Market, in Rural Economy, the town or place where any kind of articles, whether for the purpose of consumption as food, or other means, are exposed to sale. The advantages of having these near and convenient, are of vast importance to the farmer in the disposal of his different products. And in this view it becomes the duty of every farmer, before renting a farm, to carefully ascertain its situation in regard to markets for the sale of agricultural productions. The markets in the more fertile and populous parts of this country, are in general, a late writer supposes, good, and by means of turnpike-roads, inland navigations, or sea-carriage, cany of access; but were the regulations which have been proposed to be adopted by government, respecting the sale of grain establish'd, and one general form for weights and measures fixed upon, they would be still more improved. The state of the markets in the remote parts of this part of the island, as well as Scotland, is very materially different; and while the proprietors of these districts remain so inattentive to their own interests, it is not probable that any material alteration will take place for the better. The loss and inconvenience which the Welsh and Highland farmers are often subjected to, by being obliged to dispose of their cattle on credit, are very great, and require the exertion of the chief proprietors in the particular districts, to apply with effect in order to remove them. In these districts, it is supposed, the cultivators of grain are as ill situated, in regard to markets, for the sale of the produce of their farms, as those who keep breeding flocks of cattle and sheep. The effects of the want of markets, as described in the Report of Pembroke, applies very particularly to them. "The number of inhabitants, who live by handicrafts or services, or who buy their provisions, is but small in proportion to those employed in agriculture, which occasions the demand for corn and butcher's-meat in our markets to be small. Hence, those who grow a large quantity of corn, find a great difficulty in selling it. We have corn dealers at the ports, who purchase corn during the autumn and winter months, at a price always much below what is sold at the same time in the open markets. When wheat is six shillings the bushel in the market, the dealers will hardly give five, and other grain in proportion. The reasons for this difference between the dealer's price and the market price are these: he buys with a design to export his corn to Bristol, or some other English port; he must take care in buying, to provide for house-rent, portage, freight, insurance by sea, commission on fairs, and at the port he sells it to; and, lastly, for his own trouble and capital employed. Besides all these expenses, he runs another material risk: our corn is generally so damp, that it will not keep in the lofts without being laid thin, and turned at least once a-week. If, in going to a port, a vessel meets with contrary winds, and is delayed on her voyage, the cargo frequently heats to such a degree, as to reduce its price below prime cost, and then the dealers suffer a great loss by the venture." From this account of the state of the markets in the remote parts of this country, it is supposed, "may be inferred, the advantages which the proprietors of such districts would derive by establishing manufactures, whereby markets be brought home, as it were, to every farm. Where that cannot be effected, inland navigations, where practicable, as being infinitely preferable to turnpike-roads for the carriage of corn to market, and for bringing manures in return, ought to become the next object of the proprietor's attention. By these the polluters of distant corn farms, are often put nearly upon a footing with those in the more immediate neighbourhood of the belt markets in the country. But it may frequently happen, that it would be impracticable to establish extensive manufactures, such as would have the effect of creating a market for the surplus produce of a district, and physically impossible to form canals, so as to open a communication with other distant markets; in such cases, good level well made roads are the only alternative. Thee, although an expensive mode of conveyance, are highly beneficial, particularly in inland districts remote from markets, and where it is impossible to form canals. Corn and meal are frequently carried in very great quantities from the southern counties of Scotland, to the Edinburgh and Glasgow markets, which, without turnpike-roads, would scarcely be practicable, at least the expense to the farmers would be so great as to amount almost to a prohibition, and would necessarily compel them to turn their attention to breeding and grazing, rather than the tillage system of husbandry, which, under such circumstances, would certainly turn out the most profitable." The degree in which the situation of a farm is, in regard to markets, must obviously influence both proprietors and tenants, in making choice of particular rotations or modes of cropping in preference to others. Where no exertions can approximate markets to a farm, which would otherwise be well adapted to the cultivation of grain, breeding and grazing, or other species of live stock, is, it is supposed, the best method in which such farm can be occupied. These, if not fold in the district, can be carried to distant markets almost without roads, and at a comparatively trifling expense. Were the markets for the sale of cattle in the north of Scotland, and in Wales, as well regulated as in other parts of this kingdom, the most beneficial consequences would ensue, as except in these districts, scarcely any improvement can be suggested. The dealers in cattle residing in the various districts of Scotland, except those in the south and southwest, generally move their cattle southward at two seasons, August and October; at which periods, what may be called the two great national markets for the sale of black cattle are held at Falkirk in Stirlingshire. There it is not uncommon to see 30 or 40,000 black cattle exhibited for sale in one day; these being either purchased by dealers from England, or by some of the principal people in that line in Scotland, and thence driven forward to markets in the former part of the country. Probably nineteen out of twenty of the Scotch cattle enter this country by the way of Carlisle; and matters are so contrived, that there are cattle fairs, one succeeding another at proper intervals, during the whole course of the journey from the lat place to the southern parts of Surry. From Carlisle to the southern parts of Yorkshire, the droves are conducted along the same line of road. They are then branched off from the great London road in different directions; some going through the eastern parts of the country towards Norfolk, Suffolk, and Essex; and the remainder through the western part of Nottinghamshire, Leicester, Northamptonshire, Buckinghamshire, &c.; and such as are not sold in these districts, are sent to Barnet in Middlesex, as a centre, and are there exposed to sale. When any of them remain unford after Barnet fair, which, owing to a combination of unfavourable circumstances, sometimes happens, they are sent forward to markets in Surry, Dorset, &c. which also succeed each other in the same manner. "From this arrangement, were the farmers in the remote districts to receive ready money for their cattle when sold, it is presumable, that from the competition
competition which generally takes place among the dealers at the provincial fairs, they would receive a fair adequate price, considering the risk of lameness or death, bad fakes, and the great expense attending driving cattle to such distant markets."

In the Agricultural Report of the West-Riding of Yorkshire, it is observed, that a "very considerable corn-market is held at Knaresborough in that county, where dealers from the western parts of the riding attend, and purchase grain from the farmers in that neighbourhood; a great part of which is re-fold at Shipton-market, in Craven, and carried still farther westward, where corn is scarce, and gives employment to a number of people who are concerned in this traffic. It is under circumstances of this kind that public markets for grain can be considered as advantageous to the growers or purchasers of corn. The first cannot get his commodity disposed of at home, hence willingly goes a flage to meet his merchant; and the latter being sure to meet with a supply, attends upon market day, with his horses and carts, for conveying it to the place where he is to use it, or dispose of it again. By this mode no time is lost, no unnecessary labour incurred; whereas, were all the grain in the kingdom to be sold in the public market, as some wild imaginations recently proposed, a great waste of both must necessarily happen. Let us just suppose, that such a law had been passed, and that the grain sold at Knaresborough was not to be drove to the well bounds of the riding, but that it was wholly to be consumed in the neighbourhood of that place; and say where would be the advantage arising from setting down the facks in the market? It might happen that a baker or maltster purchased the very wheat or barley which was grown by his next door neighbour, which, in conformance of such mistaken law, could not be sold without being first offered to fale in this public manner. Would not the trouble of driving it to market by the farmer, and of driving it back again by the baker or maltster, be just so much lost labour to them, without affording the smallest advantage, nay, rather occasioning a positive loss to the public consumer, upon whom every expense of this kind must necessarily fall in the end?" And Mr. Donaldson very justly concludes on the subject of grain, from what has happened in the scarcities of this article in France during the administration of M. Neckar, and more recently in this country, that "while every person must agree, that the regulation of the public markets of the country falls naturally and properly under the direction of the legislature, it is believed there are none who suppose that, during an impending scarcity in this infall, it is either a prudent measure, or one likely to alleviate the evil, that the savans of the crown should become the national importers. The unfettered speculations of the merchant are the only recourse to be depended upon, under such circumstances, for an abundant supply of the markets. See Corn Laws, and Bounty.

Mr. Middleton remarks, in respect to the caufes that increase the price of animal food in the markets, that "a scarcity of vegetable food for the fattening of cattle, from whatever cause it may arise, whether from a droughty summer, or a severe winter, uniformly produces full markets, and a confecuent fall in the price of the cattle thus prematurely forced to them;" but that "this temporary great supply and low price is, as certainly, quickly followed by a corresponding dearth of fat cattle, and considerable advance in the price of animal food. This circumstance, therefore, though it first lowers the price to below, and then advances it to above par, has a tendency, on the whole, to augment the prices, because, at such a time, the beaufs and sheep are sent to market with much less beef and mutton on their bones than they ought to have. Hence a dry burning summer glut markets with cattle less than half fat; four or five months later the markets are very thinly supplied, and then, of course, the prices rise to an extraordinary height. Every sudden and great advance in the rate of animal food may primarily be traced to this cause. There are, of course, other causes which tend to produce this effect, but they are of low operation; such as the increasing prosperity and opulence, which enables a greater number of individuals to live on butcher's meat than formerly; while, in the opinion of some people, the present war has greatly lessened the demand for the innocent food of animals. But that a prosperous peace would have advanced the price much more, by means of general industry, and the consequent increase of wealth, by such means.

Mr. Marshall, in his excellent work on the landed property of England, flates, that "when we consider how much the value of farm lands depends on their locality with respect to markets, it becomes an object of high importance to their proprietors to meliorate their situation in this respect. And he suggests, that there are three methods of improving the value of them in what respects markets, as by the facilitating the conveyance of the produce to distant markets; through the means of roads, railways, or water-carriage; by establishing new markets, in situations where inhabitants have increased, since the establishment of those which are now frequented; and by an artificial increase of inhabitants; by drawing together the consumers of produce; by encouraging manufactures upon, or in the vicinity of them. For while a manufactory continues to flourish, the value of the lands around it cannot fail to be increased." But that, "before an advantage is derived from this kind can be prudently carried into effect, the evil as well as the good which it may bring to the estate requires to be calculated. A populous manufactory, even while it flourishes, operates mischiefvously in an agricultural disfrit; by propagating habits of extravagance and immorality among the lower order of tenantry; as well as by rendering farm-labourers and servants dissatisfied with their condition in life. And the more it flourishes, and the higher the wages it pays, the more mischiefvously it becomes in this respect. Moreover, lands bear a rental value in proportion to the rate of living, in the district in which they lie; so that while a temporary advantage is reaped by an increased price of market produce, the foundation of a permanent disadvantage is laid. And whenever the manufactory declines, the lands of its neighbourhood have not only its vices and extravagance entailed upon them; but have the vicious, extravagant, helpless manufacturers themselves to provide for. This, however, only applies to particular kinds of manufactories." In this country, we have "instances of manufactures being highly beneficial to agriculture. The linen manufacture in Yorkshire, and the woollen manufacture of Devonshire are so; and have been so during a length of time. And the most intimate connection between them is, where the grower manufactures his own produce. And this primitive connection is still found in the island. In North Wales, the character or callings of sheep-farmer and woollen manufacturer are joined in the same perfon. The wool is carded and spun, and the yarn woven, under the roof of the grower. If the farmer himself does not throw the shuttle, he employs a labourer or labourers, who affit alternately, and, as the seasons or circumstances require, in the works of agriculture and manufactory." And that "a similar kind of reciprocal benefit
MARKET.

...aris from the cotton manufactures of this country, where not only the spinners, but the weavers, afflict occasionally in the works of husbandry; in weaving, hay-making, and harvest-works: an advantage which, in an hazardous leaen, is at once a private and a public good. And add to this another advantage of village manufacturers. When, in the uncertainty of commercial concerns, the demand flags for a time, the country finds, that, instead of having a load of enfeebled artificers, mere manufacturers, to support in idlenes, it thereby acquires an additional supply of useful hands, enured to the works of the field, to forward its cultivation, and affl in its improvements. While at all times the increase of inhabitants which this valuable species of manufactury suppies, increases the demand for marketable produce in the immediate neighbourhood of its growth." This can, however, only be the cafe of a few instances, as manufacturing laubours are seldom useful for farm-bunefes. This is much the cafe in Lancashire, and other large manufactury districts.

In the Rural Economy of the Midland District, it is stated, "that markets ought to be adapted to the mutual advantage of the producers and consumers at large, but particular to those of the peculiar town or neighbourhood. And, therefore, that hucksters may be injurious to such markets, both by being too freely admitted, as well as by being wholly excluded, as mere market towns tofily depend for their supplys upon the market day, when, in a time of scarcity, such dealers may in a very short time clear the market, and leave the inhabitants defitute of the week's provisions; while, on the contrary, when totally precluded from even purchasing the surplus, the market itself, as well as the inhabitants, must be injured, as the producer will, of course, endeavour to find another market where he can sell his produce with certainty, without the risk of having it to bring home again, or disposing of it at an under price to the monopolizers of the town; in conquence of which, the market becomes indifferently supplied, and the articles of inferior quality and more expensive." It would, therefore, it is supposed, be a regulation of great utility, as has been found in actual practice in this district, for the market to open at a flated time, and to permit no huckster to become a buyer till an hour afterwards; as by such means the inhabitants are certain of a supply, without the market suffering any injury. And Mr. Middleton states, in his Report of the State of Agriculture in the County of Middlesex, that, "in regard to the markets, there are in the country part of the district nine weekly ones held, namely, at Barnet, on Monday morning; at Brentford, on Tuesday; at Southall and Finchley, on Wednesday; at Uxbridge, Hounslow, and Edgware, on Thursday; at Staines, on Friday; and at Enfield on Saturday. That at Uxbridge market a great deal of corn is sold, and there is a large public granary over the market-place, for the purpose of depositing it from one week to another. And at Hounslow market there is a considerable flow of fat cattle; such of which as are not disposed of there are sent on to Smithfield-market, in the city of London, which is famous for the sale of bullocks, sheep, lambs, calves, and hogs, every Monday, and again, though in a less degree, on Friday. On the latter day there is also a market for ordinary hores." And "that this is the only public market within the bills of mortality for the sale of live cattle." He gives the following statement of the number of black, or neat cattle, and sheep, annually brought for sale to this market, from the year 1731 to 1795, being 63 years, which he has divided into seven averages of four years each, namely,
MARKET.

Years.  Cattle.  Sheep.
1791  99,838  729,800
1792  107,263  753,469
1793  116,488  729,810
1794  109,064  717,990
Average  101,075  707,456

The writer, however, has not been able to procure an account of the number brought to Smithfield in 1795 and 6, but he is pretty sure it must be greater than that of the preceding years; on account of the unusual difference in the price of animal food, having occasioned a very large quantity of lean cattle to be prematurely sent to market. But in the above account it may be seen that the supply has been advancing with some degree of regularity both in the number of cattle and sheep during the last forty-five years. The number of cattle now sent to market is more, by 26,881, than it was twenty-five years ago; and of sheep 1,47,565. As and as it is a matter of general notoriety, that the cattle and sheep of England have also been gradually and progressively increasing in their individual weight, owing partly to the attention paid of late years to the improvement of the breed, and partly to their being much better fed now than formerly, and indeed much better than they could possibly have been before the introduction of turnips and clover; it is not perhaps an unreasonable, or unfounded conjecture, to suppose that the increase, in point of weight, has kept pace with the advance in respect to numbers, during the aforesaid period. If so, it will follow, it is conceived, that, including number and weight, the annual increase in forty-five years is, in neat cattle, upwards of 72 per cent. and in sheep near 53. Upon the whole, he can safely affirm, that including all the other supplies of animal food, and considering that they also, as well as cattle and sheep, come to market much better fed, and consequently much increased in weight, above what they were forty-five years ago, the consumption of the metropolis is at this time full one-half more than it was then. And since this last period the increase has gone on in a progressive manner.

The following is given as a comparison between the weight of bullocks, &c., as it was one hundred years ago, and as it is at the present time, viz.

It is therefore concluded, that at the end of the above year the annual consumption of London was somewhere about 110,000 head of neat cattle and 777,000 sheep; and that any person,possessing some degree of judgment in cattle, and at the same time the desire of looking at a great variety of live flock, cannot perhaps spend a few hours more satisfactorily, than in examining the market at Smithfield. He will there very soon discover, that, for want of a greater attention to the excellence of breed, both in neat cattle and sheep, a very large proportion of the produce of the faul of this kingdom is wasted in producing bones and offal, instead of meat. It is indeed astonishing, that men, at least in the present day, should with so much difficulty be prevailed on to breed beef and mutton, in preference to horns, skins, and bones. Since this statement was made much correction in this respect has taken place.

But besides these markets there are others, as Leadenhall-

market, which is the greatest in London, for the sale of country-killed meat, and is the only skin and leather market within the bills of mortality; and Newgate-market, which is the second great place for country-killed meat; and at both these markets pigs and poultry killed in the country are sold, together with fresh butter, eggs, &c. to an astonishing amount. These laf and many other markets are held daily, and almost constantly well supplied with most sorts of animal food, &c.

And the three markets of Smithfield, Newgate, and Leadenhall supply the butchers round London almost entirely, and to the distance of twelve miles; partly indeed to twenty miles. It is a general opinion among the butchers, that they can buy live cattle in Smithfield cheaper than at any other place. The cattle exposed for sale at this market have been drove until they are empty, weary, wailed, and foot-fore, and consequently flew to a great disadvantage; so much so, that graziers who have followed their cattle, especially sheep, to Smithfield, frequently do not know their own flock, and when they have been flown to them, they were shocked at their deteriorated appearance. If they should not then be sold and slaughtered, the waiting would continue so much, that it would require several weeks of rich food to raise them to their former fatteness. And the bullocks and sheep brought to these markets are only over-heated by the journey, but they are also often most savagely beaten with bludgeons, goaded with darts, and hocked about their legs in the market during, perhaps, ten hours, and then drove to the slaughterhouses (if they have the good luck to escape thieves in the characters of bullock-hunters), and knocked down while their blood is yet in that inflamed state, and their flesh bruised. Such meat mutt, it is conceived, be very detrimental to the health and longevity of man. Much better is that which is killed in the country without driving, when the animal is in full health, and sent to Newgate and Leadenhall in clean and cool packages. If this could be done by all, it would remove a great nuisance from London, would probably improve the health of its inhabitants, and certainly prevent many, and sometimes fatal accidents. Besides, there is a fish-market, which is held every morning at Billingsgate, where all the dealers are served very early; first, those who keep fishers in various parts of the town; and next, the hawkers, who, during the forenoon, cry them through the streets. This market receives a considerable portion of its supply of fresh fish by land-carriage, from every distance within the limits of England and parts of Wales. Much is also brought from the sea up the Thames in boats, some even from Norway and Newfoundland, as well as intermediate distances, packed up in ice. The quantity of dried and pickled salmon, of cod, herrings, and haddock, is also very great. The whole, probably, amounts to about one-sixteenth of the beef and mutton.

And there is likewise one corn-market, which is held at the corn-exchange, in Mark-lane, principally every Monday, but in a less degree every Wednesday and Friday. In this market an immense quantity of grain is disposed of; but no statement of the exact amount has been hitherto given. The whole seems a sort of monopoly of a most important and necessary article, which should not, by any means, be suffered to continue.

And in addition to these there are also three public markets for hay and straw in this country, namely, Whitechapel, Smithfield, and St. James's; all of which are held every Tuesday, Thursday, and Saturday. And London is likewise in part supplied with the same articles from a market held every Monday, Wednesday, and Friday, in Southwark.
And "the barracks on Hounslow-heath furnish a ready market to the farmers in that neighbourhood for their hay, straw, and oats, as well as a fund from which to obtain a supply of manure. In this neighbourhood, some farmers sell their hay and straw to jobbers, who take it at the barn door, after the weight of the trusses, draw it away in their carts, and re-sell it." In these markets "hay is all sold by the load of 36 trusses, each truss weighing 56 lbs. except hay which weighs 60 lbs. till the 4th day of September, and afterwards 56 lbs. only; by which regulation a load of new hay, till the 4th of September, yearly, weighs a ton, and after that day only 18 cwt. It is sold daily in large quantities at the different hay-markets, and a regular book kept by the clerks of each market, for the inspection of the public, mentioning the names of the seller, the buyer, the falceman, and the price of each load. This seems to have been intended to secure a fair and honest dealing; but it fails, almost entirely, in effecting so good a purpose; great impositions being practiced.

"The best meadow hay, is principally bought for the feeding of gentlemen's saddle and coach horses at from four to six guineas per load; the more ordinary, by the livery-stable keepers, coach-makers, and retailers, at from three to five guineas. And the hay of ryegrass and clover, mixed, is generally bought by coach-makers, &c. for ordinary dairies. The finest clover hay is generally bought for the brewers, distillers, and farmers' horses, for the rack, and for cutting into chaff, at from five to six guineas and a half the load.

The straw from different kinds of grain brought to the London markets, is likewise sold by the load, which consists of 36 trusses, of 36 lbs. each. Wheat straw is generally used in the stables, for bedding of horses. The rye straw is used by brick-makers, to cover their bricks, by collar-makers, and for packing. The barley straw for packing, and by gardeners. The oat straw is also used for packing, and the winter support of cattle, as saddle horses in straw yards, &c. The bean straw serves to litter farm-yards, and farmer's stables. And the pea straw and tare straw to feed farmers' horses in the stables, and fodder-horses in straw-yards. There are the same regulations at the different markets with respect to straw hay, and the price of each load for some time past, has been from 5s. to 45s. per load of 10 cwt, and 9 lbs. It has been lately considerably higher in general.

The coal-exchange or market is in Thames-street, "where the dealers buy and sell. But the consumers are not permitted to buy there, owing to the dealers having obtained a completely infamous monopoly of the market. The annual quantity sold is about 600,000 chaldrons. A chaldron of coals, as delivered to the consumer, is thirty-six heaped bushels, but it is much larger measure between the ship owner and the dealer, and even to such consumers as buy five or more chaldrons at a time; an allowance is then made in the term ingrain, which increases the chaldron to full forty bushels."

It must be extremely evident that the due regulation and establishment of suitable and convenient markets must be of the greatest importance to the success and improvement of the agriculture of the kingdom, as by such means a proper stimulus or encouragement can only be held out to the farmer to extend his means of cultivation. The inconvenience of the want of markets, may in many instances be considerably relieved by the forming of canals and the constructing of railways. See CANAL AND RAILWAY.

MARKET Harbour. See Harbor
MARKET Hill, a post-town of the county of Armagh, Ireland. It is a thriving town, the neighbourhood of which may be considered as classical ground. Gosford castle, the residence of sir A. Acheron, the friend of Swift, (whose descendant is now lord Gosford,) adjoins the town, and near this is Draper's hill, a name given to a farm taken by the dean, on which he intended to build, and which was so called that

"When none the Draper's praise shall sing,
His signs aloft no longer waving;
His famous letters made woful paper,
This hill may keep the name of Draper;
In spite of envy forty full,
And Draper's vie with Cooper's hill." Swift.

Market hill is 58 miles N. by W. from Dublin.
MARKET Lavington. See Lavington, East.

MARKING-YARN, in ships of war, is white yarn spun the wrong way, and put into all cargoes of three inches and upwards, as the king's work. Blankl. Nav. Expox. p. 103.

MARKLAND, Jeremiah, in Biography, a learned critic, son of the Rev. Ralph Markland, known as author of a work entitled "The Art of Shooting Flying," was born in 1663. He received his early education in Christ's hospital, from whence he was elected to Peter-house, Cambridge, of which, in due time, he became a fellow, and a tutor, but refused to enter into holy orders. He lived much in retirement, and his course is distinguished by few events. In the year 1743 he resided at Twyford, and in the following year he went to Uckfield in Sussex, where he resided till 1752, when he removed to a farm-house at Milton near Dorking, in which he lived till his death in 1776, when he had attained to the great age of eighty-three. He humbled company, and was seldom seen beyond his garden. His circumstances were narrow, but his heart was liberal, and his hand at all times ready to afford assistance to the needy, to the utmost extent of his means. By espousing the cause of an oppressed widow with whom he lodged at Milton, he involved himself in an expensive lawsuit, which reduced him almost to indigence. His works are as follow: "Epitola Critica," addressed to bishop Hare, and published in 1723. In 1728 he published an edition of the "Sylva" of Statius; and in 1740 "Notes on Maximus Tyrius," which are said to have done great credit to his critical powers. He displayed great facility likewise in his "Remarks on the Epitiles of Cicero to Brutus" with a dissertation upon four orations ascribed to Cicero. In 1761 he published an excellent grammatical treatise "De Grammatica Latina declinatione imperfecta, et inde formativa Latinae tertia," which was annexed to an edition of the "Supplices Mulieres" of Euripides; published in 1763, and reprinted in 1775. He assisted Dr. Taylor in his editions of Lyfias and Demotheles; Dr. Mudge in his "Hippolytus," and Mr. Bowyer in an edition of Sophocles, and also in his conjectures on the New Testament, in which the passages illustrated by this critic are marked with an R. Gen. Biog.

MARKOV, in Geography, a small island of Russia, in the Frozen sea. N. lat. 71° 50'. E. long. 138° 14'. MARKOVO, a town of Russia, in the government of Irkutsk; 56 miles S.W. of Kirenef. MARKOW,
MARKOW, a town of Lithuania, in the palatinate of Wilna; 60 miles E.S.E. of Wilna.

MARKOWSKA, a town of Poland, in Volhynia; 24 miles E. of Lucko.

MARKOTITZ, a town of Moravia, in the circle of Olmutz; 18 miles S. of Olmutz.

MARKS, Lake of, called also Shikkeb el Low-deh, a large lake of Africa in Bledugerd, reaching near 60 miles from E. to W. and about 18 miles broad, interspersed with several small islands, one of which, however, is large, and though uninhabited, well flocket with date trees. These trees are, by a fabulous tradition of the Arabs, ascribed to the fomes of dates, which the Egyptians brought with them for sustenance, when they invaded this country; whence the circumjacent territory is denominated "Babrya Pharaon," or the Plains of Pharaoh. The situation of this lake, with regard to the sea, the Syrtes, and the river Triton, has induced some writers to take it for the "Palus Tritonis" of the ancients, and to consider the above-mentioned island as the Cheironicus of Diodorus Siculus and the Phala of Herodotus. Moreover, Pallas, who, with Libyan women, attended Scylus in his African expedition, and who was supposed to have owed her origin to this lake, might have refided in this island. N. lat. 35° 50'. E. long. 8° 50'.

MARKT BiEBART, a town of the duchy of Wurzburg; 24 miles S.W. of Bamberg.

MARKT Hohenluben, a town of Saxony, in the county of Reufs; eight miles N.W. of Greitz.

