there "rose up the chief of the fathers of Judah and Benjamin" (ch. i. 5.), and he calls the Samaritans "the adversaries of Judah and Benjamin" (ch. iv. 1.); and hence we may infer, that these two tribes were the principals, and that the others were only accessories. And if they did not return at this time, they cannot be supposed to have returned, at least in a considerable body, at any future time; for history informs us of no such adventure, nor do we know either the time or occasion of their return, or who were their conductors in this expedition. Josephus, who knew his country for several years in and about a condition as any time since the captivity, affirms (Antiq. lib. xii. cap. 5. § 2.), that Ezra sent a copy of the decree of Artaxerxes to all of the fame nation throughout Media, where the ten tribes lived in captivity, and many of them came with their effects to Babylon, desiring to return to Jerusalem; but the main body of the Israelites abode in that region; and therefore it hath happened, says this Jewish historian, that there are two tribes in Asia and Europe, living in feclusion to the Romans; but the ten tribes are beyond the Euphrates to this time; and he then adds, with the vanity of a Jew, speaking of his countrymen, that they were so many myriads, that they could not be numbered. Others, who have found no sufficient authority for admitting that the ten tribes of Israel were
C A P T I V I T Y.

were restored in the same manner as the two tribes of Judah and Benjamin, have therefore affirmed (see Pusey's Comm. pt. 1. b. 1. 7) that the ten tribes of Israel, which had separated from the house of David, were brought to a full and utter destruction, and never after recovered their places again. But those who were thus carried away (excepting only some few, who, joining themselves to the Jews in the land of their captivity returned with them) were falling into the sages and idolaters of the nations among whom they were planted, to which, indeed, they were too much addicted while they remained in their own land, after a while became wholly absorbed in them; and thence utterly losing their name, their language, and their memorial, were never after any more mentioned. To this statement, however, it has been very justly objected, that if the whole race of Israel became thus extinct, we shall in vain expect the fulfilment of the numerous prophecies, that promise the future conversion and restoration of Israel as well as of Judah. The truth, says bishop Newton (Diflcerations on the Prophecies, apud Works, vol. vii. p. 195, &c. ed. 8vo.), seems to lie between these two opinions. "Neither did they all return to Jerusalem, neither did all who remained behind, comply with the idolatry of the Gentiles, among whom they lived. But whether they remained, or whether they returned, this prophecy of Hiasah (ch. vii. 8.) was fully fulfilled; the kingdom, the commonwealth, the land of Israel was utterly broken; they no longer maintained a separate religion; they joined themselves to the Jews from whom they had been unhappily divided; they left the name of Israel as a name of distinction, and were thenceforth in all common called Jews. It appears from the book of Esther, that there were great numbers of Jews in all the 127 provinces of the kingdom of Ahasuera, or Artaxerxes Longimanus, king of Persia, and they could not all be the remains of the two tribes of Judah and Benjamin, who had refused to return to Jerusalem with their brethren; they must, many of them, have been the descendants of the ten tribes whom the kings of Assyria had carried away captive; but yet they are all spoken of as one and the same people, and all without distinction are denominated Jews." See also Acts, i. 9. ch. xxvi. 7. James, i. 1. Without doubt, several persons of all the ten tribes are now in being, though we cannot discern them from the other Jews, with whom they are confounded and intermixed.

It appears, therefore, to be a fact, that the ten tribes of Israel were in a manner lost in their captivity, while the two tribes of Benjamin and Judah were restored and preferred several ages afterwards. Should an inquiry be made into the reason of this difference, it may be alleged, that the ten tribes had totally revolted from God to the worship of the golden calves in Dan and Bethel; and for this, and their other idolatry and wickedness, they were suffered to remain in the land of their captivity.

The Babylonish captivity comprehended that of the kingdom of Judah, or of the two tribes of Judah and Benjamin, who adhered to the house of David, and lasted 70 years. The mode of eliminating its duration has been attended with some difficulty, on account of the different captivities of the Jewish nation, which occurred about the same period. Of these there have been reckoned five. The first happened in the fourth year of Jehoiakim, B. C. 605, when Nebuchadnezzar, admitted to partnership with his father in the kingdom of Babylon, marched to Carcemiithim, with a great army, to recover from the king of Egypt all that he had lately conquered in Syria and Phcenicia. In the course of this expedition, he invaded and ravaged Judaea, besieged and took Jerusalem, made Jehoiakim his subject and tributary, transported the richest children of the royal family and of the nobility, and among the rest Daniel and his companions, to Babylon, to be bred up there for councils and laws in his palace, and also carried away the vessels of the house of the Lord, and put them in the temple of his god at Babylon. (Dan. i. 1. 6.) The second captivity happened in the fourth year of Jehoiakim, B. C. 602, when Nebuchadnezzar, immediately after his father's death, returned to Judaea, made captives of many Jews, and bound them king in order to carry him to Babylon; though he released him afterwards to his kingdom, having received the strongest assurances of subjection and allegiance. Notwithstanding these professions of obedience, Jehoiakim again rebelled, in the 11th year of his reign, B. C. 597. Nebuchadnezzar, hearing of this revolt, came against him with a prodigious army, and threatened all Judaea with destruction. Intimidated by this menace, Jehoiakim surrendered himself into the hands of his enemies, who slew him, together with many of the nobles, in Jerusalem, and placed his son upon the throne. (2 Chron. xxxvi. 6.) Afterwards repeating of what he had done, and fearing left Jehoiakim should embrace some future occasion of revenging his father's death, Nebuchadnezzar returned within three months, carried that unfortunate prince into captivity, and appointed Zedekiah to reign in his stead. (2 Chron. xxxvi. 9, 2 Kings. xxiv. 17. &c.) This may be reckoned the third captivity of the Jews by the king of Babylon. On this occasion Mordecai and Ezekiel were among the captives. (Esth. ii. 5, 6. Ezk. k. i, 2.) The fourth was in the 11th year of Zedekiah, 593 B. C., when the whole land was made desolate, when the city and temple of Jerusalem were destroyed, (the city being taken and burnt after a siege of 18 months, in the year B. C. 587, and the temple burnt in the year B. C. 586.) and when Zedekiah, king of Judah, was taken with letters of brazen, and carried prisoner to Babylon, where he died. (2 Kings. xxxiv. 3, 9. 2 Chron. xxxvi. 16. Ezk. xli. 13.) The fifth captivity occurred in the 21st year of Nebuchadnezzar's reign, B. C. 584, when that monarch sent Nabuzadana, captain of his guard, to revenge the death of Gedaliah, governor of Judah. Nabuzadana desolated the land, and carried to Babylon the wretched remains of that miserable nation.

To each of these captivities the date of the period of 70 years has been referred. But the fact of them, in the fourth year of Jehoiakim, B. C. 606, seems to be the most accurate commencement of this period, and is the most agreeable to Scripture. The interval extending thence to the second year of Cyrus, B. C. 538, when the Jews were permitted to return to their own land, amounts to 70 years; for Cyrus conquered Babylon towards the close of the year, B. C. 538, so that the year following, viz. 537, was the first year of his reign, and 536 the second, and the 7th from the fourth year of Jehoiakim. The date of the Babylonish captivity may be ascertained, says Playfair, (Chronol. p. 45.) by the following facts. Nebuchadnezzar became master of Tyre in the 34th year of his reign, the 26th of Jehoiakim's captivity, and 573 B. C. (57 B. C. Blair) as we learn from the Tyrian annals. (Josiph. cont. App. l. 5. 21.) Cyrus took Babylon in the 14th year of Hiram, and 56th after it had been taken by Nebuchadnezzar, i. e. in the end of the year 538 B. C. In this inference, therefore, the Tyrian records confirm the sacred chronology.

The captivity and restoration of the two tribes were foretold; and moreover the precise time of both events was also prefixed and determined by the prophet Jeremiah, ch. xxv. 11. xxvi. 10. This prophecy was first delivered (Jer. xxv. 1.) in the fourth year of Jehoiakim; and this same year Nebuchadnezzar began to put it in execution. If the
commencement of the 70 years' captivity be fixed at the time when Jerusalem was burnt and destroyed, their conclusion will fall about the time when Damascus, the son of Hadad, p. 187, in three different times, and in three different manners, and therefore possibly all might have been intended, tho' the first was without doubt the principal object of the prophecy. The prophets Isaiah (xli. 28.) and Ezekiel (xxvii. 10, &c.) have previously given very lively pictures of the happy days that should succeed the captivity, which were actually realized; for the people returning to their own country, enjoyed the blessings of liberty and influence. The people were multiplied, their cities were inhabited, and their fields were cultivated. Whilst the 12 tribes were dispersed and lost, those of Benjamin and Judah, or the Jews, were restored, not so much for their own sakes, as for the sake of the promises made unto the fathers, the promise to Judah that the Messiah should spring from his tribe, and the promise made to David that the Messiah should be born of his family. It was therefore necessary for the tribe of Judah, and the families of that tribe, to be kept distinct until the coming of the Messiah. But since these ends have been fully answered, the tribes of Judah and Benjamin are as much confounded as any of the rest; all distinction of families and genealogies is lost among them, and the Jews themselves acknowledge as much, when they say, that when the Messiah shall come, it will be part of his office to restore their families, and let the stranger be a stranger.

The captivity, considered as a dispensation of providence, will appear to have been highly necessary and proper, if we reflect, that the lenity of God was manifest in bringing this terrible overthrow on the Jews so gradually, after a succession of judgments from Lev 30, and have preserved the family for the space of 22 years, during which should have been a warning to them, and by experience have convinced them, that the threatenings denounced by the prophets would certainly be executed:—that it was a just punishment of their sins, particularly of their idolatry:—that it was the most effectual means to produce their reformation, the great end proposed by divine wisdom; and indeed it had this effect, in a very considerable degree, for they never more fell into idolatry, but retain the greatest abhorrence of it even to this day:—that they had so far neglected the law of God, written by Moses, as the rule of their conduct in all affairs civil and religious, and the ground of their happiness, that at one time it was almost unknown and lost among them (2 Kings, xxvii. 8, 12:—) and this dispensation was also calculated to produce beneficial effects among the nations, whither they were carried into captivity. The Jews, notwithstanding their depravity in their own country, during the captivity of 70 years, must have been a burning and shining light, all over the countries of the east.

Besides the captivities already enumerated, there happened another considerable captivity and dispersion of the Jews in the time of Ptolemy, the son of Lagus, usually called Soter, about the year B.C. 310, who invaded Judea, besieged and took Jerusalem, and carried away 100,000 of the inhabitants captives into Egypt, planting them in Alexandria and adjacent places. Ptolemy, though at first he treated Jerusalem and Judea with great severity, considering afterwards the foundations on which they had perished in the fidelity they had sworn to their governors, on this and a variety of other occasions, and convinced that this quality rendered them worthy of his confidence, chose 30,000 of the most distinguished among them and of such as were most capable of serving him, and appointed them to guard the most important places in his dominion. Many of the Jews followed their captive brethren of their own accord, partly by the favour of the king, who gave them equal privileges with those of Alexandria, and partly by the fertility of the country. To this colony, from which sprang the Hellenists, became very considerable. The last captivity of the Jews was that which happened in consequence of the destruction of their city and temple under Titus about 40 years after our Saviour's ascension. See JERUSALEM.

CAPTIVITY, princes of the, are heads or chiefs of the Jewish nation, appointed for the administration of justice among them, during their captivity both in the east and west, since the destruction of their temple by the Romans. The prince of the captivity in the east, is said to have had the government of the Jews who dwelt in Babylon, Chaldeæ, Assyria, and Persia. The prince of the captivity in the west, had the direction of those who lived in Judea, Egypt, Italy, and other parts of the Roman empire. The Jews make a great difference between the patriarchs of Judea, and the princes of the captivity at Babylon. The latter were called "rabbans," and were supposed to have descended from David, in a direct line by the males; the former or patriarchs, called "rabbins," only descended from David by the females. The patriarch, who reigned in Judæa, made Tiberias the place of his customary abode, and affixed the title of "Rabbinoth," i.e. the head of the fathers or patriarchs. He prefixed in assemblies, decided in cases of conscience, levied taxes for defraying the charges of his visits, and dispatched subordinate officers through the provinces to execute his orders. As to the princes of the captivity of Babylon, or the east, their origin and succession are unknown, as it appears that they sprung up till about the end of the second century. While the temple subsisted, the eastern Jews, as well as western, continued subject to the high priest. The first of these princes is said to have been Huna, at the close of the second century; and from Huna to the perfection of the talmud, i.e. 400 years, they scarcely produced three. Calmet. See ZECHMALOTARCHA.

CAPTURE, a prize, or prey; particularly that of a ship taken at sea. Captures made at sea were formerly held to be the property of the captors after a possession of twenty-four hours; but the modern authorities require, that before the property can be changed, the goods must have been brought into port, and have continued a night in port, in a place of safe custody, so that all hope of recovering them was lost. Blackst. Com. vol. ii. p. 401. See Prize and PRIVATEER.

CAPTURE also denotes an arrest, or seizure of a criminal, debtor, &c. at land.

CAPTURE, de Détenteurs. There existed under the old government of France an order, by which every interdict of a province or commissary of war was authorized to pay 100 livres to any person or persons, who should apprehend or secure a debtor, and 500 livres for every man, that
could be proved to have enlisted a soldier away from either the regular army or the militia.

CAPUA, in Ancient Geography, a city of Italy, the metropolis of Campania, derives its name, according to Strabo, from caput, head. It was situated at some distance to the north of Naples, near the mountains; and it was the chief and most important city of Magna Graecia. According to Pline, it was one of the three most celebrated cities known to the ancients, which placed it next to Rome and Carthage.

"Altera d'eft omnis Carthago, atque altera Roma,
Nunc profana jaect, propriorque fepulta fepulchro."

It is laid to have been founded by the Tyrrhenians, who had extended their power into Magna Graecia, about 48 years before the foundation of Rome, or 900 years before the Christian era. When the Sabine made themselves masters of the country, Capua fell into their hands, and Livy feeks the etymology of its name in that of their chief, called "Capys." The alluring fertility of the adjacent country, and a lucrative commerce, poured, at an early period, immense wealth upon its inhabitants, so that it became one of the most extensive and magnificent cities in the world. Riches produced excessive luxury and iniquities, in both which respects, Capua is particularly noticed by ancient writers. The luxury of Capua is laid even to have surpassed that of Sardis itself. See Athen. Diopritosiph. l. xii. p. 528. ed. Caubon. By its influence it exasperated neighbouring nations, which, on account of its eminence, was not able to repel; and therefore it was reduced to the necessity of endangering its own safety by engaging the succour of needy auxiliaries. The Roman soldiers who were sent to the defence of Capua, were on the point of making it their prey; and the voice of the Roman people often loudly expressed their wish for a removal from the barren unwholesome banks of the Tiber, to the garden of Italy, near those of the Volturno. Jealous, and not without reason, of the ambition of Rome, or naturally incontinent, as Livy and some other writers suggest, the Capuans warmly espoused the quarrel of Carthage; and Hannibal, after the battle of Cannae, made Capua his winter-quarters. In this scene of luxury and dissipation, if we may credit Livy and some other historians, the rough and invincible soldiery of the Carthaginian general were metamorphosed by pleasure and indolence into soft minions, never afterwards fit to cope with the Romans in the field. Hence, it became a proverb, "Capuam Hannibali Cannas fulce!" i. e. Capua was to Hannibal what Canea had been to the Romans. The judicious Monteffini observes, that the Carthaginian army, enriched by so many victories, would have found a Capua wherever they had gone. The pernicious effects of idleness and luxury are unquestionable; but the frequent defeats which Hannibal afterwards gave to the Romans, the several towns which he reduced in the sight of the Roman armies, and the bravery with which he maintained himself in Italy for 13 years, after the winter spent at Capua, conturn us to ascribe some degree of rhetorical exaggeration to the accounts of the Roman historians. Indeed, Livy himself points out a cause of the declension of the Carthaginian power in Italy, which is very different from the delights and debaucheries of Capua. Hannibal, disappointed of promised succour by a domestic faction, and deserted by the Gauls and Italians, who were not natural allies of the Carthaginians, was under the necessity of withdrawing from the scene of contcnt, and of yielding to a superior force, which drove him from Italy. Liv. l. xxiii. c. 13 and 32. l. xxvi. Whether Capua brought on the ruin of Hannibal or not, Hannibal, without doubt, occasioned the ruin of Capua. After the departure of the

CARTHAGINIANS, Capua, which had been long invested, surrendered at discretion to the consuls Appius Claudius, and Q. Fulvius Flaccus, in the year of Rome 542. On this occasion, 30 senators were decrated and put to death; the nobles imprisoned for, and the citizens, sold and dispersed. Vibius, Hannibal's principal friend, escaped this ignominious fate by a voluntary death; for which the mob insisted upon throwing open the gates to the enemy, he afforded his fixed associates, and fell down with them to a simple banquet; after which, each of the guests swallowed a profound draught, and expired in full possession of their freedom. Although the buildings were left undamaged, Capua was consigned to the lodging place for the inhabitants of the adjoining plain, a warehouse for goods, and a granary for corn. However, in process of time, about 172 years after this event, Cesar sent thither colonies, and restored it to its ancient privileges. Ciceron appears to have been the patron of this new city, and to have had it charge the inspection of the sea-coast from Formiae, A. U. C. 104, B. C. 50. In this command of Capua he calls himself the "episcopus" of the Carthaginian coast, and he also mentions when proconsul of Cilicia, the "dioeceses" that were annexed to his government, and hence it is inferred, that these names, which were afterwards applied to it, in the Christian church to characters and powers ecclesiastical, were carried with them in their original use, the notion of a civil authority and jurisdiction. See Dioce. As Capua had been always the common secondary, or place of educating gladiators for the great men of Rome, Cesar had a famous school of them, at the time when Cicero had the command of it. This school he had maintained under the best masters for the occasions of his publick fiews in the city; and as they were very numerous, and well furnished with arms, there was reason to apprehend they would break out, and make some attempt in favour of their master, which might have been of dangerous consequence in the then existing circumstances of the republic; and, therefore, Pompey thought it necessary to take them out of their school, and distribute them among the principal inhabitants of the place, affigning two to each master of a family, by which he secured them from doing any mischief. Cic. ad Attic. 7. 14.

Tiberius, A. D. 26, dedicated in this place a temple to Jupiter, and in the reign of Nero, A. D. 57, the colonies of Capua, and also of Nocera, which were almost extinct, were revived and strengthened by a number of old foldiers, sent thither with the same privileges as the ancient inhabitants. When the cities of Campania were divided between Vitellius and Vespasian, Capua maintained its attachment to the former, and in consequence of this preference, the third legion was quartered there for the winter, and the most illustrious families were treated with ignominy. At length, Generiue the Vandals, in the times of the Vandals, was more cruel than the Roman conquerors had been; for he massacred the inhabitants, and burnt the town to the ground. Narres rebuilt it; but in 841 it was totally destroyed by an army of Saracens, and the inhabitants were driven into the mountains. Some time after the retreat of these savage invaders, the Lombards descended again into the plain, but apprehending their force not to be sufficient for the defence of a circuit so extended as the old city, they built a smaller one on the river Volturno, chusing for its site that of Castrinum, which had distinguished itself in the second Punic war by the resistance of its garrison against Hannibal, and calling it by the old name of Capua. Since the foundation of the new city, old Capua, distant from it about two miles, has remained in ruins, occupying a considerable extent of ground. Of these, the most worthy of notice is the amphitheatre, which, though
CAP

in a degraded and defolate state, indicates its former grandeur. Two small villages now occupy part of the spacious inclosure of this city, which was the centre from whence the via Appia, via Latina, via Domitana, and others, branched off towards different provinces of Italy. Along the edges of these roads the ancients buried their dead in magnificent mausolea, some few of which are yet standing, and point out the direction of the highways. The "concechia," a vulgar name given to one of these monuments, from a supposed resemblance to a dilapid, is the hand-some, and 

C A P

famous and noble, with columns placed upon a square tower.

In 854, Landulph formed at Capua an independent earldom, dismembered from the duchy of Benevento; and in the course of a few generations, it acquired the title of a principality. In the 11th century, the Normans of Apulia expelled the Lombard race of princes, and Richard their chief became prince of Capua. The grandsons of Tancred of Antequera drove out the descendants of Richard, and united this state to the rest of his possessions.

Capua is at present a neat little city of Naples, in the country of Lavora, frated at the foot of a mountain. the seat of an archbishop, founded in 968. It contains, beside the cathedral, one collegiate, 16 parish churches, and 12 convents. It may be considered as the key of the kingdom: for though far removed from the frontier, it is the only fortification that really covers the approach to Naples, from which it is distant about 15 miles. The streets are more open and airy than those of other towns in this kingdom, and the buildings better. Many of them are constructed with materials brought from the ancient city. N. lat. 41° 7'. E. long. 15° 3'.

CAPUCHIN. See Cow, and next article.

CAPUCHUNS, religious of the order of St. Francis, in its strictest observance. The Capuchins are thus called, from capuce, or capucun, a stuff cap, or cowl, wherewith they cover their heads; and which they added to the ordinary Franciscan habit. They are clothed with brown or grey; are always bare-footed; and never go in a coach, nor ever shave the head.

The Capuchins are a reform made from the order of Minorit, commonly called Cordeliers, sat on foot in the sixteenth century by Matthew de Bassi, a religious observant of the monastery of Montefiascone, who, being at Rome, said he was advertized several times from heaven, to procure the rule of St. Francis to the letter. Upon this he made application to pope Clement in 1525, who gave him permission to retire into a solitude; together with as many others as would embrace the strict observance; which some did accordingly. In 1528, they obtained the pope's bull. In 1530, the order was brought into complete form; Matthew was elected general, and the chapter made constitutions. In 1543, the right of preaching was taken from the Capuchins by the pope; but in 1545, it was restored to them again with honour. In 1578, there were seventeen general chapters in the order of Capuchins.

The Capuchins were at first restrained from spreading out of Italy; but Charles IX. of France, writing to pope Gregory XIII. to demand some Capuchins, that pope, by a bull, dated in 1575, took off the prohibition, and granted them leave to settle any where. The cardinal of Lorraine, built them a convent at Moudon, and Henry III. another at Paris, in the rue St. Honoré. F. Zach. de Boverio has written the annals of the Capuchins in Latin, in three volumes folio, from the year 1524 to 1634.

CAPUCHIN, in Zoology, the name of a particular species of pigeon, in shape and make much like the jacobine, or jack, but somewhat larger than that; its beak also is longer; and it has a tolerable hood of feathers on the back part of its head, but has no crest or crown down the shoulders as that species has. Its marks are the same with the jacobine, and it seems to be no other than a bastard breed between that and a common pigeon.

CAPUCIN MONKEY, in Zoology. See CAPUCINA SIMIA.

CAPUCIN POWDER, in the Materia Medica. See CEVILLA, SABIDILLA, and VERATRU.

CAPUCIATTI, in Entomology, a species of PHALARA, (Bombix), that inhabits Europe. The wings are dentated and serrate, with a dorsal reflected tuft.

CAPUCINA, in Zoology, a species of SIMIA, of the long-tailed, or sapunj tribe, called by Pennant the Capucin monkey. This kind is distinguished by having no beard, the tail hirsute, (and prehensile); hair and limbs black; haunches covered, or without calloritis. Simia imberbis nigra, cauda longa hirsuta, facie fuscata. Lin. There are three kinds of monkey, simia trepida, appella, and capucina, that are nearly allied to each other; some consider the two last as varieties of the same species; Schreber makes them distinct.

Gmelin describes this animal as being about the size of the domestic cat: the general colour brown, with the head, legs, and tail black; face sometimes black, sometimes flesh-coloured; tufts approximate; nose carinata near the eyes; a black retracile wrinkle just under the hair of the forehead; tail long, curved, and shaggy, with hair, which it carries spirally rolled up, and often coiled round the neck. In the Levanian Museum is a specimen of this animal agreeing with the description given of the species by Mr. Pennant and Dr. Shaw. The face is round, flat, and flesh-coloured; encircled with upright whitish hairs; the breast covered with long hairy yellowish white hairs; top of the head blackish; hair on the shoulders and upper part of the back lighter than on the lower part; tail as in the former species; toes with crooked claws instead of flat nails.

Simia capucina is said to be a native of South America. The animal smells musky, has a wailing voice, sometimes shrieks like the cica, or when irritated yelps like a whelp, and terrifies or repels its enemies by hideous howlings.

CAPUCINUS, in Conchology, the name by which Rumphius distinguishes conus monacha of Limnae.

CAPUCINUS, in Entomology, a species of BOSTRICHUS in the Fabrician family, (Derm denes, Linn. and Boffichius, Geogr.). The colour of this insect is black, with red abdomen and wing-cases; and retuse thorax. Inhabitants Europe.

Obi. Lepechin describes a variety of this insect with a black abdomen. This is found in Siberia.

CAPUCUSUS, the name given by Walsh to the Limnan butterfly, Papilio PHEICL. which fee.

CAPUL, in Geography. See CAPUL.

CAPURA, in Botany, Linn. Mant. 255. Schreb. 599. Wild. 68; Jaff. 176. Leaves and flowers of the genus... Cor. Cal. mon. Cor. monopetalous, tubular; tube cylindrical; border with five roundish divisions, the outer alternate ones narrower. Stam. Filaments scarcely any; anthers fix, oblong, within the tube; the alternate ones higher. Fig. Germ superior, triangularly roundish, truncate; style cylindrical, very short; stigma nearly globular. Peric. Berry
**CAP**

La Maree thinks it has some affinity to the genus Dais. Eff. Ch. *Calyx; Bres.,* or *Bavor;* within the tube. *Stigma* nearly globular.

Sp. *C. purpurea;* a tree. Branches alternately in pairs at right angles with each other, purplish. Leaves deciduous, opposite, egg shaped, resembling thistle of biennia xylochilum, entire, rather acute, or very short petioles. Flowers in axillary clusters, purple, shorter than the leaves.

A native of the East Indies.

CAPURSO, in Geography, a town of Naples, in the county of Bari; 2 3/4 miles S.E. of Bari.

CAPUT. See Head.

CAPUT, in the University of Cambridge. See Cambridge.

CAPUT Bavarice, the head of the barony, in Ancient Customs, denotes the ancient or chief seat or castle of a nobleman, where he made his usual residence, and held court: sometimes also called *caput boronei,* or the head of the honour.

The caput baronice could not be settled in dower; nor could it be divided among the daughters in case there were no sons to inherit; but was to descend entire to the eldest daughter, *ceteris filiabus absque justitia.*

CAPUT Celci, in Anatomy, the commencement of the large intestine, which is also called the ceacum. See Intestine.

CAPUT Draconis, a denomination given by some to a fixed star of the first magnitude, in the head of the constellation Draco, called also by the Arabs *rofhab and elumab.* See Node.

CAPUT Gallinoginis, or Verumontanum, in Anatomy, a small projection of the profile or cone, projecting into the lower part of the urethra, where that canal penetrates the profile, and having on its surface the openings of the ducts, formed by the union of the vasa deferentia, and vesiculae seminales. See Generation, Organs of.

CAPUT Jjumii, a name given to Ah-Wednesday, as being the first day of the Lent-fall.

CAPUT Lupinum. An outlawed slave was anciently said to have *caput lupinum,* and might be knocked on the head like a wolf, because, having renounced all law, he was to be dealt with as in a state of nature, when every one that should find him might flay him; but now the wilful killing of such a one is murder, unless in the endeavour to apprehend him.

CAPUT Medusa, in Astronomy, a northern constellation included in that of Perseus.

CAPUT Medusa, in Botany, Morif. Hist. iii. p. 316. See Elymus Caput medusa. See also Euphorbia Caput medusa.

CAPUT Mortuum.— *Tete morte,* Fr. Todkenalge, Germ. This term is at present obsolete. It was used by the old chemists to express the refudia of distillation after all the volatile parts had been driven off by the action of heat. Those refudia were at first thrown away as of no value. Glauher was the first who particularly employed himself in their examination, and was rewarded for his pains by the discovery of the salt that bears his name, (fulphat of foda), in the caput mortuum remaining after the distillation of mutric acid from common salt and green vitriol; and of fulphat of potash in the refidue after the distillation of nitric acid from nitre and fulphat of iron.

CAPUT Pancreatis, in Anatomy, that portion of the pancreas, which is attached to the duodenum. See Pancreas.

**CAP**

CAPUT Purpurium, surname head, a denomination given by the Romans to an order of battle more frequently called century.

CAPUT Purga, a barbarous term used by some physicians to denote medicines which cleanse the head, either in the way of exciting, more frequently called cardinals; or by chewing in the way of salivaition, called *opophagismatus.* See Ehrina and Stomata.

CAPUT Sertorii, in Anatomy, a species of *Amsoria,* the shell of which is oblong, flattened, and divided by one with a long perforated hook. Lion. Pm. Since.

Inhabits the seas of the Norway fenn, and is generally found adhering to the madrepora porifera. Shell white, longitudinally flattened. Upper valve prominent behind, declining at the anterior part, and marked with a groove in the middle; lower valve rounded, and retuse before.

CAPUTA, in Ancient Geography, a town of Armenia Minor. Ptolomy.

CAPUTIATI, or CAPUICATI, in Ecclesiastical History, a sect of fanatics, so called from a singular kind of cap that was the badge of their faction, which infolated the province of Burgundy, the diocese of Auxerre, and several other parts of France, towards the close of the 12th century, and excited much disturbance among the people. They wore upon their caps a leaden image of the Virgin Mary, and they publicly declared that it was their purpose to level all distinctions, to abrogate magistracy, to remove all subordination among mankind, and to reform that primitive liberty and natural equality that were the inestimable privileges of the first mortals. They were attacked with the force of arms by Hugo, bishop of Auxerre. Moths. Ecc. Hist. vol. iii. p. 128.

CAPUTUADE, in Geography, a port of Africa, in Byzacium, where the Roman fleet landed the troops that made war against Gellier; distant, according to Photinius, five days' journey from Cartaghe. Justinian, he adds, built a town in this place inclosed by strong walls.

CAPYAE, in Ancient Geography, a town of the Peloponnesus, in Arcadia, near Mantinea, according to Dion. Hal. and Strabo, who supposed it to have been built by Amasis.

CAPYBARA, or CAEBBARA, in Zoology, the American name of a species of Cavia, found in that part of the world, and called by English writers the *water cavy,* or *river cavy.* It is distinguished by having no tail, and the fore-feet threecornered, and palmated. See Cavia.

CAPVS, in Entomology, a species of *Sphinx,* (Zygaena) of a black colour, with the tip of the anterior pair white. Fabr.—Inhabits Surinam.

CAPPTIUM, in Ancient Geography, a town of Sicily. Ptolomy.

CAR. See Carr.

CAR, or KAR, signifies in the oriental languages a town; and of course enters into the composition of the names of several places.

CAR, or CAM LOUGH, in Geography, a small lake in the county of Armagh, Ireland, at the foot of Slieve Gullion mountain, from which a narrow and rapid stream flows for a course of about four miles, when its waters contribute to the supply of Newry canal. This lake, river, and a small village, all of the same name, are mentioned on account of the great business done on the banks of the stream. So elevated is the source of it, that there are a great number of feet of mills, all of which are overfour. So sudden, indeed, are the falls, that no head of water is required as a millpond for any of the works, the tail-race of the higher mill being the head of the next below, and so in succession until
it reaches the valley. In the space of within two miles, there are four extensive bleach-greens, three of which can finish 50,000 webs in a year; one very large boiling-mill, beside two other flour-mills; a flax-mill, and some other manufactories about to be established. These numerous works furnish an eminent instance of the superior spirit and industry of the people in this part of Ireland, who so eagerly seize every natural advantage for forwarding and increasing their trade. Cooke's Armagh.

CARA, in Botany, France, Gert. tab. 25. fig. 8. See DISCOCHEA australis.

Carabine, in Geography, a river of European Russia, which directs its course towards the Arctic Ocean, and forms the boundary between Asia and Europe, for the space of about 140 miles; the Carabian chain terminating so far from the sea of Cara-bol, or Kara-bol.

CARABA, or Carabie, in Botany, attains in Guiana the height of 40 feet, and consists of numerous branches, covered with long, narrow leaves of a green colour. Its numerous white blossoms are succeeded by nuts about the size of a large chestnut, the form of which is angular and flat; within the thin, brown, hropy shell is contained a white oleaginous kernel. From these kernels the Indians extract, by bruising, macerating, and boiling, a yellowish, bitter, butyric acid oil, with which they constantly grease and rub their naked skins; thus defending themselves from mosquitoes, softening their skins, and preserving them from taking cold by dews, rain, &c. Bancroft's Guiana, p. 81.

CARABAYA, or Carabaya, in Geography, a district or jurisdiction of South America, in the diocese of Cuzco, and vice-royalty of Buenos Ayres, commencing on leagues S.E. of Cuzco, and extending above 50 leagues. The greater part of it is cold; but the valleys are fertile, producing various sorts of fruits, grain, and pulse, and affording sufficient pasture for cattle of all kinds. This province has several gold mines, particularly that called Aporana, which is very rich and the metal 25 carats fine, and also silver mines, which produce vast quantities of that metal. The river which separates this province from the mountains of the wild Indians abounds so much in gold, that at certain times the Caziques send out a certain number of Indians in companies from the towns in their respective districts, to the banks of the river, where, by washing the sand in small wells dug for that purpose, they soon find sufficient quantity of gold to pay the royal tribute. This kind of service they call Chicama.

CARABE, or Karabe, denotes yellow amber.

CARABIA, in Ancient Geography, a town of Macedonia, placed by Ptolemay in Moongia.

CARABIN, or Carbine, in French Canon carabies, is a fire-arm about a tenth of an inch smaller in the bore than a musket, and about five inches shorter, having its barrel about three feet one inch long, and its whole length, including the fock, about four feet one inch. Carabines, or canons carabies, have the outside of their canons or barrels of the same figure and form with those of common muskets. But they are generally, or at least often riddled on the table, having longitudinal grooves sometimes straight, but much oftener circular or spiral, running the whole length of the bore. When grooved, they are generally fired with leaden bullets, that are rammed down along the grooves with iron rammers or ram-rods, which running, together with the force and velocity with which they are driven back along the same grooves by the inflamed powder, considerably alters their shape and figure. The common observation, however, that a ball so rammed down and fired from such a piece goes further than one of the metal that has windings, in consequence of its being long enough in the barrel for the complete inflammation of the charge of powder, is founded in mistake. The grooves, when they are made winding, give the ball a sort of rotatory motion round its axis in the direction of its flight, that prevents its deflection from the path of its projection.

CARABINEER, or Carabinier, in French Carabier, was a soldier chosen from among the bell and bell-expect shooters, who served sometimes on foot, but generally on horseback, and carried a carabine larger than the ordinary fuses, and commonly riddled. But, in the French service, the distinction itself is greater than the carabines. They immortalized themselves at the battle of Fontenay. Any deficiencies in it, either in men or officers, were filled up by the regiments of French cavalry, according to their seniority. As to the time of rating it, or its seniority of creation, it would have been the twelfth regiment in that service; but in consequence of some other regiments having the name of Royal, and therefore standing before them, it only occupied the twenty-second rank or place.

Formerly, all regiments of light armed horse were called carabines. But, since the establishment of hussars and chasseurs, they have lost that appellation. And now all the heavy foreign cavalry are denominated carabiniers.

CARABINS, otherwise called Argulity, were a species of hussars in the ancient French militia, and sometimes acted on foot. There were choien and resolute men. All the principal officers of the army used to have them as their guards. And they were often stationed at the outposts for the purpose of harassing the enemy, guarding narrow passes, &c. In action they generally engaged in front of the dragoons, or on the wings of the line. The term comes from the Arabian word Karib, which signifies generally a warlike instrument of any kind.

CARABUS, in Entomology, a genus of Coleopterous insects that have the antennae filiform; thorax somewhat heart-shaped, truncated behind, and with the wing-cases margined.—This is the essential character of the genus Carabus, but which is distinguished further by having fix feelers, each of which has the joint oblique, and truncated: the abdomen ovate; and the posterior thighs furnished with an appendage at the base. The mouth is also small, the lip, in some entire and truncated as in the true Fabrician carabi: dentated as in his fcarabaeus, or trifid, as in his mammora, all which belong to the Linnaean carabi, except a few of the Scarites that are Tenebrose of that author. The legs of the carabi are also long, the thighs compressed, shanks round and ciliated within, the anterior part sparse, and the tars of all the legs composed of five joints.

Olivier divides the Linnaean Carabii into a variety of new genera, as echinus, callophoe, galala, brachinus, anthiap, manicore, saraite, lefteve, and odacanth. An arrangement somewhat similar to this appears in the different systems.
CA R A B U S.

The proposition of Fabricius, but not the same, and further alterations will have been adopted by other French authors besides Olivier. We think the carabi may, notwithstanding, be extremely well distinguished by adhering much nearer to the example of Linnaeus; the mantiocers and scarites we should ourselves separate as distinct genera from the carabids, but it is impossible to conceive the necessity of rendering the Linnaean genus into so many parts as Oliver has to form so many new genera—improvement, and not innovation, should be the leading object of naturalists when they prefix to devote from the authority of their predecessors. That the Linnaean carabi, even if we abide by the Linnaean method, should be separated into distinct tribes, is sufficiently apparent to every entomologist; we only mean to maintain that by thus dividing them into tribes, they may with few exceptions be retained under one general title with more convenience, and more propriety, than under each a number of different genera as the French writers are inclined to make of them. Fabricius even feems aware of this, for although he forms new genera of part of the Linnaean carabi, his own genus carabus is divided into four distinct sections:—I. Thorace cunato. — II. Thorace politæ angustato. — III. Thorace rotundato-marginato proniato obtuso. Mr. Marsham, in his recently published work, Entomologia Britannica, has also shown that it is far better to subdivide the Linnaean carabi into sections than to constitute new genera; the species of carabus found in England, which are those that chiefly demanded his attention, he divides into six sections, in the following manner. 1. Thorace politæ augusto.—2. Thorace politæ truncato integro, elytris equali.—3. Thorace politæ truncato integro, elytris angulitori.—4. Thorace politæ truncato integro elytris anguli for, sub-dulcato, attenuato.—5. Thorace politæ rotundato.—6. Thorace remoto. Gmelin divides the carabus genus into only two parts, distinguishing the insects according to their size, majorites and minorites, in the last edition of the Linnaean Systema Naturae. Turton, in his translation of that work, entirely deviates from his author; he adopts the Fabrician subdivisions, and this is certainly an improvement, but it should have been mentioned as such. The following arrangement of the numerous species of this genus will be found to correspond as nearly with the Linnaean and Fabrician authorities as the latest observations and discoveries of authors will conveniently admit.

Many of the insects of this genus possess the same habits of life. They live in the earth, under rocks, or in decayed wood, and are for the most part unknown. In the larv or perfect state a number of the species are definite of wings, but they are remarkably active, and run swiftly. Some kinds avoiding the light appear only in the night time, while others range about in the middle of the day, and seem to be most vigorous when the sun shines intensely hot, at which time numbers of them may be seen running in pathways, and shady places. If these insects are closely pursued, they emit a strong, and highly fetid odour, and when caught immediately eject both from the mouth and vent, a dusky greenish, or in some species, a reddish liquor of an extremely acrid and caustic nature, the smell of which is similar, but rather more powerful than the odour it sends forth when pursed. This offensive humour seems to be a provision of nature designed to compensate for having denied these creatures wings to facilitate their retreat from other voracious insects that are furnished with wings, the smell being alone sufficiently repulsive, it is reported, in many species, to check their ferocious pursuers till they can retire to some place of safety. They can also, as we may know by experience when handling them, defend themselves extremely well by means of their jaws with which they can pinch forcibly, and no doubt inflict a severe wound on the generality of insects; one or two species of the winged kind of carabi, if not more, are able to terrify their antagonists by making a loud, and frequently repeated snapping noise, which has been compared to the explosion of a musket in miniature. The faculty is more completely exhibited in the little species which the French call Bombardier, Carabus cephalus of Linn. Fam. Succ., and of later entomologists. It has been ascribed by some lively writers, that "the insect poisons the extraordinary faculty of discharging from behind, on being purfed or irritated, a bluish, fetid, and penetrating vapour, accompanied by a very smart explosion." "And this operation (it is added) the insect has the power of repeating ten, twelve, or even twenty times in succession with equal violence, thus frequently sleeping by terrifying its pursuers." (Shaw, Zool.) Another historian of this prodigious musketeer infils that "the smoke emitted at the time of each explosion is so dense as to completely conceal the insect for the space of a few moments from its purfurers, during which interval the warlike creature, like an able warrior, may, and does frequently effect its retreat in good order under cover of the smoke occasioned by its own fire." The record of this last account excites a smile; we with that much of the last mentioned circumstances may not prove a geffy tale for the credit of those who have attested to it. This insect, it really appears on credible authority, is able to make a loud noise, either by means of the vent, or by rubbing its wing-cases violently together, and to repeat the noise at pleasure, or as its dangers may require; what has been further stated must be at least received with caution by those disposed even to listen attentively to reports so marvellous.

The ancients considered the carabi as poisoomous, and supposed that if their cattle happened to devour any of them, which might often happen when they were grazing, an inflammation of the intestines would ensue. The carabi formed also an article in their materia medica; both Hippocrates and Pliny speak of them, and attribute to them the fame properties as the cantharides.

The species of this genus are as follows.

Section III. Thorace heart-shaped.

CARABUS MAXILLÆS, of Linnaeus, is one of the largest species in this genus. It inhabits the Cape of Good Hope. Olivier describes the species from a specimen in the Bankian cabinet. This insect is aperous; black; mandibles expanded, and as long as the head; thorax produced behind, and bilobate. Obs. The antennae are black with the tips fuscous; head expanded, flat in front, with the shield rounded and entire; mandibles acute, or pointed at the tips and entire; shells glabrous, black, and very slightly dotted. Fabr. This must not be confounded with manticora maxillæna of Fabricius, which De Geer calls a carabus (C. tuberculatus).

CARABUS THORACICUS. Aperous, or without wings, black; thorax lengthened behind into two lobes; sides and margins of the shells villosus, white. Fabr. Thumb. Obs. This is much allied to the preceding insect, and inhabits the same country.

CARABUS CORIÆCUS, one of the Linnaean species. This is of the aperous or wingless kind; its colour black and opaque; shells connected with intricate subangular dots. Linn. An inhabitant of Europe, and called by Geoffroy Buprestis ater.

CARABUS GLABRATUS; aperous, entirely black, very smooth,
and glossy. Fabr. Obs. This is the Carabus glaberatus of Paykull, and Carabus cornescus of Herbst. Inhabits Germany and Sweden.

Carabus violaceus, of Linn. and Paykull, is a species nearly allied to the former. It is apterous, of a black colour, with smooth shells, the edges of which, and the margin of the thorax are violet.

Carabus purpurascens, is of the apterous kind, and a black colour, with striated shells; margins of the thorax and shells violet. Inhabits Germany. Fabr.

Carabus auratus, Carabus cornescus of Linnæus. This is apterous, of a black colour, with wing-cases and rough intricate dots. Paykull, Monogr. This is called by Geoffroy Buprestis micro-violacea. Inhabits woods in Europe. Mr. Marlham describes the Linnæan-carabus intricatus as an English species. Vide Ent. Brit.

Carabus calcaratus, of Scopoli. Carabus problematicus of Herbst. This insect bears a strong resemblance to C. purpurascens, but has the body flattened, and is in other respects distinct. It is of the apterous kind; colour black; thorax and wing-cases edged with azure; shells striated, and marked with a triple row of impressed dots.

Carabus carabus. Apterous; black; thorax and shells very smooth, and brassy-green. Inhabits South Carolina.

Described by Fabr. from the cabinet of Cayot d'Orce of France. It is of a large size with the head black, and brassy behind; thorax brassy, and with an impressed dorsal line; shells without spots; body and legs black. Fabr.

Carabus bipunctus. Apterous, black, thorax and wing-cases with smooth, with three streaks of oblong elevated dots. Size of the following species.

Carabus gemmatus. Apterous, black, shells striated with a triple series of double, or two lobed brassy dots. Fabr.

Carabus frigatus of De Geer. An European species.

Carabus concolor. Apterous, black, wing-cases striated, with a triple series of excavated dots. Fabr. This inhabits Germany. Size smaller than carabus bor
tenfis. The head is black, glossed with copper, and inma
culate; thorax black, thinly tinged with azure; excavated dots of the same colour as the shells, not brassy as in bor
tenfis, and the body black.

Carabus tenebrifis. A North American species of the apterous kind, and black colour; shells somewhat smooth, fuscous, with a triple series of excavated dots. Found in decayed beech trees in Europe, Helwig.

This resembles carabus bor
tenfis; the antennae are black with the first joint ferruginous; its head coppery, and mouth black; shells irregularly punctured; and body black.

Carabus arvenfis. Apterous, black, and coppery; shells striated with a triple series of hollow dots. Paykull, Monogr. Inhabits Europe, principally Germany. Probably the same as Carabus cornescus, Marsh. Ent. Brit.

Carabus brunneus. Apterous, black; shells very smooth, and punctured with a triple row of black dots. Inhabits Hungary, Smith. Obs. The body is entirely black, and the margins are not brimih, as in some analogous insects.

Carabus rufifis. An insect the size of C. bor
tenfis, found on the shores of Patagonia, and preferred in the Bank
fian cabinet. This is apterous; shells striated, greenish, with a triple series of brassy hollow dots, and retuse at the base. Fabr. Obs. The antennae of this insect are brown, but at the base black; the head greenish, with black mouth; thorax green, and impressed on each side at the base; shells with created frise; body black.

Carabus Madeira. Apterous, black, with the shells re
tuse at the base. Described by Fabricius from a specimen in the Bankfian cabinet found at Madeira. Much allied to the preceding; the antennae black with fuscous apex; shells slightly striated, and marked with a triple series of minute greenish impressed dots: legs black.

Carabus convescens. Apterous, convex, black, smooth, with the posterior part of the thorax emarginate. Paykull. A native of Germany.

Carabus auratus. Apterous; shells golden and furrowed; antennae and legs fuscous. Linn. Inhabits Europe.

Carabus splendidus. Apterous; above bronzed, and glossy, future of the shells coppery. Found in Jamaica. Bof. Obs. This is a large species. The head is marked with two furro-s, and brassy, its mouth and antennae black; shells very smooth; body black. Carabus splendidus of Gmelin.

Carabus naturalis. An insect resembling the foregoing, but inhabit the Terra del Fuego, decribed by Fabricius from a specimen in the Bankfian cabinet. This is of the apterous kind; shells striated, and greenish with golden future.

The antennae of this species are dark brown, ferruginous at the base; head green, mouth fuscous; thorax green, golden margin; shells slightly striated with a triple series of ferruginous dots; break greenish; legs ferruginous.

Carabus nitens. Apterous; shells rough, greenish, with longitudinal raised lines, golden margin, and black legs. Linn. Carabus aureus of Degeer.

Carabus aurontins. Nearly allied to the former; it is of the apterous kind, with rough greenish shells marked with three longitudinal raised lines, and fuscous thighs. Inhabits Germany.

Carabus mortiklifis. Apterous; thorax coppery; shells striated, coppery, with longitudinal elevated dots, and rugged furrors. Fabr.

Carabus rugosus. Apterous, black; shells with rugose frrors, and three rows of elevated dots between them. Described by Fabricius from the cabinet of Sehelledt as a native of Morocco; it is twice the size of carabus granulatus.

Carabus elatus. Apterous, blackish-brassy, with rows of coppery excavated dots between the frise. Linn. Inhabits Europe.

Carabus granulatus. Apterous, blackish; shells brassy, with rows of oblong raised dotted between the frise. Linn. &c. Inhabits Europe.

Carabus refraus. Apterous; shells smooth, and black, and wider than the thorax; head very narrow.

This is an European species, and has been described by authors under various names; Degeer calls it carabus coadu
maturus.
natus, Linnaeus tenebris rostratus, and Paykull as well as Fabricius carabus rostratus, and by Fabricius in his appendix cyclus rostratus.

Carabus attenuatus. Apterous, black, shells slightly glazed with coppery, with a triple series of elevated dots; thorax narrower; head very narrow. Panzer, &c. This inhabits Europe, particularly Germany; in the full work of Fabricius it flutters in the new genus cyclus under the specific name of attenuatus.

Carabus eleminatus. Apterous; thorax with reflected margin; shells violaceous; body black. Fabricius. This and the following species inhabit South America, and are described from the Hunterian museum.

Carabus unicolor. Apterous; thorax with reflected margin; body black, and shells flat-topped. Carabus attilivinus. Apterous, black; thorax somewhat heart-shaped, and narrow; head attenuated behind; shells grooved and furrowed. Fabr. An Indian species, in the Bankian cabinet.

Carabus luciphthalmus. Apterous, black; shell-friated; thorax with short impressed lines at the base. Linn. Inhabits Europe, and is found in England.

Carabus plumos. Winged, depressed, black, with slightly frilated wing-cases. Fabr. Ent. Syll. Carabus pinguis of Paykull, and carabus elphius of Faun. Ent. Obs. Mr. Marsham in his Ent. Brit. considers this insect the same as the foregoing; namely, carabus luciphthalmus of Linn. Fabricius tells us it is rather larger, and has the body entirely black, and without spots; thorax heart-shaped, smooth, and without the little impressed lines at the base as in the former insect.

Carabus fritialis. Winged; black; thorax at the base with an impressed dot; wing-cases frilated, and glabrous in the middle. Described by Fabricius from the Bankian cabinet. Inhabits the shores of Patagonia.

Carabus falsulapis. Winged, pale; head, and dorsal spot on the body black. Fabr. A native of Saxony.

Carabus arenarius. Winged, pale; with two black dorsal spots on the wing-cases. Inhabitants sandy shores of Wales. Described from the Bankian cabinet. Fabr.

Carabus lateralis. Winged, black; thorax and shells marginated with ferruginous. An European species, and inhabits woods. Daldorf.

Carabus picicornis. An Italian species of the winged kind, with the head, antennae, and legs rufous. Muf. Allioni.

Carabus flavicornis. Winged, black; margin of the thorax, with the antennae, and legs yellowish. Paykull. Inhabitats Saxony. Hybner.

Carabus fulvescens. Winged, black; thorax canaliculated; shells frilated and smooth; antennae and legs smooth. Inhabits the woods in Germany. Smidt.

Carabus fuscus. Winged; thorax grooved with two stripes on each side; antennae and thanks of the legs piceous, or pitchy. Linn. and Schaeffer. Found in European woods.

Carabus femoralis. Head and thorax brassy; wing-cases dull, and frilated; thighs rufous. Inhabitats Sierra Leon. Bankian cabinet.

Carabus terricola. Winged, black, and glossy; wing-cases with smooth flax; extremity of the antennae, and the legs rufous. Paykull, Monogr. Inhabitats Germany, and is found under stones. Fabr.

Carabus maculatus. Winged; thorax with an impressed black dot on each side at the base; thighs rufous. Paykull. Inhabitats England.

Carabus americanus. Winged, black; thorax, antennae, and legs ferruginous. A native of America.

Carabus jammi. Winged; thorax ferruginous; wing-cases azure. Fabr. Carabus bicolor of Olivier. Inhabitats Carolina. Obs. The antennae are yellow, black, with the first joint rufous; head advanced, cylindrical, and brown; body black, with ferruginous feet.

Carabus somani. Winged, entirely ferruginous, except the wing-cases, which are blue-black. Inhabitants America.

Carabus crepitans. Winged; head, thorax, and legs ferruginous; wing-cases black. Linn. Le boutpare a fete, coree et petits rouges et tete bleus. Geoff. This is the best-furnished of French writers mentioned in the introduction, which is said to profess the faculty of terrifying its enemies by repeated loud explosions and fetid vapours emitted from the vent, whence its name crepitans. "Terrefactus creptus in hollem pellere tentat." This singular species inhabits Europe. Mr. Marsham describes it as a native of this country. Ent. Brit. Fabricius speaks of a variety of this species about half the size, that occurs in Germany.

Carabus feloleta. Ferruginous; wing-cases azure; with the future at the base ferruginous. Fabr. Found abundant in France under stones. It is much smaller than C. crepitans; there is a rare variety of it in which the future is the same colour as the wing-cases.

Carabus amoeboides. Winged, bluish-black with frilated wing-cases, and a rufous spot on the posterior part. Fabr.

An inhabitant of the South American islands, and allied in appearance to the former. The head is brassy-green, and glossy. Antennae black, with the first joint rufous. Thorax heart-shaped, punctured, brassy-green with a small impressed line on each side at the base.

Carabus humberalis. Winged, black with frilated wing-cases; spot at the base, and the legs rufous. Inhabitants Italy. Allioni.

Carabus tribulus. Winged, brassy-green; wing-cases with two white spots; antennae and legs yellow. A native of Guinea. Iferc.

Carabus oblongipunctatus. Winged, black, with frilated wing-cases, and numerous impressed dorsal spots. Inhabitants Germany.

Carabus varicolor. Thorax somewhat cordate or heart-shaped; black; shells azure; base of the abdomen and legs rufous. Fabr. Inhabitants Austria.

Carabus assilirius. Ferruginous; shells frilated, and black, with a pale spot at the base. Inhabitants Austria. Fabr.

Carabus cinclus. Winged, fuscous; head and thorax brassy-green; margins of the wing-cases, and legs pale. Inhabitants Coromandel. Bankian cabinet.

Carabus nitidulus. Winged, black; margin of the wing-cases shining-brassy. Inhabitats Kamtschatka. Bankian cabinet. Obs. The head and thorax black, glazed with coppery; wing-cases frilated, the frax punctured alternately. Legs black.
CARABUS.

CARABUS Diom. Winged, black; wing-cases frilled; bimacule at the base, and the legs ferrugineous. Inhabits Saxony, Hymer, &c.

This is of the middle size; head smooth, black; antennæ ferrugineous. Thorax heart-shaped, and grooved; body black; legs ferrugineous.

CARABUS agilis. Winged, russet; wing-cases and abdomen black. Paykull. Inhabits Sweden. The crown of the head is black, and the wing-cases truncated.

CARABUS fusculus. Winged; thorax ferrugineous; wing-cases truncate, frilled, greenish; head flat, and black. Fabr.

Described as a native of South America from a specimen in the cabinet of Dr. Hunter. It is of the middle size; antennæ black, with fuscous tips; thorax elongated, heart-shaped, and slaty grooved; wing-cases shining; abdomen black with ferruginous vent; legs black, thighs russet at the base.

CARABUS aleus. Winged; thorax russet; wing-cases fuscous with three fuscous spots. Inhabits Italy. Bosc.

This is very much resembles a cincticeps. The body is of the middle size; elongated, and more depressed than usual in the carabus genus. The antennæ are ferrugineous, with the third joint longer, incurved, and thick at the end; head black and glossy, mouth ferrugineous; shells slightly frilled; legs fuscous.

CARABUS atricapsillus. Winged; thorax fuscous; wing-cases telfaceous, and obtuse; head black. Linn. Inhabits Europe. Considered by Fabricius and others as a variety only of Paykull’s carabus agilis. It varies frequently in having the margins of the shells black. This insect is found in England.

CARABUS 4-pustulatus. Winged; yellow, with fuscous wing-cases, each marked with two yellow spots. Fabr.

Inhabits Africa. Described from the Bankian cabinet. This is an insect of small size; its antennæ are fuscous; thorax heart-shaped, yellow with an impressed dorsal line; wing-cases slightly frilled and truncated.

CARABUS oblongus. Winged; black; thorax oblong; wing-cases frilled, fuscous, with yellow antennæ and legs. A native of Germany. Smidt. Off. This is a small insect, with a black shining head, and yellow feelers; thorax grooved, black, and shining; flirts on the wing-cases crenated; abdomen pitchy.

CARABUS rubens. Winged; thorax ferrugineous; wing-cases rounded, telfaceous, with the head fuscous. Inhabits Germany. Fabr. This very much resembles carabus atricapillus; the shells are frilled, and without spots; the head fuscous.

CARABUS Iogetatus. Apterous, black; shells with nine furrows, and ten white dots. Linn. Inhabits Africa. Called by Degeer carabus alboguttatus.

CARABUS 6-guttatus. Apterous, black; wing-cases smooth; with two grey spots. Inhabits India. Olivier, Donov. Inf. Ind. &c. This is of a large size; the shell is square, and entire: jaws advanced, blunt, and pointed; legs black.

CARABUS 4-guttatus. Apterous, black; thorax with two large pitchy tubercles, and a small grey spot on each side; wing-cases furrowed; with elevated carinated lines, and two remote grey spots. A native of Africa.

CARABUS 7-guttatus. Apterous, black; above brown; shells frilled with seven white dots. Fabr. Inhabits the Cape of Good Hope.

CARABUS tabidus. Apterous, black; wing-cases with russet furrows. Fabricius.

Described from the Bankian cabinet as a native of the Cape of Good Hope. Its size is about half that of carabus 4-guttatus; the front is grooved on each side; thorax with two raised dorsal lines on the back part; wing-cases rather pointed behind; body deep black.

CARABUS nigripennis. Apterous, fuscous; shells grooved, and black. Inhabits the Cape of Good Hope. Occ. &c.

CARABUS varioguttatus. Apterous; wing-cases flat and smooth, with white fuscous margin and spots on the disk. A native of the East Indies, described by Forskál. Off. The eyes are telfaceous; lateral margin of the thorax whitish; wing-cases with five white dots on the disk; body black.

CARABUS exclamationis. Apterous; margin of the thorax white; wing-cases with a white margin, line, and dot in the middle. Fabricius. From Barbary.

CARABUS triloculatus. Apterous, black; edges of the thorax white; wing-cases whitish, with black line anduture. Inhabits Germany. Described by Thunberg under the name of carabus lineatus.

CARABUS cephalatus. Apterous, black, very smooth, with convex thorax. Linn.

CARABUS circinellides. Apterous, and black; wing-cases ovate, flat, ferrugineous, and villous edged with white. Inhabits the Cape of Good Hope. Stock. Trans.

CARABUS leucicus. Apterous, black, depressed; thorax and shells very smooth. Inhabits Coromandel.

CARABUS tricuspisulatus. Winged; black; antennæ, and legs ferrugineous; shield tricuspidate. Inhabits Barbary. Mus. Desfontaines.

CARABUS calydonius. Winged; head with an obtuse projecting horn; mandibles horned.

Scarites calydonius. Roffi. This kind inhabits Italy. The head is large with a large obtuse compressed horn in front; mandibles with a strong recurved tooth; shells punctured in flurce.

CARABUS complanatus. Winged, yellowish, with two black bands on the wing-cases. Linn. Found in St. Domingo.

CARABUS binaculatus. Winged, black; head and wing-cases truncated; dots at the base, and band in the middle ferrugineous. Linn. Inhabits India. Donov. Inf. Ind. &c. The thorax is variable in this species. Being sometimes yellow; sometimes black; and not unfrequently spotted.

CARABUS triquintulatus. Winged, black; with two yellow spots on each wing-case, the posterior ones approximate; legs yellow.
CARABUS.

A native of Siam. Size of the last species, and which, as Fabricius intimates, may prove to be only a variety of it. The head is flat, smooth, and black, with the mouth telfaces; thorax flat, smooth, black and without spots; wing-cases fringed, black with two large yellow spots; the legs yellow, with a single tooth on the anterior tibia.

**C. porcatus.** Rubious with black wing-cases, and three red dots. Inhabit the East Indies. Fabr.

The head and thorax are rufous; wing-cases fringed, and black, the red spot at the tip lunate; abdomen rufous with black margin; legs rufous.

3d Section. Thorax square.

**C. alternans.** Apterous, black; shells sprinkled with irregular impressed dots. Inhabit the East Indies. Fabricus.

This insect resembles the next species; the antennae are black, cinctures at the tip; head large; eyes globular, prominent, and telfaceous; thorax black, and immaculate; shells deeply fringed, and interfolded with smaller ones, the longitudinal fringes alternately broader, and three breaks of oblong ruffled brassy dots; legs black. Inhabit South American islands.

**C. cerinus.** Apterous, black; shells with cinctured fringes, which are broader alternately, and marked with a triple series of elevated brassy dots retuse at the tip. Fabricus.

This insect resembles the next species; the antennae are black, cinctures at the tip; head large; eyes globular, prominent, and telfaceous; thorax black, and immaculate; shells deeply fringed, and interfolded with smaller ones, the longitudinal fringes alternately broader, and three breaks of oblong ruffled brassy dots; legs black. Inhabit South American islands.

**C. porcatus.** Apterous, black; shells fringed and granulated at the tip. Inhabit New Holland, and is described by Fabricius from a specimen in the Tankian cabinet. This is of a moderate size.

**C. reflexus.** Apterous, black; wing-cases fringed, with two yellow spots. Inhabit Holland. Obf. The head is black, and fringed on each side; thorax unequally punctured, and slightly reflexed at the edge; shells connected, with eight grooves; legs black.

**C. punctulatus.** Apterous, larvate, and black; thorax camouflaged; shells grooved, with two interrupted yellow bands. Inhabit Holland. Fabr.

**C. carabus.** Apterous, black; thorax margin; legs smooth. Inhabit France. Bosc.

**C. carabus.** Apterous, black; thorax margin; legs smooth. Inhabit France and Italy. Rohr.

**C. globosus.** Apterous, black, with convex thorax, and fringed shells. A native of Morocco. Schlett.

**C. fabr.** Apterous; shells very smooth, with a triple row of brassy dots. Inhabit Barby. Believed to be the carabus auripunctatus of Paykull.

**C. fabr.** Apterous; shells very smooth, with a triple row of brassy dots. Inhabit Barby. Believed to be the carabus auripunctatus of Paykull.

In size and appearance resembles carabus insidiosus; the antennae are black, with the last joint fringulate; wing-cases very finely reticulated.

**C. carabus.** Apterous, black, and thorax dotted; wing-cases with cinctured fringes; antennae and legs fringulose. A native of Morocco. Fabr. Obf. The antennae are nearly as long as the body, whence its specific name longicornis: the head is black, with fringulose feelers; thorax rounded at the sides, dotted, and black; wing-cases black, and without spots; thighs blackish.

**C. carabus.** Apterous, black, with fringulose antennae.

This insect inhabits Germany. Helwig.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.

**C. carabus.** Apterous; antennae short and brownish; thorax smooth, black, and immaculate; wing-cases nearly smooth; body black; thumbs of the legs spinous.
C A R A B A S.

bus obtusus, but differs in having all the lower surface with the legs and antennæ ferruginous.

**Carabus hirtipes.** Winged, filly-black; head brassy and shining. Fabr. Obs. The head is brassy, with the mouth and antennæ black; wing-cases ferruginous; legs black.

**Carabus fulvus.** Winged, black; thorax variolous; wing-cases grooved, with a ferruginous spot in the middle. Found at the Cape of Good Hope. Fabr.

**Carabus hirtipes.** Winged, black; head with two rufous dots in front; antennæ yellow at the base. Inhabitants Germany. Dall. Dorf. The body of this species is entirely black; head smooth and glossy; thorax smooth; wing-cases ferruginous; legs variable from red to black.

**Carabus fulvus.** Winged, azure; mouth, thorax, and thighs rufous; wing-cases ferruginous, and truncated. Inhabitants Barbary. Fabr.

**Carabus ferruginus.** Winged; thorax roundish; wing-cases fusco, ferruginous, with anterior hyaline spots, and dots on the posterior half. A new species lately discovered in South Wales. Donov. Tour. 1807.

**Carabus clavicornis.** Winged, brassy-black, with ferruginous antennæ; antennæ at the base red. Linn. Carabus virens. Myller. Obs. This species varies in colour from brassy to brassy, coppery and green.

**Carabus lepidus.** Winged, brassy-green; thorax with two rufous dots on each side; wing-cases ferruginous. Fabr. Carabus lepidus. Linn. It is a native of Europe.

**Carabus fuscus.** Winged, black, with ferruginous wing-cases, and a large oblong spot behind; antennæ and legs rufous.

This kind inhabits South America, and resembles in size and appearance Carabus pilicornis. The head is black; rufous on the wing-cases ferruginous; body black.

**Carabus corniger.** Winged, coppery; base of the antennæ red. Linn. Inhabitants woods in Europe.

**Carabus carinatus.** Winged, brassy-green; antennæ and legs rufous. Found in Terra del Fuego. Bankian Cabinet.

This is of a small size; head brassy, and shining; mouth ferruginous, posterior part of the thorax with an impression on each side; wing-cases ferruginous, and subfusco at the tip.

**Carabus corniger.** Winged, brassy-black; antennæ and legs black. Linn. Very common in sandy places in Europe. Obs. This is carabus ovatus of Roffi, Helv. &c. and carabus affinis, Schrank.

**Carabus communis.** Winged, brassy antennæ at the base and the halves rufous. Marliani, Pauzer. Rather smaller than the former, and is found in similar situations. Pauzer speaks of a variety that has the legs entirely rufous instead of the halve only.

**Carabus ovatus.** Winged, black; shells ferruginous and smooth; antennæ and legs ferruginous. Fabricius. Inhabitants Saxony.

**Carabus rufipes.** Winged, black; shells ferruginous; antennæ and legs ferruginous. Linn. Inhabitants Europe. The species is sometimes found in England, in woods.

**Carabus abdominalis.** Winged, black; antennæ, and legs ferruginous. Inhabitants the Cape of Good Hope. Fabr.

**Carabus auratus.** Winged, azure; antennæ and legs rufous. Inhabitants Germany. Helv. Entirely resembles the Fabrician carabus auratus, except in being entirely black.

**Carabus atratus.** Winged, black; thorax ferruginous, and legs black. A native of Germany. Helv. This resembles the latter in size and aspect; the head is black; thorax ferruginous, with an impressed dorsal line, and two little impressed lines at the base; wing-cases black, with ferrugine, and cristate. Inhabitants Germany. Smidt.

**Carabus linearis.** Winged, ferruginous, with a small black line on the wing-cases. Described from the Bankian Cabinet. The species inhabits North America.

**Carabus ferruginus.** Winged, ferruginous, and entirely convex. Marli. Inhabitants England, and the rest of Europe.

**Carabus ferruginus.** Winged, ferruginous, with a broad black lunule; abdomen black. Fabr.

This is a native of Barbary. The head is dusky; shells ferruginous; legs ferruginous.

**Carabus atratus.** Winged; thorax dark; wing-cases black, with heads ferruginous; hands with a broad black lunule; abdomen black. Fabr.

This is a native of Barbary. The head is dusky; shells ferruginous; legs ferruginous.

**Carabus auratus.** Winged, black; antennæ and legs ferruginous. Marli. Inhabitants Europe. The species is sometimes found in England, in woods.

**Carabus rufipes.** Winged, black; antennæ and legs ferruginous. Fabricius. Inhabitants Hungary.

**Carabus auratus.** Winged, black; antennæ and legs ferruginous. Inhabitants Germany. Smidt.

**Carabus auratus.** Winged, green, margin of the wing-cases and the halve tesselaceous. Linn. Inhabitants woods in Europe.

**Carabus auratus.** Winged, green, margin of the wing-cases and the halve ferruginous. Linn. Inhabitants woods in Europe.

**Carabus auratus.** Winged, green, margin of the wing-cases and the halve ferruginous. Linn. Inhabitants woods in Europe.

**Carabus auratus.** Winged, green, margin of the wing-cases and the halve ferruginous. Linn. Inhabitants woods in Europe.

**Carabus auratus.** Winged, green, margin of the wing-cases and the halve ferruginous. Linn. Inhabitants woods in Europe.
CARABUS.

and wing-cases, with the legs pale. Described by Fabricius from the Hunterian Museum, and native of America. Obs. The antennae are black; pale at the base; head black, with ferruginous mouth; abdomen black; postauricular, with black legs.

**Carabus fuscest.** Winged, fuscest; wing-cases absolutely divided; antennae, margin of the thorax, and legs black. Inhabits Germany.

**Carabus nigricans.** Winged, black and glossy; thorax canaliculated; wing-cases frayed. A native of Europe.

**Carabus quadratus.** Winged; thorax rounded; black; wing-cases frayed with a pale stripe. Inhabits Senegal.

**Carabus melanocephalus.** Winged; thorax and legs ferruginous; head and wing-cases black. Linn. Paykull, &c.

This is the species of the *Drosophila rubra* of Panzer, and the *Drosophila nova* of Geoffr. Found in woods of Europe, and in England. The head is black; wing-cases deep black, and frayed; thorax red. Linn. *F. S. W.*

**Carabus cyanoccephalus.** Winged; thorax and legs ferruginous; head and wing-cases blue. Linn. Inhabits European woods, and is found in England. Denon. Brit. *Inf.*

**Carabus rufilabris.** Winged, black; antennae, month and legs rufous. Found in Germany. Smidt. Size of the preceding; body black and glossy; thorax slightly canaliculated; wing-cases frayed; mandibles of the mouth black.

**Carabus violaceus.** Winged, yellowish; head and thorax black; wing-casesfuscous and frayed. Inhabits Denmark.

This insect is of a small size. The mouth is black; antennae pale; thorax smooth, black, and without spots; body and legs yellowish.

**Carabus anethiifolius.** Winged, azure; head and thorax shining-brassy. Fabr.

Described as a native of Cayenne, from the cabinet of Von Rohr. The antennae are hairy, brown, with ferruginous base; wing-cases frayed; body azure.

**Carabus crus-major.** Winged; thorax orbiculate; wing-cases, black, with two rufous spots. Linn.—Thorax yellow, glabrous; wing-cases behind black, with two yellow spots. *Carabus crus-minor. Marth. Ent. Brit.*

This is the species of the head, tip of the wing-cases, and the abdomen black. Inhabits Germany. Smidt. Obs. This is of an oblong figure; the mouth and antennae are tesselate; thorax rounded, smooth, and without spots; wings frayed; body tesselate; with black abdomen; legs tesselate.

**Carabus apricus.** Black above, beneath ferrugineus; wing-cases with a crescent-like fringe. Paykull, Mon. Inhabits the sandy plains of Dalmatia. Supposed to be the *Carabus furcatus* of Geoffr. and G. de Gugier.

**Carabus lunatus.** Winged; thorax orbiculate and rufous; shells yellow, with three black spots. Fabr. *Carabus furcatus.* Schrank, Beyer. This insect is found in England.

**Carabus praefasciatus.** Winged, black; head and thorax brassy; wing-cases ferrugineus, with a large, common, black spot at the tip. Inhabits Europe. Fabr. *Carabus latidens.* Paykull.

**Carabus carphites.** Winged; thorax brassy-green; shells black, with a ferrugineus spot at the tip. Inhabits Italy. Dr. Allioni.

**Carabus furcatus.** Livid; wing-cases with a black abbreviated line in the middle, forked at the base.

This is of a small size, and inhabits America. The head is dusky, with a black spot between the eyes, and the wing-cases are frayed.

**Carabus fusco-vittatus.** Winged; thorax orbiculate, and rufous; shells truncated and red, with a black crost. Linn. *Carabus crus-major.* Marth. Ent. Brit. *Le chevalier noir* of Geoffr. and Buprestis cruciata of Panzer. This inhabits European woods, and is, as well as the preceding species, found in England, but rarely.

**Carabus vitatus.** Winged; thorax orbiculate, and rufous; wing-cases black, with a white stripe. Inhabits North America. Fabricius. Obs. The antennae of this are black; head rufous; scutel small, and of the same colour; wing-cases glabrous, with a longitudinal white stripe on a black ground; margin rufous; body ferrugineus with black legs.

**Carabus teneius.** Winged; thorax orbiculate and rufous; wing-cases black, with a pale lunule at the base.

The country of this insect, which Fabricius describes from the Hunterian Collection, is unknown. The head is black; mouth and antennae reddish; thorax margined, and without spots; wing-cases frayed, slightly truncated, black; abdomen black; legs pale.

**Carabus hemeroboloides.** Winged; thorax somewhat orbiculate; rufous; wing-cases black, and rufous at the tip.

**Carabus fuscus.** Winged; thorax orbiculate and rufous; wing-cases black, with a pale lunule at the base.

The country of this insect, which Fabricius describes from the Hunterian Collection, is unknown. The head is black; mouth and antennae reddish; thorax margined, and without spots; wing-cases frayed, slightly truncated, black; abdomen black; legs pale.

**Carabus hemeroboloides.** Winged; thorax somewhat orbiculate; rufous; wing-cases black, and rufous at the tip.
CARABUS.

Fabricius as an English infect. Carabus 4-guttatus of Paykull.

Carabus spinulosus. Winged; thorax black; wing-cases dusky, with two pale bands. Inhabits Europe. Carabus dentatus, Thunberg, and Elaphurus rugosiss, Fabr. Mant. &c.

Carabus doralis. Winged; thorax black; shells pale, with a large black dorsal spot. Fabr. Inhabits Germany.

Carabus biguttatus. Winged; thorax brassy; wing-cases black, with a pale spot at the tip. Inhabits woods of Norway.

Carabus guttula. Winged, deep black, with a white hylone spot on the posterior part of the wing-cases. A native of Germany. Smidt. Carabus riparius of Paykull.

Carabus tesselatus. Winged; head and thorax ferruginous; wing-cases tesselaceous. Linn. Found in Europe.

Carabus truncatus. Winged; thorax ferruginous; wing-cases fractured, abbreviated, and black. Inhabits Saxony. Hybenr.

Carabus bipunctatus. Winged, brassy; antennae and legs black; shells with two impreme dots. Linn. An European species.

Carabus abbreviatus. Winged; thorax rufous; wing-cases abbreviated and tesselaceous. Found among the rocks of Norway. Fabr.

Carabus color. Winged, brassy, and shining; legs ferruginous. Found among mosses in Europe. Fabr.

Carabus minutus. Winged, black; shells and legs piceous. Inhabits Germany, and lives in the trunks of trees. Smidt.

Obf. This, as the name implies, is a small species. The head is black; antennae piceous; thorax roundish, black, and without spots; wing-cases fractured; body black, and legs ferruginous.

Carabus pygmeus. Winged; above shining-brassy; beneath deep black. inhabits Germany. Smidt.

Carabus trifur. Winged, black, with rufous legs. Found in Germany. Smidt. Obf. Small; antennae entirely black; head and thorax glabrous and black; wing-cases fractured. Paykull speaks of a variety of this infect with piceous legs, which he says is found in Sweden.

Carabus truncatus. Winged; above dusky-brassy; beneath deep black; wing-cases obtuse. Linn. Inhabits France. Size small; antennae and legs deep black.

Carabus minus. Winged, deep black, with fratured shells. Inhabits Germany. Smidt. Obf. This is very small; head and thorax black, and without spots; antennae and legs black.

5th Section. Thorax various, or uncertain.

Carabus angulatus. Apterous, thorax angulated, brassy; shells greenish, for-purt fratured; tip and margin rugose. Marsh. Inhabit England.

Carabus gigas. Thorax truncated behind, and entire; ovate, convex, gibbous; wing-cases with created frize; legs and antennae piceous. Marsh. Taken near Colchester, by the late Mr. Curtis, on Rubi fruticiosa.

Carabus rugosus. Thorax truncated behind, and entire; black; wing-cases dusky; antennae and legs ferruginous; margin of the thorax rufous. Inhabits England. Marsh.

Carabus convexus. Black; wing-cases fratured; frize dotted; antennae ferruginous; legs piceous. An English species. Marsh.

Carabus cebestus. Ferruginous and hispid; head and thorax dusky, punctured; wing-cases fratured, with a large black spot. Inhabits England. Marsh.

Carabus fumosus. Dusty-black; wing-cases somewhat fratured at the tip; thighs pale at the base. Inhabits England. Marsh.

Carabus egerzatus. Black; antennae ferruginous; wing-cases and legs tesselaceous. An English species. Marsh.

Carabus circulatus. Black; antennae, legs, and margin of the shells tesselaceous. Found under stones by the side of the river Usk, near Crickhowell, Monmouthshire. Marsh.

Carabus porpusus-ceruliscus. Bluish-black; wing-cases fratured, with numerous punctures between the frize; antennae, feelers, and legs rufous. Found near Malton in Efex. One of the new English species described by Mr. Marsh. Ent. Brit.

Carabus fulvus. Ferruginous; legs paler; eyes black. Inhabit England, and varies in having the legs more or less pale.

Carabus leprous. Blue; base of the antennae, and legs ferruginous; shells brown, with two white spots. Inhabit Denmark. Pontopp.

Carabus Insolens. Dusty-black, beneath black; legs tesselaceous; shells fratured, the lateral margin yellowish-grey. Inhabit Siberia. Pallas.

Carabus aiaceus. Apterous, black, and without spots; thorax
CARABUS.

Thorax rounded behind and grooved. Inhabits the Cape of Good Hope. Thunberg.

Carabus humilissimus. Apterous; black; thorax lustrous; wing-cases lustrous. Thunberg. Inhabits the Cape of Good Hope. Obs. This is about the size of Carabus violaceus, but broader and more depressed.

Carabus dufciformis. Apterous, black; thorax transverse, truncated behind; shells lustrous. Thunberg. An African species, found at the Cape of Good Hope. Size of C. bartenius.

Carabus donaldus. Black; antenna and wing-cases red, with a black margin. Inhabits the Cape of Good Hope. Thunberg.

Carabus obtusus. Thorax and wing-cases fuscous; head, antenna, and legs red. Found at the Cape of Good Hope. Thunberg.

Carabus offer. Black; antenna and legs reddish; wing-cases smooth. Thunberg. Inhabits the Cape of Good Hope. Same size as Carabus vulgaris.

Carabus Capensis. Ferruginous; thorax and future of the shells with a longitudinal black line. Inhabits the Cape of Good Hope. Thunberg. Obs. The body is glabrous; abdomen black or ferruginous.

Carabus siliate. Ferruginous; shells with a black band. Inhabits the Cape of Good Hope. Thunberg. This is very closely allied to Carabus siliateus, and may be the same species.

Carabus fimbratus. Apterous, black; sides of the thorax, and margin of the wing-cases downy white. An African species. Herbdt.

Carabus Herbsti. Shells transversely undulated with three rows of golden dots. Inhabits Germany.

Carabus Pomeranus. Coppery, beneath black; shells with three rows of raised dots, and decumbent frize. A native of Pomerania. Herbdt.

Carabus cylindricus. Black, cylindrical; thorax narrowed, and grooved in the middle; shells with nine grooves, and dotted on the outer margin. Herbdt.

Carabus marchicus. Beneath black; head and thorax light grey; feelers and antennae brown, ferruginous at the base. Inhabits Prussia. Herbdt.

Carabus fimbriatus. Brown; head and thorax brassy-green; legs pale. Inhabits India. Herbdt.

Carabus mungo. Piceous; legs fimbriatus; antenna and margin of the thorax yellowish; shells with eight frize. Inhabits India. Herbdt.

Carabus Indicus. Black; antennae grey at the tip; thorax with an impressed line; wing-cases with seven grooves. Inhabits India. Herbdt.

Carabus atratus. Entirely glossy-black; thorax rounded; shells obliquely striated, with four indented dots at the future. Inhabitats Prussia. Herbdt Gmel.

Carabus bipinatus. Black, beneath brown; shells blue, with nine punctured frize, the outermost created. Inhabitats Prussia. Herbdt. ap. Fuceli.

Carabus vivi. Black; antenna and legs brown; the...
CARABUS.

CARABUS pubeceus. Black, downy; wing-cases fringed; antennae, feelers, and legs fulvous. Inhabits Europe. Müll.

CARABUS levis. Brassy; head and thorax green; wing-cases coppery; legs piceous. Inhabits Denmark. Müll.

CARABUS vernultr. Black; antennae, feelers, and legs yellow; wing-cases fringed with dots. Müll.

CARABUS pullicus. Black; wing-cases fringed; legs piceous. Inhabits Denmark. Müll.

CARABUS rubicundus. Apterous, beneath black; thorax violet; wing-cases reddish, the future and margin white. Lepechin. Inhabits Russia.

CARABUS Forsteri. Black; head, thorax, and shells glossy-green; antennae and legs rusous. Inhabits America. Forster.

CARABUS lineatus. Thorax ferruginous; wing-cases grey, with a common black line at the future, and another in the middle; legs grey; tarsi black. Inhabits America. Forster.

CARABUS fulvocarinus. Black; wing-cases with smooth fririe, the outermost punctured; feelers, antennae, and legs pale yellow. Inhabits Europe. Hoppe.

CARABUS adspersus. Apterous; above brassy-green, beneath black; wing-cases with four rows of indented gold dots and raised lines. Inhabit Europe. Degeer. Gmelin.

CARABUS varius. Above brassy-black, beneath black; body ovate and short; thorax convex; wing-cases smooth; antennae rufous at the base. Inhabit Europe. Degeer. Gmelin.

CARABUS versicolor. Brassy, body ovate and short, brassy black above, beneath black; thorax convex; wing-cases smooth; antennae rufous at the base. Inhabit Europe. Degeer. Gmelin.

CARABUS subfriatus. Shining black; shells slightly fririated, with four impressed dots. Inhabit Europe. Degeer. Gmelin.

CARABUS Pennsylvanius. Reddish-brown; head dusky; wing-cases frirated; body beneath, legs, and antennae telfaceous. Degeer. Inhabit Europe.

CARABUS balticus. Black; shells frirated, and ferruginous towards the thorax; antennae and legs telfaceous. Inhabit Saxony. Schall.

CARABUS mercus. Black; wing-cases frirated, and thorax rough and opaque. Inhabit Saxony.

CARABUS Schalleri. Black; smooth; wing-cases with very minute punctured firiie.

CARABUS S-friatus. Green, punctured; wing-cases with eight firiie; legs pale. Inhabit France. Geoffr.

CARABUS minutus. Shining-green; wing-cases with eight firiie and three impressed dots; legs pale. Inhabit France. Geoffr.

CARABUS nobilis. Black; thorax deep black; wing-cases red, with a black cross. Inhabit France. Geoffr.

CARABUS aurantius. Shining; head and shells green; thorax coppery, with twelve dots. Inhabit France. Geoffr.

CARABUS striatus. Black, thorax ferruginous; wing-cases frirated, with four livid spots. Inhabit France. Geoffr.

CARABUS nigricollis. Entirely black; wing-cases frirated, with four livid spots. Inhabit France. Geoffr.

CARABUS tenebrifer. Black, thorax broad; wing-cases frirated, with punctures. Inhabit France. Geoffr.

CARABUS f-suffus. Piceous; thorax with an excavated longitudinal line; ends of the legs spurious. Inhabit Europe. Scoptoli.

CARABUS elegans. Thorax linear, and as long as the shells; legs rufous. Inhabit Europe. Scoptoli.

CARABUS Scopoli. Brassy-green; wing-cases telfaceous, with the whole margin and band fulvous. Inhabits Carniola. Scoptoli.

CARABUS falcinarius. Black dotted; wing-cases fulvous, frirated; antennae and legs ferruginous. Inhabit Carniola. Scoptoli. Found on willows, &c.

CARABUS arenarius. Brassy-fuscous; thorax somewhat roundish, and dentated behind; legs rufous. Inhabit sandy places in Carniola. Scoptoli.

CARABUS atomarius. Apterous, black, glabrous; wing-cases edged with violaceous, smooth, and sprinkled with minute, confluent, violaceous dots. Muf. Leitk. Gmelin.

CARABUS miliarius. Apterous, black; wing-cases with elevated fuscous dots; outer margins brassy-violet. Inhabit Europe. Leitk. Gmelin.

CARABUS frutatus. Apterous, black; wing-cases ridged, the alternate ridges broken irregularly. Inhabit Europe. Leitk. Gmelin.

CARABUS cypris. Apterous, black, and coppery; wing-cases with four ridges each, containing three rows of elevated dots. Inhabit Europe. Leitk. Gmelin.

CARABUS 5-lineatus. Black; thorax rounded, laterally truncated behind with an impressed dorso line, and a double one on each side at the base; wing-cases ridged. the five innermost joining the fixth at the tip. Inhabit Europe. Leitk. Gmelin.

CARABUS tricolor. Ferruginous black; head, antennae at the base, and thorax black; wing-cases defrinated, frirated, tip truncated, and with the outer edge of the thorax ferruginous. Inhabit Europe. Leitk. Gmelin. Obi. Antennae cinereous and glabrous.

CARABUS confusa. Black; thorax rounded at the sides; wing-cases frirated, the first and eighth, second and seventh, united at the tip. Inhabit Europe. Leitk. Gmelin.

CARABUS Lefkii. Deep black; head and thorax black; wing-cases brown, with fily fixth; antennae and legs ferruginous. Inhabit Europe. Leitk. Gmelin.

CARABUS tricolor. Black; antennae and legs ferruginous; wing-cases finely frirated; head and thorax brassy, the latter with an impressed dorso line, and two smaller on each side behind. Leitk. Gmelin makes three varieties of this species; namely, B Carabus antennis basi rubris. Leitk. 7 Carabus ater. Leitk. 8 Carabus neger. Leitk. All these inhabit Europe.

x

CARABUS.
CARABUS pallidus. Ferruginous black; wing-cases frigilated; antennae rufous. Inhabits Europe. Leck. Gmel.

CARABUS quadratus. Thorax nearly square, with an impressed dorso-lateral line, and a smaller one on each side behind; wing-cases frigilated. Leck. Gmel.

CARABUS emarginatus. Black; thorax nearly square, and truncated behind; wing-cases frigilated and emarginated at the tip. Inhabits Europe. Leck. Gmel.

CARABUS erythrocephalus. Black; thorax nearly square, and rounded at the sides; wing-cases frigilated; antennae rufous; legs ferruginous. Inhabits Europe. Leck. Gmel.

CARABUS concinor. Black; thorax nearly square; shells deep black, and very finely frigilated. Inhabits Europe. Leck. Gmel.

CARABUS erythrocephalus. Black; thorax square behind; wing-cases frigilated; antennae and legs rufous. Inhabits Europe. Leck. Gmel.

CARABUS rubicoris. Black, antenne red; posterior part of the thorax truncated, with an impressed dorso-lateral line. Inhabits Europe. Leck. Gmel.

CARABUS viridatus. Greenish-black; antenna and legs rufous; wing-cases frigilated with flat finely punctured ridges. Inhabits Europe. Leck.

CARABUS multicolor. Black, head and thorax green; wing-cases bluish-green, with yellow down; mouth, base of the antennae, and the legs rufous. Inhabits Europe. Leck.

CARABUS obtusatus. Fusceous, thorax truncated behind; wing-cases frigilated; antennae and legs ferruginous. Inhabits Europe. Leck.

CARABUS obtusatus. Black; wing-cases frigilated; flanks ferruginous. Inhabits Europe. Leck.

CARABUS ecepus. Ferruginous-glabratus; thorax truncated before and jagged behind; wing-cases frigilated. Inhabits Europe. Leck.

CARABUS limbatis. Black; thorax margined, plaited behind; wing-cases frigilated; legs black-ferruginous. Inhabits Europe. Leck.

CARABUS trunculatus. Black; thorax truncated behind; wing-cases frigilated; legs ferruginous-brown. Inhabits Europe. Leck.

CARABUS chloromelas. Black, above green; antennae and legs ferruginous. Inhabits Europe. Leck.

CARABUS sinuatus. Black; wing-cases frigilated, and frigilated at the apex; antennae rufous at the base. Inhabits Europe. Leck.

CARABUS pallidicorne. Black; wing-cases frigilated; thorax truncated behind; outer margin, with the legs and antennae, pale. Inhabits Europe. Leck.

CARABUS rotundatus. Black, above brassy; thorax rounded; wing-cases frigilated; flanks ferruginous. Inhabits Europe. Leck.

CARABUS lituratus. Picceous; head, legs, and wing-cases telfacous, the belly with a common black violet spot at the tip; thorax violet. Inhabits Europe. Leck.

CARABUS cylindricus. Telfacous, cylindrical; head black; thorax orbicular and rufous. Inhabits Europe. Leck.

CARABUS 4-setatus. Black, thorax orbicular; wing-cases blue-brown, with four telfacous dots; legs telfacous. Inhabits Europe. Leck.

CARABUS 6-setatus. Brassy-black; thorax rounded; wing-cases frigilated, with three pair of impress'd dots at the future. Inhabits Europe. Leck.

CARABUS fuscicornis. Black, above brassy; thorax rounded and punctured; wing-cases with crenated frigia; antennae brown; legs rufous. Inhabits Europe. Leck.

CARABUS trispinos. Black; head and orbicular thorax brassy; wing-cases ferruginous, brassy, and frigilated with punctures; legs rufous; thigh thick; flanks spinous. Inhabits Europe. Leck.

CARABUS meffus. Ferruginous; thorax rounded; wing-cases frigilated; head brown; antennae and legs telfacous. Inhabits Europe. Leck.

CARABUS porphyropus. Picceous, thorax truncated; wing-cases frigilated; antennae and flanks rufous. Inhabits Europe. Leck.

CARABUS atratus. Black; thorax orbicular; wing-cases pale, varie'd with black; antennae and legs ferruginous fulvus. Inhabits Europe. Leck.

CARABUS lepidus. Above brassy-green, beneath bluish; thorax nearly square, with four impress'd frigia behind; anterior flanks dilated at the tip. Inhabits Eu. Leck.

CARAC, Karen, or Charedis, in Geography. See Karé.

CARACA, in Botany, Rumphi. Amb. 5. p. 373. tab. 132. See DOLICHOS bulbif. caracala, in Zoology, an animal of the lynx tribe, by some called the Perian lynx. See Felis caracal.

CARACALLA, in Antiquity, a long garment, having a fort of capuchin or hood a-top, and reaching to the heels; worn equally among the Romans by the men and the women, in the city and the camp.

Spartan and Xiphilini represent the emperor Caracalla as the inventor of this garment, and hence suppose the appellation caracalla was first given him. Others, with more probability, make the caracalla originally a Gallic habit, and only brought to Rome by the emperor above-mentioned, who did enjoined the foldery to wear it. The people called it Antonian, from the same prince, who had borrowed the name of Antonius.

The caracalla was a sort of casack, or fourout. Salmainius, Scaliger, and after them Du-Cange, even take the name casack to have been formed from that of carace, for caracalla. This is certain from St. Jerome, (ep. 126, ad Fabiolam,) that the caracalla which became an ecclesiastical garment, was a kind of cloak with a cowl; for both he, and Euclarius, (Instruction. l. ii. c. 10.), describing the

ephod,
Caracalla. 

Caracalla, in Biography and History, a Roman emperor, was the son of the emperor Severus and Julia Domna, and born A.D. 188. At the age of eight years, his family name "Bavianus," which he derived from his maternal grandfather, was changed by Severus, on his becoming emperor, into the highly respected names of Marcus Aurelius Antoninus; conferring upon him at the same time the dignity of Cæsar, which title was confirmed to him in the following year, viz. A.D. 215, by a decree of the senate. By these names he chose to be distinguished; but his infamous conduct has caused his history to be transmitted to posterity under the nick-name of Caracalla, which was occasioned by his fondness for a Gaulish robe so called, (see the preceding article) worn by him in preference to any other, and gratuitously distributed among his soldiery and the inhabitants of Rome, for their use. In his eleventh year, the emperor induced the soldiers, after the capture of Cæsiphon, to proclaim him "Augustus." Geta his brother, receiving at the same time the title of Cæsar, and the name of Antoninus. The act of the soldiery was confirmed by the senate, and Severus recompensed them with liberal donations. Before he had completed his 14th year, the emperor, whilst he was at Antioch, prosecuting a war against the Jews, in which this youth had the title of commander, and for the successful issue of which the senate decreed him a triumph, gave him the manly robe, and made him his colleague in the confuinction, A.D. 202. In the following year he married the daughter of Plautianus, the praetorian prefect, and an infatant favourite, whose abuse of the infamous power with which he was entrusted, brought him to an untimely end. Caracalla was instrumental in procuring the prefect's death, A.D. 205; and his hatred of the father was soon followed by an invincible dislike of the daughter, whom he had married against his inclination. To the ruin of Plautianus succeeded that of his family; for his son Phatus, and daughter Plautilla, were banished to the island of Lipari, where they languished in misery and perpetual alarms, till Caracalla, after he became emperor, ordered them to be killed. Caracalla and his brother Geta, who was declared "Augustus," and invested with the tributional power, A.D. 208, had conceived from their infancy an implacable hatred against one another. With a view of diverting their minds and allaying the animosity that subsisted between them, Severus took them with him in his expedition to Britain. But the ambition of Caracalla led him to avail himself of every opportunity that occurred for ingratiating himself with the officers and soldiery, and for inducing them to acknowledge him sole emperor in prejudice to his brother, whom he regarded as an odious rival. In order to halten his attainment of the sovereign power, he even attempted to murder his father, whilst he was concluding a treaty with the Britons, and receiving their arms. He afterwards intrigued with the officers and soldiery for the purpose of deposing him. Some have said, that during his left illness, Caracalla endeavoured to bribe the physician, who attended him, in order to hasten his death. Severus, who died at York, A.D. 211, was succeeded by his two sons, whom he had inculcated with the sovereign power during his lifetime, and by his last will appointed to reign jointly after his death. The early antipathy that subsisted between the two brothers was incalculable; and the intrigues, rebukes, and exhortations, both of their father and their preceptor Anipater, had been altogether ineffectual to their reconciliation. As soon as Severus had expired, Caracalla endeavoured to exclude his brother, by his influence with the army, from any share in the sovereignty; but the soldiery, protesting that they would equally obey both the sons of Severus, as he had appointed both to succeed him, was forced to acknowledge his brother partner in the empire, and to suffer the soldiery to take the usual oath of allegiance to each. After this ceremony, Caracalla concluded a shameful treaty with the Britons; and both the brothers, about the middle of summer, set out for Rome with their mother Julia, and the ashes of their deceased father. In the progress of their journey, Caracalla attempted to murder Geta; and this attempt increased their mutual animosity and jealousy to such a degree, that they afterwards marched with their separate guards, and with no less wariness than if they had been in an enemy's country; lodging constantly in different houses, and carefully watching the motions of each other. On their arrival at Rome, they were received with great solemnity: but the discord that prevailed, and that was every day increasing between the two princes, produced two contending factions; and it was therefore proposed to make a division of the empire between them. Geta, who loved a quiet life, confounded, that if Caracalla would surrender Aelia and Egypt, he would retire to Alexandria, or Antioch, and leave him in unmolested possession of the rest of the empire. But this scheme was defeated by their mother Julia. Towards the close of this year, Caracalla made another attempt to murder his brother during the feast of Saturn; and this outrage occasioned almost an open war between the two princes, and a great deal of bloodshed. In the following year, A.D. 212, he effected his purpose, on occasion of an interview which was proposed, with a view to their reconciliation; when some centurions whom he had placed in ambush rushing on Geta with their swords in their hands, and urged on by the monster Caracalla himself, dispatched him with many wounds, whilst he was seeking refuge in the arms of his mother, who in endeavouring to save him was herself also wounded. Having by this atrocious act made himself sole master of the empire, he conciliated the attachment of the army by the most extravagant donations, and by circulating reports, as well as by public declarations, that his brother was a traitor, and that he had slain him unwillingly in his own defence, he established his own power. In order to include the soldiery and the people, and to gain credit to these unfounded pretences, he repaired to the camp of the praetorian cohorts, and prostrating himself upon the ground before the images of the tutelary deities, he offered up sacrifices of thanksgiving for his happy escape; justifying himself also by similar declarations to the senate, before which he appeared, surrounded with his guards, and armed with a cuirass, he obtained the approbation of that house and venal assembly. By artifices of this nature he succeeded in prevailing with the praetorians to declare him sole emperor, and Geta a public enemy. That Caracalla himself was active as one of the executioners in
the afflication of his brother is not improbable, if we consider, that some years after this event, he consecrated in the temple of Serapis, at Alexandria, the sword which he had used in the murder of Geta. When the savage deed was perpetrated, he forbade his mother, by menaces against her life, even exhibiting any signs of sorrow on the occasion: and he actually put to death Faflilla, the only remaining daughter of Marcus Aurelius, for disobeying a similar injunction.

In order to conciliate the Senate, he made an exertion of clemency, by allowing all exiles to return to the city; and as he made no distinction between the innocent and the guilty, he thus filled Rome with multitudes of villains who had richly deserved the punishment inflicted on them. With a view of satisfying the public, Caracalla permitted the memory of his brother to be honoured, using at the same time this memorable expression, "Sit divus, non sit vindex," i.e. "Let him be a god, as long as he is not alive," and accordingly the Senate issued a decree, by which he was enrolled among the gods. Notwithstanding these apparent but unavailing tokens of clemency, and this seeming respect for his deceased brother, Caracalla was rigorous and cruel in his conduct towards all those who manifested any respect for Geta, or who had any connection with him whilst he lived; and he adopted every method which he could devise for erasing the remembrance of him from the minds of survivors. Dion Cassius informs us, that in the general massacre of his partisans and friends, he ordered all his domestics, to the number of 20,000 persons, to be inhumanly put to death; it was death even to mention his name; and no one was allowed to use it even on the stage, where it was familiarly applied to slaves. All the money that bore his name was ordered to be melted down; and the inscriptions were erased. The dead bodies of those who were massacred were treated with indignity, burnt without ceremony, or were exposed to the beasts and birds of prey. Not satisfied with the murder of perfons of inferior rank, Caracalla sacrificed to his rage and jealousy a great number of illustrious victims, among whom, Papinius, the pretorian prefect, and the most eminent civilian in the opinion of Zosimus and Cassius, that ever lived, was the most distinguished. Papinius had returned the confidence of Severus by faithful and zealous endeavours to promote union and concord between the two brothers; and having thus disgraced Caracalla, he was deprived of the post of prefect of praetorian prefect. But the immediate cause of his death was his laudable refusal to concur in furnishing Caracalla with apologies for the murder of his brother. "It is easier," he nobly replied, "to commit a parricide, than to justify it; and to accuse an innocent person is a second parricide." In short, no sex, rank, or age, escaped the cruelty of this monster of wickenedfins: and he seems to have equaled, or even exceeded Caligula in the indulgence of the most malignant passions. Indeed, in another respect he also resembled him, as a portion of real inhumanity seems to have blended itself with a temper and character radically and habitually vicious. His acts of repine and extortion corresponded to those of his cruelty; and he seems to have made it his study through his whole reign to harass and oppress his people. Fond of public spectacles, he squandered with profusion in the support of these, what he extorted from the people; and his prodigality to the soldiers, with a view of engaging their affections, was unbounded. In games and shows he himself took an active part, fighting on occasions of this kind with wild beasts, and driving chariots in the circus. Whilst he indulged a taste altogether unfavourable to his high rank and office, and the meanest kind of curiosity and iniquitous, he defied every quality that was likely to command esteem; and his ignorance, and his contempt of literature and of learned men, were notorious. His debaucheries were as detestable as his other bad qualities; and yet, with an unpronounceable hypocrisy, he affected zeal for chastity and even for religion, though he forbade any one's calling him by the names of the divinities he worshipped: but his pretended piety was blended with a passion for the delusive arts of magic and judicial astrology.

Having established in the capital of his empire a character detestable for cruelty and oppression, and levelling the press of complaints against the Roman people by extending them to all the subjects of his empire, he determined to trace the footsteps of Alexander the Great, for whom he professed an extraordinary veneration, in the path of military glory. Ambitions of resembling this conqueror in every circumstance of his history, he conceived it to be his duty to associate upon the most intimate terms with his ministers, and to take part with them in all their military labours and exertions; and having thus fitted himself, as he conceived, for all the offices of a great commander, he left Italy, A.D. 213, and commenced his expeditions by visiting Gaul, where he exercised such cruelties that he was more hated and abhorred there than he had ever been at Rome. He afterwards crossed the Rhine, and conducted an expedition against the Catti and the Alamanii, now full mentioned in history; but he was obliged to purchase a peace with large sums, and the liberty of returning with safety into the Roman dominions. As soon as it was known in Germany that he had bought a peace of these people, all the nations inhabiting that extensive country flew to arms, and compelled him to grant them yearly pensions, the supply of which reduced him to the necessity of coining false money. In an interview with the Barbarians on this occasion, he was guilty of an act of perfidy, which of itself is sufficient to fix an indelible stain on his memory. Having ordered all the youth of Noricum to take arms, and join him, he commanded his troops to fall upon them and to put them all to the sword. For this pretended victory he assumed the title of "Alamanicus." From the borders of the Rhine he marched to the Lower Danube, and obtained some favorable advantages over the Barbarians, then hardly known, but afterwards too intimately connected with the affairs of declining Rome, called by the Romans Geta, and in subsequent times Goths. Having made an agreement with the Dacians, he passed from the banks of the Danube into Thrace; and afterwards crossing the Hellespont, he arrived at Ilium, and paid obsequious honours to the memory of Achilles at his supposed tomb. The death of Fellus, his favourite freedman, whom he is supposed to have poisoned, for the purpose which he proposed, furnish him with an opportunity of resembling Achilles in his funeral of Patroclus. Accordingly, he spared no expense in rendering the obsequies of Fellus extremely pompous. From Ilium he went to Pergamus, to seek relief in the temple of Aesculapius, under the disorders of mind and body, of which he had reason to complain, and which were probably owing to the agitation of remorse and terror. Having spent the winter at Nicomedias, he prepared for attacking the Parthians and Armenians; but Artabanus was under a necessity, on account of the intestine divisions of Parthia, to avert the attack by a timely submission. By the baleful perfidy, he made captives of Abgarus, king of Edessa, and the king of Armenia; but the only fruit which Caracalla reap'd from his perfidy was the defeat of Thecoritus, one of his generals, the consequent shame he so justly merited, and the universal detest of all mankind. However, he possessed a soul incapable of feeling such humiliations; and therefore gloried in the success of his exploits, and wrote haughty and boastful letters.
letters to the Senate on the occasion, as Caligula had done before him. At Alexandria, whither he next went, he profitably availed himself of an opportunity that offered itself of avenging himself on the Alexandrians for some raillery which these voluble and facetious people had formerly thrown out against him. The measure he adopted for this purpose was the most horrible massacre which history records. Having declared his intention of rendering personal homage to the god Serapis, the Alexandrians received him with every possible token of respect. Upon his first entrance into the sacred temple, he sacrificed whole hecatombs, and burnt upon the altar a great quantity of incense. From thence he proceeded to the tomb of Alexander, and rendered peculiar honours to the deceased hero. All these specious and pompous appearances served, however, to conceal his black design of extirpating the inhabitants of Alexandria. In the midst of the festivities produced by the delusion he was practising, he directed, from his pont in the temple of Serapis, his troops to fall on the assembled inhabitants and to make an undistinguished slaughter. Many thousands of natives and strangers fell in the carnage, and an universal pillage succeeded, which, with the fevers that followed this horrid massacre, reduced their flourishing capital almost to a state of desolation. This desolation, however, was but a temporary evil; for Caracalla not long afterwards, Alexandria recovered its splendour by its own resources, and soon became again the second city of the empire. Caracalla having completed his purposes of vengeance at Alexandria, determined to proceed towards Parthia; and making Artabanus's refusal to give him his daughter in marriage a pretext for violating the peace which had been concluded between the empires, he ravaged a large tract of country, plundered the cities, and after overrunning all Media, drew near the royal capital, where, like a dastardly enemy, he vented his fury even upon the dead, opening the tombs of the Arsacidæ, and scattering their ashes to the wind. Upon his return to Mesopotamia he boasted that he had conquered the Parthians, whom he had not even seen, and in his letters to the Senate and Roman people, he pretended that he had subdued all the East, and obliged every country beyond the Euphrates to acknowledge their laws. In consequence of these pretences, he obtained from the Senate the appellation of "Parthicus," and a decree for a triumph. The war would have been furiously renewed if a domestic conspiracy had not put an end to the miseries inflicted on the world by this detestable tyrant. M. Opillius Macrinus had risen from a low station to the post of praetorian prefect; but he had incurred the jealousy and hatred of Caracalla, whose suspicion was increased by the prediction of a diviner, that he was to succeed him on the throne. The circumstances of Macrinus were become critical, in consequence of some dispatches from Rome, which accidentally fell into his hands; and in order to evade the stroke which was meditated against him, he employed a disconnected centurion, named Martialis, to assassinate the emperor. Accordingly, while he was pursuing his journey from the city where he had wintered, to Carthage, for the purpose of being a fasciace in the temple of the Moon, a call of men obliged him to alight: Martialis seized the opportunity when he was almost alone, to dispatch him with a stab. The assassin instantly fled; but he was pursued, and, by some of the emperor's attendants, killed Caracalla on the 8th of April, A.D. 217, at the age of 29 years, and after a reign of six years, two days; his death was regretted by the feliciter Macrinus treated as a god, a prince whom he had been instrumental in killing; and the Senate, by his orders, decreed him divine honours. Thus, this monster, detested by heaven and earth, had his temple, his priests, and festivals, established for the worship of him at Rome. The authors who lived under Caracalla were Q. Suetonius Sarmionicus, murdered by his order; Titus Marius, and Oppian. The principal historians of this period are Herodian, Dion Callius, and Spartian. Crevier's Hist. of the Emperors, vol. viii. Aug. Uni. Hist. vol. xiii.

CARACELLA, in Botany. See PHASEOLUS CARACELLA.

CARACARA, in Ornithology, the name under which Buffon describes the Brazilian kite. See Falco Brafifinit. The same name caracara has been also given to the gold-breasted trumpeter, Psophia Cretips, which see.

CARACARAS, in Zoology, a species of snake. See Cobræ.

CARRACCA, LA, in Geography, a sea-port town of Spain, in the province of Andalusia; two leagues E. of Cadiz.

CARACASS, a district of Terra Firma in South America, belonging to the Spaniards. It lies between the province of Venezuela to the west, and that of Cumana to the east, and is bounded on the north by the Caribbean sea, and on the south, by parts of America little known. The coast is rocky and mountainous, but its valleys and plains are fertile, and produce the cacao-tree, indigo, fugar, and tobacco. The air is reckoned clear, and the climate wholesome. Its principal towns are Caracas, the capital, y Portu Calvallo, which is a sea-port town. In consequence of the acknowledged superiority of the cacao nuts in this province, and its communication with the Atlantic which facilitates the conveyance to Europe, the culture of the cacao there is more extensive than in any district of America. However, the Dutch, by the vicinity of their settlements in the small islands of Curacoa and Buen-Ayre, to the coast of Caraccas, gradually ingrossed the greatest part of the cacao-trade. Hence the traffic with the mother country ceased almost entirely; and such was the supine negligence of the Spaniards, or such were the defects of their commercial arrangements, that they were obliged to receive from the hands of foreigners this production of their own colonies, at an exorbitant price. In order to remedy an evil so lefs disgraceful, than pernicious to his subject, Philip V. in 1728, granted to a body of merchants an exclusive right to the commerce with Caracass and Cumana, on condition of their employing at their own expense, a sufficient number of armed vessels to clear the coast of pirates. This society, sometimes distinguished by the name of the company of Guipufcon, from the province of Spain in which it was established, and sometimes by that of the company of Caracass, from the district of America to which it trades, has carried on its operations with such vigour and success, that Spain has recovered an important branch of commerce, which she had suffered to be wrested from her, and is plentifully supplied with an article of extensive consumption at a moderate price. From this institution the colony, as well as the parent state, has derived great advantage. The planters in the Caraccas are not left to depend entirely on the company either for the importation of European commodities, or the sale of their own productions. The inhabitants of the Canary islands have the privilege of sending thither annually a regifter ship of considerable burden; and from Vera Cruz in New Spain, a free trade is permitted to every port comprehended in the charter of the company. Hence arises a competition which tends to fix the price of all commodities, both purchased and sold, at its natural and equitable rate. The company has not the power of raising the former or degrading the latter.
CARACCI.

Caracci, Agostina, the elder brother of Annibale and the disciple of Ludovico, was born at Bologna in 1537; and having first studied his art in the school of Prospero Fontana, but afterwards becoming a disciple of Palma, he laid the foundation of his eminence under the direction of his inimitable Ludovico. He affixed Annibale in the Farnese gallery, but left affidius than his brother, he devoted much time to engraving, which he had learned from Cornelius Cors. "He combined," says Mr. Fubeli, "with some learning, a cultivated taste, correctness, and sometimes elegance of form, and a correggiacque colour, especially in fresco." The most celebrated picture of this master is the communion of St. Jerome, now at the Louvre, which has been often compared with its rival picture of the same subjeft by Domenichino. "These two pictures," says Mr. Fubeli, "have often been compared without much discrimination of the principles that distinguish either, and the result has commonly been in favour of Domenichino; but surely, if Agolino yields to his scholar in repose, and the placid economy of the whole, he far excels him in the principal figure, the expression and character of the faint." Agolino died in 1602. Pilkington.

Caracci, Annibale, an eminent painter of history, portrait, and landscape, was born at Bologna in 1560, and being a disciple of his cousin-german, Ludovico Caracci, he imbibed from him the bold principles of his art, as well as an ambition to arrive at perfection in the exaction of it. With this view he studied the works of Titian, Tintoretto, and Paolo Veronese, at Venice, and those of Correggio at Parma. At an early age he manifested proofs of an extensive genius, which not only surpassed the artifices of his time, but excited a general expectation of the excellence to which he attained. The fame of the Caracci having reached to Rome, Annibale was invited thither by the cardinal Farnese, and employed in painting the gallery which bears his name. But though he laboured ten years at this work, the avaricious ecclesiastic prevented him with only 500 crowns. At Rome he had an opportunity of observing the antique statues, the baso-relievois, and also the compositions of Raphael, and he was thus led to abandon his Bolognese manner, formed after that of Correggio, and to adopt another more learned, but more dry and leis natural, both in design and in colouring. There is a sameness in the manner of all the Caraccis; and the only difference between them is that which results from their diversity of temper and disposition. Annibale had more fire, boldness, and singularity of thought than the two others;
and his designs were more profound, his expression more lively, and his execution more firm. His genius was better adapted to poetical and profane, than to sacred subjects; though, when he attempted the latter, he generally succeeded. His talents were admirably formed for landscape: the forms of his trees are grand; and in representing objects after nature, he gave them a character that distinguishes them strongly. He is said to have been deficient, however, in his knowledge of the principles of the chiro, nor are all his local colours commendable: but upon the whole, no painter seems to have been more universal, more easy, more certain in every thing he did, nor more generally approved than Annibale. Annibale," says Mr. Pinelli, "though superior to his cousin and brother in power of execution and academic prowess, was inferior to them in taste, felicity, and judgment; in proof of which he deduces the matter-work of Annibale, viz. the Farnefe gallery; a work whose uniform vigour of execution nothing can equal but its imbecility and incongruity of conception; if impropriety of ornament were fixed by definition, the subject of that gallery might be quoted as the most decisive instances; the man of sense may admire the splendour, the exuberance, the concentration of powers displayed by Annibale de Caracci, but the man of sense must lament their misapplication in the Farnefe gallery." He died in 1609. Pilkington.

The three Caraccis, of each of whom we have above given a brief account, laid the foundation of that school which has been highly celebrated by the title of the academy of the Caraccis. Young men, who aspired to be great masters, reforted hither for instruction; and they were furnished with well chosen models of men and women, fine calls from the belt figures, from antique statues, and curious bafco-relievos; as well as the most capital designs of the great masters, the most instructive books pertaining to the art, and the lefions of a very noted anatomist, who taught whatever it was necessary to know, concerning the knitting of the bones, and the insertion of the muscles. Among the number of the excellent artists that were formed in this academy, were Guido, Domenichino, Albano, Lanfranc, Guercino, and many others. Pilkington.

CARACCOLI, ROBERT, a famous preacher, was born in 1475 of a noble family at Lecce in the kingdom of Naples. In early life he entered into the order of Minor Observants, and before the 30th year he acquired such reputation for pulpit eloquence, that Pope Nicholas V. dispensed with his obedience to his superior, and allowed him to dispone of himself at pleasure. Hence it has been said that he was less famous for facility of manners than for eloquence. After having been employed in several honourable commissions by the popes Calixtus III. and Sixtus IV. he became first bishop of Aquino, and afterwards of Lecce, where he died in 1495. As a preacher he was highly admired, and regarded as a model, with respect to tone, gesture, and manner, to all the young orators of his time. His sermons, which were adapted to a rude age, and which possess few graces of style, have been collected at different times; but most of them are contained in an edition at Venice, 3 vols. 1492, and at Lyons in 1592. Tiraboschi.

CARACHABAN, in Geography, a town of Persia, in the province of Ardibeizan; 80 miles W. of Tauris.

CARACO, in Zoology, an animal of the rat kind, nearly allied to the Great or Norway rat, described by Dr. Pallas as a native of Siberia. See Mus caracu.

CARACOL, in Architecture, is sometimes used for a stair-case in the form of a helix or spiral.

CARACOL, in Geography, a town of South America, between Guayaquil and Quito.

CARACOL, in the Manege, a motion which a cavalier makes half round; or a half-turn from left to right; changing hands: that his enemy may be uncertain on which side he intends to attack; whether in front or flank. The word comes from the Arabic garagel, and that from the Hebrew carac, incovere: but we have it immediately from the Spanish, where caraco signifies properly a snail, and figuratively the evolution deferred above.

CARACOL, in Military Language, is the half-turn each horseman in an army makes after his discharge, to pass from the front of the squadron to the rear.

CARACOL is also a sort of half wheel, or semicircular movement not only by one horsemans, but by a whole troop of cavalry, by means of which they perform a sort of winding, or serpentine motion, alternately on their right and on their left, in advancing towards the enemy. The object of this movement, or of the caraco, is to disquiet or annoy the enemy, to throw him into disorder or confusion, to conceal from him your intended point of attack, to induce him to divide or break, by distracting his attention, and to seize the favourable moment of falling upon him with advantage. The light horse are peculiarly calculated for this kind of manœuvre and attack. Velocity, indeed, is the principal excellence and very life of cavalry.

CARACOLI, in Commerce, a factitious metal whereof the natives of the Caribbean islands make a kind of ornament, in form of a half-moon, which is called by the fame name. The metal is brought from the Terra Firma; and the common opinion is, that it is composed of gold, silver, and copper; but the mixture is to perfect, that a metal results from the whole which never rules nor tarnishes, how long soever kept, either in the sea or the ground. The English and French goldsmiths have made frequent attempts to imitate it. Those who have succeeded best, use six parts of silver, three of purified copper, and one of gold. But the curious find all the imitations much inferior in beauty to the original metal of the savages.

M. Hauterive, procurator-general of Martinique, makes the caraco to be a compound of gold only with a sort of copper found in the Terra Firma of America. F. Labat takes it for a native, or simple metal. The Americans also make rings, buckles, cane-heads, and the like, of caraco.

CARACOMBO, in Geography, an African island, situated about 15 miles N. of the line, at a short distance N.W. of the island of St. Thomas, and a little above the mouth of the river Gabon. It produces a variety of fruits and plants peculiar to itself, besides birds and animals. It is not uncommon to find a hundred nests of birds floating on the water upon one branch of a tree, or a slender twig, thus guarding themselves against the attacks of serpents and lizards. The island is inhabited, as it is said, by an abandoned, profligate race both of men and women. The latter in particular are so lewd that they are said to prostitute themselves without discrimination and without shame.

CARACORES, in Sea Language, denote light veftals used by the natives of Borneo, and the adjacent islands, and also by the Dutch as guarda-costas in those latitudes. They are high at each end, and chiefly navigated with paddles, in the use of which they fit both within and without board, on narrow platforms of reeds, supported by bars rigg'd out across the veft, and one at the outer end on each side, which serve as balances to prevent its being upset. By placing three or four ranks of rowers on the platform of reeds
CAR

reeds outside, and some within, they can multiply their number so as to proceed with great velocity. They have triple feets of bamboo for a tail, supported by thorns, on which is hoisted an oblong sail, bent to a foot of bamboo yar at the head, and a boom at the foot. The sail is hanked up a little, the yard has a bowline to keep to windward, and a brace or vang that heads aft. The sail rolls up or forth by a winch at the end of the boom. See Plate of Birds.

CARACORUM, or Holin, in Geography, a Tartar village, the position of which is marked, in the map of M. D'Anville and the Chinese Itineraries, about 600 miles to the north-west of Pekin. This village was gradually enabled by the election and residence of the sons and grandsons of Zingis. It contained two streets, the one of Chinese mechanics, the other of Mahometan traders; and the places of religious worship, one Nestorian church, two mosques, and twelve temples of various idols, represent in some degree the number and division of inhabitants. However, a French missionary declares, that the town of St. Denis, near Paris, was more considerable than the Tartar capital, and that the whole palace of Mangou was formerly equal to a tenth part of that Benedictine abbey.

CARACT, or CARAT, in Commerce, a denomination given to an imaginary weight, which expresses the degree of goodnes, finenes, and perfecon, or imperfection of gold. The whole mals is conceived to be divided into twenty-four equal parts, i.e. twenty-four carats; and the purity of the specimen is expressed by the number of carats of pure gold it contains. Thus gold of eighteen carats fine means a compound of $\frac{17}{24}$ths of pure gold, and $\frac{17}{24}$ths of some other metal: gold of twenty-two carats fine contains $\frac{17}{24}$ths of pure gold, and $\frac{17}{24}$ths of alloy; and pure gold is called gold of twenty-four carats fine.

The word is also written carat, carvet, karat, and karat. Its original is conjectured: but we choose to follow Kennet, who derives it from caretia, a term which this author observes anciently denoted any weight, and came not till of later days to be appropriated to that which this expresses the fineness of gold, and the gravity of diamonds. Others, however, derive it from the Arabic kirat, which is a weight half of a "dunck," or grain; of whichfix made up the "dirhem," or Arabic drachm; so that twelve "kirats" were equal to a "dirhem." See the next article.

The mint-men fix the highest purity and perfection of gold at twenty-four carats; and the several degrees are estimated from the divisions hereof, which are called granns: but it is to be observed, that what care ever is taken in purifying gold, to clear it from drans, it can never be brought to twenty-four carats; but full comes short, at least $\frac{1}{4}$ of a carat, or a grain; this grain they call a "fillet"; and this sixteenth they subdivide into two eights; and each of those eights into two sixteenths: on which calculation, they say, gold may be purified as far as the full sixteenth of the second eighth, but no further. Gold of twenty-two carats, is that which has twenty-two parts of fine gold, and two of silver, or other metal; or that which, in refining, loses two parts in twenty-four of its weight. The goldsmiths generally work in gold of twenty-two carats; that being the standard gold of this kingdom. By the laws of France they are prohibited from working in gold below twenty-three carats. In England, the carat is divided into four grains; in Germany, into twelve parts; and in France, into thirty two. The Chinese reckon by touches, a hundred of which correspond to our twenty-four carats. Carat fine, as above, is the twenty-fourth part of the goodness of a piece of pure gold. Carat price is the twenty-fourth part of the value of an ounce or mark of gold. They also sometimes lay, the carat weight, which is the twenty-fourth part of the weight of the ounce or mark. Two two grains make a carat grain.

CARAT is also the weight used in weighing diamonds, pearls, and precious stones; where it confides of four grains. In this sense, the word is by some supposed to be derived from escape, a fruit which the Latins call filipr, and we called banum: each of which may weigh about four grans of wheat: whence the Latin filipa has also been used for a weight of four grains. Blumen, (Appendix to his Travels in Abyssinia, p. 68) deduces it from the name of the bean of the Kama-tree, which is called "Carat." From the gold country in Africa it passed, as he supposes, to India; and there came to be the weight of precious stones, especially diamonds.

The carat by which jewellers estimate the weight of diamonds and pearls, is about $\frac{1}{45}$ of a troy ounce. Jefreyson Diamonds.

Hence the carat is about 3 grans troy.

Carats are divided into halves, quarters, or grains; and farther, into eights, sixteenths, and thirty-two parts. Id. ibid.

CARACTACUS, in Biography and British History, one of the most renowned of the British kings.

Among the proudest defenders of our ancient liberty, scarcely any one seems entitled to such ample notice as Caractacus, the victory over whom was acknowledged even by the conquerors of the world to have been one of the most important for the complete reduction of Britain that had ever been obtained.

What were the circumstances of his early years, or whether his education at all differed from that which was usually beflown upon his countrymen, we have no means to ascertain. The earliest account we hear of him is in the reign of Claudius, when Aulus Plautius, the first Roman general who landed on the island after Jullus Caesar, commanded the expedition against Britain. The Roman commander, it appears, was unapproached at his landing, and having passed through the Britishe fates upon the coast without resistance, pushed forward through the country in quest of those who possessed themselves of arms. This was in the year 43, when, by the direction of his guide, he first overtook and defeated Caractacus.

The spirit of this illustrious chief, however, was not to be subdued at once: and though, in the progress of the Roman arms immediately subsequent to this transaction, we hear but little of Caractacus, we are not to suppose he was otherwise employed than in inspiring his countrymen with the thoughts of vengeance.

Four years after Caractacus had lost the greater part of his dominions Aulus Plautius was recalled. The affairs of the island were left in the hands of the legates or commanders of the legions; and in the interval which occurred till the appointment of Ostorius Scapula as governor, A. D. 50, the Britons were enabled to gain some few advantages. Ostorius having restored the tranquility of the Roman province in the south call parts of Britain, marched against the Ceantis, who inhabited Cheshire, and part of Lancashire, opposite to Ireland: but was soon recalled by the intelligence of an insurrection among the Britains. It was not long, however, before he was called to encounter more determined enemies. These were the Silures, who occupied Herefordshire, Radnor, Brecknock, Monmouth, Glamorgan, and, in general, South Wales, a people naturally brave and fond of liberty, but who, at that juncture, were rendered not only more confident and bold in themselves, but more formidable to their enemies by the valor of their leader. Caractacus, who, as we
have already mentioned, had left the greatest part of his own dominions, willingly put himself at the head of this brave people, to make another effort for the deliverance of his country. He was skilled, we are told, in all the wiles and stratagems of savage warfare; and in point of local knowledge had greatly the advantage of the Roman general. And of this last, indeed, he availed himself by transferring the war into the country of the Orknevers, and by choosing a place for the field of battle, which was every way favourable to his own army, and incommode to his enemies. The spot he chose, in Shropshire, near the confluence of the Culm and Tame, is still called Cararoduc, and will be described under the head of CASTLE. Its ramparts and entrenchments are yet visible; and it exactly answers the description given by Tacitus. It was situated on the ridge of a steep mountain. In some places where the sides were accessible he fortified it with masonry stones, heaped together in the form of a rampart. At the foot of the mountain flowed a river with fords and shallows of uncertain depth. And a balb of men guarded his entrenchments.

The Roman general, observing the depthness of the river, the ruggedness of the mountain, the strength of the ramparts, and the loud acclamity of the enemy, was a little dismayed at such a succession of dangers. As long, says Tacitus, as they fought with misuse weapons, the Britons had the advantage. But when Ostorius ordered his men to advance under a military shield, and level the pile of stones that served as a defence to the enemy, a close engagement followed. The Britons, unable to sustain the shock, retired slowly towards the ridge of the mountain, and were eagerly followed by the Romans. In short, the Britons, being without defensive armour, the legions and auxiliaries made prodigious havoc; and the victory, at last, became decisive. The wife and daughter of Caracatus were taken prisoners; his brother surrendered at discretion; and he himself fled for protection to Cartimandua, the queen of the Brigantes. But adversity, says the Roman historian, has no friends. Cartimandua, who was his step-mother, loaded him with iron, delivered him to the conqueror, and he, with his whole family, were carried prisoners to Rome. Even there the name of Caracatus was in high celebrity: and curiosity was eager to behold the hero who, for nine years, had made a stand against the Roman arms. The emperor too, placed in the vanquished king, he determined to render his entry into Rome as solemn and public as possible; and the people were summoned to behold the spectacle as worthy of admiration. The followers of the Britifh chief, we are told, walked in procession. The military accoutrements, the harness and rich collars, which he had gained in various battles, were displayed with pomp. The wife of Caracatus, his daughter, and his brother, followed next: he himself closed the melancholy train. The rest of the prisoners, truck with terror, defended to mean and abject supplications. Caracatus alone was superior to misfortune. With a countenance still unaltered, not a symptom of fear appearing, no sorrow, no condeemnation, he behaved with dignity even in ruin; and being placed before the tribunal delivered himself in the following manner:

"If, to the nobility of my birth, and the splendour of exalted station, I had united the virtues of moderation, Rome had beheld me, not in captivity, but a royal visitor and a friend. The alliance of a prince, defended from all illustrious line of ancestors—a prince, whose fame extended over many nations, would not have been unworthy of your choice. A reverie of fortune is now the lot of Caracatus. The event to you is glorious, and to me humiliating. I had arms, and men, and horses; I had wealth in abundance; can you wonder that I was unwilling to lose them? The ambition of Rome aspires to universal dominion: and must mankind, by consequence, stretch their necks to the yoke? I stood at bay for years: had I acted otherwise, where, on your part, had been the glory of conquest, and where, on mine, the honour of a brave resistance? I am now in your power: if you are bent on vengeance, execute your purpose; the bloody scene will soon be over, and the name of Caracatus will sink into oblivion. Preferve my life, and I shall be to late posterity a monument of Roman clemency."

Claudius, it is enough to say, charmed with the boldness of his prisoner, pardoned both Caracatus and his family. The subsquent events of the Britifh chief's life had no historian to pen them. And here we are obliged to close his history.

The speech of Caracatus, which is here translated literally from Tacitus's Annals, was finely used by Mr. Mafon, in his celebrated dramatic poem. For the sake of epitical incidents, however, he has departed from the strict line of historical truth; and has transferred the honour of taking Caracatus prisoner, and sending him to Rome, from Ostorius to Aulus Didius. Tacit. Annal. i. xii. c. 35, et seq.

CARACTERE, Fr. as a dancer, à demi-charratere, in a style neither grotesque nor terre à terre; neither wholly comic nor serious.

CARADIVA, in Geography, an Asiatic island, near that of Ceylon, at the western point of the kingdom of Jaffnapatan: called by the Dutch Amrderam.

CARAGA, in Ancient Geography, Rugga, a town of Africa, 2 leagues S.S.E. of Tidus, mentioned by Ptol.emy.

CARAGACH, in Commerce, a cotton that comes from Smrna, by the way of Naficks.

Gen. Ch. Cal. one-leaved, bell-shaped-cylindrical, deeply divided on one side, with five short teeth. Cor. papilionata, standard egg-shaped, half erect; the sides folded upwards; wings oblong; keel straight, oblong, obtuse. Stam. filaments ten, diadelphous. Fil. germ superior, oblong, smooth; style straight; stigma smooth, truncate. Peric. legume oblong, inflated, smooth. Seeds four to fix, egg-shaped, a little globular, not compressed.

Eff. Ch. Calyx five-toothed. Stigma smooth, truncate. Legume oblong, almost cylindrical. Seeds nearly spherical. 1.3 March has formed this genus for some plants which Linnaeus referred to robinia. but which differ from its genuine species, both in the fructification and general habit. Their stigma is smooth, not downy; their legume nearly cylindrical, not compressed, and their seeds not flattened, as in robinia. Their leaves, moreover, are generally abruptly pinned, and the petioles often elongated, terminating in a thorny point.

CAR

an odd leaf, but nevertheless evidently extended beyond it: the leaflets in the second year becoming a pair of short, spreading spines. Flowers yellow, filiform. *Leguminosae* an inch and half long, smooth, rather cylindrical, pointed. A native of Siberia. It grows best in a light, sandy soil, and is not injured by severe cold. Its leaves are good fodder for cattle, and are laid to produce a blue colouring matter.

2. *Carpinus betulus*, Linn. *Leaves* in six pairs, roundish, mucronate, mucronate; the leaflets filiform; leaflets simple, fleshy, but in pairs, two or three feet high. Leaves alternate, abruptly winged. *Flowers* yellow, axillary, solitary: peduncles slender long. A native of Siberia. 

3. *Carpinus betulus*, Linn. *Leaves* in eight pairs, roundish, mucronate, mucronate; the leaflets filiform; leaflets simple, fleshy, but in pairs, two or three feet high. Leaves alternate, abruptly winged. *Flowers* yellow, axillary, solitary: peduncles slender long. A native of Siberia.

4. *Carpinus betulus*, Linn. *Leaves* in four pairs, roundish, mucronate, mucronate; the leaflets filiform; leaflets simple, fleshy, but in pairs, two or three feet high. Leaves alternate, abruptly winged. *Flowers* yellow, axillary, solitary: peduncles slender long. A native of Siberia. On account of its long, tough branches, and large thorns, it is well adapted to make an impenetrable hedge; and, as it is covered with flowers near the whole of the summer, it is at the same time a very ornamental plant. It has the additional recommendation of being hardy, and able to bear the winters of our climate without injury. 

4. *Carpinus betulus*, Linn. *Leaves* in four pairs, roundish, mucronate, mucronate; the leaflets filiform; leaflets simple, fleshy, but in pairs, two or three feet high. Leaves alternate, abruptly winged. *Flowers* yellow, axillary, solitary: peduncles slender long. A native of Siberia. On account of its long, tough branches, and large thorns, it is well adapted to make an impenetrable hedge; and, as it is covered with flowers near the whole of the summer, it is at the same time a very ornamental plant. It has the additional recommendation of being hardy, and able to bear the winters of our climate without injury. 

CARAGAS, in Geography, a province of Mindanao, in the Earl Indies, situate on the easterly coast, between Subago and the Cape of St. Augustinum, which it north and south. The town of Caraga on this coast is a large town, and the principal trading port of the province. It is situated on the coast of Mindanao, and is the chief town of the province. It is the seat of the government of the province, and is the principal trading port. The inhabitants of Caraga are a warlike people, and are accounted very brave, when employed either by sea or land.

CARAGI, in Commerce, a name given to duties paid at the custom-house in the territories of the grand signor, on the importation or exportation of goods. The term is also applied to the officers of the custom-house, who collect these duties.

CARAGLIA, in Geography, a town of Piedmont, in the province of Coni; 5 miles N.W. of Coni.

CARAGNA, or CARAGNA, in Pharmacy. See CARAGGA.

CARAGROUCH, a silver coin of the empire, weighing nine drams, which does not quite amount to a French crown, of three livres Tournois. At Constantinople it goes at 120 sijors. There are four sorts of them, equally current, and of the same value.

CARAGUATA, in Botany, Plumb. gen. 10. See TILANDSIA.

CARALISSAR, in Geography. See APHIMON CARALISSAR.

CARAHISSAR. See CARAHISSAR.

CARAIOS, CAIROS, or KAIRIHOS, in Zoology, according to Mearcgrave, Pfan, and some other authors, the Brazilian name of the Virginia opium. See DIPLOPUS ODYSSEUM.

CARAIRPA, in Botany, Linn. Enc. Juffieu 434. A tree Guiana 531. a genus imperfectly known. Cliffs and order, polyandra monogyne. Cal. Perianth deeply divided into five round segments. Cor. unknown. P. Geran superiour. Peric. Capsule somewhat woody, rather three fixed, acute, and recurved at its summit, three-celled, opening from the summit to the base with three permanent valves. *Seeds* one in each cell; angular on the inner, convex on the outer side, attached to a large three-winged receptacle, which unites with the valves, forms the partitions of the cells.

Sp. 1. *C. parvifolia*, Aubl. tab. 223, fig. 1. "Leaves egg-shaped, acute, white with down underneath." A tree from fifteen to twenty feet high, much branched near the top.

3 R 2 Branches
Branches reddish. Leaves alternate, petioled, entire; ribs two, opposite, caducent. Flowers in terminal clusters; capsules hairy. 2. C. longifolia, Asl. tab. 223, fig. 2. "Leaves oblong, egg-shaped, scate, grey underneath." A larger and thicker tree than the preceding. Leaves eight inches long, and three broad. 3. C. leucoilis, Asl. tab. 224, fig. 3. "Leaves broad-egg-shaped, acuminate, dark-red underneath." 4. C. angustifolia, Asl. tab. 224. fig. 4. "Leaves long, egg-shaped, acuminate, white underneath." Leaves with more numerous lateral nerves, ten inches long, and two and a half broad. All the species are found in the forests of Guiana. The second is called caripe by the natives.

CARAITES, or CARAITES, כאריאטס, כאריאיטס, to read, a sect among the ancient Jews: wherever there are still some branches subsisting in Poland, Russia, Conantinople, Cairo, and other places of the Levant; though few or none are to be found in these western countries. About the middle of the 10th century, a particular account was taken of their number; which in Poland was 2000; at Cairo, 10000; at Damascus, 200; at Jerusalem, 30; in Babylon, 100; in Persia, 600; amounting in the whole to 15,250, and being a small number compared with the Rabbinists. It is their distinguishing tenet and practice to adhere closely to the words and letter of the Scripture, (as their name imports) exclusive of allegories, traditions, and the like.

Leo of Modena, a Rabbin of Venice, observes, that of all the heresies among those people, before the destruction of the temple, there is none now left but that of the Caraim, a name derived from mira, which signifies the pure text of the Bible; because of their keeping to the Pentateuch, observing it to the letter, and rejecting all interpretations, paraphrases, and constitutions of the Rabbinists. Aben Ezra, and some other Rabbinists, treat the Caraites as Sadducees; but Leo de Judæa calls them, more accurately, Sadducees reformed; because they believe the immortality of the soul, paradise, hell, resurrection, &c. which the ancient Sadducees denied. He adds, however, that they were doublets originally real Sadducees, and sprung from among them.

M. Simon, with more probability, supposes them to have risen hence; that the more knowing among the Jews, opposing the dreams and reveries of the Rabbinists, and using the pure texts of Scripture to refute their groundless traditions, had the name of Caraim given them; which signifies as much as the barbarous Latin, Scripture, i.e. people attached to the text of Scripture. The other Jews give them the odious name of Sadducees, from their agreement with those sectaries on the head of traditions. The real fact seems to have been, that the traditional law was opposed, as a corruption of the true religion, by a numerous body, who strenuously asserted the sufficiency and perfections of the ancient written law, explained in its literal sense. Among these were the Sadducees. But it is very probable, that the Sadducean tenets were highly offensive to many pious men, who nevertheless were not disposed to join those who received the traditional institutions. These, adhering simply to the letter of the Mosaic law, but at the same time refusing to adopt the doctrine of the Sadducees, would of course become a separate sect, which would be distinguished by some name expressive of their leading principle. It is not improbable that the opposite party gave them, in derision, the name of Scripture, or Caraites. Hence we may conclude, that this sect arose at the same time with those of the Sadducees and Pharisees. From the Jewish records it may be inferred, that this sect existed in the time of Hyrcanus. Accordingly it has been said, that upon the divisions between Hillel, the president of the Sanhedrin, and Shammay the vice-president, about 39 years before Christ, their respective scholars formed two parties, and took different names. Those who adhered to Scripture only were called Caraim, or Scripture, and were followers of Shammay; and those who were zealous for the traditions taught by the Scribes, or Rabbinists, were called Rabbinists, Sadducees, and were followers of Hillel. The Caraites jealously guarded the high antiquity of their principles, as being the followers of Moses and the prophets, in opposition to human tradition; but when the doctrines of the Rabbis were generally adopted among the Jews, the Caraites were considered as schismatics. Scaliger, Volusius, and Spanheim, erroneously, rank the Caraites among the Sabains, Magi, Manichees, and Muffilben. Wolfang, Fabricius, &c. say, the Sadducees and Eicheni were called Caraites, in opposition to the Pharisees; others take them for the doctors of the law, who were mentioned in the gospel: and in favour of this conjecture, has been alleged a tradition preferred in the Jerusalem Talmud, that there wereJerusalem, 480 synagogues, each of which had a separate apartment for the law, and another for the Talmud, or traditionary records: whence it has been inferred, that the Scripture the Rabbis were a party distinct from the Traditionaries. The Scribes, whose office it was to expound the law, from the manner in which they are usually mentioned in the New Testament, in conjunction with the Pharisees, may be concluded to have adopted, in their interpretations, the allegorical method of the Traditionaries and Cabbalists, and therefore to have commonly belonged to their party. Josephus and Philo make no mention of them; whence it is inferred, that they were more modern than either of those authors. Perhaps, this sect was not formed till after the collection of the second part of the Talmud, or the Geonica; or not till after the compiling of the Mishna.

The Caraites themselves pretend to be the remains of the ten tribes led captive by Shalmaneser. Wolius, from the memoirs of Margtheus, a Carate, refers their origin to a massacre among the Jewish doctors, under Alexander Januarius, their king, about one hundred years before Christ: because Simeon, son of Schetchach, and the queen's brother, making their escape into Egypt, there forged his pretended traditions; and, at his return to Jerusalem, published his visions, interpolating the law after his own fancy, and supporting his novelties on the notices which God had given. He communicated by the mouth of Moses, whose deposition he was: he gained many followers; and was opposed by others, who maintained, that all which God had revealed to Moses was written. Hence the Jews became divided into two sects, the Caraites and Traditionaries: among the first, Juda, son of Talbait, distinguished himself: among the latter, Hillel. Wolius reckons not only the Sadducees, but also the Scribes, in the number of Caraites. But the addresses of the Pharisees prevailed against them all; and the number of Caraites decreased: and they long remained in obscurity. At length, about the year of our Lord 750, Anan, a Babylonian Jew, of the race of David, and Sahl his follower, both men of learning, publicly disclaimed the authority of the traditionary doctrines of the Talmud, asserted the Scriptures to be the sole rule of faith, and became heads of the Caraites, or Scripture, who again grew into repute, and increased in numbers. To this later period some have ascribed the rise of the Caraites. See Mafle's Hebrew Grammar, vol. ii. p. 10. But from the history of the Rabbi Anan, who incurred great obloquy from the Pharisaical Rabbis for his heresy, it clearly appears, that he was not the author, but the reformer of the Carata sect. Rabbi Schalomon, in the ninth century, maintained its credit; and among other persons well skilled in the Jewish law, who adhered to it, we may mention Abu-Alpharens, who lived in Palmyra, and
wrote a commentary upon the Pentateuch, which added so much strength to the interest of the Caraites, that the traditional party thought it necessary to implore the affiance of the civil magistrate. Notwithstanding this, however, they continued to hold their assemblies, and published, though in a declining state.

The Caraites are but little known; their works coming only into very few hands, even among the greatest Hebraists. Buxtorf never saw more than one; Selden two; but Mr. Trigland says, he has recovered enough to speak of them with assurance. He affirms, that even after the prophets had ceased, the Jews became divided on the subject of works, and supererogation; some maintaining their necessity from tradition; whilst others, keeping close to the written law, set them aside; and it was from these last that Caraitism commenced. He adds, that after the return from the Babylonian captivity, the observation of the law being to be re-established, there were several practices found proper for that end; and these, once introduced, were looked upon as essential, and appointed by Moses; which was the origin of Pharisaism; as a contrary party, continuing to keep close to the letter, founded Caraitism.

The modern Caraites, Leo of Modena observes, have their synagogues and ceremonies; they pretend to be the sole proper Jews, or observers of the laws of Moses: calling the rest by the term Rabbanim, or followers of the Rabbinus: these hate the Caraites mortally; refusing to ally, or even to converse with them, and treating them as mamzerim, or bastards; because of their rejecting the constitutions of the Rabbinists relating to marriages, repudiations, purifications of women, &c. This aversion is so great, that if a Carait would become a Rabbinit, he would never be received by the other Jews.

The Caraites, however, do not absolutely reject all kinds of traditions; but only such as do not appear well grounded. Selden, who is very express on this point, in his " Ux. or Hebraica," observes, that besides the mere text, they have certain interpretations, which they call heretitical, and which are proper traditions. Their theology only seems to differ from that of the other Jews, in that it is purer and clearer of superstition: they give no credit to the explications of the Talmud, the rabbinical allegories, nor to any constitutions of the Talmud, but what are conformable to the Scripture, and may be drawn by it from just and necessary conclusions.

Peringer observes of the Caraites in Lithuania, that they are very different, both in aspect, language, and manners, from the Rabbinitis, wherewith that country abounds. Their mother tongue is the Turkis; and this they use in their schools and synagogues. In times they resemble the Mahometan Tartars. Their synagogues are placed north and south; and the reason they give for it is, that Shalmanezer brought them northward; so that in praying, to look to Jerusalem, they must turn to the south. He adds, that they admit all the books of the Old Testament; contrary to the opinion of many of the learned, who hold that they reject all but the Pentateuch.

Caleb, a Carait, reduces the difference between them and the Rabbinitis to three points: 1. In that they deny the oral law to come from Moses, and reject the Cabbala. 2. In that they abhor the Talmud. 3. In that they observe the feasts, as the sabbaths, &c. much more rigorously than the rabbins do. To this may be added, that they extend the degrees of affinity, wherein marriage is prohibited, almost to infinity. Their diverging tenets may be summed up in the following particulars: that there is no other rule of faith and worship besides the writings of Moses and the prophets; that all oral traditions, and all allegorical and mythical interpretations of the law are to be rejected; that all material beings were created by an incipient Deity, of whom no resemblance can be found in any thing which he has made; that he knows all things, and exercises a constant providence over all his works; that the human mind is subject to divine influence, but at the same time remains free in its opinions; that true piety takes away guilt: that after death, the soul, if it be worthy, ascends to the intellectual world, to live there for ever; but if it be guilty, it is confined to a state of pain and ignominy: that God alone is to be worshipped; and that faiths are to be freely observed. The present adherents of this fact are said to observe the moral precepts of their law more strictly than their brethren, the Pharisaic Rabbinites, with whom, nevertheless, they are thought unworthy of ecclesiastical communion. Upon the whole, the Caraites are universally reckoned men of the first learning, of the greatest piety, and of the purest morals of the whole nation.

CARALIA, in Ancient Geography, a town of Asia, in Pamphylia.

CARALIS, or CARALES, now Cappad. a town of the island of Sardinia, the capital, according to Florus, pilagado by Grecchius. It was of Phoenician foundation, according to Pausanias, and had the right of Roman citizenship, according to Pliny. Proclo mentions a promontory and gulf of the name of "Carallis."

CARALIS, or CARALLIS, an episcopal town of Asia in Iuliaea, according to Steph. Byz. or, according to the Notitia, in Pamphylia.

CARAMAN, in Geography, a town of France, in the department of the Upper Garonne, and chief place of a canton in the district of Ville-Franche; 5 leagues E.S.E. of Touloufne. The place contains 2,392, and the canton 9,161 inhabitants; the territory includes 1521/2 kilometres and 20 communies.

CARAMANGCE, in Commerce, a drug which comes from China. The Tonicynule value it very much.

CARAMANIA, in Geography, one of the divisions of Asia Minor, now a province of Turkey in Asia, situate on the fothernmost part, and extending from north to south along the Mediterranean coast, which is its southern boundary. It formerly comprehended the ancient countries of Lycia, Pamphylia, Paphloua. Lycaonia, Ifuria, Cilicia. part of Phrygia, Galatia, and Cappadocia. The Turks call the whole province Caraman-bik. Its capital is Satha. This province anciently belonged to the Caramanian princes, and was the last that submitted to the arms of the Ottomans, about the year 1488. Caramania may be divided into Greater and Lesser; the former comprehending all that part which lies to the north of mount Taurus, and the latter that part which lies southward along the coast. The coast of Caramania is for the most part mountainous, and above these high mountains it is not uncommon to see, in clear weather, a very small black cloud, no bigger than a bird. This globe of vapours is subject to great agitation; at first it is very small, then suddenly spreads, contracts, appears and disappears at intervals above the mountain, and changes its form every instant. How calm forever the atmosphere may be, a sudden and violent squall may be expected at the fight of these inflated clouds, which discharge the wind with so much rapidity and vehemence, that if a ship be not prepared to be overtaken by it, she runs a great risk of losing part of her
CARAMANICA, a town of Naples, in the province of Avellino.

CARAMANITA, a province of Terra firma in South America. Living on the river Guana, bounded N. by the district of Carthagena, E. by New Granada, and S. and W. by Popayan, in the audience of Sta. Fe. It is a valley surrounded by high mountains; and the natives extract from its waters very good salt. The capital, of the same name, lies in N. lat. 5% 18'; W. long. 72° 53'.

CARAMBIS, in Ancient Geography, a promontory of Asia Minor, in the most northern part of Galatia, according to Ptolemy, and, according to Sallust, between Heraclea and Phaphagonia; now "Capo Tifello."—Allo, a town of Asia in Phaphagonia.

CARAMBUI, Rhed. Mal. 2. 55. See Jussiensa suffruticosa.

CARAMNASSA, in Geography, a river of Hindoostan, which runs into the Ganges, near Buxar, in the country of Benares.

CARAMOUSSAL, in Naval Architecture, a Turkish vessel, having a very high stern, and rigged nearly like a ketch; that is, it has main and mizen masts and bowprit, but neither foremast nor top-gallant masts.

CARAMUEL De Llorowitz, John, in Biography, was born at Madrid in 1666; and having entered into the Cistercian order, he polished various church preferments in the Low Countries and in Germany, and at length became grand vicar of cardinal Harrach, archbishop of Prague. But suddenly abandoning the church, he allowed the military profession, and in this capacity commanded a company against the Swedes, and acted as engineer and superintendent of the fortifications in Bohemia. He then resumed his former ecclesiastical character; and was successively bishop of Koniggratz in Bohemia, of Campagna in Naples, and of Vigevano in the Milanese, at which latter place he died in 1681. His works are numerous, and indicate a singular genius; and it was said of him, that he had invention in the eighth, or highest degree, eloquence in the fifth, and judgment in the second. His "Essay on Syllogistic Grammar," was published at Brussels in 1642; and his "Daring or Asurdious Grammar," at Frankfort in 1654. He wrote a large volume on the architecture of the temple of Solomon; and published at Vigevano a work, entitled "Apostolicae, i.e. Subtilissimus, vel Nova Dialectico-Metaphysica," distinguished more by subtlety than by clarity and sound sense. He was a irrefragable defender of the doctrine of probability, and also of the infallibility of the pope. His theological writings that have been printed, amount to 7 vols. fol. Nowel. Dict. Hill.

CARAN, in Geography, a river of England, which runs into the Avon at Tewksbury in Gloucestershire.

CARANA, in Ancient Geography, a town of Asia, in the Greater Armenia, which, according to Strabo, gave its name to the province "Caranitis." Steph. Byz. places Carana, which he says was built by the Romans, and also Caranitis, in Galatia.

CARANASI, in Botany, Rumph. Auct. 5. 49. See Capparis clypeata.

CARANDA, a genus established by Gurtner for a kind of palm, described by Rumphius, the fruitation of which is imperfectly known. Spadix and spadix not known. Col. coromandel., three-leaved. Cor. none. Peric. none. Seed superior, naked, pedicelled, airded singly, or two or three together, to the base of the calyx. It is called, in the island of Ceylon, Ghikarande, which means the flanne kharande, to distinguish it from another kharande, or carandas, which Gurtner thinks is a species of Randas; but, in his opinion, even a blind man may see that the seed described by him belongs to the family of palmas. Linnæus refers a Carandas of Rumphius to his Carissa carandas.

CARRANGAS, in Geography, a province and jurisdiction of South America, belonging to the archbishopric of Paita, which begins 20 leagues W. from the city of Paita, and extends above 50 leagues. The climate of this province is so cold that it is barren in corn and grain, &c. but it abounds in cattle. Here are a great number of silver mines constantly worked, among which that called Turco is very remarkable for a fort of ore termed by miners Machacado; the fibre of the silver forming an admirable intertexture with the flanne in which they are contained. Such mines are generally the richest. There are others found in the barren sandy deserts extending towards the west of the South Sea; in which are found, by digging in the sands, detached lumps of silver, not mixed with any ore or flanne, beside which adheres in some parts to the metal. The lumps are called "Papas," because they are dug out of the ground like that root; and they have the appearance of melted silver; which proves that they are formed by fusion. The size and figure of these lumps are very different, weighing from 2 to 60 and 150 marks; these last being a Paris foot in length. Juan and Ullon's Voyage to S. America, by Adams, vol. ii. p. 151.

CARANJA, an island in the Indian sea, near the Corcan coast; 8 leagues S. of Bombay. N. lat. 18° 55'. E. long. 72° 44'.

CARANNA, in Commerce, a hard, brittle, resinous gum, brought from some parts of the West Indies, as Carthagena and New Spain; of an aromatic flavour; and sometimes used in medicine as a cephalic.

The trees from which it runs, are like the palm-tree. When it is fresh, it is white; but as it grows stale, it becomes greyish inclining to green, in which condition it is sent to Europe, where the white is seldom to be met with. It is brought in lumps wrapped up in leaves. To be of the best quality, it must be soft, of a pleasant aromatic smell, and as white as snow. As this gum is very dear, it is seldom sold unadulterated; and other sorts are often substituted in its stead, which have not the same properties. When applied to the head, it has an extraordinary virtue to relieve it from pain; which renders it highly valuable. It produces the same effects in the joints; and is so much esteemed in medicine, that it is become a proverb in pharmacy to say, Whatever the tacanibaca has not cured, the caranna will.

The Americans make a balm of it, which they pretend to be a sovereign remedy for the cure of wounds, and the hemorrhoids or piles.

CARANUS, in Ancient Geography, was, according to Strabo, the port of Aradus, situated in Syria, 7 leagues S.W. of Paltus.

CARANUSCA, a town of Belgic Gaul, occupying, as d'Anville thinks, the spot now called "Garfels," between Metz and Treves.

Gen.
Gen. Ch. Col. perianth four-cleft. Cor. petals four; neotany cylindrical, eight-toothed, bearing the stamens. Stam. eight. Pet. germ superior; style none; stigma large, falcate-shaped. Pericarp capsule one-celled, four-valved. Seeds numerous, angular, of various shapes, of a solid white subflaccid, covered with a reddish, coriaceous skin, united together in an egg-shaped mass, which entirely fills the capsule. La Marec. Willd. with the abundance of La Marec's figure.

Sp. 1. C. squamosa, Aubl. Guian. Supp. p. 14, tab. 387, Lam. Ill. Pl. 701. (Perfornia guareoides, Willd.) "Leaves in numerous pairs, oblong, acuminate." A tree fifty or eighty feet high, three or four feet in diameter. Leaves three feet long, alternate, abruptly winged; leaves large, entire, smooth, sometimes in not less than nineteen pairs. Flowers in compound racemes. A native of Guiana, where a thick bitter oil is expressed from the seeds, with which the inhabitants make themselves as a security against the bite of insects. Excellent meals for ships are made of the trunk. 2. C. melicoca, Lam. Enc. (Granatum littorum five martials, Rumph. Amb. t. 92, tab. 61.) "Leaves in about three pairs, acutely egg-shaped." A tree smaller than the preceding, sometimes producing two or three flews from the same root. Leaves four or five inches long; leaves smooth. Flowers, according to Rumphius, dioecious, yellowish, small, falcate, in compound, axillary racemes. Fruit large, containing from twelve to twenty seeds, similar to those of the preceding species.

As two other genera have been named in honour of Peron, one from New Holland, by Dr. Smith, and another from North America, by Michaux, we have retained the original name given by Aublet, though it must be acknowledged to be exceptionable, on account of its resemblance to Carapa, another of Aublet's genera.

CARAPACE, the thick, solid, firm shell, which covers the turtle or tortoise; and to which adheres those fine transparent scales, which are known under the name of tortoise-shell, of which snuff-boxes and several sorts of inlaid work are made.

CARAPALLA, in Geography, a river of Italy, in the kingdom of Naples, and province of Capitanata, which runs into the Adriatic; 9 miles S. of Manfredonia.

CARAPANATUBA, a river of Guiana, which empties itself into the Amazon, at about one third of a degree of the equator above fort Macapa. By the treaty between France and Portugal, 26th September 1811, it was concluded that the boundaries of French and Portuguese Guiana shall be determined in future by that river. These limits shall follow the course of the river to its source, whence they shall take a direction to the grand chain of mountains which divides the two rivers, and follow the windings of that chain to the point nearest to Rio Branco, between the second and third degree N. of the equator.

CARAPE, in Ancient Geography, a town of AΣα, in the interior part of the Lesser Armenia, towards the mountains. Ptolemy.

CARAPICHEA, in Botany, Aubl. Guian. See CALLICOCCA CARAPICHEA.

CARAPITO, in Geography, a town of Portugal, in the province of Beira; 4 leagues N. of Pincel.

CARAPÓ, in Ichthyology, a fish described by Marcegrave, of which he says there are two kinds, the first having a long and thin body, like a knife-blade; with the back thick, the belly very thin and narrow, and the tail pointed; the second narrower in proportion to its length, and without spots. The head of both is flat and pointed, and the lower jaw runs out a little farther than the upper. The latter character seems to prove that these fishes are varieties of Gymnurus fasciatus, rather than of Gymnurus carapó, as some writers imagine. Gmelin considers the Carapó of Marcegrave as his Gymnurus carapó, which cannot be the fact if we may depend on Marcegrave, the Gmelinian fish of that name having the upper jaw longest instead of the lower one. See Gymnurus carapó, and fasciatus.

CARARA, in Botany. Pfl. Bras. tab. 241. See AMARANTHUS VIRENS.

CARARA, in Commerce, a weight at Leghorn, and in other parts of Italy, used in the sale of wool and cod-fish, equivalent to sixty pounds of that country.

CARAROS, or CARAKUS, in Ancient Geography, a town of Africa Propria, in the vicinity of Targaron.

CARASCHULLI, in Botany. Rheed. Mal. 2. tab. 47. See BURLERIA BAXIFLORA.

CARASCOF, in Geography, a town of Poland, in the patitance of Kiov, 34 miles W. of Bialaerkiew.

CARASOU, a town of Lesser Tartary in the Crimea, once very populous, but burnt by the Russians in 1737.—Alfo, the name of two rivers in Turkey, one of Taurinum, in Caramania, the other in Romania.—Alfo, the name of a lake, being part of the canal which forms the most southerly mouth of the Danube, called by the Turks "Carakimen."

CARASSIUS, in Ichthyology, a species of CYPHRUS, which inhabits the fresh waters of Europe; CYPHRUS of Marf. Danub. supposed by some to be the same with the Rud of English writers. See CYPHRUS CARASSIUS. Obs. Among the old writers carassius was considered as a kind of generic name for the carp, bream, &c.

CARASYRA, in Ancient Geography, one of the forts of Trehe, erected by the emperor Justinian in the province of Rhodope.

CARAT. See Caract.

CARATAE, in Ancient Geography, the name of a people who formed part of the ancient Jace, and who inhabited the coast of the Cappian Sea, on the banks of the Jaxartes.

CARA-TARTARS, in Geography, or black Tartars, a people of Asia; formed by a body of Turks, incorporated by Kult-khan the grandson of Gengis-khan in his army, when he was sent to Iran by Mangou-ches, his brother, emperor of the Moguls. They now occupy the countries of Gara and Touran in Asia.

CARATCHOLIS, a people of Asia in Georgia, N. of mount Caucasus. They are also called "Karakhins" and black Circassians.

CARATING, in Chemistry, a term used to denote the mixture or combination of gold with other metals. Thus, "red carating" expresses the mixture of gold with copper, to distinguish it from the less usual one, made with silver, and denominated "white carating," and also in contradistinction to the "mixed carating" or combination of gold, silver, and copper. The degree of this combination or alloy is expressed by carats and grains. See Caract.

CARATTERE, Ital. character. A musical term, in speaking of a long of two strains; aria di due caratteri; of which the first is generally cantabile, and the second bravura. See Cantabile and Bravura.

CARAVACA, or St. Cruz de Caravaca, in Geography, a town
CARAVAG, a river of Peru in South America, famous for its golden sands.

CARAVAGGIO, in Biography. See Angelo Ameri.

CARAVAN, or Caravanne, in the east, a troop or company of travellers, merchants, and pilgrims, who, for their greater security march in a body through the deserts, and other dangerous places, infected with Arabs and robbers.

The word comes from the Arabic caravan, or caroan; and that from the Persian kerwan, or caroon, negociator, trader, or dealer. Vide. Perif. Itin. Mund. ed. Hyde. p. 67.

There is a chief, or aga, called "caravan-bachi," who commands each caravan, and has under him a number of janizaries, or other forces, sufficient for their defence. The caravans encamp every night near wells, or rivulets known to the guides; and observe a discipline as regular as in war. They chiefly use camels for their vehicles, because of their enduring much fatigue, eating little, and paddling three or four days without drinking.

In this manner trade was carried on, particularly by the nations near the Arabian gulf, from the earliest period to which historical information reaches. See Camel.

The grand fignior gives one fourth part of the revenue to Egypt, to defray the expense of the caravan that goes yearly from Cairo to Mecca, to visit Mahomet's tomb: the devotees, in this caravan, are from 40,000 to 70,000; accompanied with soldiers to protect them from the pillage of the Arabs, and followed with 8 or 9,000 camels loaded with all necessary provisions for so long a passage across deserts.

There are two regular caravans which go yearly to Mecca; the first from Damascus, composed of the pilgrims from Europe and Asia; the second from Cairo, for the Mahometans of Barbary.

Damascus is the grand rendezvous for all the pilgrims from the north of Asia, as Cairo is for those from Africa. Besides the natives of Aleppo who go to Mecca, numbers from Persia and the northern provinces assemble in that city in their way to Damascus, for which place the caravan sets out immediately after the Iftar Bairam. When the caravan sets out from Aleppo, it is conveyed for a few miles by the governor and grandees in procession, and many of the pilgrims being accompanied still farther in their way by their women and kindmen, all is in commotion on the road to Damascus for several days after the Bairam. However, the number of pilgrims who go from Aleppo to Mecca is said to be much less considerable now than formerly. This probably is owing in part to the decaying spirit of Mohammedi, but more to the decline of the trade with Mecca; for it was usual with the merchants, formerly, to make the journey several times in their lives, and the caravans were accustomed to return laden with Indian and Arabian merchandize. After the junction of the caravans from other towns at Aleppo, it proceeds to Damascus; and the number of pilgrims every year is said to amount to from 50 to 60,000; many of them repair hither four months before the time, but the greatest number only at the end of the Ramadam. Damascus then replenishes an immense fair; nothing is to be seen but strangers from all parts of Turkey, and even Persia; and every place is full of camels, horses, mules, and merchandize. At length, after a preparation of some days, this vast multitude set out confederally on their march, under the conduct of the bashaw or pacha of Damascus, and, travelling by the confines of the desert, arrive in 40 days for the festival of Bairam at Mecca; the distance between the two cities being, according to the most moderate estimate, above a thousand miles. As this caravan traverses the country of several independent Arabs, it is necessary to make treaties with the Bedouins, to allow them certain sums of money, for a free passage, and to take them for guides. On this subject frequent disputes occur between the Schiks, of which the pacha avails himself to make a better bargain; but in general the preference is given to the tribe of Sirda, which encamps to the south of Damascus, along the Hauran: the pacha sends to the Schiek a mace, a tent, and a pelisse, to dignify that he takes him as his chief conductor. From this moment it is the Schiek's business to furnish camels at a slanted price; these he hires likewise from his tribe and his allies: the pacha is responsible for no damages, and all losses are on his own account. On an average, 10,000 camels perish yearly; which form a very advantageous article of commerce for the Arabs. It must not be imagined that the sole motive of all the expenses, risks, and fatigues, incurred by the pilgrims, is devotion. Preliminary interest has a considerable share in these expeditions, and, indeed, permission to trade, during the pilgrimage, is granted by the Kuran, chap. ii. p. 23. The caravans afford the means of engrossing every lucrative branch of commerce; and almost all the pilgrims convert it into a matter of speculation. On leaving their own country, they load themselves with merchandize, which they sell on the road; the specie arising from this, added to what they have brought with them, is conveyed to Mecca, where they exchange it for muffles and Indian goods from Malabar and Bengal, the shawls of Cashmire, the shoes of Tonquin, the diamonds of Golconda, the pearls of Bahrain, pepper, and a great quantity of coffee from Yemen. Sometimes the Arabs of the deserts deceive the expectation of the merchant, by pillaging the fraggles, and carrying off detached parties of the caravan. Of the predatory spirit of the Arabs it is a singular proof, that although all their independent tribes are zealous Mahometans, yet they make no scruple of plundering the caravans of pilgrims, while engaged in performing one of the most indispensable duties of their religion. A remarkable instance of this occurred in the year 1777; when 60,000 pilgrims were plundered and dispersed over the desert, a great number destroyed by sword or famine, women reduced to slavery, immense riches lost, and above all, a solemn act of religion sacrilegiously violated. This produced a commotion in the empire, which was not soon forgotten. The plundering Arabs were the allies of Daher, who received them at Cacce, and there permitted them to sell their booty. The Porte, indeed, loaded him with the bitterest reproaches, but he endeavoured to extenuate himself, and to appease the Divan, by sending the white banner of the prophet to Constantinople. In general, however, the pilgrims arrive safe; and in this case their profits are very considerable. At all events they are recompensed in the veneration attach'd to the title of "Hadj," or "Haggy," (pilgrim); and by the pleasure of bustling to their countrymen of the words of the Caaba (See Taaba) and mount Arafat; of magnifying the prodigious crowds of pilgrims, and the number of victims, on the day of the Bairam; and by recounting the dangers and fatigues they have undergone, the extraordinary figure of the Bedouins, the desert without water, and the tomb of the prophet at Medina.

By means of this caravan, Damascus becomes the centre of a very extensive commerce. By Aleppo the merchants of
CARAVAN.

of this city correspond with Armenia, Anatolia, the Dinarbekir, and even with Persia. They send caravans to Cairo, which, following a route, frequented in the time of the patriarchs, take their course by Djefr-Yakoub, Tahbara, Nahous, and Gaza. In return they receive the merchandize of Constantinople and Europe, by way of Saide and Baitout. The home consumption is balanced by silk and cotton stuffs, which are manufactured in the distant countries, and are very well mantled by the dried fruits of their own growth, and freshmade cakes of roses, apricots, and peaches, of which Turkey confines to the amount of about 40,000l. The remainder, paid for by the course of exchange, occasions a considerable circulation of money in cultivo-house duties, and the commission of the merchants. This kind of commerce has existed in these countries from the earliest antiquity. It has flowed through different channels, according to the changes of the government, and other circumstances; but it has everywhere left very apparent traces of the opulence produced by it. See Volney's Travels in Egypt and Syria, vol. ii. Ruffell's Alkppo, vol. ii.

The caravan from Cairo in Egypt is composed, not only of pilgrims from every part of Egypt, but of those that arrive from all the small Mahommetan states on the African coast of the Mediterraneum, from the empire of Morocco, and even from the negro kingdoms on the Atlantic. During the months of April, May, and June, in every year, the rich caravans from the interior of Africa arrive at Cairo; carrying thither a considerable quantity of three species of gums, elephants' teeth, damarins, pan,-os, rich feathers, gold dust, and black slaves; and in return they convey into their own country告le peasants, coral, amber, glads-ware, broad swords, cloths, and all kinds of clothing, which are purposefully made by the manufacturers of Cairo to suit the African taste. When assembled, the caravan consists of 500 to 1,000, and the number of camels employed in carrying water, provisions, and merchandize is still greater. In the month of Ramadan, viz. one month previous to the departure of this caravan from Cairo, begins the fair, vulgarly called 'Maulad (or, the birth of the prophet). Strangers of every nation and religion repair hither to dispose of their merchandize. At this fair, European merchandize is the most required; and of coin the sequin of Venice is preferred. The pilgrims purchase them at the highest price, as it is the coin from which they derive the greatest profit. The women are not less anxious to obtain them than the men, for the purpose of ornamenting the head and bosom. The journey, which, in going from Cairo, and returning hither, is not completed in less than 100 days, is performed wholly by land; and as the route lies mostly through sandy deserts, and barren uninhabited wilds, which seldom afford any refreshment, and where often no sources of water can be found, the pilgrims always undergo much fatigue, and sometimes must endure incredible hardships. Of this caravan an early and good description is published by Hakluyt, vol. ii. p. 205, &c. Maillet (Decript. de l'Egypt, part ii. p. 121, &c.) has entered into a curious and minute detail with regard to it; and Pococke (vol. i. pp. 188, 261, &c.) has given a route, together with the length of each day's march, which he received from a person who had been 14 times at Mecca. Upon the return of the caravan to Cairo, another fair begins, more sumptuous and rich than that already mentioned; where strangers barter for new commodities, and part with those which they had not been able to fall at the departure of the caravan. Thus the commerce of Cairo extends by land as far as Mecca in consequence of this yearly pilgrimage, and also into the interior of Africa by the caravans of pilgrims.

Great as these caravans are, we must not suppose that all the pilgrims who visit Mecca belong to them. Such consider-
of Sibbeel, and at the close of the following day they arrive at the town of Angela. From Angela, which is subject to Tripoli, and famous for the abundance and excellent quality of its dates, they proceed in one day to the village of Gui Xarra, and another brings them to the long ascent of the mountain of Gerdoebah, Descending from this height, where they procure, during five days of their passage over it, a scanty supply of unpalatable water, they enter the narrow plain of Geggibib, which is sandy and uninhabited, but fertile in dates, annually gathered by the people of Dana, a town dependent on Tripoli, and situate on the coast at the distance of eight days' journey from Geggibib. After a march of three days they are conducted to a defolate mountain called Bufeiena, that furnishes only water; and in three days more they enter the dominions of the independent republic of See-wah. From See-wah, the caravan proceeds in a single day to the miserable village of Umfeetr, situate at the foot of the mountainous defect of le Morga, whence, after seven days, it arrives at the hill of Huaddy l'Otrion, distinguished by a small convent of three Christian monks, under the protection of Cairo. By these monks the travellers are hospitably entertained; and thence they continue their course, and on the fifth day reach the city of Cairo, from whence, at the proper season, they pursue their route to Mecca.

The other two caravans from Sennaar and For, are extremely various in their motions; sometimes not appearing in Egypt for the space of two or even three years, and sometimes two or more distinct caravans arriving in the same year. The perpetual changes in their several governments, and the caprices of their despots, are in a great degree the occasion of this irregularity. The road also between these two places and Cairo is often infested by bodies of independent Arabs, as that of Sennaar by the Abadé and Shailké, and that of For by the Cubba-Beeth and Bedaâit.

The departure of a caravan from Dar-Fur forms an important event: it engages the attention of the whole country for a time, and even serves as a kind of chronological epocha. The period of their arrival at Cairo is as uncertain as that of their departure; for they travel indifferently either in winter or summer. The journey from Alfal to Sennaar requires much less time than that from Alfal to Dar-Fur. The roads of the defect are not distinguishable by any permanent marks; and as they are perfectly ignorant of the camps, and so imperfectly acquainted with the fixed roads, they are obliged to a loaf for the road, and sometimes deviate into dangerous paths. In passing from Dar-Fur to Egypt, they consider 2000 camels and 1000 slaves a large caravan. Camels are indispensable for these long and fatiguing journeys, and therefore they are reared by the Arabs and Jelabs with great care: nevertheless, the merchant pays nearly as much for the camels to carry his merchandise as he did for the commodities themselves. Horses are little used by the Jelabs: they generally furnish themselves with Egyptian asses, which are afterwards sold at Soudan at an advanced price. The customary food of the drivers and servants of the caravan consists of the milk of the camel, with a few dates, together with the meal of barley, or of Indian corn, which is sometimes seasoned with oil, to which the merchant superadds, for his own use, the dried flesh of the camel, or of sheep, and concludes his repast with coffee. Water is drawn from the wells, when they occur, in leather buckets, that form a part of the travelling equipage of the caravan, and is carried in the skins of goats, through which, however, though tarred both within and without, it is often exhaled by the heat of the noon-day sun. A very easy mode of conveyance is provided for the women and children, and for persons either ill or infirm. Six or eight camels are yoked together in a row, and several tent poles are placed in parallel lines upon their backs: these are covered with carpets, and bags of corn are superadded to bring the floor to a level, as well as to soften the hardships of the camel's movement: other carpets are then spread, and the traveller sits or lies down with as much convenience as if he reft on a couch. The provisions of the Dar-Fur caravan are scanty and indifferent, nor are any of them furnished with dried meat as is common with the Fuzzaners. Few use coffee and tobacco, and the rest content themselves with a leathern bag of flour, another of bread baked hard, a leathern vessel of honey or treacle, and another of butter. In travelling from Dar-Fur to Egypt, another article is much used, especially for the females, which is the grain called millet. Of this they take a quantity after it has been coarsely ground, and caufing it to undergo a flight fermentation, they make of it a paste. When they use it they add water, and it becomes a tolerably palatable food, allaying thirst whilst it affuages hunger. Experienced travellers, among every ten camels laden with merchandise, charge one with beans, and straw chopped small, which, sparingly given, serve them during the greater part of the journey. Water, instead of being conveyed in goat skins, the evaporation of which no fluf can entirely prevent, is carried in ox hides, which the Jelabs, on their march from Soudan to Egypt, form into capacious sacks, and properly flaven with tar or oil. A pair of these is a camel's load. The "Cubba-Beeth" and the "Bedaâit," when they make any attempt on the caravan, commonly flew themselves between Legheba and Bir-el-Malka. But this road is so ill provided with any kind of accommodation for man or beast, that neither the wandering tribes, nor the ferocious animals which infest other parts of the continent, are commonly found there. The Egyptians and other whites, therefore, though they commonly carry fire-arms with them from the North, generally take advantage of the market of For, and return without any. The natives of Soudan are furnished with a light spear, the head of which is made of unhardened iron of their country. They have also a shield about three feet long, and 1 or 2 foot broad, composed of the hide of the elephant, or hippopotamus, very simple in its construction. No regular caravan of Hadgis leaves Dar-Fur, but a number of the natives make their way to Mecca, either with the caravan of merchants trading to Egypt, or by way of Sunkem or Jidda.

Upon the whole we may observe, that independent of these caravans that are formed from religious motives, most of the inland commerce of the East has been for many ages carried on by means of caravans. In former times, caravans traversed the whole latitude of Asia in 243 days, from the Chinef Ocean to the sea-coast of Syria. Silk was immediately delivered to the Romans by the Persian merchants, who frequented the fairs of Armenia and Nibfis; but this trade, which, in the intervals of truce, was oppressed by avarice and jealousy, was totally interrupted by the long wars of the rival monarchies. However, the cities of Samarcand and Bokhara were advantageously situated for the exchange of the various productions of Asia; and their merchants purchased from the Chinef the raw or manufactured silk, which they transported into Persia for the use of the Roman empire. In the vain capital of China, the Sogdian caravans were entertained as the suppliant embassies of tributary kingdoms; and if they returned in safety, the bold adventurer was rewarded with exorbitant gain. But the difficult and perilous march from Samarcand to the dirty town of Shent, could not be performed in less than 60, 80, or 100 days. As soon as they had passed the Jaxartes they entered...
the defect; and the wandering horde, unless they are restrained by armies and garrisons, have always considered the citizen and the traveller as the objects of lawful rapine. In order to escape the Tartar robbers, and the tyrants of Persia, the folk caravans explored a more southern road; they traversed the mountains of Tabib, defended the streams of the Guanges and the Indus, or expected with patience, in the ports of Guran and Malabar, the annual fleets of the Red. But the dangers of the desert were found less intolerable than toil, hunger, and the lobs of time; and therefore the attempt was seldom renewed; and the only European who has passed that unfrequented way, applauds his own diligence, that in nine months after his departure from Pekin, he reached the mouth of the Indus.

The same intercourse which was anciently kept up between the provinces in the north of Asia with Hindostan and Chins, still subsists. Amongst all the numerous tribes of Tartars, the demand for the productions of these two countries is very considerable. In order to supply them, caravans set out annually from Bokhor, Samarcaund, Thibet, and several other places, and return with large cargoes of Indian and Chinese goods. But the trade carried on between Ruflia and China, in this part of Asia, is by far the most extensive and best known. Some concern of this kind has probably been kept up between them from the earliest period; but it is greatly increased after the interior parts of Ruflia were rendered more accessible by the conquests of Zenghis Khan, and Tamerlane. The commercial nations of Europe were to well acquainted with the mode of carrying on this trade, that soon after the Portuguese had opened the communication with the East, by the Cape of Good Hope, an attempt was made, in order to diminish the advantages which they derived from this discovery, to prevail on the Busians to convey Indian and Chinese commodities through the whole extent of their empire, partly by land carriage, and partly by means of navigable rivers, to furnish the part of the Baltic, from which they might be distributed through every part of Europe. This scheme was rendered practicable by the conquests of Ivan Baflowlitz, and the genius of Peter the Great. Though the capitals of the two empires were situated at the immense distance of 6,758 miles from each other, and the route lay for above 400 miles through uninhabited desert, caravans travelled from the one to the other. But though it had been flippulated, when this intercourse was established, that the number of persons in each caravan should not exceed 200, and though they were shut up within the walls of a caravanserai during the short time they were suffered to remain in Pekin, and were allowed to deal only with a few merchants, to whom a monopoly of the trade with them had been granted; yet, notwithstanding all these restraints and precautions, the jealous vigilance with which the Busian government excludes foreigners from a free intercourse with its subjects was alarmed, and the admission of the Ruflian caravans into the empire was soon prohibited. After various negotiations, it was agreed, that two towns should be built almost contiguous, on the boundaries of the two provinces, Kiachta inhabited by Ruflians, and Mamafelin by the Busians. To these all the marketable productions of their respective countries are brought by the subjects of each empire; and the furs, the linen and woollen cloth, the leather, glass, &c. of Russia, are exchanged for the flax, the cotton, the tea, the rice, the toys, &c. of China. See Russia and China.

M. Bougon, geographer of the duke of Lorraine, has given a treatise of the caravans of merchants in Asia, wherein he shows of what they are composed; how many forts there are; the several uses of the different forts of animals in them; the price given for them; the officers and men appointed to conduct them, and the pay of each; with their manner of marching, halting, lighting, eating, &c.

In the heavy caravans, to five hundred elephants there are a thousand drudgeries, and at least two thousand horses, elected by four thousand caravans. Two men are required to lead each elephant; five to three drudgeries; and seven to twelve camels. Such a number of servants joined with the officers and pagers, the number whereof is not limited, renders the body very formidable; the pagans, indeed, are not obliged to light, but in case they revolt, provision will scarcely be allowed them afterwards, even for their money.

As few of the Arab princes have any other substance than what they can get by pillage, they keep continually spies on foot to give them intelligence of the departure and motions of caravans, which they frequently attack with inferior forces; in case of repulse, they come to an accommodation; but if the caravan be beaten, it is absolutely plundered, and the whole guard made slaves; though more indulgence is shown to strangers. The taking of a single caravan sometimes enriches a prince for ever.

The profits to be made in a caravan, during its march, are often incredible; Mr. Bougon gives instances where, by repeated bargains and exchanges, a person has made twenty thousand crowns out of a single gold watch, and thirty louis d'ors.

Any dealer is at liberty to form a company, in order to make a caravan. He in whose name it is raised, is considered as the caravan-bachelor, or chief of the caravan, unless he appoint some other in his place. If there be several merchants equally concerned, they elect a caravan-bachelor; after which they appoint officers to conduct the caravan, and decide all controversies which may arise during the journey.

In the East, days' journeys are distinguished in journeys of horde-caravans, and caravans of camels; those of horses are equal to two of camels. Mr. Remnel, in an ingenious dissertation on the rate of travelling, as performed by camels, (Phil. Trans. vol. lviii. p. 270-1457) he has shown how to apply the hourly rate of the camel's travelling by caravans as an useful scale to the geography of Africa; and he will also serve for the estimate of distances and of time, in other countries, where camels and caravans are in use. He distinguishes caravans into heavy and light. Camels loaded with from 500 to 600 pounds, which are a camel's load, form what is called the heavy caravan; and light caravans, on the contrary, are applied to camels under a moderate load, or perhaps little more than half-loaded. Having settled the mean daily rate of the heavy caravan at 18.4 British miles, reckoning 24 miles for each hour, and 10.25, if taken at 2.50, and the mean rate of the light caravan, 22.17 miles, at 2 1/2 and 22.7 at 2.50; he observes, that, in order to apply the scale with effect to the African geography, it is necessary to state the number of days that the caravans usually halt on the road. From various inquiries he concludes that, at an average, one halt must be allowed to 12 1/2 travelling days: and this, of course, must be deducted from the aggregate of the distance; or should it be averaged on each day, the heavy caravan day must be reckoned at 17.14 miles instead of 18.64, and that of the light caravan at 20.4, instead of 22.17, when the hourly rate is taken at 2 1/2 miles. It further remains to be stated from the proportion that the road distance bore to the direct distance, what length in direct distance, and in geographical miles, may be allowed for each day, for the heavy caravan, on the lengths of journey, and over tracts of country.
similar to the route of Mr. Carmichael from which the
ultimate is made. It appears that on the 28 days between
Aleppo and Raekama (opposite Mejid Ali) the mean length
of the day's journey in direct distance is about 154 geo-
graphical miles; and on the whole 45 days between Alpeko
and Bufforah, 15.8 such miles. If allowance be made for
halts, there will require a deduction of 8 parts in 100 to be
made from the gross amount of the whole journey, when
applied to the purposes of geography. Mr. Carmichael
counted the caravans' steps in order to ascertain a scale of
distance. Mr. Holfard also did the same, and measured the
length of them on the ground. The former gentleman
counted the double steps, or rather the return of the same
foot of a camel on which he rode, for an hour together on
20 different days, at such times as admitted of the greatest
variation in the rate of motion. He found the greatest num-
ber of steps to be 2420, the least 2065; and the mean of
the whole 20 hours was 2200. The latter gentleman re-
knoned the greatest 2240, least 2060; mean 2150. They
both report the double step to be 55 feet. The result of
the former account is 2.29 British miles per hour; of the
latter 2.24: each allowed his distance accordingly in his
journal. But Mr. Kennel observes, that their computed
distances fall very short of the truth. The error probably
originated from their measuring too small a number of steps
on the ground as the foundation of their calculation. The
reason of the great variation in the number of paces, in a
given time, is the plenty or scarcity of the desert thrubs,
on which the camels feed as they go on; and then such exper-
iments become useless unless the quality of the desert were
described in every part of it.

Some have reckoned five forts of caravans, viz.
Caravan, heavy, composed of elephants, dromedaries,
camels, and horses.
Caravan, light, in which there are but few elephants.
Caravan, ordinary, in which there are no ele-
phants.

Caravan of horses, that in which there are neither camels
nor dromedaries, but only horses.
Caravans, fea. companies of merchant vessels, loaded
with goods, and convoyed by ships of war. Such are those
which proceed from Constantinople to Alexandria.

Caravan is also an appellation given to the voyages,
or campaigns, which the knights of Malta are obliged to make
at sea against the Turks and corsairs, in order to arrive at
the commanderies and dignities of the order. They are thus
called, because the knights have frequently seized the
Caravan going from Alexandria to Constantinople.

Caravanier, a person who leads the camels and
other beasts of burden used in the caravans of the East.

Caravansera, a large public building, or inn,
deigned to receive and lodge the caravans.
The word comes from the Arabic carawan, or Persian
karwan or cavan, a caravan, and ferai, a large house.

Of these caravanseras, or as Chardin calls them, caravan-
ferais, there are a great number throughout the east; erected
out of the charity and magnificence of the princes, &c. of
the several countries, for the accommodation of travellers.
They are called by the Turks "houses;" and are situat-
esometimes in the towns and villages; sometimes at conve-
inent distances upon the road.

Theofe of Schiras and Caibin in Persia, are paid to have
cost sixty thousand crowns each. They are open to people
of all religions and countries, without any questions asked
or any money required.

The caravanseras are usually huge square buildings, with
a spacious court in the middle of them. They are encoun-
tered with galleries and arches, under which runs a kind
of banquette, or elevation, some feet high, where travellers
rest themselves, and make their lodgings as well as they can;
their baggage and the beams that carry them being fastened
to the foot of the banquette. Over the gate, there
is frequently a sort of little chambers, which the cara-
vanferais let out at a very dear rate to such as will be
retired.

Though the caravanseras serve in lieu of inns, yet there is
this essential difference between them and our inns, that
the traveller finds nothing at all in the caravansera either
for himself, or his cattle; but must carry all his provisions
and necessaries with him. They are chiefly built in dry barren
defert places; and are generally furnished with water from
the garden, and at a vast expense; there being no ca-
rvansera without its well of water. There are several of
them in cities; where they serve not only as inns, but as
shops, warehousc, and even exchanges.

There are some caravanseras where most things may
be had for money; and as the profits of these are con-
siderable, the magistrates of the cities to whose juris-
tration they belong, take care to florce them well; they
have an inspector who fixes the price of lodging, and
attracts trade. Such well-furnished resting places are
not to be found in India, and even the most hospitable
guesthouses cannot compare with them for the care of
the host, or keeper of the caravansera, and promised at his
return to pay him for whatever things the distressed traveller
required, and which the keeper furnished him with. Luke
xiii. 35.

There are few cities in the east without their carav-
anseras; especially within the dominions of the great Mogul.
Those of Constaninople, Ispahan, and Agra, the capitals
of these three empires, are distinguished for their magni-
culence and commodiousness. The caravanseras of Schiras
and Caibin, considerable cities of Persia, are also in high
reputation, and little inferior to those of the capital.

In Turkey, none but the grand signior's mother and fift,
with the vintners and bakhouns who have been in these
cities, are allowed to build a caravansera.

Caravansersaskier, the director, reward, or
intendant of a caravansera.

At Ispahan there are caravanseras in manner of halls
or exchanges, where goods are laid up, and exposed to view;
for which the caravansersaskier is accountable, in considera-
tion of a certain fee.

Caravel, the name of a vessel formerly used by the
Spaniards and Portuguese; the masts were inclined, in place
of being upright as usual, with triangular sails. Vessels of
this description failed fast, and would lie near the wind.

Caravel is also the name of a small vessel employed on
the coast of France in the herring fishery; and these are
commonly from twenty-five to thirty tons burden. French
vessels in the same employment in the British channel are
called Tingquarts; these are in general from twelve to fif-
teen tons burden.

Caravella, in Zoology, a species of Medusa de-
scribed in Sloane's History of Jamaica. See Medusa
Caracola.

Caraven, in Geography, a small island in the Grecian
Archipelago. N. lat. 35° 53'. E. long. 23° 36'.

Caravilla, a town of Naples, in the country of
Molise; 12 miles N.W. of Molise.

Caravan, in Ichthyology, the name of a small Brazil-
ian fish described by old writers as being of a fine bright
red colour, with innumerable black spots all over it. The exact
species
species is uncertain, but it appears to be that of the Laurus genus.

CARAUSIUS, in Biography, a native of Menapia or Maritime Flanders, who usurped the empire in Britain in the third century. According to Dr. Stukeley (Hist. of Carausius) he was a native of St. David's, and a prince of the blond royal of Britain. Although sprung from the meanest origin "villainous nature," according to the expression of Eutropius, he advanced himself by his naval skill, as a pilot, and by his experience and valour in maritime expeditions, to stations of trust and service, under Probus and his successors. Having by the display of his talents ingratiated himself with Maximian, this emperor employed him in conducting an enterprise against the Franks and Saxons, who by their piracies had rendered the navigation of the seas impracticable. With this view he was appointed to the command of a squadron, assembled at Gessoracium or Boulogne. Carausius availed himself of the opportunity which this office of trust afforded him for acquiring, by various captures of vessels richly laden with spoil, ample treasures; which he appropriated to his own use. Maximian, enraged by his treacherous and fraudulent conduct, determined to put him to death without trial. The crafty Carausius foreknew and prevented the severity of the emperor. By his liberality he had attached to his interest the fleet which he commanded; and from the port of Boulogne he sailed over to Britain; where, perfusing the legion, and the auxiliaries that guarded the island, to join his party, he boldly assumed the imperial purple, and the title of Augustus, and sat at defiance the justice and the arms of his injured sovereign. This event happened, during the joint empire of Diocletian and Maximian, A.D. 286. In order to secure his usurpation he augmented his fleet, attached to his cause by a variety of artful methods the Franks and Saxons, and whilst he defended the frontiers of his dominions against the Calvinoids of the North, invited from the continent a great number of skillful artists, and displayed, in various coins which are still extant, his taste and opulence. He still preferred the possession of Boulogne and the adjacent country. His fleets rode triumphant in the channel, commanded the mouths of the Saine and of the Rhine, ravaged the coasts of the ocean, and diffused beyond the columns of Hercules the terror of his name. Under his command, Britain defined in a future age to obtain the empire of the sea, already assumed its natural and respectable elevation of a maritime power. As he had besieged the fleet of Boulogne, he had deprived his master of the means of pursuit and revenge. After a disappoointed effort by a new armament, confining of imperial troops unaccustomed to the sea, Diocletian and his colleague resigned to Carausius the sovereignty of Britain, and reluctantly admitted their perfidious servant to a participation of the imperial honours. His civil government, whilst it lasted, was oppressive and tyrannical. He held the people in a state of perfect subjugation, and at the same time indulged his own passions and those of his mercenaries, upon whom he depended for support, without restraint and limitation. At length, however, the association of the two Caesars restored new vigour to the Roman arms; and the conduct of the British war was committed to the brave Constantius. His first enterprise was directed against Boulogne, which after an obstinate defence surrendered, A.D. 292; and thus a considerable part of the naval strength of Carausius fell into the hands of the besiegers. During the three years which Constantius employed in preparing a fleet adequate to the conquest of Britain, he feared the coast of Gaul, invaded the country of the Franks, and deprived the usurper of the assistance of these powerful allies. Before these preparations were

flattened, Constantius received information of the death of the tyrant, who was murdered, A.D. 293 (says Gibbon) or A.D. 292 (Blair's Tables) by his chief minister Allectus. See AllctiUs. Ceasar's Rom. Emp. vol. ix. Gibbon's Hist. vol. u.

CARAWAAN WANG Point, in Geography, the east point of the bay of Bataan in the island of Jav.

CARAWAY, in Botany. See Carvi carui.

CARAVAY, in Agriculture. A plant sometimes cultivated for the feed. It is a sort of crop much cultivated in Ethiopia on rich old shies of a thriving adaptable or hoary nature, in low situations. It is sometimes sown with coriander and teasel, and harvested the second year at the expense of four tillings an acre. It is commonly threshed upon a cloth in the field, being very apt to fall in gathering, which is done the beginning of July. It commonly requires two good sowings; one in April, the other in the beginning of June. The produce of this crop has often been very great, even as much as twenty hundred weight per acre, which has always a market in London, but sometimes as low as 12s. and frequently as high as 50s. on an average, 24s. or 26s. per hundred weight. It does not perfect its seed till the second or third year, when the land is fit to be ploughed up for what. For this crop the land should be prepared by two or more ploughings, and have a portion of manure applied where poor. See Carus.

CARAZOWNY, in Geography, a river on the east coast of South America, between the river Caruaya to the E.S.E. and Urache to the W.N.W. It large and navigable; but visited chiefly by a few Dutch ships, who come hither to load a kind of dyers' wood. See CARACA, or CARACA, in Ancient Geography, a town of Alia, in Parapamisia. Ptolemy.

CARBANIA, a small island of the Mediterranean, between Sardinia and the continent of Italy. Pomp. Mela. Some have thought that it is the Barren of Pliny, and the modern Cardeli.

CAREANTORIGUM, a town in the northern part of Britain, which, according to Ptolemy, belonged to the Selgove. Horshay places it at Bardana on the river Nith, above Dumfries, and Camden at Carlavock, below it; and it was therefore probably situated where Dumfries now stands, or a little below it. The name seems to be derived from "Cer vant o riy," a town near the mouth of a river. Baxter places it at Melroes.

CARBASA Caryfina, a term used by many of the ancient writers to express pieces of cloth made of the linum incompositum, or ablotos stone, which being found plentifully about Caryllium, was thence called by the name of the place. Paulusianis calls it linum Carphylum; for the same sort of reason; Carphus, a town in the island of Cyprus, being a place famous for affording large quantities of the stone in its neighbourhood.

CARBATTA, in Ancient Geography, a place of Italy in Liguria, at a small distance south of the Pads, or Po.

CARBENSIS aqua, in the Materia Medica, the name of a mineral water of Germany, of which Hoffman from Petraeus has given the following account. All about the place of its origin, and along the canals through which it passes, it deposits an earthy and ferruginous matter, which concretes into a stony hardnes. When any alkaline liquor, whether fixed or volatile, is added to these waters, they become turbid, and precipitate a whitish earthy matter to the bottom
bottom of the vessel; after the evaporation of the water they leave a fulminum, and an alkaline earth; two quarts of them yield two quinques and ten grains of the earth, and twelve grains of the salt. If it be kept for any time in a glass, or earthen vessel, it deposits a sediment of a yellow ochraceous earthy matter, and when immediately taken from the spring, it changes to a bluish brown colour, on being mixed with galls. It contains a very large portion of a soluble mineral spirit; for if a long-necked vessel be filled half full with it, and the orifice flopped with the thumb, the whole, on a little shaking, emits a fume from the top; and when the thumb is taken off, the water seeps out to several feet distance. It makes an effervegence on mixing oil of vitriol with it; but this lasts but a very little time. From the whole, it seems to contain a large quantity of calcareous earth, and some small portion of ferruginous matter; whence it purges both by stool and urine, though mildly the latter way: the former operation, which is pretty connivent, is owing to this alkaline earth meeting with an acid in the prima vis, and being by it changed into a bitter purging salt, of the nature of Gluher's.

CARBEQUI, or Alper of copper, a coin which is current in the province of Georgia in Asia; particularly at Teffis, the capital. Forty carbequis are equal to the "abagi," and ten carbequis to the "chomari."

CARBERRY, in Agriculture, a name applied, in some places, to the gooseberry.

CARBERRY, in Geography, the name of a large barony in the S.W. of the county of Cork, province of Munster, Ireland. The district of this name formerly included some of the adjoining baronies, and is supposed to have been so called from an Irish prince who governed it. It is still the largest barony in Ireland, containing 39 parishes, and 156,321 Irish plantation acres, which is more than many counties. It has, therefore, been found convenient, in managing county business, to divide it into East and West Carbery. It is a very wild, mountainous, unimproved country, with a bold rocky coast, and many harbours.

A Latin poem of dean Swift's, called "Carberic rupes," was written in 1724, whilst on a visit to a clergyman in this barony. Dr. Smith, who made more than once the same little voyage along the coast which the dean had done, observes that the dean's descriptions were as just as his numbers were beautiful. The poem, and a translation of it by Dr. Dunkin, may both be seen in Smith's History of Cork, from which this article is principally taken. In some parts of Carbery the linen manufacture is successfully carried on, especially about Dunmanway and Cloghmacnulty. Carbery, or Carbury, is also the name of two other baronies, one in the county of Sligo, and the other in the county of Kildare.

CARBERY, a small island in Dunmanus bay, county of Cork, Ireland, which shelters vessels from westerly winds, but has firths in its neighbourhood, which require attention to guard against. It is sometimes called Ileis Carbery. N. lat. 51° 31'. W. long. 9° 34'. M. Kenzie, Beaufort.

CARES, St. Jacques, a town of Martinico, in the West Indies. N. lat. 14° 35'. W. long. 61° 10'.

CARBI, in Ancient Geography, a people of Arabia Felix, according to Diodorus Siculus.

CARBIA, a place in the island of Sardina, on the route from Tribule to Sulci. Anton. Itin.

CARBINA, a place of Italy in Japygia, mentioned by Athenæus, who says that it was taken by the Tar- rentines.

CARBINIA, in Geography, a town of the department of Lianone (island of Corfica), and chief place of a canton in the district of Sartene; 5 miles E. of Tallano. The canton contains 2,066 inhabitants.

CARIO aquaticus, in Ornithology. See Petreornus Carbo, the Corvonzor.

CARBON, in Chemistry. 5. Of Carbon.

This substance abounds largely in all vegetable and animal bodies, as well as in the mineral kingdom, yet it is of very rare occurrence in a state of absolute purity. When uncombined with any foreign matter, it is transparent, colourless, intensely hard, and infusible; and, both on account of its beauty and value, is placed at the head of the gems under its commercial and mineralogical name DIAMOND.

Diamond was formerly supposed to be incombustible, and the first hint at its real nature was given by Newton. This philosopher having observed that inflammable bodies posse a, in proportion to their density, a greater power of refracting the rays of light than any other substances, was induced to rank the diamond among them, on account of the eminent degree in which it possessed this property. This conjecture was verified, in 1791, by the members of the Academy del Cimento at Florence, who confirmed several diamonds by placing them in the focus of a lens. Francis I. emperor of Germany, afterwards witnessed the destruction of several more by the heat of a furnace. These experiments were repeated by Macquer, Ronelle, Dareet, and Ceder, who ascertained, that by the concurring action of air and heat, diamond was not only evaporated, but actually burnt with flame; they also proved that when the air was excluded the highest heat of a furnace produced little or no effect on this substance.

In 1772, an experiment was made by Lavoisier, which may be considered as the first attempt to effect a chemical analysis of diamond. He burnt a few grains of this substance in a jar of common air, confined over mercury, by means of a very powerful lens, and found that the pure part of the air had disappeared, as well as a considerable proportion of the diamond, and that the residual air abounded with carboenic acid: repeating the same process only with the substitution of an equal weight of highly burnt charcoal, he found precisely analogous effects to take place, and therefore concluded that diamond and charcoal in their chemical essence were very similar to each other. In 1785, M. Moreau discovered that diamond, when dropped into melted nitre, burns like charcoal, and without leaving any residue. This fact suggested to Mr. Tennent a method of analysing diamond, which was effected with complete success. Into a gold tube, cieded at one end, and terminating at the other in a curved glass tube, were put a quarter of an ounce of nitre and 2 ½ grains of diamonds; the tube was then kept at a full red heat for an hour and a half, and when its contents were afterwards examined, the diamonds were found to have entirely disappeared, and the nitre was changed into sub-carbonat of potash; to a solution of this salt marlet of lime was added, and thus the carbamic acid was transferred to the lime: from this carbamic acid the carbonic acid was expelled by means of the muriatic acid, and was found to amount to 9.67 grains. Hence 27.6 parts of diamond and 72.4 of oxygen constitute 100 of carboenic acid. But according to Lavoisier, 28 parts of charcoal, and 72 of oxygen constitute 100 of carboenic acid; therefore diamond and pure charcoal may be considered as chemically the same.

Morveau has since endeavoured to invalidate the experiment of Mr. Tennent, and to show that diamond is pure carbon and that charcoal is an oxyd of carbon, but his experiment is so manifestly incorrect as to merit no sort of confidence.

A further proof of the analogy between charcoal and diamond is furnished by an ingenious experiment of Cluets', in which
which some pure bar iron being exposed to a high heat, in contact with diamond, this latter substance was found to have disappeared, and the iron to be converted into lead.

But though diamond is the purest form of carbon, yet its high value, its hardness, and density, forbid it to be used in ordinary household purposes; all the succeeding facts, therefore, relate to that less pure kind of carbon, which is obtained by expounding common charcoal, or, still better, lamp-black, to a high heat in close vessels.

Carbon, or prepared charcoal, is an excellent conductor of galvanism and electricity, but transmits caloric with very great difficulty; a short piece may be held by one end while it is heated red at the other, without conveying any notable warmth to the hand.

It is insoluble in water, and even the combined action of air and water produces hardly any perceptible effect upon it; hence it is that flakes of wood that are charred on the outside will last much longer without rotting than the soundest timber that has not undergone this preparation.