MARKT Offingen, a town of Bavaria, in the principality of Oettingen Wallerstein; eight miles W.S.W. of Oettingen.

MARKT Einfelder, a town of Germany, in the lordship of Limburg; 16 miles E.S.E. of Wurzburg.

MARKTL, a town of Austria, on the Trafen; 12 miles S. of St. Polen.

MARKUTCHOE, a town of Bengal; 42 miles N.N.E. of Ramgur.

MARKUWKA, a town of Poland, in the palatinate of Brachlaw; 36 miles S.E. of Brachlaw.

MARKWOTIZ, a town of Bohemia, in the circle of Boleslaw; 12 miles E. of Jung Buntzel.

MARLBOROUGH, a market town and borough, consisting of two parishes, situated in the hundred of Selkey, and county of Wilts, England. Its name is supposed to be descriptive of its position; being seated at the foot of a chalk hill, the term marle having been anciently used to denote that earth, as well as the peculiar species of clay, to which it is now definitively applied. The origin of this town is wholly involved in obscurity, for the opinion that it was the Roman station, Cunctio, is certainly erroneous. Whether it was known in the time of the Saxons is equally doubtful, as no velliges of antiquity, calculated to induce such a belief, can at present be discovered; and Domfelde-book mentions it in its flight and cursory manner, as that it is impossible to determine from that work any thing concerning its extent or condition. Probably, however, it was then merely a trifling village, and of course did not become of importance till some time after the Norman conquest; when a castle was built, some remains of which are still visible, near the inn originally erected by lord Jermford, and from its situation denominated "the castle." The great mount which appears in the gardens behind this house has been regarded by some as an immense tumulus or barrow, but that idea is successfully combated by Mr. King, who shews it to have been the foundation of the principal keep of the castle; such works being found to constitute part of the construction of all similar edifices, raised by the early Normans. In the reign of Richard I. this castle was of great strength, and was one of those seized by his brother John, (who afterwards ascended the English throne,) with the view of obtaining possession of the kingdom during that monarch's unfortunate captivity in Austria. Having failed, however, in his ambitious project, chiefly through the firmness of his mother, he was compelled to fly to the continent, leaving Marlborough castle to be defended by one of his adherents, but after the return of Richard, it was quickly reduced by Hubert, archbishop of Canterbury.

From this period to the year 1267, no transaction of moment seems to have taken place here. In that year, being the 52d of Henry III. a parliament was held in the castle, when a number of laws were enacted for the suppression of tumults, &c. and these acts are still known under the appellation of "the statutes of Marlbridge."

Marlborough was first incorporated by charter in the reign of king John, about the year 1204, but it also claims the privilege of having been a borough by preëminence for a century previous to that era. Several other charters have been granted by succeeding monarchs confirming and extending the various rights and immunities of the corporation. The government of the town is confided to a mayor and two justices, affifted by a council, and an indeterminate number of burgesses. The mayor and justices are empowered to hold quarterly feffions of the peace. An annual court for the county is likewise held in the court room over the market place, where are also a council chamber and an assembly room.

This edifice stands at the east end of the principal street, which runs from east to west, and constitutes the chief part of the town. The buildings are in general irregular, and present an appearance of great antiquity; some of them being constructed of wood, and having their fronts very curiously carved. Part of one side of this street is adorned with piazzas, which project from the houses forming an agreeable promenade for the inhabitants, and afford them shelter from the effects of rain. At the same end with the market house, or town hall, is the old church of St. Mary. The door way to the belfry is decorated with zigzag ornaments in the Saxon style. The tower is built of free-stone, and the plot of ground near this church is surmounted, by Dr. Stukeley, to have a strong resemblance to the fite of an ancient temple. A short way to the south lies an hospital, or priory, dedicated to St. John the Baptist, and said to have been founded by John Goodwin and William Rambeau. The meat market is placed about the middle of this principal street, and on the south side, at some little distance, is a private house, which formerly was part of a priory, belonging to some regular canons of St. Augustine, and consecrated by Gough to have been first erected in the reign of king John. St. Peter's church forms the chief ornament of the west division of the town. It has a lofty square tower surmounted with battlements and pinnacles; the roof is supported by light columns.

The manufactures carried on in this town are comparatively inconsiderable: indeed it may justly be regarded as deriving its main support from its advantageous situation on the high western road, and the consequent extent and superiority of its market, which is held on Saturday, and has been long celebrated for the excellence of its corn, butter's and cheese. The population, according to the parliamentary returns of 1857, was estimated at 2,677 persons, who inhabited 4,641 houses.

To the south of Marlborough, at the distance of a mile, lies the extensive foresit of Savernake, the property of the earl of Ailesbury. This forest contains a vast profusion of noble trees, some of which are exceedingly large and majestic: one, called by way of preëminence the king oak, overtops an area of at least 60 yards in diameter. A

A variety
of charming walks is disposed in different directions, eight of which diverge like rays from a common centre, placed in a spacious opening near the middle of the forest. No natural scenery can be imagined more picturesque or beautiful than that displayed in various parts of this umbrageous district, where the diversity of hill and dale, wood and water, frequently presents to the eye of the painter various interesting views.

In this forest stands a modern mansion, called Savernake-lodge, appropriated for the temporary residence of Lord Bruce, son to the earl of Ailesbury; and immediately adjoining to its eastern boundary is Tottenham-park, the seat of the noble owner himself. The house, a square building of brick, with two wings at each end, stands on the site of the ancient palace of the duke of Somerset, who so much distinguished himself in the cause of the house of Stuart. In the state rooms are several very excellent pictures; and the library contains a very “curious horn, or elephant’s tusk in the shape of a horn,” which is particularly described in the third volume of the Archæologia. Opposite to the north front of the house stands a lofty column, one side bearing an inscription in commemoration of the recovery of this majesty in 1789. The remains of Wolf-hall are the seat of Sir John Seymour, whose daughter lady Jane, unhappily for herself, attributed the notice of king Henry VIII., who put to death his former queen Ann Boleyn, and expoused this new favourite, who was destined to suffer the fate of her predecessor. It is said that the marriage was solemnised, and the supper served up in a detached building, which is now used as a barn. The town of Great Bedwin, situated in this neighbourhood, was distinguished as the scene of a battle between Wolftere, king of Mercia, and Ælfgifu, a Saxon nobleman, in the year 675. (See Bedwin, Great.) Littlecote-park, which lies on the south bank of the Kennet, about eight miles from Marlborough, would seem, more probably than that town, to have been the position of the Roman station, Cunetio. This suggebion is founded upon the fact, that this spot agrees better with the relative situation in which Cunetio is said to have stood, with regard to verdac (Heddington) and Spinis (Speen). It further derives support from the circumstance of a Roman telfelled pavement having been discovered within the park which surrounds the house. Here, also, it is known that two Roman ways intersect each other at a point called Crofs-ford. The entrenchment named Chisbury-castle, lies somewhat more than two miles to the south-east of this interference. On Martinfall-hill, at nearly the same distance south of Marlborough, is another extensive fortification. Barbury-castle is placed several miles to the north; and at Avebury are the remains of a very large and singular British structure, which has been already described under that article. (See Avebury.) Britton’s Beauties of Wiltshire, vol. ii.

MARLBOROUGH, a township of America, in Grenville county, Upper Canada, north of Oxford, watered by the Radeau.—Also, a district on the Great Pecke river, South Carolina; 25 miles long and 19 broad. —Also, a post-town, both ancient and wealthy, in Middlesex county, Massachusetts, (the “Okonmakemesi” of the Indians,) incorporated in 1660, and containing 1715 inhabitants; 28 miles W. of Boston. A mode of manufacturing Spanish brown, from a kind of earth or loam resembling bed ore, but not impregnated with particles of iron, has been lately discovered in this town.—Also, a post-town in Windham county, Vermont, containing, in 1790, 629 inhabitants.—Also, a post-town in New Hampshire, incorporated in 1776, and containing 1185 inhabitants; 26 miles from Alh-
Not particularly brittle; easily frangible.
Spec. grav. 2.300—2.700, Kirwan.

The chemical and physical characters of marle (which, according as lime or clay preponderates, receives the name of calcareous or argillaceous marle) are the following:

1. When fresh it effervesces briskly with all acids; but the argillaceous marle with greatly predominating clay, is often very little affected by acids. 2. After burning it ceases to effervesce.

3. The argillaceous marle is apt to harden in the fire; the calcareous marle becomes more friable. 4. All kinds of marle are easily vitrified.

5. When burnt they attract moisture and crumble. 6. They generally feel meagre, and the indurated kind are rough to the feel. When rather greasy to the touch, this property is caused by the minute particles of mica. 7. In the bottom of the earth the marle is always rather moily, especially the argillaceous marle. 8. All sorts of marle, when exposed to the air, crumble sooner or later in proportion to the degree of their solidity; indeed there are some kinds that are not affected in this manner within the space of three or five years; but the generality are found to crumble, within a year or two, into a loose earth ready for use.

The principal localities of indurated marle are; Saxony, Drefden, Wehau, Meissen, &c.; Austria; Bilin, Luitritz, Meronitz, and several other places of Bohemia; Bavaria; Moravia; the Palatinate; Thuringia; Heffen; England; Italy; France; and other countries where the fletz-trapp and coal formations occur.

It is chiefly found subordinate to fletz limetone, in which it sometimes forms considerable beds, alternating with compact limetone; it also occurs in coal countries, sometimes in entire beds; and it constitutes the cement of some sandstones. The circumstances under which it occurs in the fletz-trapp formation, have not yet been ascertained. That in Bohemia it passes into balsalt, has been affirmed by Renfus, is doubted by other mineralogists; but a transition of marle into limetone on one side, and into indurated clay on the other, is far from being a rare occurrence.

Indurated marle often contains iron pyrites, garnets (that of the Hifelberg, at Meronitz, in Bohemia), copper azure, malachite (that of Thalitter, &c.) Nor are petrifactions less frequently observed in it, such as gryphite, belemnites, pectinites, chamosites, amonites, &c.; and sometimes also vegetable imprefsions.

A remarkable and beautiful variety of indurated marle, which by some writers is considered as a kind of compact limetone, is that known under the name of Florence marble, or Rain marble, of which the following description is given by Brard. It presents angular figures of a yellowish-brown, on a base of a lighter tint, and which passes, in diminishing, to a whitish-grey. Seen at a certain distance, flabs of this fine remelting drawings done in bifer. One is amused to observe in it kinds of ruins; there it is a Gothic-colle half detached, here it presents ruined walls; in another place old baftions; and what still adds to the illusion is, that in these sorts of natural paintings there exists a kind of aerial perspective, which is very febibly perceived. The lower part, or what forms the first plane, has a warm and bold tone; the second follows it, and weakens as it increases its dilance; the third becomes still fainter, while the upper part, agreeing with the first, presents in the dilance a whith zone, which terminates the horizon, then blends itself more and more as it rives, and at length reaches the top, where it sometimes forms, as it were, clouds. But approach close to it, all vanishes immediately, and those pretended figures, which, at a distance, seemed to well drawn, are converted into irregular spots, which prevent nothing to the eye. This play of nature is owing to ferruginous inclusions in the figures of this marble, which otherwise is of dull fracture and very argillaceous; whence it is never used in architecture; they merely make flabs of it, which are framed like little pictures, and which are much esteemed in commerce when of certain dimenions. It sometimes occurs that the same flab is sawed in two, and the parts are set together in the same frame, so as to appear but as one piece; and the drawings on the right and left bear a resemblance which still further helps the illusion. There are some who, to outdo Nature, put painted figures at the bottom of these pictures; but this is an exuberance of the wonderful, which must be snatched by spoiling all.

Mr. Brard should have also mentioned the variety of the same Florentine marble, which, instead of the ruins, exhibits fine black dendrites, arranged in such a manner as to represent, in the most deceptive manner, groups of trees, shrubs, &c. This is called Landscape marble.

To this indurated marble must also be referred the fine variety called Cottam marble, from being found at Cottam, near Brilol. It refembles, in many respects, the last mentioned variety of Florentine marble; its ground is ash-coloured or blueish-grey, with blackish-brown spots and veins, most of which have a dendritc form, repreffenting affemblages of shrubs and trees, grottoes; &c. It is found in large oblong pieces. The singular balls, known by the name of Ludus Helionattii, belong likewise to indurated marle. They are of various sizes, from one inch to nearly one foot and a half in diameter, and generally disposed in a regular manner in beds of marle. When broken in a direction parallel to one of the largest surfaces, their interior exhibits a number of figures by which the whole mass is divided into perfectly distinct, and more or less regular prisms of from three to fix or more sides; the figures themselves being sometimes empty, but oftener filled up with another substance, which is generally granular limetone or a crystalline flate. There can be no doubt that the singular conformation of the interior of these balls is the result of a kind of contraction produced by exiccation; but it is difficult to account for the regularity of the figures, their not extending to the surface of the balls, and their being still filled with substances, which it would be most natural to suppose injected from without. These balls are found in almost all countries where marle is not unfrequent. Thofe of Francoft and of Antwerp are very regular in their internal structure; but the ifle of Sheppey, in the county of Kent, produces the largest and finest of them. They are also found of considerable fixe, and of a blueish-grey colour, in Derbyshire. Thofe of Durham are divided into small hexahedral columns of a very regular form and equal fixe, while the narrow figures separating the prisms from each other are filled with quartz. When the marle is disengaged from the quartz, thefe latter more or less represent the figure of a honeycomb.

The name of Ludus Helionattii is also given to those imitative figures, which solid pieces of indurated marle frequently assume; and which have received several other denominations, such as zingibrite, or ginger rohes, priapologies, &c.

There are also geodes of marle, which generally owe their origin to the decomposition of a nucleus originally lodged in their centre; they are either empty or drufed over with crystals mostly of calcareous spar and quartz. They are found in Milan, and in various parts of France.
portion of lime have been employed in pottery; but the most important use of marle in general is in agriculture.

Marle, or Marl, in Agriculture, a soft, unctuous, heavy friability of the calcareous kind, found extensively in some situations, at different depths under the ground. It is found in different forms in different places, and distinguished, from its appearances, into shell, clay, and stone marle. The first is supposed to have had an animal origin, as being constituted of tectaceous matters, in greater or less degrees of fineness, from the flow decomposition and attrition which they have undergone for a succession of ages, intermixed with a portion of earthy sublunacies. This is generally found in such places as have at some time been covered with water, consequently are more or less pure, and contain greater or smaller proportions of the calcareous principle, according to the differences in the nature of the deposits of the muddy or other earthy matters, with which they are blended by the sediments of such waters. But in common they are found to contain a larger proportion than the ordinary kinds of lime.

In respect to the second fort, it has, in general, a large quantity of clay in union with the calcareous material; on which account, it has a greater power of absorbing and retaining moisture than most of the other forts. Marle of this nature varies greatly in regard to its colour, being found of a brown, blue, red, and yellowish appearance. And the third fort is met with combined with sand, in different proportions to the calcareous and clayey materials, upon which the difference in its hardneds depends. But when it has a thin, flaky, or laminated structure and appearance, it is termed flate marle. On account of the portion of clay that enters into the composition of these marles, they are capable of being softened in a gradual manner, by the operation of water upon them, and at last to fall down into a powdery form. Dr. Airnley long since remarked, that all marles contained some portion or other of clay, in combination with their calcareous matter; while in lime, it is generally found that is united with it.

It is stated, on the authority of Dr. Black, in the 21st volume of the "Annals of Agriculture," that "all marles effervesc or raise up frothy bubbles, when acids are applied to them; and as water alone frequently produces the same effects, when poured on dry clay, it may be necessary, in order to guard against mistake, in making trials upon sublunacies suspected to be marles, to let them remain a little time in mixture with water, previous to their being subjected to the test of acids. The bell or richel marles being such as contain the largest proportion of calcareous earth, it frequently becomes a matter of importance to farmers to be able to ascertain the quantities, (some being found so poor in this material as to have only a twentieth or thirtieth of their weight,) in order to decide on their advantage in preference to lime, chalk, or other sublunacies to be brought from a distance. A simple and easy method, founded on the knowledge that this earth commonly contains about 40 per cent. of its weight of fixed air or carbonic acid, is proposed by the professor. It is merely by saturating the marle with muriatic, or some other acid, and marking correctly the losses of weight which it suffers by the extrication of the fixed air. Thus, if two hundred grains of marle be introduced into a vessel with a little water, and muriatic acid poured upon them until the bubbles cease to rise, the losses of weight being then found to amount to forty grains, the marle contains one hundred grains of calcareous earth. The proportion of calcareous earth contained in different marles may also be determined by dissolving it by means of the muriatic acid, diluting the liquor with water, passing it through a filtering paper, and then precipitating the calcareous earth from the clear liquid by a solution of some fixed alkaline salt."

And the following simple methods have been suggested by Mr. Donaldson, tending to show that such sublunacies as are examined are marle; but they are not by any means so correct as the above.

First, by Air.—"If a lump of true flone or clay marle be exposed to the air, it will, in a short time, break into small pieces."

Secondly, by Fire.—"When a piece of real marle is dry, break it into as small particles as possible, and put a handful into a hot coal-fire: it will crumble in the same manner as if salt had been thrown thereon."

Thirdly, by Water.—"Put a piece of dried marle into a wine-glass, and pour gently as much water thereon as will cover it: if true marle, it will gradually dissolve into a liquid or soapy sublunacy, and at the same time shoot up many sparkles to the surface of the water." But the most certain criterion, by which to prove marle of all kinds, is to put a little in a wine-glass, and pour over it a small quantity of aquafortis, or some other strong acid: if it effervesce, it is a sufficient proof of its being marle; and the degree of the effervescence, at the same time, ascertains its quality."

It is obvious, however, that these simple, but imperfect, modes should only be had recourse to, when the means of a complete analysis are not capable of being put in execution, for want of proper convenience. Though there are the above differences in the natural appearances of marles, they agree in being all capable of being reduced into a fine powdery flate, by being exposed for some time to the effects of the atmosphere. By this means, they become ultimately capable of being blended minutely with the different materials of the soils upon which they are laid. But as this common property of falling down into powder, in consequence of the absorption of moisture and carbonic acid or fixed air from the surrounding atmosphere, is much greater in some sorts of marle than others, it may afford some difference in their utility when applied to lands as manures. See Manure.

In the Farmer's Magazine, some moss-shell marles are stated to have been found to contain 82 per centum of pure chalk, or carbonat of lime, which is more than lime generally polleys, the refuse being chiefly petty sublunacies, which is a circumstance, it is said, that makes the refuse of them the more useful as a manure, than that of lime-stone, which is mostly sand or clay. These marles are also capable of being converted into quick-lime, by burning; and their solutions change vegetable colours to green, pooffing all the other properties of calcitic lime.

Marle is likewise further distinguished by its feeling fat and unctuous; and its looking, when dry, after having been exposed to the weather for some time, as if it was covered with a hoar-frost, or sprinkled with fine salt, and even when mixed with the land intended to be manured by it, the whole surface having a whitish appearance. The more marles effervesc with acids the more valuable they are as manures. In hot weather, good marle will flake with the heat of the sun like lime; especially when rain follows a hot day or two.

Good marles of different kinds abound in most parts of Lancashire, and are in very extensive use in many places, having been found to answer well in different proportions and different kinds of land. See Marling of Land.
The farmers in Staffordshire consider the soft blue marle, which is commonly found under clay, or low black ground, at the depth of seven or eight feet, the belt for arable land, and the grey fort the belt for pastures. But that which is of a brownish colour, with blue veins in it, and little lumps of chalk or limetone, generally lying under stiff clays, and very hard to dig, is most esteemed in Cheshire. The marle which is usually found at the depth of about two feet, or a yard, on the sides of hills, and in wet boggy grounds, which have a light sand in their composition, is very fat and close, and reckoned the strongest; for which reason it is particularly useful on sandy lands. It is often called peat-marle or delving-marle.

What is sometimes called paper-marle frequently lies near coal's, and flaxes like leaves or pieces of brown paper, thin, soft, and sometimes lighter even, might or more. That which some call clay-marle is very fat, and sometimes mixed with chalk-flames. There is another sort of marle which breaks of itself into square cubical bits. These two last kinds generally lie under sand or clay; sometimes about a yard deep under the former, but often much deeper under the latter. The stone, flate, or flag marle, which is a kind of soft stone, or rather flake of a bluish colour, is generally allowed very good. It easily breaks down and dissolves with frost or rain, is found near rivers and on the sides of hills, and is a very lasting fort when used as manure.

In a variety of districts of this kingdom marle discovers itself to the most negligent eye; particularly on the sides of broken hills, or deep hollow roads. Many rivers are bordered with a vast treasure of this fort, which is plundered by every flood. Boggy lands frequently cover it; and in them it seldom lies above three feet deep. It is somewhat lower under stiff clays, and marlly level grounds. The lowest parts of most sandy lands abound with it sometimes at the depth of nine feet, and sometimes lighter even, might or more. The depth of the marle itself can seldom be found; for when the upper crust of the earth is removed, all that can be seen or dug is marle, to so great a depth, that there are few if any infallences of a pit's having been entertained of it.

But the manner in which this earthly material is found, is probably different in different forts and situations.

In the Perthshire Report, shell-marle is flated to be found for the most part in small lakes, or in land-locked bogs and mosses, where there had been formerly a lake or pond, during the multiplication of the animals. The wilks, which produce the marle, it is said, live only one year, and multiply prodigiously. They are often found to adhere to the long grass, which grows in pools, where they breed; and when the grasses decay, it is laid in horizontal lamina on the marle bed, by the weight of the animals. These lamina ascertain the number of years in which the marle bed has been forming, in the same manner as rings of trees denote their age. When the wilks happen to generate in springs or other small collections of water, which are in many of other high ground, they are frequently carried down in the wet season, to the first full water; but if the stream is not able to carry them to a pond, they are sometimes left in the face of the hills, and form beds of marle in that situation. In Glentill, a property belonging to the duke of Athol, there is, it is added, marle collected in this manner, on the declivity of a hill, to the depth of thirty feet, which, at a distance, has the appearance of a white rock. And according to fame, not only wilks but bivalves produce shell marle. These wilks are of a blackish colour, and about the size of a pea; and are found in pools or springs in the months of May and June,rickling to flames and grays. Wherever the wilks are observed in lakes, bogs, or meadows, it will be proper to bore for marle; or if they be found in swampy land, or in rills of water that flow into lakes or into marshes that flagitate, it may also be proper to bore for marle in these lakes or flagnant water. Marle is found under most forts of substances, but more commonly under mo's, soft mud, and sand; more rarely under clayey strata.

*Discovering of Marle.*—This material is commonly sought for and discovered by means of boring with a tool for the purpose, somewhat in the manner employed for coal and other similar substances. A boring rod for this purpose is thus described in the Perthshire Survey. "It is made of iron, in pieces of about four feet long, which pierced into each other. In the undermost or first piece is a kind of tube, about two and a half feet long, pointed sharp, open on one side, and the fore end raised higher than the other, like a gimlet; so that when turned round, it may fill itself with the substance which surrounds it. Into this tube, which is open at the top, is put a piece of wood, as long as the tube itself, and of a conical shape, corresponding exactly to its figure. To this piece of wood is fastened a rope, of the size of one's little finger, and longer than the whole rod when all the pieces are put together. This piece of wood must stick so fast as not to come out, when the rod is pushed down into the earth or mo's, below which marle is expected to be found; but must not be so firmly fastened, as not to be easily drawn out by the rope to which it is fixed." When it is wished to bore, the piece of wood is put into the tube; screwing the piece of the rod which is fitted to the fore end on the top of the iron in which the tube is formed; then pushing down the rod into the earth or mo's, allowing the rope to go down with the rod, without twisting round it; and when the two first pieces of the rod are pushed down their full length, screw on the upper piece of the rod, which ought to fit the fore end of all the other pieces, and must have a hole in the top of it, large enough to admit of a piece of timber, two inches diameter and four feet long, with which you are to turn round the rod three or four times, having previously drawn up with the rope the piece of wood which had been put into the tube. When the tube is thus turned round, it will be filled with the substance next it; and when drawn up, will show what that substance is. You can bore deeper and deeper, by screwing on more pieces of the rod, below the piece into which the handle is received that turns it round; but for facility in unswerving, there should be a hole in every piece of the rod, that will admit of a piece of iron, of the thickness of a man's thumb and eighteen inches long. It will be necessary to have two of these pieces of iron, so as to hold the rod ready with the one, while you screw or unswerve any of the pieces with the other; and this must always be done, in putting down and taking up, when a great length of the rod is required, as it cannot be managed in either of these without, all in one piece. See *Boring-Azure.*

Marle is very common in Ireland, where it often lies not above a foot or two below the surface of the soil. But in France, though they have made in many places, they are often obliged to dig very deep for it. In many districts of this country there are also pits of this sort of great depths, but where the marle lies at such great depths, it can in very few cases be raised for the purposes of manure. In most situations where it is employed in this intention, it is found only a few feet or yards below the surface, and it is usually raised by digging pits, and where there is much water draining them either in the common way, or by the use of pumps. When they are not very deep, the belt and
M A R

M O T ready method for getting out the marle is to open a sloping mouth, sinking the pit gradually, wide enough for a cart to drive in and out; and to work the marle away circularly, keeping the pit ten or fifteen feet deep, by which means the expense of filling the cants will be much lessened. And in cases where it is raised from below loughs or ponds, it may sometimes be necessary to have recourse to boats for conveying it to their borders, in order to its being conveyed upon the lands.

In first opening the pits upon the land, it will be necessary that they be made as convenient as possible for carriage and draught, and that the leafy portion be cut away by them to the grounds. Attention should likewise be paid to the facility of laying them dry. When large pits are dug, masses of considerable size are often let down by undermining, and forcing large piles in above them. In these cases great care should be taken, as they are very apt to give way suddenly, and cause accidents.

Marle is a substance that may be made use of on most forts of soil, that are of a sufficiently dry quality to admit of its being applied. It has been found highly useful on those of the sandy, gravelly, and moory kind; upon the more heavy forts it may likewise be found beneficial in many cases, where the calcareous principles are wanting. This would at least seem to be the case with shell-marle, which Dr. Robinson says, of all others, abounds most in his district, containing more oil than any of the other kinds. In common with them, all he fupposes pulverizes the soil, and prepares the vegetable food for being absorbed by the roots of plants; in common with them also, it communicates to the soil the power of attracting the fertilizing influence of the air; but it furnishes them, by adding mucilaginous matter of its own to the soil, being the exuviae of animals, and therefore improving in a small degree the quantity of vegetable food. Mott of the common marles, however, seem to act more in a mechanical manner upon the soils, than by adding any thing of a nutrient principle to them.

In digging for the marle they use in manuring their lands in Ireland, they meet with fissile horns, and other curious fossils. The marle always lies in the bottoms of low bogs. It is never met with in any other places, and is found by boring with augers made for that purpose. It usually lies at five, seven, or nine feet depth. The obtaining it in many places is attended with very considerable expenses, in draining off the water. The manner of digging it is this: they employ six able labourers, and a supernumerary; and these cut up a hole of twelve feet square, which is filled with a pit that number of men can manage in one day. Two men dig, two throw it up, and two throw it by, and the supernumerary man supposes defects on all occasions. For the first three feet they dig through a curly earth, fit for making of turf or fuel. Under this lies a stratum of gravel, of about half a foot. Under this often, for three feet more, there is a more kindly mofe, which would make better fuel. This lower stratum of turf is always full of fissile wood, which is usually so soft, that the spade cuts as easily through it, as through the earth it lies in. Under this, for about three inches, is found a series of leaves, principally of the oak; those appear very fair to the eye, but fall to pieces on touching; and this stratum is sometimes interrupted with vast heaps of feed, which seem to be broom or furze-feed. In some places there appear berries of different kinds; and in others, several pieces of sea-plants, all lying in the same confused manner as the oak-leaves. Under this vegetable stratum there lies one of blue clay, half a foot thick, and usually full of sea-shells. This blue clay is not so tough as common clay, but is thrown carefully up, and used as marle in some places. Under this always appears the right marle; the strattm of this is usually from two to four feet thick, and sometimes much more. Phil. Transf. N 394, p. 122.

This marle looks like buried lime, and is full of shells, which are usually of a small size, and of the periwinkle kind; but there are several other sorts, at times, found among them. Among this marle, and often at the very bottom of it, are found great numbers of very large horns of the deer-kind, which are vulgarly called elks' horns. These, where they join to the head, are thick and round; and at that joining there grows out a branch, which is about a foot long, and seems to have hung jut over the creature's eyes; it grows full round for about a foot above this, and then spreads broad, and terminates in branches, long and round, turning with a small bend.

The labourers are obliged to work in a hurry in all these pits, so that they seldom bring them out whole. There are also at times found the leg-bones, and other parts of the skeletons of the same beasts: but these are more rarely only a few together, and but in few places.

MARLE, in Gardening, a fort of fissile earthy substance, which is sometimes made use of for rendering stiff adhesive garden lands more open and light in their qualities.

This material varies much in its nature, some being nearly of the nature of fuller's-earth, and of a fat enriching quality, of which there are blue, grey, yellow, and red coloured; but the blue is esteemed the best in this intension. In other cases, it has the appearance of a kind of silt stone, or rather slate, of a blueish or grey colour, called stone or flat marle, being found commonly near river sides, and the sides of hills, &c., and though hard when dug, easily diffuses by rain and froth. There are likewise calcareous, or shell and clay marles, the latter resembling a fat fort of clay or loam. This last fort is accounted good manure for improving light, loofe, sandy, garden lands. See MANURE, and MARLE, in Agriculture.

MARLE, in Geography, a town of France, in the department of the Aisne, and chief place of a canton, in the district of Laon; 13 miles N.N.E. of Laon. The place contains 1616, and the canton 9967 inhabitants, on a territory of 2371 square miles, in 23 communes.

MARLE DICE, in Hydrometery, a name given by the people of Staffordshire to a reddish marle, that breaks into small square pieces like dice, or elfe into thin flakes, in the manner of lead-ore, and looks smooth on the surface. This is a good manure, and the way of judging which of it is best, is to expel it to the air in rainy weather, or to put it in water. That which moulders soon into powder on the air, and breaks quickest in the water, is sure to be the best, and proves very beneficial to land.

Its colour is partly greyish, partly brownish-black, and also of an intermediate colour; seldom blueish-black.

Occurrs massive, and is frequently marked with impressions of fishes and marine plants.

Fracture flatly (sometimes rather indifferently so), partly straight, partly undulated flatly.

The planes of separation always shining; the planes of fracture of the flatly are flatly, rough, and generally dull, or at best, glimmering; those of the curved flatly are smooth and glinting.

Fragments generally flatly.

Retains its colour in the fire, which is glinting.
It is opaque; soft; rather mild; easily frangible.
In large flat pieces it is rather porous.
It is meagre to the feel; and moderately heavy.
Spec. grav. 2.561—2.443, Kirw.
It effervesces with acids. Before the blowpipe it first burns with a small flame, giving out a bituminous odour, and afterwards fuses into a black flag.

It is found at Eiffelen, Sangenthalen, &c. in Thuringia; at Rieggelshof, in Heffia; in the county of Mansfeld; in Switzerland, at Aigle and Bex, &c.

The varieties rich in copper are often regularly wrought as ores of this metal: no other use is made of bituminous marle flate, which, when decomposing in the air, forms an earth injurious to vegetation.

Bituminous marle flate is subordinate to the fletz limeflone formation, in which beds are sometimes formed by it. Its lowermoi stratum, which rolls on the old sandflone, is generally rich in copper ores, whence it has received the name of copper flate: these ores are copper pyrites, vitreous copper ore, variegated copper ore, more feldom copper azure, copper green, malachite, and still more rarely native copper. Besides these also some galena and carbonated iron is found in it; and its rifts are sometimes coated with felenite.

In this flate are frequently found the impreffions and remains of fishes converted into coal, and which, by the convulued and contorted attitudes in which they are feen, appear to indicate a sudden catastrophe, by which whole shoals of them perifhed. Nor is it less singular that impreffions of the fame species are generally found together.

Of this defcription is, among others; the well known marle flate from Monte Bolea, of which, and the impreffions contained in it, a detailed account has been given under the article Ichthyolite. The quantity of fishes in the marle flate of Thuringia, is generally proportionate to the quantity of copper it contains; sometimes the whole of these remains is converted into copper pyrites. In the bituminous marle flate of Rieggelshof, in Heffia, Mr. Ris has discovered some remarkable impreffions which he considers as produced by the bones of a child's hand; but, according to professor Blumenbach, the bones belonged to animals of another order of mammalia.

The bituminous marle flate passes into indurated marle; sometimes also into flinktone.

MARLHELM, in Geography, a town of France, in the department of the Lower Rhone; nine miles W. of Strasbourg.

MARLHEX, a town of France, in the department of the Rhone and Loire; 10 miles S. of St. Etienne.

MARLIEUX, a town of France, in the department of the Ain; 10 miles S.S.W. of Bourg en Brefe.

MARLINE, on board a Ship, is a small line made of hemp untwisted, that it may be the more gentle and pliable: its use is to feize the ends of ropes from farcing out. They use it also to feize the flaps at the arfe (as they call it) or lower end of the block. See Hoisting.

MARLING, in Sea Language, denotes the art of winding any small line, as marline, flpun-yarn, pack-thread, &c. about a rope, so that every turn is secured by a ffoot of knot, as to remain fixed in cafe all the refl should be cut through by friction, &c.

Marline is commonly used to fasten slips of canvas, called parfiling or parcelling, upon the surface of a rope, to prevent it from being got by another rope that rubs against it, to attach the foot of a fail to its bolt-ropc, &c.

MARLING a Sail, is when flong ftript out of the bolt-ropc, that it cannot be fowned in again, the fail is falfened by a marline, put through the eye-let holes, made in it for that purpofe, under the bolt-ropc.

MARLING-Spike, is an iron pin, tapered to a point, and furnished with a large round head. It is principally used to penetrate the twiffs or flrands of a rope, in order to introduce the ends of some other through the intervals, in the art of knotting or splicing. It is also used as a lever on any other occasions, about the rigging, particularly in fixing the fizenings upon the throuds, blockfrops, fhoes of the falls, &c. Falconer.

MARLING of Land, in Agriculture, the operation of digging up and putting marle or some fort of material of this nature upon the ground, fo as to effect its amelioration and improvement. In the application of all forts of manures, the farmer must be regulated in a great meafure by the quality of the foil, and the strength of the manure, in which experience is the fureft guide. In marling, it is particularly necessary to find the true proportion which the land requires, and much better to err in laying on too little, than too much, as more may be added at pleafure; whereas by overdoing it, the firft year's crop often fails, from the body of the marle not being sufficiently opened; and in that cafe, it will sometimes be three years before the ground comes to a proper flate. The bell direcions that can be given the farmer in the application of this manure to light foids, is to lay on the quantity which will give the degree of cohesion wanted in thofe foids. A general rule cannot be laid down in this refpect, as the quantity of marle requisite to effect the defired end must be different in proportion to the degree of lightnefs of the foil. But the quantities moft commonly employed are from seventy to eighty loads.

In Lancashire they have lately reduced the proportions of the fets, and found them to answer much better than the former larger ones. Upon lands of the fandy kinds, Mr. Young advifes from fifty to ftifty cubical yards per acre; but on thofe of the loofe, wet, loamy fort, upon which this kind of manure produces great improvement, it fhould, it is fuggelied, be laid on to the amount of a hundred yards.

And in regard to the moft economical method of doing this fort of work, it is, he imagines, that of contracting "for the whole job with some little farmer or horfe keeper who works for hire." It is not uncommon in Suffolk to give 8d. a cubical yard for all expences whatever, except that of spreading, which thofe farmers that have attention to correct management do by the day, as it is of much importance to have it well parcelling. A for where this is not the cafe, some parts of the field will have it in the proportion of two hundred loads, while others have not more than fifty. In the fame county even 9d. and 10d. per yard, is faid, has lately been given to fuch small farmers for teams sufficiently strong for this fort of bufines.

The practice and success of Mr. Rodwell in this fort of work, as detailed in the second volume of Communications to the Board, hold out much encouragement.

On obtaining a leave of a farm, of 1400 acres, at 150l. a-year, of the poor, dry, heathy kind of land, ab-undping with fern, gorse, and more particularly hag, of little value, and affording only a scanty support to ill fed fheep; his "operations were to inclofe with thorn hedges, marle, or clay, and break up 300 acres of the heath; and in the firft seven years of the leave he finifhed what he meant to improve in that term; he marled or clayed 600 acres, at 70 loads an acre, being 42,000 large tumbril loads. In this work he employed three teams, two of his own, and one he hired, for several years. It is fevere work, and the second year he loft nine horfes, attributed to feeding on pea

RAW
straw from the new broken heath, a circumstance that deserves the attention of improvers. In the 11th year of his lease he applied to his landlord for a renewal: on which the farm was valued again, and he took a fresh lease of 15 years to commence at the termination of his old one, at the rent of £116l. 13s. 10d. He immediately clayed and broke up 209 acres more, at 100 loads an acre, 40 bushels per load, including all with quick hedges and ditches from three feet wide for your deep; after this, he improved 700 acres more in the same manner. In the two leaves of 28 years, he clayed or marked 810 acres; and he has clayed or marked so much over the second time, at 70 loads an acre, that the quantity he has carried in all, is very little short of 1,40,000 loads. Upon taking a third lease, he was, in 1798-9, particularly favorable to this work, and in 49 weeks and three days carried 11,275 cubical yards, paying by measure of pits, and not by loads, which were filled and spread by four men and a boy, and carried by six horses and two tumbrils.

And "in this business of carrying clay or marle he has practiced hand-barrowing; the men can make good earnings at 10d. a yard, wheeling it 30 rod; and down to 7d. a yard at shorter distances; and he is much inclined to think, that if we had workmen used to the operation, and handy at it, like those employed in navigations, that this method would be of all others the cheapest, especially on the heavy soils. But by far the greatest part he has done by tumbrils, the expense of which put out is 5d. a yard for team, and 2½d. a yard for labour, and paying for laying picks, wedges, &c. also for itineraries that arise, the average expense to 8d. per yard, which is at least 2½d. per yard cheaper than he can do it with his own team: the reason of which is, that the man who contracts with him drives his own horses, and keeps them after them; at 8d. per yard, 140,000 yards have cost him 4958l. excepting the small proportion hired at 1½d. per yard lower."

Here a few circumstances are mentioned which he hopes may tend to render this communication useful to others, not having the experience which he has acquired. He says, he shall use but few words, but they shall be founded on positive experiment or authoritative observation. Clay is much to be preferred to marle on these sandy soils, some of which are loofe, poor, and even a black sand. Clay is to be used under a good clayey loam, some of it brick earth, and all has with vinegar a small effervescence. Marle is a white, greenish, chalky sublimation, that effervescence strongly with acids. He makes a universal rule, on a second improvement, to lay clay on the fields marked before, sometimes marle where clay was spread before; but this is not general, as clay answers best on the whole. On 90 acres, clayed 100 loads an acre, he has had after two crops, the one turnips, the other barley, coke-feed, and sold it on the ground for 1000 guineas; then turnips, a famous crop, followed by barley, on 75 acres, 16 cobs an acre; and by oats on 15 acres (poorer land), 10 cobs an acre. These crops are for the soil great; but in general his products have been highly to his satisfaction.

It is stated by Mr. Young, that the expense of this fort of work, where it is thrown from the mouths of sloping pits into the carts, will be, "upon an average, three-pence to three-pence halfpenny per cubical yard, the filling and spreading, and about four-pence-halfpenny for the teams, carts, and drivers; in all eight pence per load, or cubical yard, or 5l. 6s. 8d. per hundred loads, which will be a proper quantity for an acre of land: the benefit will last for twenty years, and the land always be the better for it."

It is sufficiently obvious, that there must be considerable variations in the expenses, from the circumstances of con-veying it from different distances, as is shown in the Survey of Lancashire.

The expense of marling upon marl land, near Liverpool, about the year 1780, is rated as follows:

<table>
<thead>
<tr>
<th>Expenses</th>
<th>£</th>
<th>s.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Getting and filling, per rood of 64 cubic yards</td>
<td>0</td>
<td>10</td>

<td>1</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

In this estimate, there were six carts, five in motion, each going the distance of twelve roods, while one flood in the pit to be filled. The size of each cart was 20 feet 36 inches (cubical), usually drawn by three horses; the weight of the load about 15 cwt. and two cubical yards of marle made about three loads. The number of workmen were six fillers and getters; usually two right-handed men at one wheel, and two left-handed at the other, with one filler behind: one getter is generally sufficient for the whole.

<tr>
<td></td>
<td>15</td>
<td>14</td>
</tr>
</tbody>
</table>

There were about 6½ rods laid upon the acre on this occasion. The men get 2½d. and the carts 7½d. per day. Getting and filling marle, it is said, is very laborious work, and requires the utmost exertion to obtain these wages; and that this work, after all, can only be effected by young men in their prime, cheered by the company of fellow-labourers, and frequent refreshments. Five working-days are reckoned equal to fix at other work, for they usually begin at half-past four in the morning, and rest one hour at breakfast, from eight to nine; rest again from twelve till two, and then work till six; and generally get out nine rods per week.

The present price (1795) is—

Since this period the expenses have been very greatly increased, so as to render marling a very heavy charge to the farmer.

In the Middelfex Report it is rated to be this: "Four men digging and filling eighty cart loads, at 4s. a score, spreading included, is 16s. One man and four horses, two days, at 1s. 11d. Total expense per acre, 21l.

An intelligent farmer, who has had considerable experience on a farm of twelve hundred acres, remarks, that, "from different trials of his own, at a very great expense, and the observations he has made on his neighbours' and the Norfolk farmers' manner of improving light sandy lands, by clay and marle, he is clearly convinced, that about seventy square yards, each of which contains about a cart load, is the proper quantity to be laid upon an acre of land, pole
MARLING OF LAND.

If more be laid on, the longer it will be before it incorporates with the soil, and, of course, the longer before any benefit can be received from it. He once saw an instance, where a farmer laid 120 loads, or square yards per acre, and gave this reason for it, that the land was too poor to be furrowed, he could not hurt it. But the consequence of it was, that after an expense that would have purchased the few simple of the land, he could not see, for many years, that he had done it any good, as it produced no better (if so good) crops, as land by the side of it that had not been clayed at all, but otherwise farmed the same. It has now, however, evidently the advantage of the other lands, having been done above twenty years. This trial was in the middle of a light field, where, by the course of husbandry, two crops are taken to one furrow till; and where this is the case, claying, &c. feldom (or never might say) answers the expense; for claying and harrowing being only a first, or beginning of improvement, by going on directly with a course of ploughing, which cannot well be avoided in light fields, it is often buried and lost before it mix properly with the soil, especially if turned in too deep by the first earth, of which great care should be taken. He would therefore recommend claying or marling only upon inclosed lands, unless where large breadth lies together, that can be farmed in any manner the occupier pleases; and in that case (as well as in inclosures) he would advise that the lands should be laid down with clover, rye-gras, and trefoil, the spring twelfth month before laying on the clay or marle, and to remain at least fix months after it, that it may have time to sink and eat itself into the flag before it is ploughed up, and then there will be little or no danger of lodging it, as it will already be in some measure incorporated with the soil.” And, “no pains should be spared to break all the lumps, and get it fine by repeated harrowings and rollings, and having all the stones picked and carried away, that the grass may get through as soon as possible, for flock to be grazing upon it, which is the great and lasting improvement; for as he observed above, claying or marling seldom or never answers where you go on immediately with a course of ploughing in the common way.” Besides, “in his opinion as much, or more, depends on the management of lands after claying or marling, as in the mere laying it on, which, however, is very expensive, and therefore a very peremptory argument in favour of that sort of management that will be the most likely to make it efficacious.” But “little need be said about the different qualities of clay or marle, as every one must be content to use such as is found on his own premises, for he never heard of any in the counties of Norfolk or Suffolk that would answer long carriage. He has seen, however, in the county of Kent, a fort of marle that the Elph farmers buy, which, after being sent many miles by water, he is informed they find answers carrying five or six miles by land. Clay that is free from frass, and marle that is not so, nor from grassy, are certainly, in his opinion, the most valuable; and even blue clay, though condemned by most farmers, he has found to answer very well on light lands, but they generally want too great a distance from each other to be judiciously got together.” However, “where there are different sorts of marle, equally convenient upon the same premises, which is sometimes the case, viz. pure clay, white foapy clay marle, clay with much marle in it, loamy clay and coke; he should certainly prefer the former for light sandy lands; on sands of a stronger nature, that have a mixture of loam with them, he should choose the foapy-marle, or that mixed with clay-marle, whichever was most convenient; but any of the inferior ones must be used, rather than submit to long carriage, especially on a large scale.”

With regard to the expenses, “the first is the filling, which, including spreading, is 25s. a hundred, or 2 d. a load, with an allowance by some farmers of 21. 6d., by others of 32. for opening the pit, and 11. a load for all the large flomes they throw out at the time of filling; the farmer to find drifts and flakes for letting down what they call the falls.” And with respect to the team, it must consist of four strong trace horses, and two shaft horses, which, for such strong work, must have very high keeping. He cannot, therefore, buy their labour at less than 21. a day each, and the carter 11. 6d. a day, which, supposing they carry, one day with another (allowing for wet weather and hindrance by accidents, &c.), 30 loads a day, will be about 51. 6d. per load more, making in the whole 71. a load for filling, carting, and spreading.” Therefore, taking the quantity of marle which is necessary on a medium, at 75 loads per acre, the statement of the expenses of this sort of work will stand thus:

<table>

See Annals of Agriculture.

A late author states, that “in Lancashire they have abundance both of flone and clay marle: the former is applied to the strong clay foils, the latter to the light, loamy, and sandy lands. The medium quantity laid on the acre is about three cubic roods, of eight yards to the rod. The expense in a great measure depends on the distance of carriage; but generally runs between six and ten ponders the acre. It is commonly laid on grass lands, a year or two before they are broken up, although sometimes on lands in a course of tillage. In either case, great care is taken to spread it as equally as possible on the surface, and to break any lumps on which the weather has not had sufficient influence.” And “the application of clay-marle to the light sandy foils in Suffolk, has been the means of greatly improving those foils; and the crops which they produce, after being marled, if the lands be not too feverely cropped, are far superior, as fully to warrant the expense. The quantity laid on the acre is about eight loads; or nearly 2500 bushels; this has been fully shewn above. And in the Isle of Man, they lay on clay marle at the rate of nearly two hundred tons the acre.”

But it is to the county of Norfolk that we are to look for the wonderful effects produced by marle. There are so great, that lands which, forty or fifty years ago, did not rent at eighteen pence the acre, now give upwards of twenty shillings. There are two kinds of marle in that county: the one of a white, or rather yellow colour, consisting almost entirely of calcareous earth; the other may properly be denominated clay marle, but from the small quantity applied to the acre, it must be of a very rich quality, compared to
to other marls; otherwise it could not operate so powerfully on the soil. Of the drift, from ten to fourteen loads are sufficient for the acre; and of the half, from thirty to forty. The mode of application varies. Sometimes it is used as a preparation for a crop of barley, or turnip; and is frequently laid on clover-leaf, before being broken up for wheat; its use in this district will be more fully seen below. Yet it is frequently observed that, "if the above county has been benefited by the marls above-mentioned, that of Forfar, in Scotland, has reaped as great advantages from shell-marl. Shell-marl, of a most excellent quality, has been for a good many years discovered in various parts of that county, and the improvements that have taken place, in consequence of the general and judicious use of that valuable manure, exceed perhaps any thing of the kind that ever happened in the same period in any other county in the kingdom. The average quantity laid on the acre, is about four hundred cubic feet; and in respect to the mode of application, it is in every respect similar to that mentioned above, as the practice in Norfolk. Great caution is, he thinks, necessary in using marl, and in adopting proper rotations of cropping after it is applied. If a large quantity be laid on at once, especially on light lands, or if the marl be laid on a second time in the course of a few years, and a number of severe crops afterwards taken, the lands will be greatly exhausted. This was experienced in many instances, when marl was first used as manure in Forfarshire; the tenants, for the most part, ignorant of the effects it would produce, laid on large quantities; which creating a great fertility, they went onewing oats, and other severe crops, till the soil became little better than a dead sub stance. This alarmed the proprietors, and induced them to include certain covenants in their leases, so as to prevent any prejudicial consequences in future. Thus have been the means of establishing a more regular system of marling husbandry in that county, than perhaps is to be found in any other part of the isle. When a field is marled, the tenant is bound to lay it out in grass, with the next or succeeding crop, and allow it to remain three or four years in pasture. When broken up for corn, a certain specific number of crops only are to be taken, before it is again laid out to grass; and so on, during the currency of the lease. The tenants are also debared from laying on marl a second time on the same field, in the course of one leaf, which is commonly for nineteen years; unless it be properly mixed with dung, or other sub stances. Thus the improper practice of overworking the land after marling, and the no less injudicious custom of repeated marlings at short intervals, are both prevented; and under these restrictions, which are in general very readily adhered to, marle is found in that district a most beneficial manure, and the lands continue in a progressive state of improvement. Although it appears doubtful whether marle, unless laid on in large quantities, be advantageously applied to strong clays, yet it seems universally agreed, that for all light, dry, sandy, and gravelly soils, it is the best manure yet discovered. That being the case, every occupier of such lands ought to be extremely attentive in searching for marle; and the proprietors and farmers in those districts where it has been lately discovered, will essentially promote their own interests, by bringing into general use a manure, which has been found in so many other districts a source of real wealth, and a means of substantial and extensive improvement."

"It is stated in the survey, that "this sub stance, in Strathern, in Pertshire, is fold from eight to ten-pence the ball, being eight cubical feet. The ordinary allowance for an acre is from forty to sixty balls. A gentleman on the Nairn estate, betwixt Perth and Dunikeld, told the writer that the farmers in that district go even the length of one hundred balls to the acre, but most of the land in that county is a deep strong loam. The most experienced improvers allow forty balls for a second marling, after an interval of fourteen years. The interval now adopted in the Stormont is nineteen years, especially on the estate of Balharry and the country adjacent. On all light land its effects are powerful and immediate; but it requires to be managed with caution. Many places of the Stormont, and indeed in all Strathmore, have been almost laid waste by the excessive application of this stimulating manure and over-cropping the ground. At Bridton the soil lost all the power of cohesion, and became so light by this cause, that it has no sward; the surface and the soil were blown away with the winds, in the same manner as dust is raised from the roads; and dens were made in some instances to the depth of five or six feet. About Bakie, along the road from Coupar to Meigle, and in many other places, the fame injury has been done to the soil, by the injudicious use of marle. He saw one field well of Blairgowrie, which had been so reduced, that after it had lain fourteen years or more in grass, it had scarcely gathered a decent sward. Mr. Smyth of Balharry, to whom he owes much of his information relative to that country, told him that the land of Fullarton had been marled every second year for a succession of ten or twelve years, which at length put the ground from carrying oats, but not from barley; which management and effect still continued in 1795. This fact seems to indicate that oats will exhaust marled land more than barley; or that the dung given to the barley crop, corrects the exhausting quality of the marle."

"But the marle discovered in Strathern has been applied very successfully to the lands in that neighbourhood, for a long time, because a succession of scouring crops is not allowed. No such congequences have followed as the in the Stormont. The expense of dragging it out of the loch amounts to three-pence the ball, and a fratum of molf, from nine to sixteen feet, must be removed, before the bed of marle in one er's of the lake can be wrought. Sir William Murray chewed him a field of thin gravelly moor laid down with marle alone, every acre of which, by such a drippling, was equal to the maintenance of four sheep. In some parts of the fame moor which had not been ploughed at all, the heath was banished in three years by a top-drilling of marle, and succeeded by a fine clofe grass."