Charcoal is not fusible by the greatest heat that can be applied; if exposed to a very high temperature in close vessels it loses little or nothing of its weight, but shrinks in size, and becomes proportionally more compact, dense, and amoriorous, and acquires a deep velvet black colour. But though charcoal is unalterable by mere heat, and yet when heated red in the open air, it speedily undergoes combustion, and is converted into Carbonic Acid; pure oxygen gas produces, as might be expected, a much more powerful effect on this substance than atmospheric air does; a piece of charcoal barely heated at one end to redness and plunged into this gas, immediately burns with an intensely white glow, and is rapidly changed into carbine acid.

Water, although it is, as we have already mentioned, incapable of dissolving carbon, is yet very obstinately retained by it, partly on account of its porous texture, and in part probably on account of a strong mutual affinity subsisting between them. When, however, charcoal is red hot, or nearly so, it decomposes any water with which it may happen to be in contact, and unites with both the elements of this substance; producing with the oxygenous bafe, according as this is added to saturation or not, carbonic acid and carbonaceous oxide; and with the hydrogenous bafe forming a heavy inflammable air, called carburretted hydrogen or hydrocarbon.

Newly prepared charcoal is capable of absorbing various gasses, with remarkable facility, and in considerable proportions. This fact had been observed by Fontana, Lamethije, Priestley, Scheele, and Morveau, but the first important series of experiments on this subject was published by Moretto, since which time Meissr. Roupee and Van Noorden of Rotterdam have made a considerable and very valuable addition of facts on this curious subject. The charcoal for the experiment being highly ignited in an open fire, to expel all the moisture and gaseous substances which it may contain, is quickly removed, and extinguished by being plunged under mercury, or inclosed in an air-tight metallic box; when quite cool it produces the following effect on the various gasses.

One part of charcoal is capable of absorbing three times its bulk of atmospheric air in four or five hours; of oxygen gas there is absorbed, at first rapidly, and afterwards more slowly, 28 times the bulk of the charcoal. Azot and hydrogen are taken up inflamnately, but only in the proportion of 1.6 of the former, and 1.8 of the latter. Of nitrous gas 8.5 parts are very slowly, and of carbonic acid 14.3 parts are very rapidly absorbed. The gasses thus taken up undergo no change except of form, nor are the residues at all altered, and they may be all again separated from the charcoal by distillation, at the temperature of boiling water.

If charcoal saturated with hydrogen in the way described is introdiced into oxygen gas, or even into atmospheric air, a considerable absorption of the oxygen takes place, and at the same time the temperature rises to about 150°. The result is the same if the experiment is inverted, that is, if charcoal charged with oxygen is introdiced into hydrogen gas. Charcoal saturated with hydrogen is even capable of decomposing nitrous gas, the oxygen being absorbed, and the nitrogen alone remaining in the cacastic state. Charcoal saturated with azot is also capable of decomposing atmospheric air, by abstracting the oxygious part, which is a remarkable proof how adverse the gaseous state is to chemical combination.

Carbon is capable of combining with sulphur; the sub stance hence resulting is called carburretted sulphur, and although all that is known is yet concerning it is due to the united investigations of Clement and Deformed, two French chemists. It is thus prepared. Fill an earthenware tube with small pieces and powder of newly burnt charcoal, fix it in a flaring direction in a furnace, and lute to the lower end a glass tube, dipping it into some water contained in a receiver. Fasten a glass tube also to the upper extremity of the earthen pipe, and fill it with short cylindrical pieces of sulphur, and fit a cork to the open end of the glass tube with a movable wire passing through its centre, by which the pieces of sulphur may be pushed at pleasure towards the earthen pipe. The apparatus being completely, heat the pipe very gradually, and as soon as the gas casually contained in the charcoal is driven out, cause the sulphur, by means of the wire, to approach the heated part of the apparatus. Allow it to remain at such a distance that it may melt as slowly as possible, and run down among the charcoal; and if these precautions are duly observed, a yellowish oily liquor will soon be perceived in the terminating glass tube, which will drop into the water of the receiver, and collect at the bottom of the tube, without all uniting with the supernatant fluid. The carburretted sulphur thus obtained is a transparent liquid, colourless when pure, but generally of a yellowish-green tinge, and of a disagreeable pungent odour, differing entirely, however, from that of sulphuretted hydrogen. The specific gravity of carburretted sulphur is about 1.3. It evaporates in the air with nearly the same rapidity as ether, and, like this fluid, sinks the thermometer during the process in a remarkable degree. If it is put into an air-pump, and the atmospheric pressure be reduced to about nine inches of mercury, the carburretted sulphur begins to assume the form of a gas; but upon restoring the common pressure, this gas will immediately again resume its liquid state. It takes fire upon the application of a flame, and burns like alcohol, giving out at the same time a sulphurous odour, and depositing both sulphur and carbon. When kept for some time in a vial with atmospheric or azotic gasses, it is diffused by them in small proportion, and renders them inflammable. It combines with nitrous gas, and the mixture burns like zine. When diffused in oxygen gas, the result is a air that explodes with such prodigious violence as to render it dangerous to set fire to even a few cubic measures at the same time. In the state of vapour it combines flowly with the caustic fixed alkalies, forming with them deep amber coloured solutions. By alcohol it is reduced to a soft papery consistence. It diffuses very easily in cold olive oil, or in ether, deposits a little charcoal, and then assumes a crystalline form.

Carbon is said by Proust to be capable of uniting with phosphorus,
CARBON.

phosphorus, but this, from subsequent experiments, appears to be a mistake.

Two of the metals are known to unite with charcoal; when combined with iron the product is called steel; and with copper it forms a peculiar sub stance, first noticed by Dr. Priestley, and named by him charcoal of copper.

The action of the alkalies upon charcoal has been but little examined into; it is certain, however, that caustic potash, by long digestion with this substance, becomes coloured and partly carbonated.

The undecomposable acids appear to have no action on charcoal, but the decomposable ones are deprived of it by their oxygen, either entirely or in part, and the charcoal is changed into carbonic acid; thus phosphoric acid and charcoal yield, by ignition, phosphorus and carbonic acid; sulphuric acid and charcoal yield sulphur, sulphurous acid, and carbonic acid. If highly dried and finely pulverized charcoal is poured into recently prepared oxyhydrogen acid gas; as soon as the two substances come into contact, the charcoal becomes red hot, and falls to the bottom of the vessel, like a shower of fire.

The neutral and earthy faults with decomposable acids are remarkably changed at a red heat by charcoal; the others suffer no perceptible alteration. Thus the sulphates are converted into sulphures, the nitrates become carbonates, while the muriats and duets remain unchanged.

The metallic faults are all of them decomposed by charcoal at a greater or less degree of heat, in consequence of the deoxygenation of their bases, independently of the action of this substance on their acids.

The effects of charcoal in clarification are both curious and important. They were first noticed by M. Lowitz of Petersburg, and have for the most part been amply confirmed by succeeding observers, although the precise cause of these remarkable changes has not been satisfactorily ascertained.

All that is essential for this purpose is, that the charcoal should be in fine powder and very dry; hence the only preparation requisite for its purpose is to pulverize some well burnt common charcoal, and then heat it in a covered crucible to a glowing red, till it ceases to give out an inflammable vapour. If it is not employed immediately, it ought to be kept in a ground flapped glass bottle, and may then be preferred unimpaired for any length of time. The effects of this prepare charcoal are very striking. Being mixed with common vinegar, or any kind of wine, a thick froth rises to the surface, and the liquors, after filtration, are found to be as limpid as water. The filtrate and moisture of the vinegar is in like manner rendered perfectly clear, inodorous and insipid; and rancid oils are also deprived of their smell and taste by repeated filtration through this prepared charcoal. Hence also its peculiar efficacy as a dentifrice; it is sufficiently hard to remove the concretions from the teeth without injuring the enamel, while it neutralizes and entirely destroys for a time any factor which may arise from a carious tooth.

§ 2. Of carbonous oxvd, or gaseous oxvd of carbon.

Dr. Priestley was the first person who efficaciously called the attention of chemists to this substance; but for a correct acquaintance with its nature and properties we are indebted to Mr. Cruickshank. It had always been objected by Dr. Priestley, against Lavoisier's hypothesis of the constitution of fixed air, that when charcoal, however dry, was distilled with scales of iron, or the red oxvd of mercury, the product was not only carbonic acid, but a large quantity of a heavy, inflammable air, resembling, in many respects, carburetted hydrogen, and supposed by Dr. Priestley to be actually this very gas. Now carburetted hydrogen consists of hydrogen, holding carbon in solution; and if it were really produced by the mutual action of carbon and a metallic oxvd, could only be accounted for upon the Lavoisian theory by the calcined presence of some water. But the gas is produced in such great abundance, even when the materials have separately been first exposed to a very high heat to drive off every atom of water, that this hypothesis is untenable; it is, therefore, an obligation of no trivial kind that the modern chemical theory is under to Mr. Cruickshank, for having shewn that this gas, though inflammable, does not necessarily contain any hydrogen whatever, but has only a simple com

The gaseous oxvd of carbon may be produced either by the partial oxygenation of carbon, or the partial deoxygenation of carbonic acid, or the solution of carbon in carbonic acid, on each of which methods we shall proceed to say a few words.

The original experiment by Dr. Priestley is the following. Equal parts of scales of iron and charcoal (each having previously been ignited in separate vessels), were put into a glazed earthen retort and strongly heated. In a short time a prodigious quantity of air came over, which, on examination, was found to consist of one tenth carbonic acid, and the remainder was "an inflammable air of a very remarkable kind, being quite as heavy as common air. The reason of this," Dr. Priestley adds, "was very apparent, when it was decomposed by dephlogisticated air, for the greater part of it was fixed air." The above two important properties, namely, the weight of this gas and its almost total convertibility into carbonic acid by oxygen, are fully confirmed by subsequent experiments.

Mr. Cruickshank, in repeating this experiment of Dr. Priestley, found, that as soon as the retort was red, abundance of gas came over, which, being examined at different periods, was found, in the beginning of the process, to be composed of one part of carbonic acid and four of carbonous oxvd, with a small admixture of carburetted hydrogen; after this, to the end of the process, the proportion of carbonous oxvd gradually increased to about six-nineteenth of the whole. Two ounces of the materials afforded many gallons of the gas.

The sublimed oxvd of zinc was next substituted to the iron scales, and distilled in the same manner with charcoal. Even before the retort became red much gas was given out, and, on increasing the heat, it came over in torrents. It contained a much smaller proportion of carbonic acid than the former, and, towards the end, composed of pure oxvd of carbon. Part of the zinc was found, in the metallic state, sublimed into the neck of the retort. In like manner, thence, the grey oxvd of manganese, and the red oxvd of copper, produced with charcoal, fir, a mixture of carbonic acid with carbonous oxvd, and, at last, the inflammable gas in a state of purity.

The distillation of charcoal and the sublimed oxvd of zinc was repeated by Clement and Deformes, with particular attention to the quantity of products from a given weight of materials. The charcoal and zinc were first heated separately, and examined. Common charcoal, when heated strongly, gave a considerable quantity of inflammable gas, and about 1/1200 of its weight of water. After an hour nothing further came over; so that, to ensure the purity of the
the charcoal, it should be used hot from the crucible or other vessel in which it has been exposed to a full red heat for half an hour. The oxide of zinc gave out nothing at all by being heated \textit{per se}; so that it may at any time be considered as pure, when previously free from accidental moisture.

It was found, by experiment, that 14.96 parts of zinc increased, by calcination, to 17.48 of white sublimed oxide, and hence it is inferred that 100 parts of white oxide consist of 82.15 metal, and 17.85 oxygen. Pure charcoal, prepared as above, was mixed, to the amount of 50 grams, \((4 / 5 \text{ grams})\) with an equal weight of oxide of zinc, which were put into a coated glass retort, communicating with lime-water through which all the gaseous products passed. When first heated, a small portion of carbonic acid gas appeared, rendering the lime-water turbid; but this soon cooled, and the gas was purely inflammable. In five hours the production of gas had entirely terminated, and the total products of the operation were as follows:

In all the preceding experiments the carbonous oxide was obtained by the partial deoxygenation of the metallic oxides and the consequent oxygenation of the carbon. In those which we are about to relate, the same gas was procured by inverting the process, that is, by depriving carbonic acid of a portion of its oxygen.

Dr. Priestley, having obtained an inflammable gas, by heating together carbonates of barites and magnetic oxide of iron, Mr. Craikshank was induced to vary the experiment in the following manner. Equal parts of chalk (heated red hot previously for ten minutes), and of iron filings were mixed together, and heated in an earthen retort, abundance of gas was given out, confining pretty uniformly of one part carbonic acid and five of carbonous oxide.

An ounce of chalk previously heated red for ten minutes, was mixed with an equal weight of zinc filings, and heated gradually in a coated glass retort. A little carbonic acid came over at first, but mixed with oxide of carbon; and when the contents of the retort were thoroughly red, nothing but the inflammable gas came over, and that in prodigious quantity. It was examined at different periods of the distillation, and proved to be wholly un mixed with carbonic acid. After the process, the retort being examined, there was found some sublimed oxide of zinc in its neck, below which was some metallic zinc, and at the bottom was a mixture of oxide of zinc, and partly caustic lime. Chalk, with tin filings, gave a similar result.

In these experiments, the carbonic acid was united to an earthy base before distillation, and consequently was exposed to the deoxygenating effect of the metallic filings in its nascent state, or, at the moment of its assuming the gaseous form, a rate in which airs of all kinds are peculiarly susceptible of chemical change. Mr. Craikshank found, however, that carbonic acid, even in the elastic state, was also susceptible of being deoxygenated by the same means, though not quite so readily. For this purpose, some dry chalk was introduced into an iron retort, over which was rammed some dry sand, and a fragment of tin filings over all. In this arrangement, the carbonic acid gas expelled from the chalk had to traverse a fragment of sand three inches thick, before it could reach the iron-filings. The gaseous products of the distillation were a quantity of undecomposed carbonic acid, together with a large proportion of the inflammable gas, and the iron filings were taken out considerably oxidated. The decomposition of carbonic acid by metals does therefore take place, when the acid is in the gaseous form, but by no means to perfectly as when in its liquid state. A similar decomposition was also effected by forcing the same carbonic acid gas successively backwards and forwards through an iron tube, the residue of which was full of iron-filings, and kept red hot by a small furnace placed beneath it. A bladder was tied to each end of the tube to receive the gas, and, by passing it twenty times slowly through the tube, two thirds of it were converted into inflammable gas.

It is obvious, that if to any base, already united with oxygen, we add a fresh portion of the base, it will have the same relative effect as abstracting part of the oxygen; and thus offers another mode of preparing carbonous oxide, which has been successfully practised by M. E. Clement and Deformes. Pelletier had previously discovered that though the native carbonate of barites is scarcely calcuble, \(\textit{per se}\), in any fire, yet it will readily part with its acid by calcination, if previously ground to fine powder, and mixed with a little charcoal. The chemists above-mentioned, in repeating this experiment with three parts of carbonated barites and one part of charcoal, obtained a large quantity of gas, composed of about \(4 / 5\) carbonous oxide, and \(1 / 5\) carbonic acid, and the barites remaining in the retort was found to be quite calcine. Here, therefore, it is to be supposed, that the carbonic acid is superfused with its own bare, and thus rendered much more volatile than before.

A more direct combination of carbon with carbonic acid was also obtained by the two associated chemists just mentioned, with precisely the same apparatus as that used by Mr. Craikshank for passing carbonic acid gas over red hot iron, except that the tube was filled with pulverized charcoal instead of iron-filings. The first sensible effect produced on the gas was a considerable dilatation, exclusive of the mere expansion by heat, and arising from the solution of a part of the heated charcoal in the gas as it passed over. After each experiment, by far the greater part of the carbonic acid was changed into the inflammable gaseous oxide of carbon, the residual carbonic acid not amounting to more than from \(1 / 5\)th to \(2 / 5\)th of the whole. The remaining charcoal being taken out and weighed was found to be considerably diminished; but the proportional loss was uniformly greater in tubes of iron, than of glass or porcelain, doublets, on account of part of the carbon being combined with the iron, and thus converting it internally into steel. The composition of the gaseous oxide, into which the carbonic acid was changed, calculated from the amount of charcoal taken up by it in porcelain tubes, appears to be about \(53\) of oxygen, and \(47\) of carbon.

The properties of pure carbonous oxide, prepared from chalk or carbonate of barites, and filings of iron or zinc, are the following. It is lighter than atmospheric air, in the proportion of 22 to 23. Hence, its specific gravity (that of water being 1000), will be 1.177, while that of atmospheric air is 1.2305; hence, it materially differs from carburetted hydrogen, the weight of which is not more than half that of common air. It suddenly destroys animal life.
It is in no degree altered by being electrized, per se, for a considerable length of time. It burns in the open air with a quiet, blue flame. When previously mixed with common air and kindled, it does not explode but burns slowly; when mixed with oxygen gas, and fired by the electric spark it explodes, but not very violently, and gives out a red flame. If a small jet, communicating with a reservoir of this gas, be let fire to, and introduced into a large balloon receiver filled with oxygen gas, it is found to burn brightly for a time, and afterwards goes out. The gas remaining in the receiver is not greatly diminished, and the inside of the vessel, though somewhat damp, is by no means fluddled with those visible drops of liquid that characterize the combustion of hydrogen. The residual gas, on examination, will be found to consist of carbonic acid with some uncombined oxygen.

The relative proportions of carbonous oxyd and oxygen requisite to mutual saturation, and the consequent production of carbonic acid, are the means of ascertaining the exact constituent parts of this inflammable gas. When 20 measures of pure gaseous oxyd are mixed with eight measures of oxygen and exploded, the whole is reduced to 18 or 19 measures, and is entirely absorbable by lime-water; it is, therefore, carbonic acid. The weight also of this latter product is found to correspond, as nearly as can be expected in experiments of this kind, with the sum of the weight of its two ingredients before mixture. One hundred cubic inches of carbonous oxyd with 40 inches of oxygen produce 92 cubic inches of carbonic acid, and the weight of the first may be estimated at 30 grains, of the second at 13.6, and of the third at 43.2; the sum of the two first differing from the third only by 0.4 of a grain.

Hence it may be inferred, that 100 parts, by measure, of gaseous oxyd of carbon, require for saturation 40 measures of oxygen gas, and produce, by combustion, about 52 measures of carbonic acid gas; or, by weight, that 100 grains of carbonous oxyd require about 45.5 grains of oxygen, and are converted into 144 grains of carbonic acid, 1.5 grain being allowed for water and casual impurities. Now carbonic acid has been found by Lavoisier and other chemists to consist of 28 parts, by weight of carbon, and 72 of oxygen; consequently 144 grains of carbonic acid (the product of the full oxygenation of 100 grains of the inflammable gas), contain 40.32 grains of carbon; therefore the remainder of the 100 grains of the oxyd, i.e. 59.68 grains, must be oxygen. Hence, carbonous oxyd may be stated as composed of

<p>| | |</p>

</table>

Or, by another calculation, 744 grains of carbonic acid contain 72 per cent., or 103.68 grains of oxygen; but only 45.33 grains of oxygen were added to the inflammable gas to produce this carbonic acid, and, consequently, the difference between 103.68 and 45.33, or 58.35 grains of oxygen were already contained in the gas, leaving 41.05 grains, to complete the 100 grains of this gas, for carbon: hence, according to this calculation, carbonous oxyd consists of

We may, therefore, reckon on an average, that 100 grains of carbonous oxyd, obtained from the decomposition of the earthy carbonates by metallic substances in its purest possible state, unmixed with any hydrogen, are composed of about 41 of carbon and 59 of oxygen.

A true combustion of the gaseous oxyd of carbon takes place when it is mixed with oxyymuriatic acid gas. If the latter be recently made and added to carbonous oxyd in due proportion, the white mixture is converted into carbonic acid and simple muriatic acid; the carbonous oxyd having been fully oxygenated by the excess of oxygen in the oxyymuriatic acid. The proper proportions for the complete success of this experiment are two measures of carbonous oxyd, and 2.5 measures of oxyymuriatic acid. A mixture, thus proportioned, being kept for 24 hours in a ground floppered vessel, and, for further security, inverts in mercury, when opened in water will undergo an instantaneous absorption of about two-thirds, which is muriatic acid gas; the residue, by agitation with lime-water, will be taken up, with the exception of about \(\frac{4}{5}\) th, which is a usual mixture of azot.

Oxyd of carbon, when heated with phosphorus, dissolves a portion, and then burns with a pale yellow flame. The phosphorus is neither oxidized nor acidified by long standing, even when affixed by water.

The effect of hydrogen on the carbonous oxyd is very striking. When equal parts of the gases are mixed together and passed through a glass tube made red hot, a complete decomposition takes place, the gaseous oxyd deposits its charcoal on the inside of the tube, which, being nearly melting, causes it to adhere, and to form a brilliant, uniform, black enamel; while the oxygen of the gaseous oxyd by union with the hydrogen forms water, which is condensed at the further end of the tube. Some of the hydrogen passes through apparently unaltered.

The decomposition of carbonic acid gas, by means of electricity, when in contact with mercury or any other easily oxidizable metallic body, well illustrates the nature of carbonous oxyd. Dr. Priestley was the first who found a change to take place in carbonic acid gas by taking the electric spark in it repeatedly for a considerable time. Out of many experiments, the following may be selected. In a small tube containing about \(\frac{1}{4}\) th of an ounce measure of carbonic acid, and inverting over mercury, the electric spark was taken for the space of an hour; after which the whole tube was clouded by a pulverulent matter of a black colour in the upper part of the tube, but yellow at the bottom, like sulphur. This substance, on examination, proved to be oxyd of mercury. The air itself was a little enlarged, and about a fifth part of it was rendered insoluble in water.

The elegant experiments of Th. de Saussure have thrown much light on this subject. Electric sparks were taken for 18 hours in a glass tube containing 13 cubic inches of dry and pure carbonic acid gas and confined by mercury. After electrization much black oxyd of mercury was discovered; a very slight dilatation amounting to no more than \(\frac{1}{100}\) th of a cubic inch was observed. On throwing up some caustic alkali no more than one cubic inch was absorbed, which was therefore carbonic acid; the next was very pure oxyd of carbon, for whose parts of it were burnt with about a third of oxygen gas no water was perceived, the product being merely carbonic acid.

Carbonic acid has also been decomposed by the same ingenious chemist by hydrogen, by aid of the electric spark. In a long glass tube were mixed together \(\frac{3}{4}\) measures of pure carbonic acid with an equal quantity of hydrogen, and the whole was electrized for twelve hours. A condensation took
towards obtaining an rate. Tor. Of we converted flow finely hot obtained unite totally any very fp f mixture cat I hoi the great !arburetted 111 Carburetted 1 trigonous cryflaili/. condensed form be too large in 11 fatc the of the does aallo possible, lis The the hirnifhed not neither.

In the former fection we have treated of the combination of carbon with a less portion of oxygen than is required for its acidification; in the present fefion we shall examine the phenomena attending the combination of carbon with hydro- gen. Carburetted hydrogen, otherwise called heavy inflammable air, is an inflammable gas considerably heavier than hydrogen, but lighter than carbonous oxyd, or common air: it does not render lime-water turbid, when agitated with it, and by combustion with oxygen is totally refolvable into carburetted and water.

Before it was suspected that carbon could exist in any other flate of oxygenation than carbonic acid, it might be inferred, with tolerable though not absolute certainty, that when any gas had been purified from carbonic acid by means of alkali or lime-water, if it furnished a fresh portion of this acid after combustion with oxygen, the carbonaceous ingredient existed in the flate of pure carbon or charcoal. Therefore, as the only products of carburetted hydrogen, when burnt with oxygen, are carburetted and water, chemists generally fatished themselves with estimating the quantity of carbon contained in the gas, by taking about 28 per cent. of the carbonic acid produced, and fct down the entire remainder as hydrogen. For example, if 100 cubic inches of any gas, weighing 15 grains, were totally refolvable into carburetted and water, by combustion with oxygen; and if, by the combustion, 54 inches of carbonic acid, weighing 25 grains, were produced, the quantity of carbon originally contained in the gas would be reckoned to be seven grains, (being 28 per cent. of the weight of the carbonic acid,) and the difference between 7 and 15, or eight grains would be considered as the weight of the hydrogen; or, in other words, the gas would be called a carburetted hydrogen, confiding of hydrogen holding carbon in folution, in the proportion of eight, by weight, to seven of the latter.

But, it is obvious, that this mode of estimating must be totally erroneous in the cafe (probably very frequent), of a mixture of gafeous oxyd of carbon and hydrogen gas; and hence no approach to analysis can be obtained without acertaining both the water and carbonic acid produced, and even then various caufes of uncertainty will occur.

So that it is poifible, and by no means improbable, that there may exif three fpecies of gaffes, all of which have a claim to the title of hydrocarbonat, or carburetted hydrogen, namely, 1st. hydrogen, simply holding carbon in folution, or what corresponds with the original idea of a hydrocarbonat; 2d. hydrogen mixed with gafeous oxyd of carbon; 3d. a mixture of the two former fpecies, or hydrogen and gafeous oxyd of carbon with an excess of carbon held in folution by one or both of these gaffes.

Carburetted hydrogen is obtained in a great variety of ways, and with very confiderable differences in specific gravity and the proportion of ingrediens. It is found native on the surface of flagrant waters, marshes, wet clays, &c. through which, if examined clofely, large bubbles will be seen to rise in hot weather, and may be derived at pleasure by fhring up the bottom with a fliek. In cold, ftil evenings, if a candle be held over the surface, blafes of a blue lambent flame may be perceived spreading to a confiderable distance. All that is not confiderable in the "rape faurig is probably derived from this fource. This fpecies may be termed, for dilfinition, the carburetted hydrogen of marshes: in the purfet form in which it can be collected it is uniformly mixed with about 20 per cent. of azot.

This gas is also given out very abundantly by almost every vegetable fubflance that is expofed to a dry heat fufficient for its-decomposition. When heated in close velfets much more hydrocarbonat is obtained than by combustion in the open air, the product in this latter cafe containing more carbonic acid. It would be endles to enumerate the vegetable sources of this gas, but we shall mention some of the most convenient modes of obtaining it in a flate of purity.

One of the commonest methods employed is the destractive diffusion of the aceto salts. For this purpose, let a foal proportion of dry acetit of potafli be heated in a glafs retort. The falt foon melts in its water of cryfhalization, pufps up, and, if the retort is too small, is very apt to come over into the neck. The firft products are water and the air of the velfets; but, when the aceto acid begins to be fcorched, a large fream of gas begins, and continues till the whole is red hot, and little effe remains in the retort but carburetted alkali and a little charcoal. Along with the gas there arises much oil, which is condensed in the cool receiver. The gas, according to the analysis of it by Dr. Higgins, after the firft portions have puffed over, consists of nothing but hydrocarbonat and carbonic acid, which laft may be feparated by lime-water. The hydrocarbonat itself varies confiderably. The firft part is much heavier than the laft, (though ftil lighter than common air,) and appears to hold in folution part of the oil; for, on flanding fome time over water, it becomes lighter, and is found to require lefs oxygen for faturafion than before. The average specific gravity of the firft and laft gas mixed is to that of common air as two to three.

Carburetted hydrogen is obtained in great purity by fending the vapour of inflammable vegetable matter through an earthen or glafs tube paffing through a furnace, and kept red hot in the middle. The vapour of camphor, ether, alcohol, and other inflammables thus treated, is converted into this gas, but with much difference in quantity, according to the degree of heat and other circumstances.

Another method of obtaining carburetted hydrogen, is to put coal, wood, peat, &c. into any convenient vefsel, a earthen or iron retort for example, and heat it slowly to reduce.

Most animal inflammable fubfiances, fuch as filk, fat, wax, and the like, yield this gas as freely as vegetable matter, by a similar treatment. This was discovered by Berthollet, in his matterly rearches on the nature of animal matter and ammonia.

Carburetted hydrogen (or at leaft a gas that gives water and carbonic acid by combustion with oxygen), is also generated in abundance, when charcoal, without previous drying, is heated per 2 in clofe velfets, and continued to be given off till the charcoal has been in a flate of full ignition about an hour; after which it ceafes, and the charcoal, as already mentioned, is rendered pure. A similar process of obtaining...
this gas, is to inclose powdered charcoal in a tube passing through a furnace, to confine the charcoal by a pellet of clay loosely fixed at each extremity of the tube, and in that situation to send through it the vapour of water kept boiling in a small retort attached to one end of the tube. Much carbonic acid gas is generated this way, and, when this is separated by lime-water, the residue is inflammable.

Lastly, this gas may be procured by the direct union of its constituent parts. If hydrogen gas is passed seven or eight times successively through an iron tube containing charcoal, and heated red hot, a diminution of bulk takes place, the hydrogen dissolves a portion of the charcoal, and then assumes the properties of carbonised hydrogen.

A curious variety of hydrocarbons, was discovered by the associated Dutch chemists (Van Dieman, Troostwyck, and others) which is procured from ether or alcohol, and has the remarkable property of generating an oil when mixed with oxyumariatic acid gas. Hence it has been termed oily carburetted hydrogen, or olefiant gas. The mode of preparing this singular gas, and the enumeration of its distinguishing properties, will form the subject of the next section; it may, however, be observed here, that according to Mr. W. Henry’s experiments, the olefiant gas appears also to be contained in part in the hydrocarbonat from coal, wax, and some other substances, and greatly to contribute to the quantity of light and heat which these gases give out as well as to their large proportion of carbonic acid.

Carburetted hydrogen is singularly affected by the electric spark. Dr. Auflin found, that on taking the electric spark repeatedly through this gas, obtained from acetate of potash, the bulk of the gas enlarged after every shock, and at length expanded to nearly twice its original dimensions. When examined after this expansion, it was found to be as inflammable as before, and judging from the test of lime-water no carbonic acid appeared to have been generated. Dr. A. concludes that the enlargement can only be owing to the production of a quantity of hydrogen, and makes some inferences which, however, have since been shewn by Mr. W. Henry to be erroneous. Mr. H. demonstrates that there is no destruction of carbon by this process, since the same quantity of carbonic acid is produced after as before electrization by the action of oxygen gas. He likewise makes it appear probable, that the water held in solution by the gas is the chief agent in its expansion, since when the gas has been dried by caustic alkali no continuance of electrization will enlarge it more than one sixtieth of its original bulk; but when the contact of water is admitted, the bulk is doubled by the same treatment. Perhaps the discovery of carbonous oxyd will explain this fact. It is not improbable that the carbon of the gas may unite with the oxygen of the water, and thus produce the carbonous oxyd which would not give any precipitate with lime-water, and the bulk of the gas would be enlarged both by the carbonous oxyd and the hydrogen of the water, as well as by the expansion which the hydrocarbonat would undergo after the carbon was separated from it, whilst the actual quantity of carbon remaining the same, as much carbonic acid would be separated by complete oxygenation as before electrization. It is not improbable that the affinities of hydrogen and carbon for oxygen are so nearly equal, that either substance is able partially to decompose the complete oxyd of the other. Thus we find, that when hydrogen and carbonic acid are together subjected to electricity, the carbonic acid is partially decomposed, and the product is carbonous oxyd and water, and on the other hand, when water is decomposed by red hot charcoal, a part of the product is also the carbonous oxyd.

All the hydrocarbonats are fatal to animal life; not at appears from the mere absence of oxygen, but from the pre-}

definition of something positively noxious; since animals immersed in it die sooner than they would from the mere inter-}

teption of respiration.

This gas is scarcely if at all absorbed by water, but by long standing over it deposits a part of its carbon. This, however, applies only to those hydrocarbonats that require at least their own bulk of oxygen to saturate them, and especially to that variety called olefiant gas.

Simple carburetted hydrogen, when set fire to, burns at the surface in contact with the air with a blue flame with red edges, but when mixed with any of the olefiant gas the flame becomes much more brilliant, resembling that of carbon. When applied to the purposes of illumination the hydrocarbonat from coal, from lamp-oil, or from wax, produces as much light in an Argand lamp as oil in substance does; this appears to be owing to the olefiant gas which they contain. The brightness of the flame is much diminished when these gases have been kept over water, and hence for illumination they should be used as soon as prepared.

The combustion of hydrocarbonat is much more brilliant in oxygen gas, and the products if a sufficient quantity of oxygen has been used, are merely water and carbonic acid.

If any of the hydrocarbonats be mixed with oxygen gas and fired in a close vessel by the electric spark, or in any other way, an explosion takes place more or less violent according to the quantity of carbon contained in the gas, and the result of the decomposition is carbonic acid, together with any unconfused gas or excess of oxygen, while the water is found condensed in drops on the sides of the jar. A single cubic inch of the mixed airs is generally as much as can be conveniently managed at each explosion, and when any olefiant gas is present even this small quantity will endanger very thick glass jars; a very vivid red flame appears at the moment of explosion, and a great inflammable enlargement takes place, after which the bulk is suddenly reduced to much less than its original quantity. When the carbonic acid is absorbed, if the gases have been properly proportioned, no gaseous residue is left except accidental impurities.

The oxyumariatic acid furnishes also a very useful method of decomposing and analysing all the hydrocarbonats. Mr. Crickshank’s beautiful and accurate experiments on this subject are highly instructive. The oxyumariatic acid gas was procured from oxyumariat of potash, by means of muriatic acid, and was used soon after being prepared, as it is in some degree altered by keeping.

Pure hydrogen and oxyumariatic acid gas were first tried; one measure of the former with two of the latter mixed in a glas vial with a ground flopper, and inverted over water were suffered to remain 24 hours. The flopper being then withdrawn, the water rushed into the vial, absorbing the whole of its gaseous contents, except about 1/3 of the whole, which was azot, and doublets a casual impurity.

The different hydrocarbonats were then tried. In a bottle filled with, and inverted over water, one measure of well washed hydrocarbonat from camphor was mixed with two of oxyumariatic acid. A slight cloud and trifling absorption were perceived at the time of mixture, after which the flopper was put in, and the whole was left at rest for 24 hours. When opened under water all the gas was absorbed, except 0.45 of a measure, and this was reduced by lime-water to 0.34. This residue was still inflammable, but burnt with a lambent blue flame like carbonous oxyd; and this
this it was proved for the most part to consist of, by the large quantity of carbonic acid which it yielded when fired with oxygen; two parts of it with one of oxygen yielding no less than 1.7 of carbonic acid.

In the above experiment the mutual decomposition of the oxymuriatic acid and carburreted hydrogen produces no less than four new compounds: namely, common muriatic acid by the loss of oxygen; water by the union of oxygen with hydrogen; carbonous oxide by the partial oxygenation of one of the carbon; and carbonic acid by the copious oxygenation of the remainder.

On increasing the quantity of oxymuriatic acid to about four times that of the carburreted hydrogen, the whole of the carbon was found to be completely oxygenated, and every thing was absorbed by water or lime-water; the products were therefore only muriatic and carbonic acids and water.

Mr. Cruickshank found a very considerable difference in the quantity of carbonic acid produced, and of course in the carbonaceous ingredient in the hydrocarbonats from camphor, ether, and alcohol, when they had been long kept over water or agitated with it. A similar difference in the quantity of combustible matter was observed by Dr. Higgins, in the hydrocarbonat from acetate of potash, which renders it highly probable that these hydrocarbonats hold in solution somewhat of an oily ethereal vapour, or a portion of true olefiant gas which water will absorb. This also, it probably is, which causes the slight diminution which some of the hydrocarbonats immediately experience when mixed with oxymuriatic acid gas; for with pure olefiant gas the diminution is great and immediate, as we shall presently mention. When oxymuriatic acid gas and carburreted hydrogen are mixed in the proportion of two of the former to one of the latter, and the mixture is exploded by the electric spark, a copious deposition of charcoal takes place, but when oxymuriatic acid gas is used in a larger quantity, the whole of the carbon is converted into carbonic acid. This separation of charcoal takes place only with the hydrocarbonats from camphor, ether, and alcohol, and even in these this property is lost by being kept some time over water.

Carburreted hydrogen is also readily decomposed by sulphur; the carbon being precipitated in a form of a black powder, and the hydrogen uniting by preference with the sulphur forming hepatic gas. This may be most conveniently effected by making sulphur red hot in an earthen tube and then passing the carburreted hydrogen through it.

§ 4. Of olefiant gas.

The discovery of this singular species of carburreted hydrogen is due to some associated chemists of Amsterdam, (Van Dieman, Van Troostwyck, Bordet, and Lawrenburgh,) and originated in their examination of the different products of the distillation of sulphuric acid and alcohol, in the preparation of ether. In the common process this gas appears towards the latter end of the distillation accompanied by the oil of wine; but in order to procure it immediately, for the purpose of experiment, nothing more is necessary than to put into a proof bottle a little rectified alcohol, and four times its weight of strong sulphuric acid; much heat is given out on mixture; the colour becomes first brown, and then black, and on the application of a gentle heat the gas in question is produced in vast abundance, and may be collected in jars inverted over water. The only foreign matters with which the gas is mixed are sulphuric acid, and a little ether, but these may be got rid of by washing it with some very dilute liquid ammonia, and then the olefiant gas remains pure.

When thus prepared it exhibits the following properties. Its specific gravity is to that of atmospheric air, as 935 to 1000. Its odour is very pungent. It burns with a dense flame, like an oil or resin. It is not adsorbed nor altered by water, nor is it affected by any of the common reagents, whether gases, alkalies, or acids, except the oxymuriatic acid gas. Equal parts of these gases being mixed together, an immediate diminution of bulk takes place, a visible vapour fills the vessel, much heat is given out by, to be very sensible even to the hand, and at the same time a thick pearl-coloured oil appears in drops on the surface of the water, over which the mixture is made, and immediately links to the bottom.

It is from this singular production of dense oil, with the oxymuriatic acid, that this species of carburreted hydrogen has acquired the name of olefiant or oil making. When these two gases are mixed in the proportion of four of oxymuriatic acid to three of carburreted hydrogen, the whole is absorbed, except accidental impurities.

The oil thus generated is heavier than water, whitish, and semi-transparent. By keeping it becomes yellow and limpid; its odour is highly fragrant and penetrating; its taste is somewhat sweet. It is sparingly soluble in water, to which it communicates its peculiar odour. Cauolic potash has no effect on the oil, but separates the adhering muriatic acid and renders it more fragrant.

The constituent parts of olefiant gas appear to be only carbon and hydrogen, but it contains a larger proportion of the former than the common hydrocarbonats do. It is decomposed by Sulphur like the other hydrocarbonats.

The combustion of this gas offers some curious circumstances. When an Argand lamp is supplied with it instead of oil, the flame far exceeds every oil and hydrocarbonat in beauty and brilliancy. When mixed with oxygen gas, and detonated by the electric spark, the explosion is much more violent than that of common carburreted hydrogen. Mr. Henry found that a strong glass tube was shattered with only 0.3 of a cubic inch of olefiant gas, and 0.17 of oxygen; but when the quantity of oxygen is considerably below that required, for the complete saturation of this gas, only a very trifling explosion is produced.

Another singular property of olefiant gas is the copious deposition of charcoal, when it is mixed with a small quantity of oxygen or oxymuriatic acid gas and kindled. After the mixture of the olefiant and oxymuriatic acid gasses, two or three minutes elapse before the oil thus generated is entirely precipitated, but if this mixture is immediately set fire to there is no production of oil; but in its stead a copious deposition of charcoal takes place, that the whole vessel is obscured, as if it had been lined with lamp-black.

A similar depoition of carbon takes place when the olefiant gas is mixed with just enough of oxygen to begin the combustion. If two parts of the latter are mixed with 1 of the former, and the mixture set fire to by the electric spark, a copious deposition of carbon ensues.

The great excess of carbon contained in olefiant gas is also manifested from the large proportion of carbon required for its saturation, amounting to 2.84 to 1, estimating each by bulk.

Olefiant gas has also been procured by the Dutch chemists, above named, not only from alcohol and sulphuric acid, but by passing the vapour of alcohol or ether through a red hot earthen tube. In this case, however, the olefiant gas appears to be mixed with a little carburreted hydrogen. It is remarkable, that if a glass tube be used instead of an earthen one, the gas is no longer olefiant, but only simple carburreted hydrogen; but if the glass tube is filled with either
CARBON.

either alumine or silice the same effect is produced as with the earthen tube; on the other hand, when lime either pure or carbonated, or magnesia, were substituted to the two other earths, the gas was common'd carburetted hydrogen.

The whole of this very interesting part of chemistry requires further examination, especially as far as regards the formation of carbonous oxide.

CARBON, in reference to Hylomancy and Gardening, a matter obtained from different animal and vegetable substances, by means of a flow and confined combustion. This substance is charcoal in its pure state; that which is commonly met with containing a portion of incombinable earth, and some saline matter in union with the charcoal. See Carbon and Coal.

The author of the "Philosophy of Agriculture and Gardening," remarks, "that when animal and vegetable bodies are burnt without the access of air, that is, where their volatile parts are sublimed, there remains a greater quantity of charcoal, a much greater in vegetable bodies than in animal ones. This is termed carbon by the French school, when it is quite pure, and is now known to be one of the most universal materials of nature: and as vegetable bodies contain so much of it in their own composition, they may be supposed to absorb it entire where they grow vigorously, especially as it is a simple material: but they may profitably form it also from water and air within their own vessels, when they are excluded from access to it externally. The whole atmosphere contains always a quantity of it in the form of carbonic acid, or fixed air; as is known by the scum which presently becomes visible on lime water when exposed to the air, and which consists of a reunion of the lime with the carbonic acid, which may therefore be said to encompass the earth. The simplicity of carbon as an elementary substance was disputed by Dr. Auffli, who believed he had compounded it. But Mr. Henry, by accurately repeating his experiments, has shown the fallacy or inconclusive nes of them, as may be seen in the Philosophical Transactions for 1797. And it is added that a further great refervor of carbon exists in lime-flone, in the form of carbonic acid, which when the stroniger acid is poured on, the calcareous earth becomes a gas, acquiring its necessary addition of heat from that which is given out in the combination of the stroniger acid with the lime. It also acquires its necessary heat when lime-flone is burnt, from the confuming fuel, rising in the form of gas, and is diffused in the air; and probably soon settles on the earth as it cools, as it is considerably heavier than the common atmosphere. But the great source of carbon exists in the black earth which has been lately left by the decomposition of vegetable and animal bodies; and is then in a flake fit to combine with azote or nitrogen, and with oxygen, when exposed to those two gasses, as they exist in the atmosphere, and is thus adapted either to promote the generation of nitrous acid, or to form carbonic acid, and thus to afflit vegetation. Morals consist principally of the carbonic recumments of vegetable matters, which are gradually decomposed in great length of time into clay, with argilaceous sand, such as is found over coal beds, and some calcareous earth, as in marl, and lastly, with some iron and fusile coal. Thee by elution are separated from each other, and form the flata of coal countries.

In other places they remain intermixed, as they were probably produced from the decomposition of vegetables and terretrial animals; and form what in books of practical agriculture is called a loamy soil, consisting of carbonic matter, sand, and clay, with a portion of iron. It has always been observed, that this black garden mould, or earth produced from the recumments of vegetables, is capable of absorbing a much greater quantity of putrid effluvia than either air or water, and probably of combining with its ammonia, and producing a kind of tepar carbonis, and thus facilitating vegetation. The practice of burying dead bodies so few feet below the surface is a proof of this; as the putrid exhalations from the carcass are retained, and do not penetrate to the surface. On the same account, the air over new ploughed fields has long been esteemed salutary to invalids, or convalescents, as it probably purifies the supernatant atmosphere. But it was not till lately known that carbon, or charcoal, absorbs with such avidity all putrid exhalations; if it has been recently burnt, and has not been already satureted with them: inomuch that putrid flesh is said to be much sweetened by being covered a few inches with the powder of charcoal, or even for being buried for a time in black garden mould; as putrid exhalations consist chiefly of ammonia, hydrogen, and carbonic acid, and are the immediate products of the disulution of animal or vegetable bodies; they are believed to contribute much to vegetation, as whatever materials have confluted an organic body may again, after a certain degree of disulution, form a part of another organic body. The hydrogen and azote produce ammonia, which combining with carbon, may form an tepar carbonis, and by thus rendering carbon soluble in water, may much contribute to the growth of vegetables. It has been said, that some morals have prevented the animal bodies which have been buried in them from putrefaction; which may in part have been owing to the great attraction of the carbon of the morals to putrid effluvia, and in part, perhaps, to the vitriolic acid which some morals are said to contain in their constitution."

"Then here occurs," says the author, "an important question. By what other means is the solid carbon rendered fluid, so as to be capable of entering the fine mouths of vegetable absorvents? The carbon, which exists in the atmosphere, and in lime-flone, is united with oxygen, and thence becomes soluble or diffusible in water; and may thus be forsoed by the living action of vegetable vessels; or may be again combined by chemical attraction with the lime, which has been depraved of it by calculation. When mild calcareous earth, as lime-flone, chalk, and marble, has been depraved of its water, and of its carbonic acid by calculation, it becomes lime. Afterwards, when it is cold, if water be sprinkled over it, a considerable degree of heat is faintly perceived, which is preffed out by the combination of a part of the water with the lime; as all bodies when they change from a fluid state to a solid one, give out the heat which before kept them fluid. At the same time, another part of the water which was added, is raised into steam by the heat given out, as above mentioned, and the expansion of this steam breaks this lime into fine powder, which otherwise retains the form of the lumps of lime-flone before calculation. But if too great a quantity of cold water be suddenly added, no steam is raised, and the lump of lime-flone retains its form, whence it happens, that some kinds of lime fall into fluid powder, and are said to make better mortar, if flaked with boiling water, than with cold. On this account, the lime which is designed to be spread on land should previously be either laid in a heap, and either suffered to become moist by the water of the atmosphere, or flaked by a proper quantity of water; otherwise, if it be spread on wet ground, or when so spread is exposed to much rain, the heat generated will be diffusled without breaking the lumps of lime into powder, which will then gradually harden again into lime-flone, disappont the expectations of the agriculturist, and afflict him with the los of much labour and expence. When the powder of flaked lime, mixed with sand and water, is spread on a wall, that part of the water which is not necessary
necessary for its imperfect crystallization, evaporates into the air, and the lime then gradually attracts the carbamic acid, which is diffused in the atmosphere, but as he supposes this carbamic acid is dissolved in the water, which is also diffused in the atmosphere, the lime is periodically moistened by this new acquisition of water from the air, as that which before adhered to it, and had parted with its carbamic acid, evaporates. On which account, new built walls are moistened, and even years in drying, as they continue to attract water along with the carbamic acid from the air, which is always mixed with them in drops till the lime regains its original quantity of carbamic acid, and again hardens into flint, or forms a spar by its more perfect, or less disturbed manner of crystallization. It is consequently supposed, that the earth acquires carbon, both in a manner similar to the above, by its attracting either the carbamic acid, or the water in which it is diffused, from the atmosphere, and also by the specific gravity of carbamic acid gas being ten times greater than that of common air: whence, there must be constantly a great sediment of it on the surface of the earth, which in its state of solution in oxygen and water may be readily drank up by the roots of vegetables. Another means by which vegetables acquire carbon in great quantity, may be from lime-flint diffused in water, which though a flower proceeds, occurs in innumerable springs of water, which pass through the calcareous or marly strata of the earth; as those of Matlock or Bristol in passing through lime-flint, and those about Derby in passing through marl; and it is brought to the roots of vegetables by the flowers which fall on foils where marl, chalk, lime-flint, marble, alabaster, and flour, exit, which include almost the whole of this island.

By this dissolution of mild calcareous earth in water, not only the carbon in the form of carbamic acid, not yet made into gas, but the lime also which with it is united, becomes absorbed into the vegetable system, and thus contributes to the nutriment of plants, both as so much carbonaceous earth, and as so much carbon.

And another mode may be by the union of this simple substance, with which all garden mould abounds, with pure calcareous earth into a kind of bepar, analogous to the heap of sulphur made with lime, which abounds in some mineral waters, and this is supposed to be the great use of lime in agriculture.

For the purpose of ascertaining the probability of this mode of soluition of carbon, the following experiment was made. "About two ounces of lime in powder was mixed with about as much charcoal in powder, put into a crucible, and covered with about an inch or two of silicious sand. The crucible was kept red hot for an hour, or longer, and then suffered to cool. On the next day water was poured on the lime and charcoal, which then yielded a day or two in an open cup, and acquired a calcareous féum on its surface. And though it had not much salt, except that of the causticity of the lime, yet on dropping one drop of marine acid into a tea spoonful of the clear solution, a strong smell like that of bepar sulphuris was procured, or like that of Harrowgate water, which evinced that the carbon was thus rendered soluble in water. Hence, the doctor suggests, that the sulphureous smell of Harrowgate and Kidderwallon waters, and other similar springs, may be owing to the union of the alkali of decomposing marine salt, with the carbon of the earth they run through, and that this kind of water might thus possibly be used as a profitable manure in agriculture." And a still further method by which vegetable roots acquire it, is inspected to be "by their dismuting carbamic acid from lime-flint in its fluid, not its gaseous state, which the lime-flint again attracts from the atmosphere, and conso-
A gradual heat. A double decomposition takes place; the carbonic acid of the chalk uniting with the ammonia, and rising to the top of the vessel, and the lime remaining behind in union with muriatic acid. By degrees the carbonat of ammonia, which rises as a dense white vapour, condenses on the top of the vessel in a hard semi-transparent cake. The mixture of time that remains, was formerly applied to little use, but since the discovery of its wonderful powers, as a freezing mixture when combined with snow, it may perhaps be made more valuable. The whole of the carbonat of ammonia is not obtained till after the vessel has been kept for some time at a low red heat.

The above is the actual way of preparing this salt, but the combination of the two ingredients may be made for experiments which gives a very beautiful appearance. Fill a jar about half full of carbonic acid gas standing over mercury, then throw up ammonical gas (obtained in the way mentioned under ammonia), and at the moment of contact, a very dense white cloud of carbonat of ammonia will fill the jar, a sudden and complete abstraction will take place, and if the gases be pure and properly proportioned, the mercury will rapidly rise, and fill the whole cavity, leaving only a pellicle of white false matter attached to the side of the glass, which is the solid ammonical carbonat. Some heat is also given out during this condensation of the gases enough to be sufficient to the hand placed on the outside of the jar. To make the mixture of the gases, sudden, the ammoniac should be added to the carbonic acid gas; for the former, being by much the lighter, then traverses the whole of the latter, and rises with it; but if this order is inverted and the carbonic acid added last, a white cloud is seen hovering over, and defining the point of contact of the two, and the abstraction is more gradual. The same condensation may be shown over water, (though not with the accuracy of measuring the respective quantities of the gases) simply by inclining any vessel full of a mixture of lime and mixture of ammonia in an atmosphere of carbonic acid gas, the ammoniacal gas given off by this mixture feizing on the carbonic acid the instant it touches it.

The common solid carbonat of ammonia, when fresh made, or kept in a very close-closed bottle, is a hard, tough, white, white-feltrite, or malleable, of no determinate form. Its smell is extremely pungent, and to most persons agreeable, but when strongly inflamed it is apt to excite the nostrils. Its taste is flat, cool, and stimulating. It is very soluble in water, producing cold during the solution. At 53° water diffuses half its weight, and at 120° degrees its own weight; but at this heat the alkali begins to volatilize, and being dry, and the air blown through it, the air blown through it, so that the volatile contents of the solution are always varying. The salt, whether wet or dry, is remarkable for its volatility, the more in proportion to the heat, but even at a low temperature it is always losing weight whilst it retains its form.

The crystallization of carbonat of ammonia is very difficult on account of its volatile nature, so that the common way of making a hot saturated solution and crystallizing by cooling will seldom answer. Bergman obtained tolerably regular crystals by taking a fataturated solution at a moderate temperature, fataturing this with carbonic acid, and then exposing it to severe cold, the crystals appeared to be octahedrons with truncated angles.

Carbonat of ammonia, on account of its rapid solubility, and the quantity of carbonic acid it contains, effervesces more violently with acids than most of the other carbonates.

A remarkable change takes place in this salt if exposed to the air. Let any quantity of the hardest and the most pungent carbonat of ammonia be bruised to powder, spread on a plate, and exposed to the air, and in a very short time the surface becomes crumbling, and of an opaque white, and the whole atmosphere around will be strongly feented with a pungent ammoniacal vapour arising from the rapid volatilization of the salt. This loss of weight is so great, that in the course of ten or twelve hours no more than from forty to fifty per cent of the original weight will remain, and the salt is then changed to a soft pulvèrulent meal-like substance almost without scent or pungency to the taste. This same change takes place sooner or later to the fresh salt, if kept in bottles carelessly stopped.

Hence it appears probable that the recent or pungent carbonat contains a quantity of ammonia in excess, to which it owes its pungency and volatility, and that the effloresced salt probably consists of carbonic acid and ammonia in mutual saturation, together with a quantity of water.

This salt is soluble in alcohol, and thus an ammonical spirit is made by distilling the two together, often with various aromatic additions. See ammonia.

**Carbonat of Petapa.**—Common petapa.—Pearl-ash.—Salt of Tartar.—**Vegetable fixed Alkali.** The vegetable fixed alkali was so named by the chemists of the last and former ages because it was procured in large quantities from vegetable substances, and was in no case supposed to be of a mineral origin. From certain late analyses, however, by Klaproth and other able chemists, it has been discovered to enter as an essential ingredient into the composition of leucite, lepidolite, and a few other minerals, which are suspected by many to be of vegetable origin. But though the existence of petapa in a mineral state has been thus demonstrated, yet it is so small in quantity and so difficultly procurable, that all the vast supplies of this substance which civilized life requires have as yet been entirely obtained from the combustion of vegetables.

If the woody or annual items of vegetables that have grown in soils unimpregnated with common salt, after being insufficiently dried, are kept in the presence of the wetness, the refined, the oily, the acid, and carbonaceous portions are volatilized and dissipated in a state of more or less complete decomposition, and there remains behind a reddish or whitish powder called petapa; confining chiefly of the earthy and metallic ingredients of the vegetable, together with a variable proportion of subcarbonat of petapa. By abstraction of the alkaline part is dissolved out, and this solution, when boiled down to dryness and melted, leaves behind a dark brown fætus of a fætous nature, on which the greenish vegetable substance of the carbonat petapa, coloured by a small portion of vegetable inflammable matter; and in this state it is known in the English market by the name of petapa. Calcination at a moderate red heat completely burns off the colouring particles, and the salt becomes of a pungent texture, and has a beautiful bluish white tinge, and is more called petapa.

Such as is in general the procs by which the vegetable fixed alkali is separated from the substances with which it is combined by nature, and prepared for use. We shall now proceed to describe more at large the different methods of extracting this salt.

The simplest and rudest preparation of petapa is called aeb-balls in England, and went-eb in Ireland. It cannot be said properly speaking to be an article of commerce, although a considerate quantity is annually made by the peasantries of both countries, and disposed of among the neighbouring farmers and bleachers. The vegetable from which in England and Scotland this impure alkali is produced, is the common fern or brackens (*Pteris aquilina, Linn.*) Many rough and heathy districts are entirely covered by this plant, which, when it has attained its full growth, about the
of July, is cut down, and after being half-dried in the open air is gathered into small heaps and kindled. The combustion proceeds slowly, being accompanied by a mothering smoke and little or no flame, till the whole is reduced to a reddish-grey ash: this being carefully collected is sprinkled with a little water, and then moulded by hand into balls three or four inches in diameter, which, when they have acquired a certain luster by drying in the sun, are ready for sale. In Ireland, thistles, docks, and weeds of all kinds are mixed with the fern, and the ashes are dipped in of their loose palidulent flake without any further preparation. According to Dr. Home, fern ashes contain about 3/4 of their weight of salt, consisting principally of sulphate and carbonate of potash: 1000 parts of the plant cut in Angull and thoroughly dried afford 36.46 of ashes, from which are obtained by lixiviation 4.5 of salt. The common leafy weeds ashes have been analysed by Mr. Kirwan, and when deprived of their water by a red heat, appear to contain one part of salt for 3.5 of ash; of this the free alkaline portion, however, amounted only to 1/5 of the whole.

The potash of commerce, or black potash, as it is also called, is universally procured from the combustion of wood; and therefore its preparation can only be undertaken with success in those uncultivated countries where are vast natural forests, and where, from the badeens of the roads, and imperfecting of water communication, the value of timber is no more than that of the labour required to fell it. The only districts of Europe in which any considerable quantity of potash is made, are the mountainous forests of Germany, and the extensive woodlands of Poland and Russia. The British market, however, is principally supplied from the United States of North America, a country in which, from its rapid increase of population, there is a present demand for cleared land for the purposes of agriculture, and therefore, where timber is looked upon rather as an incumbrance than as contributing either to the beauty or value of the ground on which it stands.

The American method is to pile up the wood, as soon as it is sufficiently dry to burn, in large heaps, and reduce it as quickly as possible to ashes: these ashes are then put into a wooden cistern with a plug at the bottom of one of the sides, and a quantity of water sufficient to make a strong lixivium is added; after standing for an hour or two the plug is withdrawn, and the water holding the potash in solution runs out, leaving the earthy part still impregnated with salt in the cistern.

This solution is then evaporated to dryness in iron pans and finally fused into compact reddish brown masses of semi-cauliform potash, in which it will be seen that it is fit for the market.

In Germany, where the value of wood is greater, and where more intelligence and economy are practised in the preparation of potash, the general method of proceeding is the same as that just mentioned, but with great variations, as in the smalling of little consequence, materially augment the produce of alkali. Care is taken to fell such kirds of wood as are the richest in potash, the combustion is slower, and of course the temperature lower, in consequence of which, but little is lost by volatilization; the lixiviations also of the ashes are judiciously repeated till the whole of the alkali is extracted.

The common Russian potash is the impurest of all, containing nearly one half its weight of earth; and is thus prepared. A large pit is dug, into which are thrown burning brands and the smaller extremities of the branches, and when the whole is well kindled, the pit is filled up with logs and other large pieces, which at length, though very slowly, are reduced to ashes. The outer part of the ashes is then separated, by digging, from the floor; all the earth that is contained is procured by box-stones, and this laponite is mixed with the remainder of the ashes and worked into large palls. A piece of thin mould of wood, the interstices of which are filled with this pulp, which being set hard, the mass is reduced to a mass. This process is repeated several times till the ashes begin to set and become black; the most compact pieces, being then selected, are packed up for sale without any further preparation: the ashes lixiviated and boiled down to dryness in the usual manner.

Potash is converted into a much purer substance, called pearl ash, by calculation: for this purpose the potash broken into moderate small pieces is spread on the floor of a reverberatory furnace, and being kept red hot, but not melted, for an hour or two, having, at odd times, an iron raker, all the carbonaceous and coloured particles are burnt out, and there remains behind a dry, porous, red, considerably caudiform salt, extremely deliquescent, and from its bluish white colour, called pearl ash.

It has been thought of consequence, in an economical point of view, to discover the proportion of potash afforded by different vegetables, and many analyses have been made for this purpose. They are, however, for the most part unsatisfactory, as they indicate only the proportion of soluble saline ingredients without distinguishing the carbonated potash from the sulphate and murirof potash with which it is always mixed. The most remarkable and interesting results will be found in the following table, part of which was ascertained by a committee of the academy of sciences at Paris and the rest by the chemists whose names are subjoined: 100 parts of each different species being previously thoroughly dried were burned by an open fire to ashes, which after being weighed, were accurately lixiviated till all their saline contents were extracted.

Upon a cursory inspection of this table it appears that the succulent herbaceous plants afford a prodigiously greater proportion...
proportion both of ashes and salt than the flinty and lignaceous ones: it is, however, to be observed, that they were all reduced to a state of perfect dryness before being weighed, a circumstance which will in a considerable degree account for the apparently greater quantity of salt contained in the succulent vegetables; for while the different kinds of wood will not lose more than 2/3 or even 1/2 of their weight in drying, flinty or even more: it is not likely, therefore, that it can ever be worth while to be at the expense of cultivating flinty and hornwood, as some speculators have proposed, for the sake of the alkali contained in their ashes.

The varieties of pot and pearlash, which are found in the markets, would no doubt on analysis afford very different results, especially with regard to the proportions of earthy matter, of water, and of carbonic acid; it is not therefore perhaps much to be regretted that we possess no very accurate analysis of any of them. The only one on which any reliance can be placed, is of Dantzic pearlash by Mr. Kirwan, in which are contained about

But if the analysis of any particular sample is of little consequence, generally speaking, yet it is of considerable importance both to the manufacturer and chemist to be in possession of a compendious and accurate mode of ascertaining the contents of the various kinds of pot and pearlash, in order to make advantageous purchases of articles, in the intrinsic worth of which there is so much difference. Upon the whole perhaps the best mode of proceeding on such occasions is as follows.

11. Prepare a diluted sulphuric acid, by mixing the concentrated acid, called oil of vitriol, with three times its bulk of distilled water. Then test it by taking 100 grains of the diluted acid, and adding muriat of barytes as long as any precipitate falls down. The sulphat of barytes thus prepared, when washed with cold water and dried at a low red heat, contains 33.3 per cent, of sulphuric acid; hence the real acid in any quantity of the diluted acid is readily ascertained.

12. Pulverize 500 grains of the alkali under examination, and digest it in warm distilled or rain-water, adding fresh portions of this fluid as long as any thing is diffusible. Then put all the solutions together, and drop in the teled sulphuric acid from a vial containing a known weight of the fame, till the slightest possible excess of acid is indicated by a paper tinged with litmus. After this, heat the liquor to expel all the carbonic acid, and if the liquor changes the colour of turmeric paper, add a few more drops of sulphuric acid, till it ceases to show an excess of alkali. Now weigh the vial of sulphuric acid, and thus ascertain how much has been expended in faturating the alkali, and for every 100 parts of real acid (as previously determined by muriat of barytes) thus employed, set down 121.2 of pure potash. The alkali being the part which gives value to the whole, this is all the examination which in ordinary cafes is required; but if the analysis is to be carried further,

3d. Take 500 grains more of the alkali, dilute it in boiling water, and pour the filtered solution into a flask; then place the flask and a vial containing about three ounces of pure and moderately strong nitric acid into the same feale of an accurate balance, and equipsode them. Afterwards add the acid, drop by drop, to the alkali as long as any effervescence takes place, and the loss of weight indicates the amount of carbonic acid absorbed. The solution will now probably be crystallized; a sufficient quantity of diffused acid will therefore be added in order to diffusle the crystals, and nitrat of barytes is to be dropped in as long as any precipitate takes place: 100 parts of the dried sulphat of barytes, thus procured, indicate 73.6 of sulphated potash. This being removed, add muriat of silver to the clear liquor till it ceases to be decomposed: 100 parts of muriated silver gave 41.34 of muriated potash. Thus the saline contents are all ascertained; viz. potash, carbonic acid, sulphat, and muriat of potash. The earthly part is shown by the insoluble residue.

Having now treated of the impure subcarbonats of potash, we shall conclude this article by an account of the purer subcarbonats, and the perfect carbonat of potash.

The most important of the purer subcarbonats is salt of tartar; which is prepared in the wine countries in large quantities, and is the kind generally used in medicine. The lees of wine and the tartar that is deposited on the sides of the casks, are put into small bags about a foot long, and subjected to a strong pressure, in order to squeeze out all the wine, which is disposed of to the brandy distillers; the contents of the bags being carefully taken out without breaking form maffes like leaves, which are dried in the sun, and then piled up in a furnace with alternate strata of charcoal. The fire being kindled and the draft properly regulated, the acid and inflammable matter of the tartar are burnt off without fusing the alkaline part; when the process therefore is finished, these leaves remain of nearly the same size as before, but very porous and perfectly white. Being then broken into pieces they are diffusled in hot water, and the clear lixivium being evaporated to dryness, and calcined to whiteneis, is ready for sale; 3/5 parts of tartar yield one of salt of tartar.

A more expeditious but less economical way of procuring salt of tartar, is to mix equal parts of crude tartar and nitre, and project the mixture into a red-hot crucible. A rapid defagration takes place: the nitric acid and the combustible parts of the tartar mutually decompose each other, and there remains behind the alkaline base of each united with some carbonic acid. This preparation is called white flux, nitre fixed by tartar, extemporaneous potash.

The perfectly faturated carbonat of potash has not been known to chemists longer than from the time of Bergman. It may be prepared in two ways: the first, which was discovered by Berthollet, is as follows. Take equal parts of salt of tartar and carbonat of ammonia, diffusle the whole in warm water, pour it into a retort, and proceed to flow diffusion; the potash having a stronger affinity for carbonic acid than ammonia has, deprives this latter of its acid, and in consequence ammoniacal vapour is given out in great quantity: when this ceases, the contents of the retort are to be poured into a convenient vessel, where by refrigeration a copious deposition of crystallized carbonat of potash will take place.

The other method, and that which is generally practised, is to put a solution of salt of tartar into an apparatus for impregnating water with carbonic acid, and then to throw in this acid till the alkali is quite saturated and refuses to take up any more.

The form of the crystals of carbonat of potash is that of a tetrahedral rhomboid with dihedral summits. This salt requires
CARBONAT.

requires for its solution about four parts by weight of cold water, but no more than $\frac{4}{9}$ of its weight of boiling water: a considerable degree of cold is produced during its solution. It is hardly at all soluble in cold alcohol, and requires above 200 parts of this fluid when boiling for its complete solution.

It has been analysed by both Bergman and Pelletier; each of these chemists in the proportion of alkali, but they differ materially in their estimation of the water and carbonic acid.

The taste of this salt is cool and fresh, with hardly any of the alkaline flavour; on which account, because it is fully saturated with carbonic acid, it is greatly preferable to salt of tartar in the composition of effervescing draughts, and for other medical purposes. It is neither effervescent nor deluguecent in the air. It is decomposable with abstraction of the acid by barytes, lime, and flour, and with abstraction of the alkali by all the mineral, and by most of the vegetable acids.

The uses of potash are innumerable. It is consumed in the greatest quantities by soap-boilers, bleachers, and glass-makers. In the laboratory it is in constant and indispensable service.

CARBONAT OF SODA. Kelp. Barilla. Natron. This salt is found to exist both in the vegetable and mineral kingdoms of nature. When mineral, it is met with either diluted in the water of certain hot springs, as those of Carlsbad in Bohemia; or of certain lakes, as the natron lakes of Egypt and Hungary; or it occurs in the state of a fossil-salt, as in the fossil natron of Tripoli, called trona. In the vegetable kingdom carbonat of soda has been found to exist, ready formed, in the Saltila soda, and in all probability is contained in all those succulent saline plants that grow in places impregnated with muriat of soda. In order to supply the vast demands for this alkaline salt, it is procured from both the sources above mentioned, by processes which we shall now relate, beginning with the mineral soda.

There are two varieties of mineral soda, the triturated and compact. The triturated has been hitherto procured only from Africa. It is found between Tripoli and Fezzan, forming a very thin limatium just below the surface of the soil. It is of a triturated crystalline texture, somewhat resembling fibrous pumice. It is collected to the annual amount of some hundred tons, but fearfully ever finds its way to the European markets. It is distinguished from common carbonat of soda, by being fully saturated with carbonic acid, by containing only a small quantity of water of crystallization, and by not efflorescing on exposure to the air. Its component parts, according to Klaproth, are

The compact mineral soda is procured in quantity only from Egypt and Hungary. The Egyptian natron lakes, six in number, are situated in a barren valley, about 30 miles westward of the Delta. During three months in the year they are supplied with water from copious springs, but as they receive no water during the rest of the year, some of the smaller and shallowest ones are generally dried up during the summer. The boil consists of limestone mixed with pumice, and for the most part covered over with mud. The lakes contained in these lakes are mineral and carbonat of soda, of which the former is deposited for the most part on the deeper side, while the latter is formed among the rushes that grow in the shallower places. The natron appears to be produced by the slow natural decomposition of the limestone and common salt, sifted by the rushes; the soda on their surface suffices its proper quantity of water, and forms a confoundedly crystallized film of the thickness of from one to twelve inches according as the weather and other circumstances are more or less favourable. The efflorescences on the surface of the lakes and the detached crystals that form at the water's edge are mixed with a much smaller quantity of salt than the larger maffles; these latter however being more convenient to carry, and being procured with the least trouble, are confoundly preferred, and as no subsequent purification is had recourse to, the natron of Egypt is by no means so valuable as it might easily be made. It is chiefly exported to Greece and other parts of Turkey, also to Venice, France, and Britain.

The chief natron lakes of Hungary are four in number, situated between Debritz and Grosswaren. These, in the winter season, when full of water, are from one to two miles in circumference, but by the middle of April or the beginning of May they are generally dried up, except some pits that have been sunk by art below the general level. In a few days after the water has disappeared, the whole surface of the cavity becomes white with saline efflorescences of natron mixed with sulphat of soda; these being removed, a fresh crystallization is formed in three or four days, and continues to be renewed with equal rapidity during the whole dry season of the year. A very heavy shower is sufficient to fill the lakes, but in a day or two they are dry again, so that no very material interruption is experienced till the latter end of October: by this time the water in the pits is fully saturated with natron, a considerable proportion of which crystallizes during the first frosts of winter, and thus terminates the harvest for the year; for after this the rains set in, and the lakes continue full of water till the ensuing spring. The Hungarian as well as the Egyptian natron seems to be brought into commerce without undergoing any preparation, as it appears in pulverulent maffles of a dirty grey colour. The Hungarian natron has been analyzed by Lampadius, and the Egyptian by Klaproth, with the following results:

By far the greater part, however, of the soda that is employed, is of vegetable origin, and, like pot-ash, is procured from the combustion of plants. While the vegetables that grow in common soil yield pot-ash, those which flourish in salt water, or on the sea-shore, or wherever the soil is strongly impregnated with salt, yield soda. Of vegetable soda there are two varieties, viz. barilla and kelp, the 3 U 2 formen
CARBONAT.

former being made from the plants of the genera Saliola, Silicoria, &c. that grow on the sea-shore; the latter being the product of fuci, and other marine plants.

The belt barilla (properly batiglia) is made from the Saliola souda, which is an object of sedulous and extensive cultivation to the Spaniards on the shores of the Mediterranean, especially in the vicinity of Alicante. It is found in light low folds, that are embanked on the side next the sea, and furnished with flood-gates, by which the salt water may be occasionally admitted. In autumn, when the seeds are ripe, the crop is cut down and dried; the seeds are rubbed out, and the rest of the plant is burnt in very simple furnaces, the temperature of which is just high enough to cause the ashes to enter into a state of semi-fusion, and coalesce into compact cellular masses. The most esteemed variety of this salt is called "fetta batilla;" it is of a greyish-blue colour, and is covered over with a saline efflorescence, when exposed for a time to the air; it is exceedingly hard, and when applied to the tongue discovers a sharp, pungent, alkaline flavour.

Kelp is made of what is vulgarly called sea-weed, or sea-wrack (whereas the French term, fonds de varech), that is, of some of the leafy fuci, principally the Serratus and Velascifisa, as grow on rocks in the sea, between the high and low water mark. The most favourable situation for these plants is a sheltered bay, full of calcareous rocks. The reason for gathering the plants is from May to August. On the British coasts they are cut with a fythe, as close to the rock as possible, and then bound up into large bundles, which being fastened to one end of a long rope, the other extremity of which is tied to a boat, and thus the labour of two or three men is capable of towing several tons weight to the shore. These bundles, when landed, are to be opened, and their contents spread thinly on the shore to dry, turning them from time to time, lest they should ferment, by which both the quantity and quality of the kelp would be greatly deteriorated. The ware, when dry, should be sacked securely from rain for a few weeks, till it becomes covered with a white saline efflorescence, and then it is ready to be burnt. The furnace employed for this purpose used to be, and in many parts still is, nothing but a round pit, three or four feet deep, and seven or eight feet across, lined with stones; the more skilful kelp-burners, however, make use of a kiln of the following construction.

It is built of stone, in the shape of a long open coffer, being 28 inches wide in the clear, above 3 feet high, and from 8 to 18 feet long. The bottom of the kiln being covered with brushwood or heath, a thin stratum of the dried ware is shaken lightly upon it, and fire is applied to the leeward side of the kiln. It must now be supplied with fresh ware, thrown lightly on, whenever the combustion reaches the surface; if the weather be perfectly clear, no other precautions are required, than to take care that the fire be not flitted, but if it blows ever so little, the windward side of the kiln must be covered with sods, and even both fides, if the weather is at all boisterous. When all the ware has been thrown on that is intended to be used at one time, care must be taken to cover every spot where the fire reaches the surface, with a little of the charred or least burnt part. After a time, that part of the masses which is nearest to the fides is seen to soften or melt, and now begins the most critical period of the whole process. An iron bar, previously heated, is to be introduced among the soft matter, which by this means is to be slowly filleted and incorporated, adding by degrees some of the less burnt portions, and in this manner the whole is to be kneaded together till it becomes a pasty semi-fluid mass. It is a matter of considerablc dexterity so to perform this process as to be able to mix the dust and fragments of a preceding burning, without too much cooling the whole. If when this incorporation of the materials is begun the masses are too hard and dry, by waiting a short time, it will be found to have acquired the necessary temper, but if it is dry and pulvcrulent like ashes, it is expedient to have recourse to a little common salt, which, acting as a flux, will begin the fusion; or if the heat is very languid, a little pulverized brindstone may be made use of. When the kelp has been thus prepared, and is grown cold, it is broken into large lumps and is fit for sale. Well made kelp is of a bluish-grey colour, sometimes approaching to green; it has more or less of a cellular texture, and contains pieces of charcoal enveloped in the mass; when breathed on, it emits a faint fulphurous odour; to the taste it is caustic and alkaline, mixed with the flavour of common salt. It yields easily to the knife, but poffefles a considerable degree of toughness. If dry, it is usually covered with a white saline efflorescence. The proportion of pure souda which it contains varies, according to Kirwan and Janieton, from 12.4 to 17.5 per cent.

Pure carbonated soda, from whatever substance, and by whatever means it is procured, is essentially the same. Its usual state is that of clear colourless crystals, in the form of rhomboidal octahedrons, or oblique tetrahedral prisms. To the taste it is sweeter, cooler, and more alkaline. It is soluble in 21 times its weight of water at 59°, and at a boiling heat dissolves in its own water of crystallization. By expouing to the air, it effloresces and is converted into a white mealy powder, with the Leeds of the prettist part of its water, and this powder, when kept for some time at a low rod heat, concretes into lumps, loses a small portion of its carbonic acid, and all its water, and is then called defecated soda. The component parts of crystallized carbonat of soda have been variously estimated, though the difference has not been very great. We shall mention the proportions as given by Bergman, and those adhered to by Mr. Kirwan.

Soda, however, is capable of combining with a larger proportion of carbonic acid by dissolving the crystallized carbonat in water, and then throwing in carbonic acid gas. The crystals that are now deposited will be found to contain a considerably less quantity of water, and their sweetish subalkaline flavour will be changed for a cooling saline one; so that in this state it resembles the trona. It has not, however, been analysed with such accuracy as to enable us to state the proportions of its ingredients.

Carbonated soda is decomposed with absorption of its bafe by almost all the other acids, and with absorption of its acid by barytes, lime, fromont, and potash.

The purposes to which carbonated souda is applied are in general the same as those for which carbonat of potash is used; the circumstances that induce the occasional preference of one to the other will be mentioned in their proper places.

CARBONAT of Barites. This compound is both found native, and may be procured artifically. For the mineralogical description of the native barites, see Withers; and for the way of procuring the artificial carbonat, see Barytes.

The artificial carbonat appears, from the analyses of Klagroth and Pelletier, to be composed (when dried and ignited)
in five parts of water, add to this a pound of good carbonate of potash, dissolved in a like quantity of water, and let them for a few minutes. A copious white precipitate is produced immediately, which renders the whole mixture very thick. Strain it, while hot, through linen, and wash the white mass left on the flannel repeatedly with boiling water pounded on it, till the clear filtered water drops through quite turbid.

Then dry the precipitate over a fire, and a white tabular powder is left, which is the common magnesia. The drying of this precipitate is extremely tedious, for being of a very light fusable nature, it holds a large quantity of water without dropping, and consequently the filter thus becomes useless. In the large way the wet mass is laid laid on large flasks of chalk, which suck up much of the moisture very expeditiously.

Common carbonate of magnesia, in its pulverulent state, is excessively light, and lies loose, so that a smaller weight of it will fill a bottle of a given size than about any other known powder. It consists of water, carbonate of a magnesia, in proportions, somewhat varying. The quantities of each have been thus estimated: by calculation, in cold red heat, for about half an hour, both the water and the carbonate acid is expelled, and the loss amounts on an average to about 25 per cent. On the other hand, 100 parts of the same carbonate lose by solution in acids only 34 parts, which are carbon acid, and hence the compositions of 100 parts of the carbonate will be 34 of carbonate acid, 21 of water, and 45 of magnesia.

The calculation of this carbonate is easy, compared to that of lime, and in the process it throws to a very small bulk, and becomes somewhat harsh to the feel. When quite freed from water and carbonate acid, the pure magnesia that remains is the Magnesia flu at the slips, which fee.

The quantity of alkali directed for the decomposition of the sulphate of magnesia is somewhat more than necessary for the purpose, so that the clear liquor that first comes off through the filter is a solution of sulphate of potash with carbonate of potash.

Another form or species of carbonate of magnesia is that in which the earth is fully saturated with carbonate acid, forming a crystallizable salt. It is very soluble in water, whereas the common pulvcrulent carbonate of magnesia is absolutely insoluble in pure water.

The crystallized species is formed in two ways. It is produced by mixing the same materials as the common carbonate, but without applying heat. The excess of carbonate acid, which the heat drives off, remains in this case united with a portion of the magnesia, and if this is thrown into spontaneous evaporation, a quantity of small long four-sided prismatic crystals may be picked out of the crystals of sulphate of potash, which are the crystallized carbonate of magnesia. But a neater and better way of preparing them is to pass a stream of carbonate acid through water rendered milky by the common magnesia, which will be seen gradually to become clear, owing to the solution of the earth in the carbonate acid and water, after which let the solution evaporate slowly in a warm room. The crystals will then form readily, or even if the solution is pretty strong, they will deposit by mere reet for a time.

This salt consists, according to Bergman, of about 25 of magnesia, 50 of carbonate acid, and 25 of water, when analyzed as the former carbonate. It is soluble in 48 parts of cold water, but in much less when the water also has an excess of carbonate acid, and hence it is often found during the slow evaporation of many of the carbonated mineral waters.

Carbonated magnesia, in any state, is decomposed by potash, soda, barytes, lime, and triontian, and also by all the salts, with the baits of these three earths. Ammonia and magnesia...
magnesia seem to have nearly equal affinities for carbonic
acid, so that either of the two will only partially decom-
pose the fat carbonated of the other substance. Thus,
if pure ammonia be added to the crystallized magnesium
carbonate, the precipitate is not pure magnesia, but the
fus-carbonat, or common magnesia; and on the other hand,
the same sub-carbonat is produced, if pure magnesia be
added to carbonat of ammonia. In either case also a part
of the ammonia unites with the magnesia and carbonic acid,
as Pouerecy has observed forming a triple salt, the ammo-
niaco-carbonat carbonat.

Carbonate of Alumina, Glycine, Zircom, &c. &c. For the
remaining earthly carbonates, see the respective earths.

Carbonates (Metallic). See the respective metals.
Carbonate of Lime, in Agriculture, a term applied to lime
in a state of combination with carbonic acid. This sort of
union is frequently met with in nature, and extends to all
the flouy subfstances which are distinguished under the title
calcareous, such as lime-flone, chalk, marble, &c. In burn-
ing or converting these subfstances into lime, they are de-
prived of their carbonic acid or fixed air; but on cooling
begin to absorb it again from the surrounding atmosphere.
See Lime.

Lime, when in the state of a carbonate, is frequently
termed effete lime, and may often be employed for the pur-
oposes of agriculture with much greater benefit than in its
calcie state, or that of quick-lime.

Carbonat Blanc, in Geography, a town of France, in
the department of Girone, and chief place of a canton, in
the district of Bourdeaus. The place contains 1800, and the
canton 16,503 inhabitants: the territory comprehends 244
kilometres, and 20 communes.

Carbon, a small river of Spain, which runs into the
Guadalquiver, a little above Seville.

Carbonelli, Stefano, in Biography, an Italian per-
former on the violin, brought into England by the duke of
Rutland, about the year 1720. He had been a scholar of Cor-
elli, and was said to play much in his manner. His hand
was not brilliant, but had a good tone, and knew music well;
as a book of 12 fodies, which he dedicated to his patron, the
duke of Rutland, testified: the first had a double-stopped
fugue in each, and the rest had pleasing melodies in correct
and judicious counterpoint; nor were they deficient of in-
vention, as far as his ideas and hand could carry him. We
have seen the book, which would be now difficult to find.
It is a folio, engraved on copper.

In 1722, he had a benefit concert at Drury-lane theatre,
of which the bill of fare is minutely given in the Daily
Contra: (see Hilt, Mus. iv. 648.) by which we may judge
of the musical dainties of the season.

Carboni was a lively and judicious leader, and, on his
arrival in England, was placed at the head of the Opera
orchestra, where he continued to lead, till 1725, when he
resigned, and was engaged by Mr. Fleetwood at Drury-lane,
and there played concertos in the second musics, and fre-
quently solos between the acts. But he resigned this station
when Handel began to perform oratorios, in which he con-
tinued to lead as long as their great author survived. Late
in life, relinquishing music as a profession, he entered into
the wine trade, and established a house, which still subsists.
He was a man of worth and probity, and honoured with
general esteem for his private virtues as well as his profes-
sional talent. While he led the band at Drury-lane, for
Richard Steel, in his comedy of The Confessing Lovers, in-
trouded him to play a solo for the amuement of Indiana,
taking occasion, after his departure, to make

Devil jun. pay him and men of talents many compliments.
He died in 1772.

Carbon, in Geography, a town of Naples, in the pro-
vince of Belfasta; 16 miles S.W. of Turin.

Carbonic Acid, Carbonic Acid Gas, or Fixed
Acid.—Aerol acid.—Mephitic acid.—Kohlenuaure, Germ.
—Acide carbonique, Fr. in Chemistry.

Carbonic acid, in its uncombined state, is only known to
us as a gas, and it is the first gas in which acid properties
were clearly discovered. It is known to be so by reducing
certain vegetable blues, by neutralizing alkalies and alkaline
earts, and by being formed by the union of a combustible
base. The sources of this acid are immense, and widely diffused.
The chief are the following.

1. The atmosphere always contains a small portion,
which varies in the immediate vicinity of places where
the precipes of respiration and combustion are going on, though
somewhat less than might be expected. The general
average is estimated at about one hundredth part. It is readily
extracted from a confined portion of the atmosphere by the
contact of lime or the calcie alcalies.

2. Almost every natural spring, as it rises from the earth,
contains a portion of this air; and some waters hold it large
portion as to give them, when exptosed to the air, a very
brill, frothy appearance, and a very sensible taste and
decidedly acid properties. The celebrated springs of Spa, Pyrmont, and Saltzer, are of this kind, and the most
highly-carbonated water of them contains about its own
bulk of the gas.

3. Every poctus in which coal, wood, or any other car-
bonaceous substance is burnt, is one which generates this
acid gas. The fame may be said of the prociss of respi-
ration.

4. The vegetation of plants under some circumstances
generates carbonic acid.

5. The spontaneous decomposition of vegetable and
animal matter produces this gas in abundance; hence fer-
mentation and putrefaction are carbonating processes.

6. But the largest store of carbonic acid that exists is that
enormous quantity which is solidified in all the inmemel beds
of lime-flone, chalk, and calcareous flones with which every
part of the globe abounds. Many of these contain 40 per
cent. or even more of their weight of this acid.

Carbonic acid gas, or fixed air, has the following proper-
ties. It is permanently gaseous at any temperature or
pressure. It is fatal to animal life, any living creature im-
mered in it perishing as soon as it would by total interrup-
tion of respiration. Hence the small, warm-blooded ani-
mal die in it almost immediately; dogs, and animals of
bulk, spредily become senseless in it, but recover, if removed
in a short time; frogs, and cold-blooded animals, lie in it
for a considerable time, owing to their power of subdivis-
ing for a time without external respiration; but when this is paft
they perish as the warm-blooded animals. This air is equally
in capable of maintaining combustion, so that a candle let
down into a jar of it is extinguished as soon as it enters
the gas as effectually as if dipped into water. Even the ad-
mixture of so small a proportion as one-ninth of carbonic
acid gas renders common air unable to maintain combination,
according to Mr. Cavendish’s experiments. It is the heaviest
of all the known gases, except the sulphureous. Hence, as
soon as generated, it falls through the atmosphere to the
lowest places, unless mingled with it by agitation or long
standing. Thus, if a jar of fixed air is inverted from some
little height over a burning taper, enough of it falls unmixed
upon the taper to extinguish it. The weight of this gas is,
in all circumstances of pressure and temperature, to that of common air very nearly as three to two; hence its specific gravity will be about 0.91850, and the weight of a cubic inch at 63° therm and 29.5 inch bar, will be about .456 of a grain.

This gas also combines readily with water and many other substances, as will be presently mentioned. Its combinations with the alkalites, earths, and metals, are called carbonates.

Carbonic acid gas, for experiment, generally from lime-dust, chalk, marble, or any carbonat of lime, either by heat or by the action of an acid, almost any of which will disdodge the carbonat from its bases, and cause it to assume a gaseous form. The mild alkalites may also be used for this purpose. The action of acids always produces an effervescence, or frothing at the surfaces of contact, owing to the rapidity with which the carbonic acid takes the form of a gas; and hence all those that effervesce with acids may be presumed (but with few exceptions), to confide chiefly of carbonat of lime. To obtain carbonic acid gas in quantity and in a regular, uniform stream, put a number of small lumps of marble or calcareous spar in any proper vessel, pour on them sulphuric or rather muriatic acid diluted, and receive the gas as it is generated. If it is collected over water, same will be lost at first, owing to the absorption of a portion by the water itself. Or, else, put some dry chalk or marble, or especially carbonat of magnesia, in an earthen retort and heat it to redness. The carbonic acid gas then comes off in abundance. When decomposed by acids, a grain of marble will yield nearly a cubic inch of gas.

As all mixtures under the inonous fermentation, give out an abundance of this gas, this affords a ready way for procuring it, and substances under experiment may be immersed in an atmosphere of the gas by being simply suspended over the fermenting vats of brewhousens.

Carbonic acid gas is readily absorbed by water; and the natural carbonated waters may be easily imitated. This fluid has a pungent, agreeable, brilk taste, and bubbles vigorously, when exposed to air, the more in proportion to the temperature. This abstraction is shown in a very easy manner, simply by filling a phial with it, then displacing about half its contents, by throwing up the gas, and then prefling the finger close against the mouth, shaking the half-full bottle violently. It will then absorb so much of the gas as to make nearly a vacuum within, which will be felt by a strong external pressure of the atmosphere on the finger that shuts the communication. This abstraction is also equally promoted by subjecling the gas to strong pressure, when in contact with the water that is to absorb it; and it is by the united action of pressure and agitation that the manufacture of the carbonated medicinal waters (such as the artificial Seltzer, and the like), is carried to such great perfection.

Water, at about 50° temperature, will absorb, by mere agitation, nearly its own bulk of carbonic acid gas; but by the combined action of pressure and agitation, three times as much may be thrown in.

Mr. William Henry, in his valuable experiments on the absorption of gasses by water, (Phil. Trans., for 1803;) has shewn that the quantity of gas absorbed is (ceteris paribus), regulated by the purity of the gas; for, even if the gas itself is obtained unmixed with any other, some addition of atmospheric air must take place from the vessels in which the experiment is made, and also from the water, which cannot be absolutely purged of common air by boiling or any other method. Hence Mr. Henry found, that if 20 measures of nearly pure carbonic acid gas were agitated with 10 measures of water, full 10 measures of the gas would be absorbed;

but if 20 of the gas, mixed with 19 of common air, were agitated with the same quantity of water, only 6 measures could be taken up. Water also parts with a great proportion of its carbonic acid by mere exposure to air, and is independent of the circumstance of removing the mechanical preflure of corks, &c.; for Dr. Browne found, that the gas would not escape from Seltzer water, when in a bottle, though a loose empty bladder supplied the place of a cork, and in which, therefore, the gas had ample room to expand itself; but a free communication with the air was necessary for this escape. The abstraction of the gas is inversely as the temperature of the water; cold water absorbing much more than warm. The diminution of absorption, on raising the heat. Mr. Henry estimates at about 7/100th of the whole for every ten degrees above 55°.

With regard to the effect of pressure, it appears that water, in all cases, takes up as great a bulk of condensed as of expanded gas, under similar circumstances of temperature.

Therefore, as the bulk of all aëroniform bodies is inversely as the pressure to which they are exposed, the quantity absorbed is directly as the pressure; that is, for example, if a pressure of 30 inches of mercury will cause a certain bulk of carbonic acid to be absorbed, a pressure of 40 inches will cause a double absorption.

The specific gravity of water, holding its own bulk of carbonic acid, is about 1.0015. This gas is readily and almost totally again expelled by heat; hence, in the analysis of mineral waters, the first step to be in general pursued is the expulsion of the gasses which it may contain, by boiling for about ten or fifteen minutes.

Carbonated water shows its acid properties by changing the colour of litmus from blue to red. This it will do, according to Bergman, when the water contains as much as 1/10th of its bulk of the gas. It is very conveniently shown, in the way mentioned by Kirwan, that is, by adding, in a thin glass tube, or jar, about equal quantities of the carbonated water, and of litmus infusion diluted, so that the blue is just distinguishable. The colour then becomes of a very dilute red, and is better remarked when compared with a similar glass tube full of the same diluted litmus liquor and plain water.

To show how the carbonic acid and no other acid that produces this change, let some of the carbonated water be boiled strongly for a few minutes, and then it will leave the blue unaltered.

But lime-water is a much more delicate test for carbonic acid, either gaseous or liquid. When a gas is to be tried, nothing more is required than to shake it with lime-water, or with barytic or silicious water, and the immediate miliness of the water will indicate the presence of carbonic acid gas in almost every case.

But with liquid carbonated water, it should be remembered, that though the first portion of carbonic acid will precipitate the lime from its solution in the form of white carbonat of lime or chalk, a greater portion of the acid will re-dissolve the carbonat of lime. So that if a highly carbonated water and lime-water be mixed together at repeated portions, the mixture will first become turbid by the separation of the carbonat of lime; then an additional quantity of carbonated water will make it again clear by re-dissolving the carbonat; after which another portion of lime-water will again make it turbid, and fresh carbonated water again clear, and so on, in proportion to the mutual saturation and super saturation of the two ingredients. Therefore, as no error can arise from an excess of lime-water, the latter, to shew, in all cases, the presence of carbonic acid, should be in equal quantity with the carbonated water. According to Bergman's valuable researches on carbonic (called by him aerial) acid,
CARBONIC ACID.

acid, lime-water will detect by its cloudiness as little as one cubic inch of the gas in 7000 grains of water, that is, where the weight of the gas is only 1/7500th of the whole.

This gas is also readily and totally absorbed from any gaseous mixture by light agitation with a solution of caustic or nearly caustic alkali. A much smaller quantity of alkali solution will suffice than of lime-water, as the former may be made much more concentrated. This is often convenient; but it is not so palpable a test, as no cloudiness or change of appearance in the alkaline solution indicates.

Carbonic acid, according to the modern system of nomenclature, signifies an acid whose bases is carbon, and hence that it is produced by the combustion or oxygenation of carbon or pure charcoal. It required the united efforts of many of the most eminent chemists to elucidate the nature of this important acid, and to shew that the very same substance which exhaled as a large component part of all calcareous floures, and was given off abundantly by many of the natural mineral waters, was also the sole product of the combination of charcoal, and all carbaneous matters. The full discovery and proof of this fact are due to Lavoisier, who made the elementary experiment of burning a given weight of charcoal in oxygen gas of known purity, (no other substance being introduced than a very minute portion of phosphorus to begin the combustion,) and found the product of the combustion to be this acid gas, the weight of which, when removed by caustic alkali, corresponded very exactly with the loss of charcoal and oxygen. Very little actual diminution of bulk takes place at first in this combustion, since the product is itself a gas, and not a liquid, as happens after the combustion of sulphur, phosphorus, &c. and therefore it is not till caustic alkali or lime-water is introduced that the production of the carbonic acid, and consequent loss of oxygen, are made apparent. From this elementary experiment, Lavoisier infers, that carbonic acid is composed of about 28, by weight, of charcoal, and 72 of oxygen, and the results of subsequent inquiries nearly, if not absolutely, confirm the accuracy of this statement.

Carbonic acid is at its highest state of oxygenation, and is the only state in which it has acid properties. United with left oxygen it forms the carbonous oxyd as noticed in the last article, in which also, the partial disoxygination of carbonic acid and consequent production of the carbonous oxdy are described.

Carbonic acid has been completely disoxyginated (that is, reduced to black pulverulent charcoal) by only one substance, namely, by phosphorus. This discovery was made by Mr. Tennant, and was followed by other valuable experiments by Dr. Pearson. (Phil. Tranf. for 1791-2.)

From the well known fact that phosphorus cannot be made by distilling phophat of lime and charcoal, the latter not having the power of decomposing this acid when united with lime, Mr. T. inferred that the united actions of phosphorus and lime might be sufficient to decompose carbonic acid by a stronger affinity with its oxygen. He accordingly put some phosphorus into a costed glass tube closed at one end, and over the phosphorus some powdered marble. The open end of the tube was then also clased, except a very small aperture, to prevent the free access of the external air, and the tube was then heated red hot for a few minutes. When cold and broken it was found to contain a black powder consisting of true charcoal mixed with both phophat and phophurate of lime, together with some undecomposed marble. In another experiment the only source of the black carbonaceous powder can be the carbonic acid of the marble, which appears to have been decomposed by complicated affinities, namely by that of part of the phosphorus for the oxygen of the carbonic acid, of the rest of the phosphorus for the lime forming the phophat of lime, and also by the phophoric acid (as fom as formed) for another portion of the lime forming the phophat of lime. Or, in other words, the carbonat of lime must undergo two different processes before the charcoal can be produced, namely, the carbonic acid must be separated from the lime to which it has a certain affinity, and also the oxygen of the carbonic acid must be separated from the carbon which is its base. The lime described from its union with the phophoric acid by the united affinities of part of the phophorus for lime, and also of the phophoric acid, when formed, for the lime. On the other hand, the carbonic acid is decomposed by the direct affinity of phophorus for oxygen, which is great, but however of itself less than that of carbon for oxygen, since, in the common distillation of phophorus, it is produced by decomposing phophoric acid with charcoal. Therefore the decomposition of carbonic acid here produced is the result of combined affinities, and could only be effected in this manner.

Dr. Pearson decomposed carbonic acid by a similar process, but with phophorus and carbon: of soda instead of carbonat of lime. Sufficient quantity of the black powder was procured in both cases to prove that it was genuine charcoal, and yielded carbonic acid again on combustion with nitre.

Many liquids absorb carbonic acid with apparently as much ease as water, such as alcohol, oil, &c. but such mixtures seem to produce no remarkable chemical change.

The affinity of carbonic acid with the alkalis, earths, and metals, is so weak that it may be displaced by every other acid, the boracic excepted. This weakness of affinity is doubtless much owing to the tendency which it has to affume a gaseous form as soon as it is enganged.

The order of the affinities of this acid in the liquid way for the alkalis and earths is boracic, carbon, lime, potash, soda, magnesia, and ammonia. With regard to the two latter indeed, the force of affinity is nearly balanced that each substance will partially decompose the carbonat of the other according to the temperature. Thus at a higher heat the ammonia, from its increased tendency to volatilization, loses much of its force of affinity with solid or liquid haifes, and then its carbonat is decomposed by magnesia, and yields carbonic acid again, and has the ammoniacal carbonat, though very imperfectly.

As the carbonic acid quits every subsistance in a high heat its relative affinities in the dry way cannot be ascertained.

CARBONIC acid, in Agriculture, an acid that abounds in nature, and is mostly found in the form of an aeriform fluid, or gas. See CARBONIC acid.

The author of the "Philosophy of Gardening," remarks, "that when vegetable substances are decomposed by fermentation, there is a quick union of oxygen and carbon; and this carbonic acid, called formerly fixed air, rises up in vapour, and flies away. But where this process goes on more slowly, as in a dunghill lately turned over, or in black garden mould lately turned over and thus exposed to the air; much of which remains in the cells, or cavities of the hot-bed, or border, this carbonic acid is slowly produced, and is absorbed by vegetable roots, he supposes, in its fluid state, or diffused in water before it acquires so much height as to fly in the atmosphere, or form of gas. This carbonic acid, when in its fluid state, or diffused in water, not in its aerial or gaseous state, is, he conceives, the principal food of plants; because their solid fibres consist principally of carbon, and their fluids of water, as is evident from their analysis."
CARBONIC earth, or salt, that sort of earth, or salt, in which there is a considerable portion of decayed vegetable matter. Boggy and other wet kinds of lands on which any decayed vegetable productions have been suffered annually to become putrid, are fairly of this kind; and likewise much ground as has been much enriched by manures, such as those of old gardens. The surface stratum of lands in general partakes of this nature. See CARBON.

CARBONNE, in Geography, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Murat; 7 leagues S. of Toulouse. The place contains 1827, and the canton 8776 inhabitants; the territory comprehends 20,674 square leagues, and 13 communes.

CARBU, a town of Italy, in the state of Genoa, seven miles W.S.W. of Pisa.

CARBULA, or Carbule, in Ancient Geography, a town of Spain, in the department of Cordoba, according to Pliny.

CARBUNCLE, in heraldry, a charge, or bearing, consisting of eight red, or lances; four of which make a common cross, and the other four a fatter. Some call these radii buttons, or flores; because round, and enriched with buttons, or pecked, like pilgrims' flowers; and frequently tipped, or terminated with fleurs-de-lys. Others blazon them, royal fleurs placed, in fatter, pale and fesse.