"However, in the trials of Mr. Chatterton, made on a farm that had been marled at some very distant unknown period before, and had, in consequence, been altered in its soil from a weak sandy gravel to a rich loamy gravel, to the depth of ten or twelve inches, or such a depth as had been moved by the plough; on discovering a pond from which marle had been taken, the year after his entering upon the farm he began with the marle. The first piece to which he applied it was that of some old standing ground, which was situated high, and was near a sharp gravel; it had but a very dry poor sward, producing only a small proportion of ordinary hay. He covered five or six acres with marle, laying about forty loads upon the acre, and after it was spread, was extremely attentive to seize a proper opportunity to harrow it small or fine, as it is fekilon in a fit sate for that work except upon a change of weather. The first year, the improvement did not make much appearance, but in the year following it was admirably great, both in the quantity and quality of the hay, and continued so long as he remained upon the farm, which was about five years, being greatly increased in value. In the following year he applied the fame quantity per acre, to a few acres in the middle of a field
MARLING OF LAND.

field that was under the plough, which was spread and ploughed in; after which oats were sown, and the crop upon the marled part was superior in strength and richness to the other part of the field: but it did not seem to have undergone so great a change as the portion of grass land just noticed. It is probable that the reason might be, that the piece sown with oats had never been marled before; while the other, from the strength and firmness of the soil, feemed to have had marle laid upon it at some time, as the top foil was much more free from pebbles, though underneath there was a very strong gravel. When the field was in the state of grass-feeds, after the oats, the colour of the grass was observed to be the strongest and richest in the place where the marle had been applied; but as the whole was potted together, the difference in the quantity of produce could not be ascertained. It is added that several other fields were marled while in the state of tillage, with about the same number of loads per acre, all of which answered very well under the plough, were fedded well with grass, and became rich pastures; but that where the land was the most gravelly and sharp, the greatest change was produced. Vide Communications to the Board of Agriculture, vol. iv.

And in the practice of Mr. Kiddle, as stated in the same work, a vast superiority was found in the use of clay marle, in the proportion of sixty loads to the acre, over that of the chalky kind, on land of the new-broken-up healthy kind, both in the turnips and crops which succeeded them, being nearly better by one half; which strongly shews the necessity of procuring, if possible, clay or marle of the clayey kind, for such sorts of soil, even if brought from some distance, as the land is by such means doubled in value; but that if it cannot be procured, and that of the chalky description presents itself, it must at all events be employed, "as without a flaple manure such land will never admit of being converted into tillage with any advantage to the cultivator; without clay or marle, land of such quality acquires no firmness, and no turnip can be grown upon it; and in the early part of autumn they will be subject to the "angerberry," and after being infected with it, they never make any progress in their growth, or are of any use for the cattle, particularly those that are in a forward state."

Mr. Marshall, in his Rural Economy of Norfolk, states, that "marle has been so long in use in that district, that there are few farms without marle-pits upon, or near them; so that searching for marle is at present seldom requisite, and the art of discovering it not much studied. The herb colts-foot (Tussilago farfara) abounding on the foil, is considered as an indication of a farm of marle being situated near the surface. But, whether this is, or is not, an infallible guide, time and accidents or intentional researches have not failed to discover beds of marle in almost every clift, and, in some places, on almost every farm, situated sufficiently near the surface to be worked with advantage. Of the quality of marles, the farmers in this district are, in a great measure, uninformed. That which falls most readily, and "gets to work" the fondest, is in the belt easterly; but, in general, the quantity of "uncallow" (namely, the marl) or covering of earth, which lies upon the head, or jamb, is more attended to than the intrinsic value of the marle. The depth of uncallow is generally very unequal; perhaps on the same farm of marle it will vary from one or two to fix or eighteet feet deep, the surface of the jam usually rising into inequalities, termed heads." And "the depth of the jam is equally uncertain: he has seen one worked twenty feet deep; but in general, he believes, ten or twelve feet may be reckoned a middling depth. The bottom of the jam being generally a white absorbent land, no pump or artificial drain is requisite to free a Norfolk marle-pit from water, which no sooner touches the land than it vanishes, as through the grate of an open drain."

It is suggested that in this county, "in working a marle-pit, the top foil is thrown back for manure; the remainder of the uncallow thrown to the bottom of the pit, and levell'd for the carts to stand upon. When the jam is low, the marle is thrown immediately from it into the carts; but if it be too high for this operation, piles are driven in a row a few feet from the face of the jam; and, as soon as a crack is formed, water is poured into it, more especially when the marle is dry and fibb'rous; and by this means many loads are thrown down at once; either to the bottom of the pit, or on to a platform level with the body of the cart; into which the marle in this case is thrown with market. Taking up the bottom of the jam is the most difficult part of the operation; the marle being first to be call up on to the bottom of the pit, and afterwards to be thrown into the carts. But by thus bringing up the bottom, two valuable things are obtained: a drain for the water, and a most convenient receptacle for the next line of uncallow. The labour bestowed on marle previous to its being put into the cart, whether it be incurred by throwing down, hollowing by pecks, crows, &c. or fetching up the bottom, is termed 'calling'—the act of throwing it into the cart being called 'filling.'—The price of calling was then three-pence to sixpence a load, according to the circumstances of the pit (the uncallow being generally done by the day); and the price for filling two-pence or two-pence halfpenny, according to the fize of the loads carried. He has known three-pence a load given for filling and spreading large loads: the price of spreading, alone, is about one shilling an acre. The number of loads carried out in a day by one team, varies, of course, with the distance to be carried; when the pit happens to lie in or contiguous to the ground to be marled, thirty having been carried; but five and twenty is, he believes, considered as a good day's work." But these prices are nearly doubled at the present period.

The quantity set upon an acre here is "equally various; depending upon two things: upon the judgment of the person who marles, and upon whether the land has, or has not, been marled heretofore. It is known, from common experience, that land which has been recently marled, receives no apparent benefit from a second dressing of the fame manure; but it is equally well known that, after some length of time has elapsed, a repetition of marling will generally answer. It is a notion generally adopted, that, in this case, the quantity ought to be greater than it was the firt or preceding time: and it being formerly the practice to set on a great quantity at once, seldom, perhaps, less than forty loads an acre, this notion has, probably, deterred many persons from doing that which would have been favourable to themselves and their country. But there is net, it is believed, any general rule known, respecting either time or quantity: he has had frequent opportunities of making observations on a farm which belonged to a landlord, who had three different tenants who had failed successively on this farm; though by no means high rented. The greatest part of it had within the memory of man been marled with not less, in all human probability, than forty loads an acre; and the tenants who failed despairs of reaping any benefit from a second marling after so short an interval of time; but this farm falling into the hands of a more judicious tenant, he has, by marling, (and by other good management) accumulated, in little more than twenty years, a farmer's fortune; during which time he marled upwards of one hundred acres; and has found, from long experience, that twenty-five loads an acre,
and the continued palfed believed, deed is, The undoubted borough, not in Mr. The but the fcreen young among forty-two palled confidence this four Blackwater, the The would He jarled, fticum, sent, vent with in temporary educated the scenes, reigns of Manure. which, their cables they and or to Cambridge, was born in the reign of Edward VI. and educated at Cambridge. He appeared upon the stage in the reigns of Elizabeth and James I., and was, like his contemporary Shakspere, both an actor and a writer of plays. He composed seven tragedies, which were highly applauded, and which, according to Mr. War ton, manifest traces of a just conception, but they abound in tedious and uninteresting scenes, or with such extravagances as proceeded from a want of judgment and the barbarous ideas of the times. He translated many classical pieces, among which were some of "Ovid's Elegies;" and the first book of "Lucan's Pharsalia." He is the author of an elegant sonnet entitled the "Passionate Shepherd to his Love," printed in Percy's refiges. Marlowe poftilled much fancy, and sometimes writes in a vein of pure poetry, with smooth verification. He is charged with irreligion and infidelity, and was licentious in his manners. His end was tragical; having quarrelled with a footman about a young woman of no reputation, he was stabbed with his own sword, that he had drawn upon his rival. This was about the year 1593. Morri.

MARLOW, GREAT, in Geography, a borough, market-town, and parish in the hundred of D.borough, Buckinghamshire, England, is situated near the banks of the river Thames, 17 miles distant from Aylesbury, and 31 from London. The manor, called in Domesday book Marlow, belonged, previous to the Norman conquest, to the earls of Mercia, but, being seized by king William, was given by him to his queen Matilda. Henry I. who inherited it from his mother, betellowed it on his natural son Robert de Melier, afterwards earl of Gloucester, from whom it passed with that title to the Clares and Despeacers, and from the latter, by female heirs, to the Beauchamps and Nevilles, earls of Warwick. It continued in the crown from the time of Richard III.'s marriage with Anne Neville, till queen Mary granted it to William lord Paget, in whole family it remained more than a century. From the Pagets it passed through several intermediate possesors to sir William Clayton, who purchased it in the year 1736. It is now the property of his descendant sir William Clayton, bart. who has a handsome seat, called Harleyford, at a short distance from Marlow.

The town of Great Marlow has been fuppofed, from the denomination Chipping Marlow, which occurs in ancient records, to have been a market-town in the time of the Saxons. It now consists of two principal streets, and three smaller. The High street is spacious, on a gradual defcent, and contains many good houses. The whole town has been recently much improved. Its prosperity has been increased by the department of the Royal Military college, which has been provisionally established here. The college consists of two departments respectively appropriated to the fenior and juvenile classes of pupils. The first clafs is detained at Wycomb, and is for the instruction of officers in the duties of the general staff; the second, at Marlow, for those who, from early life, are intended for the military profefion, and who, by these means, may be grounded in the science previous to their attaining the age that enables them to hold commissions. The whole college will shortly be removed to Blackwater, where extensive and appropriate buildings are now erecting from designs of John Sanders, esq. archi-

The church of Marlow, which is a spacious and ancient structure, consists of a body and two aisles, with a transept dividing it from the chancel. From the tower rises a wooden spire, erected in the year 1627. The nave is separated from the chancel by a screen of chalk decorated with tracery. The altar is of oak, curiously carved. The old bridge, which croffed the Thames at Marlow, is of very remote origin; among the patent rolls in the Tower are grants from Edward III. and two succeeding monarchs, allowing the bailiffs to take toll of all goods and merchandise passing over or under the bridge; the receipts to be expended in repairs. This structure becoming ruinous and unsafe, the present bridge was erected by private subscription in the year 1759. The principal charitable institutions in the town are two free-schools, one for twenty-four boys, and the other for the same number of girls, founded by sir William Borlase about the year 1624. The almshouses for poor widows, endowed pursuant to a deed of trust from John Brickhurst, esq. dated July 20th, 1668. The rents of the estates appropriated to their support now amount to forty-two pounds yearly; which have enabled the trustees to add two persons to the establishment,
blissment, which originally consisted of only four. Some faint traces of a corporation are discovered in the records concerning the town, but it does not appear that any charter for its government was ever obtained; the last mention of the mayor and burgesses occurs about the end of the fourteenth century. The first return for the borough was in the twenty-eighth year of Edward I. when Richard le Moner and Richard le Veel were chosen as its representatives in the parliament held at Lincoln. It continued to send members till the second of Edward II. after which no returns were made for 314 years, till the twenty-first of James I., when, on a petition to the house of commons, the privilege was restored. The right of election is in the inhabitants paying foot and lot; the number of voters being about 200. A market is held on Saturdays, and two fairs annually. The population in 1801 was at the parish to contain 643 households, occupied by 3336 persons. At a short distance from the town are the Temple mills, where extensive works are carried on in copper and brass.

About two miles eastward is the village of Little Marlow, which contains 128 houses, and 728 inhabitants. A beneficent nunnery was founded here about the time of Henry II.; but fearfully any part of the conventual buildings is now standing, the principal materials having been used in the construction of a farm-house.

On the south side of the Thames, nearly opposite to Great Marlow, is Bisham abbey, which appears to have been erected by William Montacute, earl of Salisbury, in the year 1338, for canons of the order of St. Augustin. It is now the seat of N. Vanitiart, esq. M. P. Lyfons's Magna Britannia, vol. i. 40. Beauties of England, vol. i. Marlow, a town of America, in Chelfire county, North Hampshire, containing 543 inhabitants.

MARSHLAND, an island of Sweden, near the W. coast, in the Norrland. N. lat. 57° 5', E. long. 11° 29'.

MARLY, Machine of, in Hydraulics, is a very complex machine for raising water at Marly, about ten miles N.W. of Paris, the principal mobile whereof is an arm of the river Seine, which, by its stream, furnishing a fall of water of three feet, turn four large wheels, which work the handles, and there with pilons raise the water into the pumps, and with other pilons force it up in pipes against the ascent of a hill to a reservoir in a stone tower. The basin of the tower, which receives the water raised from the river, is 610 feet distant from the river, and 500 feet higher than the lower end of the sucking pipes of the lower engines of the machine. The basin supplies an aqueduct of thirty-six arches; where the water is separated into different conduits which lead it to Marly, and formerly led it to Versailles and Triannon. The number of pipes in this machine is 2531; and the quantity of water raised by it amounts to 5256 tons in twenty-four hours, or near 220 tons per hour, or 42 tons per minute; but the London bridge water-works, with four wheels only, raise 11,734 tons in twenty-four hours, which is almost twice and a quarter as much. Some of the largest of our fire or steam-engines used in England, will raise as much water as that of Marly to the same height, and not cost above 10,000l. This machine, which began to work in 1682, and is laid to have cost above four millions of pounds sterling, was made by one Ranlichen, a common mechanic of Liege, and has a great many excellent contrivances; but yet does not raise all the water that it might have done, because the maker did not know how to give the river Seine all the advantages of which it was capable. Hence appears the necessity of a mechanic's being well acquainted with mathematics; or that able mathematicians should apply themselves to mechanics more than they do, and not think it below them to direct workmen. See Defaguil. Exper. Philos. vol. ii. p. 442 to 449.

According to Dan. Bernouilli's computation, the effect of the machine of Marly is not more than 3 of its absolute force; that is, there is a loss of 7 of that force. Dan. Bernouilli. Hydrodyn. p. 182.

MARLY-LA-MACHINE, in Geography, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Verfailles, situated near the Seine, and celebrated for its water-works; four miles N. of Verfailles. The place contains 1227, and the canton 12,397 inhabitants, on a territory of 90 kilometres in 17 communes.

MARMAGNE, a town of France, in the department of the Cher; four miles W. of Bourges.

MARMALADE, a confection made of the juice or pulp of some fruit, as plums, apricots, quinces, boiled with sugar, to a confection.

The marmalade of quinces is the most frequent: it is sub-astringent, and grateful to the stomach.

MARMANDA, in Geography, a town of France, and principal place of a district, in the department of the Lot and Garonne; situated on the Garonne. The place contains 5598, and the canton 14,385 inhabitants, on a territory of 172½ kilometres, in 15 communes. The trade of the town, which is considerable, consists in corn, wine, and brandy. N. lat. 44° 30'. E. long. 0° 15'.

MARMARICA, in Ancient Geography, an extensive country of Africa, bounded on the E. and W. by Egypt and Cyrenaica; on the S. by the Sahara, or deserts of Libya interior, and on the N. by the Mediterranean. After passing the Glanum Proterminorum, Cape Deris, the port Leucip, and other inconsiderable promontories and harbours, we come to Parataxonium, called by Strabo Ammonia, a city of considerable note. Florus styles this city and Pelusium the two horses of Egypt; whence it appears that he considered Marmarica as part of Egypt, and Parataxonium as a fortress of great strength. At some distance from Parataxonium, towards the frontiers of Cyrenaica, stood Apis, a town so denominated from the Egyptian deity of that name. Trierarchis, Zagylis, and other places on the sea-coasts, enumerated by Ptolemy, are so inconsiderable as not to merit attention. The principal Libyan nations inhabiting this region were the Adyrmachida and Ammoni. Some authors seem to make the Marmaridae a nation inhabiting a particular territory contiguous to the greater Catabathmus; but others incline to the opinion, that all the Libyans of Marmarica were comprehended under this appellation. Father Calmet thinks that Marmarica was first peopled by the descendants of Lehabin, the son of Mizraim, mentioned by Moses. Herodotus affirms that there was a great affinity between them and the Egyptians, in the most important points.

MARMARIA, a town of Greece, in the island of Eubea.

MARMARO-PROSERA, in Natural History, is a species of flores forming continued strata, bright and beautiful, of very lively colours, and of a constitution so fine, that they will take a good polish; in all which particulars they agree with the genus of marbles, but differ from them in that they are never calcareous, nor do they ferment with acids. To the same class belong the granites and the porphyries.

The marmaro-prosera are flowers of a compact, uniform texture, like that of marbles; some of them are vitrifiable, others not, and some are of such hardness as to strike fire with
with dele. Of this kind is the baftes. Du Bois's Hist. Ioff p. 252, &c.

MARMAROULO, in Geography, a town of Italy, in the department of the Muccio; eight miles N. of Mantua. MARMARIO, a word used by the old writers in medicine, to express phauns of fire, or the appearance of much phlegm before the eyes in some disorders.

MARMOL, Caravajal, Luis de; in Biography, born in the sixteenth century, at Granada, was taken prisoner by the Moors of Barbary, and carried to Morocco. Here he collected all the materials he could get for an account of the country, which, when he escaped from the house of bondage, he published under the title of "La Descripcion General de Africa." The French translation of this work by M. D'Abblancourt is very highly esteemed. Gen. Biog.

MARMONTEL, John-Francois, a distinguished French writer, was born in 1723. His father was in low circumstances, and obliged to exercise great frugality in bringing up his children. His early education preferred him with few literary advantages, but from his mother, whose language and sentiments were much superior to her station, he derived much benefit with respect to mental cultivation, by which he soon distinguished himself among his contemporaries. Through her influence he was sent to the Jesuits' college of Mauritius, where, with the practice of strict economy, he was enabled to go through the studies of the place. At the age of fifteen his father placed him with a merchant at Clermont; but he had a mind ill adapted to trade, and took the first opportunity of quitting it after his arrival, and hiring a garret, with a few livres that he took with him, wrote to his father that he felt a vocation for the ecclesiastical profession. He was allowed to follow the bent of his inclination, and was admitted at once into the philosophical clafs in the college of Clermont. His wants were few, and these he readily supplied by undertaking the office of instructing others in their earlier studies. The death of an affectionate father, in the second year of this occupation, was a very severe stroke upon him, but his heart was adapted to the exigency, and he instantly took upon himself the paternal charge with respect to an almost destitute family. He engaged as teacher of philosophy in a seminary of the Bernardines, and his talents almost immediately gave him a marked distinction in the society of monks, and prospects of greater celebrity soon opened upon him. He wrote an ode as one of the competitors for the prize given by the academy of "Floral Games" at Toulouf. The award was given against him, but being dissatisfied with the decision he sent his performance to Voltaire, who returned it with many commendations, and at the same time presented him with a copy of his works. He regarded this testimony of regard from so great a man as much superior to the prize for which he had been striving, proceeded with ardour in his career of studies, and obtained the prizes of several successive years. His scholars rapidly increased, and in the same proportion his gains were augmented, which he applied to the support of the family chiefly dependent on his labours. He lent for one of his brothers to be educated at his own expense and under his own eye. About this period he formed a resolution to quit his studies that he had been pursuing to fit him for the ecclesiastical profession, and by the advice of Voltaire he determined to try his fortune at Paris as a man of letters: he obtained as an introduction the patronage and protection of M. Orri, the comptroller-general of the finances. Scarcely, however, had he reached the great city, when he found that his friend had been dismissed from the ministry. He was now encouraged by Voltaire to write for the stage; he made the attempt, but in this and other efforts of a different nature he was completely unsuccessful, nor could with all the application of which he was master save himself from a state of indigence, and he was glad to undertake the education of his son, for whom he contemplated this step. This gave him admission to a select and agreeable society, and by putting him out of the reach of want his mind was free for any exertion. He accordingly set about a tragedy, which he finished, under the title of "Dois le Tiran:" it was acted in 1748, and obtained very general applause. From this moment money and fame poured in upon him: he attracted general notice, was fealed and complimented, and at once fell into the vortex of Parisian fashion. He did not, however, neglect the art to which he was indebted for his reputation, and in 1749 he brought forward a second tragedy, entitled "Arilomene." Voltaire sat with him in his box, and cordially joined in the applause which it received. His next piece was the tragedy of "Cleopatra," which was finished and acted in 1750: this was probably written in a hurry, and its success was very indifferent; and the "Hebrelides" which soon followed absolutely failed. This disappointment seemed to roufe him into action, and made him attentive to future fortune. He obtained the place of secretary of the royal buildings by the influence of Madame Pompadour, and under her brother M. de Marigny. He immediately took apartments at Versailles, and "here," says he, "thank heaven terminate the errors and deviations of my youth." In his literary capacity he was connected with d'Alembert and Diderot, and was their coadjutor in the Encyclopédie. His services to perfons in power procured him a pension upon the privileged work called the Mercure Français. In this he published his "Aesthetic," composed at a single sitting, and which was received with so much applause that he followed it with "Saloman II." the "Scruple," and others: this was the origin of the "Contes Moraux," which became so popular throughout Europe. In 1758, he quitted his office at Versailles, and went to Paris, where he became an associate with all the men of letters and artils in that capital. His happiness was, however, soon interrupted, by refusing to give up the author of some severe verses which he had immodestly repeated in company. They were accordingly attributed to him, and he was committed to the Baillie. His confinement was short, and his treatment in it was of the mildest kind. After his liberation, he made a tour through the southern provinces of France, in which he paid a visit to Voltaire, and then wrote his "Epître aux Poëtes," for the prize offered by the French Academy, and obtained the object of his ambition. In 1753 he was admitted a member of that body. His next literary production, and that which has conferred the greatest celebrity on his name, was his "Belfaire." The liberal sentiments which he had put into his hero's mouth concerning religious toleration, and the unimportance of controverted theological tenets, excited the resentment of the Sorbonne, which proceeded to a censure of the whole work, but it could not stop its career: very large imprews were dispered over France and all Europe. On the death of D'Urfu in 1772, Marmontel was appointed, without any solicitation on his part, to succeed him as historiographer of France. He prepared himself to exercise the duties of his new office by collecting materials for the reign of Louis XV.; he also engaged in the composition of the Supplement to the Encyclopédie. After he had attained to the age of fifty-four he married a young lady of eighteen,
eighteen, and it is said that this union, so very unsuitable in point of years, was the source of much real felicity. About the same period he published another work, entitled "Les Incas, or the Destruction of the Empire of Peru," which united history and fiction, and which was evidently, like the Béliare, for the purpose of inculcating liberal principles and enlightened sentiments. In 1783 he was, on the death of d’Alembert, elected to the post of perpetual secretary of the French Academy, and from this period his compositions were chiefly confined to elegies and other pieces read before the academy, as well in verse as in prose. He also employed himself in a complete edition of his works, now become very voluminous. During the latter years of his life he had to witness the stormy scenes of the French revolution: his ideas of reformation went no farther than the concessions offered by the crown in 1788, and he contemplated with horror those constitutional changes which he few meditated by the popular party. He was, nevertheless, chosen a member of the electoral assembly: but soon lost the confidence of his constituents, by opposing an unlimited liberty of the press, and he gladly retired to his country-house to remain a spectator rather than actor in the great revolutionary drama. In his retreat from the hasty and noisy world, he employed himself in writing some additional "Contes Moraux:" and a "Cours Elementaire" for the instruction of young persons, confining of short treatises on grammar, logic, metaphysics, and morals. He also drew up memoirs of his own life, addressed to his children. In 1797 he was brought forward again into public life, and chosen a representative of the department of Eure, and was, in the national assembly, particularly charged with the defence of the Catholic religion. He pronounced before the legislative body a discourse "On the free exercise of public worship," and he continued to discharge the functions of his office, till the decision which rendered null the elections of his department, with those of many others. He died, almost in indignation, in December, 1799, in the seventy-eighth year of his age; leaving a widow and two young children without support. As an author, Marmontel is characterized as warm and eloquent on grave and elevated topics, easy and lively on light ones, ingenious, inventive, and varied, full of good sense and animated with sentiment: he is almost equally successful in his addresses to the heart, the imagination, and the judgment. His "Contes Moraux" contain many fine stories, delightfully told, and scarcely has any work of the age been more popular: the morality of some of them is very doubtful, and hence the title "Moral Tales," as translated in our language, is not in all cases proper. They are fictitious narratives relative to life and manners, and in general they inculcate valuable and useful lessons. Since his death his own memoirs have appeared, and also "Memoirs of the Regency of the Duke of Orleans," printed from his manuscript, in 2 vols. 12mo.

Marmontel, after hearing the "Serva Padrona" of Pergoleii performed in 1751 at Paris, in Italian, and by Italians, was one of the first converts to the music of Italy in France. This natural, easy, graceful, and pleasing intermezzo, which produced Roullet’s famous "Lettre sur la Musique Francaise,"likewise opened the ears of Diderot and d’Alembert, the abbé Annard and Morillet, Meffre. Suard and Grimm, who ever after continued hostile to the old style of French music.

Gretry, returning from Italy in 1767, new set, at Geneva, Favart’s comic opera of "Iabelle et Gertrude," which succeeded so well, that, on the young composer’s arrival at Paris, Marmontel furnished him with other musical dramas: and they seem to have been constantly attached to each other ever after.

When Piccini arrived at Paris in 1788, Marmontel instantly became a Picciniist, and wrote a pamphlet "On the Revolutions of Music in France," which gave great offence to the Gluckists.

We have often observed, that the French talk and write on the subject of music better than the Italians: but it is all declamation. There is no part of music, vocal or instrumental, in which they are comparable to the Italians.

Marmontel’s ideas about dramatic music are scattered through the Encyclopédie, which M. Laborde has collected and drawn to a focus, in his "Essai sur la Musique," published in 1783; and in Marmontel’s "Revolutions," we have his "profeßen de fùi muficale, drawn up by himself.

But of all the reformers of French music, and partizans of the Italian, Diderot and Marmontel were perhaps the only two that were in earnest, and who seem to speak from feeling, not from system. "Woe to thefe," says Marmontel, "whole tafts and ideas usurpafs their means of gratification! The partizans of Lulli and Rameau forgot their quarrels, and united in defending French music of every kind against the Italian." Marmontel fought stoutly for melody; for the simple, elegant, and graceful melody of Italy. "Gluck," he says, "not only gives less melody, but melody of a more vulgar and common kind, than Piccini, Sacchini, and Pergolezi."

The Greeks did not allow that any pain or grief should distort and deform the features in any one of the arts. In singing, Hafle tried his most difficult passages in a mirror; and the dying gladiator, the Niobe, and the Lacoone, make no frightful faces. A pathetic and passionate air in music is not to scream or howl. No passion should be expressed in music, that is not softened into pleasure by the found, by exquisite musical tones and chords. "Melody without expression is of little effect: expression without melody is something, but not all we want. The union of melody and expression of the most perfect kind is the problem to be solved; and the melodies of Piccini, Sacchini, and Paisiello, sung by a Paccierott or a Marchesi, is the solution. Vincf first revealed the mystery, by his natural, graceful, and flowing melodies, undeformed by complication in the accompaniments. Gluck has certainly not invented a new genre. He has, indeed, improved that of Lulli and Rameau by more movement and fire; but he has injured the Italian recitative, by loading it with harmony."