CARBUNCLE, in Mineralogy. See SPINELLE.

CARBUNCLE, Carbunculus, also denotes a sort of sandy matter found in Helvola, formed of a hard earth of the same name, composed in the viscosa of the mountains, by the heat of the subterranean vapours.

Pliny and Varro speak of the carbunculus, as a peculiar kind of hot, dry, iron foil.

CARBUNCULI, in Surgery, a roundish, hard, livid, and painful tumour, quickly tending to mortification, and (when it is malignant) connected with extreme debility of the constitution. See Anthrax. When this complaint is symptomatic of the plague, a pellaginous bubo usually attends it. See Plague. The carbuncle is heated deeply, in parts provided with cellular membrane; and therefore does not form discover all its dimensions, nor the ill digested matter it contains. As this tumour is commonly a symptom of depraved health, our chief attention should be directed to the re-establishment of the patient's strength, rather than to the local treatment of the carbuncle. See the directions given under the article Gangrene, which will generally apply to the case in question.

Bleeding, purging, and other antiphlogistic means can very seldom be admissible in the treatment of carbuncles; but, on the contrary, we should support the patient's strength by powerful tonics, fermented liquors, concert air, and anti-purulent vegetables; while the tumour itself may be poulsee, and fomented with anodyne decoctions, till it be fit to be opened by the lancet.

CARBUNCULATION, the blinding, or scorching of the new-sprouted buds of trees, or plants, either by excessive heat, or excessive cold. It happens chiefly in the spring and autumnal solstices, when vegetables being covered with dewy vapours, a sudden cold comes on them, which coagulating those vapours, the nutritious juice of the plant is coagulated, and the texture of its fibres destroyed.

CARBUNCULUS, in Ornithology, ecarboule, and carbunele humming-bird. See TROCHEUS CARBUNCULUS.

CARBURET, in Chemistry, is a combination of charcoal with any other substance. Thus, carburetted hydrogen is hydrogen holding carbon in solution. The only other carbures hitherto certainly known are, carburetted sulphur, carburetted iron, and carburetted copper.
CAR

CARCARIOLA, in Geography, a town of Naples, in the province of Abiruzo Cita; 22 miles W. of Aquila.

CARCASE, the corpse, or body of a dead animal. The carcase of a fowl, capon, partridge, lea, rabbit, &c. is what remains thereof, after the four members, or limbs, viz. the legs and wings, have been cut off.

CARCASE, in Architecture, is the shell or ribs of a house; containing the partitions, floors, rafters, &c. made by the carpenter, &c. The carcase is otherwise called the framing.

CARCASO, in Ancient Geography, now Carcassone, a town of Galia Narbonensiæ, belonging to the Vacet Tectofagi, according to Ptolemy. Cæsar, in the third book of his "Bell. Gall." says, that this town furnished him with troops at the time of his war in Gaul.

CARCASS, in French Carcasse, in Hor. is sometimes a hollow case formed of ribs of iron, and covered over with tallow, &c. about the size of a shell; and sometimes is entirely of iron, like a shell with two, three, or four holes in it for the fire to blaze through. Carcasses are filled with various matters and combustibles for the purpose of setting fire to houses when thrown out of mortars. They were formerly of an oval form, made of iron bars, and filled with a composition of melted powder, saltpetre, sulphur, broken glass, horn flints, pitch, turpentine, tallow, and linseed oil, covered with a pitched cloth. They were primed with unrolled powder and quick match. The flights, however, of the oblong ones were too erroneous and uncertain, that they have been totally laid aside; and none but the round ones are used at present. The following is nearly the manner of preparing them.

Boil 12 or 15 lb. of pitch in a glazed earthen pot, or vessel; mix with that 3 lb. of tallow, 30 lb. of powder, 6 lb. of saltpetre, and as many flint-dusts as can be put in. Fill the carcases before the composition is cold, to do which, smear your hands with oil, or tallow, and fill the carcases one third full with the said composition. Then put in loaded pieces of musquet or piloth barrels, or loaded grenades, filling up the intervals between these with part of this composition, and cover the whole with coarse cloth well sewed together, keeping it as nearly as possible in a round or globular figure. Then put it into the carcases, having a hollow top and bottom with bars running between them to hold them together, and composed of four slips of iron joined at top, and fixed at the bottom at equal distances to a piece of iron, which together with the hoops, when filled, form a complete globular body. When it is quite finished, and cold, it must be steeped in melted pitch, and then infallibly immersed in cold water. Lastly, bore three or four holes at top, and fill them with fuse-composition, covering them with pitch until the carcases is going to be used. Carcasses are thrown out of mortars, and weigh from 30 to 350 lb. according to the mortars employed for throwing them. A carcase for the sea-service differs from a common shell of the same size only in the composition it is filled with, and the four holes in it, from or through which it burns or blazes when fired.

The following is a Table of experiments that were made with round case carcasses at an elevation of 45°.

CARCASE,
C A R

Carcas, is said, were first made use of by the bishop of Montre at the siege of Groll, in 1672, where the duke of Luxemburg commanded.

Carcas, in Geography, a town of Spain in Va- lenzia, seated in the valley of Xinar.

Carcassonne, an ancient town in France, and principal place of a district in the department of the Aude, formerly the capital of a county called Carcassonne, and before the revolution the residence of a governor, and the seat of a bishop, suffragan of Narbonne. It is divided by the river Aude into the upper and lower town, both of which are encompassed by a wall. The former is situated on an eminence, and has a castle which commands the whole town, and an ancient cathedral. The lower town is more considerable, and is regularly built in the form of a large square. Its streets are straight, and intersect one another at right angles, and they lead to a large square in the centre, where is a fountain formed of rock-work, and having on the top of it a statue of Neptune. The quays are ornamented with rows of trees, which form agreeable walks, and the adjacent country, which is mountainous, abounds with olive-trees and vines, and affords a fine marble, called "the marble of Languedoc." Carcassonne suffered very much on occasion of the crusade which was undertaken against the Albigenses in the beginning of the 13th century; and after having been invested by Simon de Montfort, who directed and commanded the military operations of the church, A.D. 1209, was allowed to capitulate on condition that the inhabitants should evacuate it in a state of nudity; nor was Agnes the vicomtesse, though young and beautiful, exempted from this ignominious and shocking punishment.

The place is said to contain 17,149, and the canton 18,516 inhabitants; the territory includes 124½ kilometres and 8 communes. It is 12 leagues W. from Narbonne, 19 S. E. from Toulouse, 15 N. E. from Foix, and 160 S. from Paris. N. lat. 43° 11'. E. long. 39° 25'.

Carcathicert, in Ancient Geography, a town of Asia, in Greater Armenia, near the Tigris, according to Pliny. It was a royal city of the country called "Sophenia," according to Strabo.

Carcatty, in Geography, a town of the island of Ceylon; 35 miles N. W. of Trincomaly.

Carcavee, a town of Ilria; 5 miles S S. W. of Cape Pabia.

Carcavelos, a village of Portugal in the vicinity of Lisbon, between which and the town of Oeiras is produced the sweet wine, called in England Lisbon, in Germany Portugeiswein, and in the country itself wine of Carcavelos. The vineyards are included in quintas, on a gentle declivity towards the sea, and the must is generally sent to Lisbon, where it is made into wine. This wine which is generally white, and of that colour, is drank in the country in great perfection, nor can the adulterated liquor sold in foreign countries under that name be compared to it.

Carcavi, Peter Dee, in Biography, was born at Lyons, and became counsellor to the parliament at Toulouse. He was the friend of Ferrier, who at his death left to him the care of his writings; and after the death of Merfemus he corresponded with Des Cartes, with whom he became acquainted in 1646. At the time of his correspondence, or about 1649, he was settled at Paris, where he became counsellor to the grand council, and keeper of the king's library till the death of M. Colbert. He was also the particular friend of Pascal and Roberval. Interfering with some warmth in the dispute that took place between the last of these mathematicians and Des Cartes, the correspondence between him and Des Cartes was broken off. He was distinguished by his great knowledge of books, antiquities, and medals. On the establishment of the French Academy in 1666, he was appointed geometer. He died at Paris in 1674. See Bage.

Carcere, in Antiquity, were the pits, or hurdle of the circus, within which the horses were confined, till the signal was given by the magistracy for lancing.

The word is Latin, supposed to be formed of a root car, as they were formed of a refrain or round, they were as the horses ready to run in the Olympic games a fretted cord, called "halia" served this purpose. Tancy says, that the Romans divided the halia of the Greeks, A. U. C. 435, and constructed carceres in their room.

The number of carceres was twelve. In the early days of Rome they were made of wood, which Clodius afterwards changed for marble. They were kept fast with bolts, fastened by ropes, which, the moment the signal was given, flew open all at once. Some think that only four were used at a time. See in Claud. cap. xxix. n. 6 See Circus maximus.

Carcha, in Ancient Geography, a town of Asia, in Affryria, seated on the eastern bank of the Tigris, about 50 leagues S. of Niniveh, and 25 N. of Bagdad.

Carchemish, or Carchemis, a town of Asia, in Affryria, seated in the Euphrates and belonging to the Assyrians. Whilst the Assyrians were defending themselves against the Scythians, who had conquered the whole of Upper Asia, Phrazo-Necho, king of Egypt, laid hold of this favourable opportunity for recovering the city, which was then subject to the king of Assyria. The garrison, which he left in it, was cut in pieces by Nebuchadnezzar in the fourth year of Jehoiakim, B. C. 666 (2 Chron. xxxvii. 20. 2 Kings xxiii. 29.). Carchemish is probably the Cerceium, Circeium, or Circeum of profane authors, seated in the angle formed by the junction of the Chaburs and the Euphrates with the Euphrates.

Carcherd, in Geography, a town of Persia, in the province of Chorasan; 44 miles N. W. of Herat.

Carchi, in Ancient Geography, a people of Asia in Media, according to Polybius.

Carcinus, in Geography, a small fertile island in the Mediterranean sea, near that of Rhodes.

Caricus portus, in Ancient Geography, a port of Gallia Viencheul, nearly S. E. of Marseille, and N. W. of Ciboris portus.

Carcina, or Carcines, a navigable river of Italy, in the country of the Bruni, between the promontories Cocentium and Lavinium, according to Pliny.

Carcine, or Carcinitis, the name of a town near W. of the ischus which joins the Crimean to the continent, at the mouth of the small river Calanza.

Carcinitis sinus, a gulf of the Euxine sea, between the Tanric Cheroneusis and Scythia. Strabo calls it Taurinae Abbas and Carcinetes. It was afterwards called Necro-Pyla.

Carcinum, in Opiuinum, in Zoology. See Dasyx.

Carcinoma, in Surgery, the name of a cancer, which was named Carcinoma by the Greeks, from castris, a cancer, and yμνον 1 guaw or corrode; hence comes the word carcinomatosus or cancerous. See Cancer.

Caricinum, in Ancient Geography, a town of Italy in Bruttium, probably the name with "Carchus," placed by Ptolemaeus Melas in the gulf of Squillace.

Carcoma, a port-town of Africa, S. W. of the promontory.
CAR

monitory Atsline. Ptolemy places it immediately after Cardo and Carephia.

CARCOTA, a people of Sarmatia in Europe, who inhabited that part of the country which was in the vicinity of the Carbones, according to Ptolemy.

CARPRAIG, in Geography, a small island of Scotland, in the fifth of Firth; 7 miles S. E. of Dumfries.

CARCUNAH, a town of Africa, in Ethiopian Barbary.

CARCUS, in Ancient Geography, a name given by Ptolemy to an island of the Indian Ocean, which he places near Taprobane.

CARCUETUM, a place of Spain, in Lucitania, according to the Antonian, Itin.

CARD, in the Manufacturers, an instrument consisting of a block of wood, beelt with sharp teeth, for use to arrange the hairs of wool, flax, cotton, and the like: of which there are different kinds, as block-cards, hand-cards, wool-cards, tow-cards, &c.

The word seems formed from the Latin cardus (fulcrum) which denotes the fuller's teazle; a kind of thistle whose head is used to smooth and range the nap of cloth, &c. Skin. Etym. Angl. in loc.

They are made in the following manner. A piece of thick leather, of the size of the proposed card, is stained in a frame, and then pricked full of holes, into which are inserted the teeth or pieces of iron wire. The leather is then raised by the edges of a flat piece of wood, in the form of an oblong square, about a foot long and half a foot broad, with a handle placed in the middle of one of the longer sides. The method of making the teeth is as follows: when the wire is drawn of the intended size, a number of wires is cut into proper lengths by means of a gage, and then double in a tool contrived for that purpose; after which they are bent into a proper direction by means of another tool, and then are fixed in the leather. See Carding, Cloth, and Cotton Manufacture.

Cards for wool in England, may not be imported, nor the wire taken out of old cards, to be put into new leather and boards, in order for sale; upon forfeiture thereof, or of the value, if not seized; but may be amended for the proprietor's own use, or for transportation only.

Card-playing. See Cards.

CARDALIENA, in Ancient Geography, a country of Arabia Felix. Pliny.

CARDAMENE, or Cardamina, an island of the Arabian gulf on the coast of Ethiopia. It was reparted by the island of the Magi from the Trogodic territory, according to Ptolemy and Pliny.

CARDAMILIA, in Geography, a town of European Turkey, in the Morea; 14 miles S. W. of Militra.

CARDAMINDUM, in Botany, Few. peruv. 3. tab. 8. and 2. tab. 42. See Tropeolum majus and pneorum.

Gen. Ch. Cal. Perianth four-leaved; leaves oblong-egg-shaped, obtuse, somewhat spreading, gibbosus, small, deciduous. Car. four-petalled, cruciform; petals inverely egg-shaped, oblong, wide-spreading, ending in erect claws, which are twice the length of the calyx. Stam. Filaments six, awl-shaped; of these, two opposite ones are twice the length of the calyx, the rest a little longer; anthem small, heart-shaped, oblong, erect. Fil. Germ slender, cylindrical, the length of the flamen: style none; stigma obliquely headed, entire. Peric. Silique long, the shape of a compressed cylinder, two-celled, two-valved; valves opening from the base with a spring, and rolling spirally backwards. Seeds many, roundish.

Obf. There is a variety of one species, in which the two shorter flanges are wanting. Leaves simple.

Sp. 1. C. bellidiformis, daily-leaved or alpine cress. Linn. Sp. Flora Lapp. Ed. 2. 1222. tab. 9. fig. 2. Flor. dan. tab. 20. Jacq. Misc. v. 1. 148 tab. 17. fig. 29. "Leaves egg-shaped, quite entire, only a third of the length of the petiole." Root perennial, small, fromobout. Stems very few, two inches high, erect, simple, few-flowered, smooth. Leaves egg-shaped, smooth; radical ones on long peduncles; stem ones nearly sessile. Flowers in a terminal corolla; petals white, erect, twice as long as the calyx. Silique linear, obtuse, smooth. Dr. Smith, Flora Brit. vol. ii. p. 697. Much obscurity hangs over this species. Ray's C. pumila, bellisfolium, generally quoted as a synonym, Dr. Smith says, certainly does not belong to it, and is probably arabis frineta. The only real authority for its being a native of Great Britain is Dr. Wahtering, who had specimens gathered wild in Scotland by Mr. Milne. All that he says of it is, that the root leaves are on long peduncles, and that in its larger growth there are leaves on the stem, but rarely with petals. Willdenow describes two plants, nearly allied to each other, but, as he supposes, different species. One with the flowering stem not longer than the root-leaves, and either naked or with one or two leaves on long peduncles; the other with the flower stem longer than the root-leaves, and with leaf-leaves nearly sessile. The former, a native of Lapland and Norway, he calls bellidifolia; the latter, a native of the Alps, he calls alpina. La Marck makes it an arabis, but it does not seem to be the arabis bellidiformis already described in this work. 2. C. ararifolius, araribaccus-leaved cress, Linn. Sp. Pl. (Naffurtum montanum, ararifolius; Bocc. Sic. 5. tab. 3. Herr. Par. tab. 203. Rai hist. 816. Naffurtum alpimum, paludare rotundifolium, radice rectae; Moris. hist. 2. p. 234.) "Leaves simple, somewhat heart-shaped." Root perennial, thick, sending out numerous fibres. Stems about six inches high. Leaves petioled, a little falcate, smooth. Flowers white. Silique long, burfting at the leaf touch when ripe. It poizes the qualities of ferny-gras in a greater degree than the other species of cardamine, and is often substituted for it. A native of Savoy, Tufane, &c. 3. C. nudicatius, naked-stemmed cress, Linn. Sp. Pl. Gmel. Siber. 3. p. 471. n. 43. "Leaves simple, lanceolate, scoliae-toothed; stems naked." Stems about nine inches high. Leaves about three inches long, smooth, firm. Siliques tender, diatrated, smooth, compressed between the feeds. A native of Siberia. 4. C. rivulalis, Willd. Pallas. itin. 2. App. 4. 113. t. u. Germ. tom. 3. Pl. 17. p. 264. French. Transl. "Stem and root-leaves simple, oblong, toothed. Whole plant smooth. Root perennial. Root leaves leaffed at the base into a petiole; stem-leaves sessile. Flowers small, white. Siliques reflexed. 5. C. petrea, Linn. Sp. Pl. "Leaves simple, oblong, toothed." This species is omitted by La Marck and Willdenow. Willdenow says it is a dubious plant, all the synonyms certainly belonging to arabis frineta. This, with respect to the Welsh and Scotch supposed synomyns, is confirmed by Dr. Smith. But on his authority we have retained the species; for he speaks of the true Swedith C. petrea of Linnaeus in terms implying a satisfactory
satisfactory acquaintance with the plant, which we presume is preserved in the Linnean herbarium. See English Botany, p. 469. The C. petrosa of Lightfoot is there described, and figured as a new species under the name of C. hoffiulata. But before the publication of the Flora Botanica, Dr. Smith was convinced that it is properly an arabis, and nothing more than a variety of arabis bipida, and of the Welsh plant mentioned above. A. petrosa, by Dillenius, Hudson, and Withering. As such it appears in the latter work. We now perceive that in the article arabis, we have been led into an error by following Professor Martyn, who thought the stricta of Hudson, and the bipida of Linnaeus, to be the same plant.

**Leaves terminal.**

**Leaves wharged.**

10. C. chelidonia, Linn. Sp. Pl. Pallas it. 3. 34. Linn. Coch. 398. (C. glabra, chelidoni folio; Tourn. Inst. 224. Sibthrum montanum latifolium: flore purpureo, Bar. it. 156. Nallurtium Pyreneorum, Herm. par. tab. 204.) "Leaves winged; leaflets in five, gathered." Root perennial. Stem about nine inches high, nearly smooth, with many ascending branches. Leaflets, especially the terminal one, remarkably large, roughened, with short hairs. Flowers large, purplish white, in terminal corymbs, lengthening into spikes; petals obtuse or slightly emarginate, twice the length of the calyx. A native of the Pyrenees, Italy, and Siberia. 11. C. helvola, Willd. La Marec. Allon ped. tab. 57. fig. 1. (C. Plumieri; Vri. delph. 3. tab. 38. Nallurtium thalictroid folia; Benth. Muf. 171. tab. 106.) "Leaves simple, ternate and winged; leaflets in five, obtuse, toothed, three-lobed." Root biennial. Stems about four inches high, slender. Root-leaves often ternate, on rather long petioles, terminal leaflet large, three-lobed; lateral ones irregularly egg-shaped; upper stem-leaves in five. Flowers white, twice as long as the calyx. Siliques an inch long, slender, a little compressed, with eight or ten reddish seeds. A native of Piedmont and Dauphiny. 12. C. macrophylla, Willd. (C. chelidonia, Pal. it. 3. p. 34. Lic-
petioled, remote; leaves oblong, unequal at their margin, with one or two teeth. *Flowers* in a corolla, numerous; pedicels an inch long; leaves of the calyx oblong, with a membranous edge; petals three times the length of the calyx, purple, slightly emarginate. Val. A native of Spain. 19. C. pratensis. Ladies-smock, cuckoo-flower, milkmaid. Linn. Sp. Pl. Curt. Flor. Lond. falc. 3, tab. 40. Mart. Flor. inful. tab. 42. Mart. Flor. inful. tab. 75. Woodii Med. tab. 39. Eng. Bot. 775. Flor. Dun. tab. 1390. "Leaves winged: radical leaves roundish, thiofe on the stem lanceolate." Root perennial. frequently toothed in some degree like that of coral-wort. Stem about a foot high, erect, stiff, simple. Leaves winged: root ones on long petioles, somewhat lycraphed; leaves somewhat hairy; stem ones sessile, alternate; leaves smooth, channelled, generally entire. *Flowers* large, purplish or white, in a head-like terminal corolla, becoming double by cultivation. The colour and appearance of the flowers, the flower more elongated than in any other species of Cardamine, and above all the tendency of the leaves in wet shady places to bear bulbs, give the same affinity to the genus Dentaria or coral-wort. It has the same febile qualities as the Syphyrium nairtium or water erica, but in a very inferior degree. The flowers have obtained a place in the British Pharmacopoeia on the authority of Sir George Baker, who recommended them to be taken internally in epipodiform disorders: they have even been said to cure the epilepsy, but experience has not confirmed their reputation. They were prescribed dried, which Dr. Smith observes, is not an advantageous state for plants of this natural order. See Dr. Smith in English botany, and Woodville's Medical botanist. A native of wet meadows in many parts of Europe. 20. C. amara, bitter cress. Linn. Sp. Pl. Curt. Flor. Lond. falc. 3, tab. 39. Eng. Bot. 1022. "Leaves winged: root leaflets roundish, stem ones angularly toothed. Stem taking root at the base. Antlers violet-coloured." Root perennial, toothed. Stems procumbent at the base, and taking root in the mud, then upright, a foot high or more, somewhat zig-zag. Leaves nearly smooth. *Flowers* large, white or cream-coloured; style a little elongated and oblique. Found on the banks of the Thames about London, of the Aire, Eure, and other rivers in Yorkshire, Kingstrected meadows near Newick, and in Scotland. 21. C. granulaa, Willd. Allion, pedem. (Nauturium pratense oloratum radice granulata tuberosa; Bsh. pin. 164.) "Root-leaves simple, roundish, on long petioles; stem leaves winged; leaflets lanceolate; root granulated." Root perennial. Stem near half a foot high, erect, stiff. Root-leaves entire, decurrent into the petiole: stem-leaflets obtuse, entire. *Flowers* white; petals obtuse, not emarginated, three times as long as the calyx. A native of meadows near Turin. 22. C. virgineia, Linn. Sp. Pl. (Alyum, Gron. virg. p. 170. Nauturium buria tosorios frutico; Pflim. Alm. 251. tab. 101. fig. 4.) "Leaves winged; leaflets lanceolate, one-toothed at the base." Root-leaves spread into a circle; leaflets numerous, almost imbricated; stem-leaves few, often linear, entire. La Marek thinks it a true Arabis. A native of Virginia. 23. C. farinosa, Forth. Flor. auct. p. 520. Found by Forster in the island of Teneria in the South Seas. The varieties of pratensis and amara with double flowers may be readily propagated by parting the roots. They thrive well in shady situations.

**Cardamine alpina 3-minima:** Cluf. hift. See Lepidium alpinum.

**Cardamine pulfola sativallis montana defsecoides;** Col. ecpl. tab. 273. See Lepidium petraenum.

**Cardamine solonifera; Scop. Flor. Carn. and Matthbn Miller. See Aruris Halleri.**

**CARDAMOM:** for the botanical characters, see Amomum cardamomum and refert.

The Cardamoms imported into Europe have been commonly distinguished by the epithets, Majus, Medium, and Minor; but the species from which the two former are produced have been in imperfectly delimited, and their botanical history is so confused, that nothing decisive can be said concerning them. One of the three is probably the Cardamomum of Linnaeus. The seeds of the *Minor*, which are now generally preferred for medical purposes, are said by Somner to be the produce of his A. repens, discovered by him on a mountain on the coast of Malabar, where it grows so plentifully as to supply all India with its feeds, and which on that account is called the mountain of Cardamoms. It is figured in Woodward's medical botany. They are brought to Europe in their natural bank or pad, without which they would lose a part of their flavour, and this is divided internally into three cells, in each of which are contained two rows of triangular seeds, brownish on the outside and white within. These seeds have an extremely grateful aromatic smell, and when chewed, they impart a glowing warmth, and grateful pungency to the mouth. Their virtue is extracted both by alcohol and by water; the former giving a clear, the latter a turbid solution, both yellowish. The watery infusion is highly mucilaginous. When these feeds, previously bruised, are diffused with water, a small quantity of essiential oil, about one thirtieth of the weight of the feeds, on an average, may be separated, and in this seem to reside all the aromatic qualities. It is of a pale yellow, very acid, and strongly smelling of the cardamom. The watery solution infusified yields a gummy-reflux extract; the spirituous solution gives a resinous extract much less in quantity. Neither of them are used.

Cardamom is one of the most grateful of the mild aromatic, and is used either to flavour other medicines, or as a stimulant and cordial. It agrees in general particularly well with dyspeptic flomas, and prevents the gripping or nauseating effects of many of the falous or other purgatives. A tincture is made of it both simple and compounded with caraway, cinnamon, and cochino. Cardamom also enters the composition of some other aromatic preparations.

The feeds of the Cardamomum Majus, denominated also *Grama Paradisi or Margaritae, Greater Cardamom Seeds*, we hard reddish-brown angular seeds, much larger than the last mentioned, about the size of radish seeds, generally imported without the husk, from the East Indies. The smell and flavour of these are much more aromatic and grateful than those of the lesser feeds, and the tincture is hot, biting, and somewhat coarse. It yields an essiential oil not very acid, but the watery and spirituous solutions are both highly pungent. These feeds are but little used. See Lewis's "Materia Medica," and Woodville's Medical botany.

**CARDAMUM, in Geography, an iland situate in the pallagiæ from Malacca to the fracts of Singapore, or South end of Malacca fratts.**

**CARDAMYLA, in Ancient Geography, a town of Mele-"nia, almost south of Geremia. It was one of the seven cities which Agarmonon wished to present to Ambrosia. Paulus"nias speaks highly of the temple of Minerva and a statue of Apollo "Carus," the worship of whom was common to all the Dorian. This town was detached by Augustus from Meleposia, but afterwards restored to its original masters, the Lacedemonians.

**CARON, in Geography, a voluminous philo-"phical and medical writer, was born at Pavia Sept. 24th, 1501. His father, who was an eminent civilan, and a diffin-"
guided scholar at Milan, took the charge of his education, in the early part of his life, and he particularly instructed him in mathematics, astronomy, and judicial astrology. He is said not to have been born in wedlock, and in the account he gives of his own life he says, his mother, when pregnant with him, endeavoured to destroy him, by poisoning abortion. She was a woman of strong passions, and he probably derived from her that curiosity of disposition, and violence of temper, which prevented his seizing the advantages he might have obtained from his genius and learning. At the age of 20 he entered the University of Pavia, where he professed his medical and philosophical studies with success; he then went to Padua, in 1524, and in 1526 he took the degree of doctor in medicine. In 1528 he repaired to Milan, but was some time before he acquired any credit in his profession; he was therefore reduced to great difficulties. His first appointment was that of professor of mathematics, for which he was peculiarly qualified, and a few years after, viz. in 1530, he was admitted a member of the medical college in that city. This brought him into notice; but that he was not at peace with his brethren, appears by his two chief publications, "De malo recentiorum Medicinarum medendi usu," Vent. 1536; and "Contradictorium Medicum Liber duo," Lyons, 1548: in the first he severely confutes the practice of his contemporaries; in the other the inconsistent and often contradictory accounts of the same disease, given by the most accredited writers, even among the ancients. In 1547 the king of Denmark, on the recommendation of Velsalus, invited him to accept the office of a professor in the university of Copenhagen, with a handsome salary; the offer was, however, refused, his time, we may presume, being now more advantageously employed in practice. The reputation he had acquired in this way occasioned his being sent for to Scotland, about this time, to attend Hamilton, archbishop of St. Andrews, and brother to the regent, who was afflicted with asthma, for which he had before tried the affinities of the physicians to the king of France, and the emperor, but without receiving any benefit. Cardan was more successful, for by the end of about two or three months the archbishop was so much relieved, as to allow him to return to his own country, having received a large remuneration for his services, and liberal offers to retain him in Scotland. On his return he passed through London, and is said to have called the nativity of our king, Edward VI.; but we do not learn that he forbore the short date of that monarch's existence. At Milan he continued to reside until 1559, his time being employed in the practice of medicine, and in teaching mathematics; from 1559 to 1562 he resided at Pavia, being invited to accept the chair of professor in medicine there; and from 1562 to 1570, at Bologna, where he fixed a similar office. He was now, for what cause we are not informed, thrown into prison, but as he was soon liberated, we may suppose for no very serious offence; for though haughty and turbulent, he seems generally to have acted with sufficient caution, as in whatever country he resided, he was never seriously embroiled with the church or state. It appears, also, that he had the faculty of attracting the notice, and procuring the friendship of those persons who, by their wealth or power, were most able to support him, but by the waywardness of his disposition he soon lost their favour; hence he was always in a state of indigence, which he relieved by sending to the presses some halffly effusions, which had no more of his care than it cost him to write them over. His works, therefore, which were collected after his death, and which fill ten massive folio volumes, consist of such confused and undigested medleys, that it would require more labour to put them in order than their intrinsic value would compensate. Soon after being released from prison, he was sent for to Rome, was made member of the college of physicians there, and delivered a panegyric by the pope, which he attributed to the time of his death, Sept. 21, 1576: It has been said, that he flavoured himself, in order to verify his own prediction of the time of his death; but this is improbable, because he had long before acknowledged the failure of a similar prediction. The same, however, relates (lib. 6. p. 155.), that this fact was believed. Scaliger ascertained it, and it is said that his father died in the same manner, in 1531. On him it is also said, that his eyes were white; and that he saw in the night time, and could see without spectacles. Cardan, De Vita propria, p. 10. His unquenchable thirst, we believe, was an affection derived to acquire and communicate knowledge. Though a large portion of his life was passed in a state of indigence, yet it did not appear to depress his spirits. He considered knowledge, of which he could not but be conscious he held a large share, as nobly preferable to wealth. That he had no mean opinion of his own talents, or of his value to the community, seems evident by the following, supposed to have been written by himself, and intended as his epitaph:—

"Non me terra teget, celo sed rapit in alto, Iliifiris vivam, dexta per ora vivam."

Quidquid venturus spectabit Thesaurus in annis, Cardanus nolet, nomen et uile fruitum."

Vanity seems to have been with Cardan a predominant passion; for though with apparent frankness he relates the various adventures of his life, which shew the inconstancy of his temper, he nevertheless conceals or palliates others, which were more dishonorable. Addicted to youth to judicial astrology, he pretends to deduce, by means of his skill in this science, the invariable influence of celestial bodies, an apology for the licentiousness of his opinions, and the eccentricities of his conduct. Such was his confidence in the conclusions furnished by this art, that in his treatise entitled "Epistolicus Censorius," or a calculation of nativity, he hazards many predictions concerning his own character and fortune, as well as others that related to Jesus Christ. Whilst he acknowledges a propensity to irreligion, and advances some sentiments that subject him to the fulpicion, if not to the direct charge, of atheism, he justly incurrcs the reproach of credulity and superlition. Having been accustomed, in consequence of his father's instruction, at eight in the morning on every first of April to repeat a prayer and an Ave, he conceived that he was thus secured of obtaining any favour he should ask. From numerous prodigies that occurred, both sleeping and waking, he pretended to infer what should befal him; and he sometimes seems to intimate, that, like Socrates, he was attended by a particular genius. Whilst he boasts of certain supernatural gifts that were conferred upon him, he must either be conscious of wildtul falseness, or labour under a fanatical derangement of the understanding. Indeed, many have imputed that the preponderance of his imagination over his judgment did actually produce a species of insanity. At the same time he affected singularities of dress and of behaviour, which seemed to indicate a degree of studied artifice and imposture. Under the influence of strong passions, he was frequently betrayed, notwithstanding his distinguished abilities and erudition, into errors of judgment and irregularities of conduct, which tarnished the lustre of his other laudable qualities, depreciated his character, and provoked occasion of perplexity and unhappiness to himself. These errors and irregularities aggravated, in so small degree, his domestic diftrusts. One of his sons married a woman, deftirute both of fortune and reputation, and determined to get rid of her by poison; he was convicted, condemned, and executed. Cardan attempted to justify this atrocious crime,
on the ground of the wife’s infidelity; and pretends that the

on the ground of the wife’s infidelity; and pretends that the
divine vengeance pursued the judges of his son for their sen-
tence against him. Another son behaved so ill, that he was

obliged to impiomine, and at length to defeard and disinherit him.

In his medical profeflii, Cardan was a ingenious observer,

and an admirable collector of facts; but he was at the same
time too bold to be called delusional, as to claim little or no con-
duced. He wrote on every branch of medicine; but the

volumes in which he treats of natural history, which give

accounts of extraordinary cures, or descriptions of unusual

or prenaturial productions, have been received with the
greatest favour, and have been the most frequently reprint-

ed. His accounts, however, under these heads, must not be

alas implicitly admitted; the greater part of these will be

found in his treatise “De Varitate Rerum,” fol. Baf.

1552, and again 1557. In his “Commentaries on the

Aphorisms of Hippocrates,” 1551, 4to. Padov. he records a
case of a wound in the pericardium, in which the patient

recovered, and of a person who lost a portion of the brain,
equal in fize to a hen’s egg. The man lived three years
after the accident, but in a state of faticity. In his “Dao

mattica,” Stratl. 1789, fol. he describes the difeases inci-
cident to cattle, with the manner of treating them. The 6th

book of his treatise “De Substitution,” published 1559, is
entirely botanical, and contains descriptions of numerous

plants, then firt introduced into Italy. In his “De Chirurg.
cet Sarfaparillo Radichios,” Sec. 1556, he describes the
manner of preparing the decoction of thofe roots, and of
adminiftrating them. In his “Opuscula Artern Medicam

exercitabunt utilissima,” are fome curious obfervations on
the external application of cold water, which he had

witnessed in Scotland; and external prafises of the internal
ufe of the pure element in fivers and other difeases. His

“Ars curandi parva, qua eft abhirhifima medendi Metho-
dius,” Basl. 1662, 2 vols. gives his general method of cure
in difeases, with many particular obfervations. His “Opus

novum de Sanitate trienda ac Vita producenda,” a pohif-

eous work, published in 1580, fol. contains a copious enu-

mation of articles of diet, and of direotions for the mode of
living, blended with much idle and superflitious matter.

For an account of his other medical works, &c. see Hailer
Bib. Med. pract. chirurg. anat. et botan. or Eloy’s Dict.
Hiftor. The cures which he undertook to perform by fe-
cret charms, or by the affifiance of invisible spirits, gained
for him with the vulgar, the reputation of a magician; but
in reality they were only evidences of a mind infatuated by
superftition.

In mathematical science Cardan claims a tribute of more

unrestricted commendation. In algebra particularly he

challenges the honour of having made some important difco-

very; though his pretentions, as an original inventor, have

been controverted by Tartaglia. These discoveries are contain-

ed in the 16th book of his Arithmetical writings, which was
published at Milan in the year 1545. Seel Algebra. In
order to jufify Tartaglia’s prior claim, it has been alleged,
that in a trial of skill with Antonio Maria del Fiore or
Florida, he had discovered the general theory of equations of
the third degree. The occasion of it was this: Florida
had received from his master Scipion Ferree, about 30
years before, a general rule for resolving a particular cale of
of cubic equations, expressed by \(x^3 + bx = c\). Prefuming
on this discovery, Florida provoked Tartaglia into a content,
in which each should propose to the other 30 questions; and

he who first resolved them within a limited time, was to
win the proposed wager. Tartaglia, eight days before the flipu-
tated time, discovered not only the mode of resolving the
cafe of Florida, viz. \(x^3 + bx = c\), but also the cafe \(x^3 =

b x + c\). On the day of meeting, Tartaglia resolved all his
adversary’s questions in the space of two hours, without re-
ceiving one anfwer from Florida in return. Accordingly,
the wager was decided in favour of Tartaglia, and he most gen-

erously remitted the forfeit incurred by Florida. Cardan, who
was preparing a large work in arithmetic, algebra, and

gometry, having heard of Tartaglia’s discoveries in cubic equa-
tions, was very anxious for obtaining his rules of solution,
that he might infert them in his propofed work. After
several urgent invitations, he at length prevailed on Tartag-
la to pay him a visit at Milan in the year 1539; and in a
conference, induced this mathematician to furnish him with
his rule, which he did in 27 rude Italian verbs: but he

firt exacted from Cardan a promise on oath that he would
not publish what he discofeced to him. Some difficulty af-

terwards occurring in the explanation of these verbs, and in
the ufe of the rule conveyed by them, Cardan obtained from
Tartaglia the solution he required. For some time Cardan
kept his promise, though not without fome fupofitions on
the part of Tartaglia, with regard to his integrity. At
length, however, when in 1543 he published his work en-
titled “Ars magna,” he inferted in it the solution of Tar-
taglia, attributing it to the inventor. Tartaglia complained
of Cardan’s violation of faith; and he jufifed himself by
faying, that the additions which he had made to Tartaglia’s
method of solution, gave him a right to publish it. To
this purpofe Montuclaf obferves, that Cardan had in fect
the merit of partly extending, and much illuftrating the the-
fory of Tartaglia. The difpute between them was long and
acrimonious, and terminated only with the life of Tar-
taglia in 1557. The rules which occlafioned this conflfet, have,
howevers, retained the name of Cardan: although it would
be more equitable to give them the title of the formula of
Tartaglia, since they were originally his. For a further
account of this controversy, and of the letters that paffed
between the difputants, we refer to Montuclaf’s Hift. Ma-
them. tom. i. p. 591. &c. and Hutton’s Math. Dict. art.
Algebra.

The philosophical notions of Cardan, both as they repre-

sent matter and mind, are principally detailed in his works “De
Substitutio,” and “De Varitate Rerum;” but they are so

blended with fancifical visions, and the moft extravagant

delirious effusions of myfical folly, and fo ill digested and
arranged, that they cannot be easily explained or un-

derftood. They form a kind of confused medley, delinis-
guished more by an affection of novelty and irregularity, and by
the inane of an unbridled imagination, than by a found
and difcriminating judgment; and for want of methodical
arrangement, they contribute little to the promotion of im-
portant and ufeful fience. They are, however, occasionally
intermixed with experiments and obfervations on natural
phenomena; and they are chiefly ufeful as by the freedom
and boldnefs with which the author divulged them, they
serve to emanipate the human mind from the fetters of an-
cient authority. Upon the whole, Cardan, notwithstanding
the variety and apparent originality of his writings, must be
ranked among the unsuccessful adventurers in phi-

losophy. Of his peculiar dogmas, the following may serve
as a fpecimen. “Primary matter, which remains immu-
nately the fame, fills every place, whence, without the anni-
hilation of matter, there can be no vacuum. Three prin-
ciples fubfift every where; matter, form, and mind. There
are in matter three kinds of motion; the firt, from form
to element; the second, the reverse of this; the third, the
deficient of heavy bodies. The elements, or prafive prin-
ciples are three; water, earth, and air; for naturally all
things are cold, that is, deftitute of heat. The agent in

nature
nature is celestial heat: the air, being exposed to the action of the solar rays, is perpetually in motion. The moon, and all the other heavenly bodies, are luminous from themselves. The planets are animated by an ever active principle, and are therefore never quiescent. Man, having mind as well as soul, is not an animal. The dispositions of men are produced, and all moral affairs are directed by the influence of the stars.

The mind is universally diffused, and though it appears multiplied, is but one: it is extrinsically, and for a time, attached to human bodies, but never perdurable.

In his book above-mentioned, "De Subtilitate," Cardan compares the dogmas of various religions, and the arguments for them, and it is said, puts the weather in the mouth of the Christian. The works of Cardan, treating of metaphysics, logic, natural philosophy, medicine, mathematics, and morals, were collected by Spun, and published in ten volumes folio, Lond. 1667. Of his numerous and multitudinous publications, one reason is assigned from his own confession, that his poverty induced him to fill up his fleets, with which he supplied his book-seller at a fixed price, with any thing that occurred to him.

CARDANO, in Geography, a town of Italy, in the duchy of Milan, seated on the Arno.

CARDASS, a fort of card, proper for carding fleeces of silk, to make c.appspote of it. It also is the name which the French give to those fleeces of silk.

CARDASSES is also the name which, in the cloth manufactories of Languedoc, they give to a fort of large card, which is used for carding the dyed wool, designed for making cloth of mixed colours.

CARDAVA, in Ancient Geography, a town placed by Pliny in the interior of Arabia.

CARDEN, in Geography, a town of Germany, in the circle of the Lower Rhine, and electorate of Treves, seated on the Mofelle; 77 miles N.E. of Treves.

CARDENNOSSA, a town of Spain, in Old Castile; 4 leagues from Avila.

CARDERS, in the Woollen Manufactury, are persons who prepare wool, &c. for spinning, &c. See Carding and Cloth.

Carders, spinners, weavers, fullers, fitters, and dyers, not performing their duty in their occupations, shall yield to the party grieved, double damages; to be committed until payment. One justice to hear and determine complaints.

Carders, combers, fitters, spinners, or weavers, conveying away, embalming, or detaining any wool or yarn, delivered by the clothor, or any other person, shall give the party grieved such satisfaction as two justices, mayor, &c., shall think fit; if not able or willing to make satisfaction, for the first offence to be whipped, or in the flock in some market-town, or in any other town where the offence is committed: the second offence to incur the like, or such further punishment, by whipping, &c. as justices shall think proper. Conviction by one witness on oath, or confession.

CARDI, Ludovico, called Gigioli and Gisols, in Biography, an eminent historical painter, a scholar of Santi di Titi, gave a new style to the Florentine school, and, though he did not approach nearer to the style of Correggio than any of his contemporaries, as Baldini excrestructs himself, he ac-

quired very considerable eminence in his art. He executed himself with freedom and Correggio's elegance, bound to it solid in design which he acquired from the antique masters, and from the works of Michael Angelo, Buonarroti, and other masters in correct drawings, and fit it off by judicious perspectival, and a much more lively colour than that of the Tufcan school; nevertheless, his pictures do not exhibit that contrail of tints, that impatience, that splendour, that grace of airy, that bold fore-shortenings, which confound the character of the head of Lombard art. With the general tone of his colour is Lombardishque, his drapery resembles the style of Paolo Veronese, and he sometimes approaches the depth of Guercino. To the chief of his excellent pictures, published by the grand duke of the Pegnati family, and dispersed through private collections at Florence, we may refer his Trinity, in the church of St. Croce, his St. Albert, in that of St. Maria Maggiore, the Martyrdom of Stephen, at the Sistcrs of Monte Dominii, which Pietro da Cortona ranked with the principal pictures at Florence. Mr. Anthony converting a Heretic is considered as superior to any other at Cortona. His St. Peter healing the Cripple, in the Vatican at Rome, is placed by Andrea Sacchi next to the Transfiguration of Raphael and the St. Jerome of Domenichino.

The merit of this picture, now indeed utterly destroyed by the humidity of the place, and other circumstances, procured him the title of Cavaliere. This great artist also engraved a few plates in a flight, neat style, evincing, however, the hand of a master. Among others is a small plate representing "Mary Magdalen washing the Feet of Christ, at the Table of Simon the Pharisee." The heads of the figures, which are numerous, are remarkably beautiful; particularly those of our Saviour and Mary Magdalen. He died at Rome in 1513, aged 54. Pilkington and Strutt.

CARDIA, in Anatomy. See Stomach.

CARDIA, in Ancient Geography, a town situated near the Chersonesus of Thrace, at the bottom of a gulf, and to the west of the ilithmus, which joins the peninsula to Thrace, near the mouth of the Meles. It derived its name, according to Pliny, from its being built in the form of a heart. This city was considerable, when it was surrendered to the Athenians, at the time of the contest of the king of Thrace with Philip. They founded colonies in it, in order to secure the possession of it, but afterwards abandoned it. Lyfimachus, the successor of Alexander, demolished it, and from its ruins raised the city of Lyfimachia, in the ilithmus of the Chersonesus. It probably recovered itself, as Ptolemy, five centuries after the reign of Lyfimachus, represents it as a town. There were masts of this city in silver, bronze, and gold, with the symbol of a heart.

CARDIAC, or Cordial Medicine, those substances which, by their stimulant operation, excite a agreeable sensation of warmth in the bosom, and give it a temporary degree of tone. Hence they are also called stimulants. The sensation of warmth is produced partly by the peculiar impression of these substances on the nervous coat of the bosom, and partly by the accelerated circulation in its vessels, which necessarily occasions a greater evolution of caloric. In consequence of the general sympathy of the different organs of the body with the bosom, this stimulant operation is communicated to the heart and arterial syllem, and to the brain or common senium; whence the spirits are raised, a greater propensity to motion and active thought is produced, and the general sensations of the whole frame are rendered more pleasurable. That this extension of the effect takes place in consequence of nervous sympathy, and not by any actual communication of the cordial substance to the different parts of the vessel, is
evinced by the instantaneous manner in which it is effected. Farther than this, we know nothing of the mode in which this operation is accomplished; it can only be stated, as an ultimate fact, that such a relation between the substances, which come under this denomination, and the living body, exists. No hypothesis, such as the older physicians adopted, of a chemical combination of the medicine with the fluids or solids of the body, or of a mechanical action of the one upon the other, renders the operation in the least degree more intelligible.

Although the terms Cardia, from the Greek, xρυπς, and Cordial, from the Latin Cor (both signifying the heart,) imply the same thing; yet a distinction seems to be generally made at present in their application; the term cardiae being confined more particularly to aromatic substances, and cordial being used, as including effient oils, vinous and spirituous liquids, and other diffusible stimulants.

The operation of aromatic substances and essential oils is considerably different from that of vinous and spirituous liquors. The stimulus of the former is more confined to the stomach; they do not affect the sensorium, so as to produce intoxication; they leave a lefs uneasy sensation, when their operation ceases, and therefore produce less necessity for a repetition; and they are much less pernicious to the constitution, as they do not form, when taken in excess, to occasion those morbid derangements of the viscera, (especially of the liver,) which are among the most common and fatal consequences of the abuse of wine and spirits.

Cordials, in moderate quantities, are beneficial in debilitated habits, especially where the digestive powers are weak. They give a temporary strength to the system; and, by their stimulus to the secretory vessels of the stomach, they increase the secretion of the gastric fluid, and thus, by promoting the formation of a nutritious chyle, tend to add a permanent strength to the body.

In the treatment of particular diseases, they may be advantageously combined with the more permanent tonics, as in hysteria, chlorosis, epilepsy, and some others, in which great nervous mobility prevails; with diuretics, in the dropies of old people and of debilitated constitutions; and with narcotic medicines, such as digitalis, cicutia, &c. which are liable to excite naeæs, or otherwise to disagree with the stomach. In the last flages of putrid diseases, as they are commonly called, such as typhous fever, putrid fore-throat, confluent small-pox, &c. they are of incalculable utility, (particularly wine,) and afford the last resources for supporting the sinking powers of life, and for sustaining that force and regularity of circulation, which is necessary to the performance of the functions.

Cardiac orifice, of the stomach, in Anatomy, is the opening by which the esophagus communicates with that receptacle. It is called also the esophageal, the superior, or the left opening of the stomach. See Stomach.

Cardiac opening of the diaphragm, is the superior of the two openings formed between the appendices or crura diaphragmatica, and transmits the esophagus, together with the right and left nerves of the eighth pair, or par vagum. See Diaphragm.

CARDIACA, in Botany, Hall. Helv. n. 274. See Galeobdolon.

Cardiaca, Hall. Helv. n. 275. See Stachys fruticosa.

Cardiaca, Amm. Ruth. 49, 50. Mil. Icon. 80. See Leonurus tataricus.

Cardiaca, five Leonurus. Plak. Alm. S. tab. 118. fig. 4. See Pholmis seyfliana.

CARDIACUS PLEXUS, in Anatomy, is formed by the nerves which supply the heart, and which are derived from the superior and inferior cervical, and first dorsal ganglia of the great sympathetic nerve, from the par vagum and the recurrent nerve. See Heart and Nerves.

CARDIALGIA, in Medicine, a term formerly used in a more general sense to designate any pain or uneasiness about the region of the stomah, especially if connected with a tendency to syncope (Sawange's Nooful. Meth. cl. vii. ord. 4;) but at present confined to that painful sensation of heat and accumivity about the superior orifice of the stomah, which, from the vicinity of its seat to the heart, is popularly called heart-burn. The term is from xρυπς, which signifies both the heart, and upper orifice of the stomah, and αφί, pain.

This painful sensation is produced by the irritation of an acid matter in the stomah, which refers to the upper orifice, sometimes by eructation into the esophagus and throat, and is sometimes completely ejected by vomiting. That this irritating matter is of an acid nature, is evident by the taste; and it has even been seen to produce an effervescence on falling on a marble hearth, according to Dr. Darwin, (Zoonomia, claf. I. 2, 4, 5.) When vomited, or raised by eructation, it is sometimes to intensify four, as to abrade the mouth and throat; and, in general, it produces a sensation in these parts similar to that which exists in the stomah.

The production of the acid is thus accounted for. It has been ascertained by the experiments of Spallanzani and others, that the process of digestion is effected by means of the solvent powers of the gastric juice; and that, during health, while it is perfectly performed, no degree of fermentation occurs. But when, from a deficiency of the solvent fluid, or some morbid change in its quality, digestion is delayed or imperfectly accomplished, the natural chemical changes, which a mass of animal and vegetable matter is disposed to undergo, ensue, fermentation takes place, and an acid is consequently evolved. It is obvious, therefore, that cardialgia is not to be considered as a distinct species of diseases, but as one of the symptoms of indigestion, or of the weaknesses or inactivity of the stomah; and it is produced by all the causes of indigestion. See Dispepsia. Particular kinds of food, however, are liable to produce cardialgia, in those who are pre-disposed to indigestion, rather than the other symptoms which often attend it; such as hot new bread, especially of the corner kinds, rich pastry, &c. It is a very common symptom of that morbid condition of the stomah, which exists in the early and late flages of pregnancy.

The complaint may be palliated by nutritious medicines, such as Spanish liquorice, or gum Arabic, which steth the irritated parts, and, by supplying the deficiency of mucus, preserve the sensible membranous lining of the stomah from the acrimonious fluid.

It may be perhaps relieved, and, if slight, may be effectually cured, by the use of such medicines as may combine with, and neutralize the acid, from which it originates. For this purpose the vegetable or folif alkalies may be employed in various forms; the foda-water, as a common drink, is a convenient form: the absorbent earths, as magnesia, chalk, &c. will answer a similar end. But where the complaint is severe, or of some standing, the only effectual method of cure consists in removing that state of debility of the stomah on which the indigestion depends. This must be effected by temperance and exercise, with the assistance of tonic
tive and stimulant medicines, such as alkali, colonialia, and other bitters, with a moderate portion of wine and aromatics. Care should be taken not to charge the stomach with a larger quantity of food than it can readily digest, since the overplus will necessarily tend to fermentation.

Dr. Darwin remarks, that as the saliva, swallowed along with our food, prevents its fermentation, according to the experiments of Pringle and Macbride, considerable relief is sometimes found by chewing parched wheat or mastic; or, a lack of wool, frequently in a day, when the pain occurs, and by swallowing the saliva thus collected.

CARDIFF, or CARDYFF, in Geography, the county-town of Glamorganshire, South Wales, derives its name from its situation on the river Taf, which runs along the west side of it, and falls into the Severn, three miles below the town. It consists of several spacious streets of well-built houses, and is pleasantly situated on a fertile flat, two miles and a quarter from the eastern extremity of the county, where it is joined by Monmouthshire. The town was formerly surrounded with walls flanked with watch-towers, 1280 paces in circumference, and had gates at the four cardinal points, some traces of which are still visible. Cardiff consists of two parishes, St. John's and St. Mary's, though there is at present but one church: for the church of St. Mary was, in 1627, undermined and thrown down by the inundations of the river, which still occasionally repeats its depredations. The high tower of the present church was built, it is said, at the latter end of the reign of Edward III. It is of light appearance, and of elegant appearance; having open corners and lantern spires. Here were formerly four religious houses: a benedictine priory, and houses of black, grey, and white friars. Thofe of black and white friars were founded by Robert earl of Gloucester, and continued, till the dissolution, under Henry VIII. A few remains of the white friars are still to be seen; and the ruins of the black friars are near the eastern wall and gate-way, and furnish habitations for a few poor fishermen. The chief object of attention is the ancient castle, which is a large, lately edifice, on the north side of the town wall. It was originally of great strength, and is said to have covered eight acres of ground. It was built by the conqueror Ethelhamon, in 1090, after he had possessed himself of the country of Morgannoc. The entrance is by a bold gate-way, furnished with two portcullises and maffy gates. The ruins of the castle have been repaired and modernized under the present possessor, the marquis of Bute. On the keep, which stands in the centre of the enclosed area, is a handsome octagonal tower; and a high terrace is carried round the inside of the whole extent of the embattled walls that surrounded it. This castle, situated in the midst of the Anglo-Norman territory, experienced but few of those incidents so common to many others. It is memorable as the scene of the unjust imprisonment and death of Robert duke of Normandy, by his brother Henry I. In May 1645, it was garrisoned by the Welsh loyalists for the king; but in August the following year, after sustaining a short siege, surrendered to the parliamentary forces. The inhabitants of Cardiff and its vicinity carry on a considerable trade to Bristol, and send thither great quantities of oats, barley, malt, butter, and poultry of all kinds. The ironworks of the adjacent country have greatly added to the revenue of this town, near 9,500 tons of cast and wrought iron being exported annually for London and other places. By an act which passed in 1790, a canal was cut from Penarth Point to the Cyfartha iron-works, near Merthyr Tydvil; which has greatly facilitated the conveyance of so ponderous an article of commerce to market; this canal was brought, with great ingenuity, through a mountainous country, to the extent of twenty-five miles; its head, at Merthyr Tydvil, is 508 feet higher than the lock-locks at Cardiff. By a subsequent act a branch has been extended to other works at Aberdare, and the division of the line below the town has been widened and deepened, so as to admit brigs and other vessels of 600 tons burden up to the quay. See Glamorganhire Canal. The offices are regularly held at Cardiff; and the beauty of the neighbourhood is sometimes displayed at its concerts and assemblies. By the late return the population of this town is 1870, and the number of houses 527. It is 160 miles W. from London, and has two weekly markets on Wednesdays and Saturdays.

About three leagues south of Cardiff are two islands, called the Flat and Steep Holms; on the former of which there is a light-house, and a good dwelling, where pilots frequently wait to conduct ships up the Bristol channel: this island contains sixty acres of land, and is well cultivated. A little to the west of these islands is a small one called Sulley, and three miles westward of that is another named Barry, from St. Baruch, who is said to have been interred there. Evans's Tour through South Wales, 8vo. 1824. Malkin's Scenery, Antiquities, &c. of South Wales, 4to. 1824.

CARDIGAN, in Welsh Aberteifiw, is the county-town of Cardiganshire, in South Wales. The houses stand on the declivity of a hill, at the bottom of which runs the river Teif or Tivy, which has at its mouth a dangerous bar. This is navigable at high tides for brigs of 150 tons burden, which are laden and unladed at the quay. Previous to the war here was a considerable export trade to Ireland, &c. in lead and corn; but the iron works in the vicinity furnish it, at present, with its chief commerce. About two miles from the town the river discharges itself into Cardigan-bay. A bridge of seven arches crosses the river, and near it stands the shell of a castle, which is said by many writers to have been built by Gilbert de Clare, who also fortified the town, in the time of Henry II. Powell, however, in his "History of Wales," affirms, that a castle was built here, in 1155, for the defence of the borders. This was besieged by Rhys Gryfyndid, in 1164, when it was taken, and razed to the ground. In 1176, Cardigan was a feese of peculiar public felicity, when numbers of English, Welsh, Irish, and Normans, assembled to celebrate a grand eisteddfod. The bards and minstrels of the principality displayed pre-eminent skill on this occasion. They, consequently, record the approbation and thanks of the assembly; and, being victors, were rewarded with honorary presents. In the poetical clafs, the bards of North Wales were declared the most eminent; and, in music, the minstrels of South Wales proved themselves the conquerors.

On the banks of the river stand the church, a large handsome structure; and near it are the ruins of a priory of black canons. In 1797, a new county-gazet was erected in this town. Cardigan is noted as the place where Gyraldus preached, and strongly recommended the crusade to the ancient Britons. Though the county-town, Cardigan has but little to recommend it to the attention of the historian or antiquary. Its houses and shops are upon a very small scale, and its local trade is but very inconsiderable. In conjunction with the outlying boroughs of Aberystwith, Lampeter, and Adpar, this town sends one member to parliament. The number of voters amounts to about 1200. Cardigan gives the title of earl to the family of Bcludel. Here are a weekly market on Tuesdays, and a fair annually. Evans's Tour through South Wales, 8vo. 1824. Malkin's Scenery, Antiquities, &c. of South Wales, 4to. 1824. 3 Y 2
The cardinal points, therefore, coincide with the four cardinal regions of the heavens; and are 90° distant from each other. The intermediate points are called collatereal points.

Cardinal Points of the Heavens, or, of a Nativity, in Astrology, are the rising and setting of the sun, the zenith and nadir.

Cardinal Signs, in Astrology, are Aries, Libra, Cancer, and Capricorn. See Sign.

Cardinal Winds are those that blow from the cardinal points.

Cardinal Numbers, in Grammar, are the numbers one, two, three, &c. which are indeclinable; in opposition to the ordinal numbers, first, second, third, fourth, &c. See Number.

Cardinal is more particularly used for an ecclesiastic prince, one who has a voice, both active and passive, in the Roman conclaves, at the election of a pope.

Some say, the cardinals were so called from the Latin intercalatio, which signifies the adoption in any church made of a priest of a foreign church, driven thence by misfortune; and add, that the use of the word commenced at Rome and Ravenna; the revenues of the churches of which cities being very great, they became the common refuge of the unhappy priests of all other churches.

The cardinals compose the pope's council, or senate; in the Vatican is a constitutive of pope John, which regulates the rites and titles of the cardinals; and which declares, that as the pope represents Moses, so the cardinals represent the seventy elders, who under the pontifical authority decide private and particular differences.

Cardinals, in their first institution, were only the principal priests, or incumbents of the parishes of Rome. In the primitive church, the chief priest of a parish, who immediately followed the bishop, was called presbyter cardinalis; to distinguish him from the other petty priests, who had no church, nor preferment; the term was first applied to them in the year 150; others say, under pope Silvester, in the year 500. These cardinal priests were alone allowed to baptize, and administer the eucharist. When the cardinal priests became bishops, their cardinalate was vacated; they being then suppos'd to be raised to a higher dignity,—under pope Gregory, cardinal priests, and cardinal deacons, were only such priests or deacons as had a church or chapel under their particular care; and this was the original use of the word. Leo IV., in the council of Rome, held in 853, calls them presbyteri sui cardinalis; and their churches parochiæ cardinalis.

The cardinals continued on this footing till the eleventh century; but as the grandeur and state of his holiness became then exceedingly augmented, he would have his council of cardinals make a better figure than the ancient priests had done. It is true, they still preferred their ancient title; but the thing expressed by it was no more. It was a good while, however, before they had the precedence over bishops, or got the election of the pope into their hands; but when they were once possessed of those privileges, they soon had the red hat and purple; and growing still in authority, they became at length superior to the bishops, by the sole quality of being cardinals.

Du Cange observes, that originally there were three kinds of churches: the first or genuine churches were properly called...
called parish: the second, decon
eorities, which were chapels
joined to hospitals, and served by deacons; the third were
simple oratories, where private masses were said, and were
discharged by local and resident chaplains. He adds, that
distinguishing the principal, or parish churches, from the
chapels and oratories, the same cardinal was given them.
Accordingly, parish churches gave titles to cardinal priests;
and some chapels also, at length, gave the title of cardinal
deacons.

Others observe, that the term cardinal was given not
only to priests, but also to bishops and deacons who were
attached to certain churches; to distinguish them from
those who only served them as chaplains: and by commis
sion. Titular churches, or benefices, were a kind of pa
rihes, i.e. churches assigned each to a cardinal priest;
with some flated district depending on it, and a host for
administering of baptism, in cases where the bishop him-
sclf could not administer it. These cardinals were subor
dinate to the bishops; and, accordingly, in councils, par
cularly that held at Rome in 868, subscribed after them.
It was not, however, only at Rome, that priests bore
this name; for we find there were cardinal priests in
France; thus, the curate of the parish of St. John de
Vignes is called, in old charters, the cardinal priest of
that parish.

The title of cardinal is also given to some bishops, qua
temus bishops; e.g. to those of Mentz and Milan; the arch
bishop of Bourges is also, in ancient writings, called car
dinal; and the church of Bourges a cardinal church. The
abbot of Vendome calls himself cardinallis nates.

The cardinals are divided into three classes, or orders;
containing six bishops, 50 priests, and 14 deacons; making
in all, 75: which constitute what they call the facned col-
lege. The cardinal bishops, who are as it were the pope's
vicars, bear the titles of the bishopricks affixed to them;
the rest take such titles as are given them; the number of
cardinal bishops has been fixed; but that of cardinal priests
and deacons, and consequently the facned college itself, is
always fluctuating. Till the year 1125, the college only
consisted of 52, or 53: the council of Constance reduced
them to 24; but Sixtus IV. without any regard to that
reduction, raised them again to 53, and Leo to 65. Thus,
as the number of cardinal priests was anciently fixed to 28,
new titles were to be established, in proportion as new car
dinals were created.—As for the cardinal deacons, they
were originally no more than seven, for the 14 quarters of
Rome; but they were afterwards increased to 19, and after
that were again diminished. It has been said, however,
(see Molheim, E. H. vol. ii. p. 485) that cardinal deacons
were not from the beginning members of that facned col-
lege, by whom the popes were elected. Although there
were in the Roman church long before the edict of Nicho
las (mentioned below), and there still remain, cardinal dea
cons, i.e. superintendents of those churches which have
hospitals annexed to them, and whose revenues are appropri
ated to the support of the poor; yet they were evidently
excluded from the election of the pope, which, by the
edict of Nicholas, was to be made by the cardinal bishops
and clerks alone. Accordingly we find the cardinals plainly
distinguished from the deacons in the diploma that was
drawn up for the election of Gregory VII. to the pontificate.

According to Onuphrius, it was pope Pius IV. who first
enacted, in 1562, that the pope should be chosen only by
the senate of cardinals: whereas, till that time, the election
was by all the clergy of Rome. Some say, the election of the
pope rests in the cardinals; exclusive of the clergy, in the
time of Alexander III. in 1160. And they allege, that,
in order to avoid the usual contentions and disturbances at
the election of a pope, he made a decree in the third Lat
teran council, A.D. 1179, that for the future the right of
choosing him should be vested in the cardinals only, and
that he should be a lawful pope who had the suffrages of
two-thirds of the college of cardinals: which law is still in force.
See Alexander. Others go higher still, and say, that Nicho
las II. having been elected at Siena, in 1059, by the cardinals
alone, occasioned the right of election to be taken from the
clergy, and people of Rome, only leaving them that of
conferring him by their consent; which was at length,
however, taken from them. See his decree for this pur
pose, issued in the Roman council of 1079, in Hardonni's
Acta Conciliorum, tom. vi. p. 1155. "We have
thought proper to enact," says the pontiff, "that, upon
the decease of the bishop of the Roman catholic or uni
versal church, the affair of the election be treated prin
cipally, and previously to all other deliberations, among the
cardinal bishops alone, who shall afterwards call in to their
council the cardinal clerks, and require finally the consent
of the rest of the clergy and the people to their election."

Whence it appears, that the cardinals who had the right of
suffrage in the election of his successors, were divided by
this pontiff into cardinal bishops and cardinal clerks:
meaning by the former the seven bishops who belonged to
the city and territory of Rome, and to whom it belonged
to consecrate the Roman pontiff; and by the latter, the
cardinal prebendaries or minifters of the 28 Roman parishes,
or principal churches. To these were added, in process of
time, under Alexander III. and other pontiffs, new mem
bers, in order to appease the tumults occasioned by the
edict of Nicholas II. Accordingly Alexander completed
what Nicholas had only begun, by transferring and confi
ning to the college of cardinals the right of electing to the
apostolic see, and excluding the nobility, the people,
and the rest of the clergy from all concern in this important
matter. In order to defeat the opposition of the higher
order of clergy, he augmented the college of the electing
cardinals by conferring that dignity upon the prior, or arch
prebendaries of St. John Lateran, the arch-prebendaries of St.
Peter's and St. Mary Maggiore, the abbots of St. Paul's
and St. Laurence without the wall, and, lastly, upon the
seven Palantine judges. And the inferior clergy were re
duced to silence by the promotion of their chiefs, the car
dinal deacons, to the dignity of electors. Who it was, that
Alexander III. or some other pontiff, that raised the
principal Roman deacons to the rank of cardinals, is not
certain; but it is very evident, that the design of this pro
motion was to put an end to the murmurs and complaints
of the inferior clergy, who resented highly the violation of
their privileges.

We may conclude, upon the whole, that the college of
cardinals, and the extensive authority, and the important
privileges enjoyed by them at this day, derive their origin
from the edict published at the request and under the pon
tificate of Nicholas II.; that, under the title of cardinals,
this pontiff comprehended the seven Roman bishops, who
were considered as his suffragans, and of whom the bishop
of Ohia was the chief, as also the 28 minifters, who had
inspection over the principal Roman churches; and that to
these were added, in process of time, under Alexander III.
and other pontiffs, new members, in order to appease the
resentment of those who looked upon themselves as injured
by the edict of Nicholas, and also to answer other purposes
of ecclesiastical policy. It is also unquestionable, that,
though the higher order of purpled prelates, commonly
called cardinals, had its rise in the 11th century, yet it does
The cardinals obtained the privilege of wearing the red hat as an emblem of their readiness to shed their blood for the Catholic faith, in consequence of the grant made to them by Innocent IV. at the council of Lyons, in 1245; but they are said to have first used it in the year after the council, i.e. in 1246, on occasion of an interview between the pope and Lewis IX. of France. That the cardinals were allowed to wear red shoes and red garments in the time of Innocent III. raised to the see in 1198, appears from several writers who flourished at that time; but it is not certain which of the popes conferred upon them that distinction. Paul II. erected to the papacy in 1464, added the red cap and scarlet houffons for caparisoning their horses when they rode. The decree of pope Urban VIII. wherein it is appointed, that the cardinals be addressed under the title of cardinalis, is of the year 1645; till then, they were called illugitmississi.

See further concerning the origin and rights of cardinals in Compiègne, Ducreux, Cucoons. Aubrey has given the general history of cardinals, in five volumes, 4to.

CARDINAL has also been applied to secular officers.

Thus, the prime ministers in the court of the emperor Theodorus, are called cardinalis. Cañidus, lib. vii. Formul. 41. makes mention of the cardinal prince of the city of Rome; and in the list of officers of the duke of Bretagne, in 1447, we meet with one Raoul de Thorel, cardinal of Quillart, chancellor, and servant of the vicomte de Rohan: which shews it to have been an inferior quality.

CARDINALIS is found, in Geography, a small island near the east coast of Labrador. N. lat. 59° 30'. W. long. 63° 50'.

CARDINAL, bird, in Ornithology, synonymous with Cardinalis and Loxia cardinalis.

CARDINALIS capitis bona feei, Brill. and Cardinal du cap de bonne espérance, Buff. See Loxia oris, the grandier of English writers. Le cardinal of Buffon is another bird, the Gmelinian Tanagra brasilia, which see. Cardinalis purpureus of Brill. is the Jazauchen of Marcgrave, Tanagra junta of Gmelin. Cardinalis is also the specific name of several birds in the Linnaean system, as will be noticed in their respective genera.

CARDINALITIUS, a name given by fome to the Virginian nightingale, Loxia cardinalis, which see.

CARDE, in the Manufactures, a preparation of wool, cotton, hair, or flax, by palling it between the iron points, or teeth, of two instruments, called cards, to comb, digest, and range the hairs or fibres thereof; and to dispose it for spinning, &c. See CARDS.

Before the wool be carded, it is oiled, or greased with oil; whereof, one-fourth of the weight of the wool is required, for wool destined for the wool of fiftas; and one-eighth for that of the warp. See Cloth.

CARDIOGUS, or Cardiogochus, (compounded of xéza, the heart, and ýgus, tumour) in Medicine, a dilatation of one or all the cavities of the heart. The term includes two species of dilata; viz. a partial enlargement of the heart, forming a sac, in which conglabulums is deposited, and which is usuallc denominated aneurysm of the heart; and that more common dilata, which confids chiefly in a general dilatation of the natural cavities.

The symptoms which belong to aneurysm of the heart are the same as those which accompany aneurysm of the arch of the aorta. (Baillie Morb. Anim. p. 422) See Aneu-

When the heart, or any of its cavities, is much enlarged, it is attended with fever palpitations, which are excited by the least motion or exertion, and often accompanied with sighs and difpiriting paroxysms; so that they may not only be felt by the hand, when applied to the left side, but at the pit of the stomach, and at the top of the sternum; and they may frequently be perceived by the eye through the ordinary clothing, and occasionally, it is said, may even be heard.

The other symptoms are, a fene of weight, and a constant anxiety about the chest; sometimes accompanied with a violent pain across the breast, in the abdomen, or the back; and sometimes with fainting. There is frequently great difficulty of breathing, with a fene of suffocation, which compels the patient to fit in the erect posture, or to seek repose by leaning on his breast. A purplish hue of the cheeks and lips, which varies at times, according to the degree of difticulty with which the blood is transmitted through the lungs; edema of the face, or other droptical swellings; fluctuance of the stomac; and a burning cough, are occasional symptoms of the complaint. The pulse is various in different infances; sometimes it is feeble, small, and intermitting; sometimes extremely quick and hard; and sometimes not pulsated with any contractions of the heart. When the palpitation is violent, the head is often affected with strong dilatting pulsations, which are sometimes more complained of than those of the heart itself.

The diagnosis of this affection of the heart is of considerable importance; because the most dreadful palpitations occasionally arise from morbid irritability, independent of organic disease; and the treatment must necessarily be very different in the two infances. The enlargement of the heart is generally perceptible to the hand; its stroke is less pointed, or more obtuse than natural, and is felt two or three ribs lower than in health. But, according to Dr. Ferrier, "the most certain sign of dilatation is the jarring fenfation given to the hand by each fyltole. The fyltole fears restrained, and is succeeded by a kind of thrilling, which cannot be clearly defcribed, but is entirely different from the fhake of a palpitation." (Med. Hist. and Refl. vol. i. p. 148.) Senac, with fels dilution, observes, that our principal guide, in determining the dilatation of the heart, must be the force of the palpitations, their continuance, and the facility with which they are excited, especially if accompanied by syncope and dyspnoea. (Traté du Cœur, tom. ii. chap. 8.) The symptoms, however, are sometimes obfcur and treacherous.

It is more difficult, and of less importance, to determine which of the cavities of the heart is dilated. Where the auricles only are dilated, probably the pulse will retain its strength, as the ventricles poffefs their natural power; the palpitation will perhaps be less violent; and the enlargement less perceptible to the hand. (Senac.) And the dilatation may be considered as confined to the auricles, when the palpation feels remote, and extends across the breast, as well as downwards, and when the apex of the heart does not frike the ribs very forcibly. (Ferrier.) M. Senac has farther observed, that when the right ventricle, or its auricle, is greatly dilated, the palpitations are comparatively trifling; the patients complain chiefly of a fene of weight about the region of the heart; and there is also a palpitation in the veins of the neck.

In several infances there has been a great disposition to gramineous and very thin, in proportion to the enlarged size of its cavities, the heart has little power to propel an increased quantity of blood into
means of arresting the progress of the disorder. Analogy corroborates this suggestion: for in other partial constrictions, and in collars, tones, and even direct stimulants, we are given with advantage, to recover the tone of the dilated or ruptured vessel. (Ferriar, loc. cit. p. 168.)

CARIOIDE, in Geometry, a curve so called by Cafl.

Carter. When this is formed, let the diameter A B (Plate III. Geometry, fig. 48.) of the circle A M B A, resolve about the point A, and on A B produced let B a, M N, A D, M N, &c. he always equal to A B; then will the point a describe a curve, which from its figure resembling a heart, is called cardioide.

From the construction it appears, that A N = B A + A M, and that M N M A is always double of the diameter A B, and is bisected by the circle in M.

This curve is algebraical; if A B = a, a E = x, E N = y, its equation will be,

\[ y = \frac{6a y^2 + 12x y - 6a x^2 + y + x}{12a x^2 + 8a y + 3a x^2 = 0} \]

For the method of drawing tangents, and other properties of this curve, see Phil. Trans. N. 261. sect. 8. See also Mem. Acad. Science. 1759, where M. Caret first proposed this curve.

Gen. Ch. Cal. perianth four-leaved; leaves obtuse, con-

Carpal; the alternate interior ones larger than the others. Cor.

pals four, obtuse, alternate with the leaves of the calyx, equal in size to the two larger ones. Necary four petal-

formed leaflets, coloured, inclosing the germ, shorter than the proper petals, and attached to them; two of them callous at the tip, hooked at the side, forming an upright lip; the others with equal sides forming a closed lip. Stem. filaments eight, awl-shaped, nearly as long as the nectary, united be-

anthers small. Pfii. germ three-fidged; styles three, short; stigmas fimple. Piericarp. capsule roundish, three-

lobed, inflated, three-celled, opening at the tip. Seeds glo-

bular, marked at the base with a heart-shaped scar. Gart-

ner and La Marek consider this peculiar as containing three conurate, one-celled, valvaceous capsules, united at the axis so as to take the appearance of a three-celled capsule.

Eff. Ch. Calyx four-leaved. Petals four; nectary four-

leaved, unequal. Capsule three-leoved, or rather three conurate capsules inflated.

fig. 2. Pfiifnerificarium, Bauh. pin. 743. Sloane Hist. 1. p. 238.)

"Steam and petioles smooth; leaflets with grafted teeth, smooth." Wild. Root annual. Stems three or four feet long, slender, branched, bristled, twining. Leaves alternate, twice ternate, sometimes slightly pubescent. Flowers small, white, common peduncles axillary, solitary, thread-shaped, fursished above the middle with two simple, opposite tendrils, and supporting several flowers near their extremity on short partial peduncles. Fruit short, greenish, almost smooth. A native of the East and West Indies; cultivated in England by Gerard in 1594. It flowers here in July. 2. C. irifimum, Wild. "Steam and petioles hairy; leaflets toothed, smooth." Root annual. Stem four feet high or more, climbing, deeply furrowed, thick set with hairs. Leaves alternate, petioled, twice ter-

tate; leaflets egg-shaped, acuminate, two inches and a half long, half an inch broad, simply and coarsely toothed, smooth on both sides, revised; axes of the veins pubescent

beneath

into the more dilatant branches of the arterial system. (Mor. Anat.)

In whatever cavity the dilatation exists, the disease is commonly fatal. The patients generally die suddenly, in syncope, or in a paroxysm of palpitation; sometimes in consequence of a rupture of the thin pericard of the dilated cavity, but often without any such rupture. The disease, however, is extremely irregular in its progress, and in its duration. It will sometimes appear to be stationary, or even retrograde, for a long interval, during which the sensations of the patient are tolerably comfortable, and he can use moderate exercise without inconvenience. At other times the paroxysms are frequent, and he seems in perpetual danger of expiring. The duration of the complaint has been observed, in different instances, to vary from two or three months to nine years.

Various causes have been assigned for this disease. Senac enumerates in the list, all acute diseases of the lungs, as well as althama and hydro-oxythax, fever, violent exercise, or turbulent pulsions, and excessive incontinence. According to Lancet, flute-players and preachers are subject to it; and Dr. Pictain thinks that he has observed it arise from a transference of rheumatism to the heart. Dr. Ferriar has seen it produced by raising great weights, or by too long a continuance of much bodily exertion; and all the cases which he has seen have been in young persons. It is probable that any circumstance which either acts as a strong impediment to the free passage of the blood from the heart, or which excites a violent and long-continued allusion of blood to that organ, may, in some congratulations, where there is an original weakness of it, occasion a dilatation.

Little can be said as to the cure of dilatation of the heart; for, except in the indigent flaque, all that can be done is to soothe the distressing feelings of the patient, to render his existence somewhat more comfortable, and thus perhaps to prolong its duration. With this view, much has often been done by medicine and proper management. The anxiety and palpitation may be alleviated by means of narcotic medicines, especially by digitalis and opium, which diminish the irritability of the heart and arterial system. The digitalis is sometimes extremely useful in this complaint, and has appeared to suspend its progress, and to produce long intervals of freedom from the distressing symptoms. Perhaps it may be serviceable partly as a narcotic, and partly as a diuretic; since diuretics, whatever may be the explanation, give frequent relief in disorders of the chest. All violent exercise, and great emotions of the mind, should be avoided, since they tend to produce inordinate action of the heart. Moderation in diet should be observed, and strong liquors dispensed with; so that the stomach may not, by dilution, press upon the heart, and excite it to increased action, and that the body be not heated and irritable from the quantity or quality of the food and drink. Great flatulence, or other occasional symptoms, must be palliated by appropriate medicines.

It ought not to be omitted, that in the commencement of the disease some physicians have recommended evacuations, especially by bleeding, with a view to remove the fulness of the vesicles, and therefore to diminish the mechanical momentum of the blood in the heart, as well as its stimulus to that irritable organ. This doctrine is, however, somewhat questionable. It is justly remarked by Dr. Ferriar, that the symptoms of debility which generally accompany the complaint, even at its commencement, the tendency to deliquium (fainting), the weak aflatant state of the stomach and bowels, the drophical symptoms, owing to a delay in the return of the blood, and the languid feelings of the patient, seem to point out a careful exhibition of tonics, as the most probable
CARDIUM. Beneath certain periodical almost three inches long, furred, hairy; partial glands an inch or half an inch long, fennel-cylindrical, not often furred with hairs. Flowers similar to those of the preceding species, but larger; peduncles half a foot long, furred, smooth. A native of Guiana. 3. C. cardium, Linn. Sp. Pl. "Leaves downy underneath." Similar to C. hildebrandum. Root annual. Peduncles supporting ten or eleven flowers among the tendrils, remaining, after the fructification is past, rigid. Capsules narrower, downy. A native of Brazil. 4. C. grandiflorum, Willd. Swartz. Prod. 64. Flor. Ind. Occid. 2. p. 658. "Leaves pubescent; capsules acuminate, very large." Root perennial. Leaves more acuminate than those of C. cordium, and inclining to heart-shaped at the base. Flowers and fruit three or four times as large. A native of Jamaica.

CARDISPERMUM. See Calendula hybridia.

CARDISSA, in Conchology, the name given by Rumphius to the Linnean Cardium cardisii.

CARDITIS, in Medicine, the nosological term for inflammation of the heart.

If we consider the nature and importance of the function of the heart, and the connection of the circulation, of which it is the source, with the nervous system, the state of temperature, and every other function of the body, we should be led to expect, à priori, that the symptoms accompanying an inflammation of that organ, would be sufficiently obvious, and essentially different from those, which designate an inflammation of any other of the viscera of the thorax. This, however, is very far from being the case. The symptoms which attend inflammation of the heart, are fever, pain in the situation of the heart, palpitations, an irregular pulse, cough, difficulty of breathing, and often syncope. (Baillie Med. Anat. p. 42.) It is obvious that the symptoms here enumerated are merely the common symptoms of peripneumony, or pleurisy, with the addition of palpitation, irregularity of pulse, and syncope, or fainting. But it is observed by Senac, that these symptoms are extremely uncertain; and with regard to palpitation, although its presence may lead us to suspect that the heart is affected, yet it is probably an hypothetical opinion, since in that inflammation, which arises from wounds of the heart, palpitation does not occur. (Tracté du Cœur, tom. ii. chap. 7.) With respect to the other two symptoms it must be remarked, that the presence of an irregular pulse, and the occurrence of syncope, together with the symptoms of peripneumony (or inflammation of the lungs), can only lead to a probable supposition of an affection of the heart, since they are by no means constant attendants on carditis; and the former very frequently attends other cases of pneumony. (Willan on Febris Difseas, vol. iv.) Upon the same grounds Dr. Cullen agrees with the observations of Vogl, that "the symptoms of carditis are nearly the same with those of peripneumony, but in general more severe;" and adds, that he has seen the pericardium, or membranous covering of the heart, inflamed, when no other symptoms, but those of peripneumony, had occurred. (Synopsis Med. Meth. p. 107. note.) Inflammation of the pericardium, however, cannot be distinguished in practice from inflammation of the substance of the heart. (Baillie, loc. cit.) In fact, inflammation seldom occurs in any part of the contents of the thorax, without spreading to the pleura in contact with it, as from the pleura to the lungs, from the heart to the pericardium and pleura, &c. Hence the diagnosis must be obviously impossible in many cases, where in reality more than one organ is inflamed.

Were we to collect, however, of any certain means of distinguishing carditis from inflammation of the other thoracic viscera, in a practical point of view it would be of little use, since the method of cure must be the same, whether the disease be seated in the lungs, pleura, heart, or pericardium. General blood-letting, where the pulse is hard and thready;binders to the region of the heart; gentle laxatives of colonial or neutral tinctures; diaphoretics, and diuretics; will be the principal expediency; every thing being at the same time avoided which can increase the local or general irritation.

The same causes must be considered as giving rise to carditis, which produce the other modifications of thoracic inflammation; and the same circumstances will direct us in forming our prognosis, and in adopting particular varieties of treatment. See Peripneumony.

It would appear from diffusions, that there is often a slow or chronic inflammation subsisting in the heart, which does not betray itself by any peculiar symptom. For abscesses in the sultriness of the ventricles, and ulcers on the external surface, have been occasionally found after death, when no symptoms of inflammation had previously existed. (Morgagni Epit. xxv. art. 17. Bonet, tom. i. p. 849, &c.)

CARDITO, in Geography, a town of Naples, in the province of Calabria ultima, 3 miles E.S.E. of Reggio.

CARDIAM, in Conchology, a Linnean genus of bivalves, the shell of which is nearly equilateral, equale, and in most species, convex, longitudinally ribbed, striated, or grooved, with a dentated margin: hinge with two teeth near the beak, and a larger, remote, lateral tooth on each side in both valves, and which, when the shell is closed, lock into each other. Animal inhabitant of the shell a tetys, having two small pores on the left side of the body.

COSTATUM. A large species described by Linnaeus that inhabits the African Ocean; the shell is gibbous and equale with raised, carinate, concave, membranous ribs. Muf. Lud. Ulr.—Concha esculenta, Argenville, Koman Adanfon.—Length three inches; breadth three inches and a half; general colour white, with sometimes broad brown grooves or stripes. Called by Englishcollectors the Pipe-ringed cockle.

CARDISSA. Shell heart-shaped; valves compressed and carinated with teeth; beaks approximate. Linn.—Cardissa of Rumphius, and Cera ceris of Argenville.

Smaller than the preceding, the length being only two inches and a half, and the breadth two inches. The ribs are placed obliquely, and there is a conspicuous heart-shaped depression before the beaks; the general colour is whitish sometimes spotted with fawnish colour. Individuals of this species according to Greville are occasionally found concave on one side. It inhabits the Indian Ocean.

ROSEUM. Shell heart-shaped; anterior part furred with lines, posterior flatter rather broader, and forming by their conjunction a cordate figure; one part convex, the other concave. Argenville, &c.—This inhabits the Nicobar islands, and resembles the former; shell whitish varied with rose-colour.

RETUSUM. Shell heart-shaped; valves striated, crenulated, and slightly carinated, with lunate cordiform gape behind the beaks.—This shell, which is two inches long, and nearly the same in breadth, is of a milky-white colour, thick, with the anterior part concave, and posterior convex; margin with plaited teeth. Inhabits India, Arabia, and Egypt. Born, &c.

HESICARDIUM. Shell heart-shaped, somewhat quadrilateral; valves carinated; beaks dilatant. Linn.

This is described as an inhabitant of the Indian Ocean; it resembles Cardium Cardisii; and is of an ochraceous colour, a few of the ribs are glabrous, the vent nodules with intermediate grooves wrinkled and marked with excavated dots; shell within snowy-white.
LINN. — Shell heart-shaped, carinated, anterior part obliquely truncated, thin, very smooth, glossy with golden coloured fibre; margin demarcated. Kremen. Ed. Ru-dolph.—Shell above an inch long; its native place unknown.

Medium. Shell somewhat heart-shaped, and slightly angulated; valves angulated, smooth, and fuscated. Linn. &c.

Inhabits American Seas. This resembles Cardium Her-mium; the shell is whitish, and generally fpotted with chefnut or brown; ribs numerous; hinge with a single primary tooth.

ACULATUM. Shell somewhat heart-shaped, with prominent ribs grooved down the middle and beft with large hollow aculations, and tub-petalous spines towards the circumference. Inhabits the Mediterranean and European seas. This is a large species of a brownish colour, or whitish variegated with brown bands. Found on the British coasts. Donov. Brit. Shells, &c.

ECHINATUM. Shell somewhat heart-shaped, fculcated, with fpinous carinated ribs. Linn. &c.—Inhabits European seas.

Rather resembles the left in figure, but is smaller, and paler in colour; whitish, variegated with brown. Found on the British coasts. Donov. &c.

CILIARE. Shell somewhat heart-shaped, with triangular elevated ribs beft along the edges with thin spines, Gmel. &c. A native of the African and European coasts; whitish with about eighteen ribs.

CULATUM. Shell somewhat heart-shaped, with elevated sub-triangular ciliated ribs. Inhabits the North Seas. O. Forbr. &c.

This resembles Cardium ciliare, from which it differs, among other particulars, in having about twice the number of ribs: colour cincereous, or greyish-white.

TUBERCULATUM. Shell somewhat heart-shaped, with obtuse, knotty, transversely fpirated grooves. Linn. Inhabits the Mediterranean sea, and is variously coloured and marked; sometimes white, or whitish with brown bands; sometimes brown with darker bands; ribs from twenty to twenty-three in number, convex, with a few nodalties.

ISOCARDIA. Shell heart-shaped, with arched imbricated fanses along the furrows. Linn.

An American species about two inches and a half in length, and two inches and a quarter broad; colour cincereous-white, with a few red spots or clouds; shell within white, and purple in the middle, and a single primary tooth in each valve at the hinge.

FRAGUM. Shell somewhat heart-shaped, and slightly angulated with elevated lunules down the grooves. Linn. Fragum album of Rumph.

Inhabits India. Colour white, with yellow, or sulphur lunules; within snowly; ribs flatfeft. Perhaps a small variety of the following species.

USnea. Shell somewhat heart-shaped, with lunate coloured grooves. Linn.

This inhabits India, and resembles Cardium fragum, but is twice as large, and has fewer red scales on the grooves; lips of the anterior edge incumbent.

MURICATUM. Shell somewhat heart-shaped, furrowed, and muricated at the sides. Linn.

A native of the American seas; colour cincereous, white or yellowish, mixed or fpotted with bay; margin fuscated; hinge with two red stripes within.

MAGNUM. Shell oblong, with angular grooves fuscated at the edge. Linn.

A supposed variety of this species is called the buckle by Martyn. Dons. Cones. Cardium magnum inhabits India, and America; the shell is fculcated on the margin with twenty or thirty grooves, and transversely wrinkled. Colour variable, yellowish, or brownish, with diffuse spots or tawny, and discolorus with blackish spots; within white.

FLAVELLUM. Shell somewhat heart-shaped, flattened, anterior margin fuscous, posterior one toothed. Linn.

A native of India. Back and posterior flat generally yellow, and sometimes spotted, the red white; this about twenty-seven in number, of a convex form, with the first five or six armed with fliamp spines; twelve or thirteen posterior ones with flat furrows, the intercalated ones smooth.

LAVATUM. Shell oblate, with obsolete longitudinal fliars. Linn.

This kind inhabits the American, Atlantic, and European seas. Length about two inches and breadth nearly the same: colours various, generally brown or tawny, with darker clouds and spots, and sometines bands.

SERATUM. Shell oblate, smooth, with obsolete fliars, ferrated at the interior margin. Linn.

A native of the Mediterranean and Indian seas; shell smaller and less convex than Cardium lavatum; of a yellow colour, with the backs reticulated.

ENOLE. Shell antiquated, with about twenty-eight flatfliars. transversely fpirated with obsolete recurved imbrication.

This is our common buckle, a species found in the greatest plenty buried in the sands on all the arid shores of Europe. The animal inhabiting this shell has a peculiar flavour, and is esteemed as a wholesome and palatable food; the species varies in size and colour, they occur of a large size on some of the Scottish shores. Donov. Brit. Shells.

ISLANDICUM. Shell fuscated, with about thirty-six smooth triangular ribs. Chemn.

Inhabits the North Seas, especially near the coasts of Iceland and Greenland; in its general aspect it resembles our common buckle, cardium edule, but the grooves are deeper and more numerous, and there are no fliars except the outer margin; colour blackish, sometimes banded.

GROENLANDICUM. Shell glabrous, thin, mufch colour, with angulated ferruginous lines; margin glabrous with obsolete longitudinal lines. Chemn.

Same habitat as the former, about two inches and three quarters long, and three inches and a half broad; sometimes banded with brown.

RUSTICUM. Shell with twenty remote grooves, the intermediate spaces rugged. Inhabits European seas. Gemel. &c.

Of the specific name rusticum has been affigned to more than one or two different species of this genus; the C. rusticum of some English writers is probably only a variety of C. edule. Vide Donov. Brit. Shells. C. rusticum of Chemn. may be distinct, but that is doubtful.

GLAUCUM. Shell subfusired, anterior part glaucous; posterior part with twenty grooves imbricated upwards; beaks violet. Poiret.—Inhabits the shores of Barbary. A small species.

PECINATUM. Shell somewhat heart-shaped, and pecified. Linn.—Found in the Mediterranean sea. General colour white, with the cavity under the beaks yellow; valves marked with dilated frize that are rough upwards; margins of the shells prominent.

VIRGINUM. Shell triangular, rounded, equilateral, with transverse membraneous recurved wrinkles; hinges blue. Gemel. &c. Inhabits the Mediterranean. A variety is found in the Indian and American seas.

3Z. AURICULA.
CAR

AURICULA. Shell heart-shaped, and slightly rhombiform with twenty-four ribs on each side; the grooves very finely crenulated; beaks crenulate.

Described by Forckel as a native of the Arabian seas; shell white and pellucid, two inches and a quarter long, and one inch and three quarters broad; margin of the back revolute and toothed.

TRISTE. Shell ovate and smooth; margins both of the anterior and posterior slope flattened. Linn.

Native place unknown. Shell smooth, cincereous, and radiated with white; beaks reflected.

MONSTROSUM. Shell gibbose, one side impressed and ochraceous, the other convex heart-shaped, and whitish spotted with yellow; valves with dentated ridges. Chemn. - This is a very rare species; inhabits the Nicobar islands.

LIMA. Shell gibbose with aculeated ribs, the anterior ones with recurved membranous tubercles created at the sides; the intermediate grooves granulated. Chemn. Inhabits the Nicobar islands. This shell is ochraceous, with the anterior margin flesh-colored, and the beaks reddish. A supposed variety of this species is described by Schenck, in which the ribs are more rounded, and instead of being aculeated or prickly only granulated.

RINGENS. Shell rotundate, ventricose, and white, with deep teeth at the margin, the anterior ones rosy. Lfter, &c. Inhabits the African and Mediterranean seas.

AEOLICUM. Shell thick, with longitudinal anterior fisure, and transverse fisure behind. Chemn. &c.-A native of Guinea, and the Antilles islands. Obf. This shell is very convex, and is varied with white and redish.

OBLONGUM. Shell yellowish, oblong, turgid, and clefted; posterior part glabrous, and cordiform with a crenated margin. Chemn.-Inhabits the Mediterranean. Length three inches, breadth two inches and a half; ribs about thirty. Much allied to the following species.

CASSUM. Shell somewhat fuscos, rather oblong, thick, and antquated, with a very deeply dentated margin. Schenck, &c.-Refembls Cardium oblongum, but is much larger, rather broader, thicker, and has about twenty-three flatish ribs. Also inhabits the Mediterranean, and is found in the North Seas.

PAPYRACEUM. Shell pellucid, cinereous, with thin longitudinal fissue. Chemn.-This kind inhabits India; the shell is very brittle, within white, with purplish spots.

LATUM. Shell broad with unequal sides; ribs rather flat and spinulose. Chemn. &c.

Length two inches, breadth half an inch more; colour variable, being in some individuals white on the crown, yellowish in the middle, and edged with yellow; in others the crown is brown, and the rest of the shell banded with fuscos; inside white. Inhabits Tranquebar and Nicobar islands.

MACULATUM. Shell spotted, with crowded undulated wrinkles; ribs broad; grooves very narrow, within pale rosy. Lilt.-Found in the bay of Camppehy. This shell is nearly three inches long, its breadth rather more, being three inches and three quarters.

FLEXUOSUM. Shell rotundate, fuscos with flexuous ribs, and rugose furrows.

Described by Lifter; length one inch and three quarters, and about the same in breadth. Native place unknown.

GADITANUM. Shell rounded, yellowish-white, varied with red, green, and brown, and marked with decussated fissue. Bonan. &c. Found near Cadiz. Gmelin conceives this may be an arca.

BRASILIENSE. Shell rounded; ribs broad, flat, and very minutely crenated. Frequent on the Brazilian shores. Bonan. &c.

AMBROINESE. Shell rather oblong, white with blackish spots; the ribs very convex. - Inhabits the Amboina shores. Bonan. &c.-Obf. This shell is about an inch and three quarters in length, with about twelve ribs.

SQUAMOSUM. Shell heart-shaped, equilateral, tawny white, and purplish within; ribs with imbricated scales. Gau!. -Refembls Cardium frugans, but wants the teeth at the anterior margin. Native place unknown.

RUBINOBOUM. Shell reddish, with unequal sides, and convex ribs transversely frigated. Gau!. Native place unknown.

VIRESCENS. Shell inequalities, oblong, with very fine ribs doubled above. Gau!. Native place unknown.

FASCICATUM. Shell rounded, whitish, with a brown band; ribs acute. Knoor. Native place unknown.

CANCELLATUM. Shell reddish, thin, rounded, with decussating fissue. Gau!. Small. Native place unknown.

ALBIDUM. Shell inequalities, ribbed, whitish, and purple within.

Obf. There are a few other of the larger species of Cardium described by conchological writers which we consider as ambiguous. Thefe, with several of the more minute, and micrscopic kinds, are purposely omitted in the above enumeration of species, as we are inclined to believe the infection of such would rather tend to perplex than inform the general reader.

CARDONA, in Geography, a town in Spain, in Catalo- gia, feated on an eminence near the river Cardonerio, with a strong castle, and the title of a duchy. In its vicinity are an inexhaustible mountain of salt of various colours, which, when washed, becomes white, and also vineyards, which produce excellent wine, and lofty pine-trees. N. lat. 4° 34'. E. long. 1° 26'.

CARDONERO, a river of Spain, which runs into the Llobregat, at Manxes, in the province of Catalonia.

CARDOON, in Botany, see Cynara Cardunculus.

CARDS, playing, are little pieces of thin paste-board, of an oblong figure and of several fizes, but with us commonly 2½ inches long, and 2¼ broad; on which are printed divers prints and figures; a certain number or assemblage of which serve for the performance of various games: as baflet, ombre, picquet, whilt, &c. A full pack consists of fifty-two cards.

A pack is always wrapped up in a piece of paper, on which are printed the name, figure, dwelling-place, &c. of the maker; with the label of the flamp-office of England, signifying that the flamp-duty has been paid.

Among sharper^ divers sorts of false or fraudulent cards have been contrived; as marked cards, bref cards, corner-bend, middle-bend, &c.

Marked cards, are those where the aces, kings, queens, and knaves, are marked on the corners of the backs with spots of different number and order, either with clear water, or water tinged with pale Indian Ink, that those in the secret may distinguish them. Aces are marked with single spots on two corners opposite diagonally; kings with two spots at the fame corners; knaves with the fame number transversed, &c.

Bref cards, are those which are either longer or broader than the reft; chiefly used at whilt and picquet.

The broad cards are usually for kings, queens, knaves, and aces; the long for the reft. Their design is to direct the cutting, to enable him in the fecret to cut the cards disadvantageously to his adversary, and draw the perfon unacquainted with the fraud, to cut them favourably for the sharper. As the pack is placed either endways or sideways to him that is to cut, the long or broad cards naturally lead him
him to cut to them. Brief cards are sometimes made thus by the manufacturer; but in defect of these, sharpeners pare all but the breeches with a razor or pen-knife.

Corner-bend, denotes four cards turned down finely at one corner, to serve as a signal to cut by.

Middle-bend, or King-flour-bridge, is where the tricks are bent two different ways, which causes an opening or arch in the middle, to direct likewise the cutting.