All Marmontel has said is true and reasonable; but he has not said enough. The root of the evil,—the grand, and, we fear, the invincible impediment to the introducing Italian melody on the French stage, is the finging. Gluck failed to the complaints of want of air, of graceful, passionate, or spirited melody in his operas, that they had no fingers to perform them. If the French themselves would allow this as an excuse for Gluck, and place his trivial airs to necessity, we should honour their taste and candour, and lament their privation of the delight which fine airs, well sung, afford true lovers and judges of music. But when we are told that these ballad airs are models for the rest of Europe, where good singers can be found, we think it borders upon arrogance, very unbecoming a nation just emerging from barbarism in vocal music.

The serious dramas, written for music by Quinault, have increased in favour, as poetry, in spite of Boileau’s four cenures, ever since the death of the author. The airs, however, could not be set to modern melody in their original state. And when Piccini arrived in France, and requested...
be furnished with dramas to fet, in which the songs were phrased and polished like those in the operas of Metaphasio, the true models of lyric poetry. Marmontel, in order to preserve the admirable lyric tragedies of Quinault, modernized the airs, and retained all the original beauties of the dialogue. Encouraged to this undertaking by the most enlightened men of letters, to whose judgment he submitted his labours, he prepared for Italian music the poems of Amadis, Roland, Perceus, Proserpine, Atys, Phaeton, Ixion, Theleus, and Armide; and on being applied to by the directors of the opera to let Pecchin have one of them to fet, he gave them their choice, which fell upon Roland, of which the fable was taken from the "Orlando Furioso" of Ariosto. Pecchin was unacquainted with the French language; it was therefore necessary, in explaining the poem, to accompany him in his labour step by step; and Marmontel performed this task with as much zeal and solicitude as Quinault himself could have done. The Italian composer, from these instructions, became in a short time so well acquainted with the accentuation and musical expression of French words, that the most severe critics were unable to point out a single fault which he had committed against the profousy and genius of the language. "It is well known," says M. Laborde, "how complete was the success of this undertaking; he amply fulfilled the wish of Marmontel, and resolved the problem, whether the French language was capable of receiving Italian music." We still think it is not; as the music which Pecchin and Sacchini have set to French words is very inferior to that which they have set to their own language.

The number of operas, serious and comic, which Marmontel produced for the several theatres of France, between the years 1747 and 1758, is prodigious. Very early in his life he furnished Rameau with operas for the Academie Royale de Musique; and besides his dramas that were set by others, he was author of the words of almost all the comic operas which were set by Gruet, during his long and successful career.

MARMOR, Marble. See Marble.

MARMORA, in Geography, a river of European Turkey, which runs into the Strimon, 6 miles N.W. of Emboli, in the province of Macedonia.—Alfo, a town of European Turkey, in Macedonia; 34 miles E.N.E. of Saloniki.—Alfo, an island in the straits of Constanitnople, or Sea of Marmora, about 12 leagues in circuit. It is lofty, mountainous, and tolerably fertile; it contains several towns or villages, rather populous; it has two harbours, which are by no means extensive, situated towards the south. Vesels surpised by a northerly wind, somewhat strong, repair hither for shelter. The inhabitants have a few flocks of sheep: they cultivate the vine, the olive-tree, and cotton, and gather various species of grain. Marmora formerly bore the names of Nevris, from περιος, the fawn of a doe; Elaphoneus, from ελαφος, a flag, and περιος, island; and Proconneus, from πρόκος, περιος, signifying a young flag, and περιος, island. These latter names were given to it from the number of flags which were met with in it. But Olivier thinks that none exist there at this day, as the woods are destroyed, and the mountains are almost naked. This island has received its name Marmora from a white marble, a little veined with grey and blackish, which is furnished by it in great quantities. Although the grain of this marble is not fine, nor its colours beautiful and mixed, the Greeks esteemed it formerly, and made frequent use of it; they distinguished it by the name of "Cyzicus" marble, because that peninsula afforded some, probably, of the same quality, or because the town of the same name served as an emporium for it. Fragments of it are found among the ruins of almost all the ancient cities: pillars of it are seen in various places, and particularly in the mosques of Constantinople. It is said, that the lately placed of Mahommed, at Halicarnassus, was lined with this marble. At the present day, it is only wrought for the sepulchral stones made use of by the Turks, the Armenians, and the Europeans: it is seldom employed in the construction of houses. "N. lat. 40° 30'. E. long. 27° 33'."

MARMORA, a town of Asiatic Turkey, in Natalia; 33 miles E. of Magna. N. lat. 39° 43'. E. long. 28° 28'.

MARMORA, La, a town of Naples, in Calabria Ultra; 16 miles W. of St. Severin.—Alfo, a town of France, in the department of the Stura; 10 miles W. of Conè.

MARMORICE, a town of Asiatic Turkey, on the south coast of the province of Natalia. The town is small, but situated in a bay with a narrow entrance, which is represented as one of the finest harbours in the world. N. lat. 36° 52'. E. long. 28° 30'.

MARMOROIDÆ, in Natural History, are fishes, which in their nature, texture, appearance, and other properties, resemble marbles; and only differ from them, that the bodies of this genus never form continued strata, but are only found in loose independent masses, lodged in strata of other subfamilies. M. Da Costa subdivides these into marmoriae of a plain structure, and those which contain shells, corals, and other extraneous bodies. Hift. Fossil, p. 241, &c.

MARMOSA, in Zoology. See Didelphus Murina.

MARMOSET, in Geography, a harbour in the island of St. Domingo, lying between cape Rouge and Grand Port Berhagne.

MARMOT, in Anatomy, in Zoology, a genus of Glires in the class of Mammalia; the characters of which are, that the animals of this genus have two cutting teeth in each jaw, five grinders above and four below, on each side, and that they have collar bones. This genus is very properly separated from that of Mus by Dr. Gmelin, in imitation of Mr. Pennant. M. mo, if not all the species, hibernate, or become torpid, during winter: they wander in quest of food, and for other purposes, during the day, feeding on roots and grains; they are capable of climbing, and dig burrows in the earth for their habitation; their heads are generally round and convex, having either very short ears, or none; their bodies are thick, with short hairy tail; the fore-feet have each four toes, and a very short thumb, or fifth inner toe; and the hind-feet have each five toes. The cecum, or blided gut, is generally very large.

The species are as follows:

A. MARMOTA, Mus Marmota of Linnæus. Alpine or Mountain Mouse, Alpine Marmot of Pennant, and Marmotte of Buffon. It has short round ears; the upper parts of the body are dusky brown, and the lower parts reddish. The body is thick and short; the head large and thick, flattened at the top; the nose thick and blunt, often carried erect when the animal sits; the two bones of the lower jaws are moveable on each other; the cheeks are covered and surrounded with long hairs; the muzzle has five rows of whiskers; above and below each eye is placed a black wart, on which are hairs; the legs are short; the tail is straight, and covered with long hairs; the tip of the tail is very dark, brown,
brown, almost black; the body and head measure sixteen inches, and weigh nine pounds; the tail is about six inches long. These animals inhabit the highest summits of the Alps and Pyrenean mountains, in dry places where are no trees; feed on insects, roots, and vegetables; are fond of milk, which they take by lapping with a murmuring noise; and drink very little. The Alpine marmots live in societies of from five to fourteen, basking in the sun, and place a cen- trine, which whistles on the approach of danger, when they retire into their holes, and if they cannot escape, defend themselves boldly, and bite with great fury. They form burrows with numerous passages and entrances; at the end of September they resort to their subterraneous chambers, which are well lined with moss and dry grass, and flopping the entrance with earth, they remain here in a torpid state of hybernation till the month of March. If they chance to be dug up, and are brought into a warm atmosphere, they gradually revive. They are able to walk on their hind feet, and fit up on their haunches, carrying food to their mouths with their fore-feet. They are easily caught on plain ground, but with difficulty in their holes, as they dig deeper when in danger of being taken, except during their torpid state in winter. At this time, many of them are caught for the sake of their fleeces, which is tender and delicate; partly for their lkins; and partly for their fat, which the inhabitants of the Alps esteem to be medicinal: but they are chiefly taken by the Savoyards, with a view of expelling them as hovers through various parts of Europe. In a tame state, they are very destructive to all kinds of pro- visions, clothes, linen, or furniture; and can hardly be prevented, even in warm climates, from falling into a state of torpidity in winter. They procreate in April or May, and the female, after six or seven weeks, produces two, three, or four young ones.

A. MONAX. Mus greifus of Pallas, Glis fulcus, Marmota americana or American Marmot, Monax of Edwards and Buffon, and Maryland Marmot of Pennant, has short rounded ears, blueish note and cheeks, body of a deep brown colour, and longish tail, which is very hairy. The eyes are black and prominent; the feet and legs are black, with long sharp claws; the tail is half the length of the body. This animal is about the size of a rabbit, and feeds on vegetables; its fleece is very good, resembling that of a pig. It inhabits the warmer states of North America, and the Bahamas. In America, it forms holes in the cliffs of rocks, and under the roots of trees, in which it paves the winter in a torpid state; but it is not certain that it hibernates in the Bahamas, where the climate is very mild.

A. BURAC. See BBRAC.

A. EMETRA of Pallas, Canadian Marmot, Quebec Marmot of Pennant, of a mixed grey colour on the upper parts of the body, the lower parts orange; with short rounded ears, and a hairy tail. This animal inhabits Canada, Hudson's Bay, and the other northern parts of America. It is rather larger than a rabbit, and the tail is about two inches and a half long. The cheeks are grey; the face dullly, and not black; on the back the hair is grey at the roots, black in the middle, and whitish at the tips; the belly and legs are of an orange colour; the tail is short, buffy, and of a dulky colour; the feet are black and naked, with four long, slender, divided toes, and the rudiments of a thumb on each fore-foot, and five similar on each hind, all armed with pretty strong claws.

A. PAUNOSA, Hoary Marmot, with very coarse, long, hoary fur, whitish cheeks, a black nose, and black legs; having short oval ears. Inhabits the northern parts of America; is about the size of a rabbit; with nose black at the tip; the tail is black, mixed with rufus colour; with four toes on each fore-foot, and five behind, all armed with dusky claws.

A. SUSAICA, Soulik of Buffon, Cahan Marmot of Pennant, has the upper parts of the body of a yellowish-brown colour interpersed with numerous small white spots, very short ears, hairy tail about the length of the thighs. Inhabits Cahan as far as Austria, dwells in the defert, digging holes in the black soil of the declivities of the mountains; which burrows are from seven or eight feet long, winding, with several entries, having at the bottom several apartments, stowed with corn, peas, linted, hempseed, and other grains and seeds, in separate cells, and separate holes in which they live. This animal is about the size of a large rat; the tail is covered with short yellowish-brown hair; the fore-feet have four toes, armed with long claws, and a short thumb, or rudiment of a fifth toe; the hind-feet have five toes each, the two outer ones short, and the other three long.

A. CITILICUS, Ziefel of Buffon, earlfs Marmot of Pennant, is of an uniform dark cinereous grey colour, has no external ears, a blunt note, a long slender body, and a very short tail; inhabits Hungary, Austria, and Poland; burrows like the former, and is rather larger, being nearly a foot in length.

A. ZEMNI, Zemni of Buffon, Podolian Marmot of Pennant, Zits-Jan of Le Brun, and little Earth-dog of Ranz- zinck, is of a mouse-grey colour, has short rounded ears, five toes on all the feet, and very minute eyes concealed beneath the fur. Inhabits Russia and Poland; is larger, stronger, and more mifchievous than the former. Its body is slender, covered with short, soft fur; the tail of a moderate size; the fore-teeth very large, projecting much from the mouth, the under ones being much longer than the upper; the feet are all divided into five toes, armed with crooked claws; about the size of a squirrel, and in disposition and manners resembling the Ziefel. It bites cruelly, and feeds voraciously on grains, fruits, and pot-herbs, laying up magazines of provisions in its burrows, where it paves the winter. Gmelin includes the three last described animals under one description, supposing them to be of the same species; but they are separated by Buffon and Pennant. This species is represented as inhabiting the southern parts of Russia, as far as Kamtchata, and the islands between Asia and America, in Peru and China, but rarely found in the west of Europe. The male is easily tamed, but the female is fiercer; goes with young between three or four weeks, and brings forth from three to eight young ones about the beginning of May. The fur is very good in the spring, and the fleece is reckoned to be the best. These animals are preyed on by polecats, weasels, hawks, carnivores, and eagles. They vary considerably both in size and colour. Gmelin suggests that this animal may be the same with the "Mus Ponticus" of Arisotle and Pliny.

A. GUNDI, Gundi of Pennant, is of a brick-dudd red colour, with wide open ears, which appear as if cropt, or cut off. Inhabits Barbary, near Maffrfin, towards mount Atlas. Its size is about that of a small rabbit; the tail is short; the upper fore-teeth are large and truncated, the lower ones flinder and pointed; it has four toes, armed with claws, on all the feet, and uses the fore in walking as far as the head.

A. HUDSONIUS, Hudson's Marmot, tailles Marmot of Pennant; is of a brown-ash colour, with short external ears and no tail. Inhabits Hudson's Bay. It has two cutting teeth above, and four in the lower jaw; the hairs are tint with white.

A. MAULINA, Chilipe Marmot, is of a reddish-brown colour, with sharp ears, having five toes on all the feet. Inhabit
Inhabits the woods of the province of Maturq, in Chili. This animal agrees with the common marmot in the colour and length of the hair, but is nearly twice as large; the snout is long-shaped, having four rows of whiskers; the feet have all five claws; and the tail is furnished rather thinly with hair.

MARMOT, German. See MUS Cricetus.
MARMOT, Lapland. See MUS Lemmus.
MARMOTTA. See MARMOT, supra.
MARMOTTE Volant. See VESPERTILIO Nigrella.
MARMOUTIER. In Geography, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Sarne; three miles S. of Sarne. The place contains 1900, and the canton 10,395 inhabitants, on a territory of 105,598, in 25 communes.

MARNAY le Bourg, a town of France, in the department of the Upper Saône; 11 miles W. of Bel-faon.

MARNE, a river of France, which rises in the department of the Upper Marne, about three miles to the E. of Langres, and after pursuing a course by several towns, joins the Seine at Charcanton.

MARNE, a town of Peruна, in the province of Khorasan; 110 miles N. of Herat.

MARNE, one of the ten departments of the N.E. region of France, composed of Remois and Perlinois, with a part of Brie, bounded on the N. by the departments of the Aine and Ardennes, on the E. by the department of the Meuse, on the S. by that of the Aube, on the S.W. by that of the Upper Marne, and on the W. by the departments of the Seine and Marne; about 33 French leagues in length and 30 in breadth; in N. lat. 49°. Its territorial extent is 8460,000 square miles, or 405 square leagues, and it contains 1,040,491, or, according to Hassenfratz, 348,885 inhabitants. It is divided into five circles, 32 cantons, and 469 communes. The circles are Reims, including 105,472 inhabitants; St. Menehoul, 30,839; Vitry-sur-Marne, 49,706; Chalons-sur-Marne, 37,602; and Epernay, 87,413. Its capital is Chalons-sur-Marne. Its contributions amount to 3,115,188 fr. and its expenses for administration, judicial, and public instruction, amounted in the 11th year of the French era to 520,135 fr. 33 cents. The soil of this department is industriously fertile in grain, and yields good wine and pastures. There are some forests near the extremities of the department.

MARNE, Upper, one of the ten departments of the N.E. region of France, formerly Vallage and Belfagony, bounded on the N.W. by the department of the Marne, on the N.E. by the departments of the Meuse and the Voges, on the S.W. by the department of the Upper Saône, on the S. and S.W. by the Côte d'Or, and on the W. by that of the Aube; 29 French leagues in length and 19 in breadth; containing in territorial extent 63,400,000 or 315 square leagues, and 225,539, or, according to Hassenfratz, 225,010 inhabitants. It is divided into three circles, 28 cantons, and 552 communes. The circles are Waffy, including 63,932 inhabitants, Chaumont, 75,134, and Langres, 86,824. Its capital is Chaumont. Its contributions in the 11th year of the French era, amounted to 2,315,762 fr., and its expenses to 209,033 fr. 33 cents. In this department are many pleasant valleys, which yield grain, wine, and good pastures. The wooded hills contain iron mines and mineral springs.

MARO, or MARO, a town of the principality of Oneglia; 9 miles N.W. of Oneglia.—Alfo, a town of Pegu, situated on an island formed by the mouths of the Avo; 120 miles S.S.W. of Pegu.—Alfo, a mountain of Portugal, in the province of Alentejo; 6 miles N.W. of Evora.

MAROBUDUM, in Ancient Geography, a town of Germany, which belonged to the Marcomanni. Ptolemy.

MAROLALT, in Geography, a town on the N. coast of the island of Bouro. S. lat. 41° 10'. E. long. 127° 7'.

MAROGGIO, a town of Naples, in the province of Otranto; 17 miles S.E. of Taranto.

MAROLIO, a river of Sicily, which runs into the sea, near Terra Nuova, in the valley of Noto.

MARONIA, a town of European Turkey, in Romania, near the Archipelago; 64 miles E. of Embolos.

MAROLIES, MICHAEL, in Biography, son of Claude de Marolles, famous as a champion of the league, in defence of which he killed Marivant, the royal chaplain, in single combat. The son had an extraordinary passion for study, and at the age of nineteen published a translation of Lucan. He was too eager in the pursuit of fame as an author, to attend much to devotion in the church. He applied himself chiefly to translation, and gave versions of Plautus, Terence, Lucretius, Catullus, Tibullus, Virgil, Horace, Juvenal, Persius, Martial, Statius, and the Augustan historians, Ammianus, Athenaeus, &c. He began a translation of the Bible; and he composed his own "Memoirs," which contain a vast number of anecdotes. An edition of them was published by the abbe Gonjet, in three vols. 12mo. His last work was a "History of the Counts of Anjou," published in 4to. in 1681, the year in which he died at the age of eighty-one. Marolles was one of the first who collected prints: his collection amounted to 10,000, and his catalogues of them are much valued by the curious in that walk. Moreri.

MAROLLES, in Geography, a town of France, in the department of the Aube; 6 miles N. of Bar.—Alfo, a town of France, in the department of the North; 6 miles W. of Avennes.—Alfo, a town of France, in the department of the Loir and Cher; 6 miles N. of Blois.

MAROLLES-la-Bla, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Mamers; 7 miles S. S. of Mamers. The place contains 1808, and the canton 13,993 inhabitants, on a territory of 160,598, in 18 communes.

MAROMMES, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Rouen. The place contains 1455, and the canton 14,760 inhabitants, on a territory of 142,598, in 12 communes.

MARONEA, MARONIA, in Ancient Geography, a town of Ciconia, in Thrace, near the lake Imar, it is mentioned as the place of the retreat of the 10,000. Mela places this town on the bank of the Nile: but Steph. Byz. erroneously near the Cheroneus. M. d'Anville properly fixes its situation on the coast N.W. of Stryma. According to Pline it had formerly been denominated Otagurues. As its territory produced excellent wine, it was regarded as being under the protection of Bacchus; and according to traditionary report, this wine had the perfume of nectar.

MARONI, in Geography, a river of Guiana, which runs into the Atlantic, N. lat. 5° 52'. W. long. 55° 14'.

MARONIA, in Ancient Geography, a town of Syria, placed by Ptolemy in Chaldia, between Tolmidea and Cosra.

MARONITES, in Ecclesiastical History, a sect of eastern Christians, who follow the Syrian rite, and are subject to the pope; their principal habitation being on mount Libanus, or between the Arabians to the north and the Druzes to the south.

Moheim informs us, that the doctrine of the Monothelites, condemned and exploded by the council of Constantinople,
nople, found a place of refuge among the Mardaites, signifying in Syrian rebels, a people who took possession of Lebanon, A.D. 676, which became the asylum of vagabonds, slaves, and all sorts of rabble (see Melkites); and about the conclusion of the seventh century they were called Maronites, after Maro, their first bishop; a name which they still retain. None, he says, of the ancient writers, give any certain account of the first person who instructed these mountaineers in the doctrine of the Monothelites: it is probable, however, from several circumstances, that it was John Maro, whose name they had adopted; and that this ecclesiastic received the name of Maro, from his having lived in the character of a monk, in the famous convent of St. Maro, upon the borders of the Orontes, before his settlement among the Mardaites of Mount Libanus. One thing is certain, from the testimony of Tyrus, and other unquestionable witnesses, as also from the most authentic records, that the Maronites retained the opinions of the Monothelites until the twelfth century, when abandoning and renouncing the doctrine of one will in Christ, they were re-admitted to the communion of the Roman church. The most learned of the modern Maronites, have left no method unemployed to defend their church against this accusation; they have laboured to prove, by a variety of testimonies, that their ancestors always persevered in the Catholic faith, in their attachment to the Roman pontiff, without ever adopting the doctrine of the Monophysites or Monothelites. But all their efforts are insufficient to prove the truth of these assertions to such as have any acquaintance with the history of the church, and the records of ancient times; for to all such, the testimonies they allege will appear absolutely fictitious and delusive of authority. Eccl. Hist. vol. ii.

Paulinus Nairo, a Maronite, settled at Rome, has published an apology for Maron, and the roll of his nation. His tenet is, that they really took their name from the Maro, who lived about the year 200, and of whom mention is made in Chrysolorum, Theodore, and the Menologium of the Greeks. He adds, that the disciples of this Maron spread themselves throughout all Syria; that they built several monasteries, and, among others, one that bore the name of their leader; that all the Syrians, who were not tainted with heresy, took refuge among them; and that, for this reason, the heretics of those times called them Maronites.

Volney traces the origin of the Maronites, called also Mavards, at the end of the sixth age of the church, to a hermit named Maroun, who lived on the banks of the Orontes, and who, by his fasting, his recluse mode of life, and his austerities, became much respected by the neighbouring people. It seems that, in the disputes which at that time arose between Rome and Constantinople, he employed his credit in favour of the western Christians. His death gave new energy to the zeal of his followers; and it was reported that miracles were wrought by his remains; hence many persons assembled from Kinefrin, Awamur, and other places, and built at Hama a chapel and a tomb, whence from arose a convent, very celebrated in that part of Syria. As quarrels between the two metropolitan churches increased, a monk, named John the Maronite, about the end of the seventh century, obtained, by his talents for preaching, the reputation of being one of the most powerful supporters of the cause of the Latins, or partisans of the pope. Their opponents, who espoused the cause of the emperor, and were on this account called Melkites, or royalists, made at that time great progress in Lebanon. In order successfully to counteract them, the Latins sent among them John the Maronite, who, having been presented to the agent of the pope at Antioch, and duly consecrated bishop of Djebail, was sent to preach in those countries. John, collecting his partisans, and augmenting their number, found it necessary to refit the force of the Melkites by force; and having assembled all the Latins, he settled with them at Lebanon, and there formed a society independent with respect to both its civil and religious government. John, having established order and military discipline among the mountaineers, and having provided them with arms and leaders, they employed their liberty in combating the common enemies of the empire and of their little state; and professedly became masters of almost all the mountains as far as Jerusalem. A schism likewise took place among the Mahometans, which facilitated their converts. After a variety of events, partly propitious and partly disastrous, about the year 1215 the Maronites effected a reunion with Rome, which they were never widely separated, and which still continues. William of Tyre, who gives this relation, observes that they had 40,000 men able to bear arms. The peace they enjoyed under the Mamlouks was disturbed by Selim II., but the time and attention of this prince being occupied about other objects, they joined the Druzes and their emir in making encroachments on the Ottomans; but these commotions were unfortunately, for Amurath III., lending against them Ibrahim, pacha of Cairo, that general reduced them to obedience in 1538, and subjected them to the annual tribute which they still pay. Since that period, the pachas, deferring to extending their authority and extortions, have frequently attempted to introduce their garrisons and agas into the mountains of the Maronites; but being confidently repelled, they have been compelled to abide by their treaties. The submission of the Maronites, therefore, only consists in the payment of a tribute to the pachas of Tripoli, of whom they hold their country, which they annually pay out of one or more pensions, that is, permon of emprises and property, who assign their respective shares to the districts and villages. This impost is levied chiefly on the mulberry-trees and vineyards, which are the principal, and almost the sole objects of culture. The form of government is founded, not on any express convention, but merely on usages and customs. This inconvenience would have disappeared, if they had not been prevented by many fortunate circumstances. The principal of these is religion, which, placing an insurmountable barrier between the Maronites and the Mahometans, has precluded ambitions men from leaving themselves with foreigners to enslave their countrymen. The second is the nature of the country, which every where affording strong defences, enables every village, and almost every family, to oppose, by its single force, all uttermost of sovereign power. A third reason may be derived from the weakness of this society, which having been always surrounded by powerful enemies, has only been able to reft the empire by maintaining union among its members; and which can only be sustained by taking from each other, and by reciprocally guarding the safety of each, others peron and property. Thus the government prefers a natural equilibrium, and customs supplying the place of laws, the Maronites are to this day, equally strangers to the oppressions of despotism and the disorders of anarchy.

The nation may be considered as divided into two classes, the common people and the shaiks; by which must be understood the most eminent of the inhabitants, who, from the antiquity of their families, and the opulence of their fortunes, are superior to the ordinary class. They all live dispersed in the mountains, in villages, hamlets, and even detached.
touched houfe; which is never the cafe in the plains. The whole nation consists of cultivators. Every man improves the little domain he possesses, or farms, with his own hands. Even the sheiks live in the same manner, and are only distinguished from the rest by a bad pelis, a horse, and a few slight advantages in food and lodging; they all live frugally, without many enjoyments, but also with few wants, as they are little acquainted with the inventions of luxury. In general, the nation is poor, but no one wants necessaries; and if beggars are sometimes seen, they come rather from the sea-coast than the country itself. Property is as sacred among them in Europe, nor do we fear there those robberies and extortions so frequent with the Turks. Travellers may journey there, either by night or day, with a security unknown in any other part of the empire, and the stranger is received with hospitality, as among the Arabs; it must be owned, however, that the Maronites are less generous, and rather inclined to the vice of parsimony. Conformably to the doctrines of Chrlftianiety, they have only one wife, whom they epoufe frequently, without having seen, and, always without having been much in her company. Contrary to the precepts of that faith religion, however, they have admitted, or retained, the Arabic custom of retaliation, and the nearest relation of a murdered person is bound to avenge him. From a habit founded on distrust, and the political state of the country, every one, whether fhak or peafant, walks continually armed with a mufket and poniards. This is, perhaps, an inconvenience; but this advantage results from it, that they have no novices in the use of arms among them, when it is necessary to employ them against the Turks.

As the country maintains no regular troops, every man is obliged to join the army in time of war, and if this militia were well conducted, it would be superior to many European armies. From accounts taken in late years, the number of men, fit to bear arms, amounts to thirty-five thousand. According to the usual mode of computation, this would imply a population of about a hundred and five thousand souls; and, if we add the priests, monks, and nuns, di!fered in upwards of two hundred convents, and the inhabitants of the maritime towns, such as Djebail, Batroun, &c. we cannot suppose it lefs than a hundred and fifteen thoufad.

This number, compared with the extent of the country, which is about a hundred and fifty leagues square, gives even hundred and sixty inhabitants for each square league; which will not appear a small population, when we consider that great part of Lebanon consists only of barren rocks, and that the foil, even where it can be cultivated, produces very little.

In religious matters, the Maronites are dependent on Rome. Though they acknowledge the supremacy of the pope, their clergy continue, as heretofore, to elect a head, with the title of Batrak, or patriarch of Antioch. Their priests marry, as in the firft ages of the church; but their wives must be maidens, and not widows, nor can they marry a second time. They celebrate masses in Syrac, of which the gospel, alone, is read aloud in Arabic, that it may be understood by the people. The communion is administered in both kinds. The Hdt is a small round loaf, unleavened, of the thickness of a finger, and something larger than a crown piece. On it is the impression of a leaf, which is eaten by the priest, who cuts the remainder into small pieces, and, putting them into the cup, administers to each person with a form which is not in Europe, nor do we fear there those robberies and extortions so frequent with the Turks. These priests have not, as among us, benefices or fixed revenues; but they subsist on the produce of their maffes, the bounty of their hearers, and the labour of their hands. Some of them exercise trades, others cultivate a small piece of land, and all are industriously employed, for the maintenance of their families, and the edification of their flock. Their poverty is reconciled by the great respect which is paid them; their vanity is incessantly flattered; whoever approaches them, whether rich or poor, great or small, is anxious to kiss their hands, which they fail not to present; nor are they pleased that the Europeans withhold this mark of reverence, so repugnant to our manners, though not thought humiliating by the natives, who are accustomed to it from their infancy. In other respects, the ceremonies of the Catholic religion are not performed more publicly, or with less restraint, in Europe than in the Refurrection. Each village has its chapel and its priest, and each chapel its bell; a thing unheard of in any other part of Turkey. The Maronites are vain of this privilege, and that they may not be deprived of it, will not suffer a Mahometan to live among them. They assume to themselves, also, the privilege of wearing the green turban, which, except in their territories, would call a Chrifiian his life.

In the small country of the Maronites there are reckoned upwards of two hundred convents for men and women. These religious are of the order of St. Anthony, whole rules they observe with an exactness which reminds us of earlier times. The dress of the monks is made of brown coarse woollen stuff, and resembles that of the Capuchin friars in Europe. Their food is the same as that of the peasants, with this exception, that they never eat fish. They observe frequent fasts, and make long prayers at flated hours in the night as well as the day; the remainder of their time is employed in cultivating the earth, or breaking the rocks to form the walls of the terraces which support their vineyards and mulberry plantations. Each convent has a brother shoemaker, a brother tailor, a brother weaver, a brother baker; in a word, an artist of every necessary trade. We almost always find a convent of women close to one of men; yet it is rare to hear of any scandalous report. These women themselves lead a very laborious life, and it is this activity, doublets, which secures them against all the mischiefs attendant on idleness. So far, therefore, from being injurious to population, we may affirm that these convents have contributed to promote it, by increasing by culture every article in a proportion greater than its consumption. The most remarkable of the houses of the Maronite monks is Koz- haze, six hours journey to the east of Tripoli. There they exorcise, as in the firfl ages of the church, those who are still possessed with devils; for such persons are still to be found in these countries. From the account, says Volney, given me by intelligent observers, it appears that those possessed are no other than persons afflicted with idiocy, madness and epilepsies; and it is worth remarking, that possession and epilepsy are denoted by the same Arabic word, kabah and kubah.

The court of Rome, in affiliating the Maronites, has granted them an hofpitium, at Rome, to which they may send several of their youth, to receive a gratuitous education. It should seem that this institution might introduce among them the ideas and arts of Europe; but the pupils of this school, limited to an education purely monastic, bring home nothing but the Italian language, which is of no use, and a flock of theological learning, from which as little advantage can be derived; they accordingly soon assimilate with the rest. Nor has a greater change been operated by the three or four millionaries maintained by the French capuchins at Gazar, Tripoli, and Bairout. Their labours consist in preaching in their church, in instructing children in the catechism, Thomas à Kempis, and the Psalms, and in teaching them to read and write. Formerly the Jefuits had
had two missionaries at their house at Antoura, and the Lazarites have now succeeded them in their mission. The most valuable advantage that has resulted from these apostolical labours is, that the art of writing has become more common among the Maronites, and rendered them, in this country, what the Copts are in Egypt; that is, they are in possession of all the arts of writing, intendants, and kiayas among the Turks, and especially of these among their allies and neighbours, the Druzes. Volney's Travels in Egypt and Syria, vol. ii.

Mohammed observes, that the subjection of the Maronites to the spiritual jurisdiction of the Roman pontiff, was agreed to with this express condition, that neither the popes nor their emissaries should pretend to change or aboli$h any thing that related to the ancient rites, moral precepts, or religious opinions of this people: so that, in reality, there is nothing to be found among the Maronites that favours of popery, if we except their attachment to the Roman pontiff, who is obliged to pay their great account of attachment for his friendship. For, as the Maronites live in an utmost diffuseness, under the tyrannical yoke of the Mahometans, the bishop of Rome is under the necessity of furnishing them with such subsidies as may appease their oppressors, procure a subsistence for their bishop and clergy, provide all things requisite for the support of their churches, and the uninterrupted exercise of public worship, and contribute in general to lessen their misery. It is certain that there are Maronites in Syria, who still behold the church of Rome with the greatest veneration and approbation; nay, what is still more remarkable, great numbers of that nation residing in Italy, even under the eye of the pontiff, opposed his authority during the 17th century, and threw the court of Rome into great perplexity. One body of these non-conforming Maronites retired into the valleys of Piedmont, where they joined the Waldenses; another, above six hundred in number, with a bishop, and several ecclesiastics at their head, flew into Corsica, and implored the protection of the republic of Genoa, against the violence of the inquisitors. Exel. Hist. vol. iii.

The Maronites have a patriarch, who resides in the monastery of Confolia, in the mount Libanus, and assumes the title of patriarch of Antioch, and the name of Peter, as if he seemed desirous of being considered as the successor of that apostle. He is elected by the clergy and the people, according to the ancient custom; but, since their reunion with the church of Rome, he is obliged to have a bull of confirmation from the pope. He keeps a perpetual celibacy, as well as the rest of the bishops of his jurisdiction: as to the rest of the ecclesiastics, they are allowed to marry before ordination; and yet the monastic life is in great esteem among them. The monks are of the order of St. Anthony, and live in the most obscure places in the mountains, far from the commerce of the world.

As to their faith, they agree in the main with the rest of the Eastern church. Their priests do not lay masses; but all say it together, standing round the altar. They communicate in unleavened bread; and the laity have hitherto partaken in both kinds, though the practice of communicating in one has of late been getting footing, having been introduced by little and little. In Lent they eat nothing, unless it be two or three hours before noon; their other fasts are very numerous.

MAROO, in Geography, a town of Himdoolan, in the circuit of Ruutunpur; 18 miles N.W. of Ruutunpur.

MARON, Vt, in Scot Language, is to put one or more sailors ashore upon a desolate island, under the pretence of their having committed some great crime. This detestable expedient has been repeatedly practised by some inhuman commanders of merchant-ships, particularly in the West Indies.

MAROONGAS, in Geography, a small island in the Solano Archipelago. N. lat. 6° 5'. E. long. 120° 53'.

MAROONS. See JAMAICA.

MAROOTS, OR IDAANS, or Idabans, people who inhabit the N. part of the island of Borneo, near and upon the skirts of the high mountain of Keneebaluoo; called, in old maps, "St. Peter's Mount." These people believe that the deity is pleased with human victims. An Idaan or Maroot must, once at least in his life, have imbued his hands in the blood of a fellow-creature. They are said to do it often, adorning their houses with skulls and teeth, to show how much they have honoured their author, and laboured to avert his chali{hment. Several in low circumstances will club to buy a Bifayan Christian slave, or any one that is to be sold cheap; that all may partake of the benefit of the execution. Some also believe that throes, whom they kill in this world, will serve them in the next. They are acquainted with a subtle poison, called ppoo, the juice of a tree, in which they dip small darts: and sometimes thrust through a hollow piece of wood, called by the Soolooos "Samqui," from which issue infant death, to any one who is wounded by them. The Idaans pen hogs, and eat pork. They carry their rice, fruits, &c. to the sea-side, and bury it from the Badoos, who often manufacture it by gathering sea-weeds and burning them, making a ley of ashes, filtering it, and forming a better kind of salt in square pieces, by boiling it in pans made of the bark of the anebang. These pieces of salt are carried to market, whither both the Idaans and Musulmen resort, and pass as a currency for money. The Mahometans preclude Europeans, as much as they can, from having intercourse with the Idaans and Maroots; but at Balambangan, and on the island Lavan, near Borneo, the Idaans in their boats bring hogs, fruits, &c. and are glad to fee the English eat pork like themselves. "Forell's Voyage.

MAROS, a town on the W. coast of the island of Celebes. N. lat. 4° 47'. E. long. 120° 6'.

MARTOS, a river of Hungary, which rises on the borders of Moldavia, and runs into the Thraya, near Zegedin.

MAROSTICA, a town of Italy, in the Vicentin, encompassed with walls, and containing several churches; 11 miles N. of Vicenza.

MAROTIC STYLE, in the French Poetry, denotes a peculiarly gay, pleasing, yet simple and natural manner of writing, introduced by Clément Marot, and since imitated by other authors, but with more succeas by De la Fontaine and Rouillé.

The difference between the Marotic and the burlesque style is thus assigned: the Marotic makes a choice; the burlesque admits of all. The first is the most simple; but its simplicity has its nobleness: and, while its own age will not furnish natural expressions, it borrows them from former times: the latter is low and grovelling, and borrows false and foolish ornaments from the crowd, which people of taste despise. This one refers itself to Nature; but examines, first of all, whether the objects the painter be fit for its paintings, and takes nothing but what carries with it somewhat of delicacy and merit: the other runs headlong into buffoonery, and affects every thing that is extravagant and grotesque. See Burlesque.

MAROTII, in Botany, is a tall tree growing in Mohlar, with leaves like those of the bay, bearing a round oblong fruit, including a very large, hard, and yellowish stone, containing ten or eleven kernels. The oil extracted from these or kernels of the fruit, cafes paines, and cores the 411 leaves.
feabies and itching, being rubbed on the parts; it is also for eyes inflamed with falt humour; and, mixed with a fine, it is successfully applied to impurities and abscesses in cows, and other cattle, and heads of burden. Rut Hill, Plant.

MARPOULE, in Geography, a town of Austraian Poland, in Galicia; 60 miles N.E. of Lemberg.
MAROWLY, a town of Hindoothan, in the circar of Gohind; 15 miles S. of Narva.
MAROZZO, a town of Naples, in Abruzzo Citta; 20 miles S.E. of Lecceana.

MARSHALP, a town of Austraia; 6 miles E. of Styrags—M. in a town of Wurttemberg, on the Neckar; 8 miles N.N.E. of Stuttgart. N. lat. 48° 5'. E. long. 6° 21'.

MARPEUS, the mott lofty mountain in the island of Paros, situated W. of the harbour of Marmora, which furnishes more particularly the marble obtained by the Greeks from Paros.

MARPESSUS, in Ancient Geography, a town of Phrygia, on the river Pausania (L. x. c. 12.) places it among the Phocceans, at 240 stadia from Alexandria of the Troade, in the vicinity of the river Ladon.

MARPURG, Frederik Wilhelm, in Biography, an eminent and voluminous writer on music, and a composer, at Berlin, whose works on the theory and practice of the art may be justly said to surpass in number and utility those of any other author who has treated on the subject. He was, perhaps, the first German theorist who could patiently be read by persons of talent, so addicted were former writers to prolixity and pedantry.

This author's Oeuvr d'effu, as a musical writer, was a periodical work, entitled "The Musical Critic on the Score, 1747," Then followed his "Art of playing the Harpsichord, in Three Parts," from 1750 to 1755. After which "A Treateise upon Fugue and Counterpoint," in German, 1753, and in French, 1756. This is the best book of the kind that is extant, except Padre Martin's "Saggio di Contrappunto," which, for vocal fugues, is perhaps superior; but for instrumental, M. Marpurg's work is still more useful. The historical part, however, is scanty and imperfect. For, in the enumeration of organists of different countries, though M. Marpurg, who had been in France and civilly treated there, is very grateful; yet he mentions no English composer of any kind but the feeble and flimsy Felting, who, though a worthy man and much esteemed by his friends, was far from a great player or good composer. Among organists, he just mentions Stanley and Keeble; but of Handel's sublime oratorio orfheuses and manner of playing the organ he is wholly silent; nor does he ever seem to have heard of our Roffengrave, Magnus, J. James, Kelway, or Worgan, who, in 1756, was an excellent extempor fughitt. And the examples of canon and fugue are too indifferently given to serve as models of excellence to young students. Indeed, M. Marpurg was so in- genious as to confide to us, at Berlin, that he had injured his work by partiality to friends, whose productions he had frequently cited, against his judgment. About this time, 1756, fugues began to lose their favour, even in Germany, where their reign had been long and glorious; but Roultouan's "Lettre sur la Musique Françoise," and the beautiful melody, taste, expression, and effects of theatrical compositions, so much cultivated in Italy and in all the German courts, brought about a general revolution in music, which Vinci, Haffe, and Porpora began, and Pergolesi finished. In 1754, M. Marpurg began the publication of his "Historical and Critical Essays towards the Advance-
power not only to defend herself, but to cruise and take prizes; this is such an alteration of the condition of the ship, that the risk must be materially changed from that which the underwritter took upon himself, and consequently the contract is thereby determined. Thus, a cafe occurs, in which a ship, injured as a private trader, afterwards takes letters of marque, without the consent of the underwriters, this discharges the underwriters, though no ufe be made of the letters of marque. In another cafe, letters of marque were taken out, but without the proper certificate, and only to entice feamen to enter, without any intention of cruising; this did not vary the rife, fo as to avoid the policy, even though the captain, againfis his instructions, cruised and took prizes. When the feamen were procured, these letters of marque could have no legal ufe, and thus it was the fame as if no letters of marque had been on board. When no certificate of clearance is taken out, in pursuance of the flat, 33 Geo. III. c. 66, the letters of marque are declared void; and the captain is subjected to a penalty for departing without it.

MARQUESAS, LES MARQUISES, or MARQUIS OF MENDOZA'S ISLANDS, a group of iflands in the South Pacific ocean, first discovered in 1595 by Alvaro Mendana de Neyra; and visited by Capt. Cook in the year 1774, by Marchand in 1791, and by the Missionaries in 1797; of which we have an account by these several navigators, and also by Mr. George Forster, Mr. Reinhold Forster, Capt. Chanel, and Surgeon Roblet. These iflands are five in number. viz. La Magdalena or Madalena, at the diftance of eight leagues to the north by eafit from the middle of the group, nearly in the latitude of 10° 25', long. 138° 50'; St. Pedro or O-Niteo, about three leagues in circuit, and of a good height, lying fouth, 41 leagues from the E. end of La Dominica, not known by Capt. Cook to be inhabited; La Dominica or O-Hivahea. (See La Dominica.) Figueroa, in his account of Mendana's voyage, represents this ifland as exhibiting an enchanting aspect: according to him, vall plains displayed a fmiling verdure, and divided hills, which rofe with a gentle aclivity, and were crowned by tufted woods; while a numerous population announced the riches and fertility of the soil. However, after an interval of two centuries, that elapfed between the two voyages of Mendana and Cook, this ifland prefented to Mr. G. Forster a very different appearance. He describes it as a high and mountainous ifland, of which the N.E. point is very fleep and barren; but farther to the N. he observed some vallies filled with trees, among which was now and then discovered a hut. As the haze cleared away, "we faw," says this writer, "many craggy rooks like fpires, and feveral hollow summits piled up in the centre of the ifland, which proves that volcanoes and earthquakes had been active there in changing the face of the country. All its eafern part is a prodigious fleep and moif perpendicular wall, of a great height, which forms a sharp ridge, flattened into fpires and precipices." This difference of appearance, according to the descriptions of two writers, is ascribes by Marchand to the terrible effect of one of those great convulsions of nature, which totally diffigure the parts of the fueface of the globe on which their ravage is exercifed. The next ifland is Santa Chriftina, or Chriftiana, which fee; and Hood's ifland, which is the northernoft, situated in S. lat. 9° 36', and N. 13° W., 55 leagues diltant from the E. point of La Dominica. (See Hood's Ifland.) These iflands occupy one degree in latitude; and near half a degree in longitude, viz. from 138° 47', to 139° 13' W., which is the longitude of the W. end of La Dominica. The trees, plants, and other productions of these iflands, says Capt. Cook, as far as we know, are nearly the fame as at Otaheite, and the Society Ifles. The refreshments they afford are hogs, fowls, plantains, yams, and some other roots; likewife bread-fruit and cocoa-nuts, but of thefe not many. At firft these articles were purchased with nails, heads, looking-glaffes, and fuch trifles, which were fo highly valued at the Society Ifles, but were in no esteem here; and even nails, at laft, lost their value for other articles far lefs ufeful. The inhabitants of these iflands, collectively, are without exception the fmall race of people in this fea. For fine flape and regular features, they perhaps surpass all other nations. Nevertheless, the affinity of their language to that spoken in Otaheite and the Society Ifles, fhews that they are of the fame nation. The men are painted, or curiously tattooed, from head to foot. The figures are various, and seem to be directed more by fancy than cuftom. These punctures make them appear dark; but the women, who are but little punctured, youths, and young children who are not at all, are as white as fome Europeans. The men are, in general, tall; that is, about five feet ten inches, or fix feet; but none were obferved fat and hufy like the "Earees" of Otaheite, nor were any fen that could be called mejage. Their teeth are not fo good, nor are their eyes fo full and lively as thofe of many other nations. Their hair, like ours, is of many colours, except red, of which Capt. Cook faw none. Some have it long, but the more general cuftom is to wear it fhort, except a bunch on each fide of the crown, which they tie in a knot. They obferve different modes in trimming the beard, which, in general, long. Some part it, and tie it in two bunche under the chin; others plait it; some wear it loose, and others quite fhort.

Their cloathing is the fame as at Otaheite, and made of the fame materials; they are neither fo plentiful nor fo good. The men have, for the moft part, nothing to cover their nakednefs, except the "Marra," as it is called at Otaheite; which is a flip of clothe palled round the waitz and betwixt the legs. This fimple dress is fufficient for the climate, and answers every purpose which modelly requires. The drefs of the women is a piece of cloth, wrapped round the loins like a peticoat, which reaches down below the middle of the leg, and a loose mantle over the fcoulders. Their principal head-drefs, which appears to be their chief ornament, is a fort of broad fillet, curiously wrought of the fibres of the hulk of cocoa-nuts. In the front is fixed a mother-of-pearl shell, wrought round to the fize of a tea-faucer. Before that, another, smaller, of very fine tortife-shell, perforated into curiouf figures. Alfo before, and in the centre of that, is another round piece of mother-of-pearl, about the fize of a half crown; and before this another piece of perforated tortife-shell, the fize of a flilling. Besides this decoration in front, fome have it alfo on each fide, but in smaller pieces; and all have fixed to them the tail-feathers of cocks or tropie-birds, which, when the fillet is tied, and upright; fo that the whole together makes a veryightly ornament. They wear round the neck a kind of rufl or necklace, made of light wood, the outer and upper fide being cerved with small red peas, which are fixed on with gum. They a coffin a few bunches of human hair, fainted to a fling, and tied round the legs and arms. Sometimeis, in reach of hair, they make ufe of short feathers; but all the above-meniond ornaments are seldom seen on the fame perfons. Their ordinary ornaments are necklaces and amulets made of shells, &c. None were obferved with ear-rings, and yet all bad their ears pierced. Their dwellings are in the vallies, and on the fides of the hills, near their plantations. They are 4 H 2 built:
buiit like those of Otaheite; but much meaner, and only covered with the leaves of the bread-tree. Most of them are built on a square, or oblong pavement of stone, raised some height above the level of the ground. They have also such pavements near their houses, on which they set to eat and amuse themselves. In their mode of eating, these people, says Capt. Cook, are not so cleanly as the Otaheiteans. In their cookery they were also dirty. Pork and fowls are dressed in an oven of hot stones, as at Otaheite; but fruit and roots roast on the fire, and after taking off the rind or skin, put them into a platter or trough with water, out of which men and hogs eat at the same time. Capt. Cook could not say, whether it was the custom for men and women to have separate meals.

They seemed to have dwellings, or strong holds, on the summits of the highest hills. Their weapons are clubs and spears, resembling those of Otaheite, but somewhat nearer. They have also flails, with which they throw stones with great velocity, and to a great distance, but not with a good aim. Their canoes are made of wood, and pieces of the bark of a soft tree, which grows plentifully near the sea, and is very tough and proper for the purpose. They are from 16 to 20 feet long, and about 15 inches broad; the head and stern are made of two solid pieces of wood; the stern rises or curves a little, but in an irregular direction, and ends in a point; the head projects out horizontally, and is carved into some rude resemblance of a human face. They are rowed by paddles, and some have a sort of lattice fast made of matting. Hogs were the only quadruped seen by our navigators; and cocks and hens the only tame fowls. However, the woods seemed to abound with small birds of a very beautiful plumage, and fine notes; but the fear of alarming the natives hindered their shooting so many of them as they might have desired.

For other particulars relating to the disposition and manners, &c. of the Mendocans, we refer to Captain Marchand’s account, given under the article Santa Christiana. We shall here add some relations, that serve to correct or to enlarge the account of these people furnished by Capt. Cook. Capt. Chanel, cited by Marchand, is very far from confirming the reproach of filthinefs, which Capt. Cook has applied to these islanders; he says, on the contrary, that, having repeatedly been present at their meals, for which men, women, and children of the fame house assemble twice a day, at noon and before night-fall, he was surprized at the great cleanliness which prevailed, and which is observable in their whole habitation; he adds, that he has seen the inhabitants of La Madre de Dios, in the island of Santa Christiana, make very frequent use of water for washing themselves. Surgeon Roblet also says, that both men and women wash their hands and face several times in the day. To their frequent use of water, is ascribed their freedom from cutaneous diseases, pimples, ulcers, &c. which are common in the burning climates of the tropical zone. It is affirmed, that in various respects they are more cleanly than the inhabitants of Otaheite, extolled by Capt. Cook. Their diet, it is observed, is more vegetable than animal. From the cocoa-nut they extract an oil, which is probably employed in the seasoning of their dishes; and which is principally used to anoint their whole body; and the women especially confide a great quantity of it for maintaining the gums and luster of their hair. Their common drink is pure water, and, occasionally, cocoa-nut milk. As they have the pepper-root, and make use of it as a sign of peace, it is suppos'd that they may also prepare the same dainty beverage from it, with which the other islanders intoxicate themselves. Capt. Chanel presumes, not without reason, that they procure a strong liquor from the root of ginger, rather than from that of pepper. This beverage, however, they use with moderation, for Marchand says, that no individual was seen here, who manifested the slightest appearance of intoxication. Their mode of building their houses on stone platforms, and their use of flints, the structure of which is particularly described by Marchand, indicate, that the island of Santa Christiana must be exposed to inundations. Of these flints, curiously constructed, the natives of this island make very dextrous use; and it is said, that in a race, they would dispute the palm with the most experienced herdsman of France.

It does not appear that in Santa Christiana, they have either laws or chiefs; strength being everything, and the weak obeying the strong. Of their religion, we have no better information than of their government. During the stay which the French made in this island, they saw nothing which could make them think, that its inhabitants paid any worship to a supreme being; pleasure, says Marchand, is the divinity of the country; no superstitious, no ceremony, no priest or juggler. In the Missionary voyage, we have the following account of the customs and manners of the people about Resolution bay, more especially as they relate to religion, and they are different from the account given by the French voyagers. “Their religious ceremonies resemble those of the Society island. They have a Morai in each district, where the dead are buried beneath a pavement of large stones, but with such exceptions, as in the case of the chief Honoo. They have a multitude of deities. Those most frequently mentioned are Opooananite, Ooko, Onamoo, Opeepeetye, Onooko, Octanow, Fattu-at-poo, Onor-te; but none who seem superior to the rest, though the extent of my information (says the Missionary) is small on this head. They only offer hogs in sacrifices, and never men. The chief Tenea preaches over four districts, Ohita-hoo, Takehuy, and Innami, all opening into Resolution bay, and Onopoho, the adjoining valley to the southward. He has four brothers; but none of them seem invested with any authority; and Tenea himself with less than the Otaheitean chiefs. There is no regular government, established law, or punishment; but custom is the general rule.”

As to their food, we are informed that they have no regular meals, but eat when they are hungry. When they have a hog, they eat of it five or fix times a day; and when without animal food, they use the roasted bread fruit, figs, mahi, pudding made of it and other vegetables, white-nuts, and a palle made of a root resembling the yam; and this they often do through the day. The women are not allowed to eat hog, and are probably restrained by other prohibitions as at Otaheite, and seem much more servile to the men, and harshly treated. They are employed in making cloth and matting, but not in co经纪人, except for themselves. “I have never observed (says one of the missionaries) any of the men, from the chief to the toutoo, at work, except a few old persons making cords and nets; they are idle about, and bask in the sun, telling their stories, and begging the time.” As far as concerns the perfons, drefs, canoes, &c. of these people, the missionaries found them exactly as they are described in Cook’s second voyage.