The inventor of cards is not known, nor even the age when they first appeared; but by the matter they were always made of, viz. leaves of paper, they should seem to be much posterior to the time of Charlemagne. The hon. Daines Barrington, Mr. Bowle, and Mr. Gough, in their three essays on the "Antiquity of Card-playing." (Archeologia, vol. vii.) seem to agree that the Spaniards have the best pretensions to be considered as the original inventors of this amusemént. Others have traced their invention to about the year 1300, for the purpose of diverting the King of France, who was fallen into a melancholy disposition, and ascribe it to Jaquemin Grignon, a painter in Paris. Accordingly in the accounts of the treasurer of that prince the following article occurs: "Paid fifty fix francs of Paris to Jaquemin Grignon, the painter, for three packs of cards, gilded with gold, and painted with diverse colours and devices, to be carried to the king for his amusemént." From this article it appears, that playing cards were originally very different in their appearance and their price from what they are at present. They were gilded, and the figures were painted or illuminated, which required no little skill and genius, as well as labour: and the price of each pack was no less than 186. Sd. of Paris, a very considerable sum in those times. This last circumstance is one reason that playing cards were little known and used for several years after they were invented. By the four suits or colours, the inventor might design to represent the four states or classes of men in the kingdom. The cœurs or hearts denote the gens de cœur, choir-men or ecclesiastics. The nobility or prime military part of the kingdom, is represented by the ends or points of lance or pikes, which through ignorance of the meaning of the figure, we have called spades. By diamonds are designed the order of citizens, merchants, and tradesmen. The trefoil leaf, or clover graft, corruptly called clubs, alludes to the husbandmen and peasants. The four kings are David, Alexander, Caesar, and Charles; representing the four celebrated monarchs of the four ancient nations under Charlemagne. The Queens represent Argine (for Regina, queen by defeat), Esther, Judith, and Dalia; which are typical of birth, piety, fortitude, and wisdom. The knaves denote the servants to the knights; others apprehend that the knights themselves were denoted by these cards, because Hogier and Lahire, two names of the French cards, were famous knights at the time when they were supposed to be invented.

The first certain notice of their having been known in England occurs in a record in the time of Edward IV. On an application of the card-makers of London to parliament, A.D. 1463, an act was made against the importation of playing-cards; 3 Edw. IV. c. 4. From this statute it appears, that both card-playing and card-making were known and practised in England before this period, or about 50 years after the era of their suppotted invention. Mr. Gough observes (ubi sipra), that the use of cards among the Chinese is evident, not only from a Chineese painting which represents their ladies playing at a game with something much thicker in substance than cards, yet shaped and numbered like them, but also from a pack of Chineese cards in his possession, made of the same materials as the Europeans. However, the devices on these cards are very different from those known in this part of the world. Although card-playing was introduced at comparatively a late period in England, and the progress of it was at first slow, it at length became sufficiently rapid and extensive, to the cost of many unfortunate gamblers, and the loss of many others, who spend too muc;h of their time in this infatuating amusemént.

Lord Lyttelton in his Persian letters (and Miscellaneous works, vol. i., p. 113), admirably stales those who indulge their propensity for this kind of diversion to excess, and who risk sums of money which it is not convenient for them to lose; or, in other words, who pretend it to the purpose of gaming. Selim represents himself as sitting at a house in London, where he had a number of tables in a room, round which were placed several sets of men and women. They seemed (lays he) wonderfully intent upon some lots of painted paper, which they held in their hands. I imagined at first that they were performing some magical ceremony, and that the figures I saw traced on the lots of paper were a mystical talisman or charm. What more confirmed me in this belief was the grimaces and distortions of their countenances, much like those of our magicians in the act of conjuring; but inquiring of the gentleman who introduced me, I was told they were at play, and that this was the favourite diversion of both sexes. But, as he proceeds, I see no signs of mirth among them: if they are merry, why do not they laugh, or sing, or jump about? If I may judge of their hearts by their looks, half of these revellers are ready to hang themselves! that be may, said my friend; for very likely they are losing more than they are worth. How! said I, do you call that play? Yes, replied he, they never are thoroughly pleased unless their whole fortunes are at stake. Those cards you see them hold, are to decide whether he who is now a man of quality shall be a beggar; or another, who is now a beggar, and has but just enough to furnish out one night's play, shall be a man of quality, &c. &c.

The method of making playing cards seems to have given the first hint to the invention of printing; as appears from the first speciments of printing at Haerlem, and those in the Boulien library.

Cards, making of. The cutting of the moulds, or blocks, for these cards, is precisely the same as that used for the first books; and a sheet of wet or mofit paper is laid on the form, or block, which is first lightly brushed over with an ink, made of lamp-black mixed with flafe and water; and then rubbed off with a round Ii, in the hand. The court-cards, they colour by help of several patterns, called "tincelles," consisting of papers cut through with a penknife; within the apertures, or incisions of which, the several colours, as red, &c. are severally applied (for at the first printing, the card has only a mere outline.) These patterns are painted with oil colours, to keep them from wearing out by the brushes: being laid on the paste-board, they slide a brush full of colour loose over the pattern; which leaving the colour within the apertures, forms the face or figure of the card.

This, very probably, was the way of the first printing at Haerlem; as might have been discovered long ago, if it had been confidered, that the great letters in our old manuscripts of nine hundred years ago, are apparently done by the illuminers, after the method of card-making. By 43 G. III. c. 69, a duty is imposed of 21. 8s. on every dozen packs of playing cards imported: and for every pack of cards, made in Great Britain, the stamp duties by several acts amount to 2s. 6d., and for every pair of dice, 17s. 6d.
Places of making them are to be entered under a penalty of 5l., and forfeiture of the cards, dice, materials, and utensils. Makers of cards shall fend to the commissioners of the stamp-office a sufficient quantity of paper in order to have as many acres of paper impressed upon them as he shall desire; and a device, denoting the said acre of paper, shall be stamped on every pack used in Great Britain or intended for exportation, which device shall distinguish cards designed for home consumption from those intended for foreign consumption:—and wrappers inclosing cards for use in Great Britain shall have the name of the maker or any other particular word printed on them, according to the direction of the commissioners, who shall denote one of the 6d. duties charged on cards in Great Britain on each of such wrappers. Officers shall enter houses or places where cards and dice are made or sold, or suspected to be made, or any public gaming-houfe, to search and examine whether such cards are stamped; and the owner or occupier refusing such entrance or search shall forfeit 1s. No materials for cards or dice shall be removed till they are fitted, on pain of double duty; nor shall any cards or dice be removed, till they are duly marked or sealed, on pain of forfeiting the fame and treble value. Entry shall be made once in 28 days on oath, under a penalty of 20l., and the duties shall be cleared off once in every six weeks, on pain of double duty. Selling or using unlamped cards or dice, incurs a forfeit for each pack and for every one of such dice of 1s. with full costs. Altering the stamps subjects to a forfeiture of 20l. and the sale or purchase of such stamp incurs the same forfeiture. A person who takes off the stamp of any playing cards, or outside paper of any parcel or pack of cards, for the purpose of using it again, shall be guilty of felony, and transported for any time not exceeding seven years. The selling of wafte cards, not previously rendered unfit for use in playing, incurs a forfeiture of 20l.; and any perfon who sells any cards, as second-hand cards, in packs or parcels, the wrapper of which has been broke open, unless every card be rendered unfit for play, forfeits 5l. for each such pack. If any perfon counterfeit the stamp on cards or dice, or the wrapper, or knowingly sells the fame with a counterfeit stamp, or fraudulently uses any of the stamps provided by the commissioners, he shall be guilty of felony without benefit of clergy. No cards or dice shall be exported or exposed to sale without being stamped, until after the expiration of ten days after notice to the stamp-office by the maker of the quantity to be exported, and of the place to which they are intended to be conveyed, nor until a proper certificate be delivered to the custom-house officer at such port or place in Great Britain. Cards or dice may be removed by the maker without payment of the duties, provided the fame be stamped for exportation, and a bond be given for exporting them within the time, and landing them at the port therein mentioned. Cards for exportation shall before packing be marked as the commissioners direct; and persons using or selling such cards, marked for exportation, in Great Britain, shall forfeit 20l. for every such pack: and any perfon rebaiting any parcel of cards, entered and shipped for exportation, shall forfeit 50l. and if any perfon concerned shall inform against an accomplice, he shall be admitted as evidence, and be indemnified.

Cards, in Manufacture. See Card.

CARDUCHI, in Ancient Geography, a people of Asia, who were descended from the ancient Scythians, and divided into a great number of tribes. According to Strabo they were at a period subsequent to that of the famous retreat of Xenophon better known by the name of Parthians; a nation which became such a terror to

the Romans, M. De L'Isle, in the explication of his map of Xenophon's retreat, alleges several arguments to prove that they were the same with the present Cardi, and that their country was the same which the Romans called Carduca, a large and mountainous territory on the coast of the Tigris, and the modern Curdistan; though it is probable, that the present tract which goes by that name is of much greater extent than that which the Carduchi then possessed, who only occupied the mountainous parts of it. Before the period of the retreat of the Greeks, they had defeated a Persian army of 120,000 men, none of which ever returned, the roads being impassable. Upon the approach of Xenophon's army they betook themselves to flight with their wives and children, and gave the Greeks a favourable opportunity for supplying themselves with plenty of provisions. Xenophon was much harassed by loose bands of these people, who discharget upon them and his rear-guard which he conducted, vollies of darts and stones. The Carduchi were much superior to the Greeks in the use and strength of their bows. We are told (Diod. Sic. lib. xiv. Xenophon, Anab. lib. iv.) that they were of such prodigious length, that they bent them with their feet; the arrows were in proportion, so well tempered and keen, and darted with such violence, that no shield could repel them; so that, by being able to throw them at such a distance, they kept themselves out of the reach of their enemies.

CARDUEL, or CARThU, in Geography, a name given to the cañon part of Persian Georgia; the capital of which is Tefta.

CARDELS, in Ornithology, the name under which the common gold-finch is described by Genefer, Aldran- dus and others. See Fringilla Carduelis, Linn. Carduelis Americana of Buff is the American gold-finch of English writers; Fringilla iritis, Gmel. Carduina, in Ancient Geography. See Carduchi. Carolunculus, in Botany, Linn. ic. 2. p. 20. See Carthanaus Carduncellus. CARDUNCULUS. See Cynara.

CARDUUS, in Ancient Geography, a name given by the ancient Latin writers to several kinds of prickly plants, and particularly to the cardc, (discus fallumn) formerly used in carding wool, as it still is in dressing cloth. The word is said to be derived from caruo, (Gr. karuo) a technical verb denoting the operation of cleaning wool from its impurities. Thiffle, Linn. gen. 925. Schreb. 1254. Wild. 1433. Julf. 175. Vent. vol. ii. p. 499. Gart. 932. Chardun, La Marek Ernaye. Clafs and order, synggenof polygama equili. Nat. ord. capit. Nat. Capept. Linn. Capnepheur, Jutf.

Gen. Chal. Cal. common, swelling out in the middle, imbricated; scales numerous, lanceolate; terminated by a simple spine; in some species brown, in others white. Cer. Flores all furnished with flaments and a pifiil, uniform, tubar, funnel-shaped, nearly equal, reflexed; tube very slender; border creft, five-cleft; segments linear, equal, one more deeply serrated than the rest. Stam. Filaments five, capillary, short; anthers united, forming a hollow five-touched cylinder. Fil. Gern egg-shaped; style thread-shaped, longer than the flaments; stigma simple, awl-shaped, naked, emarginate. Peru. none; except the permanent, somewhat converging, common calyx. Seeds solitary, inwardly egg-shaped, a little four-cornered; down sullie, long, deciduous. Recep. hairy.

This genus, like most of the others in the claff syngenofia,
C _ARDUUS_.

is differently characterized by different authors. Some have divided the _Lauraeana_ genus into two: _Carduus_ including only those species which have a capillary down, and _Cirsium_ containing those whose down is feathery. Willdenow has united the latter with _Cirsium_, and makes the essential difference between _Carduus_ and _Cirsium_ to depend entirely on the nature of the down. _La Marck_, on the other hand, has abolished the _Cirsium_ of Link, which, he says, has a character too vague to be admitted; and has distributed its species between _Carduus_ and _Cirsium_, observing, that some species of _Carduus_ in the _Species Plantarum_, approach rather too near the character of _Cirsium_. After a careful consideration of the subject, we are inclined to adopt his arrangement; and have constructed accordingly the generic and specific characters of _Carduus_ given above, adding from _Garten_ "down deciduous," which has the function of _Dr. Smith_; though we are not without apprehension, that this character may not be found in all the present acknowledged species.

Species. _Leaves deciduous._

1. _C. lanceolatus._ Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Wild. 1. Gert. tab. 162. fig. 1. Monif. Bleff. 144. (Cirsium _murale_ Linnae. _C. lancifolium_.) "Leaves toothed—spines; peduncles naked, very long, one-flowered; calyxes spiny, inclined." _Root_ annual. All. Bienn. _La Marck_. _Stem_ two or three feet high. _Root-leaves_ scarcely petioled, growing close to the ground. _Stem-leaves_ smooth, bright green, spotted with white, half-bracing the stem, and running down it so as to form three uninterrupted membranous wings, oblong-egg-shaped, pinnatifid nearly to the middle; lobes furnished with spines. _Flowers_ purple, small; peduncles woolly and white, especially towards the summit, generally naked, but sometimes with a small leaf or two; _spines_ of the calyx bright, not pungent._Down_ simple. A native of Italy and the south of France.

2. _C. peregrinus._ Wild. 2. Retz. Obf. 1. p. 27. (C. _luteus_ peregrinus camerarii, _Kai_. hist. 312.) "Leaves fcoffolled, spines; down; underneath; peduncles generally naked, many-flowered; calyxes spiny, deciduous." _Root_ annual. _Stem_ three feet high, branched, fringed, smooth; terminal branches downy. _Leaves_ fcoffolled, spotted with white thorns. _Flowers_ red; _florets_ few, rarely longer than the scales of the common calyx; _peduncles_ terminal and axillary; _terminal_ ones branching, winged, long, from three to five-flowered; axillary ones short; _scales_ of the calyx a little downy, deciduous, furnished with soft spines. _Seeds_ small, white, beclouded with a whitish pellucid gum, which makes the down so strong to them, that it cannot easily be separated; down capillary. A native of Spain. _Ray_.

3. _C. lanceolatus._ Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Eng. bot. 1. 7. (C. _lanceolatus_ Wild. 10.) _Spear thistle_. "Leaves pinnatifid, hirtip; segments diversificated; calyx villous; stem hairy." _Root_ biennial, branched. _Stem_ three or four feet high, erect, strong, branched, furrowed, many-flowered. _Leaves_ alternate, woolly underneath; _lobes_ pinnatifid, or pinnate at the base; _segments_ alternately diversificated, mucronate—spiny; _spines_ yellow, shining._Flowers_ terminal, erect, large; _calyx_ egg-shaped; _scales_ acutely spiny, ascending, clothed, like the under surface of the leaves, with a white, cotton-like web; _florets_ uniform, _purple_; _petioles_ yellow. _Seeds_ ineradely egg-shaped, shining; down feathery. _Dr. Smith_. A native of white places and road sides throughout Europe, flowering from June till winter.

4. _C. nutans._ _Mulk thistle_. Linn. Sp. Pl. 3. Mart. 4. Lam. 3. Wild. 6. Eng. bot. 107. "Leaves interruptedly deciduous, spiny; _flowers_ drooping; _scales_ of the calyx lanceolate; their upper part spread-
C A R D U U S.

five depressions resembling nectarous glands. A native of
 Dutch banks and hedges, flowering in June and July. 12. C. rigo-
frentia, Lam. 16. "Leaves decurrent, narrow, fcellop-
toothed, spinous, culead; flower large, terminal." Stem
simple, scarcely a foot high, a little downy, sometimes two-
flowered. Flowers dark green, beft here and there with a
woolly down. 

Flower purple; calyx leaves three. 

C. tendiarius, Lam. 16. "Leaves decurrent, pinnatifid-
Toothed, spinous; peduncles without leaves, downy;
calyxes deciduous." Root perennial. Stem from one to
three feet high, white, with hairs. Roots leaves somewhat
lanceolate, a little fcelloped; fimu-leafes oblong, toothed.
Pubescent on both sides, white, and almost woolly un-
derneath. 

Flowers purple; peduncles short, white with 

three, neither winged nor spinous; pedicels with three or
four flowers; calyces about the fize of a hazel nut, oblong;
scapes awl shaped, creft, spreading, with small fpines; florets
often nine or ten; border creft. Linn. 18. C. angustif.
Linn. jun. Supp. 348. "Leaves decurrent, runnicate,
spinous; calyces nearly fellite, terminal." C. Arabicus,
Willd. 3. Jacq. t. 1. tab. 166. Collect. i. p. 56. "Leaves
decurrent, oblong, fcelloped, spinous, white-veined, villous
underneath; flowers fellite, rather clustered; calyces cylin-
drical." Willd. C. galatætis, Lam. 21? "Stem winged,
branched; upper wings broader; leaves decurrent, angu-
larly toothed, spinous, downy underneath; flowers fellite,
axillary and terminal." La Marc. We have transferred
the specific character given by each of the three authors,
because the identity of the plants has not been absolutely
acertained, though it seems highly probable. Professor
Marty, however, considers the arabicus and the australis as
difficult species, n. 3, and 11. Stem about a foot high,
woolly or cottony. Leaves alternate, remote, fellite, scarcely
decurrent all the way from one to another, oblong, somewhat
fcelloped at the fides, a littie cobwebbed, the lateral veins
running out into white fpines. Linn. jun. Oblong, fcel-
loped in a pinnatifid manner, toothed, spinous, attenuated
at the base, smooth, and white-veined above, woolly-villous
underneath; the root and lower fpem one petioled, the reft
decurrent. Willd. Decurrent, almost petioled, angular,
toothed, spinous, green above, white and cottony underneath.
Linn. The white veins are not mentioned by La Marc;
his specific name implies them. 

Flowers terminal and lateral, terminal ones several, lateral ones solitary, fellite.
Linn. Willd. Calyx-fceans lanceolate-egg-shaped, 

Pretfe clofe. Willd. Somewhat spreading. Linn. A native
decurrent, fcelloped, spinous, downy; calyces somewhat cylin-
drical, aggregate, fellite; scales lanceolate, rather creft." Root
annual, fpindle-shaped, small. Whole plant white, with
down. Stem four feet high, erect, stiff, but little branched,
furred. Leaves fcellopd, most woolly underneath, 

broadly decurrent. 

Flowers pale purple, terminal, cluttered, fellite; calyx slender, pale, fcarcey woolly; scales 

lanceolate, even, smooth, rather creft, but little nerved, 

acutely spinous; florets from ten to fifteen; down deci-
duous, capillary, rough. There was long much contro-

vert among British botanists concerning this thistle; the herba-

rium of Linnaeus at length determined that it has not been
infected among his works. Dr. Smith was for some time
incliued to consider C. pynceocephalus, auratis, and the
plant before us, as only varieties of the fame specific. He
oberves, however, that the two former have fewer scales in
their calyx, the falk lefs winged, and their flowers,
whether fellite or pedunculated, are much fewer together,
with lefs numerous florets. See Eng. Bot. La Marc's
acahtoides is clearly the prent plant, and he speaks of it
as very common in uncultivated ground, dry ditches, and
under the shelter of walls in France and other parts of

Europe.
CARDUUS.

Europe. In Great Britain it appears to be very local, though abundant where it has once gained a footing. It is common about London, growing, as Curtis observes, in the very inlets. We have observed it about the flots of Edinburgh and Sunderland, and should have supposed it confined to the neighbourhood of populous towns, if we had not found it in great plenty at Blackpool in Lancashire, about the dry banks, which are the only fencés of the infested land in that naked part of the country. 20. C. argenteus, Linn. Matt. 250. Mar. 10. Lam. 8. Willd. 18. Jacq. Hort. tab. 192. (Cirsium asperatum minus, foliis ad limbum argenteis.) “Leaves decurrent, roundish, spiny; peduncles somewhat downy, one-flow- ered; calyx-eggi-shaped, mucronate, not pungent.” Root annual. Stem a foot high, zig-zag, smooth, alternately branched. Leaves small, oblong, green, spotted with white, especially about the indentations. Flowers small, purple, fearfully opening, terminal; peduncles very long, one-flow- ered, downy, erect; calyx falling off entire with the ripe seeds; scales closely imbricated, erect; down capillary. Linn. and Lam. A native of Egypt. 21. C. cyanus, Linn. Sp. Pl. 9. Mar. 15. Willd. 19. 20. a. mariculosa, Gmel. f. 2. p. 43. tab. 15. B. poeipenos, tab. 16. “Leaves decurrent, pinnaflid, linear, entire, without spines, petioled, downy underneath.” Root perennial. Stem in a. nearly simple, with few leaves; in a. much branched, the upper leaves much dilated at the base, the lower ones with linear pinnae. Down capillary. Willdenow makes them distinct species. A native of Tartary. 22. C. canus, Linn. Matt. 108. Mar. 14. La Mareck 10. (Carduus tuberosus, Jacq. Vind. 280. from the description. Auft. 1. tab. 42. 43. Cirsus canus, Willd. 4. Cirsium tomen- tosum radicibus bulbofa. Bauh. hist. 3. p. 44. C. monta- num maximum, Rai. hist. p. 305.) “Leaves decurrent, white. Stem four feet high, green, angular, cobwebbed. Leaves somewhat scolloped, toothed; fringed with white, scarcely pungent spines; keeled. Flowers solitary, purple, terminal; peduncles long, with a few small floral leaves; calyx not pungent, marked with a white line on the outside. Linn. Down feathery. A native of Auffria. 23. C. pce- tinatus, Linn. Matt. 279. Mar. 15. Iam. 11. Willd. 21. “Leaves decurrent, lanceolate, pinnaflid pectinate; pedun- cles very long; flowers drooping as the seed ripens.” Root biennial. Whole plant smooth. Stem two feet high, erect. Leaves with a pale keel, deeply toothed, so as to resemble a comb; teeth equal, lanceolate, large, entire, but lightly ciliated; ending in a flat spine, furnished at their base with a small delind tooth. Flowers purple, the fize of the common cardonk, toothed; peduncles very long, one-flow- ered, somewhat downy; calyx-alaes linear, spreading; anthors white; pili long. Linn. Raised by Limmus from seeds brought among other kinds from Pennsylvania. 24. C. alpnyx, Willd. 23. Wahlit. and Kitaib. pl. rar. Hung. “Leaves semi-decurrent, pinnaflid, acuminate; segments two-lobed, ciliated-spinos; peduncles downy; calyx-alaes linear-awl-shaped, spreading.” Stem a foot, or a foot and half high, simple. Leaves on both sides. Flowers pur- ple, two or three at the tip of the stem; peduncles leafless, downy. Down capillary, rough. A native of the Croatian Alps. 25. C. defloratus, Linn. Sp. Pl. 21. Mar. 16. Lam. 12. Willd. 24. Jacq. Auft. tab. 89. Hall. helv. 677. tab. 18. fig. 2. “Leaves decurrent, lanceolate, ferrated, somewhat ciliated with spines, smooth; peduncles very long, woolly, one-flow- ered.” Root perennial. Whole plant smooth. Stem sometimes simple, only a foot high, one-flow-er; sometimes branched, a foot and half high. Leaves dark green; peduncles leafless, a little cottony towards the summit. Flowers purple, often drooping at the base upwards. Down capillary. A native of Auffria, Switzerland, and the northern provinces of France. 26. C. femininus, Willd. 27. “Leaves semi-decurrent, ferrated, spiny, grey underneath; peduncles very long, one flowered, woolly.” Similar to preceding, but its leaves are shorter, grey underneath, and leaf deeply ferrated; the calyx-alaes spreading. A native of the northern part of Peru. 27. C. medius, Lam. 13. Gouan. Illust. 62. tab. 24. Mar. 43. excluding the reference to Allioni pedem. (Cicus Gouani, Willd. 6.) “Leaves decurrent, pinnaflid, spiny at their edges; stem one-flow- ered; calyx-alaes without spines, spreading, bristle-shaped.” Similar to C. defloratus, but its leaves are villous underneath, larger and more divided. Root perennial. Stem a foot and half high, simple. A native of the Pyrenees. 28. C. carlinef- bus, Lam. 14. Willd. 8. Vahl. Symb. i. p. 157. “Leaves decurrent, smooth on both sides, pinnatifid; pinna angularly cut, spiny; peduncles one-flowered, woolly under the flower.” Lam. Stem a foot and half high, erect, branched, smooth, spiny, woolly near the summit. Leaves resembling those of the preceding species in shape, but smooth on both sides; spines strong, yellowish. Flowers purple, seldom more than three; calyx-alaes lanceolate-awl-shaped, spreading, rather pungent. Vahl. A native of the south of France. 29. C. carlinef- bus, Willd. 42. Mar. 7. Gouan Illust. 62. tab. 23. (Cirisus pyrenaeus, Linn. 1 Carduus tomentosus pyrenaeus, Thouin. fult. 441.) “Leaves decurrent, pinnaflid, downy; segments palmate, spiny; flowers chaffered.” Vahl. Root perennial. Stem a foot high, or more, white with down, sometimes panicell-branched; branches axillary, alternate, solitary. Root-leaves three or four inches long, somewhat lanceolate, petiolate, woolly; pinnules on each side from twelve to fifteen, imbricated, three or five-Leaf, the lobes alternately smaller, end- ing in a strong yellow spine. Stem-leaves crowded, very like those of the root, but as they approach the top of the stem the pinnules are narrower and less palmaroted. Flowers purple, from four to eight; peduncles short, woolly; calyx in flowering time very smooth, green, acuminate-egg- shaped; scales loosely imbricated, but not quinquefollo, nearly equal, a little pungent; the inner ones somewhat violet-purple, more slender, flexible and soft. Gouan. A native of the Pyrenees, and of the Alps about Col Tende. La Mareck believes it to be the cardina pyrenaeus of Linnzeus. 30. C. argemone, Lam. 15. “Leaves decurrent, broadly egg-shaped, twice pinnaflid, ciliated, smooth on both sides; peduncle terminal, one-flow- ered.” Lam. Stem about a foot high, simple, smooth. Leaves ciliated, with very small spines. Calyx smooth; scales close, not pungent. Described from a single specimen in the herbarium of Thouin, brought from the Pyrenees by abbé Pourret. 31. C. montifruitifolius, Linn. Sp. Pl. 16. Mar. 17. Lam. 17. Gouan. Monsp. 422. (Cirus Monsp. Willd. 9. Cirsium folius non hierifus, Sanguis compactus, Bauh. pin. 577.) “Leaves decurrent, lanceolate, somewhat repand, or a little scolloped, smooth, unequally ciliated; peduncles alternate; calyxes not pungent.” Linn. Root perennial. Stem four feet high, channelled, a little branched, greenish below, slightly cottony towards the summit. Leaves almost entire, a little glaucous, the lower ones entirely decurrent, middle ones semi-decurrent, upper ones feathery. Flowers purple, remarkably small for the size of the plant; calyx-alaes small, expanding at the points. Down feathery. A native of the south- west of France. 32. C. pyrenaeus, Lam. 18. Mar. 45.? Jacq. obs. 4. p. 11. tab. 95. Gouan. Illust. 63. (Cirsium pyrena- eum.)
CULUS

Circaus pyreus, Lam. 55. "Leaves decurrent, lanceolate, a little repand, downy underneath, ciliate-spinous; flowers clustered." Lam. Perhaps only a variety of the preceding: it is, however, larger, and confinely distingished by its leaves being cottony and whitish underneath, by the long, yellow-white, pungent spines with which the leaves are ciliated, and by its clustered flowers at the top of the stem. The root-leaves are more than a foot long, narrowing into a petiole. Lam. A native of the Pyrenees. We are in doubt whether the pyreneni of professor Martyn be the same plant. His only synonyms are Jacq. obl. 4. 11. Ger. Prog. 179. n. 13. and J. & Linn. pedem. n. 140, tab. 1. neither of which are quoted either by La Marek or Willdenow. His specific character accords sufficiently with La Marek's, except in deferring the leaves as downy on both sides; but his larger description taken from Allioni does not seem to be consistent with it. It is as follows. Stem three feet high, or more, fribated, green, smooth. Leaves alternately felifi, and decurrent with ears; almost winged, or very deeply gashed, with few teeth, ending in a longer spine; the whole edge ciliate with short spines. Flowers at the top, three or four, with a small leaf under each; peduncles cobwebbed. Top of the stem almost naked; calyx-feales not pungent, linear, reflected at the end. This description agrees better with C. pratensis of La Marek, which is certainly not the pratensis of the English botanists; but there are some differences, as will appear from the following description. 33. C. ambiguus. (C. pratensis, Lam. 25. C. pratensis aphiodeli radices, folis profunde et teniiter lacinia. Baul. pin. 377.) "Leaves semi-decurrent, pinnatifid-laciniate, ciliated, smooth on both sides; flowers generally foliary, pedunculated." Root perennial. Stem three or four feet high, litfled, a little branched. Leaves smooth, and green on both sides; spines not pungent; root leaves long, pinnatifid; pinnules cut into deep segments; lower leaves leaves cut in the same manner, and at least semi-decurrent; upper ones smaller, less divided, less decurrent, many of them fible. Flowers purple, resembling those of C. monspeliensis. A native of the south of France, described by La Marek from a living plant. La Marek observes that it may possibly be C. tubulosus of Linnaeus, but not all his synonyms. 34. C. chinus, Mart. 20. Jacq. Hort. 3. tab. 5. "Lower leaves semi-decurrent, fespinnatifid, ciliate-spinous: upper ones embracing the stem or fible; stem not fipous; peduncles one-flowered." Nearly allied to the preceding, if it be more than a variety. Stem five or six feet high, branched from top to bottom, angular, viscid, erect. Leaves lanceolate-oblong; the upper surface fribate smooth, and deep green; the lower somewhat villous, and paler, but no where woolly; acuminate and pinnatifid; segments lanceolate, ciliate-spinous, fercally pungent; root-leaves a foot and half long. Flowers purplish fial-colour, erect; peduncles terminal on each branch. one-flowered, near the flower a little woolly, and suffrilled; calyx egg-shaped, not fiform; scales with an oblong, glinmate bump on the back, ending in a short, dark, dark purple spine. Seeds fribine: down feathery. A native of China, received by Jacquin about the year 1779, from Marefig of Pads. 35. C. creticus, Lam. 20. (Cirrus creticus athis, Lam. 20. (Cirrus cireticum officinale, C. lanceolati-folio. Tour. Cor. 32.) "Leaves decurrent, pinnatifid, smooth underneath; segments diversifid, spinous; flowers small, clustered; calyx scales small, somewhat fipous." Stem a little branched near the fumity, spinous, fribated, almost smooth. Flowers resembling those of C. lanceolatus, but narrower. Flowers purple; calyx globular. A native of the Isle of Candia, described by La Marek from a dried specimen in the herba-
bottom. 

Leave lanceolate-lanceolate, two or three inches long, green and smooth above, except at the base, a little rolled back on the sides; throat of the former year remaining withered and dry at the bottom of the stem. 

Flowers purple, terminal; calyx egg-shaped, contracted at the top, glaucous green; scales simple, stiffish, acute but not pungent; anthers purple, each terminating at the bottom in two curv. filaments very hairy at the top. 

Seed egg-shaped, grey; down very long. 

A native of the Upper Calabria, gathered in 1783 by Angelo Fusani. Before that, it was known to exist only in the Herbarium of Ferrarisi Imperiai, under the name of Jacca. 42. C. dollatus, Linn. Sp. Pl. 13. Mart. 24. Lam. 26. 

Foliis integris, floribus purpureis, Toon. 420. (Cnicus dollatus, Willd. 42.) 

"Leaves sessile, linear-lanceolate, entire, not pungent, downy underneath; axillary spines in pairs, somewhat branched; flowers fiddle, lateral, and terminal." In habit resembling Centaurea calcitrapa. 

Root annual. 

Stem a foot high, much branched, a little corymbose. 

Leaves three inches long, green above, very narrow at the base. 

Flowers purple, solitary; peduncles with two or three floral bracts; calyces scales lanceolate-sharp, pungent. 

A native of Sicily and the country of Nice. 43. C. dentatus. 

(Cnicus dentatus, Willd. 11.) 

"Leaves embracing the stem, lanceolate, doubly toothed, spinous, woolly underneath; stem one-flowered; calyx scales lanceolate-egg-shaped, mucronate, prepelled close." 

Stem half a foot high or more, simple, erect, furnished, especially near the flower. 

Leaves on the stem generally four; lower ones somewhat petiolate; upper ones embracing the stem, narrowed at the base. 

Rai Sup. 179.) 

"Leaves sessile, lanceolate, edged with spiny teeth, downy underneath; stem leafy, one-flowered; calyx not pungent." 

Linn. "Calyx-scales mucronate." 

Wildl. Stem slender, a foot or eighteen inches high, furnished with 26 or 28 leaves, which diminish in size from the bottom to the top. 

Thum. Jap. 305. 

"Leaves sessile, linear, ciliate-spinous, smooth; flowers terminal, solitary." 

Stem a foot high, herbaceous, erect, round, brassed, not pungent; branches alternate, spreading, a little downy near the top. 

Leaves two inches long, spreading. 

Flowers small; calyx a little downy at the base. 

A native of Japan. 46. C. giganteus, Desf. Atl. 2. p. 245. tab. 221. 

C. lebar. Foyr. im. 2. p. 201. (Cnicus giganteus, Willd. 19.) 

"Leaves embracing the stem, egg-shaped, falcate, kid with slightly hairy, downy underneath; lobes spinous; peduncles about three-flowered; calyxes globular; scales lanceolate, spinous, prepelled close. 

A native of Algiers. 47. C. lanatus. (Cnicus lanatus, Willd. 21.) 

"Leaves falcate, lanceolate, falcate, falcate, smooth, downy underneath, spiny at the edges; calyx oblong; scales egg-shaped, mucronate, recurved." 

Stem erect, falcate, smooth, branched. 

Leaves two inches long. 

Peduncles naked, one-flowered, pubescent. 

(C. maculis albis exotica, Bahm. pin. 381. 

C. latifolius echinos oblongis purpureis hermis, Bahm. pin. 380. C. luteus syriacus, Cam. Hort. 35. tab. 10. 

Cnicus syriacus, Willd. 45.) "Leaves embracing the stem, oblong, toothed, spinous, white-veined; flowers nearly sessile, bracteated; calyx-scales oblong-lanceolate, prepelled close, mucronate." 

Wildl. Root annual. 

Stem two or three feet high, erect, simple, almost smooth. 

Leaves angularly falcate, green, spotted with white; lower ones 

Vol. VI. 

<what
what toothed, ciliate, woolly underneath; stem nearly naked, one-flowered; calyx villous." Root perennial, creeping; fibres long, staple, fleshy. Stem erect, about a foot and half high, simple, seldom more than one-flowered, rounded, narrow, woolly. Leaves unequally toothed, sometimes a little scolopaded, ciliate with stronger and more purplish spines than those of C. heterophyllus, roughish, ciliate beneath, but not fleshy white; root-leaves three or four, pinnate; stem-leaves two or three, smaller, remote, embracing the stem. Flower purple, terminal, at first nodding, afterwards erect; peduncle a little thickened at the top, fleshy white; sepals lanceolate, erect, ending in a weakish spine; down as in C. heterophyllus. A native of myrtle places in France and England. We are informed by Dr. Smith, (Eng. Bot.) that Linnaeus took up his distichous from books, without having it in his herbarium. All his synonyms are said by La Maree to belong to the present plant, species having been sent him from the neighbourhood of Olenus, which perfectly agree with Lobel's figure. It seems, therefore, probable that he accidentally prefixed an erroneous specific character to his synonym, and that his differences has no specific existence. 54. C. ferrugineus, Linn. Sp. Pl. Mart. 32. (Castr. Meth. Nat. 199. (Jacq. Ind. Nat. 199. and tab. 1. 257.) (Cucumis ferrugineus, Willd. 26.) "Leaves embracing the stem, lanceolate, entire; flowers ferrugineus, bracteate, peduncles one-flowered." Linm. "Leaves filiform, lanceolate, remotely serrate, ciliate, with small spines, green on both sides; calyxes not pungent, oblong, convex; down fleshy, very long." Linn. According to Linnaeus it differs from C. helenoides in its smaller, scarcely narrowed stem, and narrower leaves, with the floral ones lanceolate, not asp-flowered. Willdenow adds that in this species the stem is branched, and the leaves green on both sides. La Maree affirms, that his ferrugineus resembles his helenoides (which, however, is heterophyllus), in nothing but the generic character. It appears, nevertheless, from his description, that there are many points of resemblance, and that his plant is probably the ferrugineus of Linnaeus, as we think it certainly is that of Willdenow and Jacquin, though Jacquin says the stem is simple when wild, and branched only when cultivated. A native of Siberia, Switzerland, and Austria. 55. C. tartaricus, Linn. Sp. Pl. 23. Mart. 33. Linn. "Leaves embracing the stem, lanceolate; sepals fimbriatus, awn-flowered; flowers with two leaves." Linm. "Leaves embracing the stem, oblong-lanceolate, toothed, ciliate, purplish, peduncles one-flowered; calyxes bracted; scales lanceolate, spinous. Wild. Habit and size of the preceding. Linn. Root perennial. Stem a foot and a half high, smooth, sometimes simple, and sometimes with a branch or two, each bearing a single flower. Leaves little scolopaded, toothed, smooth on both sides; root-leaves long, petiolate; stem-leaves rather distant. Flower yellowish white; bracts generally three, small, lanceolate, ciliate. La Maree. Calyx-scalles with a white keel. Linn. A native of Siberia and the Alps. 56. C. poirundifolius, Mart. 41. (Cucumis carnicolius, Wildl. 33. C. oldianus, Scop. Carn. 1009. tab. 51.) "Leaves heart-shaped, embracing the stem, oblong-egg-shaped, toothed, ciliate; root-leaves oblong, obtuse, scolopaded, ciliated; flowers terminal, somewhat clustered; calyxes involucrate; scales lanceolate, spinous. Wild. Root perennial. Stem hairy. Root-leaves petiolate, hairy on both sides; petals hairy. Flowers yellowish white; calyx involucrate, with three lanceolate ciliate leaves. Wildl. 57. C. angustifolius, Linn. 54. "Leaves sessile, long, narrow; toothed, ciliate; flower involucrate by about five linear bracts. Stem near two feet high, a little branched, and somewhat woolly. Leaves green, smooth on both sides, opposite, others alternate. Flowers solitary, terminal. Cultivated in the royal garden at Paris, and said to be a native of the Alps. 58. C. carnicolius, Linn. 32. (Cucumis carnicolius, Willd. 33. C. carnicolius, Scop. Carn. 1009. tab. 51.) "Leaves embracing the stem, long, pinnatifid; pinnules parallel, ciliate-spinous; bracts ciliate, entire, rather coloured, covering the flowers." Nearly allied to the three preceding. Root perennial. Stem sericeous, smooth, weak. Leaves large, dilated, pale green; lower ones narrowing into the petiole. Flowers yellowish white, terminal, clustered; bracts ciliate. A native of meadows in many parts of Europe. 59. C. poirundifolius, Willd. 34. Walsh. and Kew. P. Rar. Hung. "Leaves embracing the stem, egg-shaped, somewhat fimbriate, ciliate, serrated, root-leaves fimbriate; flowers yellowish; calyx-scales lanceolate, the lower ones spreading. Root biennial. Stem naked toward the top, with or without clustered, terminal flowers. Leaves pinnate beneath; root-leaves a foot long, oblong-rounded, a little scolopaded. A native of Hungary. 60. C. ferreolus, Willd. 35. Vill. Delphi in. p. 12. tab. 19. (Cucumis antarcticus, Wildl. 36. "Leaves heart-shaped, embracing the stem, pinnatifid, lanceolate at the top, ciliate-spinous, rather woolly underneath; flowers clustered; calyx-scales lanceolate egg-shaped, mucronate, spreading at the tip." Root perennial. Leaves dilated at the base, pinnatifid and toothed in the middle, elongated, and lanceolate at the end. Flowers white, terminal. 61. C. ferrugineus, Lam. 41. "Leaves embracing the stem, entire at the base, pinnatifid-peckinate towards the top, green on both sides; branch-leaves very entire; flowers rather clustered, terminal." Root perennial. Stem two or three feet high, more or less branched. Leaves divided in their upper part into lanceolate segments resembling the teeth of a comb, each ending in a spine. Flowers two or three together, pale or yellowish, acquiring a purple tint from the colour of the anthers; calyx smooth, not pungent. Cultivated in the royal garden at Paris, supposed to have been brought from Tartary. 62. C. montanus, Willd. 37. Vill. and Kitaib. Pl. Rar. Hung. "Leaves embracing the stem, pinnatifid, rugged, spinous-ciliate; segments alternate, oblong-lanceolate three-nerved; stem branched; flowers clustered; calyx-scales egg-shaped, spreading at the tip. Root perennial. Flowers purple. A native of dry mountains in Croatia. 63. C. rivularis, Mart. 38. (C. rivularis, Willd. 35.) "Leaves toothed, ciliate, naked, embracing the stem; root and lower stem leaves pinnatifid; flowers clustered, capitulate; calyx-scales lanceolate-egg-shaped, pre-fused clove." Wildl. Root perennial. Stem usually single, two or three feet high, erect, round, hollow, a little villous, angular at the bottom, ciliate at the top, with a few dilated bracts; generally quite single but sometimes with short, one-flowered, axillary branches; sometimes, especially towards the top, covered with a white wool; ending either in a single flower, or a few collected into a head, rarely fix or seven, and in that case the lower ones are produced. Leaves somewhat villous, deeper green above, whitish underneath; root ones lanceolate, narrowing into the petiole. Flowers purple; calyx egg-shaped, somewhat glabrous, but not villous; leaves lanceolate-acuminated, not pungent, outer ones dark green, inner ones dark purple and gradually longer; down somewhat flattered. A native of Austria and Hungary. Profeilor Martyn has quoted Scopoli n. 1025. tab. 54. under both C. carnicolius and C. rivularis, adding to the latter a reference to Jacquin, and by referring from one to the other, seems to think they may possibly
C A R D U S.

Possibly be the Lance plant. He has neathew all given diff

tinct descriptions of each, of the forms from Scopoli, and
of the latter from Jacquin, which do not very well accord
with each other. Willdenow, who had shewn specimens of
both, has kept them separate. 67. C. salsugineus, (Culcins
suitugineus; Willd. 29.) "Leaves twirled, ciliated; leaf-leaves
embracing the stem, pinnatifid, root
ones undivided, oblong; stem twilled; calyces ciliate, pedicled clole." 

Root perennial. Stem hairy. 

Leaves smooth, befit with very few, feathery hairs. A 

native of moat meadows about Salzburg. 65. C. annuus, 

4. p. 204. tab. 16. (Culcins tidgen; Villid. 28. Ciriun. 

Hall. n. 176.) "Leaves oblong- lanceolate, <nitous, spii-

rons at the edges, pinnatifid; segments oblongly lobed.

calyces oblong, bracteated." Martyn supposes it to be the

name with C. muticoxis of Villars, fee n. 57. A native of

Switzerland. 69. C. Alliurn, (Culcins medius; Willd. Cirun.

median. Allion ped. n. 542. tab. 49.) "Leaves

sehile, pinnatifid; segments generally three-echt, ciliate-

spinous; item branched, calyces naked; seles, egg-lanceo-

late, mucronate, pedicel clole." Root perennial. Perfectly 

distinct from C. medus of Gunne (nee n. 275) which has

been quoted as a synonym, notwithstanding it has decer-

rent leaves. Willd. from a living plant. 67. C. radulae, 

Villid. 29. "Leaves pectinate-pinnatifid, naked, rugged;

segments linear, not purgent. terminal one egg shaped; upper

leaves sessile; calyces-leafed sharped, mucronate; inner

ones elongated, linear, colored." Root perennial. Stem

branched, many-leaved. Leaves green on both sides; lower

ones petioloed. Flowers violet. Donn. capitally. 

A native of calcareous mountains in Hungary. 68. C. leucphi-

Lam. 29. Villars delph. 3. p. 33. tab. 10. "Leaves

egg-shaped, pinnatifid-toothed, at the base, serrated; after

underneath upper ones sessile; item one-leaved; calyces-

leafed egg-shaped, not purgent." Similar in habit to the pre-

ceding. Root perennial. A native of mountains in Dauphiny.

69. C. nitidus, Wildl. 32. Waldit. and Rital. pl. 

rar. Hung. 1. p. 52. tab. 52. "Leaves not purgent; root-

leaves egg-shaped, toothed, cut at the base; item-leaves

pinatifid-linear; item one-leaved; calyces-leafed egg-shaped,

mucronate." Root perennial. Upper leaves entire, linear-lan-

celolate. A native of calcareous mountains in Hungary.

and Autl. tab. 60. (Culcins crisitbelus; Linn. Sp. Pl. 4. 

Wildl. 37. Ciriun acanthoides montana, flore flavicente: 

Tour. Illust. 448.) "Lower leaves petioloed, egg shaped, 

deeply pinnatifid; pinnules parallel, three-nerved; peduncles

naked, one-leaved." Root perennial. Stem 

a foot and half high, generally ample, nearly smooth. 

Leaves nearly smooth, greenish; lower leaves near together, toothed,

spinos ciliated; upper ones embracing the item, dilated, 

narrow. Flowers yellowish white, terminal, nodding. A 

native of France and other temperate parts of Europe. 71. 

C. tricaflus, Lam. 35. (Ciriun; Hall. helv. n. 175. 

Cardus-ciriun maximum profunde laciniam. Pluk. tab. 

154. fig. 2.) "Leaves embracing the stem, pinnatifid, 

ferrated, ciliated; flowers ferrile, about three, cluftrated at 

the top of the item." Root perennial. Stem two or 

three feet high, ample, a little cotty under the flowers. 

Lower leaves petioloed, egg-shaped, a little cut or doubly

toothed, green and smooth above, with short hairs on their

hindmost nerves; upper leaves embracing the item, deeply 
pinnatifid; pinnules parallel, narrow, ciliated. Flowers 
purple; calyces smooth, not pungent. A native of Auvergne 

and Dauphiny. La Marc observes, that this and the pre-

ceding have been confounded by Linneus and Haller. 72. 

C. oholoucus, Mart. 44. (Culcins oholoucus; Willd. 38. 

Culcium; Hall. helv. n. 245. Hall. helv. n. 174.) "Leaves 

and stem, the item, densely pinnatifid, dilat-

ated, pinnules lanceolate, these serrated, uppermost con-

ferrate; peduncles ferrated; calyces lanceolate, mucro-

nate. Stem pungent. Flowers yellowish orange. A 

native of Switzerland and Savoy. 73. C. Lactiflora, Lam. 

37. "Leaves embracing the stem, pinnatifid, mucronate, 

pinnatifid, grey underneath; flowers about leaves, clufтратed 
at the top of the item; terminal one crad." Stem a foot 

and half high, simply, abundantly leafy, cotty in its upper

part. Leaves appressed, green and leathert above, white, 

cottony underneath, pinnules half dark yellow; 

pinnules narrow, curved upwards, ending in a weak spine. 

Flowers large, purple; calyces smooth, not pungent. A 

native of the Alps about Grenoble. 75. C. caesiufos, 

Lam. 53. "Leaves embracing the stem, pinnatifid; 

pinnules laciniate upwards." Stem two feet high or more, 

cottontowards the top. Leaves green and dark leathet above, 

lightly villous and pale underneath, yellowish; 

root leaves large, petioloed; item ones smaller, 

embracing the item. Flowers large, with which a red tint from 

the colour of the anthers, partly clustered several together at 

the top of the item, partly solitary, peduncled, in the axil 

of the upper leaves; calyces smooth, not pungent. Cultu-

rated in the royal garden at Paris, and said to be a native 

Lam. 39. (Culcins althienuus; Wildl. 29. Ciriun ammifolius; 

Dit. Est. 81. tab. 69. fig. 30.) "Leaves sessile, pinnatifid, 

scollaped, ferrated, not purgent; item much branched;

calyces villous, somewhat ferrated." Root perennial. Stem 

ten or twelve feet high. Leaves green above, cottony and 

white underneath. Flowers purpulc, single at the top 

of each branch; calyx woody; bractes several, narrow, 
toothed, forming an involucreum. 75. C. bulbifusa, Lam. 

44. (Culcins bulbifusa, Monspeliense, flore flavifloro: cu-

bilibrums, folis Lacinios, J. Bauh. 3. p. 43. C. bul-

bulbifusa monspeliense; Lab. le. n. 10. Ciriun, 

Hall helv. n. 177.) "Stem naked above, with one or two 

flowers; leaves deeply pinnatifid; pinnules cut, 

lobed, ciliated, ending in a small spine; flowers solitary. 

Root composed of several bulbs or tubers. Stem a toot 

and half or two feet high, slender, furtated, cottony, espcri-

arily near the top, with two or three leaves on its lower part. 

Leaves almost all petioloed, greenish above, and beftit with 

short, thinly ciliated hairs, cottony and white underneath. 

Flowers purpure, rather small terminal; scales egg-shaped, 

mucronate, not purgent. A native of Germany, Switzerland,

and the South of France. There is a variety in the 

neighbourhood of Paris, with leaves almost entirely green. 

La March observes that Linneus was probably unacquainted 

with this plant, having erroneously referred Lobel's C. bulbifusa 

to his tuberosus from which it is perfectly distinct, its 

leaves not being decurrent. He conceives that the tuber-

osas of Linneus may possibly be the plant which he has de-

scribed under the name of pratensis, and which we o a co-

nt of the uncertainty have called ambiguus, (fee n. 23) 

pratensis as a specific name being pre-occupied. 77. C. 

laciniatus, Lam. 45. (Jacae scelleta f. tubulosa; Palhern. i. 

154. "Stem leafy, branched, leaves deeply pinnatifid, 

green on both sides; pinnules laciniated, spinos ciliated, 

peduncles one flowered." Distinguish from the preceding.

Its leaves are not decurrent; it therefore is not the tuberos-

uses of Linneus. Stem a foot and half high, smooth, chan-

nelled. Leaves large, somewhat petioloed. Flowers large, 
purple or white, peduncled; calyces not purgent. Described 

from a dried specimen in the herbierium of Justell and sup-

posed to be a native of the Alp. 78. C. arvensis, Lam. 

1842. p. 851.
Eng., 1755. C. ferratula arenaria, Linn. Sp. Pl. Mut. Wildd. Carduus vulgarifolius var. mam. (Rai syn. 1754.) Creeping or way thistle. "Leaves sessile, pinnatifid, spiny; , metal pinnate, calyxes egg-shaped, slightly spiny; down featherly. Root perennial, creeping, tapering, descending deep into the ground, not easily extripated. Stem three feet high, erect, round, smooth, many-flowered. Leaves slightly decurrent, alternate, smooth, lobes unequal, ciliated, spiny. Flowers purple, rarely white; calyx egg-shaped; scales broad-lanceolate, preped close, woolly at the edges, with a short, spreading spine; down deciduous, root permanent as in C. arenaria. Dr. Smith. A native of most parts of Europe. 79. C. dio- color, (Cnicus diofrorum, Wildd. 189.) "Leaves sessile, pinnatifid, hairy, downy underneath; pin- nules two-lobed, divaricated, spiny; calyxes globular, cobwebbed, pubescent, fleshy egg-shaped, preped close, ending in a spreading spine." Root biennial. A native of North America. 80. C. orientalis, (Cnicus orientalis; Wildd. 17.) "Leaves sessile, pinnatifid, smooth, downy underneath; pinnules lanceolate, spiny; calyxes egg- shaped; scales preped close; outer ones awl-shaped, inner ones lanceolate." Stem downy. Leaves narrow, downy on the midrib above, snow-white underneath; pinnules with a spine at the tip, and at the upper part of the base. Calyx only half the size of that of C. lanceolatus. A native of the Eaa. 81. C. cyanoides, Linn. 28. (C. cnicus folius lanceolatus, Tourn. Cor. 31. Cnicus cyanoides; Wildd. 16.) "Leaves sessile, obovate, pinnatifid, downy underneath; pinnules angular, divaricat ed, spiny; flower large, terminal." Stem erect, flinted, cottony. Leaves smooth, and shining above, very white underneath. Flower purple; calyx-cales lanceolate, pungent; outer ones reflexed, and widely spreading. A native of the isle of Canda. 82. C. ciliatus, Hort. New. 3, p. 144. Murray Com. Goett. 1784, p. 35, tab. 5. (Cnicus ciliatus; Wildd. 12.) "Leaves embracing the stem, hispid, pinnatifid; pinnules two-lobed, divaricated, spiny, downy underneath; calyxes egg-shaped, scales lanceolate, spiny, ciliated, reflexed." Root perennial. Stem many from the same root, five or six feet high, hairy, round, with prominent lines, and horizontal white hairs, branched on the upper part; branches about a foot long, compound, alternate, ac- eeding; branches three, short, zig-zag. Stem-leaves a few, about half long, ferning each other. Stem-leaves about a foot long, half embracing the stem, horizontal, al- ternate, rough, and green above, with fleshy coloured veins, which end in waved-awned fimbriae of the same colour. Flowers terminal, solitary, yellowish white; calyx cylindric, oblong, broader at the base; scales yellow, linear, preped close, end- ing in a weak spine. Seed top-shaped, four-cornered; down abundant, feathery. A native of Siberia. 83. C. leucocephalus. (Cnicus leucocephalus; Wildd. 13. Cdition creticum altaesium C. lanceolato foli flore albo; Tourn. Cor. 32.) "Stem-leaves sessile, pinnatifid, hispid, downy underneath; pinnules lanceolate, spiny at the tip; calyxes cylin- drical, alternate, villous, involuted, scales oblong, preped close, ending in recurved spines." Wildd. Root-leaves pectolored; pinnules lanceolate, two-lobed, divaricated, ciliated at the edges, spiny at the tip; pinnules of the stem-leaves undivided, revolute at the edges; with a strong, yellow spine at the tip, at the bottom of each indument. Flowers alternate, axillary, on short peduncles; involucrum of three or five leaves. A native of Crete. 84. C. echinatus, Def. fan. atl. 2, p. 247. (Cnicus echinatus, Wildd. 14.) "Leaves sessile, pinnatifid, hispid, woolly underneath; pinnules two-lobed, divaricated, spiny; calyxes egg-shaped, woolly, bracteated; scales awl-shaped, spiny, preped close." Stem a foot high, erect, firm, twined, woolly; branches erect, forming a kind of corymb, one-flowered. Leaves resemb ling those of C. lanceolatus; hispid above, with numerous short, yellowish hairs, repand-pinnatifid; lobes remote, ending in a long yellowish spine, solitary or in pairs, one larger. Flowers a second part longer than those of C. lanceolatus; peduncles leafy, fringed, woolly; bracts narrow-lanceolate, surrounding the calyx; calyx egg-shaped, woolly; scales closely imbricated, spiny and lobe at the tip. Desf. A native of Barbary. 85. C. ericifolius, Linn. Sp. Pl. 16. Mart. 27. Lam. 29. Eng. bot. 350. (Cnicus ericifolius, Wildd. 15.) Fryars crown. Fryars thistle. Woolly headed thistle. "Leaves sessile, pinnatifid, to two ranks, spiny, rough; pinnules alternate, erect; calyces globular, woolly." Root biennial. Stem three or four feet high, erect, round, twined, smooth, many-flowered, much branched; branches spreading. Leaves spreading, alternate, deeply pinnatifid with two ranks of oblong divaricated segments, which point alternately up- wards and downwards, armed with strong spines, rough above with small rigid, close-prefixed bristles, woolly under-neath. Flowers purple, or white, large, terminal, solitary, erect; peduncle leafy; calyx globular, or somewhat de- predd, scales linear, numerous, spreading, beautifully cob- webbed, tipped with a leafy appendage, coloured, ciliated, smooth, micraceous-spiny; down feathery, deciduous. A native of England and most parts of Europe, on a calcareous soil. 86. C. ferox, Lam. 30. (Cnicus ferox; Linn. Mart. 72. Mart. 2. Wildd. 11.) C. lanceolatus valdivianus acu- las, Tourn. Inft. 450. Carduus tomentosus. Label. ic. 2, p. 111. "Leaves sessile, pinnatifid; pinnules lanceolate, dilated; flowers large; bracts linear, very spiny." La Mark observes that this plant is so far from being of a different genus from the preceding, as Linnæus makes it, that it is fearcelly a distinct species. Root biennial. Stem not so high as that of C. ericifolius. Leaves sessile, or a little embracing the stem, not decurrent as represented by Linnæus, greenish, and rough with numerous spines above, a little cottony, and whitish underneath. Flowers large, pur- ple; bracts ending in a strong spine, rough at their edges and over their whole surface, with a great number of very sharp spines. A native of the nouth of France. 87. C. spinifolium, (Carduus comolius, Lam. 31. Cnicus spinifollis, Linn. Sp. Pl. 3, Mart. 6. Wild. 48. Carduus poly- cephalon, Lam. 380. Circuitum, Hall. h. 172. tab. 32.) "Leaves embracing the stem, lanceolate, pinnatifid, spiny; stem simple; flowers whorled, clustered at the top among numerous leaves." 88. "Heads of flowers naked, without spines." Stem a foot and half high, furrowed. Leaves near the flowers cloves flet, pubescent, yellowish, with long sharp spines. Flowers yellowish white; calyx-scales smooth, ending in a long spine. A native of the Alps. If 88. be not, as Haller thinks it, a distinct species, it is a very remarkable variety. Lam. 38. C. echinocephalus. (Cnicus echino- cephalus; Wildd. 40.) "Leaves sessile, rigid, deeply pin- japifid, downy underneath; pinnules linear, spiny at the tip; calyxes globular, smooth; scales lanceolate, spines, spreading." Root perennial. Stem from four to six inches high, fimple, erect, down. Leaves alternate, crowded; pinnules entire, dilatant. Flowers solitary, terminal, or on short branches from the axils of the upper leaves; calyx- scales purple. A native of Tauria. De Beer. 89. C. aculeus, Linn. Sp. Pl. 26. Mart. 38. Lam. 49. Eng. bot. 101. (Cnicus aculeus, Wildd. 40.) Dwarf thistle. "Stem- leas; calyx smooth." Root perennial, woody, blackish. Leaves defrizzed, spreading in a radiate manner, and cov- ering a space often not less than a foot in diameter, petioled, smooth, pinnatifid; pinnules somewhat palmated, spiny. Flowers purple, large, generally solitary, almost sessile; calyx
CARDUUS.
calyx egg-shaped; seeds lanceolate, scarcely keeled; somewhat ciliate at the tip, slightly spinous. The nature of gravi-
velo and chalky palustris in many parts of Europe, not a
usual English plant, but abundant in Norfolk, where it
is the pest of the sheep down. When cultivated in a garden,
and sometimes when wild on a rich soil, a stem is produced
bearing several flowers; it is then the C. dubius of several
German botanists. 90. C. inermis, (Cnicius inermis, Willd.
22.) "Leaves pinnatifid, lanceolate, glossy, toothed, downy
underneath; root leaves pinnatifid; calyx-sectes egg-lanceo-
late, membranous at the edge, pricked close."
Root perennial. Stem crowded, green, slightly villous. Root-leaves a
foot long, or more, deeply pinnatifid, toothed; lower lem-
anes five or six inches long, attenuated at the base, acu-
minate at the tip, pinnatifid in the middle; upper ones un-
divided, attenuated both ways, toothed. Flower solitary,
terminal, very large; calyx-leaves, as well as the whole
plant, without spines. Native country unknown. 91. C.
pinatifida, Cavan. l.c. 1. p. 58. tab. 83. (Cnicius pinati-
fidus, Willd. 47.) "Leaves petioled, oblong, pinnatifid,
toothed, woolly; calyx-cylindrical, terminal, teeth pricked
close, oblong, cartilaginous, mucronate; tips spreading.
Root annual. Stem four or five inches high; simple, erect,
downy. Leaves egg-shaped, somewhat lyrate, without
spines, clothed on both sides with a fine wool; midrib and
veins downy. Flower solitary. A native of Spain. 92. C.
7. Willd. 50. Centaurnum majus, folius circinnatur; Morif.
lii. 3. p. 131. tab. 25. fig. 2.) "Leaves pinnatifid; calyx-sectes acu-
satile; roots acuminate." Root perennial. Leaves without spines. A native of the Pyrenees and of Si-
beria; Georg. k. t. 1. p. 229. 93. C. hirtifolium, (Cnicius,
Linn. Mutt. 572. Mart. 8. Willd. 51. Centaurna cylae-
bus membranaceus. Gmel. Sb. 2. p. 86. tab. 38.) Root
perennial. Stem two feet high, crept, somewhat angular,
feebly woolly, one-flowered. Leaves numerous, feebly,
without spines; greyish; pinnules alternate; upper leaves
smaller, more nearly entire; root leaves petioled; segments
lanceolate, serrated. Flower violet, terminal, feebly;
calyx large, globular; scales loose, egg-shaped, villous, grey;
florets fix-felt; segments linear, acute; flumes white,
longer than the corolla; style longer than the filaments,
thread-shaped, violet. Willd. A native of Siberia. 94. C.
cartho漫aides, (Cnicius cartho漫oides, Willd. 52.) "Leaves
without spines, feebly, oblong, toothed; root-leaves some
undivided, others pinnatifid; calyx-feebly, villos."
Root perennial. Stem erect, round, thick, frutished. Flower purple,
large, terminal, foliaceous; calyx-sectes roundish-egg-
shaped. Willd. A native of Siberia. 95. C. terramos, (C.
ceratium, Linn. Sp. Pl. 6. Willd. 53. Mart. 9. Cardus,
Gmel. lib. 2. p. 27. tab. 19.) "Leaves embracing the
item, egg-shaped, toothed; root-leaves heart-shaped; pe-
tioloed, winged, spinospinothoed; calyx feebly, gen-
tally solitary, corolling; terminal; root perennial." A native
intertupique pinnatis; Gouan illus. p. 63. Cirium, Jacq.
vind. 276. subf. tab. 13. Spop. Cam. 4. 1800.) "Leaves
pinnatifid, linear, revolute at the edge, downy; stem nearly
naked, one-flowered, calyx-sectes downy, egg-lanceo-
late, squarrose." Willd. Root perennial. A native of Austria,
and the south of France. La Marek affirms that the pla-
st of Clivus and of Gouan are perfectly distinct, and that both
of them are filiferous species of Serratula. We have no
doubts whether our fix preceding ones do not properly be-
long to that genus, their calyx-sectes not appearing truly
spinos in the moat lax skull of the term; but as Willdow
has placed them under his Cnicius, of which a spinos calyx-
seft enters into the essential character, we have not thought
fit to remove them. In the membranous, cartilagineous or
squamous edges and terminations of their calyx-sectes,
they may be thought to approach those species of Car-
thus which have leaffy appendages to those sectes. That is
still more the case with C. eriophorus. But as a compound
spine, or more than one to each scale, forms the essential ge-
eric character of Carduus, as Le Marek has determined it,
they cannot be placed under that genus. Le Marek's
definition, indeed, is altogether artificial; and it would
perhaps be more conducive to scientific accuracy and per-
ciseness if Carduus as well as Cnicius were incorporated
with Carduus. The genus would not be much larger;
and it might easily be divided into well-defined sections,
if we had thought that the form of our work authorized us
to innovate such a change, and have relieved us
from the necessity, to which we have reluctantly
submitted, of no longer calling the well known marianus a
cardus. But all the liberty that we allow ourselves is to
execute our own judgment when authors differ, and to fol-
low those who appear to us to have most clearly followed
the rules of nature.

Of the propagation and culture of plants of this genus,
little is to be said. In their wild state, the Author of nature
has made abundant provision for their increase, by
annexing to their seeds a light, and often feathering them,
which makes them readily lost in the air, and scatters them far
and wide over all the neighbouring fields. As they are sus-
ceptibly considered rather in the light of noxious weeds than of
ornamental plants, few of them are admitted into the flower-
garden or greenhouse; and those few are valued more for
their rarity than for their beauty. Some of them, how-
ever, if it were not for the general prejudice against them,
might with advantage be sparingly introduced into the bor-
ders of the pleasure ground. Of the native English species,
the erioporus, the heterophylos, and the nutans are the
most striking. The first two have the additional recom-
dendation of being not common; and we should suppose
that every one who spends any part of the summer months at Bus-
ton, must think the close ranks of the last which line the sides
of all the stone walls, a real ornament to that naked country.

By the farmer the whole tribe is held in abhorrence, and
marked for destruction. The annual and biennial kinds are
easily got rid of by cutting them down with a weeding hook
in corn fields, and moving them in pastures before they ripen
their seeds. But those that are perennial can be extirpated
only by plowing the fields, and carefully gathering the roots.
Of these, the most tormenting to the English farmer is the
arvensis, which on account of its creeping root that strikes
depth into the ground, has been called by Curtis the cursed
thistle. Thistles in general, it cannot be denied, make part
of the curle pronounced upon the ground at the original fall
of man from his native innocence. "Curled is the ground for
thy sake: thorns and thistles shall be thine until thou return
unto the ground." In what manner the human race would have
lived if they had never learned, we are not able to determine;
and as we have no experience to afford us in our inquiries,
it would be folly to attempt to guess. But of this we are
sure, that with their present feelings and habits, they
cannot attain even to a moderate degree of happiness unless
they engage in some kind of useful labour. A blessing has
therefore, been graciously intermingled with the curse. To
fail in it is an advantage, for which he ought to be
highly thankful, that he is obliged to cultivate the earth for
the comfortable support of his life, and that no part of the
produce of the ground is spontaneously raised to that state
of excellence which is most conducing to his enjoyment.
Let
Let no one then presume to assert that thistles are made in vain, even though it should be allowed that they have no other use than to prevent a considerable part of mankind, either from the intolerable little fleas of doing nothing, or from the painful confusions of having done mischief. On this supposition, they are not without a final cause, in which the wisdom and the goodness of the adored Creator are equally conspicuous.

But in the works of God there is always a manifest use. Limnæus has observed, that the carduus lanceolatus protects by its spines the annual plants which have grown themselves in its neighbourhood, and give them an opportunity of maturing their seeds without disturbance. Dr. Withering adds, that if a heap of clay be thrown upon it, nothing would grow upon it for several years if the seeds of this plant were not wafted to it by the wind, which vegetate and afford shelter for other plants, so that the whole becomes fertile. The truth of the latter observation we are rather inclined to doubt. But supposing it to have little or no foundation in fact, the pious philosophical mind will readily perceive other valuable purposes in the general economy of nature, to which this despised and hated race of vegetables are subservient. The seeds afford sustenance to several kinds of birds, which either serve to replenish our tables, or delight us with the melody of their notes, the beauty of their plumage, and the elegance of their flight. The leaves are eaten by various insects, which though they do not appear immediately useful to man, may, for ought we know, be important links in the great chain of creation, on which the welfare of the whole depends. Or, if they be not either immediately or remotely useful to man, who will presume to think that infinite benevolence do not create distinct ranks of beings, merely for the sake of giving them capacities and means of enjoyment, and of adding to the general mals of happiness which is bountifully diffused through the universe?

Carduus marianus, Linn. See Carduus angustifolius. See Dipsacus fullonum.

Carduus foliis glosseis ad infeas juniperi, Moris. See Dipsacus fullonum.

Carduus brahii, foliis albis, Bauh. pin. See Brodiaea cacumin.

Carduus acantha l. brunæ næs, Bauh. hiß. See Acanthus mollis, or smooth Acanthus. See Acanthus mollis, or smooth-leaved Acanthus.

Carduus perforatus, Jacq. Autt. tab. 248. Willd. i. 33. See Acanthus perforatus, where we have described it. But as its calyx-spines, though reflexed, are not hooked, it is properly a carduus.

Carduus incurvus, Hall. helv. n. 165. Capitalis in vertice congesta, fœnunmis reflexis, Gmel. Sib. 2. tab. 24. See Acalyphiæ coronata.

Carduus caule ramoso, Gmel. Sib. 2. n. 38. tab. 17. See Acalyphiæ coronata.

Carduus pratensis latifolius, Bauh. pin. 375. Lob. ic. 2. p. II. See Carduus oleraceus.

Carduus carduus erectus, Moris. hift. 3. tab. 34. fig. 10. See Carduus tingitanus.

Carduus chamissonis, Moris. hift. 3. tab. 53. fig. 17. See Carduus corymbosus.

Carduus serotinoides, Baii Sup. 199. See Xeranthemum prostratum.

Carduus pharaccophthalmus, Bauh. pin. See Echinops.

Carduus foliis lutescentibus, Lob. ic. 2. 17. See Dipsacus fullonum.

CARDWANG, CAFE, in Geography, a cape on the N. coast of the island of Java. S. lat. 5° 35'. E. long. 107° 10'.

CARDY, or CARGY, two small rocks on the eastern coast of Ireland, about two cables’ length E. of Newhaven point, and near a mile north of Ballbriggen, in the county of Dublin, which are dry about half ebb. N. lat. 53° 38'. W. long. 6° 11'.

CARDYMUS, in Ancient Geography, a mountain of Asia, near the Tigris, and probably not far from Niphis.

CARDYTHENES, a people of Asia, in Syria, inhabiting the small territory called Cyrcottica, according to Pliny.

CARE, a place of Spain, between Liminium and Saragolla. Anton. Impt.

CAREARA, in Geography, a town of Persia, in the province of Segelana; 8 miles N. of Kin.

CARECARDAMA, in Ancient Geography, a town of India, on this side of the Gangis. Ptolomy.

CAREDIVA, in Geography, an island of the Indian Ocean, on the western side of the island of Ceylon.

CAREERING, a term, in the Sea Language, used for the laying of a vessel on one side, to caulk, ship up, or trim the other side.

The word comes from career, which signifies the fame, formed of the Latin curare, the heat of a fish.

A ship is said to be brought to a careen, when the greatest part of her hasting, &c. being taken out, and a pontoon, or another vessel lower than herself, laid by her side, she is hauled down to it as low as occasion requires, and there kept, by the weight of ballast, ordnance, &c. as well as by ropes, lest it should strain her masts too much. This is done with design to trim her sides, or bottom, to caulk her seams, or to mend any fault she has under water. Hence, when a ship lies on one side in sailing, she is said to sail on the areen.

Ships of war are generally careened every three years.

The half careen is when they can only careen half the ship, not being able to reach so low as the bottom of the keel.

CAREER, or CAREER, in the Mares, a place inclosed with a barrier, wherein they run the rings.

The word is also used for the race, or course of the horse itse., provided it does not exceed 200 pace.

In the ancient circus, the career was the space which the bigger, or quadrige, were to run at full speed, to gain the prize. See Circus.
CARES, in Geography, is a town of PimIENT, in the province of Lérida; 6 miles N.W. of Lérida.

CAREBALI, a province of Eastern Finland, is now the government of Viborg; which lies. This country became a part of Sweden in 1293; in 1338 part of it was surrendered to Russia; and in 1721 the greater part of the remainder was given up to the empire.

CAREMA, a town of Piedmont, in the marquisate of Ivrea; 8 miles N.W. of Ivrea.

CAREMBOUE, a town of the island of Madagascar, near the south coast. N. lat. 25° 20'. W. long. 84° 1'.

CARENAGE Bay, a bay on the west coast of the island of St. Lucia. N. lat. 1° 37'. W. long. 60° 50'.

CARENE town. See St. George.

CARENI, in Ancient Geography, a people mentioned by Pline, and placed in the northern part of the isle of Albion, or in the north-western part of Scotland. They are also called Carini. They seem to have dwelt about Lochbay, on the N.W. coast of Ross-shire. Camden places them in Crainifie.

CARENI, a people of Asia, towards Perse; placed by Steph. Byz. between the rivers Cyrus and Ephrates. Procopius says that these people offered to Cofroz money to avoid being pillaged; but that he refused it, because they were not Christians.

CARENNAC, in Geography, a town of France, in the department of the Lot and Garonne, seated on the Dorodognne; 24 leagues N.W. of St. Céré.

CARENTAN, a town of France, in the department of the Channel, and chief place of a canton in the district of St. Lo, situated in a marshy soil, which makes the air infulibrious. It has a port for small vessels; its principal commerce consists of butter and cattle. The place contains 2857, and the canton 11,951 inhabitants; the territory comprehends 182.4 square kilometres and 15 communes. N. lat. 49° 18'. W. long. 1° 21'. 50'.

CARENTIA, or Garentia, in Ancient Geography, a town of Italy, belonging to the Libici, placed by Clever towards the confines of the Scyliotes and the Padus.

CARENTOIR, in Geography, a town of France, in the department of Morbihan, and chief place of a canton in the district of Vannes; the place contains 5110, and the canton 71,249 inhabitants; the territory includes 200 square kilometres and 7 communes.

CARETOMAGUS, in Ancient Geography, a place of Gaul, in Aquitania Prima, E. of Divona (Calhors), and W. of Segodunum (Rhodes).

CAREUVE, in Geography, a town of the island of Celyon; 54 miles N.W. of Trincomalee.

CAREOT, in Ancient Geography, a people of European Sarmatia. Prolemy.

CAREPULA, a town of Africa, placed by Prolemy in Mauritania Cufarienis.

CARERA, in Geography, a small trading place between Culture on the coast of Coromandel, and Montipolie, or Great Poli, 31 leagues N. and N.E. by N. from it.

CARE, in Ancient Geography, a town of Spain, in the territory called Tarragonenis. Phioy.

CARES, or CARE, in Geography, a town of European Turkey, seated on mount Athos, in an elevated and pleasant situation; it has several convents, and a market every Saturday, for corn and other provisions; 17 miles S.E. of Salamis.
CAREW, Thomas, an English poet of the 17th century, belonged to the family of the Carew in Gloucestershire, which originally descended from that of Devonshire. Having been educated in the university of Oxford, and farther improved himself by travelling, he was honourably received at court, and much respected for his polite and elegant accomplishments. Charles I. appointed him gentleman of the privy chamber, and fever in ordinary; and by Ben Jonson, Sir William Davenant, and other poets of that period, his abilities and performances were extravagantly admired and applauded. It redounds, however, much more to his praise, that he was intimate in his youth with the great earl of Clarendon, who speaks highly of his amiable qualities, and of his talents for light poetry of the amorous kind, in the elegance and fancy of which he had few equals. From him also we learn, that Carew, after passing 50 years of his life in a careless and licentious manner, died (about the year 1659) with sentiments of penitential remorse and unfeigned respect for Christianity. He left behind him several poems, which have been frequently reprinted, and a masque, entitled, "Caelum Britannicum." Biog. Brit.

CAREW, Richard, was a defendant of the Cornish branch of the Carew family, and born in 1553. After spending three years in the university of Oxford, and about the same time in the Middle Temple, he travelled into foreign parts; and upon his return settled in his native county. The only original work written by him, if we except "The true and ready way to learn the Latin tongue," which is ascribed to him, was his "Survey of Cornwall," published in 4to. at London, in 1603. This work, which is much commended by Camden, has been since in a great degree superceded by Dr. Borel's excellent publications relative to the county of Cornwall. Mr. Carew was held in high estimation for his talents and learning by several of the most eminent scholars of his time; and particularly by Sir Henry Spelman, who extols him for his ingenuity, virtue, and learning. He died in 1620. Biog. Brit.

CAREW, George, brother of the preceding, was educated at Oxford, studied the law in the inns of court, and then travelled to foreign countries. On his return, he was called to the bar, and enjoyed some posts of honour and profit. Queen Elizabeth conferred upon him the honour of knighthood; and he was employed at home in treating with the Scotch concerning an union between the two kingdoms, and abroad in foreign embassies, first to Poland and afterwards to France. During his residence in the latter country, he formed an acquaintance with several literary persons, and particularly with Thuanus, to whom he communicated hints relating to Poland, which were of use to that excellent author in compiling part of his history. After his return from his French embassy in 1609, he drew up, for the use of James I., a periphrastic "Relation of the State of France, with the Characters of Henry IV. and the principal persons of that Court," which valuable tract was communicated, in MS., by the earl of Hardwicke, to Dr. Birch, who published it in 1749, at the close of his "Historical View of the Negotiations between the Courts of England, France, and Brabant, from the year 1502 to 1617." This intelligent writer commends it as a model upon which ambassadors may form and digest their notions and representations; and Mr. Gray also represents it as an excellent performance. From a letter written by Thuanus to Camden,

who heard him at every period of his fame, were his greatest panegyrics.

CAREUS, in Ancient Geography, a town of Asia, in the country called Caricena. It was separated from the Grannus to the north-west by a small chain of mountains. Sabro.

CAREY, in Geography, a town of Germany, in the Territory of 35 miles S.W. of Balzana.

CAREY, a small bay in the gulf of Darien, which has two islands before it that are moderately high, and covered with trees.

CAREY, in Grammar, a character in this form (a) denoting that there is something inserted or interlined, which should regularly have come in where the character is placed. This mark is also called a circumflex, when placed over one vowel of a word, to denote a long syllable; as "Euphrates."

CAREY, in Zoology, synonymous with Caretta, which sec.

CARETTA, in Geography, a small low island, about 4 of a league from the main, lying on the coast of Peru, in the Southern Pacific Ocean, 3 leagues from the cape of Cangaln, or St. Gallan.

CARETTA, in Zoology. See Testudo caretta. Caretta is sometimes applied to the species Testudo imbricata, Kuorr, &c.

CAREW, George, in Biography, earl of Totnes, the defendant of an ancient family in the west of England, which came over probably from France with William the Conqueror, and originally derived this name from Carewcastle, in Pembrokehire, was born in 1557. At the age of 15 he was admitted a gentleman-commoner in the university of Oxford, where he made a good proficiency in learning, particularly in the study of antiquities; but being inclined to a military life, he went to Ireland, and served against the earl of Desmond. Having successively occupied several important posts, and commanded abroad in the expedition against Cadiz, in 1596, he was appointed president of Munster, in 1599, and in the following year treasurer of the army, and one of the lords-justices of Ireland. When he was advanced to the office of governor, he found the country in a state of open rebellion; and yet by his prudence and valour he succeeded, with a small force, in reducing it to the queen's obedience, and in counteracting the hostile designs of the Spaniards, who landed at Kinsale, in 1601. Having settled the province in a firm and universal peace, he obtained permission to resign his office in the beginning of the year 1603; and arrived in England three days before Queen Elizabeth's death. Upon the accession of King James he was particularly noticed, and advanced to several posts of honour, and, in 1605, created a baron, by the title of Lord Carew of Clifton in Warwickshire, as he had married the daughter and heiress of William Clifton, Esq. When the crown devolved on Charles I., he was created, in 1625, Earl of Totnes. Having established the character of a faithful subject, a wise and valiant commander, an honest councillor, a good scholar, and a patron of learning, heclofed his life at the Savoy, in London, in 1629, and was buried at Stratford-upon-Avon, near Clifton, whence he took his first title. After his death his natural son, Thomas Stafford, published, in 1633, a work written under his direction, and entitled "Pacata Hibernia," or The History of the Wars in Ireland, particularly within the Province of Munster, during the years of his Government, fol. illustrated with 17 maps. In the Bodleian library are also four large volumes of chronologies, charts, &c. relating to Ireland, which were collected by Sir George Carew; and his materials for writing "The History of the Reign of King Henry V." are inserted in Speed's Chronicle. Biog. Brit.

CAREW, Thomas, an English poet of the 17th century, belonged to the family of the Carew in Gloucestershire, which originally descended from that of Devonshire. Having been educated in the university of Oxford, and farther improved himself by travelling, he was honourably received at court, and much respected for his polite and elegant accomplishments. Charles I. appointed him gentleman of the privy chamber, and fever in ordinary; and by Ben Jonson, Sir William Davenant, and other poets of that period, his abilities and performances were extravagantly admired and applauded. It redounds, however, much more to his praise, that he was intimate in his youth with the great earl of Clarendon, who speaks highly of his amiable qualities, and of his talents for light poetry of the amorous kind, in the elegance and fancy of which he had few equals. From him also we learn, that Carew, after passing 50 years of his life in a careless and licentious manner, died (about the year 1659) with sentiments of penitential remorse and unfeigned respect for Christianity. He left behind him several poems, which have been frequently reprinted, and a masque, entitled, "Caelum Britannicum." Biog. Brit.
in the spring of the year 1671, it appears that he was then lately deceased. Bong. Brit.

*CAREX*. in Botany, (derivation uncertain, supposed by some from the Greek verb, name, tend, afford, in allusion to the sharp edges of the triangular flank, and apposite to the character given of it by Virgil,

Gen. Char. Flowers disposed in one or more oblong, imbricated carins; the male and female in some species on the same, in others on distinct carins. Male. Cal. glume one-valved. one-flowered, lineolate, acute, concave, permanent. Cy. none. Stam. filaments three, biied, shaped, erect, longer than the calyx; anthers exed, long, linear. Female Cal. none. Car. petals none; ovary inflated, oblong-egg-shaped, contracted upwards, opening at the tip, sometimes with two teeth, permanent. Flo. germ three-fidled, within the ovary; style simple; stigmas either three or two, awl-shaped, incurved, long, acuminate, pubescent. Petiole none, except the enlarged nectary which protects the seed. Seeds fingle, acutely egg-shaped, mostly frequently three-fidled, one angle often less than the other.

Eff. Char. Seed included in the permanent nectary.

An admirable monograph of the British species has been published by the Rev. Dr. Goodenough, in the Transactions of the Linnean Society, of which we have gratefully availed ourselves. Mr. Wahlenberg, of Upsal, has also written an excellent monograph of the genus published in "Kongl. Vetenskaps Academiens Nya Handlingar Fir Aprili, Majas Janus, 1852," and republished in the fourth number of the Annals of Botany. We have made our arrangement, and drawn up the article before this work fell into our hands, but have since infilled all his new species, with fresh additions to the others as seemed important. From him we have also borrowed the references to the coloured figures, published by Mr. Schkuhr of Wittenberg.

Of the earlier modern botanists Linnæus appears to be nearly the only one who retained the term carex, and used it in its ancient acceptation. It was not employed either by Tournefort or Ray. Tournefort united several species under the vague appellation of cyperoidæ; one or two of which, if rightly understood, have both male and female flowers on the same spike; but his generic character comprehends those only which have in them separate spikes. Ray has adopted a still more exceptionable name, gramine cyperides; and has been justly accused by Dr. Goodenough of including cyperus under it, and thus "making the thing likened include and refer itself for its original;" but in justice to our great countryman it ought to be added, that though in the introduction to the genus, as it stands in his Synopsis, he has, perhaps, inadvertently made cyperus one of the divisions of his gramin cyperides, in the subsequent nomenclature of species he has carefully kept them distinct. We may observe, by the way, that this impropriety is of frequent occurrence in the writings of Jaffœau and other French botanists.

About the beginning of the last century, Micheli and some others applied the term carex to those species, which have male and female flowers on the same spike, calling the other, egg-shaped cyperides or spicoidæ. Linnæus extended it to both, and formed the preceding generic character, to which, as to its substance, all subsequent authors have acceded. Dr. Goodenough, indeed, doubts whether the two families may not be advantageously again divided; but with due deference to this excellent naturalist, whose name must always carry with it a great weight of authority, as Linnæus's generic character is clear and definite, and especially as the two families sometimes run a little one into the other, it is surely more conducive to scientific precision to keep them together; and the ease of the investigating student is quite as well consulted, by making these subdivisions of one large genus.

A great diversity of opinions has prevailed with respect to the proper appellation of this part, which Linnæus has called the nectary. Tournefort calls it a vehicle, which afterwards becomes a capsule. Ray does not appear to have noticed it. Linnæus himself, when he speaks of it in an advanced state, sometimes calls it a tube; but more generally, though in defiance of his own definition, a capsule. Germer, in the first volume of his great work, "de floribus et feminis plantarum," calls it a conspicuous nut, formed of the indurated corolla, observing that it is not a true pericarp, but a mere involution of the seed, since it permits the pupil to pass freely through it, which is contrary to the nature of a pericarp. If this eminent botanist had lived to publish a second edition of his work, he would probably have called it an angium. See the preface to the second volume, p. 32. La Mare, regarding only the form, calls it, not unjustly, though not very scientifically, an urceole. Dr. Smith, in several parts of his English botany, has expressed an inclination to consider this puzzling appendage to a very simple flower, as a true permanent corolla, which gradually hardens, and finally becomes an envelope of the ripened seed; but afterwards, in consequence of suggestion from Dr. Goodenough, supported by his own deliberate judgment, was induced to call it an aril, "as a name much better expressing its true nature than the hypothetical one of nectary, the erroneous one of capsule, or even the analogical denomination of corolla." As such it is described in his Flora Britannica. See also the fifth volume of the Transactions of the Linnean Society, p. 265. It may be proper to add, that in the third volume of the same Transactions there is a paper by Dr. Goodenough, in which he intimates a belief, that all carices displace their seeds by the opening of the point of what he there calls the capsule; and as this opening is observed in some very early, and in others not till they are quite old, in the former case it has been described as opening, and in the latter as quite closed. In a very recent number of the English botany, Dr. Smith still continues to call it a cunic, a term which as it leaves the matter ad hoc judicis, we shall employ in the following descriptions, in all cases where we do not use the more general term, fruit.

In dividing the genus into sections, Linnæus separated those which have stigmas from those which have peduncled female spikes. Dr. Goodenough observes, that this has been a source of great perplexity; for cultivation, or in a natural state a luxurious growth, does away the whole distinction. The peduncle, moreover, is often or in a great degree concealed by the sheath of the foliaceous bracte. Thus C. diffis always has its spikes on long peduncules, but as they are embraced by the sheaths, Linnæus placed them nearly stigmas. Dr. Goodenough has therefore proposed a new mark of distinction, founded on the proportion which the peduncle bears to the sheath, and where in the same under every variation of foil and cultivation. If the sheath be of twice the same length as the peduncle, he calls it virginæ equans; if half the length, divisiadi; if about a quarter, abbreviata. 

Species
Species. * Spike simple, simple.

* Fruit lanceolate-triangular, not egg-shaped, not gibbous, beaked, more strongly ribbed, and on both sides, rough near the tip at the angles, membranous and entire at the orifice, finally spreading in a deflexed direction, acuminate, so as to render the spike squarrose; ligmas two. Sent to Dr. Smith and Dr. Goodenough from Switzerland by Mr. Davall; discovered in Mearnshire by professor James Beattie jun. of Aberdeen, and on Landfowl-hill near Bath by Mr. Grouet and Mr. Lambert. 3. C. capitata, Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Flor. dan. 372. Wahlen. 2. Schkuhr 2. tab. Y. fig. 80. "Spike simple, egg-shaped, bearing both male and female flowers, the male ones above, fruit neither ferrated nor rough at the edges, scarcely nerved, imbricated, spreading." * Root perennial. * Glumes scarcely green at the back. Linn. "Spike somewhat globular, male flowers at the top; ligmas two; fruit circinate-ovate, a little convex on one side, flat on the other, quite smooth and even, slender, obtuse at the edges; leaves filiform." Wahlen. A native of Lapland, but not of Great Britain, as Linneus supposed. 4. C. leptoclada, Wahlen. 3. (Po-lytrichoides; Willd. MSS.) "Spike with few and rather scattered flowers; ligmas two; fruit oblong-elliptical, enarginate; leaves very narrow." A native of North America. 5. C. polycarpos, Linn. Sp. Pl. 3. Mart. 3. Lam. 3. Leers tab. 14. fig. 1. Flor. dan. 166. Eng. bot. 1051. Schkuhr 3. tab. A. fig. 3. (C. pylllophora; Linn. jun. Supp. 413. Ehr. Phyt. n. 7. Wahlen. 4. C. minima, cap-fulis deorum deflexa; Mich. gen. 65. tab. 33. fig. 1.) "Spike simple, with both male and female flowers; upper ones male; fruit divericuated, reflexed, tapering at both ends; ligmas two." * Root perennial, fibrous, not creeping as in C. dioica. * Stems often a foot high, simple, slender, smooth, leafy near the base. * Leaves bristle-shaped, in tufts, rigid, smooth, channelled, nerve, nearly as long as the stems. * Spike linear, erect, at first refimbelling that of C. dioica, in which state it is figured in Flora danica. * Male flowers, numerous; glumes brown, finally preloded close; female holessly imbricated, finally reflexed; glumes deciduous, being forced off by the bending back of the open germ. * Fruit elliptical-lanceolate, sharp-edged on each side, finely cloven at the tip; stigmas slender, two, obtuse, flowing, reflexing, forming a spike not resembling that of a fleu, whence the trivial name; ligmas two. * Seed elliptical brown. A native of marshy ground in England and other parts of Europe, flowering in June. 6. C. obtusa, Wahlen. 5. Liljeblad Act. Stockh. 1793. tab. 4. "Spike of about four flowers; ligmas three; fruit inversely egg-shaped, inclining to globular, somewhat conic, patent-diverging; orifice transparent, two-lobed; leaves very narrow." A native of Sweden in dry gravelly soil. 7. C. petraea. Wahlen. 6. "Spike with numerous male flowers at the top, three scattered female ones at the base; ligmas three; glumes somewhat circinate, large, very brittle; fruit top-shaped, very ten, erect; stem acutely angular. A native of rocky mountains in the north of Lapland. 8. C. pyrenica. Wahlen. 7. "Spike many-flowered, dense; female flowers numerous; ligmas three; fruit narrow-oblong, with a short, beak, diverging." A native of the Pyrenees. 9. C. poaceiflora, Mart. 45. Light-foot Flor. Scot. tab. 6. fig. 2. Smith Flor. Brit. n. 4. Schkuhr 4. tab. A. fig. 4. (C. pratula;鹤uff. 402 and 657. C. lennoeboechn; Linn. jun. Supp. 413. Ehr. Phyt. n. 8. Mart. 55. Wahlen. 8.) "Spike simple, with few flowers; fruit spreading, awl-shaped; ligmas three." * Root perennial, creeping. * Stems from three to five inches high, spreading, smooth, obscurely triangular. * Leaves generally two, even, channelled, about half the length of the stem. * Spike loose; flowers from four to six; terminal; one of them male, erect; the rest female, spreading, finally bent down. * Fruit somewhat triangular, furrowed; ligmas three. According to Lightfoot there are sometimes only two. A rather rare native of alpine marshes in Scotland, flowering in June. * In the north of Sweden common. 10. C. squar-roya, Linn. Sp. Pl. 4. Mart. 4. Lam. 4. "Spike simple, with male and female flowers, cylindrical; lower flowers male; fruit imbricated, horizontal." * Spike thick. * Fruit with a long linear beak. One of the largest species in the genus. Linn. A native of Canada, Kalm. 11. C. hirta, Mart. 46. Wahlen. 10. Swartz. Prod. 18. (C. uncinata; Schkuhr 7. tab. G. fig. 30. C. polycarpo; Cavallis Icon. vol. p. 151. tab. 464; fig. 1.) "Spike rather long, male flowers at the top; ligmas three; glumes oval, as long as the fruit, obvolute; fruit oblong, obtuse, convex on one side, a little concave on the other, ciliated, with a long and hooked awn." Wahlen. A native of mountains in Jamaica; Swartz. Chili, Cav. Isle of France. Grondal. 12. C. uncinata, Linn. jun. Supp. Mart. 5. and 53. Lam. 6. Wahlen. 11. "Spike very long, thickened above; male flowers at the top, ligmas three; glumes adnate, oblong, short; fruit oblong, with a short and roundish beak, and a rather long, hooked awn." Wahlen. The most beautiful species in the genus. * Female flowers occupying two thirds of the spike;awn curved above the middle, thickened at the joint. Small spikellets sometimes hang down at the side, which are perhaps barren. Linn. jun. A native of New Zealand. Forlil. 13. C. cri-

15. C. Bellardi. Mart. 48. Wahlen. 15. Allion. Ped. 2395. tab. 92. fig. 2. Schkuhr 25. tab. D and H. fig. 17. (C. myriofolia; Villars Dauph. 2. 104. tab. 6?) " Spike somewhat compound, linear; spikelets of two flowers, upper one male; lower female, with three gligms; glumes somewhat crenulate, large, very brittle; fruit top-shaped, flanged; stem round; leaves filiform." Wahlen. * Root fibrous. Stamens numerous, about seven inches high, filiform, somewhat curved. Leaves convoluted, filiform, somewhat curved, about the height of the stem. Spike about an inch long; flowers generally solitary, alternate, sessile; so that the spike seems to be interrupted; glumes egg-shaped, acute, without awn, bay with a whitish edge. Allion. A native of Piedmont. Although these two authors do not exactly agree in their manner of describing the inflorescence, the difference seems to be only verbal. The myriofusus of Villars, which he supposes to be the same plant, and which he says has hermaphrodite flowers and half naked seeds, must be distinct, and if his description be exact, is a Carex. 16. C. capnoides. Wahlen. 14. Thumb. * Spikelets male at the top, somewhat compound, near together; gligms three; fruit oblong, acute, convex on both sides, obtusely angular, a little curved outwards, broad somewhat foliaceous, leaf round. 17. C. cyperoides. Linn. jun. Suppl. 413. Mart. 6. and 54. Lam. 5. Wahlen. 33. Schkuhr 28. tab. A. fig. 2. (C. bohemicum, Schreb. grami. tab. 28. fig. 3. Mich. gen. p. 76. tab. 33. fig. 19. Cyperus minor, capitatis inflatus; Buch. Cent. 4. p. 34. tab. 61. Scirpus pica multipartita. femininus cordatis; Gymn. ibid. v. 1. p. 81.) " Head terminal, roundish; flowers absolutely simple, also, filiform, involucres long. Fvrescens absolutely filiform, (which is angular), pedicellate, forming a little umbel, Linn. jun. La Marck adopts all the younger Linnaeus's synonyms; but gives the following description, which appears to be taken from Schreber, resembling Cyperus in its general habit and involucre, and Scirpus in the disposition of its flowers. Root perennial. Stems about a foot high, triangular, sheathed in their lower part with a few gligmic, narrow leaves. Head round, terminal, composed of numerous close spikelets. Flowers on the outside of each spikelet male, on the inside female; glumes white; pili longer than the tube; style bifid. Involute four-leaved. Maryn inadvertently gives it twice, with precisely the same synonyms to both, but annexes Schreber's description to n. 6. and the younger Linnaeus's to n. 54. If they really belong to the same species, Linnaeus's plant must be a very singular variety with one-flowered spikelets, for such the pedicel determines them to be; it proves also that the species, whether one or two, ought not to be placed in the first section. Wahlenberg gives the following specific character of his cyperoides: " Spikelets male at the base, forming a head; glumes linear-bristle-shaped; fruit biculpidate; bracts clote together, foliaceous, long." A native of Bavaria, the Lowland and Sabina. 18. C. cinerea. Mart. 19. Lam. 16. Wahlen. 16. Hall. helv. n. 1. 157. Allion pedem. n. 2935. tab. 92 fig. 3. Schkuhr 25. tab. D and H. fig. 17. " Stem and leaves rigid, curved; spike single; glumes awned. Root perennial. Stems slender, naked, scarcely longer than the leaves. Leaves narrow, rough-hairy, three or four inches long, a little curved. Spike short, apparently simple, but composed of two or three clustered spikelets. Glumes lanceolate, acute, red, membranous, and whitish at the edges. A native of high mountains in Switzerland, Dauphiny and Piedmont. 19. C. incisa. Mart. 57. Lightfoot Flor. Scot. 154. tab. 24. Smith Flor. Brit. 10. Good enough. Wahlen. 19. Schkuhr 19. tab. H. fig. 25. (C. juncofolia; Allion. pedem. 2925. tab. 92. fig. 4. Flor. Dan. 432) " Spikelets clustered in a head; lower flowers female, bracts membranous; stem roundish, smooth; leaves channelled." Dr. Smith. Very nearly allied to the preceding, if it be more than a variety. Root perennial. Stems three inches long, ascending, naked, even, on the sea-flower curved, on moist mountains often straight. Leaves shorter than the stem, linear, channelled, even, nerved. Spike compound, short, nearly conic when in flower, obtuse when in seed; spikelets roundish, few-flowered, brownish. Blades shorter than the spikelets, partly embracing the flower-cone, elliptical, obtuse, slightly keeled. Glumes egg-shaped, brown, white at the edges, with a very slender keel. Fruit egg-shaped, acute, green, brown at the tip, undivided, smooth at the edges. Stamine capillary, very long, white. Stigmas two, brown. Seed lenticular. Lightfoot describes his plant as having no involucre and such it appears in his figure. Dr. Smith attributes to it two bracts which are represented very distinctly in Mr. Sowerby's figure in English botany. Dr. Goodenough was honoured with a fight of Lightfoot's original specimen in her majesty's herbarium, but fearful of doing any injury by handling it, forebore taking a minute description. We are doubtful of the figure in Flora Danica, though quoted both by Dr. Goodenough and Dr. Smith. It appears to differ not only in habit, but also in the structure of the pithe. If it be our plant it is taken in an advanced state of fructification, and without the bracteae. It seems probable that the latter may be generally pulled off by the ripening fruit. Specimens of this plant were sent to Dr. Horn from the deep, loamy sand at the mouth of the river of Navia, and from the valley of the Skern in Derbyshire and the Shetlands. Dr. Smith received others from Professor Beattie, gathered near Aberdeen. It flowers in July and August. 20. C. fastidiosa. Mart. 50. Lam. 7. Wahlen. 12. Allion. Flor. ped. 2397. Hall. helv. 1555. Scheuch. grami. 495. Prodr. tab. 4. t. p. 438. fig. 11. Villars Dauph. 2. 105. " Spike compound, egg-shaped, brown; spikelets clustered." Lam. Root perennial. Stem naked, triangular, often a little curved, about the length of the largest leaves. Leaves about three inches long, near two lines broad, tufted, gras-like, keeled. Spike short, a little conical, brown or black, naked at its base; spikelets ten or twelve, egg-shaped, acute, blunt, forming a regular cluster. Sometimes there are two long, pointed leaves under the spike, sometimes only one, and sometimes none. According to Haller the plant has an unpleasant smell, both green and dry. A native of boggy ground on mountains in Switzerland, Dauphiny and Piedmont. La Marck considers the juncofolia and fastidiosa of Allioni as the same plant, and quotes C. incisa of Lightfoot as a synonym; but Dr. Smith, who gathered both on the hill called Roche near Mount Cenis, has determined them to be perfectly distinct, and the juncofolia to be Lightfoot's incisa, though on the Alps it is seldom curved. Wahlenberg, on the
the other hand, makes all the three distinct species, and gives the following specific characters of the junctifolia and incurve.