As to the population of these islands, we have no satisfactory account. The number of inhabitants, says Mr. G. Forster, cannot be very considerable, on account of the small size of the islands which they occupy. Such spots as are fit for culture in these islands are very populous; but as they are all very mountainous, and have many inaccessible and barren rocks, it is to be doubted whether the whole population of this group amounts to 50,000 persons. From Marchand’s voyage, and the statement which it contains, it appears
appears that it would be granting much to the island of
Santa Christina to give it 1000 inhabitants for every league of
cost, and in all, 7000; to suppose 6000 for La Dominica,
which Mr. Forster, on account of the fertility of the
greater part of its soil, rightly presumes not likely to pre-
sent a population so numerous as that of S. Christina ; and
to admit 6000 for La Madalena, whose circuit is six leagues:
the total number of the inhabitants of the three large islands
might then amount to 19,000 individuals, which might be
extended to 20,000, if we allow a few inhabitants to the
small island of San Pedro and Hood's island. This result is
very wide of that of 50,000 individuals according to Mr.
Forster's statement; and yet this is supported by the French
voyager to be exaggerated. Cook's Second Voyage, vol. i.
Marchand's Voyage, vol. i. Missionary Voyage.

MARQUETRY, Inlaid Work; a curious kind of
work, composed of pieces of hard fine wood of different
colours, fastened, in thin fices, on a ground, and some-
times enriched with other matters, as tortoise-shell, ivory, tin,
and brass.

There is another kind of marquetry made, instead of wood,
of glasses of various colours; and a third, where nothing
but precious stones, and the richest marbles, are used: but
these are more properly called mosaic work. The art of in-
laying is very ancient, and is supposed to have passed from
the east to the west, as one of the spoils brought by the Ro-
mans from Asia. Indeed, it was then but a simple thing;
or did it arrive at any tolerable perfection till the fifteenth
century, among the Italians. It seems finally to have ar-
ived at its height in the seventeenth century, among the
French.

Till John of Verona, contemporary with Raphael, the finest
works of this kind were only black and white, which are
what we now call marceces; but that religious, who had a
genius for painting, stained his woods with dyes, or boiled
oils, which penetrated them. But he went no farther than the
representing of buildings and perspectives, which require
no great variety of colours. Tho' who succeeded him, not
only improved on the invention of dyeing the woods, by a
secret which they found of burning them without con-
suming, which served exceedingly well for the shadows; but
they had also the advantage of a number of fine new woods
of naturally bright colours, by the discovery of America.
With these affinities, the art is now capable of imitating
any thing; whence some call it, the art of painting in wood.
The ground, whereon the pieces are to be arranged and
 glued, is ordinarily of oak or fir, well dried; and, to pre-
vent warping, it is compos'd of several pieces glued together.
The wood to be used, being reduced into leaves of the thick-
ness of a line, is either stained with some colour, or made
black for shadow: which some effect by putting it in a
fire extremely heated over the fire; others by steeping it in lime-
water and sublimate; and others, in oil of sulphur. Thus
coated, the contours of the pieces are formed according to
the parts of the design they are to perform.

The last is the most difficult part of marquetry, and
that wherein most patience and attention are required. The
two chief instruments used herein are the saw and the vice;
the one to hold the matters to be formed: the other to take
off from the extreme, according to occasion. This vice is
of wood, having one of the chop fixed, the other moveable,
and is opened and shut by the foot, by means of a cord
fastened to a treadle. Its structure is very ingenious, yet
simple enough, and will be easily conceived from the figure,
Plate XXIII. Miscellany, fig. 3. The leaves to be formed (for
there are frequently three or four of the same kind formed to-
gether) are put within the chaps of the vice, after being glued
on the outermost part of the design, whose profile they are to
follow: then the workman, pressing the treadle, and thus hold-
ing fast the piece, with his saw runs over all the outlines of
the design. By thus joining and forming three or four pieces
together, they not only gain time, but the matter is likewise
the better enabled to sustain the effort of the saw; which,
how delicate soever it may be, and how lightly soever the
workman may conduct it, without such prudence, would be
apt to raise splinters, to the ruin of the beauty of the work.

When the work is to consist of one single kind of wood, or
of tortoise-shell, on a copper or tin ground, or vice versa,
they only form two leaves on one another, i.e. a
leaf of metal, and a leaf of wood or shell: this they call saw-
ing in counter-parts; for by filling the vacuities of one
of the leaves by the pieces coming out of the other, the
metal may serve as a ground to the wood, and the wood to
the metal.

All the pieces, thus formed with the saw, are marked,
to know them again; and the shadow being given in the
manner already mentioned; they veneer or fatten each in its
place on the common ground; using for that purpose the
English glue. The whole is then put in a press to dry,
planned over, and polished with the skin of the sea-dog, wax,
and shae-grafs, as in simple veneering; with this difference,
however, that in marquetry, the fine branches, and several of
the most delicate parts of the figures, are touched up, and
finisht with a graver.

They are the cabinet-makers, joiners, and turn-men, among
us, who work in marquetry; and the enamellers and flute-
cutters who deal in mosaic work: the instruments used in the
former are mostly the fame with those used by the ebonists.
See Ebon.

MARQUIE, or MARQUE'S, Fr. corrupted from Mar-
quise, signifies a tent or cover made of strong canvas or Ruffia-
duck, which is thrown over another tent, and serves to keep out
rain.

MARQUION, in Geography, a town of France, in the
deptment of the Straits of Calais, and chief place of a
canton, in the district of Ares. The place contains 668, and
the canton 14,293 inhabitants, on a territory of 137½
kilo-

MARQUIS, or MARQUES, Marchis, a title given to
a person in possession of a considerable demesne erected
into a marquise by letters patent; holding a middle
place between the dignity of a duke and that of an earl
or count.

The word, according to some authors, comes from the
Marchiomin, an ancient people, who inhabited the marches
of Brandenburgh. Others derive it from the German marcke,
limit; and others from marcius, which, in the Celtic language,
signified a wing or caupon. Niceol derives it from the corrupt
Greek menehas, province. Alciat and Pauchet bring it
from marz, hofis, taking a marquis to be properly an officer
of horse. Menage derives it from marc, frontiser; and
Selden, Kranziss, and Hottomas do the same. Lastly,
Pasquier fetches marquis from the old French marche, limit;
or from marchir, a piece; the guard of the frontiers being
committed to them. Marquises were anciently governors of
frontier cities or provinces, called marches. Such as, in
particular, were the marches of Wales and Scotland, while
each continued to be an enemy's country. In Germany,
they are called margraves.

The person, who had command there, were called lords
marchers, or marquises; whose authority was abolished by
statute 27 Hen. VIII. c. 27; though the title had long be-
fore been made a mere enigma of honour; Robert Vere,
earl of Oxford, being created marquis of Dublin by rich-
chard
church II. in the eighth year of his reign. 2 Inlit. 5. Sen-
den’s Titles of Honour, p. 216.
Marquis is originally a French title: the Romans were
unacquainted with it. In the Noutus Imperii, they were
called comites limitantes. The first time we hear of marquises,
marcbiones, is under Charlemagne, who created governors
in Gasceny under this denomination.
Aclint has started a question, whether a marquis or count
should have the precedence? To decide it he goes back to
the ancient function of counts; and observes, that counts,
who are governors of provinces, are above marquises, who
are only governors of frontier; and that marquises, who
are governors of frontier cities, are above those counts
who are governors of small towns. He adds, that, in consequence
of this distinction, the book of chelas sometimes places marqui-
ases above counts, and sometimes counts above marquises.
Froilart observes, that the marquise of Juliers was
erected into a county: but now-a-days, neither marquises
nor counts are any longer governors; and as they are mere
titles of honour, the counts make no furor of resigning
the precedence.
Marquis’s Coronet. See Crown.
Marquis, Grand, in Geography, a town on the E. side
of the island of Grenada. N. lat. 12° 9’ W. long. 61° 4’.
Marquis, Cape, a cape on the N. coast of the island
of St. Lucia. N. lat. 15° 50’. W. long. 6° 42’.
Marquis Islands, a cluster of small islands in the Florida
stream. N. lat. 24° 35’. W. long. 82° 30’.
Marquise, a town of France, in the department of
the Stras of Calais, and chief place of a canton, in the
district of Boulogne. The place contains 1400, and the canton
2562 inhabitants, on a territory of 2352 kilometres, in 21
communes.
MARK, a division of the county of Aberdeen, in Scot-
land, towards the south, between the rivers Dee and Don.
MARRA, in Ancient Geography, a town of Afa, in Sy-
ría, situated on an extensive plain, to the E. of the river
Orantes, N.E. of Apamea, and S. of Chalcis. Marra still
retains its ancient name, and it is held by the pacha of Damas-
cus, as an appanage deriving immediately from the sultan.
Homs, Hama, and Marra pay 400 purses, or about 20,000l. ;
30 miles N. of Hama.
MARRABOO, a town of Africa, in the kingdom of
Bambarra, on the Niger: this town is a considerable mart
for salt, which is brought by the Moors for sale to the Negroes;
150 miles S.W. of Sego. N. lat. 12° 50’. W. long. 5° 10’.
MARRADI, a town of Etruria; N.E. of Florence.
MARRAT, a town of France, in the department of
the Puy de Dome; nine miles S. of Thiers.
MARRIAGE, a civil and religious contract, whereby a
man is joined and united to a woman, for the ends of pro-
creation.
The essence of marriage consists in the mutual consent
of the parties. Marriage is a part of the law of nations, and
is in use among all people. The Romans account it a
factament.
The public use of marriage institutions consists, according
to archdeacon Paley (Philos. vol. i.), in their promoting the
following beneficial effects: 1. The private comfort of in-
dividuals: 2. The production of the greatest number of
healthy children, their better education, and the making of
due provision for their settlement in life: 3. The peace of
human society, in cutting off a principal source of contention,
by affixing one or more women to one man, and protect-
ing his exclusive right by functions of morality and law:
4. The better government of society, by distributing the
community into separate families, and appointing over each
the authority of a master of a family, which has more actual
influence than all civil authority put together: 5. The ad-
ditional security which the state receives for the good behav-
ior of its citizens, from the solicitude they feel for the
welfare of their children, and from their being confined to
permanent habitations: 6. The encouragement of industry.
The woman, with all her moveable goods, immediately
upon marriage, paffes wholly, in potestas evertis, into the power
and dispofal of her husband.
The first inhabitants of Grecia lived together without
marriage. Cecrops, king of Athens, is said to have been
the first author of this honourable institution among the
people. After the commonwealths of Greece were settled,
marriage was very much encouraged by their laws, and the
ablation from it was disconfounded, and in many places
punished. The Lacedemonians were very remarkable for
their severity towards those who deferred marriage beyond
a limited time, as well as to those who wholly abstained from
it. (See Lacedemonians.) The Athenians had an ex-
press law, that all commanders, orators, and perfons en-
trusted with any public affair, should be married men.
Polygamy was not commonly tolerated in Greece. The
time of marriage was not the same in all places: the
Spartans were not permitted to marry till they arrived at
their full strength: the reason assigned for this custom by
Lycurgus was, that the Spartan children might be strong
and vigorous; and the Athenian laws are said to have once
ordered, that men should not marry till thirty-five years of
age. The feaon of the year which they preferred for this
purpose was the winter, and particularly the month of
January, called Ganelaion. The Greeks thought it fea-
dalous to contract marriage within certain degrees of con-
trariety, whilst most of the barbarous nations allowed
incestuous mixtures.
Most of the Grecian states, especially such as made any
figure, required their citizens should match with none but
citizens, and the children were not allowed to marry without
the consent of their parents. The usual ceremonies in pro-
moting fidelity was killing each other, or giving their right
hands, which was a general form of ratifying all agree-
ments. Before the marriage could be solemnized, the gods
were to be consulted, and their assent implied by prayers
and sacrifices, which were offered to some of the deities that
superintended these affairs, by the parents, or nearest rela-
tions of the persons to be married. When the victim was
opened, the gall was taken out and thrown behind the altar,
as being the seat of anger and malice, and therefore the
aversion of all the deities who had the care of love, as well
as those who became their votaries. For the particulars
relating to the bride and bridegroom, see Bride and Brud-
groom.
The ceremonies of the Spartan marriages being different
from all others, deserve to be mentioned at length, as re-
lated by Plutarch. “When the Spartans had a mind to
marry, their courtship was a sort of rape upon the persons
they had a fancy for; and those they chose not tender and
half-children, but in the flower of their age, and full ripe
for a husband. Matters being agreed between them, the
votaries, or woman that contrived and managed the plot,
shaved off the bride’s hair close to her skin, dressed her up
in man’s clothes, and left her upon a mattress: this done,
the bridegroom entered in his common clothes, sober and
composed, as having humped at his ordinary in the common
hall, and stole as privately as he could into the room where
the bride lay, untied her virgin girdle, whence nunc prima is
to deflower, and took her into his embraces. Having stayed
a short
MARRIAGE.

a short time with her, he returned to his comrades, with whom he continued to spend his life, remaining with them as well by night as by day, unless when he roved a short visit to his bride; and that could not be done without a great deal of circumspection, and fear of being discovered. Nor was the wanting (as may be supposed) on her part, to use her wit in watching the most favourable opportunities for their meeting, and making appointments when company was out of the way. In this manner they lived a long time, insomuch that they frequently had children by their wives before they saw their faces by day-light. The interview being thus difficult and rare, served not only for a continual exercise of their temperance, and farthered very much the ends and intentions of marriage, but was a means to keep their passion still alive, which flags and decays, and dies at last by too easy access, and long continuance with the beloved object.” Potter, Archæol. book iv. c. xi. p. 295, seq.

The Romans, as well as the Greeks, disapproved of polygamy; and they encouraged marriage by the “jus trium liberorum.” A man who had no child was entitled by the Roman law only to one-half of any legacy that should be left him, that is, at the most, could receive only one-half of the testator’s fortune. A Roman might not marry any woman who was not a Roman. Among the Romans, the kalends, nones, and ides of every month, were deemed unlucky for the celebration of marriage; as was also the feast of the Parentalia, and the whole month of May. The most happy feasons in every respect was that which followed the Ides of June.

The Roman laws speak of secund marriages in very hard and odious terms: “Matre jam secundam nuptias funeclata, L. iii. C. de fec. nuptis.” By these laws it was enacted, that the effects of the husband or wife deceased should pass over to the children, if the survivor should marry a second time. By the law Hae sidohal, Cod. de fec. nupt. the survivor, upon marrying a second time, could not give the person he married a portion more than equal to that of each of the children. In the primitive church, the respect to chastity was carried so high, that a second marriage was accounted no other than a lawful whoredom, or a species of bigamy; and there are some ancient canons, which forbid the ecclesiastics from being present at second marriages.

Marriage, by the Moslem law, was subject to several restrictions: thus by Levit. chap. xviii. ver. 16, a man was forbidden to marry his brother’s widow, unless he died without issue; in which case, it became enjoined as a duty. So he was forbidden to marry his wife’s sister, while she was living, ver. 18, which was not forbidden before the law, as appears from the instance of Jacob.

The ancient Roman law is silent on this head; and Paulinian is the first who mentions it, on occasion of the marriage of Caracalla. The lawyers who came after him stretched the bonds of affinity so far, that they placed adoption on the same foot with nature.

Affinity, according to the modern canonists, renders marriage unallowable to the fourth generation, inclusive; but this is to be understood of direct affinity, and not of that which is collateral or collateral. “Affinis mei affinis, non eft affinis meus.” It is farther to be observed, that this impediment of marriage does not only follow an affinity contracted by lawful marriage, but also that contracted by a criminal commerce; with this difference, that this last does not extend beyond the second generation; whereas the other, as has been observed, reaches to the fourth.

In Germany, they have a kind of marriage called mar-
pays for his bride a marriage present, or "kalym," consisting of arms or a coat of mail; but he must not see her, nor cohabit with her, without the greatest mystery. That reserve continues during life. The father makes the bride a present on the wedding-day, but reserves the greater part of what he intends to give her till the birth of her first child. On this occasion the pays him a visit, receives from him the remainder of her portion, and is clothed by him in the draps of a matron, of which the principal distinction is a veil.

The Hebrews also purchased their wives, by paying down a competent dowry for them: and Aristotle makes it one argument to prove that the ancient Grecians were an uncivilized people, because they used to buy their wives; and in proportion as they laid aside their barbarous manners, they left off this practice.

The ancient Assyrians fold their beauties by an annual auction. The prices were applied by way of portion to the more homework. By this contrivance, all of both forts were disposed of in marriage. Among the old inhabitants of Germany, as well as the Jewish patriarchs, and the Grecians, the husband paid money to the family of the wife, whereas now the wife brings money to her husband. This alteration, says Paley, has proved of no small advantage to the female sex, for their importance in point of fortune procures for them, in modern times, that affability and respect which are always wanted to compensate for the inferiority of their strength, but which their personal attractions would not always secure.

The English law considers marriage in no other light than as a civil contract: the benefits of the matrimonial state being left entirely to the ecclesiastical law, to which it pertains to punish or annul incelesious or other unscriptural marriages. The law allows marriage to be good and valid, where the parties at the time of making it were willing and able to contract, and actually did contract, in the proper forms and solemnities required by law. As to their being willing to contract, "confensum, non concebendum, faciat pastum," is the maxim of the civil law in this case; and it is adopted by the common lawyers. (Co. Litt. 53.) The disabilities or incapacities for contracting are of two sorts: first, such as are canonical, and, therefore, sufficient by the ecclesiastical laws to avoid the marriage in the spiritual court; such as pre-contract, consanguinity, or relation by blood; and affinity, or relation by marriage, and some particular corporeal infirmities. But these disabilities in our law do not make the marriage ipso facto void, but voidable only by sentence of separation; and marriages are allowed valid to all civil purposes, unless such separation is actually made during the life of the parties. Thus, when a man had married his first wife's sister, and after her death the bishop's court was proceeding to annul the marriage, and baHardize the issue, the court of king's bench granted a prohibition quadam loco: but permitted them to proceed to punish the husband for incest. Salk. 548.

By 32 Hen. VIII. c. 38. it is declared, that all persons may lawfully marry, but such as are prohibited by God's law, &c. And that nothing (God's law excepted) shall impeach a marriage but within the Levitical degrees: these are enumerated in the eighteenth chapter of Leviticus, and are illustrated by lord Coke in this manner: a man may not marry his mother, father's sister, mother's sister, sister, daughter, daughter of his son or daughter, father's wife, uncle's wife, father's wife's daughter, brother's wife, wife's sister, son's wife or wife's daughter, and daughter of his wife's son or daughter. And a woman may not marry her father, father's brother, mother's brother, brother, son of her son or daughter, mother's husband, aunt's husband, sister's husband, husband's brother, and son of her husband's son or daughter. Accordingly, a table was set forth in the year 1565, specifying at large the prohibited degrees. It is observed, that the degrees prohibited by the Levitical law are all within the fourth degree of consanguinity, as established by the computation of the civilians; all collaterals, therefore, in that degree, or beyond it, may marry. By the civil law first cousins are allowed to marry; but by the canon law both first and second cousins are prohibited. Therefore, when it is vulgarly said, that first cousins may marry, but second cousins cannot, this probably arose by confounding these two laws: for first cousins may marry by the civil law, and second cousins cannot by the canon law. But by the forefied flat, 32 Henry VIII. c. 38, it is clear that both first and second cousins may marry. By the same statute all impediments arising from pre-contracts to other persons were abolished, and declared of none effect, unless they had been confirmed by bodily knowledge; in which case the canon law holds such contract to be a marriage de facto. But this branch of the statute was repealed by 2 and 3 Ed. VI. c. 33. How far the act of 16 Geo. II. c. 53. (which prohibits all suits in ecclesiastical courts to compel a marriage, in consequence of any contract) may collaterally extend to revive this clause of Henry VIII. th's statute, and abolish the impediament of pre-contract, judge Blackstone leaves to be considered by the canonists. We shall here observe, that on a promise of marriage, if it be mutual on both sides, damages may be recovered, in case either party refuses to marry; and though no time for the marriage is agreed on, if the plaintiff avers that he offered to marry the defendant, who refused it, an action is maintainable for the damages; but no action shall be brought upon any agreement except it is in writing, and signed by the party to be charged. The canonical hours for celebrating marriage are from eight till twelve in the forenoon.

Difabilities of another fort are those which are created, or at least enforced, by the municipal laws. These civil disabilities make the contract void ab initio, and not merely voidable, by rendering the parties incapable of forming any contract at all. The first legal disability is a prior marriage, or having another husband or wife living; in which case, besides the penalties consequent upon it as a felony, the second marriage is to all intents and purposes void. See Bigamy, and Polygamy.

The next legal disability is want of age: therefore, if a boy under fourteen, or a girl under twelve years of age, marries, when either of them comes to the age of consent they may disdare, and declare the marriage void, without any divorce or estray in the spiritual court. This is founded on the civil law: but the canon law pays a greater regard to the constitution than the age of the parties; for if they are "habeis ad matrimonium," it is a good marriage, whatever their age may be. And in our law it is so far a marriage, that, if at the age of consent they agree to continue together, they need not be married again. (Co. Litt. 79.) If the husband be of years of discretion, and the wife under twelve, when she comes to years of discretion he may disadare, as well as she may; for in contracts the obligation must be mutual; both must be bound or neither: and so it is, nisi veris; when the wife is of years of discretion, and the husband under. (Ibid.) However, in our law it is so far a marriage, that if at the age of consent they agree to continue together, they need not be married again. Another incapacity arises from want of consent of parents or guardians. By the common law, if the parties themselves were of the age of consent, no other concurrence was necessary to make the marriage valid; and this was agreeable to the canon law. But by several statutes
A married Jew, orders Alfo, of perfon for forbidden Domat. hcence; marriage or calce And not puhlish civil fuch purfuance and 19. ip/o contraft, let non Fleta or it that puhlished, be reasonably commiffion, father, estate, totally discretion are did expecting. father, issue prince inconveniences, decency land, fhe did continue to be marry the of twenty-one, not being a widow or widower, who are suppos'd emancipated, without the conftent of the father, or, if he be not living, of the mother or guardians, fhall be absolutely void. However, provision is made, where the mother or guardian is non compos, beyond fun, or unreasonably froward, to defpife with fuch conftent, at the difcretion of the lord chancellor; but no provision is made, in cafe the fherd fhould labour under any mental. or other incapacity. A fourth incapacity is want of reafon. It is provided by 15 Geo. II. cap. 30, that the marriage of lunatics, and perfons under phrenzies (if found lunatics under a commifion, or committed to the care of trustees by any act of parliament) before they are declared of found mind by the lord chancellor, or the majority of fuch trustees, fhall be totally void.

By the ancient law of England, if any Christian man did marry with a woman that was a Jew, or a Christian woman did marry with a Jew, it was felony, and the party so offending fhould be burnt alive (3 Inf. 89); or as the author of Fleta fays, burned alive. But when both parties are Jews, they are allowed to marry; and are not under the restraints of the flature of 26 Geo. II. c. 33. By the civil law the woman is forbidden to marry again within the year of marrying, unless with a special dispensation from the prince; by rea fon of the uncertainty to which husband the issue may be ong, and because a reverential marrying and pious regard to the memory of her deceased husband, are in decency expected. (Wood. Civ. L. 124. 2 Domat. 126.) And lord Coke fays, for the avoiding of fuch inconveniences, this was the law before the confuet; let every widow continue unmarried for twelve months; and if the fhall marry, let her lose her dower. (1 Inf. 8.) But the divine and the canon law leaves no fuch injunctions. (Wood. Civ. L. 122.) Also, by the common law of England, a widow is not prohibited from marrying at any time after her husband's death. If a woman marry to foon after the death of her husband that the child may belong to either father, it is laid the child may choose his father. Co. Litt. 883.

Laffly, the parties mufl not only be willing and able to contract, but must actually contract themselves in due form of law, to make it a good civil marriage. Any contract made, per vecla de praefenti, or in words of the present tenfe, and in cafe of cohabitation per vecla de futuro allo, between perfons able to contract, was before the marriage act deemed a valid marriage to many purposes, and the parties might be compelled in the spiritual courts to celebrate it in facie eclefe. But these verbal contracts are now of no force, to compel a future marriage. Nor is any marriage at prefent valid that is not celebrated in some parish-church or public chapel, unless by dispensation from the archbishop of Canterbury. It must alfo be preceded by publication of banns, or by licence from the Spiritual judge. No parfon, vicar, &c. shall be obliged to publish banns of matrimony, unless the persons to be married have, seven days before the time required for the first publication, deliver to him a notice in writing of their true names, and of the houfe or houses of their refpective abode, within fuch parish, &c. and of the time that they have dwelt in fuch house or houses. And the faid banns fhall be published upon three Sundays preceding the solemnization of marriage, during the time of public service. In cafe the parents or guardians of either of the parties, who shall be under the age of twenty-one years, fhall openly and publicly declare, or caufe to be declared in the church or chapel, where the banns fhall be fo published, at the time of fuch publication, their difpofition to fuch marriage, fuch publication of banns fhall be void. And when the parties dwell in divers parifhes, the curate of the one parish fhall not solemnize matrimony betwixt them, without a certificate of the banns being thrice afked, from the curate of the other parish. In all cafes where banns have been published, the marriage fhall be solemnized in one of the parish churches or chapels where fuch banns have been published, and in no other place. A marriage in pursuance of a licence (except a special licence) mufl be solemnized in fuch church or chapel where the licence is granted; and no licence of marriage fhall be granted by any archbishop, bishop, &c. to solemnize any marriage in any other church, &c. than in the parish church, &c. within which the usual place of abode of one of the parties fhall have been for four weeks immediately before the granting fuch licence. By the fame flature, all marriages fhall be solemnized in the presence of two credible witnefls at the leat, besides the minifter, who fhall sign their attestation thereof; and immediately after the celebration of every marriage, an entry thereof shall be made in the parish-regifter, expressing that the faid marriage was celebrated by banns or licence; and if both or either of the parties be under age, with con tent of the parents or guardians, as the cafe fhall be, signed by the minifter, and also by the parties married, and attested by the two witnefls prefent. It is held to be alfo effential to a marriage, that it be performed by a perfon in orders (Salk. 119.); though the intervention of a pri eft to folem nize this contract is merely juris positivis, and not juris naturalis aut devini; it being faid that pope Innocent III. was the firft who ordained the celebration of marriage in the church (Moor. 170), before which it was totally a civil contract. And in the times of the grand rebellion, all marriages were performed by the judictes of the peace; and these marriages were declared valid, without any fuch solemnization, by 12 Car. II. c. 33. But as the law now stands, we may upon the whole collect, that no marriage by the temporal law is void, that is celebrated by a perfon in orders; in a parish church, a public chapel, or elsewhere by fpecial dispensation; in pursuance of banns or a licence; between fingle perfons; confenting; of found mind; and of the age of twenty-one years; or of the age of fourteen in males, and twelve in females, with con tent of parents or guardians, or without it in cafe of widowhood. And no marriage is voidable by the ecclecafical law, after the death of either of the parties; nor during their lives, unlefs for the canonical impediments of precontract, if that indeed ill extis; of confanguinity, and of affinity, or corporal incommixture, fulfilling previous to the marriage. Blackft. Com. vol. i.
By 26 Geo. II. c. 33, the substance of which has been already recited, if any person shall solemnize marriage in any other place than a church, &c. where banns have been usually published, unless by a special licence, or without publication of banns, unless licence of marriage be first obtained from some person having authority to grant the same, every such person knowingly so offending, shall be guilty of felony, and transport for fourteen years; the prosecution to be within three years. By the same statute, to make a false entry into a marriage-register; to alter it when made; to forge or counterfeit such entry, or a marriage licence, or aid and abet such forgery, to utter the same as true, knowing it to be counterfeit; or to destroy or procure the destruction of any register, in order to vacate any marriage, or subject any person to the penalties of this act: all these offences, knowingly and wilfully committed, subject the party to the guilt of felony without benefit of clergy. But this act does not extend to the marriages of the royal family; nor to Scotland; nor to any marriages among the people called Quakers, or among persons professing the Jewish religion, where both the parties are Quakers or Jews respectively; nor to any marriages beyond the seas.