21. C. junctifolia. n. 17. "Spikes feffile, male at the top, collected into a small oblong head; fruít rather roundish-depressed, attemerated; glumes two, ligulas two; item round, incised; leaves convolute; involucrums very short." C. incurve. n. 19. "Spikes seffile, male at the top, closely collected into an oblong, globular head, few, somewhat di-verging; fruít circum-rotate, ficipitiglous, beaked; orifice very entire; ligumas two; item rather acute; angular, somewhat incurve; leaves convolute." 22. C. junctifolia, Wahlen. 18. (Schauens monocics; Engl. bot. 1427.) "Spikes feffile, male at the top, clustered into a long spike; fruít oblong, attemerated, slightly beaked; orifice very entire; ligumas two; leaves very narrow, convolute." A native of Wiltmorland in England, sent to Swartz by Mr. (doublests Dawson) Turner. From this circumstance, added to its not being mentioned by any British botanist, we think it almost certain that this plant is no other than Schauens monocopus of English botany, which remained for some time undetermined, and as Dr. Smith observes, was taken by every body, even the Mr. Schkuhr, for a Carex: but in that case Wahlenberg has greatly erred in describing the fructification.

23. C. junctifolia, Hoff. Schkuhr. Car. 18. tab. G. and 1. fig. 32. "Spikes feffile, male at the top, collected into an ovate head; fruit ventricose, roundish, rather flatly convex, ribbed, slightly ferrated at the edge; orifice two-toothed; ligumas two; item acutely angular; leaves very narrow." 24. C. Blandifas, Linn. Sp. 5. Mart. 7. Lam. 9. Wahlen. 13. Vill. Dauph. 2. 196. tab. 6. Schkuhr. tab. 4. fig. 4. (C. aculeata, Becc. fig. ver. 1. 125. n. 9. gr. junctif. Benth. pl. 6. n. 12. prod. 13. tab. 13. Hall. 2. 599.) "Spikes egg-shaped, triangular, ternate, clustered, terminal, feffile; involucrums twofold." Linn. Root perennial. One leaf of the involucrums longer than the spikes, the other shorter. Spikes three or four, collected into a head, white, oblong; glumes of the male flowers on the upper part of the spiklets bacculate; of the female flowers gibbos; fylle long, three-cleft. Linn. Stem naked, triangular, at least seven inches high. Leaves all radical, rather narrow, half the length of the item Spikes three, feffile, short, reddish brown or whitish, forming a kind of three-lobed spike. Segraver. A native of Mount Baldo and the neighbourhood of Verona. La Marek thinks it must be rare, neitherb Haller nor Allioni having described it, and he himself having never seen it, but conjectures that the following may be a variety of it without the involucrums.

25. C. triperitum, Mart. 39. Allioni. ped. n. 239.8. tab. 92. fig. 3. Hall. helv. 1356. (C. lobata; Lam. 8. Wahlen. 23. Vill. Dauph. 2. 157.) "Spike compound, egg-shaped, somewhat lobed, terribus-brown, glumes mucronate." Linn. Root perennial. Stem triangular, naked, a little longer than the largest leaves. Leaves four or five inches long, two lines broad, tufted, gramineous, keeled. Spike short, naked at its base, commonly three-lobed; lateral, lobes very short; spiklets about twelve, feffile, male at the top, egg-shaped, clustered; ligumas two. A native of Switzerland, Dauphiny, and Piedmont. 26. C. bipartita, Mart. 60. Lam. 11. Allioni. pedem. 2301. tab. 80. fig. 5. "Stem round, naked; spikes two, upper one compound, terminal." Root perennial, fibrous, throwing out several ilems and leaves in a tuft. Stems four or five inches high, twice the length of the leaves, triated, cylindrical. Leaves gramineous, smooth, a little rolled in at their edges, irritated, acute, almost pungent. Spikes two, upper one an inch long; spiklets feffile, alternate, clustered; lower one near the other, shorter, egg-shaped, pedicellated; bracte reddish brown, acute; glumes egg-shaped, acute, not awned, brown, whitish at their edges as they grow old. Sometimes, but rarely there is a third spike beneath the other two. A native of spousy ground on the mountains of Piedmont.

27. C. drupa, Mart. 58. Goodenough 2. Smith. 33. Lam. 5. pers. 6. Trans. vol. 6. tab. 149. fig. 2. Wahlen. 27. Engl. bot. 1025. Schkuhr tab. v. feg. 61. (C. hybridus; Lam. 17. Gramen cyperoides ex monte Baldo. Spicã divulgã; Rai Syn. 443.) Spike once or twice compound; bracte leafy, erect; fruit mostly spreading; root creeping." Root perennial, creeping horizontally to a considerable extent, black, strong, twolied. Stem a foot high and more, upright, weak, naked, triangular; angles roughish upwards. Leaves narrow, upright, bright green, rough at the edges and keel, various in length. Spike an inch long, egg-shaped, often doubly compound at the base, of a dark ruby colour, denfe, rather compressed; spiklets several, irregularly clustered, egg-shaped, acute; female flowers low, much numerous, and flowering foemel, which, as Dr. Goodenough observes, offers a considerable elongation of the style waiting for their impregnation.

28. C. junctifolia, Hoff. Schkuhr. Car. 18. tab. G. and 1. fig. 32. "Spikes feffile, male at the top, collected into an ovate head; fruit ventricose, roundish, rather flatly convex, ribbed, slightly ferrated at the edge; orifice two-toothed; ligumas two; item acutely angular; leaves very narrow." 24. C. Blandifas, Linn. Sp. 5. Mart. 7. Lam. 9. Wahlen. 13. Vill. Dauph. 2. 196. tab. 6. Schkuhr. tab. 4. fig. 4. (C. aculeata, Becc. fig. ver. 1. 125. n. 9. gr. junctif. Benth. pl. 6. n. 12. prod. 13. tab. 13. Hall. 2. 599.) "Spikes egg-shaped, triangular, ternate, clustered, terminal, feffile; involucrums twofold." Linn. Root perennial. One leaf of the involucrums longer than the spikes, the other shorter. Spikes three or four, collected into a head, white, oblong; glumes of the male flowers on the upper part of the spiklets bacculate; of the female flowers gibbos; fylle long, three-cleft. Linn. Stem naked, triangular, at least seven inches high. Leaves all radical, rather narrow, half the length of the item Spikes three, feffile, short, reddish brown or whitish, forming a kind of three-lobed spike. Segraver. A native of Mount Baldo and the neighbourhood of Verona. La Marek thinks it must be rare, neitherb Haller nor Allioni having described it, and he himself having never seen it, but conjectures that the following may be a variety of it without the involucrums.
broad, green. Fruit spreading in every direction, egg-shaped, ribbed, mucronate, febrilely coniculate, not clavate, round on each side; ligmas two. Common in wet, rich, warm ground, flowering in May and June. All the English botanists took this for C. marna in of Linné, till the fortunate acquisition of the Linnean museum by Dr. Smith, they found their mistake. It is remarkable that La Maree fell into the same mistake. Dr. Goodenough, indeed, supposes that Linnaeus, and the Swedish botanists after him, confounded the two plants, not distinguishing the different position of the male and female flowers, a character which fails La Maree as a sufficient distinction between this species (his marnicia) and vulpina, though in other respects nearly allied. 30. C. curta. Vent. 61. Gooden. 5. Smith 4. Willd. Wild. Herb. Edel. 19. tab. 2. fig. 3. Schkuhr. 33. tab. C. fig. 15. (C. aculeata, Lightfoot. Flor. Dan. tab. 285. Lam. 21.) C. brizoides, Hudf. C. dongata, Leers 157. tab. 14. fig. 7. Gr. cyper. elegans, Rau Syn. 423. n. 6. and 7. 3d. ed. Pluks. Phyt. tab. 34. fig. 4. Rel. Rudb. 2. f. 54. C. cyper. spicis curtis divulsis. Leefcl. Pruff. 117. tab. 32.) "Spikeslets about six, elliptical, a little separate, naked; glumes egg-shaped, rather acute, membranous; tunic entire." Dr. Smith. "Root perennial, rather creeping. Stem a foot high, triangular, smooth except in the upper part. Leaves linear, flatly upwards, narrow, somewhat glaucous, roughish, nearly as high as the stem. Spikelets from four to six, or more, febrile, generally alternate, elliptical, obtuse, many-flowered; the lowest sometimes but rarely furnished with a bract; lower flowers male, fewer than the female. Glumes egg-shaped, membranous, remarkably tender; white, shining, with a flender green rib. Fruit egg-shaped, compressed, acute, smooth; ligmas two. Seed exactly elliptical. A native of watery places in England and Scotland and other parts of Europe, readily distinguished in a state of maturity by its shiny spikelets. 31. C. canecacea, Linn. Sp. Pl. 16. Mart. 17. "Spikelets roundish, remote, febrile, obtuse; fruit egg-shaped, rather obtuse." Similar to curta; so much so that Leefcl's figure referred by Dr. Goodenough and Dr. Smith to curta, is almost equally expressive of both; but when they are brought together, a wide difference presents itself. The curta is smaller in all its parts; its bracteae, moreover, are silvery and very tender; whereas in the canecacea they are membranous and hard, as in the root of the genus, and are brown with a white edge, which gives it a real, hoary appearance. See Dr. Goodenough's remarks in Linn. Trans. vol. ii. p. 147. Wahlenberg, however, not withholding what has been advanced by Dr. Goodenough, unites the curta of that able botanist with the canecacea of Linnaeus, (at least of the flora Suecia,) under the following specific character. "Spikelets five, male at the base, rather near together; glumes nearly as long as the fruit; fruit roundish-ovate, rather acute, convex on one side, leafo on the other; angles rather obtuse; one two-toothed; ligmas two. B. "Upper spikelets aggregate; fruit spreading, acute, convex on one side, nearly flat on the other; angles rather acute." 32. C. elongata, Linn. Sp. Pl. 15. Wahlen. 41. Schkuhr tab. E. fig. 25. "Spikelets oblong, febrile, remote; fruit egg-shaped, acute." Linn. "Upper spikelets male at the base, rather near together, in a kind of raceme; rather densely fleshy; glumes farrifith; fruit oblong-acuminate, convex on both sides, obtusely angular, ribbed, curving a little outwards; orifice nearly entire; ligmas two." Wahlen. A native of Europe. 33. C. foliacea, Linn. Sp. Pl. 15. Wahlen. 47. Schkuhr tab. P. p. 10. "Spikelets somewhat egg-shaped, roundish, febrile, remote; fruit egg-shaped, roundish, not awned, divaricata."
and axillaris. 12. Mart. 17. Lam. 23. Wahlen. 51. Eng. Bot. 832. Flor. Dan. 372. (C. angulifolia capitula pulchella, Mich. Gen. 70. n. 2. tab. 33. fig. 15. 16. Gram. Cyp. Rai. Syn. p. 423. n. 11. Pink. Phyt. tab. 43. f. 3. Maris. £. 8. tab. 12. f. 173.) " Spikelets alternate, solitary, near the edge. Spikelets alternate, solitary, eggl-shaped, white, about six or eight; three or four of the lowest very diffus; bracteae gramineae; male flowers lowell; glumes broad-egg-shaped, membranous, white, with a green keel. Fruit egg-shaped, acuminated, longer than the glume, obtuse at the edge in the upper part, generally acute at the orifice; Rigma two. " Seed (long) " a native of moist groves, and banks of ditches, in fandy places, flowering in May and June. 41. C. gibba, Wahlen. 53. (C. remoti, Thumb. Floir. Jarg.) " Spikelets male at the base; lower ones somewhat ternate, rather diffus; glumes short; fruit somewhat lenticular, beaved, very convex on one side, a little fo on the other, thin and entire at the edges; orifice two-toothed; Rigma two; bracteae foliaceous, long, rather narrow; leaf limb." A native of Japan. 42. C. axillaris, Mart. 12. Gooden. 8. Smith Flor. Brit. 9. Linn. Tran. v. 2. tab. 19. fig. 1. Wahlen. 53. Eng. Bot. 993. " Spike interrupted; lower spikelets in remote clusters; upper ones solitary, all feefe; bracteae elongated; seed-ficile-convex. " Root perennial, fibrous. Stem erect, strong, Rifft, from to three feet height; triangular; angles rough. Leaves shorter than the stem, rough at the edge, and near the tip of the keel. Spikelets more turgid than thoofe of C. remoti; the lowest bracteae about the height of the stem; the others shorter. Lower flowers male; glumae egg-shaped, acute, ornerous, bowmifh, with a green keel. Fruit egg-shaped, acuminated, a little longer than the glume, obtuse at the edges near the tip; Rigma two. " A native of wet ditch banks, flowering in June. The axillaris of Linneas is nothing more than his remoti, infected through inadvertence with nearly all the same synonyms, and with no material difference in the specific character. Dr. Goodenough observes, that Buddle is the first who noticed this species, and distinguished it from the more common remota. A specimen is preserved in his Herbarium. p. 31. n. 6. It has been found since by Mr. Curtis near Putney, and by Mr. Woodward near Norfolk. 43. C. chordoriza, Linn. Jun. Sup. p. 414. Mart. 07. Wahlen. 22. Schkuhr 17. tab. G. fig. 31. Ehrl. Phytot. 77. " Spikelets male at the base, rather close together; fruit semi-globular, woody, elongated at the base; Rigma two; lowest leaf very short; the other sheaths leafless; root flender, creeping." Wahlen. A native of Sweden. 44. C. betoeyum, Linn. Jun. Sup. 68. Ehr. Phytot. n. 28. Wahlen. 45. Schkuhr. 42. tab. 11. f. 97. " Spikelets four, male at the base, crowded, somewhat globular; glumes nearly as long as the fruit; fruit egg-shaped, acute, convex on one side, a little fo on the other, rather obtusely angular, spreading; Rigma two; leaf Retail. " A native of Sweden. 45. C. ovalis, Mart. 65. Gooden. 6. Smith Flor. Brit. 7. Eng. Bot. 306. (C. leporina, Hudf. Relh. Sibth. Lam. 16. Leers. t. 14. f. 6. Ehr. Phyt. n. 38. Gram. cramer. spica e pluribus ficicis, &c. n. 2. Schuchz. tab. 10. f. 19. Morif. tab. 12. f. 290.) " Spikelets about fix, oval, near together, alternate; glumes lanceolate, as long as the fruit." Root perennlal, creeping. Stem a foot high or more, erect, acutely triangular, rough at the angles, leafy at the base. Leaves deep green, flat, keeled, nearly as long as the stem, and flecting its lower part, alternate, roughifh on the edge and keel. Spikelets from four to fix, of a ruby green colour, elliptical; bractteae at the base of each spikelet lanceolate; the lower one longer than the roll, and ending in a leafy point; male flowers inferior, few; females numerous; glumes egg-lanceolate, acute, membranous at the edge, with a green keel. Fruit lanceolate, acuminate, convex on one side, nearly entire at the orifice, rough at the edge; Rigma two. " Seed roundifh, elliptic. Dr. Smith. Common in wet marshy places, flowering in July. 46. C. leporina, Linn. Sp. Pl. 8. Wahlen. 3. " Spike compound; spikelets egg-figured, yellow, near together, after the manner of cornflowers; the flowers to Maton and Schuehler, confounded this species with the preceding. It is, however, as Dr. Goodenough observes, perfectly diftinguifhible. The fpecimen in Linneas's herbarium, now in Dr. Smith's collection, is a smaller plant, with only three nearly glofular bifpikelets, blunt and shorter glumes, and fruit entirely smooth. It is a native of the higher Alps. Wahlenberg nevertheless still confiders the leporina of Linneas, and the ovalis of Goodenough, as one and the fame plant. 47. C. divus, Mart. 55. Gooden. 14. Smith Flor. Brit. 15. Schkuhr 12. tab. Ww. fig. 89. Eng. Bot. tab. 629. (C. canecenae, Hudf. a. M. curieae; 8. Wahlen. 28. C. nemorofa spica longa divus, &c. Mich. Gen. 69. tab. 33. fig. 10. Gram. Cyper. spica longa divus. Rai Syn. p. 424. n. 11.) " Spike elongated, twice compound, often branched at the base; lower fpkelets remote; fruit nearly erect, nearly smooth at the edge." Root perennial, fibrous. Stem a foot high or more, weak, somewhat reclining, naked, acutely triangular; angles rough, especially near the tip. Leaves narrow, longer than the stem; edge and keel rough. Spike interrupted; its lower parta pale green; lower wedgelets remote, sometimes in pairs; the lowest often compound; bracteae small, broad-egg-shaped, sharply keeled, ending in a rough bristle-shaped leaflet, often longer than the spikelet; upper flowers male; glumae egg-shaped, acute, white; lower ones generally with a green keel. Fruit egg-shaped, convex on one side, without ribs, smooth, white, green at the tip, cleft or only at the tip; Rigma two. Seed orbicular, comprefled. A native of moif woods, flowering in May. 48. C. Schreberi, Wahlen. 35. Wild. Schkuhr 30. tab. B. fig. 9. " Spikelets five, male at the base, somewhat chiftered; glumes as long as the fruit; fruit ovate-ovate, rather acute, a little convex, rather acutely angular; orifice margi- nate; leaves very narrow; root creeping." A native of family near Berlin. 49. C. lagopina, Wahlen. 37. (C. leporina, Fl. Dan. tab. 214. Approximata, Hoppe Herb.) " Spikelets three, male at the base, clustered; glumes rather small; fruit somewhat circinate, acute, somewhat beaked, convex on one side, a little concave on the other, obtuse and quite entire at the edges; orifice two-lipped; Rigma two." A native of the Lappland mountains. 50. C. Frymuin, Wahlen. 38. Wild. Schkuhr 38. tab. G. fig. 34. " Spikelets five, male at the base, a little dittant, somewhat globular; glumes lanceolate, as long as the fruit; fruit roundifh-in- feriorly egg-shaped, beaked, membranous at the edges; orifice bifid; Rigma two. " A native of North America. 51. C. vulsima, Lin. Sp. Pl. 10. Mart. 11. Lam. 19. Gooden. 15. Smith 16. Eng. Bot. 307. Leers, tab. 14. fig. 5. Flor. Dan. tab. 308. Wahlen. 29. Schkuhr. 10. tab. C. fig. 10. (C. paludis major, Mich. Gen. 9. tab. 33. fig. 13. Gram. Cyper. Rai Syn. 423. n. 8. Morif. t. 8. tab. 12. f. 24. G. patinae cyperoides, Ger. Em. 213.) " Spike thrice compound, compressed, obtuse; fruit diverging; glumes acuminated; flens with comprefled, very acute angles. " Root perennial, fibrous, forming thick tufts. Stem two feet high, erect, Rifft, strong, ofen contracted in a fingular manner, when it becomes the rachis of the spike, concave and acutely
acutely triangular; angles very rough. Leaves deep green, broad, higher than the stem, rough on the edges and keel. Spike oblong, sometimes a little interrupted; spikelets egg-shaped, upper flowers male; bracteas egg-shaped at the base, bristle-shaped at the tip, rough, spreading widely; glumes egg-shaped, acuminate, membranous, brown, with a green keel. Fruit diverging, egg-shaped, acuminate, convex on one side, ribbed, cleft, and rough at the tip; ligmas two. Seed elliptical-ovate. A native of marshes and the banks of rivers. 52. C. glomerata. Thumb. (C. vulpina, 2. Wahlen.) " Spike oblong; stem obtusely angular; leaves broad, rather short. A native of the Cape of Good Hope. 53. C. brizoides, Lem. Sp. Pl. 18. 18. 29. Cana, n. 1172 Wahlen. 39. Schkuhr tab. 2. fig. 12. (C. specia teretiusculus alternis fe contiguousibus. Hall. Helv. 244. Mich. Gen. tab. 33. fig. 17.) "Spike compound, two-ranked, naked; spikelets oblong, contigious; stem naked." It appears from the herbarium of Linnaeus that, early in life, he called the curta of Dr. Goodenough brizoides, there being a specimen of it so named by himself; but afterwards, as our excellent naturalist observes, he seems to have forgotten his own original determination upon the matter, for the specific character given in the Species Plantarum must have been intended for another plant. There is a specimen in the herbarium of Sir Joseph Banks, named brizoides, which answers entirely to this specific character, to the synonym of Haller, and to the figure of Micheli, and which Dr. Goodenough is perfused is the brizoides of the Species Plantarum. It is the only specimen he has seen, and he has drawn the following description from it. Root perennial, creeping. Stem erect, naked, triangular; angles acute, rough. Leaves pale green, flender, longer than the stem, rough on the edges and the keel; the lower ones shorter and shorter on the other side. Bracteas about seven, round, or a little oblong, rather in two ranks, near together, moll frequently contigious; lower flowers males; glumes oblong, acute, pale, with a green keel, somewhat tender, with a delicate white edge, about as long as the fruit. Fruit oblong, acute, smooth, somewhat triangular, minutely ferrated at the edges, cleft at the tip, flat on one side; ligmas two. Dr. Goodenough adds, that the true brizoides is very properly described by Schreber in his Spicilegium Fl. Lipl. p. 63. n. 675. See Linn. Transf. vol. ii. p. 148. According to La Marck it differs from C. ovalis, his leporina, in having its spikelets longer, acute, more flender, and not compacted. His description does not materially differ from Dr. Goodenough's, but he observes, that the spikelets are often curved, like those of bromus pininus. Wahlenberg gives the following specific character, which identifies his plant with those described by Goodenough and La Marck. "Spikelets numerous, male at the base, contiguous, somewhat lanceolate, sometimes curving outwards; fruit ovate-lanceolate, very convex on one side, a little concolor on the other; spikelets five, finely ferrated at the edges; orifice bifid." A native of France, Switzerland, and Carniola. 54. C. microperma, Wahlen. 30. " Spike thrice compound, thickish; spikelets, male at the top, clefted; glumes pointed; fruit small, ventricose-ovate, with a short acuminate beak, acutely angular, somewhat diverging; ligmas two leaves rather narrow." A native of Pennsylvania, preferred in the herbarium of Thunberg. 55. C. arenaria, Linn. Sp. Pl. 6. Mart. 8. Lam. 14. Gooden. 10. Smith 11. Wahl-n. 32. Eng. Bot. 928. Schkuhr 8. tab. B. fig. 6. (C. maritima humilis, Mich. Gen. 67. tab. 33. fig. 4. Rai Syn. p. 423. n. 5. Pluk. Phyt. tab. 34. fig. 8. locul. Plufr. tab. 31.) " Spikelets clefted, spliced, almost monocious; bracteas membranous; lower ones granimous; stem triangular; leaves flat." Root perennial, creeping just below the surface in all directions, fealty, with downy fibres. Stem a foot high, numerous, erect, except when they are borne down by the sand, naked, sharply triangular, roughish in the upper part. Leaves spreading the base of the stem, erect, acuminate, rough at the edges. Spike egg-shaped, compound, compressed; spikelets alternate, two together, brown, many-flowered; bracteas lanceolate, keeled, membranous at the base, the lower ones lengthened out into a leaf; male flowers in the upper part of each spikelet, very numerous in the upper spikelets; females milu numerous in the lower; glumes egg-lanceolate, brown, free, united to the stem, flat, acute, ribbed, bordered with a membrane on each side on the other part, rough at the edge, cleft at the tip; ligmas two. Seed elliptic or obscurely triangular. Frequent among the sand of the sea-flower, flowering in June. 56. C. repens, Bellard. App. Flor. Pedem. (C. arenaria, 2. Wahlen.) " Spikelets rather near together; bracteas small, scaly, awn-knots; stem roundish. A native of Pedmont. 57. C. intermedius, Gooden. 11. Smith 12. Wahl-n. 31. Schkuhr 9. tab. B. fig. 7. (C. diliicta, Mart. 55. Hufl. Reh. Systhopt. C. arenaria, Leers, tab. 14. fig. 2. C. picata, Pollin. n. 875. Lam. 15. Rai Syn. p. 423. n. 4. Pluk. Phyt. tab. 34. fig. 7, not good. Moref. 8. tab. 12. t. 32. " Spikelets clutered, spliced, some of the lowest and the terminal one female; intermediate ones male; stem triangular, erect." Root perennial, creeping, but striking deep into the ground. Stem a foot high and more, erect, flif, naked, acutely triangular, rough at the angles. Leaves spreading the base of the stem, scarcely as high, erect, flat, roughish at the edge and on the keel. Spike oblong, obtuse, rough-brown, fof, little compressed, not at all two-ranked; spikelets near together, numerous, imbricated towards the top, egg-shaped, often one or two male flowers at the top of the female spikelets, and one or two female ones at the base of the males; bracteas egg-lanceolate, membranous, keeled, brown, with a white edge; lower ones ending in a bristle-shaped leaf; glumes egg-shaped, brown, with a pale nerve, membranous and white at the edge. Fruit egg-shaped, acute, bordered with a membrane on each side, rough at the edge, cleft at the tip; ligmas two, sometimes three. A native of marshy ground. 58. C. uliginose, Linn. Sp. Pl. 7. Mart. 9. Lam. 13. " Spike compound; lower spikelets remote, furnished with a long granimous bracte; item round." Similar in appearance to C. arenaria, but the root is not manifely creeping. Stem a finger's length, round, glossy, naked. Spike more compacted than in any other species, rust-colour spikelets seven or eight; at the base of the spike there is a leaf of the same length with it, erect, glossy, linear. Leaves next the root alternate, convex beneath, channelled above, glossy on both sides, linear, acuminate, hispid, as long as the stem. A species frequently known, and not retained by Wahlenberg. 59. C. paradoxa, Wahl. 24. Wild. Aet. Berol. Schkuhr. 23. tab. E. fig. 21. " Spikes male, forming a panicle; lower branches a little disent; fruit roundish-oval, slightly convex; angles rather obtufe; orifice two-toothed; ligmas two." A native of wet ground about Berlin and Hall. 60. C. teretiuscula, Gooden. 16. Smith 15. Linn. Transf. v. ii. tab. 19. fig. 3. Eng. Bot. 1055. (C. paniculata, 2. Wahlen. C. diandra, Schlank.) " Spike twice or thrice compound, denfe, rather pointed; spikelets clefted; spliced spreading, g-bbous; item roundish." Root fibrous, somewhat creeping, not from a tuft. Stem a foot or a foot and a half high, acutely triangular, but the sides between the
CAREX.

the angles are convex, which gives it the roundish appearance expressed in the trivial name. *Leaves erect, somewhat rigid, about the length of the stem, rough at the edges and on the keel. Spike oblong-egg-shaped; spikelets egg-shaped; upper flowers female; bracts egg-shaped, membranous, the lowest with a rough, often very short foliaceous point; glumes egg-shaped, brown, membranous at the edge, white, with a very even keel. Fruit brown, egg-shaped, acuminate, very convex on the outside, rather flat on the other, gibbous on both sides at the base, hispidly ferricated on both sides near the tip, greenish cloven at the tip; ligmas two. Seed orbicular, gibbous on the outside. A native of boggy ground. Mr. Crowe of Norwich is the first English recut discoverer of this plant, but it was known to Ray, as is evident from the addition to his description of the next species. Synop. p. 197. 18th. ed. 422. 53. *C. pachyandra, Linn. Sp. Pl. 17. Mart. 18. Lam. 24. Weyl. 25. Leers tab. 14. fig. 4. Eng. bot. 1054. Schkuhr 23. tab. C. fig. 20. (C. ficica multiplici ferrugineae; Mich. gen. 68. tab. 53. fig. 7. C. ficica longiroei lata. Rax Syn. 422. n. 1. Morill. § 8. tab. 12. fig. 25. Cyperus alpinus longus inodorus; Schucezh. Prod. 27. tab. 8. fig. 2.) Spike trichome compound, panicle branched, acute, interrupted; fruit spreading, bracted; seed acutely triangular, with a bristle-shaped keel. Glumes two. Fruit egg-shaped, convex on the outside. The spike varies in being more or less branched. A native of wet, sandy ground, flowering in June. *C. rivularis, Wahlen. 26. Wildlen. Schkuhr 21. tab. C. c. fig. 87. "Spikelets male at the top, five, rather near together, oblong; glumes as long as the fruit, mucronate; fruit roundish-ovariculate, somewhat beaked, membranous at the edge near the tip; orifice divided, ligmas two." A native of Hungary on the banks of rivers. *C. flaccis, Wahlen. 55. (C. indica, Schkuhr 27. tab. B. b. fig. 85.) "Spikes compound; branches aggregate, male, and linear at the top; glumes oval; bracteoles flat, triangular, nearly globular, rather obtuse; orifice margiunate; ligmas three: leaves narrow, a little incurved at the edges. A native of the Cape of Good Hope. 64. C. indicus, Linn. Mant. 574. Mart. 19. Lam. 26. Wahlen. 56. "Spike cylindrical, panicked, pinnate; a few of the lowest flowers female." Linn. Semen a foot and a half high, erect, obscurely triangular, smooth and even. *Leaves on the stem remote, rough at the edges, often longer than the stem. Panicle formed of many alternate, flill, triangular, spreading racemes; spikelets alternate, nearly sessile, in two rows, remote, spreading, imbricated on all sides with awl-shaped scales, with two or three female flowers at the base; bracteoles falcate. Fruit egg-shaped, acute, triangular. Linn. Stigmas three, Wahlen. A native of the East Indies. 55. C. polyplachys, Wahlen. 57. Swartz. Flor. Ind. Occid. App. "Spikes compound, pinnate; branches crowded, numerous, attenuated upwards, glumes three; glumes lanceolate; bracteoles falcate; fruit lanceolate, with an awl-shaped recurved beak; seed fluff. A native of the highest mountains in Jamaica. 66. C. clavatula, Wahlen. 58. (C. succidea; Swartz. Append.) "Spikes compound; branches rather near together, few, weak, with scattered flowers; glumes lanceolate, bracteoles falcate; fruit oblong; with an awl-shaped beak curving outwards, ligmas three; stem falcate; leaves very narrow." A native of mountains in Jamaica. 67. C. faberlii, Wahlen. 59. (C. laca; Swartz. Flor. Ind. Occid. App. "Spikes compound; branches clustered, somewhat globular-ovate; bracteoles falcate; fruit ovate, acute, a little curved outwards; ligmas three; stem feebly, leaves very narrow." A native of mountains in Jamaica. 68. C. crinata, Wahlen. 62. "Spikes double compound; branches and branchlets divergent; bracteoles falcate; fruit ovate, with a short beak rather curved outwards; ligmas three." A native of the neighbourhood of Canton in China. 69. C. ovata, Rudge in Linn. Trans. vol. 7. p. 96. tab. 9. fig. 1. "Spikes egg-shaped, pendulous; fruit egg-shaped, acute." Stem erect, triangular; angles acute, rough. *Leaves erect, slender, rough at the edges. Spikes four or five, peduncled; flowers densely imbricated; glumes egg-shaped, acute, brown, as long as the fruit; bractes at the base of the peduncle a little embracing the stem. Fruit egg-shaped, compressed, acuminate, cloven at the tip; ligmas three, glandular, rather thick. A native of Newfoundland. 70. C. magellanica, Lam. 25. tab. N. fig. 51. (C. oblongo-lanceolata.) Spikes oblong, on long peduncle, fruit compressed, lenticular. In habit and face resembling Juncus commelina. Stem five or six inches high, leafy. *Leaves as long as the stem, two lines broad, smooth, flat, straight. Spikes three or four, half an inch long, brown or blackish, a little compressed; peduncles almost capillary, the length of the spikes; glumes brown, acuminate; bracteoles falcate. Fruit smooth, compressed, lenticular, yellowish, shorter than the glumes; ligmas three; gathered by Commoner in the fruits of Magellan. 71. C. brunnnea, Mart. 20. Lam. 27. Wahlen. 59. Thum. Flor. Japon. p. 38. Schkuhr tab. X x. fig. 3. "Spikes peduncled, linear; male flowers at the top." Stem a foot high, triangular, falcate. *Leaves linear, acute, liriiated, keeled, entire, smooth, bright, longer than the stem. Spikes about twelve, half an inch long, pointed, straight, smooth, on capillary peduncles; glumes egg-shaped, acute; ligmas two. A native of Japan. 72. C. fabulata, Wahlen. 69. "Spikes narrow, rather long, somewhat densely flowered, male at the top; peduncles falcate; fruit ovate, triangular, shorter than the glumes; glumes ending in an awn much longer than the fruit; fruit ovate, triangular, depressed, beaked, bicuspitate; ligmas three; leaves broad." A native of the Isle of Bourbon. 73. C. Forsteri, Wahlen. 81. (C. debilis; Forl. C. recurvata; Schkuhr 100. tab. N. fig. 84.) "Spikes on long naked peduncles, cylindrical, pendulous, male at the base; bracteoles with rather long falcate, foliaceous, very long, remote; fruit oblong-ovalate, attenuated, with an awl-shaped recurved beak; male spikes two; ligmas three. A native of New Zealand. 74. C. atrata, Linn. 26. Mart. 77. 31. Lam. 12. Wahlen. 114. Gooden. 36. Smith 28. Flor. Dan. 158. Schkuhr 41. tab. X. fig. 77. (Cyperoides alpinum spicis atriis; Schucezh. Agr. 487. tab. 11. fig. 2.) "Diandrous; spikes egg-shaped, peduncled, at first upright, pendulous in fruit, peduncles feebly falcate; male flowers at the bottom of the terminal spike; fruit compressed." Root perennial, foliaceous. Stem a foot high and more, erect, triangular, liriiated, leafy at the base; angles feebly rough. *Leaves shorter than the stem, bright green, broad, flat, rough at the edges. Spikes often four, egg-shaped, dense, many flowered; terminal one with male flowers below, female above; the others with female flowers and a mixture of diandrous hermaphrodites; bracteoles foliaceous, embracing the stem but feebly falcate, spreading; the lowest often longer.
longer than the stem; peduncles triangular, smooth and erect; glumes eggy-shaped, black. Fruit indistinct, a little shorter than the glumes, broad-elliptical, compressed, yellow, without ribs, smooth, scarcely hanked, emarginate at the tip. Spike triangular, short, brown, ligulam-three. A native of mountains in Wales, Scotland, and other parts of Europe. 75. C. digitata, Link. 19. Mart. 32. Lam. 190. (Hall. helv. 1875.) Gram. carophylli Nemorti, forma multiplici. Bahn. 184. 4. Schkuhr, 456. Ang. nutt. folio, Moril. hist. 3. p. 243. 4.1. Cypereides Mitch. gen. 65. tab. 32. f. 14.) "Male spikes fiddle, oblong; lower one axillary: leaves almost thread-shaped." Nearly allied to the preceding, but smaller, with narrower leaves and spikes nearer together, mutuating at a hard foot. L. Marek. Root perennial. Stem naked, slender, about the length of the leaves. Leaves four or five inches long, (to, Lam.) near a line broad, falcate-acute, acute, fruirated. Spike one male, two female, nearly on a level; one female lower, proceeding, according to L. Marek, from an oblong, membranous, reddish sheath; according to Link, from the axil of a leaf as long as the stem. Fruit a fiddle-shaped. A native of mountains in Lapland, Switzerland, Dauphiny, and Piedmont. Wahlenberg confers the peduncle of Schkuhr 62. tab. 11. fig. 37 as only a variety of digitata; and affords that the peduncle of Linnaeus is not now known to the Swedish botanists. St. C. clandellina, G dou. Smith 20. Wahlen. 190. Schkuhr 67. tab. X. fig. 44. (prostrata. Mart. 190. Leyser. 175. Villars Dauph. 2. 205. SchuBb. Spic. flor. l. 1613.) Scario. Lam. 37. Cypereides montana, SchuBb. 407. tab. 10. fig. 1.) "Braetes membranos, seldom foliaceous, fheathing; female spikes remote, few-flowered, enclosed in the sheaths; leaves channelled." Root perennial, fibrous. Stem in tufts, an inch or two long, rather erect, obviously triangular, smooth. Leaves three times as long as the stems, erect, deep green, very rough at the edges. Male spike terminal, solitary, erect, lanceolate, many-flowered; braetes sheathing, membranous, obtuse; glumes imbricated, lancetolate, brown, membranous and white at the edge; females two or three, lower, remote, alternate, peduncled, small, few-flowered, (two, sometimes one-flowered, Lam.) each coated with its bracte. Fruit inversely egg-shaped, triangular; orifice entire; tigmas three. Seed triangular. The leaves which overshadow the stems at their first appearance are those of the preceding year, which usually continue green till their predecessors take their place. A native of mountains in Switzerland and Dauphiny. In England it has hitherto been found only on exposed sunny spots about St. Vincent’s rocks near Bristol. The singular circumstance of the braetal sheaths enclosing the female spikes as well as their peduncles, induced Dr. Goodenough to call the species clandellina, a trivial name which is to be preferred as being differenitatively expressive, though it has not the claim of priority. 81. C. alta, Mart. 72. Wahlen. 104. Schkuhr 88. tab. O. fig. 55. Scop. 1948. Allion. pedem. 2322. (Hall. helv. 1377. Scheuchz. tab. 10. fig. 4. Mich. gen. 61. n. 79. 80. C. argentea, Villars Dauph. 2. 206.) "Spikes peduncled, white, sheaths long, obtuse; filaments and style long, white." Stem round, slender, with three white leafy sheaths. The two upper spikes from one sheath, the lower fingle. Glumes of the male spike almost transparent; of the female spikes keeled, acuminate; anthers terminating in a lucid point; female flowers few. Fruit turgid, roundish, smooth, frurated, growing black in autumn. Seed triangular, shining, acuminate. Linnaeus was either unacquainted with this species, or confounded it with digitata. Scop. 83. C. Pennsylvanica, Lam. 36. "Spikes variegated with brown and white; male terminal, obtuse; female fiddle, egg-shaped, either with or without a bracte." Stem one or two inches high, upright, very slender, triangular, leafy only at the base. Leaves scarcely half the length of the stem, lefs than a line broad, flat, frurated. Male spike terminal, upright, a little acute; glumes obtus. 4 C"
CAREX.

oblung, obtuse, smooth, reddish brown, membranous and white at their edges. *Female spikes* a little below the male, sessile, egg-shaped, short, few-flowered, sometimes without, and some with a bract, scarcely the length of the spike; glumes similar to those of the male. At the base of the male spike there is sometimes the rudiment of another female spike not distinctly separated from it. A native of Pennsylvania and New York. 84. *C. faginea*, Wahlen. 100. Wahlen. (C. glomerata, Schkuhr 65, tab. 1, fig. 41.) "Female spikes about two, nearly sessile, globular; bracts somewhat embracing the item, leafy, crowded; fruit nearly globular, beaked; orifice two-lipped; stigma three; male spike slender; leaves very narrow." 85. *C. sarca*, Wahlen. 175. "Female spikes few-flowered, nearly sessile; male, slender; bracts somewhat embracing the item, leafy, crowded; fruit nearly globular, beaked; orifice two-lipped; stigma three; male spike slender; leaves very narrow." A native of North America. 86. *C. pilulifera*, Linn. Sp. Pl. 24. Mart. 28. Lam. 29. Gooden. 37. Smith 37. Eng. bot. 885. (C. montana, Linn. Sp. Pl. 21. Hud. 407.) *C. pilulifera*, Fin. Dan. tab. 1043. C. conglobata, Mari. 70. Allion. pedem. n. 2314. Hall. leh. n. 1372. Scheuch. tab. 10. fig. 8, 9. *Gra men cypérôides*, Rau syn. p. 421. n. 19 and 20. Pluk. Phyt. tab. 91. fig. 8.) "Bracteal sheaths none; female spikes sessile, crowded, roundish, glumes mucronate; fruit roundish, villous." *Root* perennial, fibrous. *Stem* often recurved, incurved, about nine inches high, feebly, naked, rough near the top. *Leaves* deep green, rough at the edges and on the keel. *Bracteas* bristle-shaped, short, triangular, feebly at all sheathing. *Male spike* lanceolate, acute; glumes of a rusty brown colour, lanceolate, acute, with a green keel, and a membranous white edge. *Female spike* two or three, feebly, close together, roundish, spreading; glumes egg-shaped, acute, coloured like those of the male. *Fruit* shorter than the glumes, roundish, obliquely triangular, green, villous on all sides. *Seed* nearly globular, yellowish. It varies with blunt glumes, less conspicuously keeled. Dr. Smith. This is certainly the *C. montana* of the Linnean herbarium, and Dr. Smith concludes from the reference to Plukener, that he described it from that author as his original *piulifera*, without having a specimen before him. Dr. Goodenough thinks it certain that the *pike* of oncid and the same plant under two names; in its more fruitful state with three female spikes, calling it *pilulifera*, and in its more starved appearance when produced on elevated dry plains, where it has only two, and sometimes only one, *montana*. La Mareck has a montana which he thinks may possibly be the montana of Linnaeus, excluding the synonymy. It seems to differ from pilulifera in having shorter leaves, blackish spikes, and fruit more evidently dry, and quotes as probable syn- onyms, cypérôides and *faginea*. Two species of C. pilulifera, from different localities, are described by Scheuchzer. This is from Switzerland by M. Vahl. Wahlenberg, who with respect to Swedish plants must be good authority, determines the pilulifera and *montana* of Linnaeus to be different plants, and gives the following specific characters. *C. pilulifera*, n. 112. Wahlen. Schkuhr 46. tab. 1. fig. 39. "Spikes nearly sessile, globular; male, slender; bracts partly embracing the item, somewhat foliaceous, attenuated, near together; glumes mucronate, rather long; fruit somewhat globular, acute, pubescent; stigma three; item feebly, finely ferrate." 87. *C. montana*, Linn. Wahlen. 109. Schkuhr 53. tab. F. fig. 29. "Spikes rather few-flowered, nearly sessile; bracts crowded, somewhat scaly, embracing the item; keel cupulitate; bracts pitch-coloured, mucronate, as long as the fruit; fruit oval-wedge-shaped, rather acutely triangular, a little rough; stigma three; leaves very narrow." 88. *C. mucronata*, Mart. 71. Wahl. 40. Allion. pedem. n. 2318. Hall. leh. 1374. Mich. gen. tab. 32. fig. 3. Schkuhr 46. tab. K. fig. 44. "Spikes sessile, near together, very short; glumes lanceolate, mucronate." *Stem* a foot high, naked at the top. *Leaves* rush-like. *Spikes* generally three; male, longer; round; females two, five-flowered; glumes oblong, ovate-lanceolate, pale about the edge; nerves yellow, shining, bracteal leaf of the lower spike with a long ferner point, much longer than the spike. Haller. *Stiga* two. Wahlen. 89. *C. congiobata*, Linn. Mart. 17. Mart. 27. Lam. 32. Smith 38. Leers. 200. tab. 15. fig. 7. Wahlen. 108. Schkuhr 51. tab. F. fig. 29. "Bracteal sheaths very short; female spikes nearly sessile, cylindrical, obtuse; glumes elliptical, acute; fruit downy." *Root* perennial, creeping. *Stem* a foot high, erect, naked, acutely triangular, angles near the top rough. *Leaves* shorter than the item, erected, flat, bright green, roughish both sides, and at the edges. *Bracteas* foliaceous, a little spreading, scarcely longer than the item. *Male spikes* lanceolate, rather obtuse; glumes lanceolate, of a rusty brown colour, with a green keel, the upper ones slightly mucronate. *Female spik es* generally two, not very near together, cylindrical, obtuse, various in length, on short peduncles; glumes elliptic-egg-shaped, scarcely mucronate, of a rusty brown colour, with a bright green keel. *Fruit* about the length of the keel, densely imbeded, roundish, a little compressed, feebly triangular, green, clothed on all sides with dense, short down, which at first is white, and finally of a gold colour. *Seed* white, obliquely triangular. Dr. Smith. *Stiga* three. Wahlen. Found by Mr. Telfitie in meadows near Merfon Morely, Wiltshire. La Mareck's plant, which does not materially differ, was gathered in the neighbourhood of Paris. 90. *C. fasciata*, Linn. Sp. Pl. 25. Wahlen. 140. (C. esculentum alpinum fasciata, Mich. gen. gen. 23. tab. 32. fig. 41.) "Spikes three, egg-shaped, sessile, alternate; male oblong." *Terminal* spike male, of a pale rusty colour. *Female spikes* two, the lower one with a bristle-shaped leaf, shorter than the spike; glumes the length of the pedicel; germs black, triangular; styles black, bifi, long. A native of the mountains of Lapland and Switzerland. La Mareck supposes that it feebly differs from the preceding. Wahlenberg gives it the following character, which proves it distinct. "Spikes nearly sessile, rather densely flowered, very obtuse; male oval; glumes circinate, white at the edge; bracts partly embracing the item, with sharp angles, foliaceous, very narrow, dilated; glumes nearly as long as the fruit; fruit oblong, oval upwards, flat on both sides, rather acute, a little curved outwards; orifice equals; stigma two." 91. *C. pracax*, Mart. 84. Lam. 31. Jacq. Andl. tab. 446. Gooden. 22. Smith 36. Wahlen. 98. Schkuhr. 59. tab. F. fig. 27. (C. fasciata, Hud. C. montana, Reli. 353. Lightf. 557. Gram. cyp. vernum minimum, Rau syn. 421. Greg. em. 22. Marl. 8 tab. 12. fig. 11.) "Bracteal sheaths nearly as long as the peduncle; spikes egg-shaped, near together; glumes a little mucronate; fruit roundish, pubescent," *Root* creeping, and branching out into several leafy tufts. *Stems* ascending, from three to six inches high, naked, obliquely triangular, smooth. *Leaves* short, rigid, recurved, a little revolute, roughish, especially at the edges. *Bracteas* erect, often wanting; sheaths short, dilated upwards. *Male spike* inversely egg-shaped, rather obtuse; glumes elliptical, of a rusty colour, bluntish; anthers sulphur-coloured. *Female spik es* generally two, near together; on short peduncles, egg-shaped, nearly erect; glumes

**Carex.**

Plumes broad, egg-shaped, rather pointed, of a rufous colour, with a green keel. *Fruit* scarcely the length of the glume, roundish on the showy part, keeled, pubescent, green, brown at the tips. *Stigmas* three. **Seed** white.

A native of dry exposed situations and heaths, flowering in April. 92. C. trifoliae. Mat. 39. Wahlen. 101. Schkuhr tab. W 70, 87. 109. Thumb. 38. "Spikes three, fillicle, linear, male longer. *Female* spikes from Montana, tufted. *Male* spikes three or four, acute; lower one distant from the others, in the axil of a narrow leaf; glumes acute, reddish, with a green keel. Found by Consolario in the Isle of Bourbon. 100. C. Virginitana. (C. helicis. Lam. 35. "Female spikes two, fillicle, erect, with male flowers at the top; male terminal, remote; item naked." Stem about a foot high, slender, compressed above, triangular below, rough. *Leaves* as long as the stem, near two inches broad, flat. *Male* spike terminal, an inch long; glumes oblong, brown with a white edge. **Female** spikes dilated from the male, fillicle, upright, linear, preened close, reddish brown, with some male flowers at the top; lower one with a bracteal leaf as long as the spike. A native of Virginia, Pennsylvania, &c. described by La Marek from a dried specimen. 101. C. stenoptera. 417. Schkuhr tab. 10. fig. 12. "Spikes erect, variegated; male egg-shaped; lower female peduncled, axillary." Stem an inch and half, or two inches high, with three or four short, upright, acute, flaccid-leaved. *Root leaves* dilated, slightly keeled, smooth, about the length of the stem. **Spikes** three or four; male terminal, upright; glumes oval, smooth, mucronate, brown, with a green keel, and a membranous, whitish edge; females upright, obtuse, rounded, covered like the male. A native of mountains in Switzerland. 102. C. alpina. Mart. 77. Alpin. p. 1585. (C. gymnoepis, Villars dauph. 2. 26. Wahlen 99. Schkuhr 50. tab. G. fig. 35. "Lowest female spike radical; fruit triangular, elongated." Stems from three to nine inches high, naked. *Leaves* in tufts, two lines broad, keeled, acuminate, smooth except at the tip. *Spikes* very small; male none long; glumes egg-shaped, obtuse, with a yellow keel and white edge; upper female spike fillicle, an inch below the male, few flowers; bracteal flaccid, awned; lower one with about six flowers, on a peduncle, three inches long or more. There are sometimes, but rarely, three female spikes. A native of Piedmont and Switzerland.

The alpestria of La Marek agrees in some respects with the preceding, but as he has nothing of the great distance of the lower female spike from the others, from which circumstance Villars took his trivial name, it must be a different plant. It was received from the neighbourhood of St. Maurice in the Vaud, and as it gives no synonyms, certainly is notconfined to the Mendocino. We shall call it for the present 103. C. Lamarckii, "Female spikes about three or four; upper ones fillicle; fruit smooth, globular, mucronate." Stem seven or eight inches high, naked, slender, cylindrical, compressed, dilated. *Leaves* in tufts three or four inches long, glaucous, flaccid, smooth. *Spikes* three, or four of a rufous colour; male terminal, half an inch long; nine rather obtuse, membranes at the edges; the upper female spikes short, nearly fillicle, each with a pointed bracteate about its own length; lowest larger, peduncled, in the axil of a very narrow bracteal leaf longer than the spike; glumes egg-shaped, rather blunt, smooth, rufous, membranous and white at the edge. Fruit smooth, almost globular, mucronate. 104. C. tenuifolia. Lam. 52. Poiret. Voyage en Barbary. Vol. 2. p. 254. "Female spikes erect, few-flowered; lower ones dilated on long peduncles; upper ones nearly fillicle; leaves very narrow." Root perennial, creeping, blackish, surrounded at the top with numerous brown filaments. Stems several, six or seven inches high, very slender, triangular, compressed, moderately leaved. *Leaves* very narrow, flaccid smooth, green, keeled, a little folded in at the edges, longer than the stems. *Male* spikes terminal, about half an inch long, upright, oblong, acute, of a rufous colour.

4 C. s.
**CAREX.**

Female spikes upright, less than the male, few-flowered, of a rufset-green colour, dilant from each other, upper one near the male with a feley bracte; the two others peduncled and axillary; the lowest in a very long, capillary peduncle, which springs almost from the bottom of the stem; glumes egg-shaped, scarcely acute, greenish and fringed on the edges, brown or rufset-coloured at the edge near the tip. The plant of Barbary on moil, elevated ground. This plant is nearly allied to the alpilus of Allioni, but differs in the breadth of the leaves, and colour of the glumes. 105. C. bardeformis, Villars, 72. (C. hartdeformis, Villars, 2. n. 43, tab. 6.)

Spikes very thick; peduncles fleshet; bractes foliaceous, very long; the lowest nearly radical, the others rather near together; fruit egg-shaped, acuminate, somewhat beaked, very convex on one side, a little concave on the other, ferricate at the edges; orifice hid; ligmas three; male spikes two.” A native of Dauphiny. 106. C. pennis, Wahlen. Goop. Schkuhr 69, tab. O. Y, fig. 54. “Spikes thin, oblong, rather many-flowered; peduncles naked; bractes somewhat foliaceous, rather remote; fruits short; fruit oblong, lanceolate, with a flench edge, acutely and finely ferriate at the edges; ligmas three, orifice one-lobed.” A native of the Austrian Alps. 107. C. atrata, Wahlen. 137.

Schkuhr 74. tab. L. fig. 46. “Spikes oval; peduncles naked; bractes foliaceous, dilant; orifice very short; glumes broad-ovate, obtuse, fruit ovate, pointed; orifice obtusely one-lobed; ligmas three; stem acutely angular.” A native of Switzerland. 108. C. ferruginea, Mart. 78. Wahl. 84. Allioni, ped. n. 2333. Scop. Carn. 1150. Hall. helv. 1390. Schuech. 10. 6. (C. alpina, Schrank.)

“Male spike acuminate; female two or three, flender, peduncled; glumes rufset-coloured; fruit bifoem.” Stem half a foot high, pale green. Male spike an inch long, glumes long, narrow, acuminate, rufset-coloured, with a green keel. Female spikes three or four; the first with a short bracte, the second with a leaflet as long as itself, the third with a longer leaflet; glumes green with a rufset-coloured edge; ligmas three. A native of Switzerland. Pedmont, and, if Scopoli be right in thinking his plant the same as Haller’s, of Carnicia, though it is not alpine there as it is in the Grifona. 109. C. sepimentum, Villars dauph. 2. 214. Stems eight or ten inches high, flender, hard. Leaves in tufts, long, hard but flexible, continuing through the winter till the new ones come up when they are completely bleached. Spikes three; male blackish, variegated with grey; female loose, peduncled; glumes blackish-brown with a green keel. Fruit triangular, blackish, smooth, except near the top. Seed triangular, grey, elongated. A native of Dauphiny. Professor Martya gives it as a conjunctival synonym of the preceding, because Villars has referred to Scopoli and Haller with a mark of doubt. 110. C. fedigida, Mart. 79. Wahl. 83. Allioni, ped. 2344. Hall. helv. n. 1391. Villars dauph. 2. 215. (C. variegata; Lam? C. fialingoius, Schkuhr. 76. tab. C. c, fig. 47.) “Female spikes three or four, two-rowed; fruite long, pointed.” Mart. “Spikes three, nearly erect, brown and white; glumes membranous at the tip; fruit acuminate, roughish.” Lam. Stem half a foot high and more, naked. Leaves a line broad or more, smooth, except at the edge. Male spike near an inch long, often fertile at the bottom; glumes sharply lanceolate, shining bay, with a green or yellowish keel. Female spikes axilary, lower ones pendant. Hall. Villars says it differs little from his fenni¬erici. La Marck refers to Haller and Allioni with a mark of doubt. He gives the following description from a dried specimen gathered on the mountains of Dauphiny. Root perennial, strong, with greyish or brown fibres. Stem from seven to ten inches high, flender, naked. Leaves unequal in length, the largest five inches long, and little more than a line broad, fringed, smooth, hard, firm. Male spike terminal, upright, five or six lines long; glumes obtuso; very membranous and white at the top, brown on the back with a whitish line. Female spikes two, peduncled, especially the lowest, short, brown, variegated, pendant when in fruit. Fruit egg-shaped, acute, orifice long, obtuse; leaves somewhat recurved, rigid; fruit rather compressed.” Root perennial, thick, creeping. Stem from three to five inches high, often curved, naked, rigid, acutely triangular; angles rough. Leaves rigid, recurved, rather glaucous, rough at the edges and on the keel. Bractes foliaceous, shorter than the spike, often recurved, arched at the base. Male spike short, egg¬shaped, rather obtuse, thick, rarely two; glumes obtuse, with a delicate greenish keel. Female often three, egg-shaped; two upper ones seifile, near the male, lower rather remote, erect, on a short peduncle; glumes elliptical, obtuse, black, with a white edge and a fine green keel. Fruit longer than the glumes, densely imbricated, elliptical, rather compressed, flatish on one side, smooth, brown outward, sometimes lengthened at the tip, and recurved; orifice always undivided, ligmas two, thickish. On the top of the Snowdon in Wales; Ben Lamond and other mountains in the highlands of Scotland, flowering in June and July. 111. C. brachyphylla. Wahl. 82. Schrank. Schkuhr 83. tab. P. fig. 58. “Spikes on long naked peduncles, very narrow, short, loosely flowered; bractes fleshy, somewhat foliaceous, rather remote; glumes short, somewhat mucronate; fruit lanceolate; orifice two-toothed; ligmas three; stem bristle-shaped; leaves very narrow, convolute.” A native of Switzerland. 112. C. palla, Gooden. Linn. Tran. vol. iii. tab. 17. Smith 29. Wahl. 142. (C. fuccta; Schkuhr. 52. tab. C. c, fig. 88. C. globularis var. Vahl.) “Digynous; bractial seifile none; spikes egg-shaped; lower one peduncled; fruit elliptical-inflected, somewhat beaked, emarginate.” Root perennial, creeping. Stem nearly erect, six or seven inches high, frilled, triangular; angles rough towards the top. Leaves nearly erect, flat, rough at the edge. Bracte foliaceous, embracing the stem feely lanceolate, rather at the edge. Male spike terminal, erect, lanceolate, many-flowered; females often two, remote, egg-shaped, erect; the lower on a long peduncle, the upper on a short peduncle, with a very short spike, often one, peduncle rough; glumes all elliptical-lanceolate, obtuse, blackish brown, with a fine white edge and a faint nerve. Fruit spreading, longer than the glume, elliptical, smooth, not ribbed, pale at the base, blackish brown at the tip, shining. Seed triangular; ligmas two. A native of mountains in the highlands of Scotland, flowering in July. 114. C. pallasii. Linn. Sp. Pl. 29. Mart. 54. Lam. 46. Wahl. 121. Schkuhr 92. tab. K. k, fig. 99 Flor. Dan. 1950. Leers 201. tab. 15. fig. 4. (Gram. cryper. Rai fyn. 146, n. 8. Pluk. Phyt. tab. 34. fig. 5. Mich. gen. 61, tab. 32. fig. 13.) “Bractial seifile very short; spikes cylindrical, peduncled; fruit-bearing ones pendulous; fruit elliptical, inflalted, obtuse.” Root perennial, fibrous. Stem a foot high or more, erect, leafy at the base, triangular; angles rather acute near the top, rough. Leaves flat, pale, somewhat hairy, roughish at the edges. Bracte foliaceous, erect, considerably longer than the stem, with very short seifile. Male spike terminal, lanceolate, erect, dense,
CAREX.

dense, pale rust-colour; females three, peduncled, fruit erect, afterwards pendulous; peduncles triangular, smooth, and even; glumes egg-shaped, acuminate, yellowish, with a green keel. Fruit the length of the glumes, elliptical, inflated, very obtuse, awnless, without ribs, smooth, pale green. Stigmas three. Seed triangularly-irregularly egg-shaped. A native of moist pastures and woods in England, and other parts of Europe, flowering in May and June. 115. C. echinata, Wallen. 6a. Thumb. in Herbar. "Spikes nearly cylindrical, thick; male club-shaped; bracts sheathing the peduncle, foliaceous, remote; glumes nearly as long as the fruit, mucronate; fruit roundish, oval, gibbous, curved outwards, beaked; stigmas three; leaves very broad." B. C. cylindracea. "Spikes cylindrical, thickish; male several; bracts foliaceous, broad, and long." C. tritica (C. chas. var, Thumb. Prod. p. 14.) "Spikes oval, very thick, male at the top; glumes as long as the fruit, a little cupuliform." A native of the Cape of Good Hope. 116. C. flava, Linn. Sp. Pl. 15. 18, Lam. 28. Wahlen. 61. Eng. Bot. 1294. Flor. Dan. tab. 1647. Leers, tab. 15, fig. 6. (Graham pahure echinatum, Rai Syn. p. 421. n. 18. Ger. Bot. 17. G. cyper. Mor. § 6. tab. 12. fig. 19.) Marsh hedgehog-grass. "Branched spikes short, nearly the length of the peduncles; female spikes roundish; fruit beaked, curved downwards; stem nearly smooth." Root perennial, creeping. Stem often a foot high, erect, leafy below, triangular; angles generally smooth and even, sometimes a little rough. Leaves bright green, erect, rather broad, flat, longer than the stem, rough on the edges and on the keel, marked with two rough lines on their upper side towards the extremity. Breasted foliaceous, much longer than the stem; upper ones spreading, deflexed, with a very short keel; the lowest with a longer keel, ± 1 leaf spreading. Male spike lanceolate, crenate, deflexed, very seldom more than one; female about three, roundish, egg-shaped, spreading; upper ones generally near together, most commonly crenate; lowest more remote, peduncled; peduncle a little shorter than the keel; glumes egg-shaped, tawny, with a green rib. Fruit longer than the glumes, spreading every way, egg-shaped, inflated, smooth, ribbed, crenate, at the tip, triangular; angle not at all rough; stigmas three. Seed small, triangularly-irregularly egg-shaped, black. Common in boggy meadows, flowering in May and June. 117. C. obtusa, Oeder, Roth, Hoffmann. Ehrh. Wildt. Schkuhr 35. tab. f. (C. flava, & flavecens, Wahlen. C. extensa, Reih. Flor. Cant.) "Bracts rather dilated; fruit oblong-irregularly egg-shaped, a little inflated, with a short awl-shaped beak, not recurved; orifice two-toothed; stem softly angular; leaves narrow, the lower ones the longest, incurved at the edges." Wahlen. Common near Yarmouth. Mr. Dawson Turner observes (Icet Botanists Guide, vol. ii. p. 75.), that he can find no satisfactory marks of distinction between this and the preceding species, and yet it is so constant in its appearance, in all situations, whether wet or dry, that though Schkuhr is inclined to consider it only as a variety of flava, he cannot but believe it distinct. He adds, that Mr. Brunton pointed out to Dr. Smith the same leading distinction as was noticed by Dr. Roth, the fruit expanding in all directions, and not at all recurved. Mr. Turner supposes that it has been mistaken by many Botanists for the much more rare C. extensa. 118. C. exsetosa, Mart. 80. Gooden. 25. Linn. Trans. vol. ii. tab. 21. fig. 7. Smith 33. Wahlen. 65. Eng. Bot. 833. Sch. tab. X. x. fig. 72. (Cyperoideae echinatum majus, Dill. in Rai Syn. 421.) "Breasted leaves and peduncles very short; bracts very long; female spikes roundish; fruit egg-shaped; stem smooth." Root perennial, fibrous. Stem near a foot high, erect, or ascending, sometimes curved, obscurely trig.
half long; glumes densely imbricated, elliptical, obtuse, with a short point, blackish; keel sharp, green. *Trianthema* three or four, rarely five, cylindric, erect; lower ones very remote, on longer peduncles, and often compound or branched at the base; all of them sometimes with male flowers at the top; glumes egg-shaped, black, pointed; keel green, smooth, except at the point. Fruit longer than the glumes, egg-shaped, scarcely beaked, smooth, thinning, purplish within and at the tip, pale without, with two principal green ribs, besides several small ones running longitudinally at some distance from the margin; figmas three. Common in many parts of England and Scotland, but not generally undersown, flowering in June. 122. *C. palaestina*, wall. *C. palaestina* Schkuhr, tab. S. fig. 67. "Spikes broad lanceolate; peduncles fleshy; bract long, foliaceous, lower ones very remote; sheaths short; fruit oblong, with a long acuminate beak, convex on one side, a little concave on the other, prefoliate, ciliate at the edges, orifice bifid; figmas three." A native of Austria. 123. *C. betaeferma*, Wahlen. 67. "Spikes somewhat thread-shaped, straight; flowers scattered; peduncles fleshy; bracts foliaceous, long, remote; fruit oval-ventricose, elongated at the base, attenuated at the top, curved outwards; orifice quite entire; figmas three." A native of North America. 124. C. jucunda, Mart. 91. Scop. Carn. v. 1163. Mich. Gen. 55. n. 19. "Spikes very remote; male longer than the females, which are nearly fleshy; fruit brown, triangular, smooth; seed triangular." Stem a foot high. Leaves scarcely two lines broad. Upper female spike sometimes with male flowers at the tip; lower with a leaf longer than the spike. 125. *C. flava*, linn. Sp. Pl 39. Mart. 35. Lam. 57. Wahlen. 96. Schkuhr 92. tab. I. 1 fig. 170. Eng. Bot. 1705. "Sheaths elongated, about half the length of the peduncles; female spikes rather loose, dilate; fruit inflated; orifice smooth." *Root perennial, creeping. Stem from 2 to 4 inches high, erect, obtusely triangular, smooth. Leaves glaucous, short, rather erect, rough at the edges and top of the keel.* Bracte foliaceous, acute, shorter than the stem; sheaths long, furrowed, pale, or yellowish. *Male spikes* one or two, lanceolate, acute, denser; glumes rusty brown, obtuse, various in breadth, with a green keel. *Female spikes* generally two, sometimes with male flowers at the top, remote, erect, on slender peduncles twice as long as the sheaths; glumes loosely imbricated, egg-shaped, finely brown, acute, awnless, membranous at the edge, with a green keel; figmas three. Fruit egg shaped, longer than the glumes, inflated, blunted, entire, smooth, obscurely ribbed, of a light greenish, or yellowish hue. *Seed short, triangular, brown, frequently inflected with the diacate called filament, which turns it into footy dust.* Dr. Smith. A native of moist ground, flowering in May and June. 126. *C. recurvata*, Mart. 70. Hudson p. 413. 2 Ed. Flor. Dan. 105. Eng. bot. 1536. (C. glauca; Scop. Carn. v. 2. 223. Polich v. 2. 164. C. limbata B; Leers 201. tab. 15 fig. 3. C. flava; Wahlen. 157. Schreb. Schkuhr 98. tab. O. P. ag. 57. a-b. Gram. cyp. folis cariosphilis, spicis pendulis in Ral Syn. p. 418. n. 5. Morif. § 8. tab. 12. fig. 14.) "Sheaths short; female spikes cylindrical, pendulous; fruit elliptical, triangular, roughish; root creeping." *Root perennial, sheathed with brown scales. Whole herb glaucous. Stem from eight to eighteen inches high, erect, convexly triangular, rough upwards. Leaves shorter than the stem, erect, broad, flat, rough-edged. *Bracte foliaceous, erect, nearly as long as the stem; sheaths short, with a small appendage on each side.* Male spikes various, mostly solitary, sometimes two perfectly distinct and both peduncled, when solitary often compound, with one or two spikellets, sessile at its base; glumes imbricated, egg-shaped, blunt, brown, a little pale keel. *Female spikes* two or three; sometimes with male flowers at the top, the upper ones sometimes nearly sessile, the next on a long peduncle, the lowest often on a very long one springing from the very bottom of the stem, all at first erect, afterwards pendulous, cylindric, very dense; glumes egg-shaped, some what pointed, blackish, with a white edge and yellowish nerve; figmas three. Fruit imbricated, elliptical, bluntly triangular, swelling, entire, more or less downy or rough, of a rusty green, soon becoming black. *Seed short, triangular; common on moist ground, flowering in May and June. 127. *C. palaestina*, wall. 152. (C. atrofasciata; Schkuhr 92. tab. V. fig. 82.) "Spikes peduncled; peduncles naked, curved backwards; bracts loosely sheathing, finely foliaceous, dilute; fruit oval, acuminate, flattish on both sides, acutely angular, beaked, black; orifice two-toothed; figmas three; male spike oblong, recurved. A native of mountains in Sweden, and Iceland. 128. *C. latijuga*, Wahlen. 94. Schkuhr 98. tab. M. fig. 49. "Spikes very narrow, rather looselyflowered; peduncles partly naked; bracts closely foliaceous, remote; sheaths very long; fruit elongated-egg-shaped, triangular, curved outwards at the tip, quite entire; figmas three, leaves very broad. A native of Virginia, in the herbarium of Thunberg. 129. *C. palaestina*, Wahlen. 93. Schkuhr 78. tab. M. fig. 49. "Spikes linear, looselyflowered; peduncles naked; bracts sheathing, foliaceous, remote; fruit somewhat oval, acutest; orifice transparent, two-leaved; figmas three; leaves ciliate." A native of Moravia, in the herbarium of C. limi. 130. *C. limi*, Linn. Sp. Pl. 27. Mart. 32. Lam. 45. 3. Smith 27. Gouden 24. Wahlen. 122. Schkuhr tab. T. fig. 107. flora Dan. 646. (Cyperoids spica pendula, lacerata, glumis apicem vel inciso rutilante variata; Schiffiz. Acta. 443. tab. 13. fig. 13.) "Sheaths very short, linear, acute; female spikes egg-shaped, pendulous; fruit elliptical, compressef; root creeping." Dr. Smith. *Root perennial, throwing out suckers; foliage cloathed with a thick down. Whole herb rather glaucous. Stems ascending, a foot high, triangular, frayed, rough, lax, at the base. Leaves linear, narrow, flat, shorter than the stem, rough at the edges, sheathed at the base with brown scales. Bracts erect, resembling the leaves but smaller; sheaths brown, slightly margined, membraneous and white at the edge. Male spike terminal, erect, lanceolate, reddish brown; glumes egg-shaped, acute. Female one or two, peduncled, drooping, finally pendulous. Egg shaped, many-flowered, dense, hand-like; glumes broadly elliptical, somewhat pointed, green at the back, deep green-coloured at the edge; peduncles very long, triangular, smooth. Fruit imbricated, a little longer than the glumes, elliptical, compressef, ribbed, smooth, entire, scarcely beaked; figmas three. Seed elliptical, triangular, a little compressef, brown. A native of dry boggy places in England, and other parts of Europe. 132. *C. leucophaea*. Wahlen. 95. "Spikes oblong-elliptical, rather slender, shorter than the flowered, pendulous; peduncles naked; bracts foliaceous, rather narrow; remort sheaths rather long; glumes obtuse, as long as the fruit; fruit oblong-elliptical, rather obtuse, triangular, compressed; orifice obtuse orifice very entire; figmas three; stem fuscous. A native of the turfy borders of lakes in Lapland. Female spikes similar to those of the preceding species. 150. *C. capitoja*, Linn. Sp. Plan. 34. Mart. 38. Smith 42. Wahlen. 139. Eng. bot. 1507. Schkuhr 48. tab. B. fig. 8. c. d. (Grann. Caryophyllichum; Dill. in Ral Syn. p. 418. n. 6.) "Dygnous; bracteae arudi, not theiling; spikes fuscous, cylindrical, obfute; fruit permanent." Root creeping, but short, forming
forming dense, entangled tufts. Stems from nine to twelve inches high, erect, acutely triangular, roughish upwards. Leaves erect, almost as tall as the stem, narrow, acute, of a bright not glaucous green, rough at the edges and keel. Bracteae like the leaves, but much smaller, without any sheath, accompanied at the base by a pair of round black aliciae, which are largest in the smaller bracteae. male spikes almost always solitary, lanceolate, erect; glumes brown, obtuse, unnarrowed, with a green nerve. Female spikes two or three; crowded, sessile, erect, cylindrical, floribund, obtuse; glumes elliptical, obtuse, close, black, with a green nerve. Fruit elliptical, broad, compressed, ribbed, green, smooth, permanent after it is ripe; fLigmas two. Seed compressed. Dr. Smith. A native of moist ground in Sweden and England. 133. C. frutica, Mart. 83. Gooden. 140. Lindl. Trans. V. 2. tab. 21. fig. 9. Smith 43. Wahlen. 38. Schlüchtern 49. tab. V. fig. 73. (C. cypelata; Huds. p. 412. Lightf. 561. B. C. acuta, and Leers 204. tab. 16. fig. 1. Hult. hyl. n. 1450. on the authority of Davall. C. chata; Mart. 86. Allion. pedem. n. 2344. Gram. cyper. Rari syn. p. 418. n. 4. Locl. Trans. 116. tab. 30.) "Diggins; bracteae slightly auricled, not fleating; spikes nearly sessile, cylindrical, elongated, acute; fruit deciduous." Root perennial, creeping. Whole herb rather glaucous, double the size of the preceding. Stem about two feet high, erect, sharply triangular; rough upwards. Leaves erect, longer than the stem, rough on the edges and keel; nut-leaves embracing the stem, with the feathers split into threads after the manner of open network. Bracteae similar to the leaves, sessile, erect, straight, accompanied at the base by two oblong aliciae which soon dis-appear; sheath none. Spikes on short peduncles, erect, an inch and half or two inches long, linear-lanceolate, rather narrow, very dense, many-flowered; all the glumes elliptic-lanceolate, obtuse, pruinose, close, black, with a green nerve; male spikes often two; females generally three, often with male flowers at the top; ligmas two. Fruit imbricated, egg-shaped, acute, compressed, ribbed, green, smooth, deciduous as soon as ripe. Seed similar to that of the preceding species. A native of marshy places in various parts of Europe. 134. C. japonica, Mart. 40. Lindl. 51. Thunb. flor. japon. 58. "Spikes monocious, peduncled, erect; female ones peduncled, egg-shaped; male terminal, linear." Root fibrous. Stem about seven inches high, leafy, triangular, erect, weak, smooth. Leaves alternate, fleating, smooth, erect; lower ones shorter than the stem; upper ones over-tapping it. Male spikes terminal, linear, longer than the others. Female spikes two or three, erect, egg-shaped, furnished with bracteae. A native of the island of Nippon, flowering in June. L. Marte. judges observes, that from this description the spikes are improperly said to be monocious. 135. C. planginacea, Lam. 49. "Male spike short, dark purple; female spike remote, erect, slender; stem sheathed, leaves ribbed." Root-leaves in thick tufts, oblong-lanceolate, flat, about an inch broad, ribbed like theophant, purple at their base. Stem slender, straight, jointed, higher than the leaves, and furnished in all their length with numerous alternate, naked, pointed, purple fleathes, of which only the lower terminate in short leaves. Male spike more than half an inch long, terminal, oblong-egg-shaped, straight, nearly black or dark purple; glumes smooth, oblong-egg-shaped. Female spikes four or five, straight, very slender, distant from each other, on short peduncles which are partly concealed by the sheath; glumes loosely imbricated, smooth, membranous, acuminate, purplish at the tip. Supposed to be a native of South America; cultivated in the open air at Paris, where it flowers early in the spring. 136. C. hispida, Lam. 54. "Female spikes hispid, axillary, erect; flowers dilated; leaves flat." Stem in a tuft, from five to nine inches high, leafy. Leaves alternate, flattened, flat, like those of junco, plano- smooth, two or three lines broad; root-leaves shorter than the others. Male spike terminal, bright, pale or yellowish, scarcely an inch long; glumes lanceolate-egg-shaped, recurved. Female spikes three, an inch long, alternate, axillary, bright, bluish, peduncled; glumes alternately, dilated, mucronate, membranous, white. A native of New York, Pennsylvania, and Virginia. 137. C. fragrans, Wahlen. 118. "Spikes on rather short peduncles, linear, elongated at the base, loose; bracteae partly embracing the stem, foliaceous, rather dilated; glumes ovate, elliptical, mucronate; fruit oblong, depressed, pointed, orifice two-toothed; ligmas three; stem acutely angular." A native of North America. 138. C. lomana, Wahlen. 142. "Spikes peduncled, slender, and tapering, zig-zag, nodding; bracteae partly embracing the stem, foliaceous, dilated, very long; glumes with a long diverging awn, fruit somewhat globular, pointed; orifice quite entire; ligmas three." A native of Pennsylvania. 139. C. oblongifolia, Wahlen. 86. Mart. 93. Lam. 54. Retz. Obs. Fafe. iii. p. 42. "Spikes erect; male terminal; female four, peduncled; fruit acuminate." Stem seven or eight inches high, triangular, smooth. Leaves longer than the stem, rough at the edges. Female spikes resembling those of the next species, but are upright, remote, foliaceous, more slender, and are each furnished with a slender bracteae nearly the length of the spike. A native of China. 140. C. pseudocyperus, Lam. Sp. Pl. 32. Mart. 37. Lam. 53. Wahlen. 117. Smith. Engl. Bot. tab. 152. Selkirk 25. tab. M m. fig. 122. (Gram. Cyper. p. 419. n. 12. Moris. $8. tab. 12. fig. 5.) "Bracteae scarcely fleating; spikes cylindrical, pendulous, many-flowered; fruit spreading, surrowed, beaked, cloven." Root perennial, fibrous. Stem a foot high or more, erect, leathyr, sharply triangular; rough at the angles. Leaves pale green, fleating, rising, rough above, and at the edges. Bracteae less than the leaves, and scarcely fleating. Pedicels very long, triangular, slender, rough, sometimes two from a bracteae. Spikes cyndrical, many-flowered, dense; male erect, red; female about four, on peduncles about their own length, greenish, at first erect, but soon pendulous; glumes egg-shaped, with long, very rough awns. Fruit spreading, lanceolate, triangular, ribsbed, smooth, beaked, cloven; ligmas three. Seed elliptical, triangular, white. Not very uncommon in wet shady places, flowering in June. 141. C. cymata, Lam. 55. "Spikes long, bristy, rather pendulous; glumes bristy, several times longer than the fruit." Stem about two feet high, triangular, leafy. Leaves fluated, long, three or four lines broad: upper stem one, longer than the stem. Spikes about five; male an inch and an half long, terminal, linear, with sometimes a few female flowers at the base; glumes narrow, linear-angle-shaped, yellowish or reddish; females near three inches long, alternate, axillary, peduncled, drooping; glumes very narrow, linear-bristle-shaped, ciliated, spreading, much longer than the fruit. Fruit roundish-egg-shaped, smooth, angular, slightly mucronate. A native of Virginia. 142. C. miceliss, Wahlen. 89. Hoff. Schkuhr 84. tab. p. and V v. ffi. 59. (C. ampalacea, Wulfen.) "Spikes thickish, short; peduncles sheathed; bracteae somewhat foliaceous, rather remote; glumes acuminate, as long as the fruit; fruit broad, inversely egg-shaped, with a rather long bicuspidate beak; ligmas three." A native of Moravia. 143. C. san-ophylu, Wahlen. 73. "Spikes fix-flowered, very thick; peduncles somewhat sheathed; bracteae foliaceous, very res-
CAREX.

The fruit is oblong-conical, inflated, beaked, diverging; orifice bifiid; ligilias three. A native of North America. 144. C. foliulata, Linn. 51. Mart. 36. Wahlen. 74. Schkuhr 73. tab. N. fig. 52. Linn. Transv. vol. vii. tab. 9. fig. 4. (Gram. Cyp. Plk. Mart. 96. tab. 419. fig. 1.) "Spikes terminal, peduncled, male and female; fruit awl-shaped, the length of the spike." Stem two feet high, triangular. Leaves narrow. Male spike terminal, oblong, peduncled, accompanied in the fimple axil by a female spike, consisting of seven or eight conic-awl-shaped, spreading, seed-vessels each as long as the spike itself, big with the seed, Linn. The figure in the Linnaean Transactions, taken from a specimen in the possession of Mr. Rudge, and corresponding with one in the herbarium of Sir Joseph Banks, has two female spikes, as has also Pluknet's figure, quoted by Linnaeus. Found by Kalm in Canada. 145. C. iutaeformis, Rudge in Linn. Transv. vol. vii. p. 97. tab. 9. fig. 3. (C. foliulata, Linn. 48? C. lurida, Wahlen.) "Female spikes few-flowered; fruit inflated, egg-shaped, with a long pointed beak." Stem erect, triangular; angles rather obtuse, smooth, but rough above the lower bracte. Leaves longer than the stem, broad, dark green, rough at the edges and on the keel. Male spikes terminal, linear, on a long peduncle. Female spikes with loosely imbricated flowers on very short peduncles; glumes oblong-egg-shaped, acute, half the length of the fruit. Fruit oblong-egg-shaped, much inflated, erect, fruited, with a long acute beak, cloven at the orifice; ligilias three. Styles egg-shaped, triangular, smooth, acuminate, yellow. A native of Carolina. 146. C. pendula, Linn. 57. Huth. p. 411. Gooden. 20. Smith 21. Curtis Flox. Lond. tab. 63. Schkuhr 85. tab. Q. fig. 60. (C. agallachys, Linn. jun. Supp. 414. Ehrl. Phyt. n. 19. Wahlen. 76. C. maxima, Linn. 56. Scop. Carnii. n. 1166. Allion. Flor. Ped. n. 241. Hall. Helv. n. 136. Gram. Cyper. Rni. Syn. p. 420. n. 15. Morif. § 8. tab. 12. fig. 4. Barel. Icon. tab. 45.) "Sheaths elongated, nearly the length of the peduncle; spikes cylindricl, very long, nodding; fruit crowded, egg-shaped, acute." Root perennial, fibrous. Stem from three to fix feet high, erect, firm, leafy, smooth, triangular; angles roughish towards the top. Leaves broad, deep green, rigid, hard, rough at the edges and on the keel, rather glaucous underneath. Breaks foliaceous; lower ones very long, hanging down in a curve, sheathing; sheaths nearly the length of the peduncles. Spikes from five to seven, peduncled, curvilinearly pendulous, cylindrical, many-flowered, very dense; the highest male, sometimes with female flowers at the top; the rest commonly female; glumes lanceolate, acuminate, brown, with a green keel. Fruit egg-shaped, triangular, rather inflated, smooth, beaked, at length emarginate; ligilias three. Seed triangular, brown. A native of woods and moist hedges in many parts of Europe, flowering in May and June. 147. C. virgata, Mart. 88. Huth. p. 411. Gooden. 21. Smith 22. Eng. Bot. 994. Schkuhr 30. tab. N. fig. 53. (C. leptofolchys, Mart. 92. Linn. Supp. 414. Ehrl. Phyt. n. 48. Wahlen. 68. Gram. Cyper. Rni. Syn. p. 419. n. 11.) "Sheaths elongated, nearly equal to the peduncle; spikes filiform, loose, a little drooping; fruit lanceolate, triangular, ribbed." Root perennial, fibrous. Stem two feet high, erect, slender, leafy, triangular, smooth. Leaves light green, broad, thin, rough on the edges and keel. Breaks like the leaves, shorter than the stem; sheath nearly as long as the peduncle, crowned by a tabular membrane. Spikes fix or eight, peduncled; the highest male, the red female; glumes lanceolate, greenish. Fruit lanceolate, triangular, acute, ribbed, smooth, green, ligilias three. Seed elliptic, triangular. A native of woods and hedges in several parts of England, but not common, flowering in April and May. 148. C. flexuatica, Mart. 89. Huth. p. 411. Gooden. 31. Smith 23. Flor. Dan. 424. Eng. Bot. 995. Schkuhr 94. tab. L. fig. 141. (C. veleria, 2 Sp. Pl. C. diymea, Linn. jun. Supp. p. 414. Ehrl. Phyt. n. 58. Wahlen. 79. C. patula, Linn. 45. Pollieh. vi. ii. 557. C. capillaris, Lcrs 202. tab. 15. fig. 2. Hall. Helv. n. 1395. Gram. Cyper. Rni. Syn. p. 419. n. 10. Morif. § 8. tab. 12. fig. 9.) "Sheaths half the length of the peduncle; spikes slender, a little loofe, drooping; fruit egg-shaped, triangular, beaked." Root perennial, fibrous. Stem two or three feet high, erect, leafy, smooth, convexly triangular. Leaves bright green, rough above, very rough on the edges and keel. Breaks like the leaves, with longer sheaths. Spikes fix or eight, from drooping, slender, rather loofe; one, rarely two, male; all with flender peduncles more than half the length of the sheath; glumes egg-shaped, acuminate, membranous, white, with a rough green keel. Fruit egg-shaped, triangular, with a long beak, smooth, emarginate at the tip; ligilias three. Seed triangular, brown. It is distinguished from the preceding by the strucrure of its fruit, which has three prominent angles, but no intermediate ribs, and ends in a long cloven beak. Linneaus made it only a variety, and has celebrated its utility to the Laplanders, who use it eated and dressed as a redding to protect them from cold. Common in woods and thickets, flowering in May or June. 149. C. elongata, Mart. 85. Gooden. 32. Wahlen. 86. Smith 24. Eng. Bot. 1098. (C. ventriccosa, Curt. Flor. Lond. tab. 68. C. triifora, Wild. Phytog. tab. 1. fig. 2. Cyperorides, Morif. tab. 32. fig. 5. C. veit ceanum humile, loculusaria, Tour. infl. 130. confirmed by his herbarium.) "Sheaths much shorter than the peduncles; female spikes dilant. erect, five-flowered; fruit inflated, beaked." Root perennial, fibrous. Stem a foot and half high, erect, leafy, obliquely triangular, fruited, smooth. Leaves with long sheaths, pale green, rough on the edges and keel. Breaks like the leaves, but with shorter sheaths which closely unfold the slender peduncles of the female spikes, sometimes for a third part of their length, and sometimes for more than half. Male spike terminal, erect, many-flowered, linear, closely imbricated; glumes elliptical, ruf-coloured, with a white membranous edge and a green keel. Female spikes from three to five, remote, loofe, erect; peduncles triangular, rough; flowers from two to four or five; erect; glumes involute, beaked, pointed, with a green keel. Fruit egg-shaped, triangular, ribbed, smooth, rather long-beaked, with a membranous nearly entire orifice, finally becoming inflated; ligilias three. Seed inversely egg-shaped, triangular. A native of woods but rare, flowering in May and June. 150. C. griffii, Wahlen. 129. "Spikes on naked peduncles, with fix loosely-set flowers; bristles sheathing, long, foliaceous, very remote; glumes cuspidate; fruit oblong-oval, triangular, rather acute; orifice quite entire; ligilias three. Native country unknown; preferred in the herbarium of Swartz. 151. C. caseacea, Wahlen. 87. Suter Flor. helv. 2. n. 57. Schkuhr tab. B b. fig. 117. "Spikes two-flowered at the base, male at the top; peduncles long, naked, flacid; bristles sheathing, long, foliaceous, remote; the lowest radical; fruit broad, inversely egg-shaped, roundish, ending in a point; ligilias three; male spike flacid; leaves narrow." A native of Switzerland. 152. C. capillaris, Linn. Sp. Pl. 28. Mart. 33. Lam. 44. Smith 25. Wahlen. 91. Schkuhr 82. tab. O. fig. 58. Flor. Dan. 168. Scop. Carn. tab. 59. (Cyperorides alpinum; Séguyer. Veron. vol. 3. tab. 3. fig. 1.) "Sheaths half the length of the peduncles; female spike egg-shaped, rather
rather loose, drooping: fruit acuminate. Root perennial, fibrous. Stem erect, from three to five inches high, roundish, slender, filiform, smooth. Root leaves sometimes not half the length of the stem, narrow, acute, flatish, rough on the edges towards the tip. Male spikes erect, linear, of a silvery-brown colour, with about ten flowers. Female spikes two or three, nodding or pendulous, egg-shaped, brown, with fewer flowers; all the glumes egg-shaped, brown, membranous and white at the tip. In an early stage of the inflorescence, all the spikes seem to proceed almost in an umbellate form from the sheath of a common bract each leaf which involves half the length of the peduncles; but as the fruitification advances, the stem elongates and each appears with its proper, but flatter, bracteal leaf and sheath. In this state it is figured in Flora Danica. Fruit egg-shaped, triangular, acuminate, a little inflated; ligaments three. Seed elliptical, acutely triangular. A native of mountains in Scotland and other parts of Europe. flowering in July and August. 153. C. exilis, Wahlen. p. 59. "Spikes thickish, short, rather densely flowered; peduncles long, naked, curved backwards; bracts loosely sheathing, foliaceous, dilated; glumes short; fruit oblong, attenuated, somewhat diverging; orifice oblongated; ligaments three; leaves hairy." A native of North America, preferred in the herbarium of Turner. 154. C. flexilis, Rudge. Linn. Tran. vol. 7. p. 98. Tab. 10. fig. 1. "Female spikes oblong-egg-shaped, pendulous; fruit egg-shaped, beaks acuminate." Stem flexilis, triangular, smooth. Leaves shorter than the stem, erect, thin, hairy at the edges and on the base. Male spike near an inch long, terminal, erect, slender. Female spikes three or four, on long peduncles, oblong-egg-shaped, finally pendulous, two near the summit of the stem; the others remote with longer bracteal leaves; glumes shorter than the fruit, egg-shaped, acute, hairy at the edge. Fruit oblong-egg-shaped, beaked, cloaked; ligaments three, glabrous. Seeds egg-shaped, triangular, smooth. A native of Newfound-land. 155. C. flexilis, Rudge in Linn. Transf. vol. 7. p. 97. tab. 9. fig. 2.) "Female spikes filiform, loose, pendulous; fruit oblong, with a long-pointed beak." Stem slender, filiform, triangular, angles not rough. Leaves longer than the stem, pale green, laciniate at the edge. Male spike terminal, erect, linear. Female spikes zigzag, about four, three near the top of the stem, the other remote; peduncles capillary; glumes oblong, smooth, acute, half the length of the fruit. Fruit oblong, with a long, slender, cloaked beak; ligaments three. 156. C. acuta, Linn. Sp. Pl. 75. Mart. 41. Gooden. 43. Smith 44. Wahlen. 136. Schkuhr 52. F. t. 52. b. (C. gracilis, Curt. Flor. Lond. tab. 6. - Mart. 96. C. verna x Lam? Gram. cyperoidaes majus angulifolium; Rai Syn. p. 417. n. 2.) "Digynous, spikes filiform; drooping in flower, erect in fruit; fruit elliptical, obtuse, entire at the orifice." Root perennial, creeping far. Stem varying in length with the moisture of the situation, sometimes two feet high and more, drooping at the summit when in flower, afterwards becoming erect, acutely triangular; angles rough. Leaves bright green, erect, curved near the tip, rough on the edges and keel. Spikes nearly feathery, filiform, slender, elongated, dense, many-flowered; glumes oblong, acute, awnless, black with a white nerve; male spikes two or three; female three or four, often with female flowers at the top, the lower ones at length becoming peduncled; ligaments two, white. Fruit infertile, elliptical, obtuse, compressed, ribbed, green, smooth, deciduous. Seed small, inversely egg-shaped, double-keeled, not triangular. Common on the banks of ditches and rivers, flowering in May. 157. C. pubescens, Gooden. 43. Smith 45. Eng. bot. 827. Wahlen. 127. Schkuhr 52. Vol. VI.

Spikes cylindrical, female one peduncled; sheaths very long; glumes pointed; fruit triangular, with a cloven beak.”

Root perennial, creeping. Stem erect, sometimes two feet high, triangular; angles smooth below, rough above the lowest spike. Leaves erect, narrow, glaucous, acute, rough at the edges and on the keel near the tip. Bractes foliacious, erect, narrow, the lowest often overlapping the flem; sheaths none. Male spikes two or three. rather remote, filiform, acute; glumes elliptic-lanceolate, blunt, brown, membranous at the edge, with a yellow keel. Female spikes two, rarely three, more than twice as long as those of veficaria, and much more flender, blunt, lower ones on short peduncles; glumes more acute than those of the male; figmas three. Fruit imbricated, spreading, longer than the glumes, almost globular, inflated, ribbed, smooth, yellowish, with a linear cloven beak. Seed small, elliptical, triangular, fellite, tipped with the long style. Common in Scotland and the northern countries, more rare in the south, flowering in May. 167. C. rostrulata, Wahlen. 75. (C. globularis, Vahl. Schkuhr 71. tab. G. fig. 93.) “Spikes on the peduncles, oval; bractes somewhat foliacious, dilatant; sheaths very short; glumes nearly as long as the fruit, obtuse; fruit somewhat globular, shining, acuminate, somewhat two-lipped; figmas three; flem round; leaves convoluted.” A native of sub-Alpine mountains in Lapland. 166. C. puri-

mala, Mart. 44. Lam. 43. (Wahlen. 71. Thumb. Flor. Jap. 59. Schkuhr tab. Y y. fig. 112.) “Male spikes two, terminal, fellite; female two, peduncled, oblong, erect.” Stem very short, scarcely any. Leaves linear, attenuated, convolute, smooth. Male spikes linear; the lower one half the length of the other. Female spikes smooth. Fruit smooth, inflated, egg-shaped, beaked; figmas three. Scarcely to be distinguished from C. veficaria, except by its almost total want of a flem, the spikes appearing to rise directly from the surface of the ground. A native of Japan. 167. C. birta, Linn. Sp. Pl. 37. Mart. 43. Lam. 61. Wahlen. 70. Smith 51. Eng. bot. 685. Schkuhr 105. tab. U. fig. 108. (Gram. cyper. Rai Syn. p. 418. n. 7. Morif. tab. 12. fig. 10.) “Hairy; spikes short, cylindrical, remote, sheaths nearly as long as the peduncle; glumes awned; fruit hairy.” Root perennial, creeping far, with downy fibres. Stem about two feet high, acutely triangular; angles rough. Leaves scarcely so tall as the flem, erect, flat, acuminate, more hairy underneath, rough at the edges; sheaths long, generally very hairy upwards, but in watery places they sometimes become smooth. Bracte like the leaves, as long as the flem; sheaths hairy, including nearly the whole peduncle. Male spikes two, rather remote, unequal in size, lanceolate; glumes egg-shaped, pointed, brown, hairy on the outside, with a yellow keel. Female spikes three, remote, peduncled, erect, cylindrical, short; rather loofe; glumes smooth, egg-shaped, with long awns, a broad membranous white edge and green keel. Fruit loosely imbricated, egg-shaped, acute, ribbed, hairy on both fides, somewhat beaked, deeply cloven; figmas three. Seed unevenly egg-shaped, triangular, tipped with the permanent style. Common in marshy ground; flowering in May and June. 168. C. fajfeiculata, Wahlen. 128. Link Flor. Luf. Schkuhr 99. tab. figmas three." A native of Portugal. 169. C. fliformis, Linn. Sp. Pl. 23. Mart. 27. Smith. 52. Wahlen. 77. Schkuhr (6), tab. K. fig. 43. (C. tomentosa, Linn. fid. Flora. 5. hirta, Flor. dan. tab. 570. exclusive of the separate spicke, which is C. hirta.) "Spikes egg-shaped; sheaths nearly as long as the peduncles; glumes pointed; fruit downy; leaves channelled, smooth." Root perennial, creeping. Whole herb smooth. Stem two feet high, erect, slender, round, smooth, ruff-like, except towards the top, where it often has three rough angles. Leaves upright, straight, narrow, channelled, without any sharp keel, pointed, rough at the edge. Bracteae like the leaves, overlapping the stem; sheaths short, but nearly as long as the peduncles, serried by small auricles. Male spikes two, rarely one, rather remote, unequal in size, lanceolate; glumes elliptic-oblong, rather acute, blackish, with a yellow nerve. Female spikes two, rarely one, rather remote, egg-shaped, erect; glumes like those of the male, but often slightly awned, smooth. Fruit imbricated, egg-shaped, ribbed, blackish, clothed with short, tawny down, ending in a short, close bead; figmas three. Seed elliptical, triangular, terminated by the short style. Dr. Smith, to whom we are almost entirely indebted for the specific characters and descriptions of all the British species. A native of England and Scotland, but rather rare, flowering in June. 170. C. gigantea, Rudge in Linn. Trans. vol. vi. p. 590. "Male spikes round, erect; females larger, turgid, fruit inflated, glom- bular, beaked, acuminate, spreading." Stem erect, tri- angular, smooth. Leaves broad, dark green much longer than the stem, bifid at the edges and on the keel, ribbed; spaces between the ribs knotty. Male spikes three; two upper ones near together; lower one more dilatant; glumes deeply imbricated. Female spikes three, far exceeding in size those of every other species; the upper one a little incurved, fiddle; the others alternate, pendulous, pendulous; flowers loosely imbricated, divaricated; glumes oblong-egg-shaped, awned, keeled, white and tender at the edge, half as long as the fruit. Fruit globular, much inflated, fritated, loosely imbricated, divaricated, beaked with a long awn; orifice with two teeth; figmas three; seed triangular, smooth. A native of Carolina. 171. C. paniculata, Wahlen. 131. Schreb. in Muhlen. Aéf. Amenc. "Spikes cylindrical; males se- veral; peduncles long, reclinat; bracteae partly embracing the stem, foliacces, dilatant; glumes terminated by a long serrated point; fruit roundish, pointed; orifice emarginate; figmas two; stem lax." A native of North America. 172. C. maritima, Wahlen. 132. Flor. dan. tab. 704. Schkuhr tab. W. fig. 74. "Spikes on long peduncles, pendulous, cylindrical; males several; bracteae partly embracing the stem, foliacces, dilatant; glumes with long points; fruit nearly orbicular, pointed; orifice emarginate; figmas two; leaves broadish." A native of the sea coast in Norway. 173. C. suspidata, Wahlen. 133. "Spikes on short peduncles, oblong-cylindrical; bracteae partly embracing the stem, foliacces, somewhat dilatant, remote from the male spike; glumes with rather long points; fruit somewhat orbicular, pointed; orifice emarginate; figmas two; leaves soft, a little incurved at the edges." A native of muddy shores in Norway. 174. C. rauben, Wahlen. 134. "Spikes on short peduncles, oblong-cylindrical; bracteae partly embracing the stem, foliacces, rather remote; fruit somewhat orbicular, rather large, pointed; orifice emarginate; figmas two; leaves soft, incurved at the edges; stem very long, nearly as equal in length to the sea-coast of Norway. 175. C. aquatica, Wahlen. 135. "Spikes on short peduncles, somewhat linear, thickened and club-shaped above; bracteae partly embracing the stem, foliacces, long, rather remote; fruit somewhat punctulate, rather small, pointed; orifice quite entire; figmas two; stem firm, obtusely angular; leaves stiff, incurved at the edges; the lowest stem, rather shorter." A native of the banks of rivers in Lapland. 176. C. hirta, Schkuhr tab. 51. fig. 64. "Spikes nearly sessile, stout, male linear; bracteae foliacces, dilatant; glumes rounded, rather thick, nearly as long as the fruit; fruit egg-shaped, slightly on both sides, rather acute; orifice terminated; leaves very narrow, somewhat convolute." A native of alpine marshes in Lapland. 177. C. hispida, Wahlen. 137. Schkuhr tab. 8; fig. 64. "Spikes nearly sessile, cylindrical, very densely flowered; males several; bracteae partly embracing the stem, foliacces, long, rather remote; glumes as long as the fruit, mucronate; fruit inversely egg-shaped, lupid at the edges, with a somewhat two-toothed limb.; leaves broadish." A native of Barbary. C A R E Y, in Geography, an island situated in the Persian gulf. CAREY, Henry, in Biography, a poet and musician, who, perhaps, among philosophers, men of science, and artists of the first class, may be deemed somewhat too factious to be allowed a record here. But as he had the power of exciting mirth without profanity, indecorum, or licentiousness, which none of his buffoon predecessors, such as Cor- nyfel, Coriat, Tom Brown, Tom D'Urby, George Alexander Stevens, &c., could do; we think that, at least as long as many of his works are still in use, he should not be plunged into the gulf of oblivion. For though he was not a deep musician, or a great poet, he had genius and abilities in both these arts sufficient to interest and amuse the public by his productions, if not in a sublime manner, yet in a way not disgraceful to himself, or his admirers. This being premised as an apology for the hero of this article, and for his biographers, we shall proceed to detail the principal events of his professional life.

Of his birth and parentage we know nothing; and of his education are only certain that he was not a regular bred musician. It has been said, indeed, that he had his first lessons from a German of the name of Wicheloom Lennert; that Rufingavre had been kind to him; and that he was, in some sort, a disciple of Gemminian. But the result of all these instructions did not, as his friend Lamp, a man of truth, used to say, enable him to make a bafe to his own ballads.

Poor Carey has been under-rated by his biographers, in ranking him as a man of humour, a writer of ballads, and an inventor of melodies, below Tom D'Urby. Carey's humour may sometimes be low, but it was never gross or immoral; and D'Urby's was nothing else. For in the fix volumes of "Pills to purge Melancholy," there is scarcely an innocent song to be found.

The first we hear of Carey was, that he produced two farces in the year 1715, one of which, the Contrivances, is said in the Biographia Dramatica, to be a very entertaining piece, which had good success in its day.

In 1730, it appears, that when Miss Rafter, afterwards the celebrated Mrs. Clive, first appeared on the stage of Drury-Lane as a singer, it was at the benefit of Harry Carey, who seems to have been her singing-matter; the manner in which this benefit was announced in the Daily Puf, December 3d, is so singular that we shall transcribe the paragraph for the amusement of our readers. After naming the play, which was Greenwich Park, and the additional entertainments of singing; particularly a dialogue of Purcell by Mr. Carey and Miss Rafter, and a cantata of Mr. Carey's by Miss Rafter, there is an apology from Carey, for "the true
edly of half an act,” not being performed; but a promise is made of indemnification by the entertainments between the acts. The editor of the paper then adds; “but at our friend Harry Carey’s benefit to-night, the powers of music, poetry, and painting, assemled in his behalf, he being an admirer of the three fitter arts; the body of musicians meet in the Haymarket, whence they march in great order, preceded by a magnificent moving organ, in form of a pageant, accompanied by all the kinds of musical instruments ever in use from Tubal Cain to this day; a great multitude of bookfellers, authors, and printers, form themselves into a body at Temple-bar, whence they march with great decency to Covent-garden, preceded by a little army of priests and devils, with their proper instruments; here the two bodies of music and poetry are joined by the brothers of the pencil; when, after taking some refreshments at the Bedford Arms, they march in solemn procession to the theatre, amidst an innumerable crowd of spectators.”

Poetry and music, in high antiquity, formed but one profession, and many have been the lamentations of the learned that these fitter arts were ever separated. Honest Harry Carey and Jean Jacques Rousseau are the only bards in modern times who have had the address to reconcile and unite them. The Honefl Yorkfircman of Carey and the Devin du Village of Rousseau are indisputable proofs that popular brains, at least, if not learned and elegant music, may be produced by the writer of a dramatic poem. Carey, without musical learning, invented many very pleasing and natural melodies, which neither obscured the sense of the words, nor required much science to bear. But either from the ambition of the figner, or expectations of the audience, music is not suffered to remain simple long upon the stage; and the more plain and ancient the melodies, the more they are to be embellished by every new performer of them. The tunes in the Beggar’s Opera will never appear in their original simple garb again.

In 1732, he produced the words of two serious operas; Amelia and Taraminta. The firit of these was let by Lampe, and the second by the late Mr. Smith, Handel’s disciple, friend, and successor, in superintending the performance of oratorios.

In 1734, his mock tragedy of half an act, called Chrono- Ilagonologus, was first performed at the little theatre in the Haymarket; a piece of humour that will always be in fashion, as long as extravagance and bombast shall dare to tread the stage.

In 1736, and for several subsequent years, his little English opera, entitled The Honefl Yorkfircman, was almost always in conflagrant run. The year 1737 was rendered memorable at Covent garden theatre by the succefs of the burlesque opera of the Dragon of Wandefty, written by Carey, and fet by Lampe, “after the Italian manner.” This excellent piece of humour had run twenty-two nights, when it was stopped, with all other public amufements, by the death of Majefly Queen Caroline, November 30th, but was resumed again on the opening of the theatres in January following, and supported as many representations as the Beggar’s Opera had done, ten years before. And if Gay’s original intention in writing his musical drama was to ridicule the opera, the execution of his plan was not fo happy as that of Carey; in which the mock heroic, tuneful moniter, recitative, splendid habits, and style of music, all conpired to remind the audience of what they had been and heard at the lyric theatre, more effectually than the most vulgar street tunes could do; and much more innocently than the tricks and tranfactions of the molt abandoned thieves and profi!itors. Lampe’s music to this farceal drama, was not only excellent fifty years ago, but is still modern and in good taste.

In 1738 Margery, or the Dragoon; a sequel to the Dragon of Wandefty, written with equal humour, and as well fet by Lampe, came out; but had the fate of all sequels. When the novelty of a faulted is faded away, and the characters have been developed, it is difficult to revive the curiosity of the public about persons and things of which opinions are already formed. The Dragonfis appeared but few nights, and was never revived.

Name, or the parting Lovers, was produced after these, and likewise fet by Lampe; but the occasional songs and aulitas in which he wrote and fet to music himself, are innumerable. His burlesque birth-day ode, turned the odes of Cibber into ridicule as effectually as Pope’s Dunciad could do. And his ballad of Sally in our Alley, had the honour of being praised by Addison for the poetry, and Geminius for the tune. But though poor Carey was a successful poet and musician, he was always indigent and heavy on the hands of his friends. He seems to have been professionally active, he taught music at small boarding schools and private houses upon low terms, and had no particular vice or extravagance laid to his charge; but whether his embarrased circumstances, domestic unhappiness, the malignity of rival but less successful writers, or from whatever cause, in a fit of infancy or defpondency, Oct. 4, 1743, at his houfe in Warner Street, Cold bath fields, he terminated with a cord a life which he had innocefly, and not unfeafly, spent.

This precise date of his fatal catastrophe totally invalidates the claims that have been made of late by his fon for the honour of having written and fet the loyal and national song at the time of the rebellion in 1745, God save great George our King! which we have cogent reasons to believe was written for king James II, while the prince of Orange was hovering over the coast. And when he became king, who durst own or fign it? We are certain, that in 1745, when Dr. Arne harmonized it for Drury lane theatre, and C. B. for Covent-garden, the original author of the melody was wholly unknown.

Carey’s, chicken, or geese, Mother, in Ornithology. See Procellarta gigantea.

CARRA, in Geography, a town of Arabia; 175 miles N.W. of Janam.

CARRAFANO, or CASTEL-NUOVO DI CARFAGNANO, a town of the duchy of Modena, and capital of a lordship, which is partly in the Modenese, partly in the Bolognese, and partly in the republic of Lucca; 18 miles N. of Lucca, and 37 S.S.W. of Modena.

CARGADORS, a name given by the Dutch to a kind of brokers, who make it their fole business to find freight for ships which want lading, and vessels for merchants or passengers who want conveyance to fuch or fuch a place.

CARGO, the lading or freight of a ship. See Freight.

CARGO, portly, is that which contains something of every fort necessary to furnish the tmaders of the place it is fent to, with parcels fit to fill their foops, and invite their customes. Officers and tailors on board a veffel are allowed to carry a small cargo, or “paccoletti,” not exceeding a certain bulk or weight, for their own account, without paying any freight.

CARGO is sometimes alfo ufed for an invoice of the goods wherewith a ship is laden. See Invoice.

CARGO also denotes a weight ufed in Spain and Turkey, amounting to about 300 English pounds.

CARGO in Geography, a small island in the Persian gulf, near the coast of Farivatan.
CARHAIX, a town of France, in the department of Finisterre, and chief place of a canton in the district of Chauny, situated on the Yer, in a fruitful country, that feeds great numbers of cattle, with plenty of game; 64 leagues S. of Morlaix. The place contains 1734, and the canton 13,164 inhabitants; the territory comprehends 32,854 square kilometres and 9 communes.

CARHAM, a village of England, in the county of Northumberland, which defers notice on account of the singular events that have occurred in its vicinity. Near this place a battle was fought between the English and the Danes, in which 11 bishops and 2 English counts were slain, besides a great number of soldiers. Here likewise was fought, in 3518, a battle between the English and the Scots, in which the latter were victorious. In the 74th year of Edward I. an abbey was burned here by the Scots, under the command of Wallace; and in the 44th year of Edward III, 1370, Sir John Lilburn was defeated near this place by the Scots, under the command of Sir John Gordon, and taken prisoner with his brother. Carham is distant 5 miles E. of Kello, and 28 N.W. of Alnwick.

CARIA, in Ancient Geography, a province of Asia, occupying the south-western part of Asia Minor, or Anatolia. It is bounded on the north by Ionia, Lydia, and the river Meander, which separated it from Ionia; on the east by Great Phrygia and part of Lydia, its natural boundaries being high mountains; and on the south and west by the sea. Geographers, however, are not agreed about its precise limits. Their different opinions may be seen in Cellarius's Ancient Geography. This country was for some time called Phoenicia, because the Phœnicians had considerable establishments in it; but it is said to have taken the name of Caria from Car, the brother of Lydos; and it comprehended a small province, forming a kind of peninsula towards the south-west, called Doris, which see. The interior of this country presents some chains of mountains; the chief of which were Latmus, on the west towards Miletos, and the Montes Calendici, towards the south-east near Calinda. The principal towns of Caria were Miletos, Myndus, Halicarnassus, Cenamus, Bergafa, and Cnidus, which were situated along the western coast. The Rhodians possessed a part of this country towards the south, under the name of Perae, which see. In the interior of the country are found Alabanda, Apollonia, and Antiokia ad Meandrum, Aphrodias, Stratonece, Alinda, Pedasus, and, towards the south, Carinus, Calinda, &c. Caria was less cultivated than it might have been, because the inhabitants employed themselves very much in maritime concerns. Its mountains, however, furnished numerous flocks, and its wool was held in high estimation.

The Carians claimed the honour of being aborigines, (though some authors ascribe their origin to the Pelasgi, and others to the Cretans), and traced their name and origin to Car, the brother of Lydos and Myfus; and they thought this genealogy was confirmed by the antiquity of the temple of Jupiter the Carian, built at Mylasa, where, from time immemorial, they assembled in common with the Lydians and Myfians. Hence they concluded that they had the same ancestors with these people, according to the report of Herodotus. Homer, says Stephanus Byzantinus, represented the Carians as barbarians, because they were enemies to the Ionians; but the epithet ἄραξασικος, which this ancient poet applies to them, shews, that he referred to their language, and not to their political conduct. The Carians multiplied themselves to such a degree under the government of the descendants of Car, that they extended their establishments to the neighbouring islands. Accordingly they took possession of the isle of Rhodes, belonging to the Phœnicians, and thus the seer of this warlike nation to the other islands of the Aegean sea was completed. Thus relates Minos II. drove the Carians from the island of Erythrae; but Herodotus informs us, that Minos allowed them the possession of these islands, together with unconfined liberty to cultivate them, and an exemption from tribute, on condition of their furnishing his fleet with a number of vessels. In process of time different colonies of Carians were introduced into Caria, and the original inhabitants were obliged to retire into the mountains, and to fortify themselves against the attacks of their enemies. At length the fertile soil of their mountains retreated reduced them to a state of poverty, which ruined their courage; and they conformed vessels and traversed the sea, and thus acquired a degree of power, which gave them the rank of a maritime empire. Lauchus refers this period to the interval that elapsed from the 11th to the 27th olympiad. Diodorus Siculus fixes the epocha of the maritime power of the Carians immediately after the taking of Troy, and pretends, that by means of their vessels they got possession of the isle of Lycus. Herodotus says, that they very much contributed to the perfection of the military art by their ingenious inventions. The Carians, who were both a maritime and military people, affixed in establishing Pharnacesius on the throne of Egypt, and he recompensed their services in a very liberal manner. Thus attached to the interest of his house, they succoured Apricus, the last of the descendants of this prince, when Egypt attempted to emancipate themselves from his power, and for some time resisted the attacks of all his enemies; but when Apricus fell, they were obliged to submit to the conqueror. Amanis, conscious that they would afford him very considerable support, engaged them in his cause, by assigning to them a territory in the district of Memphis, the capital of his dominions. They evinced their attachment to Pharnacesius, the son and successor of Amanis, when Cambyses undertook the conquest of Egypt. Accordingly they joined his army; but when the Persians proved victorious, the surviving Carians retired into their own country, which had suffered much from its contests with the kings of Lydia. Alyattes was the first of all the successors of Gyges who formed the project of reducing the Carians to his dominion; but he probably did not succeed, as Herodotus reckons Caria in the number of the provinces annexed to the empire of Lydia by the arms of Cyrus. After various struggles in defence of their country and their liberty, they were at last obliged to submit to the Persians, upon the reduction of Miletus. In the expedition of Xerxes against Greece, the Carians assisted him with 70 vessels, which were annexed to his naval armament. Lydamis, to whom, according to Pausanias, the Lacedemonians erected a statue, ascended the throne of Caria towards the 85th olympiad, and was succeeded by Hectoramus, who made Myfusa the capital of his kingdom. He was allowed by the Persian court to possess the kingdom of Caria till his death, which happened in the 99th or 100th olympiad. His successors reigned 42 years. Artemisia, the second of that name, married Mavolus her brother, according to Arrian, who pretends that custom authorized such marriages in Caria. This prince reunited the whole of Caria under his dominion, and fixed his residence at Halicarnassus, which surpassed in magnificence all the cities of Caria. Mavolus made successful attacks on the Ionians, Lydians, and Lycians; and under his conduct the Carians got possession of the island of Rhodes. At the death of Mavolus, in the 4th year of the 106th olympiad, B.C. 353, the Rhodians threw off the yoke of the Carians; but Artemisia, the sister and widow of this prince, reduced them to their allegiance, and
and also the inhabitants of the island of Cos, who had imitated their neighbours in their revolt. At the death of Artemisia, Idrieus assumed the reins of government, and when he died, the Carians conferred the crown on Ada, his sister and wife. Diodorus Siculus says, that the Persian king gave the inviolability of the kingdom to a fatrap; but Ada courageously refuted him, and at length, deprived of her dominions, the retired to the fortress of Alinda, which she maintained till the arrival of Alexander in Asia. When Alexander had gained the battle of the Granicus, he penetrated into Caria, and re-established Ada in possession of her kingdom. Arrian says that Ada adopted Alexander; but Plutarch conjectures, that this conqueror adopted Ada, and always called her his mother.

Cariana, a town of Asia Minor, in a country of the same name. Ptolemy places it in Lycia. Caria was also an episcopal town of Asia, placed upon the Maeander.

Caria, a name given by Arrian to a maritime country of Scythia, on the Euxine sea. It was an establishment of Carians, on this side of the Dorylithenes, and at a distance from the Tanais.

Caria, in Entomology, the name by which several travelers distinguished those Mishicous insects that infest the East Indies, Africa, and other parts of the world, and which are known among modern naturalists by the name of Termites, and white ants. See Termes.

CARIABAD, in Geography, a town of Hindooftan, in the foubah of Oude; 40 miles N. of Lucknow.

CARIACO, a large gulf in the province of Comana, Terra Firma, South America. On the northern side at its mouth is Fort St. Yago, in N. lat. 10° 7', W. long. 63° 30'; and on the southern side cape Bordones.

CARIACOU, the chief of the small islands dependent on the island of Grenada, in the West Indies; situated about 4 leagues from the Rosene, which is equally distant from the north end of Grenada. N. lat. 12° 30'. W. long. 61° 22'. It contains 6013 acres of land, and in general is fertile and well cultivated, producing in feasonable years a million of pounds of cotton for exportation, besides corn, yams, potatoes, and plantains sufficient for the maintenance of its negroes. The cultivation of sugar has been found less successful in this island than cotton, though it still continues to be made on two plantations. The number of inhabitants in 1779 was 5000; but they have since decreased. See Grenada. Caracci forms a 7th parish belonging to Grenada; and by an act passed in 1784, a bishop is provided for a clergyman in this parish. The parish town of this island is Hillborough.

Cariacou, in Zoology, a species of Cervus, which see. CARIAMA, in Ornithology, the name of a Brazilian bird, described by Marcgrave in his History of Brazil; this is the crested feremacc, Patandra cribrata of modern naturalists.

Carianers, Carayners, in Geography, a people of singular description that inhabit different parts of the Birmian empire, particularly the western provinces of Dalla and Baffien; several societies of whom also dwell in the district adjacent to Rangoon. None of them are to be found higher up than the city of Prome. They are a simple innocent race, speaking a language distinct from that of the Birmans, and entertaining rude notions of religion. They lead altogether a pastoral life, and are the most industrious subjects of the flat: their villages form a fetch community, from which they exclude all other sects, and never reside in a city, nor intermingle, nor marry with strangers. They profess, and strictly observe, universal peace, not engaging in war, nor taking part in contests for dominion; and thus they are placed in a state of subjection to the ruling powers. Agriculture, the care of cattle, and the rearing of poultry, are almost their only occupations. A great part of the provisions consumed in the country is raised by the Carians, who particularly excel in gardening. The oppression which they have lately suffered has induced numbers of them to withdraw into the mountains of Arracan. They have traditional maxims of jurisprudence for their internal government, but they are without any written laws; custom, with them, constitutes the law. Some of them learn to speak the Birmian tongue, and a few can read and write imperfectly. They are timid, honest, mild, in their manners, and very hospitable to strangers. Symes's Embassy to Ava, vol. ii. p. 100.

CARIATA, in Ancient Geography, a town of Asia, in Castriana, destroyed by Alexander.

CARIATI, Nuisa, in Geography, a town of Naples, in the province of Castralia Citra, situated on the S.W. coast of the gulf of Tarento; 25 miles N. of St. Severino, N. lat. 39° 58'. E. long. 16° 6'. At the distance of 2 miles S.W. of the former is Cariati Vecchio, in the same province, the seat of a bishop, suffragan of St. Severino. It is farther from the sea, towards the river Caneta. Cariati is a principality belonging to the family of Spinelli, one of the most opulent feudal families, divided into several branches, and possessed of very capital hills in Castralia. The founder of this family was John Battist Spinelli, who was very much distinguished by Ferdinand the Catholic, on his arrival at Naples, and enabled to purchase Cariati and other considerable estates, since augmented by the prudence of his descendants. The city is small, and thinly inhabited, on account of the weakness of its situation, and dread of the Turks, who, before a treaty was concluded with the Porte, were continually ravaging this coast. Its cathedral is a very heavy Gothic structure, dedicated to St. Peter, and the only parish. The surrounding hills are gay, and pleasingly covered with fruit-trees; the woods behind them produce manna of excellent quality; much Turkey wheat is cultivated in the lands below, and extensive patters afford luxuriant and wholesome fulness to a great flock of oxen, buffaloes, sheep, goats, and llamas.

CARIATIDES, or Cariates, in Architecture. See Caryatides.

CARIBALDI. See Caribaldi.

CARIBBEAN sea, in Geography, that part of the Atlantic ocean, which is bounded on the north by the islands of Jamaica, St. Domingo, Porto Rico, and the Virgin islands, on the east by the Caribbean islands, on the south by the country of Terra Firme, and on the west by the Musketto shore.

CARIBBEE islands, a range of islands extending in a kind of semicircular form, from Tobago in the south, to Porto Rico in the north, and enclosing as it were between them and the main land the Caribbean Sea. They were discovered by Columbus in his second voyage, in November, 1493; and thus called by him from the name which the natives of Hispaniola gave to their ancient poecellers. The term Caribbee or Charliean is rigidly applicable only to the windward islands, which were inhabited by the Caribbees or Charrabaes; and the four large islands of Cuba, Jamaica, Hispaniola, and Porto Rico, are denominated leeward islands. But English mariners appropriate both terms to the Caribbean islands only, subdividing them according to their situation in the course of the trade wind; the windward islands terminating by their arrangement with Martino, and the leeward commencing at Dominica, and extending to Porto Rico. The Caribbean islands are eminent-
CAR

int ier, and in a commercial view highly advantageous; their chief poiffons are the English and French. Barbadoes, Antigua, St. Christopher's, St. Vincent, Dominica, Grenada, Montserrat, Nevis, and the Virgin isles are British; and the French poiffons Martinique, Guadalupe, St. Lucia, Tobago, and some isles. To the Danes belong St. Croix, St. Thomas, and St. John, parts of the Virgin group; the Swedes hold St. Bartholomew; and the Dutch St. Eustatius. Of the whole group lying between the 55th and 60th degrees of W. longitude, and the 15th and 16th degrees of N. latitude, Barbadoes and Guadalupe are the most important; and the latter, including Grand Terre, and Baffle Terre, is the most considerable in size. For a farther account of each isle, see its appropriate article.

CARIBBEES, or CHARAIBES, the ancient poiffons of most of the isles above mentioned. Columbus in his first voyage received information, that several of these isles were inhabited by a people of this name, who were fierce, bavage, and predatory, the terror of the mild and inoffensive inhabitants of Hispaniola, and who delighted in the horrid banquet of human blood. In his second expedition, he found this information to be just, and was himself a witness of their trepid value. In their habitations, when he landed at Guadalupe, he found relics of those feasts which they had made upon the bodies of their enemies taken in war; and at the same time, he released several of the natives of Porto Rico, who, having been brought captives from thence, were released as victims for the fame horrid purpose. See CARRIBAL. The fame character for value and intrepidity has been invariably maintained by these people in all subsequent contests with the inhabitants of our continent; and even, in our own times, they have made a gallant stand in defence of the large territory which the rapacity of the Europeans had left in their poiffon. M. de Chanaval, an intelligent and philosophical observer, who visited Martinique in 1751, and resided there six years, gives the following description of the Caribbees. "It is not the red colour of their complexion, it is not the singularity of their features, which constitutes the chief difference between them and us. It is their execrable simplicity; it is the limited degree of their faculties. Their reason is not more enlightened or more provident than the instinct of brutes. The reason of the most gross peasants, that of the negroes brought up in the parts of Africa most remote from intercourse with Europeans, is such that we discover appearances of intelligence, which, though imperfect, is capable of increase. But of this the underdaunting of Caribs seems to be hardly susceptible. If found philosophy and religion did not afford us their light; if we were to decide according to the first impression which the view of that people makes upon the mind; we should be disposed to believe that they do not belong to the same species with us. THEIR RUPID eyes are the true mirror of their souls; it appears to be without functions. Their indolence is extreme; they have never the least politeness about the moment which is to succeed that which is present." Voyage à la Martinique, p. 44, 45, 51. M. de la Borde, Terre, and Rochefort, confirm this description. Mr. Edwards (ubi infra) very properly observes, that M. Chanvalon seems to have formed his judgment of all the Charaibes from the few with whom he had any communication, and that he makes no allowance for their degradation in a state of captivity and servitude; though he admits this circumstance and wrongly urges it in favour of the African blacks in the West Indies. The Caribbees evidently appear by the marked distinction of their character to be a separate race from the inhabitants of the larger islands. Their language is totally different; and among themselves, they have a tradition, that their ancestors came originally from some part of the continent, and having conquered and exterminated the ancient inhabitants, took possession of their land, and of their women. Hence they call themselves "Babares," which signifies a man come from beyond sea. Accordingly, the Caribbees hold two distinct languages, one peculiar to the men, and the other to the women; nor has the language of the men any thing common with that spoken in the larger islands; whereas the dialect of the women confiderably resembles it. The tradition derives from this circumstance considerable confirmation. The Caribbees themselves imagine, that they were a colony from the "Gallis," a powerful nation of Guiana, in South America. But as their fierce manners approach nearer to those of the people in the northern continent, than to those of the natives of South America; and as their language has some affinity to that spoken in Florida, their origin should be deduced rather from the former than the latter. In their wars, they still observe their ancient practice of destroying all the males, and preferring the women either for servitude or for breeding. Rochefort in his account of the Antilles, published in 1698, conjectures, that they sprang originally from Florida, and describes them as a colony of Appalachian Indians, who, being driven from the continent, arrived at the windward islands, and exterminating the ancient male inhabitants, took possession of their lands, and of their women. But being unable to subdue the inhabitants of the larger islands, these retained their distinctive manners and character. Mr. Edwards agrees in opinion with thofe, who trace their origin to a South American colony. To this purpose he says, that there anciently existed many numerous and powerful tribes of Charaibes on the southern peninsula, extending from the river Oronoko to Effegubes, and throughout the whole province of Surinam, even to Brazil, some of which still maintain their independence. With one of these tribes Sir Walter Raleigh formed an alliance, in his romantic expedition to Guiana in 1595; and he affures us, that the Charaibes of that part of the continent spoke the language of Dominica. Mr. Edwards, indeed, inclines to the opinion of Hornius, who assigns to these people an oriental ancestry, that migrated to the west across the Atlantic; and in confirmation of this opinion he alleges a similitude in the language of the Charaibes to the ancient oriental dialects, and also a striking resemblance in their customs and manners to those of the inhabitants of the east. The word "Charaibe," he says, in the Arabic language, signifies a robber or despoiler, an appellation frequently bestowed by the natives on the invaders of their country. As there were priests or prophets in Brazil under the appellation of Charaibes, they might have been called בֶּרֶב, as men who offer בֶּרֶב, corban, an offering (see Lev. i. 2); and καρπίας is the Greek for a priet of Cybele, or one of the Corybantes. But if the national name be derived from the warlike and predatory life of the Charaibes, we may derive it from בֶּרֶב, signifying in Syr. and Arab. to lay waste. The noun denotes a sword or spear, and בֶּרֶב Sam. war.

Mr. Edwards has given us an highly interesting description of these savages; their national manners, habits, education, and such political and religious institutions as savages could fabricate; of all which we shall present our readers with the following concise epitome, referring to the author himself (ubi infra) for a more ample detail. Every trait in the character of a Charaibe marks him for a foreigner. The antipathy which this fierce race bears to the unoffending and more cultivated nations of the larger islands of Hispanic,
paniola, Cuba, and Jamaica; his robust and muscular form, his towering, independent spirit, disdainful of restraint, and impatient of calamity; his dreadful feat on the human flesh of captives, whilst towards his own brethren he is faithful, kind, affectionate, and peaceable; and the incitement which he makes on his fearrified, panting alternately with black and crimson, to render him terrible to his enemies in battle:—all conspire to proclaim him an exotic, transplanted either by design or accident from some distant clime, and bearing with him to his new abode the internecine impositions of his primitive age. A Charaibe youth is educated amidst accumulated toils and sufferings. One of the earliest maxims inculcated on his tender mind was to bear exquisite pain without murmuring:—like the Spartan youth at the altar of Diana, he was scourged until agonizing nature was nearly exhausted; but no light was heard, no tear was seen to fall; for, if the severities which he suffered occasioned the least sign of weakness or sensibility, he was disgraced for ever. Public honours and national rewards crowned the fortitude that never shrunk from inflicted torture:—above all things, he was taught to cherish an inexorable hatred, and an intractable thirst of revenge, against his natural enemy, the Arrowawks (which see), the inhabitants of Hisp aniola, Cuba, and Jamaica. When more mature years called the Charaibe to the field, stripes, burning, and flogging, constituted the trial of him who was to lead the national troops to action. His heart thus hardened, and his nerves thus fledged, he beheld the unbounded carnage of his foes without the least remorse, nor checked his savage squadrons in the career of their fanatical vengeance. Of their political maxims, one very prominent but disgusting feature is displayed in that abortive villainy in which the Caribbes keep their women. They are mere household drudges through life, and are denied even the privilege of eating in the presence of the tyrant husband. Mr. Edwards, on this subject, very justly oberves, that the first visible proof that a people are emerging from savage manners is a display of tenderness towards the female sex. As the successful warrior was allowed to appropriate to himself as many of the captives as he thought fit, and his countrymen presented to his choice the most beautiful of their daughters in recompense of his valor; this last mentioned testimony of public esteem and gratitude probably gave rise to the institution of polygamy, which prevailed universally among the Charabes, and still prevails among those of South America. This institution, says Mr. E., is the more excusable, as their women, from religious motives, carefully avoided the nuptial intercourse after pregnancy. Their females, on attaining the age of puberty, were distinguished by a sort of bulky, or half boot, made of cotton, which surrounded the snall of each leg. In other respects both males and females appeared naked. Their hair, which was of a shining black colour, was dressed and adorned with peculiar attention; and the men, in particular, decorated their heads with feathers of various colours. On the death of a relation or friend, they cut it short like their flaves or captives, to whom the privilege of wearing long hair was rigorously denied. Like most other nations of the New Hemisphere, they nicely eradicated the incipient beard, and all foppish hairs on their bodies. On the birth of a child, its head was confined between two small pieces of wood, placed one before and the other behind, which, being firmly bound together, elevated the forehead, and occasioned this and the back part of the skull to resemble two sides of a square. They resided in villages, which resembled an European encampment; and their cabins were built of poles fixed circularly in the ground, drawn to a point at the top, and covered with leaves of the palm tree. In the centre of the village was a building, larger than the rest, which served as a kind of hall, or state house, where their youth were educated to emulation, and trained to martial enterprise by the renown of their warriors, and the harangues of their orators.

Few arts and manufactures can be supposed to flourish among savages: yet the Caribbes ingenuously manufacture a subtilisn kind of cotton cloth, which they spin with various colours, and of which they make kamosos, or hanging-beds; they also fabricate ornamental veils of baked clay; they work very elegant balusters of the fibres of the palmetto-leaf; and their bows and arrows are slighlty with circular flint and neatness. Among the Caribbes of the continent, there was no division of land, every one culti-

vating in proportion to his exigencies. Their food, both vegetable and animal, except in the circumstance of their eating human flesh, seems to have been much the same with that of the natives of the larger islands. However, they held the flesh of some animals in abhorrence; such as that of the peccari, or Mexican hog, the marmot or fox-sow, and the turtle. They frequented also to eat the ed, abundantly sup-
plied by several of their rivers. In some of these respects they manifested a conformity to the customs of the Jews. It is a singular circumstance, that on the birth of the first for the father retired to his bed, and failed with a fraticellus that often endangered life. A similar practice has been recorded concerning the Tybarenians of Africa, and the Iberians of Spain, and is still obsered by the people of Japan. This ceremony of fathering was succeeded by rejoicing, drunken-
ness, and debauchery. They indulged extraordinary grief for their dead; they not only deplored their hair, but when the master of the family died, the surviving relations, after burying the corpse in the centre of his own dwelling, with many demonstrations of unaffected grief, quitted the house altogether, and erected another in a distant situation. It was their custom to place the dead in the grave in a sitting posture, with the knees elevated to the chin. As to their religious opinions and practices, we may observe, that they entertained the expectation of a future state, and pleaded themselves with the fond conceit that their departed relatives were secret speculators of their conduct, sympathizing in their sufferings, and participating in their welfare. But regarding the soul as incapable of the fame impressions and obnoxious to the fame passions, as when allied to the body, they deemed it a religious duty to their deceased heroes, to sacrifice at their funeral. Some of their captives which had been taken in battle. Immortality, without military glory, was considered by them as a curse; to the brave and virtuous, as to their wives and captives, they allotted a kind of Mahometan paradise; but to the degenerate and cowardly they sighed a fate of punishment somewhere beyond the mountains, and an ignominy aggravated by captivity and servitude among the Arrowawks. The life of the Charaibe is not passed without acts of devotion paid to the universal Father. In every cottage is erected a rustic altar, compo-

sided of banana leaves and reeds, on which they offer to the Deity the earliest of their fruits, and the choixeit of their provisions. His religion, in fact, however, is a religion of horror; in part, perhaps, the result of the tremendous irregularities of the climate. They mark an avenging deity, amid the madnes of the hurricane, and amid the convulsions occasioned by frequent earthquakes. In the loud thunder of the tropic, the voice of the incensed deity is heard, while his arm in imagined vengeance launches the lightning which fires the flailng fields of corn, and ampi-

hilitates the proming barrel. Accordingly, besides the
writings which they paid to beneficent deities, they not only believed in the existence of demons and evil spirits, but offered to them also by the hands of their "Boyex," or pretended magicians, sacrifices and worship; wounding themselves, on such solemnities, with an instrument made of the teeth of the augurs, which inflicted horrible gashes; conceiving, perhaps, that the malignant powers delighted in groans and misery, and were to be appeased only by human blood. (Robertson's America, vol. ii. Edwards's Hill of the Well Indians, vol. i.)

CARIBBEAN. See Paria and New Andalusia.

CARIBOU, an island towards the call end of Lake Superior, in North America, S.W. of Montreal bay. N. lat. 47°, W. long. 83° 30'.

CARIBOU, in Zoology, an American animal of the flag kind. See Cervus carbon.

Gen. Ch. Male. Col. very small, with five teeth. Cor. monopetalous, funnel-shaped; tube slender, long, gradually flattened downwards; border five-cleft; segments lanceolate-linear, obtuse, obliquely and spirally revolute. Stamina ten, at the top of the tube of the corolla; five alternate one shorter; anthers oblong. Female. Cal. persistent small, five-toothed, permanent. Cor. pentapetalous. Linn. Gart. five-cleft, Jiff. Vent. Linn. petals or segments lanceolate-linear, very long, erect below the middle, reflected and twisted above. Pyg. germ superior, egg-shaped; styles short; stigmas five, oblong, expanding; widened, truncate, and crenulate at the summit. Fr. ric. berry large, five-furred, one-celled, fleshy. Seeds numerous, attached to five receptacles in the middle of the berry, obovate, egg-shaped, pointed, encloled in a brittle, wrinkled tunic or aril.

Species. 1. C. papaya. Linn. Sp. Pl. (C. vulgaris, B. Lancy. Meth. Papaya caraica, Gart. tab. 137. fig. 2. Linn. Milt. Pl. 81. Papaya-marmal, Rheem. Mal. tab. 15. fig. 1. Ambapaya, tab. 15. fig. 3. Abbrev. of Carib.) Common papaya tree. "Loches of the leaves flattened." Somewhat the habit of a palm. Rost perependicular, whitish, spongy, of a disagreeable taste and smell. Stem twenty feet high; a foot thick; naked almost to the top, marked almost its whole length with the scars of fallen leaves, of a tender sub-tance like that of the banana, solid towards the base, hollow in its upper part. Leaves on petioles near two feet long, the lower ones almost horizontal, upper ones erect, deeply divided into seven, nine, or eleven, sinuate and garded lobes, alternate, near together. Flowers axillary, white, sweet-scented; male in slender, pendulous racemes, two or three feet long; pedicell short; females numerous, on short simple peduncles. Fruit about the size of a small melon; various in its form, sometimes angular, and flattened at both ends, sometimes oval or round, and sometimes pyramidal, yellow when ripe; containing a yellow succulent pulp of a sweetish taste and aromatic smell. It is seldom eaten raw, but, when boiled, is esteemed a wholesome sauce to any kind of flesh meat. It is also sometimes pickled in vinegar, and is frequently preferred in sugar, and sent to Europe with other tropical sweetmeats. When ripened in our stores, it does not acquire its proper flavour, and is even bad by Miller to be detectable. The whole plant abounds with a saucy sound Jude. Male flowers are occasionally found on the female plants, and female on the male ones. A native of both the East and West Indies. 2. C. papaia. Linn. Sp. Pl. Efl. Pte. tab. 39. fig. 1. "Loches of the leaves entire." Stems more frequently branched than that of the preceding. Leaves less divided, and often entire. A native of Sumatra and Peru. 3. C. fiesieta, Gmel. Syn. Nat. F. B. Lancy. Method. Abb. Guian. ii. p. 918. tab. 346. "Leaves simple, leaflets quite entire; stem with laminated leaves." Fruits branched at base to less than a third of its height. Leaves fivelug, smooth, pointed, green above, whitish underneath. Berry yellow, egg-shaped, smooth, marked with several longitudi- nal furrows; fleshy yellow, succulent. A native of Guiana and Brazil.

The shrill species only has been cultivated in Europe. It is easily propagated by seeds brought from its native climate, which should be sown in a hot bed early in the spring. When the plants are near two inches high, they should be transplanted separately into small pots filled with a light, gentle, loamy soil, and plunged into a hot-bed of tamer's bark. As they advance in growth they will require larger pots and when they are too tall to remain under frames, they must be placed in the tan-bed of the frove, where they will grow to the height of near twenty feet in three years, and produce flowers and fruit. In every period of their growth they should be sparingly watered. Mart. Mil.

N. B. The amona triboba, trifid frutet cufland-apple, is also called the papaw-tree in the southern states of North America.

CARICA, among Ancient Naturalists, denotes a kind of fig peculiar to Syria; sometimes also the dried fig. It is also used in ancient writers to denote the fruit of the palm tree, otherwise called cariotes, which was fent annually to clients on New Year's day, as a present or acknowledged by their patrons.

CARICA, in Zoology, a species of Mures, which fect.

CARICATO, had loaded: a term in Mijus, usually applied to the base finger in an Italian biricella. as Baffo caricato; to a long of which the accompaniments are too full; or to any thing crowded or overcharged. See Charge.

CARICATURA, in Painting, a loading, or exaggeration of the defects of an object represented, with a concealment of the beauties or advantages of it; yet so as to preserve a resemblance.

The word is Italian, formed of carica, a load, burden, or the like.

CARICOUS Tumour, in Surgery, is a fig-like excresence, (usually named ficus by the moderns) situated near the anus or pudendum, and frequently arising from illicit amours. See Ficus.

The etymology of the term carious has been sometimes mistaken. It is derived from carica, a dried fig, and does not mean the same as karpodes; although the editors of a new medical and phisical dictionary, copying the error of Quincy, say that "the carious tumour is called by Hip pocrates karpodes:" whereas, another term word (according to Galen, Suidas, Erodian, Hefychius, Philocrates, and others), denotes a kind of luxurious reu, composed of blood and various condiments, invented by the Lydians, and which Varinus supposes the obtained the name of karpodes, because it was of a blackish colour, resembling boiled walnuts. Vide Gorriei Def. Medic. Lexic. Schelchu, and Econ. Hippocr. Pafli.

CARICUM, a cathartic application for cleaning for-
Caries.

del, ulcers, and eroding fungous flush. See Hippocrates de Ulecibus; and *spona*, in Galen's Exegesis. It is prepared of black hellebore, sandarach, *fusana eris*, washed lead, sulphur, opomint, and cantharides; these being mixed, are made up with oil of cedar into a liquid medicine. Sometimes there is added arum, in decoction or juice, or the powder of it mixed with honey. The dry medicine or powder, for the same purpose, is prepared of the same ingredients, omitting the oil of cedar, and the honey; it is also made of black hellebore and sandarach only.

CARICUS, in Ancient Geography, a river of the Peloponnesus, in Laconia.

CAR RIDES, or CARIDA, a town of Asia Minor in Phrygia. Beth. Byz.

CARIDEN, in Geography, an island of Asia, in the Indian sea, near the west coast of the island of Ceylon: 12 miles long and two wide. N. lat. 8° 30'. E. long. 75° 57'.

CARLBOEFE mountains, a ridge of mountains in the western part of North America. N. lat. 58° 45'. W. long. 115°.

Caries, in Surgery, is a term which implies a corruption or putridity of some part of the animal body: this word was used by the older surgeons, and especially by those of the middle age, to denote a foul or corroding ulcer of the genitals, arising from impure coition; but we now almost exclusively apply it to a diffilution of the bony structure, either in an actually dead state, or tending to death. The most general definition of caries, is into the dry and the moist.

The former species may best be compared with a dry gangrene of the soft parts. The bone is white, dry, and dead, but otherwise smooth and even; no appearance of putrefaction, matter, or exulceration is visible; only it is observed, that the bone is incapable of adhering to the surrounding soft parts, or when separated from them, of again forming an adhesion with them. In the majority of cases, this caries begins at the surface; much more rarely in the internal substance, of the bone. Sometimes it changes into the humid caries.

The humid caries is, with respect to a bone, the same as an ulcer with regard to the soft parts. In this disease the bone is yellow, brown, or black, corroded, uneven, partly conformed, and a fetid matter issues from it. It is distinguishable into the occult, and the open caries.

In the first, the bone is still covered with soft parts, and the external integuments are either entire, or there exists already an ulceration, which nevertheless does not lay the bone bare. In the first case the integuments over the diseased part of the bone are walled, relaxed, oedematous, red or livid; without, however, being inflamed. The patient constantly feels gnawing, lancinating pains in the bone below the part, which are increased by external pressure; and when the disease of the bone is of any considerable extent, the patient is generally affected also with a low hectic fever.

In the second case, the ulcer in the soft parts is generally very obliterative and of a foul appearance, without any manifest cause; it discharges a great quantity of very ill-conditioned matter, and it is relaxed and surrounded with fungous excrecences. All endeavours to heal it prove ineffectual, or if it does in time, it soon breaks out again; and frequently, when the cause of this obliterative is not discovered, these ulcers are conceived to be of a malignant and cancerous kind.

The open humid caries may be known by the more or less copious discharge, which has an intolerable and peculiar fætus, leaning with black spots, and discolouring the silver probes that are introduced into it, and in which generally small black particles are seen to float. The ulcer in the soft parts is relaxed, uninflamed, spongy, and much inclined to bleed, and the bone is entirely bare, soft, uneven, corroded, brown or blackish. Sometimes a great quantity of fungous flux grows out of the bone itself, which easily bleeds, covers the bone, and thus renders both the diagnosis and the cure of the disease more difficult. This species of caries may be compared with fungous ulcers of the soft parts. In another species of caries, the bone seems to be gradually converted into mucous sub stance.

The humid caries begins either in the inner part of the bone or at its surface. In the former case, the patient first experiences for a long time violent pains in the bone, which are not increased by external pressure; after which the bone becomes swelled, the disease makes its way through the bone, attacks the soft parts, and terminates in an open caries. This species of caries, which begins in the interior substance of the bone is far more dangerous than that which commences on its external surface; in other respects there is no material difference between the two species; for the internal caries is frequently produced by external causes, and the external caries may sometimes proceed from internal caries. Caries is sometimes combined with an enlargement of the bone, and that most frequently when the caries begins in the centre of the bone; however, it occurs also not infrequently in the caries which begins externally. This swelling, nevertheless, does not alter the character and manner of treating the caries; it may occur as well in a mild as in a malignant caries, and sometimes after the original disease has been cured, the swelling may remain during the life of the patient.

Besides these, several other subdivisions of the caries may be enumerated; such as,

1. The gangrenous caries, which is a variety of the dry caries. The colour of the bone is not much changed at first, but when the exfoliation begins, it becomes greyish, afterwards brown, and finally black. The exfoliation takes place more easily than in the other species of caries, after the manner of a perceptible exfoliation. The same also happens here which is observed in the separation of gangrenous sub stance in the soft parts. (See the Art. Gangrene.)

2. Another variety of the humid caries is the worm-eaten (caries of Petit, which may be compared with an ulcer of the soft parts, having many cavities, and when the discharge proceeds from corrupted marrow; or with an abscess, the matter of which oozes out through a number of small orifices in the skin. The bone becomes spongy, and full of holes, but it is not very black. The discharge is copious, and generally it blackens silver probes. Portions of the bone separate themselves; however, no regular exfoliation takes place, unless this species of caries is changed by art into the above-mentioned gangrenous caries. The bone is gradually decayed and consumed by the suppuration, and it becomes so brittle that it can hardly be touched without breaking.

3. The fungous caries is in all respects similar to the preceding, except that spongy flesh, which readily bleeds, grows out of the carious bone.

4. The phagedenic caries. In this disease, the periosteum is thickened, the bone becomes soft, and from its carious surface a fungous substance, of a red or yellow colour, forms forth. When the disease spreads deeper, it gradually destroys all the osseous fibres. This species is distinguished from the fungous caries mentioned above by the circumstance, that in the latter the spongy flux proceeds from the holes of the bone, the edges of which, though discoloured, still remain hard and offensive; whereas, in the phagedenic caries,
CARIES.

The affection first appears wherever the fungous flesh surmounts the bone, and on the surface of the bone. We may therefore be disposed to determine whether the bone were carious or not. For when we rub it under the fingers, it is not smooth, and the end of the bone, its surface, though uneven, does not seem to be very rough, neither can any considerable discoloration be perceived in it.

5. The fungous caries is discovered on opening a fungous abscess, when frequently the bone beneath, though of the natural colour and smooth, is found to be detached from all connection with the soft parts. Being now exposed to the air, it gradually becomes discoloured, and, with some degree of roughness, as far as it no longer adheres to the subjacent parts, sufficiently evinces that the circulation in it is interrupted. Another species of fungous caries is that which occurs in white swellings of the joints. (See Wrinfe Swelling.)

6. The cancerous caries commences with an enlargement of the bone; which in some parts is soft, and its internal substance neither fibrous nor cellular, but seemingly composed of an irregular accumulation of carious matter. It is covered with a tenacious or cartilaginous fibrous tissue, from which a smooth fungous exudation grows out, and exudes a limpid acid and fetid ichor. The patient complains much of deep-seated, pulsating, and very acute pain; and the ulcer bleeds profusely in consequence of the gradual corrosion of the walls at its surface. This species of caries may be compared with a cancer of the soft parts, to which it also is frequently superinduced, when the cancer has spread itself as deep as the bone. (See Cancer.)

As a species of caries, may also be mentioned that gradual wearing away and consumption of the bone, which takes place when they are exposed to constant pressure, as for example, in aneurisms, hydroceles internus, &c.

The Necrosis is, indeed, generally considered as a disease of the bones distinct from caries; however, it may not improperly be looked upon as a species of the dry caries, with a total privation of the living principle.

In all cases in which an ulceration of a bone discharges a large quantity of matter, the surgeon must not rest till he has discovered and sufficiently opened the source from whence the discharge proceeds. The humid caries spreads itself constantly farther and farther; and that more rapidly, and in a more violent degree, the looser the bone is, and the more the discharge of matter is obstructed by any cause. Moreover, the consequences of the humid caries are as various, and of the like nature, as those of ulcers; for not only the functions of the disintegrated part, but also those of the neighbouring organs, are always more or less affected; the patient is weakened by the daily loss of fluid; his blood is vitiated by the absorption of the matter, and a hectic fever is produced, with a constant state of tertian fever.

The most frequent causes of the dry caries are external injuries, whereby a bone is laid bare; and in consequence of a deficiency of nutritive fluid, the ascents of the external air, or the contact of vitiated liquids, destroys the living principle and dries up. In such cases it retains its vital powers longer in young subjects than in old. Sometimes this species of caries takes place spontaneously; probably when any pannicula acuminatus, especially of the atheal or venereal kind, is deposited upon the periosteum.

The humid caries is produced by causes similar to those of ulcers in muscular parts; and may even be produced by such ulcers, when they penetrate as far as the bone. This caries may therefore be divided into as many species, as there are species of ulcers, with respect to their causes; and of local causes the most frequent are the ulceration, erosion, and violent condition of the bone.

The danger in caries depends, as in ulcers, upon the absorption of unhealthy matter, the dry bones of fungi, and the consequent hectic fever; but in caries, the absorption of matter takes place to a much greater degree, and, to the sick, is more pernicious, as the disease is deeper seated, and the matter extremely acrid and corrupted. The propensi, depends upon the situation or condition of the bones, the extent of the caries, its cause, and its duration. (See Ulcer.)

The dry caries requires for its cure that the dead substance be separated from the living; and this is done either by a perceptible or imperceptible exfoliation, which is effected either by a chymurgical operation or the efforts of nature. When the surgeon foresees that an exfoliation is about to take place, he must open the ulcer in the flesh sufficiently, and keep it open, in order that he may be able to extract the separated portions of bone. But in an imperceptible exfoliation this is not necessary. A perceptible exfoliation generally takes place when the dead portion of bone is strong and thick; but a thin layer of dead bone commonly exfoliates imperceptibly, as do loose and fungous bones; hard and firm bones commonly exfoliate perceptibly. In young subjects the bone is more readily comminuted, and the imperceptible exfoliation is much more frequently observed, than in old ones. (See Exfoliation.)

In the perceptible exfoliation, the dead portion of bone first becomes whitish and dry; after some time it begins gradually to raise itself, and yields a sort of hollow sound, when struck upon with a probe; at length a fissure is formed in the circumference of the dead part, which separates the dead from the living portion of the bone. This fissure gradually becomes wider, and at the same time the piece of bone becomes more and more elevated; new flesh is found between the living and dead bone, which as it rises separates the dead portion, until at length it grows loose, and finally falls off. The bone beneath is then found covered with granulations which in some degree supply the place of the lost portion of the bone, and in time become osified.

The exfoliation is entirely a work of nature, but the surgeon must promote it. He must first endeavour to remove the internal cause of the caries; then if the exfoliation be judged inevitable, destroy completely the life of the diffused portion of bone, and promote its separation. The internal causes of caries are to be removed in the same manner as those of ulcers. Externally may be applied warm brandy, and various tinctures prepared with it. The diffused portion of the bone is to be kept constantly wet with pieces of lint dipped in spirituous liquors. But when the diffused portion of bone is so thick and firmly that it cannot be penetrated by these fluid applications, another mode of treatment is necessary. There are three different methods according to which we may proceed; but, of these, that which is most adapted to the peculiar circumstances of the case must be chosen.

We may either burn the bone by applying a red-hot iron, or we may bore a number of holes, the more the better, (by means of a perforator or small trephine), but so as never to pierce the sound portion; in order that the above-mentioned remedies may be able to penetrate into and entirely dry out the bone; or we may remove, by means of a scraper, so much of the bone, that the remaining layer may easily be penetrated by drying remedies. It is however well to be attended to, that when the life of the bone is entirely destroyed, the drying remedies should no longer be employed.
Caries.

as they then will answer no purpose, and at the commencement of the exfoliation will even be hurtful. Moreover, these remedies should come into contact with the whole circumference of the diseased portion of the bone, but (if possible) not with any of the sound part.

The first of these objects must be attained by laying bare the whole diseased portion of the bone by means of incisions; and the second, by not laying the bone bare further than it is diseased, or by covering the denuded found portion with lint spread with some emollient ointment, also by not inuring the lint with too large a quantity of the drying remedies as will come into contact with the found parts, and by not using these remedies longer than is necessary. It is also particularly requisite, when a red-hot iron is to be applied, that the carious part should previously be well dried out, in order that the heated fluid may not come into contact with and destroy the found portion of the bone.

As soon as the life of the diseased portion of the bone is completely destroyed, the surgeon usually employs such remedies as promote the exfoliation, suppuration, and growth of the new flesh; such, for example, as the ball, Ascaris, either alone, or mixed with a little oil of turpentine, the ung, albae, or refine fibre, &c. These remedies are applied warm; but in order that they may be able to penetrate to the living part of the bone, holes are bored into different parts of the diseased portion with the perforator; and the more numerous and large these perforations are the better. Every hole, however, ought to penetrate as far as the living part, and we are directed by many surgeons to continue boring till some blood appears. As soon as this has been done, the bone must be covered with warm emollient applications. Should the exfoliation not take place under this treatment, we may conclude either that the diseased portion of the bone is not entirely deprived of its life, in which case the application of the drying remedies must be repeated, or the cure is impeded by some internal cause, which must be discovered and removed. When the diseased bone begins to grow looser, it will be proper to shake it gently from time to time, without exciting, however, either pain or bleeding, in order to accelerate its separation; and when the exfoliation has been completed, the ulcer is to be treated like a simple, clean abscess.

A much more speedy and perfect cure, however, may be effected when the surgeon performs the separation himself. This is particularly necessary when the diseased portion of bone is very thick; but it is only admissible, when we have a free and unobstructed access to the whole circumference of the diseased bone. According to the difference of the situation and form of the bone, the separation of it is performed in different ways. When only a thin layer of bone is diseased, it may be scraped off with the scraper, or with the exfoliative trepan, or still more conveniently with a piece of glass. A thick layer of bone is to be separated with the chisel and hammer; and that this may be done without using great force, or producing a violent concussion, the bone must be previously bored through with the perforator; we must allow only attempt to chisel off small pieces at a time; and that the whole of the diseased portion has been removed, we may know by the whole surface of the bone becoming red and bloody. When the bone is flat, and diseased through and through, we may apply the trepan, and in cylindrical bones we may sometimes saw off the diseased portion. A bone that is diseased throughout must be extracted. As soon as the whole of the diseased portion has been separated the remaining part is to be treated like a simple wound, and the bone is to be dressed with emollient warm applications, under the use of which it generally becomes covered with flesh in a short time. In order that it may not again become diseased, it must be carefully defended against the cold, air, and spirituous substances. In many cases the surgeon cannot remove the whole of the diseased portion of the bone, and in this case he must combine the two methods of cure with each other; that is, he must remove the greater part of the diseased bone, entirely destroy the life of that which is left behind, by the application of the remedies formerly mentioned, then perforate according to Belofie's method, and dress the part with emollient applications.

The method of cure in the humid caries is nearly the same as that used in the dry; only in the former it is necessary that the discharge should be diminished, its condition improved, and at length that it should be dried up; since, till that has been done, no exfoliation can take place. If it proceeds from an internal cause, this must, if possible, be removed. Thus a cure is frequently obtained; however not always, for often the caries remains in consequence of local causes, in which case it must be treated as a local diseased. In such a case the surgeon must promote the evacuation of the matter by every means in his power; he must lay the bone sufficiently bare by means of incisions; the limb must be kept in a dependent position; and the ulcer covered with light dressings, in order that the thinner part of the discharge may run through; and in general every thing which might occasion a stagnation and accumulation of the matter in the ulcer must be most carefully avoided. But when the bone swells, and a quantity of matter is discharged from the ulcer, disproportionate to its apparent magnitude, so that we have reason to conclude the matter fluctuates in the fungous substance, or hollow of the bones, and there carries on its ravages in secret, the bone must be laid open in time by means of the trepan or perforator. Moreover, in all cases of humid caries, it is very useful to dress the ulcer with sponge or dry lint.

When the caries penetrates deep into the bone, we may apply spirituous tinctures and fomentations externally; but in using these remedies, the directions which we have formerly given are to be observed.

Of the internal remedies which contribute to improve the condition of the discharge, fala foetida has been recommended in the form of pills as one of the most efficacious; as it generally deprives the matter in a few days of all its fetor and acrimony, and thus sometimes is alone sufficient to produce the exfoliation and cure. In obstinate cases of caries, good effects have been produced by the use of time-water, hemlock, oak-bark, cinchona, and opium taken freely; but we are, nevertheless, too often disappointed in our expectations from medicine, and no one plan will be efficient in all such cases. And, whatever plan may be adopted, it will beat the same time particularly necessary to breathe a pure air, and use an appropriate diet.

When the cause of the caries has been removed, and the condition of the discharge improved, the exfoliation and cure are sometimes promoted by the judicious application of a bandage to the part.

Should the means that have already been mentioned be found inadequate to produce the desired effect, the surgeon is obliged to have recourse to more powerful ones; in order thereby to convert, as it were, the humid caries into the dry, and to accelerate the exfoliation and cure; for this purpose a red-hot iron is often our only reliance. As an excellent remedy against caries, Mr. Lentin recommends phosphoric acid, prepared according to Green's method. One part of this to be mixed with seven parts of distilled water, and applied to the bone itself, or used as an injection. Internally, the pure phosphoric acid has been administered, in doses of 1 C, 1 G, to 20 drops, three a day, in water, or a liniment.
Caries.

Sometimes Mr. Lenfant added a little myrrh to it, for external
application; or mixed the phosphoric acid with an infusion
of fumice, leadtum, or earl. laeias.

When the diseased bone is covered with much fungous
fluff, this must first be removed by means of cautious applica-
tions, in order that it may not obstruct the operation of the
red-hot iron on the bone. When the caries penetrates to
deep into the bone that the operation of the cantery does
not extend quite through it as far as the bone, a part of the
diseased portion may be removed with the ferper, or the
chisel and hammer. In flat bones, under which important
parts are situated, as, for example, the cranium, the applica-
tion of the red hot iron must either be omitted or performed
with great caution. When any of these means have been
applied to a sufficient extent, the surgeon must treat the dis-
order as a dry caries. If exfoliation does not commence within
the space of about 25 days, the remedies must be renewed.

Caries sometimes renders it necessary that the limb should
be amputated; namely, when a bone of one of the extremi-
ties is either entirely, or particularly at the joint, carious
through and through; and especially when the muscular and
more important parts are in a great measure affected by the
disease of the bone, and either correde or destroyed, as may
happen in what is named the Cancerous Caries. It has,
however, been observed, that, after this operation has been
performed, the disordered often breaks out in some other part, and
renders all medical assistance ineffectual. If, on the contrary,
the muscular parts have suffered but little, although the bone
is very carious, amputation ought not to be performed; but
all that the surgeon can and ought to do, will be to lay bare
the whole of the diseased bone by excisions, and to separate it
from the soft parts with the scalpel, and from the founded
portion of the bone with the saw. In these cases, nature some-
times supplies the portion of the bone that has been lost, and
though this should not happen, the operation above mentioned
is still preferable to amputation in this particular case.

Neither is amputation always admissible when the caries
proceeds from some internal cause, and this has not been
removed. It must also be avoided when the patient is already
greatly exhausted by the disease; however, the surgeon need
not be deterred by the mere presence of hectic fever; as this
arises principally from the irritation or absorption of matter,
and disappairs, together with its cause, after the operation
has been performed. It also happens, not unfrequently, in
cases of old caries, in which the constitution has become ac-
climated to the discharge, that troublesome symptoms super-
vene upon amputation, which perhaps may be prevented by
means of injections.

When the carious bone is covered with a great deal of
fungous fluff, defective remedies and prejudice must be
applied; and should these not prove sufficient to extirpate it,
we must use a humble, or the actual Cautery. In these
cases there is generally also some internal cause present, which
we must endeavour to remove by means of appropriate exter-
nal remedies. In that species of caries in which the bone is
converted into a kind of flaky substance, the internal and ex-
ternal use of lime-water has been found beneficial; the sur-
geon must, however, always attend at the same time to the
internal cause.

Concerning that species of caries which begins in the in-
ternal substance of the bone, see Syphilis and Necrosis;
and for the venereal caries, see Syphilis. Likewise,
concerning carious teeth, we refer to the article Teeth.
See also Epistaxis and the Spur.

Although we have here laid down the rules of practice,
which the gentiurny of surgeons follow in the treatment of
caries, it must still be acknowledged that no subject in the
whole compass of the art is more liable to obscurity and de-
bate. The modes of treatment adopted by one surgeon, will
be often regarded as either useless or pernicious by another;
so that while we are obliged to describe certain plans of
chirurgical management, it is with a full conviction that no
one method will be universally approved. The following re-
marks of M. Boyer, of Paris, are submitted to our readers, as
defering their attention, and as being among the latest
with which the public have been favoured by any systematic
writer.

"There is perhaps," says he, "no disease in which the
indications of cure are more vague than in caries, and none
in which the treatment is less regular. The ancient preferred
unctuous or relaxing applications, but they preferred acid irri-
tating substances, such as the powder of euphorbium, tincture
of aloes and myrrh, oil of turpentine, mineral acids, cali-
dical alkali, or even the actual cautery. Monro, Tenon, and,
in imitation of them, some modern practitioners, have pre-
dered the use of unctuous andeomulent applications; but, in order
to discover the preferable mode of treatment, it is neces-
sary to take a close view of the evil against which it is to be
directed. We must then consider, that a bone affected with
caries is a prey to a morbid action of its own parts, and that
this action creeps from one part to another, and pervades
the whole with greater or less rapidity, if art does not come to
the assistance of nature to arrest its progress.

"If the caries be produced by some affection of the system,
this should be ascertained and combated with appropriate re-
medies. Thus the use of mercurial and fuming medicines
arrests the progress of caries proceeding from the venereal
disease, and aids nature in separating the unbound from the
found part. The use of spirituous drinks, vegetable diet, and
acids, removes at once fever and the caries, to which it had
given rise, &c. &c. But if it has been occasioned by an ex-
ternal caufe, or if it has remained after the internal one has
been removed, so as to be reduced to the state of a mere to-
pical affection, its progress may be arrested, and the separa-
tion of the diseased parts facilitated by the use of such sub-
stances as fumiate the parts, or such as absorb and neutralize
the fluids which tend to propagate the morbid action. Thus
the defection of a carious ulcer has been effectual by the use
of an absorbing powder and pledges of lint that had been
dipped in tincture of aloes and myrrh.

"If these remedies be found inefficual, recourse must be
had to more active ones: a pledge of lint dipped in a solu-
tion of nitrate of silver, may be applied on the carious part,
and renewed every day. This portion of the bone is by this
means quickly dried up, and reduced to the state of a simple
necrosis; the propagation of the morbid action is arrested,
and nature effects a separation of the diseased parts.

4. If the caries be very humid, that is, if a great quantity of
fumes flow from it, these remedies, even the mercurial nitrate,
will be of no effect. The fumes will induce the neglect, and
abate the cautery so much, that its action is considerably en-
feibled. Caustic paraffin would be subject to the same incon-
veniences. In these cases, the actual cautery is a remedy to be
preferred to all others: by its action the carious part is
incised, to which reduced to the state of an inorganic dry sub-
stance, and the caries thus converted into necrosis. This
remedy is applicable to every case of humid caries where the
surrounding soft parts have not a manifest tendency to cancer.
Sometimes, however, the soft parts surrounding a carious
bone have that tendency in so advanced a degree, that the
actual cautery would necessarily occasion the development of
that morbid state. The general rules to which the use of the
actual cautery may be reduced are as follows:

5. In the first place, all the carious part of the bone must be
laid bare, whether by cutting away the soft parts, or destroy-
ing them by cautery. The latter method being tedious, in-
convenient, and uncertain, should not be used unless when the
patient will not submit to the use of the knife. The bone
being in this manner laid bare and scraped, the surgeon pro-
vides himself with several cauterizing irons of the same form,
because the application of one is seldom sufficient. It will al-
so be necessary to provide a number of caules when the cautery
is to be applied on a bone from which the soft parts
cannot be completely raised, as, for instance, on the os co-
cocygis, or sacrum: by means of these caules, the hot iron
can be introduced without injuring the soft parts. In every
case it will be necessary to protect the surrounding parts as
much as possible from the action of the cautery.

6. The iron, whatever may be its size, should be heated
white, as the hotter it is the more rapid and less painful is
its action. On the instant of its application, a black thick
smoke rises from the surface of the burning bone, the smell
of which resembles exactly that of burning horn: the great
quantity of fumes quickly diminishes the heat; for which
reason a second is to be immediately applied with the same
precautions; and a third, if the two preceding have not
burned deep enough. Care should be taken to extirpate
the diseased by burning every part that is affected; and if the
use of the cautery has not always had the success expected
from it, the failure of it is to be attributed to the timidity of
the operator. A carious bone becomes worse by the appli-
cation of the actual cautery, if the evil be not entirely
rooted out; just as a cancerous tumour becomes irritated,
and makes a more rapid progress, if imperfectly cau-
terized.

The actual cautery acts by evaporating the noxious
fluids in which the carious bone was immersed; by chang-
ing the caries into necrosis, and by irritating the sub-
jacent, found parts, and exciting that action of the ve-

icles by which the dead part of the bone must be thrown off.

7. It is almost superfluous to remark here, that this ope-
ration cannot be undertaken with any hope of success, if the
internal cance of the caries will exist." - Bayer's Dicæases

CARIGE, in Ancient Geography, a town of Italy, on
this side of the Ganges. Ptolemy.

CARIGNAN, in Geography, a town of France, in the
department of the Ardennes, and chief place of a canton,
in the district of Sainte-Menehould. Formerly a proprietory,
called "Joye," belonging to the dukes of Luxembourg, the
dukes of Burgundy, and the house of Austria, but at length ceded
to Louis XIV., who changed the name, and erected it into a
duchy; three leagues E.S.E. of Sedan. The place con-
tains 17,000, and the canton 10,923 inhabitants: the territory
comprehends 225 kilometres and 27 communes.

CARIGNANO, a town of Piedmont, in the district of
Savigliano, and capital of a principality, to which it gives
name, seated on the Po, over which it has a hardstone
bridge. It gives the title of prince to a collateral branch of
the house of Savoy. This town was plundered and
burned by the French in 1556, and in 1544, the fortifica-
tions, except the citadel, were razed, and most of the
churches destroyed. It is about 15 miles S. of Turin. N.
latt. 44° 32. E. long. 7° 25'.

CARIGNANO, a town of the island of Sardinia; 15 miles
W.N.W. of Terra Nuova.

CARIGUE, an island in the river Shannon, on the coast
of the county of Kerry, Ireland, opposite to Scattery
Island. Near it are the ruins of Carrigfoil castle, once
a place of great strength, the lands belonging to which were
granted to Trinity College, Dublin.

CARIGUEIA, in Zoology. See Didelphis Opossum.

CARIGUEIBUR. See Mustela rufescentis.

CARILL//E, in Ancient Geography, a town of Italy,
mentioned by Silius Italicus, and supposed to belong to the
Picentini, who inhabited the district now called Principato
Citra.

CARILLONS, a species of chimes frequent in the Low
Countries, particularly at Ghent and Antwerp, and
depicted on a number of bells in a belfry, forming a complete feries
of scales, of tones and semitones, like those on the harps-
ichord and organ. There are pedals communicating with
the great bells, upon which the carillonneur with his feet
plays the bale to sprinkle air, performed with two
hands upon the upper species of keys. These keys are pro-
fected flocks, wide enough slender to be struck with vi-
ence and velocity by either of the hands edgeways, without
the danger of hitting the neighboring key. The player is
provided with a thick leather covering for the little finger
of each hand, to guard against the violence of the stroke.
These carillons are heard through a large town.

Carillon is likewise the name of a small keyed instrument
to imitate a peal of hand bells. The tones are produced by
box hammers striking iron bars of different lengths. Handel
used to accompany his air in Milton's Allegro, "Or let the
merry bells ring round," on this instrument. And in Saul,
the chorus "Welcome, welcome, mighty king,"

CARILLONEUR, the musician who plays the caril-
lons, or chimes with hands and feet; an officer of extreme
labour, peculiar to Holland and the Netherlands.

CARILLONEUR of Suffolk, in Ornithology, the chiming
thrush, Turdus tinninubularis.

CARILOCUS, in Ancient Geography, now Charlevi,
a town of Gaul, belonging to the Adui. Ptolemy.

CARIMCURIN, in Botany, Rhed. Mal. See Jus-
ticia echinata.

CARMINGOLA, Rhed. Mal. See Pontederia cin-
gartis.

CARMON, in Geography, one of the chief towns in the
kingdom of Yokor, which occupies the southern extremity of the
Cherifone, in the peninsula of Malay, or Malacca.
CAR

CARINUS, a chulter of islands in the Indian Sea, B. lat. 5° 43', E. long. 100° 15'.

CARIMPANA, in Baluny, Rhed. Mal. See Beorasa, Sus flabifepigia.

CARIM-TUMBA, Rhed. Mal. See Nifta, medi-bahita.

CARINA, a Latin term, properly signifying the keel of a ship, or that long piece of timber running along the bottom of a ship, from head to stern; upon which the whole structure is built, or framed.

CARINA is also frequently used for the whole capacity or bulk of a ship; containing the hull, or all the space below the deck. Hence the word is also sometimes used, by a figure, for the whole ship.

CARINA is also used in the ancient Architecture. The Romans gave the name carina to all buildings in the form of a keel, as we shall give the name sacre to the middle or principal vault of our Gothic churches, because it has that figure.

CARINA, among andinifius, is used to denote the spinu duri. As likewise for the librun rudiments, or embryo of a chick, appearing in an incubated egg. The carina consists of the entire vertebrae, as they appear after ten or twelve days incubation. It is thus called, because crected, in form of the keel of a fish.

CARINA, in Baluny, Eng. keel. A name given to the lowest petal of a papilionaceous flower which generally envelopes the flamen and petals, in allusion to its shape, which has some resemblance to that of a boat. It sometimes consists of two distinct pieces, but is generally simple, attached to the receptacle, and firmly locked in with the other petals by two long claws. A leaf, a scale, and a nectary are also said to be carinated, or keel-shaped, when they are longitudinally hollow above, and have a corresponding, sharpish protuberance underneath.

CARINA is also used by some Chemifts, for the twentieth part of a drop.

CARINE were weepers, or women hired, among the ancient Romans, to weep at funerals: they were thus called from Caria, the country whence most of them came.

CARINA, in Ancient Geography, a town of Aes, placed by Ptolemy in Mada.—Alfo, a town of Aes Minor in Myfia, or in the Eolide; mentioned by Herodotus.—Alfo, a town of Aes, in Phrygia, towards Galetia. Pliny.—Alfo, a mountain of the island of Crete, which, according to Pliny, was nine miles in circuit.

CARINACOU, in Geography. See Caricou.

CARINANA, Carisen, or Sarignena, a town of Spain in Arragon, about 44 miles from Longaria, containing 2056 inhabitants, and two convents.

CARINANTHA, in Entomology. See Papilio.

CARINI, in Ancient Geography, a people of Germany, partly of those who were comprehended under the general name of Vandals, and whose habitation was near the Casanus Sinus. Pliny.—Alfo, a people of Germany, in the vicinity of the Helvetians.—Alfo, a people of ancient Britain, called Carniæ, which see.

CARIN, in Geography, a town of Sicily, pleasantly situated in a fertile valley, surrounded by high rocks, and in a well cultivated district, abounding in wine, grain of various kinds, olives, and all sorts of fruit. The town is singularly neat, contain 4000, (Sinburne,) or 7000, (De Non,) inhabitants, and gives title of prince to the family of Grus, who inhabit an old Gothic castle seated on a rock. It is distant one mile from the sea-shore, and 18 miles from Palermo. The adjacent territory produces a great quantity of excellent manna, as well as oil and wine. A long ridge, like a rampart, and some remains of a wall, are said to indicate the site of "Hieron," a city mentioned by Thucydides, as the birth-place of Laus, the most celebrated constern in Greek history, who was carried off when Nicias the Athenian general landed here in his way from Italy, plundered the town, and sold the inhabitants for slaves. Near the land, at some distance round the bay of Carini, lies the Isole delle Femine, formerly a place of banishment for criminals.

CARINISH Point, a cape of Ireland well of Bally-dunyan bay, in the county of Cork, and a little east of Durlies Island. It is more frequently called Carinish. N. lat. 51° 4', W. long. 10° 4'.

CARINOLA, a town of Naples, in the country of La vera, the site of a bishop, suffragan of Capua; 1 mile N. E. of Capua.

CARINTHIA, a duky of Austria, bounded to the east by Stria, to the north by the fame, and the archepiscopal of Salzburg, to the west by Tyrol, and to the south by the republic of Venice and Carniola. It derives its name from the ancient Carni, who were a colony of the Cetti, called in later times Carantani and Carniæ; and it was formerly a part of Carnia and Novium. The country is very mountainous and woody. Its principal mountain is the St. Ulrich, St. Helena, St. Veit, St. Lawrence, and the mountain of Lohi, which separates Carniola from Carniæ. There are also others, no less lofty, that incline towards Tyrol. These mountains yield very good iron; the iron-mines near Friesach on the north, and in the tract among the sprigs of the Lysers, being particularly famous. In the district of Villach are found rich lead mines, a beautiful blue granite, and fire marble, or lunachelli. The fertile dales of this country produce wheat and other corn, but not enough for the supply of the inhabitants. Carnithia has a number of lakes, the largest of which is that called Wordsee, eight miles long, and abounding in fish, and also many rivers, the principal of which are the Drau, issuing out of Tyrol, and traversing Carnithia from east to west; the Gail, the Moll, the Lysers, the Glen, the Gurk, and the Lavant. The cities of Carinthia, of which Clagenfurthe is the capital, are eleven; its market-towns 25; its villages, &c. 28,000; its houses 49,000; its convents 20; clergy 1010; nobles 386; burghers and tradesmen 4753; peasants 27,013; herds of oxen 50,000; peasants, with Upper Stria, 17,000. The inhabitants are partly defended from the ancient Germans, and partly from the Wends. The archbishop of Salzburg, and the bishop of Bamberg, have considerable territories in this country. The principal manufactures of the country are those of iron and steel. In 1528 the emperor Rudolph I. conferred this duchy as a fief on the count of Tyrol, who entered into a compromise with Albretch of Anria, by virtue of which, it was to descend, on the extinction of his male issue, to the heirs of Albrections; and when this happened, in the year 1331, the emperor Lewis of Bavaria recognized this duchy to the Austrian duke Otto, who, in 1335, was invested with it. The duchy is governed by a land-capitan; and to the military rate of the house of Austria it has been accustomed to contribute annually 657,695 florins. Christianity was introduced into this duchy in the 7th century; and the whole country acknowledges the Roman Catholic church, though it contains many protestants and adherents to the Lutheran doctrine.

Carinthia is divided into Lower and Upper. The principal towns of Lower Carinthia, are Clagenfurthe, the capital, St. Veit, Friesach, Volken, St. Andree, Wolfsberg, and Gurk; and those of Upper Carinthia are Villach and Gmuud.

CARINUS,
CARINUS, in Biography, a Roman emperor, was the eldest son of the emperor Carus, who, soon after his father's election, in the year 282, was admitted, together with his brother Numerian, to a participation of the imperial power; and both, being arrived at manhood, were honoured with the title of Caesar. Carinus was extremely viscious from his youth, and devoted to dissolute pleasures. He was, however, valiant and active; and, therefore, when his father departed for the prosecution of the Parthian war, the young prince was directed, first, to suppress some troubles which had arisen in Gaul, and afterwards to fix the seat of his residence at Rome, and to assume the government of the western provinces. Upon the death of Carus, near the close of the year 283, the two young princes, Numerian and Carinus, were unanimously acknowledged as Roman emperors. Born and educated in a private station their sudden elevation required an uncommon share of virtue and prudence; but Carinus was singularly deficient in these qualities. On his arrival at Rome from the Gallic war, he abandoned himself to the luxury of the capital. He blended in his character effeminacy with cruelty, a love of pleasure with a gross and indolent spirit, and an indifference to public virtue with consummate vanity. In the course of a few months he successively married and divorced nine wives, none of whom he left pregnant; and whilst he wallowed in the grovelfest pleasures, he beheld with incredulous horror those who might remember his former obscurity, or confude his present conduct. He banished, or put to death, the friends and counsellors of his youth; and whilst he affected an arrogant and regal demeanour among the senators, he selected his favourites, and even his minillers, from the dregs of the populace. The palace, and even the imperial table, were filled with fenders, dancers, prostitutes, and all the various retinue of vice and folly. Before the death of his father, the conduct of Carinus had filled him with shame and regret, and he determined to let him abide, and to adopt in his place the brave and virtuous Constantius, who was at that time governor of Dalmatia. But the sudden death prevented the execution of his purpose, and afforded his worthless and degenerate son an opportunity of displaying to the Romans the extravagancies of Elagabulus aggravated by the cruelty of Domitian. The unrestricted profusion with which he indulged his propensities to every kind of pleasure, supplied him with the means of exhibiting the Roman games of the theatre, the circus, and the amphitheatre, with uncommon splendour; and the vast prodigality which he manifested in this way was enjoyed by the Roman people with surplafe and transport. Upon the death of Numerian, Diocletian was elected emperor by the Roman army, assembled at Chalcedon; and the new emperor, fully apprized of the general dissatisfaction occasioned by the conduct of Carinus, made preparation for a civil war. In the spring of the year 283, the forces of the East and West encountered each other in the plains of Margus, a small city of Maesa (now Servia), in the neighbourhood of the Danube. The Eastern army had been reduced in number, and its strength had been exhausted; so that it was not in a condition to contend with the legions of Europe. Its ranks, on the right wing, were broken, and Diocletian despaired of the purple and of life. But the advantage which Carinus had obtained by the valor of his soldiery, he fonl low by the idleness of his soldiers. A slave, whose wife the licentious emperor had seduced, feized the opportunity of revenge, "and by a single blow, (says Gibbon,) extinguished civil discord in the blood of the adulterer." Crevier's Rom. Emp. vol. ix. Gibbon's Hist. vol. ii. chap. 12.

CAROLEE, a name given by the Canadians to a fledge, by which they transport themselves over the same, from place to place, in the most agreeable manner, and with a degree of velocity that appears almost incredible; for, with the same horse, it is possible to go 50 miles in a day, as light is the draft of one of the carriages, and so favourable is the snow to the feet of the horse. This cariole will hold two persons and a driver, and is usually drawn by one horse. Its shape is varied according to the fancy and taste of the owner. Some are open, and others covered. The former is commonly like the body of a curricle, put upon two iron runners or rods, similar in shape to the rim of a pair of skates; the latter consists of the body of a chariot put on runners in the same manner, and entirely covered with fur. The cariories glide over the snow for forty yards and with so little noise, that it is necessary to have a number of bells attached to the harness, or a person continually flowing a horn to guard against accidents. The rapidity of the motion, and the sound of these bells and horns, conduct much to cheerfulness, for you seldom see a dull face in a cariole. Wild's Travels, vol. i. p. 362.

CARIOPHYLLUM, in Botany, one of the synonymous names of madrepora, frigidula, Glas. CARIS, the flate of a bone purched or rotten. See CARIPI.

CARIPI, a kind of cavalry in the Turkish army. The caripoi, to the number of about 1000, are not slaves, but bred up in seraglios or fneminiaries, like the reft; but are generally Moors, or renegado Christians, who, having followed their fortune, and being poor, and having their fortune to seek, by their dexterity and courage have arrived at the rank of horse guards to the grand signor. Their march with the Unfiga on the left hand behind him; their pay is twelve apers per day.

The word carpi signifies poor and stranger; an appellation paid by the Chalcondylas to have been given them, because chiefly brought out of Egypt, Africa, &c.

CARIPOUS, in Geography, a people of South America, inhabiting a country to the north of the river Amazon, who are at perpetual war with the Caribbees.

CARIS, in Ancient Geography, now le Cher, a river of Gaul, called also Carus.—Alfe, one of the names of the isle of Coz.—Alfe, a town of Phrygia. Steph. Byz.

CARISSIPIC, in Geography, an ancient castle in the isle of Wight, near Newport, where king Charles I. was imprisoned thirteen months. It has a governor and a garrison.

Gen. Char. Cal. very small, five-elept, acute, permanent. Carp. montepetalous, funnel-shaped; tube much longer than the calyx, cylindrical, somewhat ventricose at the throat; border five-elept, spreading; segments oblong, acute, shorter than the tube. Stam. filaments five, very short at the top of the tube; anthers oblong, within the throat. Petl. gern superior, roundish; hyale thread-shaped, the length of the tube; stigmas thickish, slightly bifid. Petalae, berry somewhat globular, small, twocelled; peritnym thin, membranous. Seeds solitary, or two together, egg-shaped, somewhat compressed.

C R A R

Pl. 118. fig. 1. (Echites spinosa, Burm. Ind. 69. Carandas, Rumph. Amb. vii. p. 57. tab. 25. Lexicam Malar- basicum, Philk. Alm. tab. 305. fig. 4.) *Leaves ellipti-
tical, obtuse.* Linn. *Leaves egg-shaped, mucronate, reticu-
larly veined; segments of the corolla lanceolate.* Willd. A shrub. Stem fifteen feet high, much branchied; branches generally furnish'd at their knots with flat, fliff, opposite, spreading spines, often simple, sometimes bifid, not perfectly axillary. Leaves opposite, entire, foonath, a little coriaceous, on very short petioles. Flowers white, resembling those of the common jasmine; peduncles generally trifid. Berry dark red. of a pleasant acidulous flavour. La Mareck, from a dried specimen. The specimen from which Willdenow formed his description has mucrone leaves; but in La Mareck's figure they are perfectly obtuse and entire. A native of the East Indies, where it is made into an excellent sweetmeat. Lauriero found, on the east coast of Africa, a plant which he supposes the same; but, if his description be accurate, it must not be a different species, but will require a small alteration in the generic character. It is a small tree, about six feet in height, with twilled, spreading, dichotomous branches; branchied, more simply, dichotomous flowers; egg-shaped, acute leaves, and a one-celled berry, containing many roundish im-
bricated seeds. 2. *C. falciata,* Linn. Enum. and Illfitt. *Leaves lanceolate, oblong, mucronate, growing narrower towards the petiole.* A shrub. Leaves smooth, shining, veined, only half as broad as in the preceding species, and resembling those of the almond tree; petioles longer. Spines opposite, oblong, simple, spreading horizontally. Flowers smaller. A native of the East Indies, communicated by Somerat, but perhaps only a variety. 3. *C. spina-
narum,* Linn. Mant. 539. Linn. III. pl. 118. f. 2. (Spina spina-
narum, Rumph. Amb. vii. p. 76. tab. 19. fig. 1.) *Leaves egg-
shaped, acute, veined; segments of the corolla lanceo-
late-oblong.* A shrub, five or six feet high, much branchied, spreading. Branches slender, cylindrical, dichotomous, some-
what zig-zag. Spines in pairs, opposite, generally simple, sometimes bifid, situated at the bifurcations and knots of the stem. Leaves scarcely an inch long, resembling those of the myrtle, opposite, egg-shaped, acute, entire, coria-
ceous, smooth, shining above, finely veined, on very short petioles, so as to appear nearly fleshy. Flowers terminating, from two to five together on each petiole; tube of the corolla red, cylindrical, a little fleshy at the middle; border white, spreading; segments five, lanceolate, acute. Berry blackish, about the size of a pea, egg-shaped, two-celled. Seeds two in each cell, elliptical, convex on one side, flat on the other. La Mareck. A native of the East Indies. Lauriero found a plant in Cochinchina, which he suppos'd to be the same, and for which, in conjunction with another observed by him in Africa, he formed a new genus. But it differs so much, not only from the description of Linnaeus, but also from that of La Mareck given above, which was taken from dried specimens both in flower and fruit, that it must be a different plant. See STIGMARIA. 4. *C. edulis,* Willd. 3. (Antura, Forikal. Drefe. 63.) *Leaves egg-
shaped, acute, without veins; branches villous near the top; segments of the corolla lanceolate-linear.* A native of Arabia Felix. 5. *C. arduina,* Linn. Enum. and Ill. (Arduina bifiponita, Linn. *Leaves heart-egg-shaped, mucronate, nearly without veins, evergreen; spines bifid at the tip. See ARUDINA. La Mareck is the first who ob-
erved that the arduina and carifia of Linnaeus are properly one genus, to which opinion Juffien has acceded.

CARIBA, in Ancient Geography, a town of Abia Minor, in Phalagia. Pliny and Pudency. CARIBIA REGIA, surnamed ARCELIA, a town of Spain, in the department of the Gades. The ruins are found in a place called Cariba.

CARISSIMI, in Antiquity, a quality or appellation given by the emperors of Constanitople to presidents, governors of provinces, and others.

CARISSIMI, GIACOMO, in Biography, a Roman musical composer of the 17th century, whose productions were not only the delight of his contemporaries, but are still sought and hoarded by the curious as precious relics. He was, very early in life, appointed maestro di capella to the German college at Rome, in preference to all other candidates. Alberto della Valle, an excellent judge of music, speaking of the compositions of Carissimi, which he heard at the vespers performed on Easter Monday, by the nuns only, at the church dello Spirito Santo, in florid music, with such perfection as he never in his life had heard before; and on the last Christmas eve, in attending the whole service at the church of St. Appollinare, where every part of it was performed agreeably to its solemn an occasion; though, by arriving too late, he was obliged to stand the whole time in a very great crowd, he remained there with the utmost pleasure, to hear the excellent music that was performed. In the beginning, he was particularly enchanted by the Venita exultemus, which was more exquisite than words can describe. "I know not," says Valle, "who was the author of it, but suppose it to have been the production of the Maestro di Capella of that church." There was no matter in Italy at this time, 1640, whose compositions this description will so well suit, as those of the admirable Carissimi, who was now, in all probability, the Maestro di Capella in question; though so young, that his fame was as yet un-
fledged; however, it was in composing for this church that he acquired that great and extensive reputation which he enjoyed during a long life, and which his offspring, or musical productions, still deservedly enjoy.

Kircher, in his Musurgia, (tom. 1. p. 693.) describes his music and its effects in terms of high panegyric; and speaks of him as a master then living, 1650, who had long filled the place of composer to the Collegio Apollinare with great reputation. He began to flourish about the year 1635, and, according to Mathebon, was living in 1672. His productions are very numerous, though it does not ap-
pear that he ever composed for the theatre.

His sacred and secular cantatas, and motets, have always had admission into every collection of good music. It has been often asserterd by musical writers that he was the inven-
tor of cantatas; but it has already been shewn, that these feme de camera, or monodies, had a more early origin. Carissimi, however, must be allowed not only the merit of transferring the invention from the chamber to the church, where he first introduced cantatas on sacred subjects, but of greatly improving recitative in general, rendering it a more expressive, articulate, and intelligible language, by its approximation to speech and declamation.

Many of Carissimi's works are preferred in the British Museum, and in Dr. Aldrich's collection at Christ-church, Oxford.
There is something interesting in the most trivial compositions of this admirable matter, and in his works may certainly be traced more traits of fine melody than in those of any composer of the 17th century. Of twenty-two of his cantatas preferred in the Christ-Church collection, Oxon, there is not one which does not offer something that is still new, curious, and pleasing; but most particularly in the recitatives, many of which seem the most expressive, affecting, and perfect, that we have seen. In the airs there are frequently sweet and graceful passages, which more than a hundred years have not impaired. It is, however, in the divisions of this, and of all old music, that the time when it was composed, and the changes of taste, are chiefly discoverable. These are the fashionable forms and trimmings, which soon give way to others; but the principal ground-work, or materials, if good at one time, would not lose their value at another.

Besides Carissimi’s numerous secular cantatas, duets, trios, and four-part songs, his compositions for the church, where he first introduced instrumental accompaniments, discover more genius, elegance, and design, than those of any preceding or contemporary composer. Stradella’s untimely death perhaps only prevented him from writing as much, and as well, as Carissimi.

Kircher, the contemporary of Carissimi, after a jilt eulogium on his compositions in general, and telling us that he had the power of exciting in his hearers whatever affection he pleased, speaks of his oratorio of Jephtha, and the new and admirable effects produced in it by his knowledge of harmony, modulation, and happy expression of the passions. The chorus in his sacred drama, Floraire filia Israel, which follows the lamento della figlia di Jephte, is as remarkable for the accuracy of fugue and imitation, as for its expressive performance.

According to Mattheson, the famous German composer, Karl the younger was sent by the emperor from Vienna to Rome, in 1649, to receive lessons from Carissimi; who is said to have acquired a considerable fortune by the exercise of his profession, and to have lived to the age of 90.

He appears to have been the favourite composer and model of Dr. Aldrich, who was possessed of a complete collection of his works, which he frequently used in his own hand, and seems to have studied with great attention. And Purcell manfully formed his style on the productions of Carissimi and Stradella, particularly in his recitative and secular songs.

Carissimi was not only a man of superior genius and abilities, but a bold contrapunctist; as we find, in one of his masses, several new harmonies which were thought unwarrentable more than a century after his death, in 1672. He is much, and justly, praised by Kircher, in his Mufurgia; his compositions were greatly admired by Dr. Aldrich, who adopted English words to several of his movements in his masses, which were long performed in the chapel of Christ-Church college, Oxford.

In a mass, in the key of C, we have a 7th per saltum, unprepared, and unresolved on the 8th, the base descending a 3d.

The symphony in this mass resembles so much the overture style of Lulli and Handel, that primogeniture seems to entitle him, and not Lulli, to the invention. Lulli was born in 1633, and, in 1649, when Carissimi was celebrated by Kircher, and organist of the college Apollinare, Lulli was but 16.

Salvini says that this great contrapunctist, when he heard himself praised for his flowing, majestic, noble, and facile style of composition, used to exclaim: “Hah! how difficult it is to acquire this facility!” knowing so well the pains he had taken in acquiring it: and who, adds Signorelli on this passage, will deny that in the poetry of Metastasio, there is that natural flow and facility of which Horace describes:

Ut sihi quivis
Speret idem, judici multum, fructuosa lux, Ovius ibiam.

Beauty, in works of art, is acquired by great pains and labour, says an old Greek, Προσθέσον σας παλαιστικά. The gods fell to mortals whatever is excellent and beautiful, at the price of immense labour and sweat of their brows. Epicharmus, the comic philosopher.

CARISTI, in Ancient Geography, a people of Spain, placed by Ptolemy in the Tarragonenses, assigning to them the town of Tuscantium. M. d’Aville places them on the northern coast of Hispania Citerior.

CARISTIA. See CharisTia.

CARISTO, Castle Riso, in Geography, a town of European Turkey, in the island of Negroport; the see of a Greek bishop. Suffragan of Negroport. It is situated at the southern extremity of the island; 54 miles S.E. of Negroport.

CARISTUM, in Ancient Geography, a town of Italy in Liguia, placed by Livy in the territory of the Scatilinates. It was little south of Dertona.

CARITAS. The poculum caritas, or grace-cup, was an extraordinary allowance of wine, or other liquors, wherein the religious at festivals drank, in commemoration of their founder and benefactors.

CARITHMI, in Ancient Geography, a people of Germany, placed by Ptolemy between the Vantiones and the Vibes.

CARITY, in Geography, a river of Scotland, which runs into the Elke, in the county of Forfar.

CARIUM, or Curium, in Ancient Geography, a place in the island of Cyprus, where was the foret of Apollo.

CARIUSS, or Corius, a river of Asia, in Carmania, the mouth of which is placed by Ptolemy near the Persian gulf.

CARIUS, in Mythology, an epithet of Jupiter among the Milesians, probably appropriate to the worship of the Carians.

CARK, or Carke, in Commerce, a certain quantity, or measure, of wool equal to a thirtieth part of a sarl. Car.

CALK. See Chur.

Carl Gustavus, or Eschilstuna, in Geography, a town of Sweden, in the province of Svedama; 54 miles W. of Stockholm.

CARLAT, Le, a town of France, in the department of the Arrigie, and district of Mirepoix; 22 miles N. of Tarascon.

CARLAT, a town of France, in the department of the Cantal; 5 miles S.E. of Aurillac.

CARLENTINI, a town of Sicily, about 2 miles from Lentini, containing 3000 inhabitants, built by Charles V. with a view of making it the head-quarters of his troops in Italy, and almost ruined by an earthquake. It was placed on an eminence to be out of the reach of the uninhalome vapours of the marshes. The housetes are so low, that the streets still resemble a camp.

CARLEPONT, a town of France, in the department of the Oise, and district of Compiegne; 4 miles S. of Noyon.

CARLETON, George, in Biography, a learned bishop in the 17th century, was born at Norham in Northumberland, in 1559, and was chiefly indebted for his education, first in grammar learning and afterwards at the University of Oxford, to the care and liberality of Bernard Gilpin. After
having continued many years in the university, where he distinguished himself as a logician, orator, and poet, and more especially as a divine, he was advanced, without any previous ecclesiastical preferment, to the bishopric of Landaff, to which he was elected in 1617, and consecrated in 1618. In this year he was sent by king James I. to the synod of Dort, and took an active part in the defence of episcopacy. Having given satisfaction by his conduct on this occasion, he was immediately on his return, in 1619, promoted to the See of Chichester, where he remained till his death in 1628. He was a person of bold judgment and various reading, and tried by Camden for his proficiency in divinity, and in other polite parts of learning. To the Papists he was a bitter enemy, and with regard to the doctrine of predestination a rigid Calvinist; he wrote several books both in Latin and in English, of which the principal are his "Heroici Characteres," or Heroic Charactexs, Oxon. 1607, 4to; "Pythes examined, and proved to be due to the clergy by a divine right," Lond. 1616 and 1611, 4to: "Jurisdiction royal, episcopal, papal, wherein declared how the Pope hath intruded upon the jurisdiction of temporal princes, and of the church," Lond. 1616, 4to: "Concilium Ecclesiae Catholice contra Tridentinos, de Scripturis, ecclesia, fide, et gratia," Lond. 1613, 8vo. "A thankfull remembrance of God's mercy," Lond. 1614, which passed through several editions; "Antiromanism" against judicial Althology, Lond. 1624, 4to; "Vita Bernardi Gilpinii," Lond. 1626, 4to, published in English, Lond. 1639, 4to and 1636, 8vo. &c. &c. He was also concerned in the Dutch Annotations, and in the new Translation of the bible, undertaken by order of the synod of Dort, but not completed and published till the year 1637. The son of the bishop by his first wife, Mr. Henry Carleton, embraced the cause of the House of Commons in the civil war with King Charles I., accepted a commission in the parliamentary army, and shewed himself to be an enemy to the bishops. He was chosen representative for Arundel in Suffolk, in the short Parliament, which met at Westminster in 1640. Bp. of Brit.

CARLETON, DUDLEY, viscount Dorchester, an eminent flatman in the 17th century, was the son of Anthony Carleton, esq., and born at his father's seat in Oxfordshire in 1573. Having finished his education, at Wotton-under-Edge school and at Christ Church College, Oxford, he travelled abroad for further improvement. After his return, he became secretary to Sir Thomas Parry, ambassador in France, and in 1603 he occupied the same office in the house of the earl of Northumberland. About this time he was also gentleman of the privy chamber. In the first parliament of king James, he was representative of the borough of St. Mary's in Cornwall, and distinguished himself as an active member and an able speaker. In 1605 he accompanied Lord Norris into Spain, and at the close of this year he was summoned home under a suspicion of being concerned with his former patron, the earl of Northumberland, in the gunpowder-plot; and though on his arrival he was confined, he was very honourably discharged. In 1619, he was appointed ambassador to the court of Brussels, but that embassy not taking place, he was sent in the same capacity to Venice, and previously received the honour of knighthood. During this embassy, he established the character of an able negotiator, and was a principal agent in concluding a treaty between the kings of Spain and the duchy of Savoy. He was also instructed to invite the republic of Venice to accede to the league between the king of Great Britain and the protestant princes of the union in Germany; but his proposal was not accepted. Soon after his arrival in England from Venice, in 1615, he was appointed ambassador to the States-General; and in this capacity he spent the most active period of his life, from 1616 to 1628. He was the last who published the privilege of a seat in the council of state for the United Provinces, which queen Elizabeth had obtained for her ambassadors. Upon his arrival in Holland he was soon involved in the disputes between the Arminians and Calvinists, which then agitated that country; and the part he took in the politics which gave rise to the synod of Dort, excited his attachment to the Calvinistic cause and the public liberty of Germany. Many circumstances occurred in the course of this embassy which rendered his situation peculiarly difficult and trying; but during the progress of them he conducted himself with great firmness and prudence, although the disputes at home between Charles and his parliament, and their dislike to his favourite minister, the duke of Buckingham, thwarted many of the principal plans in which he was engaged. In 1624, Sir Dudley Carleton returned to England, and was appointed vice-chamberlain of his majesty's household; and, at the same time, he was joined with the earl of Holland in a negotiation at the court of France, which terminated only in partial success. Upon his return to England he found parliament much agitated by the mismanagement of public affairs; and being chosen as a representative for the borough of Hastings, he endeavoured to allay the ferment that occurred during the prosecution of his patron, the duke of Buckingham. His conduct, however, on this occasion, gave great offence to the friends and supporters of liberty in parliament; but it was very acceptable to an arbitrary court, and procured for him one of the rewards to which he aspired, a seat in the house of peers, by the title of baron Carleton of Kimberley, in the county of Surrey. Soon after, he was sent as ambassador extraordinary to France, for the purpose of exacting and justifying the dismission of the queen of England's French servants. In this unpleasant negotiation he manifested his usual prudence and adroitness. In 1627 it became necessary for him again to reform his character of ambassador in Holland; but he found the States-General very differently disposed towards this country than they were during his former embassy, nor was he admitted as he had before been into their councils, the ambassador from England having been deprived, by a particular resolution, of that seat in the council of state. He remained, however, in Holland, conducting a variety of interesting negotiations, till he was recalled in 1628. Soon after his arrival he was created viscount Dorchester, and secretary of state. In this capacity he was a principal agent in completing the treaties with France and Spain, and in conducting several foreign transactions, for which he was better qualified than for the internal concerns of the nation, which were now become very intricate and disordered. He seems to have been inclined to arbitrary maxims of government, and to have acquiesced in the dangerous measures of Buckingham, Laud, and others, which widened the breach between the king and parliament. He did not live, however, to witness the diabolical extremity in which they terminated; for having long struggled with the disorders occasioned by frequent returns of the House of Commons, he died in February 1631. He wrote a number of letters, speeches, &c., on political topics; but the most valuable of his remains is a series of dispatches, while abroad, from which a selection of "Letters to and from Sir Dudley Carleton during his Embassy in Holland, from January 1625 to December 1629," was published by Lord Hardwicke, in one volume 4to, in 1757, with an historical preface; a second edition appeared
CAR LIN, CARLIN, or CARLINE, in Commerce, a small silver coin, current in Naples and Sicily, equivalent to about four-pence English.

Gen. Ch. Calyx common dwelling, imbricated; scales numerous, loofe, acute; inner ones disposed in a circle, very long, spreading, glossy, coloured, forming a kind of ray to the common flower. Neaon monopetalous, funnel-shaped, equal, androgynous; tube slender; border five-clft. Stem. Filaments live, capillary, very short; anthers united into a hollow cylinder. Pfl. Germ short; style fimple, the length of the flaments; flagoz oblong, bifo or entire. Peric. none, except the permanent contracted calyx. Stcfts solitary, roundish; down divided into fomewhat chaffly, branched, and teathery rays. Recept. chaffy; chaff eif at the tip into fomeral fegments.

Eff. Ch. Calyx radiated with long, coloured, marginal feales.

tony and white on both fides, spreading widely on the ground. Flower fie from fix to fix inches in diameter; outer fcales of the calyx very fpinous; inner ones white above, purplifh underneath; receptacle thick and feffy. A native of dry fihills in Italy, Spain, Germany, and the fouth of France. 2. C. caulefcent, Lam. 2. Bauh. Pin. 380. Tourn. 500. (C. clariolus, Clafs. hif. 2. p. 155. C. accuris, Willd. 1.) "Stem one-flowered; flower rather large; leaves long, narrow, piniate, green on both fides; pinia gaifeed and toothed." Lam. Reeft perennial. Stem from fix to ten inches high, redcliff, slightly cotony, leafy, generally fimple and one-flowered. Leaues very long, efpecialy the lower ones, divided to the midrib. Flower terminal, considerably fmalier than that of the preceding species. A native of a fandy foil in fificlered situations on the Alpfs and other countries in Southern Europe. Lamninus confiderd thefe two plants as varieties of the fame species, as did alfo Haller and Scopoli, but Lam. MARCK afcerts that they are perfectly diftinct. Both of them have a fefhy receptacle which is eaten by the inhabifants of their native mountains, and is faid to equal that of the artichoke in flavour, while at the fame time it exceeds it in size. It is, however, not likely to rival that fefulent on the tables of the luxurifus, as it has been found not to flourifh in cultivated ground. The roots of both fpecies are aromatic, and are alfo used for food when young and tender, but in adult plants they acquire an acrimonious quality, and are then recommended as a diuretic, fudorific, and alepharmic medicine. The dofe of the root, when dry, is from one to two draufs; when fresh, from two draufs to half an ounce, but is more frequently given in a decoction than in fubftance. Allion. and Bofc. 3. C. aggregata, Willd. 3. Waldii. and

something of its ancient splendour, and was accounted a city." Soon after the Romans had quit the island, Carlisle was entirely abandoned to the northern invaders, and by them completely ruined and left waste. In this state of desolation it remained till the reign of Egfrid, king of Northumberland, who ordered it to be rebuilt, and accompanied it with a wall. He afterwards bestowed upon it the celebrated St. Cuthbert, who visited his new acquisition in the year 696, and, according to Bede, "was visited by the towns-people to see their walls, and a fountain, or well, of admirable workmanship, constructed therein by the Romans." St. Cuthbert was bishop of Lindisfarne; and by Egfrid's grant, Carlisle became an appendage to that see, and so continued till the year 1135, when Henry I. constituted it a separate bishopric. During the incursions of the Danes, in the eighth and ninth centuries, Cumberland was exposed to frequent ravages, and this city underwent its full share of calamity, for it was wholly consumed by fire; its inhabitants were massacred, and its walls overthrown.

"Its very foundations," says Dr. Todd, "were buried in the earth, so that, it is said, large oaks grew upon them; and this is not only attested by our historians, but also evinced by some discoveries that have lately been made of large unhewn oak trees buried ten or twelve feet below ground." In this desolate state the city remained nearly two hundred years, when Walter, a priest, and follower of William the conqueror, repaired a few of the ruined habitations, and attempted to re-establish a religious institution, that had either been founded by St. Cuthbert, or about the time: on this occasion the conqueror issued a mandate, that the inhabitants of Cumberland, but particularly of Carlisle, should be subject to the episcopal jurisdiction of Durham; from the predeceivers of whose diocefan they had received chrihrianity.

When William Rufus returned from his intended attack on Malcolm, king of Scotland, about the year 1094, he made a visit to this city, and perceiving its importance as a frontier station, gave orders that it should be completely restored, and entrusted the execution of his plan to the above Walter, under whose direction several public edifices were built, a strong fortress erected, and the whole defended by a wall of circumvallation. These buildings are supposed to have been raised by Flemish artificers, a colony of whom was settled here by Rufus, but soon afterwards removed to North Wales, and the isle of Anglesey, and its place occupied by a body of South Britons, who were directed to cultivate the neighbouring lands, and to teach the natives the art of rendering the fertility of the soil conducive to their subsistence. From this era, Carlisle may be regarded both as a military station, and a city, and for several centuries its vicinity to Scotland occasioned it to experience many vicissitudes. Having been ceded by Stephen to the Scottish king, David, about the year 1136, it was made a place of retreat by the latter, after his defeat in the dreadful battle of the Standard, in 1138; and here also he received the pope's legate, Alberic, by whose influence all the female captives that were brought into Carlisle, were set free. The chief object from the Scottish leaders a solemn promise, that in future incursions, they would spare the church, and withhold their swords from the aged, from women, and infants; an injunction which humanity dictated, but which the savage customs of the contending nations had not before admitted into the modes of warfare." Carlisle, from this period to the time of Edward I., was subjected to several disastrous events. The 35th year of that monarch, 1307, will be ever memorable in the annals of this city, from the parliament that met here January 20, and continued sitting till the Palm Sunday following, during which period several important acts were passed, and laws made to promote the expedition which the king was then meditating against the Scots. Edward remained at Carlisle till June 28, when he proceeded towards Scotland, but, being felied with a flux, expired at Burgh-on-Sands, on the seventh of the following month. In 1338, Carlisle was besieged by the Scots, and the suburbs burnt; as was frequently the case during the contentions between the rival houses of York and Lancaster. The wealth of the city was so much reduced by these repeated outrages, that Edward IV. consented to the inhabitants one half of the annual rent of 80 pounds paid to the crown, and also granted them the lordship of the royal fisheries at Carlisle. The war between Charles I. and his parliament once more involved this city in the horrors of a siege, and the general distress was increased by the calamity of famine. The blockade commenced October 9, 1644, and continued till the ensuing June, when the place surrendered to general Leffey, who commanded for the parliament. During the intermediate time, the wants of the inhabitants and garrison were so great, that not only horses, but even dogs and rats were eaten; and hemp-feeds were substituted for bread till a small quantity of the provisions was consumed; the city was then given up on honourable terms. The last occurrences of this nature, of which Carlisle was the scene, were those which accompanied the rebellion in 1745, when it surrendered, after a short siege, to the forces of the Pretender. The situation of Carlisle is extremely fine; it stands on a gentle rising ground, in the midst of extensive and fertile meadows, terminated by the diftant mountains, and watered by the Eden, the Caldew, and the Peurler. The two former of these rivers flow on different sides of the city; and their banks and contiguous meadows afford a number of pleasant walks to the inhabitants. In high floods in the winter feaon the low lands are sometimes inundated, and in the city those periods appears excessively wet, or often rising from the midst of a vast lake. The improvements that have been effected at Carlisle, since the union with Scotland, are exceedingly numerous. It was then more celebrated for the strength of its walls, and forts, than either for the neatness of its buildings, or the respectability of its inhabitants; but as the prospect of future commotions vanished, manufactures were introduced, and a taste for improvement accompanied the increas of wealth. This being attended with an augmented population, alterations and improvements were rapidly made. At the commencement of the last century, the dwellings of the inhabitants were mostly formed of wood, clay, and thats, exhibiting singular specimens of poverty and vitiated taste. The gables ended fronted the streets; and the diminutive windows, projecting porches, and clumsy oaken doors, fastened together with large wooden pins, corresponded in form with the gables. The streets were badly paved; and the gutters, or rather trenches, on each side, were so wide and deep, that small bridges were in many parts placed over them for the convenience of passengers. These obstructions have been removed; most of the houses have been rebuilt with propriety and even elegance, and many new ones erected in the modern style. Some very material improvements are now making in the entrance to the city. The space included within the walls is somewhat in the form of an irregular triangle; the buildings, however, extend considerably beyond those limits, but are chiefly spread in the vicinity of the city gates which are three in number, and respectively denominated from their contiguity to the English, Irish, and Scottish kingdoms. The English gate is connected with the building called the citadel, which is of an oblong shape, having a round tower at each end, with slender
flander openings for the discharge of arrows. These openings are singularly contrived, the apertures diverging outward, but gradually decreasing to the inner side, where they become narrower. The towers are low, but apparently of great strength; and, together with the gate-towers, were built by Henry VII. The city walls are principally formed of squared stone, and on the south and east sides supported by numerous buttresses. Various flights of steps lead to the top, whence the prospects are in many parts extensive and interesting. The public buildings are various; yet those which chiefly engage the curiosity of the visitor, are the castle, and the cathedral. These edifices, or at least certain parts of them, are of considerable antiquity, but have undergone many vicissitudes, and experienced various alterations.

The castle stands on the north-west angle of the city, and consists of an outward and inward ward. Within the latter is the great tower, dungeon, or citadel of the castle. This is of a square form, and very lofty, with walls of vast thickness, and constructed according to the modes of defence employed before the invention of cannon. It has since been strengthened according to the modern system, and defended by a half-moon battery and a very large platform, mounted with cannon under cover of the outward wall. The outer ward contains the governor's house; and is one of the gates of the castle the old portcullis is still remaining. This torture was made the prison of the unfortunate queen Mary, for some time after her landing at Wrotham, and the apartments wherein she was lodged are still shown.

The cathedral was erected at various periods, and displays specimens of different styles of architecture. Some part of it is apparently as old as the Saxon times, but the greatest portion is more modern. Several parts of the building are extremely beautiful; but on the whole it appears to much disadvantage, having “been curtailed of its fair proportion” in the civil wars, at which period about 30 yards of the nave was pulled down to erect guard-houses and batteries. The opening was afterwards closed with a wall, and the space within the wall, and the transept fitted up as the parochial church of St. Mary, as the entire west end had formerly been; and divine service is regularly performed in it.

The arches in this part of the cathedral, and in the transept, are circular, and the shafts extremely massive; the height of each being only 14 feet two inches, while the circumference is 17 feet and a half. The choir was begun by bishop Welton in the reign of Edward III., and finished by the succeeding bishops, Appleby, and Strickland. The expences were chiefly defrayed by subscription; and indulgences and remissions of penance were also granted to such of the laity as should by money, materials, or labour, contribute to the pious work; copies of various orders and letters patent granted for the occasion are preserved in the bishop's register. Several ancient monuments are remaining in the cathedral, supposed to be for the bishops Welton, Appleby, and two or three others, but uncertain for whom; and on the north side of the choir, near the altar, is a curious monumental brass plate, erected to the memory of bishop Henry Robinson, who was born in this city about the year 1556, and became celebrated for his piety and learning. The whole structure, and indeed most of the buildings in this city, are composed of a coate, but durable, kind of red freestone. Bishop Tanner remarks, that “this is the only episcopal chapter in England of the order of St. Aultin.” Before the dissolution of the monasteries, several religious houses were established in this city; and some few remain are yet visible. The cathedral itself seems to have belonged to a priory. The chapter-house and cloisters flow on the south side of the cathedral, but were pulled down during the civil wars. The only church in Carlisle, besides that of St. Mary's in the cathedral, is St. Cuthbert's; this is a plain modern building erected in 1728, on the site of the ancient structure, which appears to have been originally built before the destruction of the city by the Danes. The other edifices for religious worship are three meeting-houses for Quaker dissenters, one for Quakers, one for Methodists, and a Catholic chapel. The three principal streets range nearly in the shape of the Roman Y, and meet at the market place, where the town hall, moot-hall, and council-chamber are situated. Here the offices courts and quarter sessions are held, and most of the public business is transacted. The corporation records are also kept here; and the representatives for the city elected. In this diffused part of the kingdom, prisoners are frequently obliged to remain without trial several months, as the sentences are only held once a year. Near the gas are some buildings called charity houses, where decayed freemen, and widows of freemen, are permitted by the corporation to live rent-free. The poor are maintained in a workhouse erected by subscription about the year 1750; prior to that time, they were either formed out, or had a weekly allowance at their own houses. A dispensary was instituted July 1, 1782, for the relief of the indigent sick, and upwards of 15,000 persons are computed to have been relieved since its establishment. Carlisle has received many royal grants, and been invested with great privileges by different monarchs, but nearly all the original charters have been confirmed by the fires that have frequently defoliated the city. Charters of confirmation have been granted by Edward I., Henry V., and VIII., and every succeeding sovereign, to the reign of Charles I., who ordered some alteration to be made in the mode of electing the different officers. The city was first represented in parliament 25 Edward I.: the members are chosen by the free burgesses, who are about 700 in number. The population and buildings of Carlisle and its suburbs, have increased in a very rapid manner during the preceding century; but the augmentation has principally been made within the last 40 years. By the return made under the late population act, the number of houses was found to be 13,386, of inhabitants 10,221. In the year 1761 various new works were established; a company from Newcastle began the calico printing business which has progressively increased ever since, and now furnishes employment to many hundreds of men, women, and children. There are four print fields, which employ a thousand persons, and pay upwards of 20,000l. to the revenue annually. Besides these, there are eight other manufactories; and some of them execute every branch, from preparing the raw materials, to the completion of checks, calicoes, muffins, and all kinds of fancy-work. A brewery has been established, and three others have been lately erected; a wool manufactory has also been built; and so greatly has the trade of the city increased, that the duty paid on licences and exciseable articles amounts to more than 110,000l. yearly. Its growing importance is evinced by the establishment of two banks, both of which have been opened within a few years. Carlisle is 303 miles N.W. from London; and has two weekly markets, Wednesday and Saturday. Hutchinson's history of Cumberland, 2 vols. 410.

CARLISLE, the chief town of Cumberland county, in the state of Pennsylvania, North America, pleasantly and fabulously situated in the post-road from Philadelphia to Pittsburgh, 124 miles W. by N. from the former, and 178 E. from the latter. The town contains about 400 houses, chiefly of stone and brick, and about 1500 inhabitants. The streets intersect one another at right angles; and the public
public buildings are a college, court-house, and gaol, and four edifices for the public worship of the Presbyterians, Germans, Episcopalian, and Roman Catholics. Dickin-

son college has a principal, three professors, a philosophical apparatus, and a library consisting of about 5000 volumes. Its revenue arises from 4000l. in funded certificates, and 13,000 acres of land. N. lat. 46° 12'. W. long. 77° 12'.

CARLISLE Bay, a bay on the west side of the island of Barbadoes, in which stands Bridge-town, which see.—Alfo, a bay of the island of Antigua; three miles W. of Falmouth. —Alfo, a bay on the south coast of the island of Jamaica. N. lat. 17° 37'. W. long. 77° 6'.

CARLTON, s. E. of Lagrow, a bay, on the north coast of the island of Bermuda, or New Greenwich, in the Southern Pacific Ocean, between How's Point and Portland's Island. S. lat. 10° 42'. E. long. 164° 16'.

CARLOCK, CARLISLE, or CARLOCK, a provincial term sometimes made use of to signify the weed charlock. See Carlisles.

Carlisle, in Commerce, a fort of fish-glue, or fishflas, imported from Archangel. It is made with theurgeon's bladder; and is used for clarifying wine, as also in dying. The belt comes from Allaran, a city in Mufcowy, at the mouth of the river Wolga, where they catch great quantities ofurgeon.

CARLOMAN, in Biography, eldest son of Charles Martel, succeeded his father in 741 to the dominion of Austra-

fia. After many warlike expeditions, which were attended with success, and in which he displayed equal courage and ability, he conceived a disgust with the world, and deter-

mined on religious retirement. Accordingly, he made a

journey to Rome with a splendid retinue, and having in his own name, and in that of his brother Pepin, presented mag-

nificent gifts to the holy see, he received the clerical tonsure

from the hands of pope Zachary in 747. He afterwards

retired to a monastery on mount Sarzeau, where he became a monk of the order of St. Benedict; and withdrawing for
greater privacy to the abbey of mount Caffin, he spent his
remaining days in the offices of the convent, and the exer-
cises of devotion. He died at Vienne in Dauphiny in 775.

Carloman was also the son of Pepin the Short, and

younger brother of Charles Martel, and was consecrated at Soif-

fons, in 768, to the sovereignty of Austrasia, Burgundy, and part of Aquitaine. Being on ill terms with his brother,
a serious contetl between them was expected to have taken
place; but it was prevented by the death of Carloman in
771, which left his brother sole poiffessor of the French
monarchy.

Carloman was also the son of Lewis II., called the
Stammerer, and, in conjunction with his brother Lewis III.,
succeeded his father in 879. France was at this time dif-
tracted by intestine competitions for power; and whilst Car-

loman, affihled by his brother, was besieging Vienne, in a
contetl with Bolon, who had established the kingdom of
Aries, or Provence, Lewis was called upon to repel the
Normans, who made inroads on the northern side, and died
in 852. Carloman, in consequence of this event, was de-
clared king of France, and abandoning the siege of Vienne,
marched into Picardy, where with a sum of money he pur-
chased the retreat of the Normans. He was soon after-
wards wounded in hunting the wild boar, and died in 884, at the early age of 18, before the consummation of a mar-
riage, which he had contracted with a daughter of Bolon.

Carloman was also king of Bavaria, and in 876 suc-
ceeded his father Lewis I. king of Germany in the sovereignty of Bavaria, comprifing, besides that province, Boh-
emia, Moravia, Carinthia, Austria, Scavonia, and part
of Hungary. With the design of annexing Italy to his do-
minions, he marched his army into the country, but after a paral success in Lombardy, he was induced by a false alarm to abandon the accomplishment of his purpose, though he retained the title of king of Italy. He died of a pailly in 882. Mod. Un. Hist. vol. xix.

CARLONI, GIOV. BATTISTA, an eminent painter of history, was a native of Genoa, and having protected the

trained his art at Rome and in the school of Pagnigano at Florence, he became one of the most fertile, original, and

ferticulous minds of Italy. The most splendid works of this sort, and of his brother Giovanni, are the frescoes of the
cathedral of Cutiatato at Genoa, which exhibit a won-
ndetul effect of colouring. He survived his brother 59 years, and distingulished himself by this novel style in the church

collections of Liguria and Lombardy. His powers were very various; and he is said to have possessed equal facility in

oil and fresco, colour and design, velocity and correctness.

He had incessant employment, and was unrivalled in dili-

gence and perseverance. After a prolonged life of 86 years, he died in 1680. Pikkington by Fuseli.

CARLOS, in Geography, a feast on the north coast of

Terra Firma, situated on an island which commands the

channel between the gulf of Venezuela and that of Maracaybo

on the fourth, little more than 20 miles N. from the town of

Maracaybo.

Carlos, a town of Veragua, in New Spain, 45 miles

S.W. from Santa Fe, situated in a large bay, having a num-

ber of small and defert islands at its mouth. N. lat. 7° 46'.
W. long. 82° 16'.

Carlos, a town of North America, in the province of

Nicaragua, seated on a river which runs from the lake of

Nicaragua into the Caribbean Sea. N. lat. 11° 42'. W.
long. 69° 45'.—Alfo, a town of the island of Cuba; 62
miles E. of Havana.

Carlosa, a town, in the interior part of Brul, on the

south-east side of St. Francis river, and north by west

from Villa Nova. S. lat. 15°.

CARLOSTADIANS. See Carolstadians.

CARLOTTA, la, in Geography, a town of Spain, in

the province of Andalusia, built in 1769 for German and

Italian emigrants; 15 miles S. of Cordova.

CARLOVINGIANS, in History, the title by which the

French kings of the second race have been distinguished,

and which was first derived from Charles Martel, (see his ar-
ticle,) and commenced with his son Pepin in 752, and ter-
minated with Louis V. in 987. They reckon 14 kings of
this family. The mutual obligations, says Gibbon, (Hist. vol.
ix, p. 150; &c.) of the popes and the Carolingian

family, form the important link of ancient and modern,

civil and ecclesiastical history. On the part of the popes,
the most essential gifts which they conferred on the Carlo-
vingian race were the dignities of the kings of France, and

of patron of Rome. See Pepin and Carlomagno.

On the other hand, the gratitude of the Carolingians was
adequate to their obligations, and their names have been

consecrated as the favours and benefactors of the Roman

church. Her ancient patriomony of farms and houses was

transformed by their bounty into the temporal dominion of
cities and provinces; and the donation of the Exarchate,
(see,) was the first fruits of the conquists of Pepin.

CARLOW, or CATHARLOUGH, in Geography, a county in

the province of Leinster, Ireland, which lies between

Kildare on the north. Queen's county on the north-west,

Wicklow on the north-east, Wexford on the south-east, and

Kilkenny on the south-west and west. It is 26 Irish miles

(33 Eng.) in length from north to south, and 23 (29 Eng.)
Car

at its greatest breadth, but it narrows to the south in the form of a wedge. It contains 117,050 Irish acres, or 214 square miles, (220,008 acres, or 344 square miles English measure,) and 8763 houses, which, at five to each house, would give a population of about 44,000, which is certainly a moderate computation. The number of parishes is 52, none of which are wholly improper; but in confederation of unions they form only 17 benefices, all in the diocese Leighlin. Some idea may be formed of the religious state of the country from four of these benefices being without a church, and only one of them having a glebe house. The number of members which represent it in the imperial parliament are three, two for the county, and one for the town of Carlow. The river Barrow, which is navigable, runs through this county from north to south, and for many miles forms its western boundary. The woody hills which skirt the northern part present a beautiful and varied scenery. The river Slaney also conveys it in its passage from Wicklow to Wexford. That part of Carlow which lies on the east of the Barrow is covered with rough and high hills. Another mountainous tract continues all along the bounds of Wicklow, beginning at the north with the high and rocky mount Leinster, and terminating in that which is called Blackstairs. But the champaign country is very rich and fertile. When Mr. Young was in this county in 1776, he observed cultivation rising up the sides of the mountains; he found also that the hiring tenant was in general the occupier, and that the average rent of the county was 15s. per acre, which was about the average rent of the whole island. Rents, however, have probably risen considerably in consequence of the improved state of the country with respect to inland navigation. The mineralogy of the country is very imperfectly known, but from the account of Mr. D. Stewart, published in the Transactions of the Dublin Society, by which he was employed, there appears to be abundance of marl, lime-stone, gravel, great variety of clays, some of them light and foamy, some iron ore, and a great deal of oxied of manganese.

Carlow was made a county by king John during his visit to Ireland in 1210, having been before called Hydrene, and Hy-Cavanagh. It was part of the territory, of which Strongbow acquired the sovereignty by his marriage with Eva daughter of the king of Leinster, confirmed to him by king Henry as suprême lord of Ireland; and it was afterwards held by his descendants, the earls Marefchel. The principal towns are Carlow, Leighlin bridge, and Tullow.

The above article is chiefly taken from Dr. Beaufort's excellent memoir accompanying his map of Ireland; but Mr. Young's tour, and other works, have been consulted. No authentic account of Carlow has yet been published.

Carlow, a borough and port town, and the affixe town of the county of the same name, situated on the river Barrow. It was formerly called Catherloch, or Cathroch, i.e. the fortress in the late, and gave name both to the county and barony in which it is placed. It was early fortified, some say by king John, others by John Comlaile of Cheiller, and Hugh de Lacy, whilst the building of the castle is attributed to Eva, the wife, or Isabel, the daughter of Strongbow. It was certainly deemed of some consequence as a fortress, and therefore had its full share of the calamities which have for so many centuries devastated Ireland. It does not appear, however, to have been large. Boats speak of it with contempt, but it has since increased, and was, at the union, deemed worthy of sending a burgess to the imperial parliament. It has a manufacture of a coarse kind of wooden cloth, but it is not considerable. The junction, however, of the grand canal with the Barrow, and the improved navigation of the river, will probably occasion the further increase of the town. The appearance of music is cheerful, from the number of white houses scattered up and down in the neighbourhood. It is regularly built, has some good public edifices, and has a neatness Superior to most towns in Ireland. The castle is a fine ruin overlooking the Barrow. The Roman Catholics have a large factory here. Carlow is 39 Irish miles S.E. of Dublin, on the great southern road, in N. Lat. 52° 52' W. long. 7° 56'. Dr. Beaufort's Book of Roads, &c.

Carlow, a military town of Selva, in which the Greek bishop of Selvania resides; founded by the princes who concluded there with the Turks in 1699, and also for its sacred wine.

Carlsbad, a town of Bohemia, in the circle of Sanz, on the river Eger, celebrated for its baths of hot water, discovered in 1757 by the emperor Charles IV., as he was hunting; 56 miles W. of Prague.

Carlsbad, or Caroline Water. These very singular and celebrated hot mineral waters I have engaged (as they deserved) the attention of many naturalists and chemists. They are situated at the town of Carlsbad, in Bohemia, on the banks of the river Toepich, or Teply, which joins the Eger, a tributary to the Elbe, and were first brought into high repute by the emperor Charles IV. about the year 1757.

There are several springs of this water within a small compass, of which the principal one, called the Parol, or Forus, oozes out with great vehemence in a large body through a natural vault or incrustation of flataclite, which it has formed by long deposition.

The temperature of this fountain is invariably 165° Fahr. at all seasons, and hence it always lends forth a considerable body of steam. Some of the other springs are only 120° to 125°. The taste of this water is strongly alkaline, saline, rather bitter, and strongly chalybeate. It has scarcely any smell, and contains nothing hallucinogenic.

This water is remarkable for a very rapid deposition of carbonat of lime as it cools, which forms a very hard and beautiful flataclite, or petrifaction, that encrusts any wood, mofs, &c. which happens to remain in it for a day, and soon chokes up any pipe through which it is conducted. Along with the carbonat of lime, the iron which it holds is also precipitated, forming with the former a beautifully variegated flataclite, which takes a high polish.

This water has been analyzed by several eminent chemists, and particularly by Bergman, and by Dr. Becher in his elaborated treatise on this spring, and more lately by Klaproth. The latter only we shall give, which however agrees very nearly with the others.

Carlsbad water contains carbonat of soda, sulphat of soda, muriat of soda, and, when full hot, carbonat of lime held in solution by carbonic acid, fex, carbonat of iron, and a portion of uncombined carbonic acid.

It will not be uninteresting to give in a few words the method by which this excellent chemist proceeded in the analysis of this very compound water.

A given quantity, quite hot from the spring, was first placed in a retort of known capacity, and brought to boil, and the boiling continued till no more air-bubbles were given out. The gas was carefully collected over water, and when examined, was found by the test of lime-water to be pure carbonic acid, excepting the portion of common air of the velfets. This way, however, was not quite so accurate as if a mercurial bath had been employed.

The existence of iron in this water, (as in the Bath waters,) is only ferment to tefts when applied immediately at the spring itself. Under these circumstances, if some of the 

Vol. VI.
fresh water is put into a bottle containing a slice of the gall-
nut, a very tenible purple colour is produced immediately.
But on cooling, the minute quantity of iron which it con-
tains separates as a fine flocculent whithish-brown oxide, and
the tell of gall no longer produces any effect.

To discover the actual quantities of the ingredients, 100
cubic inches of the water were gradually evaporated to a
small bulk, during which, an earthy sediment was formed,
which was separated by the filter. This sediment was di-
gested with muriatic acid, which dissolved only a part, and
left a loon slimy earth, which proved to be silex. The mu-
ritic solution was then treated with prussiat of potash, which
caused a blue precipitate of prussiat iron to subside, after
which, the lime that remained in the solution was thrown
down by carbonated alkali. The prussian blue therefore
indicated the quantity of oxyl of iron in the water, and the
carbonated alkali reprecd the carbonat of lime.

It then remained to separate the salts from the clear solu-
tion, being the water lefled to a few ounces by evaporation.
It having been proved by previous tests that the water con-
tained a naked alkali, probably carbonat of soda, and a
salt with sulphuric acid, and another with muriatic acid, the
basis of which was not an earth, but an alkali, there remain-
ed little doubt but that soda was the base in all, (no other
freed alkali being ever found in mineral waters.) The only
object that remained, therefore, was to reprecd the actual
quantity of uncombined carbonat of soda, and the quantity
of the sulphuric and muriatic acids.

Previous experiments having been made on the power of a
given sulphuric acid to satura the soda, some of the same acid
was added to the water till an accurate saturation of the
naked alkali was produced, by which the quantity of the
latter was discovered. The whole was then decomposed by
acetated barytes, and the sulphuric acid of the sulphat of
barytes formed thereby confused therefore of the portion of
acid added to satura the uncombined soda, and of that
which already exisled in the water in the form of sulphat of
soda. By subtracting the former portion from the whole
quantity of acid indicated by the sulphat of barytes pro-
duced, the remainder was the acid belonging to the sulphat
of soda in the water originally, whence the proportion of
this salt could also be estimated. Lastly, the quantity of
muriated soda was found by precipitating the muriatic acid
by nitrated silver.

From these experiments it is concluded, that a hundred
cubic inches of the Carlbad water contain,

Of carbonic acid, 32 cubic inches.
The cubic inch of water here used is equivalent to 290
grains of distilled water.
The average quantity of water daily drank by the visiters
is not less than about five pints, divided in about fourteen
cups. The usual time spent in the use of the water is about
four weeks. The water is used in a great variety of dili-
ders. It is highly serviceable in dyspeptic complaints, ob-
structions of the abdominal visera, diseases of the kidneys,
and urinary passages, and of the utinie system in females.

The actual quantity of saline matter which is conically
poured out with the water, (almost the whole of which is
wasted) is very enormous when the elimate is carried to the
supply of water during a year. Dr. Becker estimates the
main sping alone to throw out hourly 705 emmers, each
either being about half a cubic foot; and hence in the year
it will throw out 5,887,900 cubic feet. These contain
the following quantities of salts, (reduced to pounds avor-
dupsis.)

besides earths and iron, and also 59,459 cubic feet of car-
bonic acid gas.

It is estimated also that the water of all the other springs
united, equals that of the great spring, whence the above
numbers may be doubled, and this large quantity has been
annually poured out, for a certainty, during 430 years, to
the year 1800.

No other advantage is made of this spring by way of manu-
ufacture, except that annually some hundred pounds of
sulphat of soda are prepared from it.

CARLSBRUN, in Geographie, a town of Bohemia, in the circle of Chrudim; 6 miles S. of Leutnitzhelm.

CARLSBURG, a village of Germany, in the circle of Franconia, and bisporial of Wurzburg, with a caffle, built by
Charles the Bald, situate on the Maine, oppofite to Carliltad.

CARLSCRONA, or CARLSCROON, a feaport town of Sweden, in the province of South Golithland, which derives
its origin and name from Charles XI. who laid the founda-
tions of a new town in 1680, and removed the fleet from
Stockholm to this place, on account of the advantageous
situation, and fecurity of the harbour. The greater part of
the town stands upon a small rocky island, which rises gently
in a bay of the Baltic; the suburbs extend over another
small rock, and along the mole close to the bafon, where
the fleet is moored. The way into the town from the main
land is carried over a dyke, and along two wooden bridges
joined by a barren rock. The town is luscious, confining of
some houfes of brick, but moily of wood, and one or two hand-
some churches, and containing about 18,000 inhabitants.
The suburbs are fortified towards the land by a stone wall.
The entrance into the harbour, which is naturally difficult,
on account of a number of shoals and rocky islands, is
secured from the attack of an enemy's fleet by strong forts,
built on two islands, under the batteries of which all vessels
must pafs. A dock, planned by Bollem, has been hollowed
in the solid rock; it was begun in 1714, and finished in
1724; but having been found too small, it has been since
enlarged, and is capable of receiving a ship of the first rate.
Its dimensions are 190 Swedish feet in length, 33 in depth,
and 46 in breadth; and it contains 300,000 cubic feet of
water, of which it is usually emptied in 10 hours, by the
labour of 50 men, who are employed at the fame time in
pumping, and relieved every half hour. As this is at prezent
the only receptacle of ships under repair, new docks have
been projected and begun upon a stupendous plan; in the execu-
tion of which it was proposed to construct 30 docks, for
building and laying up the largest ships, at the extremity of
the harbour. A bafon, capable of admitting two men of war,
was designed to communicate, by flues, with two smaller
bacons, from each of which it was proposed to extend five
rows of covered docks; each row being separated by walls
of
of stone, and each dock provided with stone gates, so as to be filled or emptied by means of pumps. Close to the docks, it has been intended to construct magazines for naval stores, and to inclose the whole with a stone wall. This project was begun in 1572, and resumed by Charles III. At the commencement of the works, 25,500l. were annually expended; but the funn has since been lessen'd to about 600l. per annum, and the number of docks reduced to 20. The primary intention of this grand plan was to obtain dry docks, for the purpose of keeping the whole fleet entirely covered from wind and weather. Difficulties have, however, occurred, which have retarded the completion of this work; and in many years they have only finished one dock, the bottom and sides of which are of hewn granite, with rows of granite pillars that support the roof: so that it bears rather the appearance of a colonnade to a temple than a receptacle for ships.

The ships are built at Carlscrona chiefly by English artificers, and as the provinces of Blekinge and Skane, though they abound with oaks, do not furnish enough for a continued supply, the Swedes procure their ship-timber from Germany. From their own territories they are supplied with masts and yards, pitch and tar, and the greater part of the flux used in the navy; the ropes and sails are manufactured from Riga hemp. They call cannon, and make gunpowder with Swedish salt-petre. The harbour of Carlscrona is large and commodious, with depth of water sufficient for ships of the first rate to carry their lower tier of guns. This town is the 15th in order of the towns that vote in the diet. N. lat. 56° 20'. E. long. 15° 26'. 15'. Cox's Travels, vol. iv.

CARLSELD, a mini-town of Germany, in the circle of Erzgebirg, seated on the river Wilzich. It was founded in 1678.

CARLSGRAF CANAL. See Canal.

CARLS-INTEL, Great and Little, or Charles's islands, lie about a Swedish mile from the coast of the island of Gothland; in which was formerly a quarry of marble, used for building the churches of Gothland.

CARLSKAMN, or Carlshaven, lat. 54° 02'. a sea-port of Sweden, in the province of Blekinge, on the Baltic, built in 1658 by Charles X. and improved and fortified by Charles XI. In this town are a woollen manufacture, a forge for copper, and a timber-yard. It has the 15th vote in the diet, contains about 1200 inhabitants, and is distant 22 miles W. from Carlscrona.

CARLSMARCKT, a town of Sielca, in the principality of Brier; seated on the river Stover, and 9 miles E. of Brier.

CARLSRUHE, or Karlsruhe, a town of Germany, in the circle of Swabia and margravate of Baden, situated in a forest, where the prince has a fine palace and gardens. It was founded by the margrave, Charles-William, in 1715, and is constructed on a regular plan. It contains of one principal street, about an English mile in length, which is at a considerable distance in front of the palace, and in a direction parallel with it. All the other streets go off at right angles from this, and are so arranged, that the view in each of them is terminated by the front of the palace. The houses are as uniform as the streets, being all of equal size and height. Here are four churches, two for Roman Catholics and two for Protestants, a synagogue for the Jews, and about 400 houses. The margrave of Baden has contrived every means in his power to introduce industry and manufactures amongst his people. Accordingly there is a considerable number of English tradesmen in this place, employed in manufactures similar to those of Birmingham, and instruct the inhabitants in that line of trade. Here are also many watchmakers from Geneva, whom the prince has engaged to settle in the town by granting them various privileges. Carlshohe is distant 3½ miles N.W. from Durlach, and 14 S. from Philippstede.

CARLSSTADT, a town of Sweden, in the province of Varmeland, built on the island of Tingwalla, formed by the two branches of the Chara-Elb river, which, after encompassing it, unite and fall into the lake Wenner. The island is 12 miles, and the town ¾ mile in circumference. It was built by Charles IX. whose name it bears. The streets are broad and straight; and, excepting the cathedral and school, the houses are constructed of wood painted. It is a bishop's see; and the episcopal palace, which is likewise of wood, but not painted, has a front to extensive, and with so many windows, that it appears like a manufactory. The town contains 1500 inhabitants, who carry on a commerce of iron and wood across the Wenner, and import sugar, tea, and spices. It has a linen and woollen manufacture, and in its vicinity is a medicinal spring. In the order of the diet it has the 38th voice, and is a place of considerable trade. N. lat. 51° 27'. E. long. 13° 15'.

CARLSTAD, a town of Germany, in the circle of Franconia, and bishopric of Wurzburg, on the Main; 12 miles N.W. of Wurzburg.

CARLSBAD. See Marstrand.

CARLUCAT. See Carlus.

Gen. Ch. Cal. fpathe univeral; leaflets four, lanceolate, concave, frayed, spreading, one another, caducous, terminated by four or five points; fpathe common cubical, four-flowered; fpathe proper oval, crowned with numerous round teeth. Car. none. Stam. in the male flowers numerous, very short, inserted into the receptacle. Pfl. in the female flowers; germ cubical, hollowed at the top into two furrows crossing each other; styles four, filiform, very long; stigma resembing an anther. Peric. berry cubical, one-celled. Seeds numerous, small, oblong, even. The male and female flowers are intermingled on the same frpaxid.

CARLUX, or Carlux, in Geography, a town of France, in the department of the Dorodogne, and chief place of a canton in the district of Sarlat; 6 miles E. of Sarlat. The place contains 619, and the canton 5863; inhabitants: the territory comprehends 122½ kilometres and 15 communes.

CARMACE, in Ancient Geography, a people of European Sarmaca, placed by Piny in the vicinity of the Palus Nacot.

CARMAGNOLE, in Geography, a fortified town of Piedmont, in the marquisate of Saluzzo, which formerly gave the title of count to the eldest son of the marquis. The name is a diminutive of Carmagna, which was a town in its neighbourhood, that funk in size and importance, whilst the latter, by an ascension of its inhabitants, increased. In the war between the French and Imperialists, 1691, it was fortified by the former, and made one of the strongest places on the frontiers of Piedmont. The four faubourgs built by the French at some distance from the town are well peopled, and divided into four parishes. Within the walls Carmagnola has only one parish; and the whole number of inhabitants in the faubourgs and the town is estimated at 6700. The market is well supplied, and much frequented by perfoms from the adjacent countries, as well as by the Piedmontese themselves. It is 11 miles S.S.E. of Turin, and 13 N.N.E. of Saluzzo. N. lat. 44° 42'. E. long. 7° 34'.

CAR
CARMANICUS SINUS, or Gulf of Carmania, the name given by Ptolemy to the Persian Gulf: the sea which washed the coasts of Carmania was called Carmanianus Pelagus; and the ancient name of mount Pangæus was, according to Plutarch, Carmanianus Mons.

CARMANOR, a name which, according to Plutarch, (De Floro.) was given to the river Iincus; and mount Taurus was, as he says, denominated Carmanianum monte, from Carmanor, the son of Bacchus, who lived there and his life in hunting.

CARMARA, a town of India, placed by Ptolemy on this side of the Ganges.

CARMATHIANS, or KARMATIANS, in History, an Arabian sect, which bore an inveterate malice against the Mahometsans, and which began to occasion disturbances in the year of the Hegira 277, A. D. 890. It is said to have derived its origin from an Arabian preacher of the name of Carmath, in the neighbourhood of Cufa, who assumed the lofty and incomprehensible style of the guide, the director, the demonstration, the word, the holy ghoold, the camel, the herald of the Messiah, who had converted him in a human shape, and the representative of Mohammed, the son of Ali, of St. John the Baptist, and of the Angel Gabriel. In his mystic volume, the precepts of the Koran were refined to a more spiritual lense; he relaxed the duties of ablation, fasting, and pilgrimage; allowed the indiscriminate use of wine and forbidden food; and nourished the fervour of his disciples by the daily repetition of 50 prayers. The idlenesses and ferment of the riotous crowd awakened the attention of the magistrates of Cufa: a timid prosecution affihied the progress of the new sect; and the name of the prophet became more revered after his person had been withdrawn from the world. Carmath, or Karmata, contrived by his fanatism to form a very large party of followers, out of whom he chose 12, as his apostles, to govern the sect, and to propagate his doctrines. The governor of the province feigned the prophet, and committing him to prison, swore that he should die; but a damsel belonging to the governor, overhearing this menace, took the key of the dungeon from under her master’s head as he slept, and having released the prisoner, returned it to the place from which she had taken it. His adherents took this occasion of reporting, that God had taken the prophet, who had made his escape into heaven. He appeared afterwards in another province, and declared to his followers, that it was not in the power of any one to do him hurt; notwithstanding which, his courage failing him, he retired into Syria, and was not heard of any more. His sect, however, continued and increased; and his 12 apostles divided themselves among the Bedoucens, “a race of men,” says Abulfeda, “equally devoid of reason and of religion,” and by the success of their preaching, they threatened Arabia with a new revolution. The Carmathianas were ripe for rebellion, since they disclaimed the title of the house of Abbas, and abhorred the worldly pomp of the caliphs of Bagdad. They were insusceptible of discipline, since they vowed a blind and absolute submission to their Iman, who was called, in their apprehension, to the prophetic office by the voice of God and the people. Instead of the legal tithes, he claimed the fifth of their subsistence and spoil; the most flagitious crimes were no more than the type of disobedience; and the brethren were united and connected by an oath of fealty. After a bloody conflict, it prevailed in the province of Bahrein, along the Persian Gulf; the tribes of the desert were subject to the shepheard, or rather to the sword, of Abu Said and his son Abu Taher; and these rebellious Imans could muster in the field 107,000 fanatics. The mercenaries of the caliph were dispersed in every action; the cities of Recess and Baldae, of

Cufa
Carmel is not only the name of the mountain, but of a city which is said to have been built upon it, and of a heathen deity worshipped in it, without either temple or altar, as Tacitus tells us (Hist. 4, 20). It is supposed, however, that these have been of some temple upon it, since Jamaihah (in Vit. Ptolemy) forms us, that this place was the favourite retreat of Hyphasis, who spent much time alone in the temple. According to the Greeks, called it 'Oepeis oxi hour, the mountain and temple of Jupiter. Sometimes says, that Vishnupat ascended this mountain, and offered a sacrifice to the deity of the place, when he came into Syria in order to seduce the Jews who had revolted. This mountain has been celebrated and revered among Christians, on account of its having been the residence of Elijah, who is supposed to have lived in a cave, which is there shown, before he was taken up into heaven; and in the summit of it is a chapel dedicated to this prophet, which affords an extensive prospect over the sea and land. This is also said to have been the scene, where Elijah called for a fire from heaven, which consumed the divine sacrifice, thus convincing the Israelites of their folly in hating between their God and Baal. (1 Kings, xix.)

On this account the Christians began, from the earliest ages, to manifect a more than ordinary veneration for it; and both the mountain and cave of Elijah, as well as the place where they say his garden was, are visited and revered not only by Christians and Jews, but also by the Mahometans. We are likewise told, that a church with a monastery was erected on this mountain in some of the early ages of Christianity, and that when, by the lapse of time and the fury of its enemies, it was decayed and almost destroyed, a new one was afterwards erected by the zeal of a Calabrian priest, who founded the order of the Carmelites, since spread through all the Roman Catholic countries, and of whom there is still a certain number, living in this ancient monastery. See Carmelites.

Carmel was also a city of Palestine in the southern part of the tribe of Judah, seated on a mountain of the same name, which was part of a long chain of mountains, that pafled through the southern part of Palestine and over the lower coast of the Asphalite lake, and bounded the country of the Amalekites. This city was the residence of Nabai the carmelite, Abigail's husband; and it was on this mountain that Saul returning from his expedition against Amalek, erected a trophy. (1 Sam. xvi. 11.)

Carmel, Knights of Mount, are a military order of knights Hospitallers, instituted in 1607, by Henry IV. of France, under the title, habit, and rule of our Lady of Mount Carmel, and in confederation of a bull of pope Paul V. in 1608, united to the order of St. Lazarus at Jerusalem, with all its commanderies, priories, and other goods for its endowment. The founder proposed it to consist of one hundred French gentlemen, who should be obliged, in times of war, to march close to the kings of France, as their guard. Authors are much divided, whether to call this a new institution, or a reformation of that of St. Lazarus; though it is generally accounted a new institution. See Lazurus.

Carmel, in Geography, a township of America, in Dutchess county, New York. By the last census of 1790, 237 of its inhabitants were electors. See Lazurus.

Carmel, in Geography, a river of Scotland, which runs into the Irvine, in Renfrewshire.
CARMELITE WATER. See Carmes, Eau de.

CARMELITES, or White Franciscans, or the order of our Lady of Mount Carmel, an order of religious, making one of the four tribes of mendicants, or begging friars; and taking both the name and origin from mount Carmel, (above described,) formerly inhabited by the prophets Elijah and Elilah, and by the children of the prophets; from which this order pretend to descend in an uninterrupted succession.

The manner in which they make out their antiquity has something in it too ridiculous to be rehearsed. Some among them pretend they are descendants of J. C. who, as well as the virgin Mary, are said to have assumed the habit and profession of Carmelites. Others go farther, and make Pythagoras a Carmelite, and the ancient Druids regular branches of their order. The learned Jesuit, Papebroch, was accused before the tribunal of the Roman pontiff, by the Carmelites, on account of his having called in question the dignity and high antiquity of their order. The conject on this subject was long and tedious; but it was so far determined, or at least suspendered, in the year 1665, by Innocent XII., that silence was imposed upon the contending parties: although the Carmelites affirm to this very day, that the prophet Elijah was the parent and founder of their ancient community.

Phocas, a Greek monk, speaks the most reasonably; he says, that in his time, viz. in 1185, Elijah’s cave was full extant on the mountains, near which were the remains of a building, which intimated there had been anciently a monastery; that some years before, an old monk, a priory of Calabria, whose name was Berthold, by revelation, as he pretended, from the prophet Elijah, fixed there, and assembled ten brethren. In 1250, Albert, patriarch of Jerusalem, gave the found a rigid rule; which Papebroch has first printed. This rule consisted of 16 articles; one of which confined them to their cells, and enjoined them to continue day and night in prayer; another prohibited the brethren having any property; another enjoined falling from the feast of the holy cross till Easter, except on Sundays; abstinence at all times from flesh was enjoined by another article; one obliged them to manual labour; and another imposed upon them a strict silence from vespers till the tierce the next day. In 1257, or according to others, 1226, pope Honorius III. approved and confirmed this rule; though it was afterwards mitigated by Innocent IV. On the conclusion of the peace between the emperor Frederic II. and the Saracens in 1229, the Carmelites quitted the Holy Land, under Alan the fifth general of the order. Some of them were sent to Cyprus, in 1238, and founded a monastery in the forest of Fontania. Some Sicilians at the same time returned to their own country, and founded a monastery in the suburbs of Meffina. St. Louis brought some of these Carmelites with him from the Holy Land into France. Many of the popes gave them the title of “Brothers of the Blessed Virgin.”

The Carmelites came into England in the year 1240, and erected a great number of monasteries. Their first houses were at Alnwick in Northumberland, and Allesford in Kent. In England and Wales they had about forty houses. This order is eminent for the devotion of the feaculary, for its missions, and for the great number of saints with which it has stocked the Romish church. In the 17th century, there were four canonizations in this order, viz. of S. Theresa, S. Andrew Corin, S. Mag. de Pazzi, and S. J. de la Croix.

In the 16th century S. Theresa, a Spanish lady of an illustrious family, undertook the difficult task of reforming the Carmelite order, which had departed much from its primitive sanctity, and of reftoring its neglected and violated laws to their original credit and authority. Her associate

in this arduous attempt was Johannes de Santa Cruza, and her enterprise was not wholly delineate of success, notwithstanding the opposition she met with from the greatest part of the Carmelites. Hence the order was, during the space of 15 years, divided into two branches; of which one followed a milder rule of discipline, while the other embraced an inftinate of the most severe and self-denying kind. The former, viz. Carmelites of the ancient observance, were called the mitigated, or moderate; and the latter, or those of the strict observance, were called Barefooted Carmelites.

The ancient observance has only one general, under whom are forty provinces; and the congregation of Montana, which has a vicar-general.

Barefooted Carmelites are a reform of the ancient Carmelites, set on foot in 1540, by St. Theresa; so called from their going bare-footed.

She began with the convents of nuns, whom she restored to the primitive austerity of the order, which had been mitigated by Innocent IV. in 1245, and at length carried the same reform among the friars. Pius V. approved the design, and Gregory XIII. confirmed the reform in 1558; at the particular desire of Philip II., king of Spain. This separation of the bare-footed Carmelites from those of the ancient observance was confirmed, in 1587, by Sixtus V., and completed, in 1609, by Clement VIII., who allowed the former to have their own chief, or general. But, after having withdrawn themselves from the others, these austere friars quarrelled among themselves, and in a few years their differentions arrived at such a height, that they were divided anew, by the pontiff last mentioned, into two communities, each of which was governed by its respective general, and had its peculiar constitutions: the one the congregation of Spain, divided into six provinces; the other called the congregation of Italy, comprehending all the rest, not depending on Spain.

The habit of the Carmelites was at first white, and the cloak laced at the bottom with several folds. But pope Honorius IV. ordered it to be changed for that of the Minims. Their scapulary is a small woolen habit of a brown colour, thrown over their shoulders. Instead of linen shirts, they wear lnsey-wolsey, which they change twice a week in the summer, and once a week in the winter.

CARMELO, in Geography, a river on the coast of New Albion, S.E. of Francisco bay. N. lat. 36° 5'.

CARMELUM PROMONTORIUM, in Ancient Geography, a maritime point of mount Carmel near Caipha. See ACRE.

CARMELUS, in Mythology, a deity of the Syrians, who inhabited the vicinity of mount Carmel. He had an altar, but no temple. Tacitus (Hist. II. 78.) says, that a priest of this deity predicted to Vespasian, that he should be emperor.

CARMEN, an ancient term among the Latins, used, in a general sense, to signify a verse; but in a more peculiar sense to signify a psalm, charm, form of exortion, exclamation, &c. couched in a few words, placed in a mystic order, on which its efficacy depended.

Scuton derives Carmen from the Celtic cermn, the front of joy, or the verses which the ancient bards sung, to encourage the soldiers before the combat; adding, that the Greek κερκος signifies combat and joy; which is true; but then it does not come from the Celtic cermn, but from κερκος, I rejoice.

Some fetch the origin of the poetical carmina, or verses, hence: and say, they took that name from their resemblance to tse spells; others, on the contrary, say, that the spells had their origin from the poetical verses, and took their name from their resemblance to those; it is at least certain,
certain, that many of the ancient chansers, wherewith dieses were supposed to be cursed, were metrical verses, to which, in these ages, greater efficacy was ascribed than to mere words or profe.

Vigenerce, again, derives carmen from Carmenata, because that prophets couched their predictions in verses, or choral prologues; but others say, the prophets took the name Carmen from carmen, on the latter account.

CARMEN, was anciently a denomination given to preceptors, laws, prayers, imprecations, and all solemn formulas, couched in a few words, placed in a certain order, though written in prose.

In which sense it was, that the elder Cato wrote a "Carmen de moribus," which was not in verse, but prose.

CARMEN falubre, a sect of ancient verses composed by Numua, sung by the salii, accompanied by the clashing of Ancylos or sacred bucklers. See Ancylo.

Carmen also denotes a form of prayer, or words whereby divers among the ancients devoted themselves. Such was that of the Decii, spoken of by Pliny, Hist. Nat. lib. xxxviii., cap. 2.

CARMEN, or Carmina, in Geography, an island near the west coast of Norway, about 14 miles long and two broad. N. lat. 59° 30'. E. long. 5° 29'.

CARMENIAN WOOL, a denomination given to a kind of goat's hair, brought from Carmenia, or Carmania, a country of Asia Minor. See Carmelia.

CARMELTALIA, a feud, among the old Romans, celebrated annually on the 11th of January, in honour of Carmona, or Carmentis, a prophetess of Arcadia, mother of Evander, with whom she came into Italy, 60 years before the Trojan war. After her death she was admitted into the number of the Divi indigetes of Rome. Dionysius Hal. and Plutarch say, that Carmenata was the "Themis" of the Greeks. The solemnity was also repeated on the 15th of January, which is marked in the old calendar by Carmelitalia relata. This feast was established on occasion of a great fertility among the Roman dames, after a general reconciliation with their husbands, with whom they had been at variance, in regard of the use of coaches being prohibited them by an edict of the senate.

The women celebrated this feast: he who offered the sacrifices was called Scaccobis Carmentalis.

Authors are divided about the origin of the word Carmen: Vigenerc says, the prophetess was so called quia carmis verba, out of her frenzy; by reason of the enthusiasm the frequently fell into. Others say, she took her name from carmen, verse; because her prophecies were couched in verses; but Vigenerc, as before noted, maintains carmen to be derived from Carmenata.

CARMELTALIS PORTA, in Ancient Geography, a gate of Rome, situated on the banks of the Tiber, at the foot of the Capitol, in the place called "Montanara." It was also called Scelerina, because the 300 Fabians, defeated by the Etruscans, on the banks of the Crmara, made their escape from Rome through this gate.

CARMES, EAU DE, the Carmelite water, or compound balm water, famous in France, and most parts of Europe for its extraordinary cooling virtues. It is said to be extremely reviving, to be good in all sorts of fits, apoplexies not excepted; and to relieve the gout when it attacks the Roman. The Carmelites at Paris, who make considerable advantage by vending this water, keep the preparation of it a great secret. See Melissa.

CARMINATIVE, in Materia Medica, a denomination formerly applied to those articles of the Materia Medica, which poifefs the property of distilling wind from the bowels.

The origin of this absurd term has been ascribed to those times of ignorance and superstition. In the practice of medicine, in the hands of licential and ignorant men, was intimately connected with magic, predictors, and other rites of deception: among which, incantations in verse (carmas), recited during or preceding to the administration of the remedies, were frequently related to. In several cases, disorders, especially in the form of hysterical complaints, and in some of the forms of stomatitis, or inflammation, the operation of medicines of this class is extremely quick; their effects are obvious and unequivocal, and the relief which they afford is extremely considerable: hence they were peculiarly adapted for the accomplishment of incantations. It is not improbable, however, that the term may have been originally adopted in a metaphorical sense. A medicine operating thus quickly, and producing almost instantaneous relief, might be said to operate like a charm; and it might therefore be figuratively, but quaintly denominated carminative. The word is scarcely to be found in the medical language of the present day.

The substances included under this denomination, are of an aromatic or gracefully delicious nature; consisting chiefly of the essential oils of vegetables, either pure, or suspended in water by distillation, or combined with volatile salts or other stimulants; of the left active forms of the ethers, or the dulcific spirits, as they were formerly called, &c. The stomach when greatly dilated with wind, becomes unable to relieve itself (like the bladder, after a long retention of the urine), partly in consequence of the weakened state of the over-tretched fibres of its muscular coat, and partly, perhaps, from a contraction of the cardia, or upper orifice. For, however difficult it may be to explain it, the fact is well known, that a loss of power to act, and a morbidly increased or spasmodic action, are both consequences of the debility of the muscular fibre. The mode of operation of the carminative medicines, therefore, on the contractile coats of the stomach, by which it is relieved from the distention of wind, consists chiefly in exciting to a certain degree of action the dilated and weakened muscular coat, by which the accumulations are propelled, though the upper orifice; but partly also in revolving any flight spasmodic contraction of that orifice, which may exist. For as debility produces, so stimulants counteract, both the diminished and the morbidly great action of the muscular structure.

CARMINUM is a beautiful red precipitate of the colouring matter of Cochinilla, which see.

CARMINIUM, in Ancient Geography, Carmignana, a place of Italy, near Aletium, over against Lupia, and before Tarentum, in Messapia.

CARMONA, in Geography, a town of Spain, in the province of Andalufia; it was known to the ancients by the name of Carmo, placed in Bética, to the south of Ibera, and south-east of Hilipolis, and esteemed by Caesar one of the strongest towns of the country. Philip IV. in consideration of a present of 40,000 ducats, gave it the title of city. It is built on a declivity, looking down upon a rich valley, which is bounded by distant hills, excepting only to the south, where a wide opening gives a pannage to the Guadalquivir. It contains 12,685 persons, and includes 7 parish churches, with 5 conven for men, 2 for women, and 2 hospitals; and they reckon in this place more than 100 oil mills: about 20 miles N.E. from Seville, and 40 S.W. from Cordova. N. lat. 37° 14'. W. long. 5° 37'.
belonging to the house of Aulonia. N. lat. 46° 15'. E. long. 5° 37'.

Chats and order, pennantaria digynia.

Gen. Ch. C.d. permanent, with five acute segments. Coret. monoptepalous: tube short; border with five acute divisions. Stem. five. Pflr. germ superior, globose; styles two: stigmata simple. Peric. drupe globose; but with five cells and five seeds.

According to Ventenat, it is nearly allied to Ehretia.

Carmoyle Road, in Geography, an anchorage in Belfast loch, on the north-eastern coast of Ireland, where large vessels, which load or unload at that port, usually lie.

Carmulita, a town of Hindoostan, in the fomofah of Dowhatabad; 70 miles N. from Vizapour, and 88 E. from Poonah. N. lat. 18° 40'. E. long. 75° 22'.

Carmyllissus, in Ancient Geography, a town of Asia Minor, in Lycia, situated in a small valley, at the foot of mount Antaracus; mentioned by Strabo.

Carna, in Geography, a town of Arabia Felix, according to Ptolemy and Strabo, the latter of whom says, that it was the largest town belonging to the Minocas, a people who inhabited the coast of the Red Sea, and who were neighbours to the Sabaeans.—Also, a town of Phenicia, the "Carnes" of Pliny.

Carnabadium, in the Materia Medica of the ancients, a name given to a drug frequently mentioned by the Greek and Arabian writers.

Carnabat, in Geography, a town of European Turkey, in the province of Romania; 50 miles W. of Burgas.

Carnaborus, a town of Poland, in the palatinat of Red Russia; 63 miles S. of Halicz.

Carnac, or Karrac, a village of Egypt, about 1½ mile below Luxor (which see), consisting of miserable cottages, which serve as a foil to the magnificence of the splendid ruins by which they are surrounded. These comprehend obelisks, some of which are very beautiful and well preserved, rows of sphinxes, and a number of terraces, composed of basaltic with a dog or lion's head, of Egyptian sculpture, which formed to serve as avenues to some principal building; mutilated statues; walls covered with historical engraving; which is a representation of men, horses, chariots, and battles; portions of great elevation; colonnades of immense size; and columns of astounding brilliancy; granite and marble; and towns of prodigious dimensions, supported by capitals, and forming the roof of magnificent buildings, &e. &c. Bruce fugites, that Luxor is Di. ipolis, and that Carnac, together with that place, constituted the "Jovis Civitas magna" of Ptolemy.

Carne, or Carnac, in Ancient Geography, a people placed by Pliny in the European Sarmatia, near the Cimmerian Bosporus.

Carnal Manasal, in Geography, a town of Arabia; 45 miles S.E. of Mecca.

Carnalis, in Ancient Geography, a town of Asia Minor, placed by Ptolemy in Armenia Minor.

Carnaloch, or Carn Lough, in Geography, lies in the country of Arran, Ireland, near the mouth of the small river Gleavey, which falls into Glenarm bay; 2 miles N. of Glenarm, and 108 N. of Dublin.

Carmanart, a river of the country of Galway, Ireland, which falls into the bay of Galway; it has several branches, one of which proceeds from Loughrea. This river is partly subterraneous, and it forms a turlogh; i.e. a spot which in winter appears as a lake, but in summer is dried up, and reclaimed a good deep-walk.

Carnapole, a factory on the Malabar coast of India, S.S.E. from Cochin.

Carnarium, a channel-house, or repository for the bones of the dead.

Carnasa, or Carsana, in Ancient Geography, a town of India, on this side of the Ganges. Ptolemy.

Carnatic, or Carnada, in Geography, a country of Hindoosan, lying along the coast of Coromandel, from Cape Comorin, in N. lat. about 8° to about 16°. It is bounded on the north by the country of Golecanda, on the east by the bay of Bengal, and on the west by the Myfore, Dindigul, and Travencore. The dominions of the late Mahomed Ally, nabob of the Carnatic, and an ally of the East India company, commence on the south of the Guntow Ciree, called also Mortizanaugar and Condavir, and extend along the whole coast of Coromandel to cape Comorin; including Tanjore, Marawar, Titchinopoly, Madura, and Ténivelly, all being appendages of the Carnatic. Under this description, the Carnatic is not less than 570 British miles in length from north to south, but no where more than 120 wide, and commonly no more than 75. "Such a long narrow tract of country," says major Kennell, "bordered by an active and powerful enemy, whose territories are, moreover, of a compact form, and his force more readily collected, must always be subject to have its distant provinces cut off from its affluence; or, if it divides its force, for their separate defence, the safety of the whole will be endangered." The Carnatic, says this ingenious geographer, anciently comprised all that part of the peninsula that lies south of the Goudegama and Toombuddra rivers, from the coast of Coromandel eastward to the Gout mountains westward, and divided into Bollagaut (which see), and Payengaut; the former being the western part, and the latter the eastern part, or the Carnatic, according to its present definition. The revenue of the nabob is fixed at about a million and a half sterling per annum; out of which he was accustomed to pay a subsidy of 160,000l. per annum, to the East India company, towards the expense of their military establishment. The evils attendant on the improvident conduct of the nabob have been frequently felt in past times, and measures have been adopted for guarding against them in future. This nabob has been one of the most ancient, and was supposed to be one of the most faithful, allies of the British nation in India: and Mahomed Ally is said to have been established in the government of Arcot (the capital of the Carnatic), and its dependencies, chiefly by the active cooperation of the British power in India. During the war, in 1780, a combination was formed against the Carnatic, between the French and the famous Hyder Ally, and his successor Tippoo Sultan; and they had made some progress towards the conquest of it, till they were stopped by the interposition of Great Britain. In consequence of this event, it became necessary that an adequate military establishment should be maintained by Great Britain for the defence of that country; and, in 1787, a regular contract was settled to that effect; the nabob Mahom d' Ally agreeing to pay an annual subsidy for the support of the troops, amounting to 15 lacs of pagodas. After the war, in
1793, between Great Britain and the late Tipoo Sultan, it was represented to the marquis Cornwallis, that the nabob was unable to discharge these pecuniary engagements, and an indulgent modification of that treaty was framed, which reduced the subsidy to nine lacs of pagodas. In both treaties, however, it was stipulated, that the nabob should contract no alliances, nor cut off correspondence with any European or other power, without the knowledge and concurrence of the British government. Upon the death of Mahomed Ally, in 1793, he was succeeded by his eldest son Omutul Omrah. The second son of the nabob, viz. Azam ul Omrah, whose fate is unknown to us, left behind him a son Azeen ul Dowlah, who was kept a prisoner in the palace of the nabob at Chepauk, till the death of his uncle, the late nabob. The nabob Omutul Omrah professed that he succeeded to the possession of the territories of his father under all the obligations of the treaties of 1787 and 1792, and a reciprocal friendship subsisted, for some time, between him and the English company. Nevertheless, after the fall of Seringapatam, in 1799, the original records of Tipoo Sultan, as well as his official correspondence, fell into the hands of the British government; and it was discovered, that the nabobs Mahomed Ally and his successor, Omutul Omrah, had carried on with Tipoo Sultan a correspondence, inconsistent with, and tending to the subversion of, the alliance between the nabob of the Carnatic and the India company, and incompatible with the security of the British power in the peninsula of India. Hence it was concluded, that these princes had placed themselves in the situation of enemies to Great Britain. As the nabob approached his end, instructions, dated the 7th and 9th of July, 1801, were issued by the government of the East India company, and a party of troops was stationed at the palace of Chepauk, for the purpose of carrying them into effect. On the death of the nabob, an attempt was made to adjust the affairs of the Carnatic, under the direction of Lord Clive, governor of Madras. In the mean while Omutul Omrah, the nabob, died; and the British agents were informed, that he had appointed his reputed son, Tajeel Omrah, commonly called Ally Husseain, then about the age of 18, to be his heir. In the course of the negotiation that ensued, it was alleged, on the part of the British agents, that the only adequate security for the rights and interests of the British government in the Carnatic was the entire and exclusive administration of the civil and military authority. To this proposition it was objected, that if this was to be the basis of the arrangement, the flotation of nabob of the Carnatic must be annihilated, and all the power transferred into the hands of the company. On the other hand, it was replied, that the condition now proposed actually exiled in the treaties of 1787 and 1792; and that the object of the proposed arrangement was to secure the rank, dignity, and splendour of the nabobs of the Carnatic, instead of exercising the full rights acquired by the British government. Ally Husseain, with the advice of his two khans, expressed his disapprobation of the terms proposed; and when the treaty with him was brought to this termination, it was resolved, if possible, to open a negotiation with the prince Azzeen ul Dowlah; the consequence of which was, that the prince affixed his signature to a Persian draft of the proposed treaty, on the basis of that rejected by Ally Husseain, binding himself to execute a more formal treaty, at the period of his intended installation; and on the following day he was formally introduced to the governor of Madras, as the future nabob of the Carnatic, and conducted to the palace appointed for his residence. Thus the whole substantial power of the Carnatic was vested in the hands of the India company, and a proclamation was issued expelling the nature and terms of the arrangement. The treaty bears date the gift of July, 1801, and enjoins that a permanent system for the collection of the revenue, and for the administration of civil and criminal justice, under the sole and undivided authority of the favourable company, exercized by the governor in council of Fort George, shall be established throughout every soil and province, of the entire dominions of the Carnatic.

The British possessions in the Carnatic are confined, chiefly, to the tract called the "Jagir," which extends along the coast, about 188 British miles, and 17 inland, in the widest part. Its revenue is reckoned at 7,500,000. Before the Jaghire, there are lands dependent on Cuddalore; but the amount is not considerable. The whole amount of the land revenue dependent on Madras, including the cizairs, is flated at 7,500,000. per annum. The principal towns of the Carnatic are Arcot, the capital, Madras, Ongole, Pondicherry, Cuddalore, Tanjore, Trichinopoly, Madura, and Tennevelly. The principal rivers are the Pernar, the Palifer, and the Cuvrey. The Carnatic abounds with forts and fortresses of various kinds. Carnatic-gur and Doby-gur are two noted fortresses on the ridge of hills on the west of Arcot.

CARNATION, in Botany. See Dianthus Caryophyllus.

CARNATION, Spanish. See Calliafa Vescenria.

Carnation-grafs, in Agriculture, a term applied to the finer sorts of grapes, probably from their having this kind of colour in their flowers.

Carnation-tree. See Calliafa Ilenia.

Carnation, among Dyers, red rose-colour, for which take liquor of wheat-bran a sufficient quantity, alum three pounds, tartar two ounces; boil them, and enter twenty yards of broad cloth; after it has boiled three hours, cool and wash it: take fresh clear bran-liquor a sufficient quantity, and madder five pounds; boil and adder according to art.

The Bow-dyers know that the solution of Jupiter, or delved tin, being put in a kettle to the alum and tartar, in another procees, makes the cloth, \\
&c. attract the colour into it, so that none of the cochineal is left, but the whole is absorbed by the cloth.

Carnation, Flehs-colour, in Painting, is underfoot of all the parts of a picture in general, which represent flehs; or those parts of the human figure which are naked, and without drapery.

Titian and Corregio, in Italy, and Rubens and Van-Dyke in Flanders, excelled in carnations.

It may be here observed, that the word carnation is not properly used for any particular part of the person painted, but for the whole nudity of the piece. See Colouring.

CARNATUS, in Ancient Geography, a river of Asia Minor, in Catanippia.

Carnawall, in Geography, a town of Hindooistan, is the country of Sirhind; 7 miles N.W. of Delhi.

Carnchunaig, a mountain of Scotland, near Kincardine, in the county of Rofs.

Carnk, in Ancient Geography, a town of Asia, situated on the confines of Phcenicia and Syria, placed by Steph. Byz. in the former, and by Pliny in the latter. Strabo calls it Caranos, and makes it a sea port of the Arabians.—Also a town of Asia Minor, in the Ecide. Steph. Byz.

Carnk, in Geography, a small part in the country of Donegal, province of Ulter, Ireland, in the northern part.
part of the peninsula of Inisowen; 133 Irish miles N.W. from Dublin, and about 18 N.W. from Londonderry. N. lat. 54° 14'. W. long. 5° 59'.

Car, a fishing town, or rather village in the peninsula of the Mullet, county of Mayo, Ireland, not far from the island that joins it to the other part of the county. See Mullet. N. lat. 54° 14'. W. long. 96° 50'.

Carnea, in Ancient Geography, a place of Palelinne in Batacena, north-east of mount Galaad, and south-east of Tiberias.

Carneades, in Biography, an eminent Greek philosopher, the founder as well as an illustrious ornament of the third or new academy, was a native of Cyrene in Africa, and born, according to the most probable supposition, in the 3d year of the 141 Olympiad, B.C. 214. He received his first instructions with regard to the art of reasoning from Diogenes the Icne, and when he became a member of the academy, he attended the lectures of Egefinus, and from him acquired the art of disputation which had been introduced by Arcesilaus. As the successor of Egefinus in the chair of the academy, he contributed to restore its declining reputation. Having occasion to visit Rome, in company with Diogenes the Icne and Critolaus the peripatetic, on an embassy for obtaining the mitigation of a fine inflicted upon the Athenians, by the Sicilians under the authority of the Romans, for having lated Welle Oropus, a town of Batavia, Carneades and his associates exhibited many specimens of Grecian learning and eloquence, not before known in that city. Carneades excelled in the vehemence and rapid, Critolaus in the correct and elegant, and Diogenes in the simple and modest kind of eloquence. The former having one day harangued, with great variety of thought and copiousness of diction, in praise of justice, before Galba and Cato the censor, undertook next day, with a view of establishing his doctrine of the uncertainty of human knowledge, to refute all his former arguments. He attracted the attention and excited the admiration of his auditors by the subtlety of his reasoning, and the fluency of his language; and the popularity which he acquired alarmed Cato to such a degree that he persuaded the senate to hale the return of these philosophers to their own schools, left the Roman youth should lose their military character in pursuit of Grecian learning. In his own school the reputation of Carneades, both as an orator and a philosopher, was so great, that other philosophers, when they had dismissed their scholars, came to hear him. So intent and indefatigable was his application to study, that at his meals he often forgot to take the food that was set before him. Whilst he did justice to the merit of Chryfippus the Icne, he frequently opposed him; and he used to say, that if there were no Chryfippus, there would be no Carneades, thus acknowledging he owed a considerable degree of his reputation as a disputer to the abilities of his opponent. He possessed extraordinary powers of voice, and was accustomed to speak so loud, that he needed some standard by which to regulate it; but his master told him that he had such a measure or standard in the number of his hearers. As he grow old, he was greatly disturbed by the apprehensions of dying, and frequently lamented, that the fame nature which had composed the human frame could difsolve it. After a life prolonged to very advanced age, he clofed it in his 85th, as some fay, or according to Cicero and Varrius Maximus, in his 90th year. For an account of the doctrine of the new academy, as it was epony and taught by Carneades, see Academy. Although he opposed the doctrine of the Stoics concerning the gods, he did it, as Cicero fays, not with a view to destroy the belief of superior powers, but merely to prove, that their theological system was unsatisfactory. A vowing likewise his repugnance to their opinion, concerning fate, he affirmed, on the ground of experience, the existence of a self-determining power in man, and hence inferred, that all things did not happen, as the Stoics maintained, in a necessary series of causes and effects, and consequently, that it is impossible for the gods to predict events dependent on the will of man. As the foundation of morals, he taught, that the ultimate end of life is the enjoyment of those things, towards which we are directed by the principles of nature. Brucker's Hist. Phil. by Enfled, vol. i. Gen. Dict.

Carnedde, in British Antiquity, denote heaps of stone supposed to be Druidical remains, and thrown together on occasion of confirming and commemorating a covenant. Gen. xxxi. 46. They are very common in the isle of Anglesey; and were also used as sepulchral monuments, in the manner of tumuli: for Mr. Rowland found a curious urn in one of these carneddes. Whene it may be inferred that the Britons had the custom of throwing stones on the deceased. From this custom is derived the Welsh proverb, Karr ar dy ben, ill bide thee. Rowland's Mona Antiqua Referred. See Barrow and Beriol.

Carnea, in Antiquity, a festival in honour of Apollo, furname Carnes, held in mott cities of Greece, but especially at Sparta, where it was first instituted in the 26th Olympiad.

The reason of the name, as well as the occasion of the institution, is controverted. It lasted nine days, beginning on the 19th of the month Carneus or Carnius, which fea. The ceremonies were an imitation of the method of living and discipline used in camps.

Carnel. The building of ships first with their timber and beams, and after bringing on their planks, is called carp-worke, to distinguih it from clinch-work.

Vellis also which go with mizen-fails instead of main-fails, are by some called carnels.

Carlenian. See Chalcedony.

Carnera, in Geography, one of the smaller Cape Verd islands, which is little more than a rock.

Carnero, a cape in the South Sea near Santa Maria, on the coast of Peru. S. lat. 1° 35'. W. long. 77° 20'.

Carness, a cape of Scotland, on the north coast of the island of Pomona; 2 miles N. of Kirkwall.

Carnesville, the chief town of Franklin county, in the state of Georgia, America, 100 miles N.W. of Augusta; containing a court-house and about 20 dwelling houses.

Carnew, a small town of the county of Wicklow, Ireland, near the county of Wexford. It makes a despicable appearance, but some lime and much coarse woollen are manufactured in the neighbourhood of it, and its fairs are much frequented. It is 44 miles South from Dublin. N. lat. 53° 43'. W. long. 6° 31'.

Carney, a village in Dorset, wherein their mouths become so furred that they cannot eat.

Carni, in Ancient Geography, a people who were separated from Norica by the Carnic or Julian Alps. According to Ptolemy they had three cities, "Forum Julium," "Concordia," and "Aquileia." Hence it appears that they occupied a part of the state of Venice. Orosius says that they were a Gaulish nation; and he concurs with the epitome of Livy in saying that they were vanquished in the year of Rome 635, by the confid Quintus Martius Rex.

Carnia, a name given to the territory at the bottom of the Adriatic gulf, inhabited by the Carni. It corresponded to the Venetian Friuli and a small part of Carniola.

Carni-
CARNICOBAR, in Geography, the northernmost island of that cluster in the bay of Bengal, called Nicobar. It is low, of a round figure, about 40 miles in circumference, and at a distance appears as if it were entirely covered with trees; though there are upon it several well cleared and delightful spots. The soil is a black kind of clay, and marly; producing, however, abundantly and with little care, moll of the tropical fruits, such as pine-apples, plantains, papayas, cocao-nuts, and areca-nuts; besides excellent yams, and a root called "cacho." The only quadrupeds upon the island are hogs, dogs, large rats, and a large animal of the lizard kind, called by the natives "tobouma." Of poultry they have only some few hens. The snakes, of various kinds, are numerous, and their bites are frequently fatal to the inhabitants. The timber is plentiful, and of various sorts: some of it is very large, and affords excellent materials for building or repairing ships. The natives are low in stature, but well made and remarkably active and strong; they are copper-coloured, and their features have a cast of the Malay. The women, in particular, are very ugly. The men cut their hair short, and the women have their heads, and wear no covering but a short petticoat, made of a fort of rush or dry grafts, which reaches half-way down the thigh. The men have only narrow strips of cloth tied tight about their middle. The ears of persons of both sexes are pierced when young, and by teasing into the holes large plugs of wood, or hanging heavy weights of shells, they render them wide and dilatable in their appearance. They have enormous appetites, and are addicted to excessive drinking of arrack; and much of their time is spent in feasting, and dancing. Their favourite food is pork, eaten almost raw, and their hogs, fed on the cocoanut and sea-water, are remarkably fat; but they have plenty of small sea-fish, which they strike with their lances. Their common drink is cocoanut milk, and a liquor called "foura," which oozes from the cocoanut tree after cutting off the young sprouts or flowers. This is suffered to ferment, and thus becomes intoxicating. Whilst the old men smoke tobacco, and drink fora, the young sing and dance. Their only musical instrument is a hollow bamboo, about 2½ feet long, and three inches in diameter; along the outside of which is stretched from end to end a single string made of the threads of a spider's web, and the place under the string is hollowed a little, to prevent it from touching. This instrument is played upon in the same manner as a guitar; it produces but few notes, and is generally accompanied with the voice. Their huts are commonly built upon the beach, and form villages, each of which consists of 15 or 20; and each house contains a family of 20 persons and upwards. These habitations are raised upon wooden pillars, about 10 feet from the ground; their form is round, and having no windows, they appear like bee-hives covered with thatch. They enter them below by a trap-door, and with the help of a ladder, which they draw up at night; thus, and also by bending round the pillars a smooth kind of leaf, they secure their huts from being infested with snakes and rats. The flooring is made of thin strips of bamboo, which are laid at such distances as to admit light and air. The art of making cloth is unknown to the inhabitants of this island; but they procure this as well as hatches and hanger-blades, in exchange for their cocoanut, which are reckoned the best in this part of India. They have no money, nor do they allow any value to the coin of other countries, except for the purpose of ornaments; and accordingly the young women sometimes hang feathers of dollars about their necks. The cloth they purchase, beyond that which they want for their own consumption, is intended for the Chonry market.

Chonry is a small island to the south of theirs, to which a large fleet of their boats sails every year about the month of November, to exchange cloth for canons, which they cannot make a home. This voyage is performed by means of the sun and stars; for they have not any knowledge of the compass. In their disposition there are two remarkable qualities: viz. an entire neglect of compliment and ceremony, and an aversion to disturbances. From their frequent intercourse with strangers they have in general acquired the barbarous language of the Portuguese, so common over India; their own tongue has a sound quite different from that of others, their words being pronounced with a kind of drop, or catch in the throat, at every syllable. They have no notion of a God; but they firmly believe in a devil, and worship him from fear. When they are threatened with a storm, they imagine, that the devil intends them a visit, upon which they perform many superstitious ceremonies. When a man dies, his whole live flock, cloth, hatchets, fishing lances, and every movable thing in his possession, are buried with him; and his death is lamented by the whole village. His wife, according to custom, must confer to have a joint cut off from one of her fingers; and if the refues, the must submit to have a deep notch cut in one of the pillars of her house. Polygamy is not known in this island; and they punish adultery, by cutting from the man's offending member a piece of the foreskin, proportioned to the frequency or enormity of the crime. Among these people there seems to subsist a perfect equality. Respect is paid to age, but they have no appearance of the exercise of authority one over another. Their society seems to be cemented by mutual obligations continually conferred and received. N. lat. 9° 17'. E. long. 93° 18'. Asia. Researches, vol. ii.

CARNICULA is used by some for a canuckle, more particularly for that fleshly substancce which invests the teeth.

CARNID, in Natural History, a name given by Averno to what is called carnich by more ancient writers.

CARNIFERES, in Geography, a town of France, in the department of the North, and chief place of a canton, in the district of Cambrai; the place contains 718, and the canton 14,110 inhabitants; the territory comprehends 122½ square kilometres, and 16 communes.

CARNIFEX, among the Romans, the common executioner. By reason of the odiousness of his office, the carnis was expressly prohibited by the laws from having his dwelling house within the city; but lived without the "Porta Metia," or "Eufquina," near the place defined for the punishment of slaves, called "Seftertium," where were erected crouzes and gibbets, and where also the bodies of slaves were burnt, or thrown out unburied. The carnis (according to some), was anciently keeper of the prison under the triumviri capitales, who had only the superintendency, or care of it; hence, "tradero ad carnis," to imprison. In middle age writers carnis also denotes a butcher.

CARNIFICATION, in Surgery, is the conversion of bone into flesh; of which procex many examples are referred to, and described by medical writers; but in fact, this phenomenon consists only in the absorption of the phosphate of lime, or offensive matter of a bone, leaving the fi-
brous substance, and consequently producing a flexibility of
the bone. This is not strictly a transmutation of bone into
flesh, but merely a removal of one of the component parts
of bone: viz. that which gives firmness and liability to the
defensive fluid. See Mollities Ossium, and the article
Bone.

CARNIOLA, duchy of, in Geography, a country of
Austria, bounded on the north by Carnithia and Styria, on
the west by Friuli, the county of Goraz, and the Adriatic
Sea, on the south by Istria and the Adriatic, and on
the east by Dalmatia and Croatia. Its name “Krain,” or
“Crmnia,” was probably derived from Carnia, for which
the appellation Carniola was substituted, and used as early
as the 8th century. This duchy, in its greatest extent,
measures about 150 miles from east to west, and about 100
from north to south. The country is molly mountainous;
some of the mountains being naked, others clothed with
wood, and many of them continually covered with snow.
The principal of these mountains are the Caleberg, the
Lobel, or Lymbel, separating Carniola from Carnithia, and
affording from its summit a very fine prospect, the Krim-berg,
the Carl, or Kart, the Burhanmer-wald, anciently “Al-
pes Julic,” and “Alpes Carnicae,” (see Alps;) also a high
and wooden mountain extending from the rife of the Saue,
through Carniola, into the Turkish dominions, and contain-
ing in its lead breadth three German miles, and the high
mountain of Nana, lying between Wipach and St. Veit.
Among the mountains of this country there are many fruit-
ful valleys and fields, which yield not only good pallilage,
but excellent crops of corn, hemp, flax, and nollet. It af-
fords likewise good fruit for cyder and perry, chestnuts,
walnuts, olive trees, oranges, lemons, citrons, almonds, figs,
&c. and vines, the graps of which supply very good red
and white wine. The country also breeds horned cattle
and horses in great plenty, and furnishes all sorts of fowl
and venison, and also many kinds of fish. The mountains
yield iron, lead, and copper. The Carniolan marble is
reckoned beautiful. Carniola abounds with immense caves,
and other natural curiosities. The chief rivers are the Saue,
the Laybach, the Gurk, and the Conia; and the principal
inland lakes are the Kufelkr and Wochenein, and also Circknitzer Sea. It has 31 cities, Laybach being the
capital, 35 market-towns, 200 castles, 4000 villages, and
other settlements, 38 convents, 154 parishes, 60,100 inha-
bited houses, and 6775 uninhabited houses, 75,785 families,
1501 clergy, 401 nobles, 2269 burgburers and tradesmen,
and 43,600 peasants. The common people, who are robust
and hearty, are of Slavonian extraction, but the nobility are,
for the most part, German. Among the common inhabit-
ants, occupying different parts of the country, there is a
great difference of manners, dress, and language. The two
principal languages are the Slavonic or Wundish, and the
German. The Christian doctrine was introduced into Car-
niola about the latter half of the 8th century; and the La-
thene doctrine was admitted in the 16th century; but the
inhabitants are now principally Roman Catholics, besides
some members of the Greek church. The exports from Car-
niola are iron, flax, quicksilver, red and white wine,
olive oil, cattle, sheep, eucle, linen, a kind of woolen
stuff called “mabalan,” Spanish leather, honey, ship-tim-
ber, and every kind of wood-work, such as boxes, dikes,
trenchers, spoons, knives, &c. The Slavi, called also Winds,
or Wends, took possesion of this country after the
year 548. In the time of Charlemagne and his pohtery,
it was governed by the dukes of Friuli, and afterwards by
those of Carnithia; but under Otto II. it became a pecu-
liar margraviate, probably derived from Otto I. The fo-

CARNION, in Ancient Geography, a strong city of
Gilead, in Palæstine, belonging to the half tribe of Manasséh,
on the other side of Jordan. It was to this city that Ti-
mothæs sent all the women, children, and luggage, when
Judas Maccæus was in full march against him. Either
also, after the defeat of his army, and the loss of 70,000
men, who escaped the slaughter, being closely puz-
zed by the victorious army of Judas, retreated, and many
of them fought refuge in the temple of Atargatis. Judas,
however, burnt the temple and those who were sheltered in
it; and then setting fire to the rest of the city, they all
perished likewise, either by the flames, or by his sword,
and the number of 25,000. 2 Macab. xii.

CARNION, or CARNIUM, a town of Pelo-pomumus, in La-
conia. Polybius.—Also, the name of a small stream on the
southern part of Arcadia, which ran from the south-east
to the north-west, and discharged itself into the river Ga-
thenes.

CARNITZ, in Geography, a town of Germany, in the
circle of Upper Saxony, and duchy of Pomerania; 5 miles
N. of Greifenburg.

CARNIVAL, or CARNAVAL, a season of mirth and re-
jocicing, observed with great solemnity by the Italians,
and particularly at Venice.

The word is formed of the Italian carnavale; which Du
Cange derives from carn-a-val, because the flesh is then put
into the pot, in order to make amends for the feast of ab-
stinence ensuing. Accordingly, in the corrupt Latin, he ob-
erves, it was called carnelevatum, and carnephneum; as the
Spaniards still denominate it, carnes tolendas.

The carnival time commences from Twelfth-day, and
holds till Lent. Fools, balls, operas, masquerades, ridottos,
concerts of music, intrigues, marriages, &c. are chiefly
in carnival time. During the carnival, St. Mark's place is
the grand scene of riot and folly, where mountebanks and
various other impostors are allowed to erect their shags, and
to practice on the credulity of the crowds who assemble round them. See Venice.

CARNIVOROUS, in Zoology, an epithet generally ap-
plied to animals of every description that subsist for the
most part, or entirely, on animal food. In a more limited fene
we understand by carnivorous animals, those only of a
vage and voracious nature, affimulating in our ideas some in-
 distinguishing ferocity of character in the manners of those crea-

turers when seeking and attacking their prey, as well as actually feeding on flesh. We naturally conclude, for this reason, among the principal carnivorous animals the lion, the tiger, and the wolf; or among birds, the eagle, and the kite, with a host of other rapacious creatures, upon which nature has bestowed pre-eminent advantages of courage, strength, and arms to aid them in seizing upon, tearing into pieces, those animals on which they feed: they have either formidable canine teeth, or fangs; claws, or talons; the quadrupeds possessing both, and the birds the latter: fishes with very few exceptions are carnivorous, but their only offensive weapons are the teeth, or in some species the spines and prickles disposed on various parts of the body. Quadrupeds that feed both on flesh and vegetables are more or less deficient with respect to those characters by which carnivorous quadrupeds are known; and those still more so to that of the teeth entirely on roots, barks, fruits, grubs, or other vegetables: the brute have no cutting teeth either in the upper or lower jaw; the recour have them only in the lower jaw; and the front teeth of the hulse are obtuse;—the food of those animals is vegetables.

Deferrall, and other modern French writers on zoology, form a distinct subdivision of their carnivorous; (an order of quadrupeds comprehending most of the Linnaean fera) under the title of carnivora. This subdivision comprises the three families of martins, cats, and dogs, in the following order. The first family, Meatans, or martes, contains five genera; namely, foricate, mangevole, marte, mouflette, and lourte. Suricate is a genus formed only of a solitary species, viverra tetradactyla of Linnæus; the mangevole consists of Linnaean vivere, and marte of animals separated from both the Linnaean genera, viverra and mufelle. Mouflette consists of viverra mephitis. Linn. and other Linnaean species of viverra; and the last genus, lourte, comprises part of the muscle of Linn. and lura of Erxleben. The second family are Felins, comprehending the two genera, chat (felis, Linn.) and civette (viverra, Linn.) The third family, Cynodens, contain three genera, hyène, canis, (Linn. Linn.) furnace, consisting only of one species, (canis corvo, Linn.) and chien. (canis of Linneus,) including the common dog, familiaris, wolf, lupus, and fox, vulpes.

Carnivorous animals are characterized both by their internal organization and their capacity and inclination for the destruction of their prey; their teeth are sharp and pointed, even though intimated in the back part of the mouth; and these teeth, denominated canis, are so long in most of the brutes of prey, that they pass a considerable way beyond each other when the jaws are closed. The disposition of the enamel which is confined to the surfaces of the teeth, renders them extremely hard, and this circumstance, joined to an extraordinary bulk of those muscles, employed in raising the lower jaw, give to carnivorous quadrupeds the power of breaking the strongest bones. The rapacious birds are distinguished by a sharp hard bill, furnished on each side with a pointed procys, by which they are enabled to tear and plunder the parts of the animals they feed upon.

As the digestion of animal substances is accomplished in a short time, the fluorish of the carnivorous tribes has a simple figure without any process or separations of its cavity to retain its contents, or to delay their passage into the intestines; and as animal food furnishes but little excrement, the intestinal canal is short, and either totally unprovided with those dilatations, which are so remarkable in vegetable eaters, or possesse them only in a flight degree.

Carnivorous animals are further distinguished by the extraordinary strength of their members, which are commonly furnished with sharp claws; these are so contrived, both in the beaks of prey, and the avianiting birds, that they turn inwards by the flexion of the bill, for the action of seizing any thing, and are retracted by the tension of the toes; thus giving facility and certainty to the capture and retention of fugitive animals.

The tribes of assen and fess are particularly acute in the carnivorous tribes, as it is by means of them that they discover or seek out their prey.

Carnivorous animals are usually cruel and treacherous in their dispositions; they are even inured with respect to their own species; and hence it is that their numbers are few in comparison to that of the herbivorous kind: if it were not for this wise ordinance of nature, the defenseless orders of animals would soon be devoured, and the carnivorous would become the prey of each other.

It is a dispute among naturalists, whether or not man be naturally carnivorous? Some contend that the fruits of the earth were intended as his sole food; and that it was necessity in some places, and luxury in others, that first prompted him to feed upon his fellow animals. Pythagoras and his followers looked upon it as a great impiety; and briefly abominated from all flesh, from the notion of a metamorphosis of plants and their foodstuffs. The Brummies, continue the fame to this day. The consideration Gallenus chiefly inflicts on, why man should not be carnivorous, is the structure and conformation of our teeth; most of them being either incisors or molitors; not such as carnivorous animals are furnished with, proper to tear flesh; except the bone carnivum, as if nature had rather prepared us for cutting herbs, roots, &c. than for cutting meat. To which may be added, that when we feed on flesh, if not without a preparatory coction, by boiling, roasting, &c.

'To these arguments, Dr. Wallis joins another; which is, that all quadrupeds which feed on herbs or plants have a long colon, with a cecum at the upper end of it, or some what equivalent, which conveys the food, by a long and large progress, from the stomac down wards, in order to its flower passage and longer stay in the intestines. In man, the cecum is very visible: a strong presumption that nature, which is still consistent with herself, did not intend him for a carnivorous animal.

To the arguments used by Dr. Wallis and others, to prove that man is not naturally carnivorous, Dr. Tyfon aufwers, that if man had been designed by nature not to be carnivorous, there would doubtless have been found somewhere on the globe, people who do not feed on flesh; and as history seems not to furnish any instance of this kind, may we not say, that what is done universally by the whole species, is natural? For what the Pythagoreans did in abstaining from flesh, was on the principle of a transmigration, a mistake in their philosophy, not a law of nature; and though in some countries man feed more sparingly on flesh than in others, this is owing to their own choice, or from religious prejudices. He adds, that carnivorous animals are not always without a colon and cecem; nor are all animals carnivorous which have those parts; but that the Sarische, or toffum, for instance, has, both a colon and a cecum, yet feeds on poultry, and other flesh; whereas the hedges-hog has neither colon nor cecum, and therefore ought to be carnivorous, yet it feeds principally on vegetables. And, that those animals which have both, will feed on flesh greedily enough when they can get it; and that rats and mice, which have large cecem, feed on bacon, as well as bread and cheese.

And, from the multitude of carnivorous animals which want those parts, and of non-carnivorous, which have one or both, no safe conclusion can be drawn; since we might as well argue, that because the neat-kind, lag kind, goat-kind,
kind, and sheep-kind, which live on herbage, have four stomachs, therefore all those which have not four stomachs were not diluted by nature to be graminivorous; whereas the horse kind and hare-kind have but one stomach, yet feed on grasses like the former; and, in that many animals which live on the same sort of food, the structure of the stomach is found very different; and that in others which live on different food, on fish, on fruits, on grasses, &c., the stomachs are found to be, that it is difficult to assign any difference between them: and if we cannot make a judgment what food is most natural to an animal from the structure of its stomach, which is the part most concerned in digesting it, much less can we judge from the colon or cecum, which are parts remote from the stomach, and seem rather as an echo for the reception of a species, than of use for digesting or distributing the food.

In this, however, as in most other conclusions, truth lies between the two extremes; there is an obvious connexion between the conformation of the teeth, stomach, and intestines, and the nature of the food upon which an animal subsists: and according to the rules laid down by comparative anatomists on this subject, man was designed to use a mixed food in common; but if circumstances required it, his organs were adapted to digest either animal or vegetable substances. His teeth are neither calculated for grinding coarse vegetable food, nor for tearing the flesh, or breaking the bones of animals: they are only fitted for masticating such matter when divided by machinery, or prepared by the operation of heat, in the several processes of cooking.

The stomach of man is not very capacious; he does not need a referrer, even when subduing exclusively upon vegetables, as his invention always furnishes him with the means of extracting the most nutritious parts; and, on the other hand, his stomach is formed to retain its contents for some time: if it were otherwise constructed, it would only be qualified for the consumption of animal matter.

Further, his intestines, with respect to length and capacity, hold a middle place between those of graminivorous and carnivorous animals, or rather more like the latter, on account of the degree of preparation to which we submit vegetable substances, previous to our eating them, in order to get rid of their indigestible parts.

These observations are consistent with daily observation and experience. The lower classes of people in almost all civilized nations live chiefly upon vegetable diet, and yet no rank in society possesses more bodily strength; and, on the other hand, the inhabitants of those countries in which no staples have been taken to cultivate the soil, subsist almost entirely upon the beasts they hunt down, or the fish their seas or rivers afford.

Man, therefore, in different circumstances, and in different states of society, may be either graminivorous, carnivorous, or omnivorous.

CARNUS, in Chronology, the Syracusan name for the Athenian month Metagistion; which was the second of their year, and answered to the latter part of our July and beginning of August.

CARNO, in Geography, a river of North Wales, which runs into the Severn, in Montgomeryshire.

CARNÉT, or Carnet, a town of France, in the department of the north coal, and district of Guingamp, containing about 1100 inhabitants; 6 leagues S.W. from Guingamp.

CARNONACÉ, in Ancient Geography, a people of the north-western part of Ancient Britain, placed by Ptolemy between the Creones and the Carenici, and occupying, according to Baxter, that part of the Meine which is called Affenthire.
CAR

Cyprian. He also translated the Ballads of Longus and Ariosto's History of Animals which was left unprinted. Patronized by the Ferrerse family, he was enabled to collect a rich cabinet of medals, on which he wrote an extensive treatise that was never printed. His familiar letters are esteemed the most perfect models of ease and elegance in epistolary writing. His Italian poetry has been commended; and his canzonets and sonnets have been particularly celebrated. One of these poetical pieces to the honour of the royal house of France, produced a literary dispute of a very virulent and serious nature. By some severe criticism passed upon it by Ludovico Castelvetro, a celebrated grammarian, Caro was so provoked, that he wrote a reply so infamous and libellous as to fix an indelible stain on his memory, both as a man and a Chiruken. Castelvetro was accused of procuring the assassination of a young friend of Caro, and Caro was suspected of having used means for subverting Castelvetro to the inquisition which occasioned his exile from his native country, and the hazard of his life. After the termination of this disgraceful and dreadful quarrel, Caro retired to a small villa at Fercate, where he spent his latter days chiefly in a translation of Virgil's Eclogues into blank verse, which has been highly applauded, and ranked among those performances which do the greatest honour to Italian literature. It was first published at Venice in 1581; one of the best editions is that of 1705. The "Poems" of Caro were printed at Venice in 1584, 4to. His "Letters" were reprinted at Padua in 1749, 3 vols. Svo. Tiraboschi, Nouv. Dict. Hill.

CARO, St. Hugo de. See Concordance.

CAROB TREE, in Botany. See Ceratonia Siliqua.

Carob is also a goldsmith's small weight, amounting to the 24th part of a grain. It is also called prime.

CARCEDO, in Geography, a town of Portugal, in the province of Tras os Montes; 6 miles S. of Outeiro.

CAROCH, a name which the Spaniards and Portuguese give to a kind of mitre made of paper or pasteboard, on which are painted flames of fire, and figures of demons, worn by those who are condemned to death by the tribunal of the Inquisition. See Act of Faith.

CAROENON, in Antiquity, espousals, or Carenum, names given by the Greeks and Romans to wine boiled over a slow fire, till only a half, third, or fourth part remained, and then mixed with honey or spicers. Wine thus improved acquired several other names, such as muslin, malvin, fapa defratum, &c. At this time the same operation is performed with respect to, Spanish, Hungarian, and Italian wines. In Italy, new wine which has been thus boiled, is put into flasks, and used for fallad and sauces. In Naples, it is called "mullo collo," but in Florence it still retains the name of "fapa," Plin. I. xxii. c. 2. Columella, de re rustica, l. xii. c. 25.

CAROLA, Ital. This musical term in Boccaccio, is synonymous with Bollata, which the Cruda Dictionary defines, Cenone che fi carda ballando, "a song which is sung and danced at the same time," See Ballad. It is the sene in which the word Karole is constantly used by Chaucer.

These folks of which I tell you so Upon a bale we went in the; A ladie balest hem' that bight Gladness the blissful and the light, Well could the sung and lutfy, None half so well and semetey— And course enough for forthe doing.
In 1710 the number of inhabitants in this state was computed at 6,000; in 1727 at 270,000; in 1794 at 391,751, of whom 100,742 persons were slaves; and in 1805, the number was 471,785, being about 55 persons to each square mile. Of these, 171,768 were white males, 166,116 white females, 137,286 slaves, 7,043 free blacks and mulattoes; and there appears to have been in 10 years an increase of 49,549 whites and 39,793 blacks; &c. or upon the whole of 895,552. The militia of this state consists of 50,000 men.

The principal towns of North Carolina are Newbern, the largest, Edenton, Wilmington, Halifax, Hillsborough, and Fayetteville; each of which has, in its turn, been the seat of the general assembly, and the capital of the state. But Raleigh, which is situated in Wake's county, near the centre of the country, (N. lat. 35° 56'. W. long. 79° 11') has lately been established as the metropolis. The chief rivers of this state are Chowan and its branches, Roanoke, Tar Neus, and Cape Fear, or Clarendon. Most of these, as well as the smaller rivers, have bars at their mouths; and the coast affords no good harbour except cape Fear. The most remarkable swamps in this country are those in Currituck county and on the line between this state and Virginia. See Dismal. The most noted founds are Albemarle, Pamlico, and Core founds; and the capes are Look-out, Hatteras, and Fear. See their respective names.