As the passage into Scotland is left open by the marriage act, many persons have found their way thither to be married, in a clandestine and irregular manner; and there has been a diversity of opinions concerning the validity of such marriages. Lord Stair, in his "Institutions of the Laws of Scotland," says, the public solemnity of marriage is a matter of order, justly introduced by positive law, for the certainty of so important a contract; but not essential to marriage. Thence arises the distinction of public or solemn, and private or clandestine marriages. And though persons who act contrary thereto, may be justly punished, (as in some nations by the exclusion of the issue of such marriages from succession,) yet the marriage cannot be declared void and annulled; and such exclusions are very unequal against the innocent children. But by the custom of Scotland, cohabitation, and being commonly reputed man and wife, validate the marriage, give the wife a right to her thirds, who cannot be excluded therefrom, if she was reputed lawful wife, and not questioned during the husband's life, till the contrary be clearly proved. Mr. Erskine, in his "Principles of the Law of Scotland," says, it is not necessary that marriage be celebrated by a clergyman: the consent of parties may be declared before any magistrate, or simply before witnesses. When the order of the church is observed, the marriage is called regular; when otherwise, clandestine. Towards a regular marriage, the church requires proclamation of banns in the churches, where the bride and bridegroom reside: formerly, not only bishops, but prebendaries, assumed a power of dispending with proclamation of banns, on extraordinary occasions; but this hath not been exercised since the revolution. But whether clandestine marriages in Scotland, of English parties, who refort thither to evade the English law, shall be sustained in England, hath been doubted; and very learned men have questioned, notwithstanding such marriages are valid by the law of Scotland, whether they are effective in England. Where parties are bound, by the laws of their country, to execute any important act or contract with certain solemnities; it is doubted whether they can clade their own law, by going purposely to another country, where such solemnities are not essential, and then returning immediately, when the act is done. It is a question of public law; and the most celebrated writers on public law have held, that such an act is fraudulent; it is fraudem facere legis, which the laws of all nations disallow. In a case that occurs in "Buller's Law of Niti Pius," an appeal was made to the delegates: the appellant and respondent both English subjects, the appellant, being under age, ran away without the consent of her guardian, and were married in Scotland; and on a fait brought in the spiritual court to annul the marriage, it was held that the marriage was good.

So, it has been since taken as an undoubted proposition, that a marriage celebrated in Scotland is such a marriage as would entitle the woman to dower in England.

By 35 Geo. III. c. 67, after reciting that the punishment of persons convicted of felony by virtue of 1 Jac. I. c. 11. "for restraining persons from marriage until their former wives or husbands be dead," has not proved effectual to deter wicked persons from being guilty of the said offence, it is enacted, that if any person being married, or who hereafter shall marry, do, after the 15th of May 1795, marry any person, the former husband or wife being alive, and shall be in due manner convicted thereof under the said act, shall be subject and liable to the same penalties, pains, and punishments, as by the laws now in force persons are liable to, who are convicted of grand or petit larceny.

For the proportions which marriages bear to births, and births to burials, in several parts of Europe, Mr. Derham gives us the following table:

<table>

For an account of the numbers of male and female full-born children and chryftons, and of boys and girls under ten, of married men and married women, and of widows and widowers, who died for a course of years at Vienna, Breslaw, Dresden, Leipzig, Ratibon, and some other towns in Germany, see Phil. Trans. Abstr. vol. vii. part iv. p. 46, &c.

The reader may find many curious calculations and remarks relating to this subject in Dr. Price's excellent work, entitled "Observations on Reverendary Payments." From the preceding table it appears, that marriages, one with another, do each produce about 4 births, both in England, and other parts of Europe. Dr. Price observes, that the births at Paris, as may be seen in the table, are above four times the weddings; and there are even more healthy country situations, every wedding produces above four children; and though this be the case in Paris, for reasons which he has given, he has observed nothing like it in any other great town. He adds, that from comparing the births and weddings, in countries and towns where registrars of them have been kept, it appears, that in the former, marriages, one with another, seldom produce less than four children each; generally between four and five, and sometimes above five; but in towns seldom above four, generally between three and four, and sometimes under three. It is necessary to be observed here, that though the proportion of annual births to weddings has been considered as giving the true number of children derived from each marriage, taking all marriages one with another; yet this is only true, when, for many years, the births and burials have kept nearly equal. Where there is an excess of the births occasioning an inbreed, the proportion of annual births to weddings must be less than the proportion of children derived from each marriage; and the contrary must take place, where there is a decrease; and by Mr. King's computation, about one in an hundred and four persons marry; the number of people in England being estimated at five millions and a half, whereof about forty-one thousand annually marry.

In the district of Vaud in Switzerland, the married are very nearly a third part of the inhabitants. Major Graunt and Mr. King disagree in the proportions between males and females, the latter making ten males to thirteen females in London; in other cities and towns, and in the villages and hamlets, a hundred males to ninety-nine females; but major Graunt, both from the London and country bills, computes that there are in England fourteen males to thirteen females; whence he justly infers, that the Christian religion, prohibiting polygamy, is more agreeable to the law of nature than Mahometanism, and others that allow it.

This proportion of males to females Mr. Derham thinks pretty just; being agreeable to what he had observed himself. In the hundred years, for instance, of his own parish-register of Upminster, though the burials of males and females were nearly equal, being six hundred and thirty-three males, and six hundred and thirty-three females, in all that time; yet there were baptized seven hundred and nine males, and but six hundred and seventy-five females, which is 13 females to 15.7 males. From a table formed by Dr. Price, he concludes that this proportion should have been stated at 19 to 20.

From a register kept at Northampton for twenty-eight years, from 1743 to 1771, it appears, that the proportion of males to females that were born in that period is 2361 to 2388, or nearly 13.4 to 13. However, though more males are born than females, Dr. Price has sufficiently shews, that there is a considerable difference between the probabilities of life among males and females, in favour of the latter; so that males are more short-lived than females; and as the greater mortality of males takes place among children, as well as among males at all ages, the fact cannot be accounted for merely by their being more subject to untimely deaths by various accidents, and by their being addicted to the excesses and irregularities which shorten life. Mr. Kerfleboon informs us, that, during the course of 152 years in Holland, females have, in all accidents of age, lived about three or four years longer than the same number of males. In several towns of Germany, &c. it appears, that of 7270 married persons who had died, the proportion of married men who died to the married women, was 3 to 2; and in Breslaw for eight years, as 5 to 3. In all Pomerania, during nine years, from 1748 to 1756, this proportion was nearly 15 to 11. Among the millers and professors in Scotland, twenty married men die to twelve married women, at a medium of twenty-seven years, or in the proportion of 5 to 3, so that there is the chance of 3 to 2, and in some circumstances even a greater chance, that the woman shall be the survivor of a marriage, and not a man; and this difference cannot be accounted for merely by the difference of age between men and their wives, without admitting the greater mortality of males. In the district of Vaud in Switzerland, it appears, that half the females do not die till the age of forty-six and upwards, though half the males die under thirty-six. It is likewise an indisputable fact, that, in the beginning of life, the rate of mortality among males is much greater than among females.

From
From a table formed by Dr. Price, from a register kept for twenty years at Gainsborough, it appears, that of those who live to eighty, the major part, in the proportion of 49 to 32, are females. Mr. Deparcieux at Paris, and Mr. Wargentin in Sweden, have further observed, that not only women live longer than men, but that married women live longer than single women. From some registers examined by Mr. Muret in Switzerland, it appears, that of equal numbers of single and married women between fifteen and twenty-five, more of the former died than of the latter, in the proportion of 2 to 1. With respect to the difference between the mortality of males and females, it is found to be much less in country parishes and villages than in towns; and hence it is inferred, that human life in males is more brittle than in females, or, in consequence of adventitious causes, or of some particular debility, that takes place in polished and luxurious societies, and especially in great towns.

From the inequality, above stated, between the males and females that are born, it is reasonable to infer, that one man ought to have but one wife; and yet that every woman, without polygamy, may have a husband; this surplusage of males above females being spent in the supplies of war, the seas, &c. from which the women are exempt. Perhaps, says Dr. Price, it might have been observed with more reason, that this provision had in view that particular weakness or delicacy in the constitution of males, which makes them more subject to mortality; and which consequently renders it necessary that more of them should be produced, in order to preserve in the world a due proportion between the two sexes. See Expectation of Life, and Mortality.

That this is a work of Providence, and not of chance, is well made out by the very laws of chance, by Dr. Arbuthnot; who supposes Thomas to lay against John, that for eighty-two years running, more males than females be born, and, giving all allowances in the computation to Thomas's side, he makes the odds against Thomas, that: it does not so happen, to be near five millions of millions of millions to one; but for ages of ages, according to the world's age, to be near an infinite number to one.

According to Mr. Kerseboom's observations, there are about 325 children born from 100 marriages.

Mr. Kerseboom, from his observations, estimates the duration of marriages, one with another, as in the following table:

Phil. Trans. 1768. sect. iii. p. 310.

Dr. Price has shown, that on De Moivre's hypothesis, or that the probabilities of life decrease uniformly (see Complement of life), the duration of survivorship is equal to the duration of marriage, when the ages are equal; or, in other words, that the expectation of two joint lives, the ages being equal, is the same with the expectation of survivorship; and, consequently, the number of survivors, or (which is the same, supposing no second marriages) of widows and widowers, alive together, which will arise from any given set of such marriages constantly kept up, will be equal to the whole number of marriages; or half of them (the number of widows in particular) equal to half the number of marriages. Thus, the expectation of two joint lives, both 40, is the third of 45 years, or their complement, i.e., 15 years and 4 months; and this is also the expectation of the survivor. That is, supposing a set of marriages, between persons all 40, they will, one with another, last just this time, and the survivors will last the same time. In adding together the years which any great number of such marriages, and their survivorships, have lasted, the sums would be found to be equal. It is observed farther, that if the number expressing the expectation of single or joint lives, multiplied by the number of single or joint lives whose expectation it is, be added annually to a society or town, the sum gives the whole number living together, to which such an annual addition would in time grow: thus, since 19, or the third of 57, is the expectation of two joint lives, whose common age is 29, or common complement 57, twenty marriages every year between persons of this age would, in fifty-seven years, grow to 20 times 19, or 380 marriages always existing together. The number of survivors also arising from these marriages, and always living together, would, in twice 57 years, increase to the same number. Moreover, the particular proportion that becomes extinct every year, out of the whole number constantly existing together of single or joint lives, must, wherever this number undergoes no variation, be exactly the same with the expectation of those lives, at the time when their existence commenced. Thus, if it were found that a nineteenth part of all the marriages among any body of men, whose numbers do not vary, are dissolved every year by the deaths of either the husband or wife, it would appear, that 19 was, at the time they were contracted, the expectation of these marriages. Dr. Price observes, that the annual average of weddings among the ministers and professors in Scotland, for the last twenty-seven years, has been thirty-one; and the average of married persons, for seventeen years, ending in 1767, had been 667. This number, divided by 31, gives 21½, the expectation of marriage among them; which, he says, is above 2½ years more than the expectation of marriage would be, by Dr. Halley's table, on the supposition, that all first, second, and third marriages may be justly considered as commencing, one with another, so early as the age of thirty; and he has proved, that the expectation of two equal joint lives is to the expectation of a single life of the same age as 2 to 3: consequently, the expectation of a single life at 30, among the ministers in Scotland, cannot be less than 32.25. If we suppose the mean ages, of all who marry annually to be 33 and 25, the expectation of every marriage would be 19 years; or one with another they would be all extinct in 19 years; the marriages which continue beyond this term, though fewer in number, enjoying among them just as much more duration, as those that fall short of it enjoy less. But it appears from the observations and tables of Mr. Muret, that, in the district of Vaud (dividing half the number of married persons, viz. 39,328. by the annual medium of weddings, viz. 805) the expectation of marriage is only 23½ years: so much higher are the probabilities of life in the country than in towns, or than they ought to be, according to De Moivre's hypothesis. Price's Obs. &c. See Expectation of Life, Life-annuities, and Survivorship.

Marriage, in Chivalry. See Maritagnium.

Marriage, Certificate of. By 5 W. c. 21 and 38 Geo. III. c. 145: for every piece of vellum, parchment, or paper, upon which any certificate of marriage (except of the marriage of a feaman's widow) shall be ingrossed or written, shall be paid a sum duty of 57; and writing such certificate upon the same before it be ingrossed incurs a forfeiture of 57.

Marriage, Clandestine or Irregular. See Marriage, supra.

Marriage,
MARRIAGE.

This contract formerly furnished one species of matrimonial causes, in which a party contracted to another brought a suit in the ecclesiastical court to compel a celebration of the marriage, in pursuance of such contract; but this branch of causes is now cut off entirely by the act for preventing clandestine marriages, 26 Geo. II. c. 33, which enacts that for the future no suit shall be had in any ecclesiastical court, to compel a celebration of marriage in factum ecclesiae, for or because of any contract of matrimony whatsoever.

Marriage, Dissolution of. See Divorce.

Marriage, Duty of. is a term used in some ancient customs, signifying an obligation on women to marry.

To understand this, it must be observed, that old maidis, and widows about sixty, who held fees in body, or were charged with any personal or military services, were anciently obliged to marry, to render those services to the lord by their husbands, or to indemnify the lord for what they could not do in perfon. And this was called duty or service of marriage.

Marriage, Forible. See Forcible Marriage.

Marriage, Frank. See Frank.

Marriage, Jafolution of, in Law, is one of the first and principal matrimonial causes, when one of the parties locusis or gives out, that he or she is married to the other, whereby a common repentence of their matrimony may ensue. On this ground the party injured may libel the other in the spiritual court; and unless the defendant undertakes and makes out a proof of the actual marriage, he or she is enjoined perpetual silence on that head; which is the only remedy the ecclesiastical courts can give for this injury. Blacklt. Com. vol. ii.

Dr. Godolphin says, that marriage was at first tried in the temporal courts; but afterwards, by the concession of princes, such cases were determined in the spiritual courts. The reasons why the cognizance thereof hath been permitted to the ecclesiastical judge are divers: especially because matrimony was heretofore a sacrament of the church; and the office being performed by clergymen, this of consequence brings the performance under the diocesan's inspection; and in the case of the Levitical degrees in particular, ecclesiastics are presumed to be the best judges of what is prohibited by God's law. The lawfulness of marriage is to be tried by the bishop's certificate (see Certificate), upon an issue "accoupled in lawful matrimony or not," as in a writ of dower, appeal, bailiarty, or the like. (1 Inst. 134.) And the bishop's certificate in this case is conclusive against all the world, and is the only mode of trying the issue on the plea of "ne unques accouple in loial matrimonii:" for to such a plea a mere sentence in the ecclesiastical court is not a good replication, because that would be to plead evidence, which, if it is any thing, amounts to the general issue, contrary to the rule (see 4 Bac. Abr. 60.), and to bind the court by what does not bind the bishop, who, if he see cause, may revoke the sentence. But such a sentence, unrepealed and unappealed from, is evidence to a jury; and may be pleaded in chancery. Whether a woman is a feme covert, or whether she is the wife of such a person, is triable by a jury upon the above-mentioned issue. Therefore a marriage de falsa, or in reputation (as amongst the Quakers) hath been allowed by the temporal courts to be sufficient for giving title to a personal estate, because the lawfulness of the marriage is not in issue, or the point to be tried. For the issue is whether a marriage was contracted between the parties or not, or whether the parties lived in a married state where the legality of it doth not come in question. Wood, b. i. c. 6.

In the act of 6 and 7 W. c. 6, laying a duty upon marriages, Quakers and Jews, cohabiting as man and wife, were required to pay the said duty, although not married "according to the law of England;" and there was a proviso, that nothing therein contained should be construed to make good or effectual in law any such marriage or pretended marriage; but that they should be of the same force, and no other, as if the said act had not been made. But in the act of 26 Geo. II. c. 33, there is no proviso of the like purpose; but rather the act proceeds upon a supposition that such marriages are good and valid.

In writs of dower, or other suits brought in the king's temporal courts, if issue be joined upon "not accoupled in lawful matrimonii," this being a cause which is merely ecclesiastical, the trial thereof must be by the bishop or ordinary, upon an inquisition taken before him as judge.

The proof of a marriage may be by witnesses who were present at the solemnization; by cohabitation of the parties; by public fame and reputation; by confession of the married persons themselves, although their acknowledgment might only be to avoid the punishment of fornication; and by divers other circumstances; which, if they amount to half-proof, ought to be extended in favour of marriage rather than contrary to it. (Wood Civ. L. 122.) But now, since the 26 Geo. II. c. 33, the regifter-book feems to be intended as the proper, although not the only evidence in this matter; for if there shall be any doubt as to the identity of the persons, or the like, the regifter in this respect can be no evidence at all. However, the act does not take away the evidence of presumption from cohabitation; but if the evidence be clear that the marriage was not celebrated according to the requisitions of the act, it is totally void, and no declaratory sentence in the ecclesiastical court is necessary. But in some cases an actual marriage must be proved. See Burn's Eccl. Law, vol. ii art. Marriage.

Marriage, Proof of. See the preceding article.

Marriage, Property by, is a property in goods and chattels acquired by marriage; whereby those chattels, which belonged formerly to the wife, are by act of law vested in the husband, with the same degree of property, and with the same powers, as the wife, when sole, had over them. This depends entirely on the notion of an unity of person between the husband and wife; it being held that they are one person in law; so that the being and existence of the woman is suspended during the coverture, or entirely merged or incorporated in that of the husband. (See Coverture.) Hence it follows, that whatever personal property belonged to the wife before marriage, is, by marriage, absolutely vested in the husband. In a real estate, he only gains a title to the rents and profits during coverture; for that, depending upon feodal principles, remains entire to the wife, after the death of her husband, or to her heirs, if the dies before him; unless, by the birth of a child, he becomes tenant for life by the curtesy. But, in chattel interests, the sole and absolute property vests in the husband, to be dispofed of at his pleasure, if he chuses to take possession of them; for unless he reduces them to possession, by exercising some act of ownership upon them, no property vests in him, but they shall remain to the wife, or her representatives, after the coverture is determined.

There is therefore a very consideralbe difference in the acquisition of this species of property by the husband, according to the subject matter; viz. whether it be a chattel real, or a chattel personal; and, of chattels personal, whether it be in possession, or in action only. A chattel real vests in the husband,
husband, not absolutely, but "as mode." As, in case of a lease for years, the husband shall receive all the rents and profits of it, and may, if he pleases, sell, re-suspend, or dispose of it during the coverture (Co. Litt. 46): if he be outlawed or attainted, it shall be forfeited to the king (Ploow. 263); it is liable to execution for his debts (Co. Litt. 351): and, if he survives his wife, it is to all intents and purposes his own. (Co. Litt. 350.) Yet, if he has made no disposition thereof in his life-time, and dies before his wife, he cannot dispose of it by will (Poph. 5. Co. Litt. 351: for, the husband having made no alteration in the property during his life, it never was transferred from the wife; but after his death the same remain in her absolute possession, and it shall not go to his executors. So it is also of chattels personal (or choses) in action: as debts upon bond, contracts, and the like: the husband may have if he pleases; that is, if he reduces them into possession by receiving or recovering them at law. And, upon such receipt or recovery, they are absolutely and entirely his own: and shall go to his executors or administrators, or as he shall bequeath them by will, and shall not revest in the wife. But, if he dies before he has recovered or reduced them into possession, so that at his death they still continue choses in action, they shall revest into the wife; for the husband never exerted the power he had of obtaining an exclusive property in them. (Co. Litt. 351.) And if, an estray comes into the wife's franchise, and the husband seizes it, it is absolutely his property: but, if he dies without seizing it, his executors are not now at liberty to seize it, but the wife or her heirs (Co. Litt. 351: for the husband never exerted the right he had, which right determined with the coverture. Thus in both the species of property the law is the same; in case the wife survives the husband; but, in case the husband survives the wife, the law is very different with respect to chattels real and choses in action: for he shall have the chattel real by survivorship, but not the chose in action (3 Mod. 186); except in the case of arrears of rent, due to the wife before her coverture, which, in case of her death, are given to the husband by statute 32 Hen. VIII. c. 37. And the reason for the general law is this: that the husband is in absolute possession of the chattel real during the coverture, by a kind of joint-tenancy with his wife; wherefore the law will not wrest it out of his hands, and give it to her representatives; though, in case he had died first, it would have revest to the wife, unless he thought proper in his life-time to alter the possession. But a chose in action shall not revest to him, because he never was in possession of it at all, during the coverture; and the only method he had to gain possession of it, was by being in his wife's right: but as, after her death, he cannot (as husband) bring an action in her right, because they are no longer one and the same person in law, therefore he can never (as such) recover the possession. But he still will be entitled to be her administrator; and may, in that capacity, recover such things in action as became due to her before or during the coverture.

Thus, and upon these reasons, stands the law between husband and wife, with regard to chattels real and choses in action: but as to chattels personal (or choses) in possession, which the wife hath in her own right, as ready money, jewels, household goods, and the like, the husband hath therein an immediate and absolute property, devoted to him by the marriage, not only potentially but in fact, which never can again revest in the wife or her representatives. (Co. Litt. 351.)

And, as the husband may thus generally acquire a property in all the personal subsistence of the wife, so in one particular influence the wife may acquire a property in some of her husband's goods: which shall remain to her after his death, and not go to his executors. These are called her "paraphernalia:" which see. Blackst. Com. b. ii.

**Marriage.**

Marriage of the Royal Family is excepted from the act 26 Geo. II. c. 33. (See Marriage.) But by the 12 Geo. Ill. c. 11. no defendant of his late majesty Geo. II. (other than the issue of princesse married or who may marry into foreign families) shall be capable of contracting matrimony, without the previous consent of his majesty, his heirs, &c. signified under the great seal, declared in council, and entered in the privy-council books: and every marriage of any such defendant, without such consent, shall be null and void. But in case any defendant of Geo. II., being above 25 years old, shall perill to contract a marriage disapproved of by his majesty, such defendant, after giving 12 months notice to the privy council, may contract such marriage, and the same may be duly solemnized, without the previous consent of his majesty. And such marriage shall be good except both houses of parliament shall, before the expiration of the said 12 months, declare their disapprobation of such intended marriage. And persons who shall wilfully solemnize, or affirm at the celebration of such prohibited marriage, shall, on conviction, incur the penalties of the statute of prenuptis, 16 R. ii.

**Marriage Settlement.** is a legal act, previous to marriage, whereby a jounture is secured to the wife after the death of the husband. (See Jointure.) These settlements seem to have been in use among the ancient Germans, and their kindred nation the Gauls. Of the former Tacitus gives us this account: "De dom no xuxor marito, fec xuxor maritus, affert: interfunt parentes et propinquii, et munera probant." De Mor. Germ. c. 18. And Cæsar, De Bell. Gallic. lib. vi. c. 18. has given us the terms of a marriage settlement among the Gauls, as nicely calculated as any modern jointure. "Viri, quantas pecunias ab uxoris dotis nomine acceperunt, tantes ex his bonis, afflictione facta, cum dotibus communicant. Hujus omnis pecunia conjunctum ratio habetur, fructuque fervatur. Uter eorum vita superavit, ad eum pars utriusque cum frutibus superiour temporum pervertit." The dauphin's commentator supposes that this Gaulish custom was the ground of the new regulations made by Justinian, Nov. 97, with regard to the provision for widows among the Romans; but surely there is as much reason to suppose, says judge Blackstone, that it gave the hint for our stuitable jointures. Comm. vol. ii. p. 138.

See an excellent marriage settlement by Blackstone, in the Appendix to the second volume of his Commentaries.

**Marriage.** in Socage-tenure, oronor marriage, was not any perilquisite or advantage to the guardian, but rather the reverse. For, if the guardian married his ward under the age of 14, he was bound to account to the ward for the value of the marriage, even though he took nothing for it, unless he married him to advantage. (Litt. § 125.) For the law, in favour of infants, is always jealous of guardians, and therefore in this case it made them account, not only for what they did, but also what they might, receive on the infant's behalf; but by some collusion the guardian should have received the value, and not brought it to account; but the statute (12 Car. II. c. 24.) having destroyed all values of marriages, this doctrine of course has ceased with them. At 14 years of age the ward might have disposed of himself in marriage, without any content of his guardian, till the act (26 Geo. II. c. 33.) for preventing clandestine marriages. These doctrines of wardship and marriage in socage-tenure were so diamétrically opposite to those in knight-service, and so entirely agree with those
parts of king Edward's laws, that were restored by the charter of Henry I., as might alone convince us that fiction was of a higher original than the Norman conquest. See Guardian, Scacce, and Wardship.

Marriage vow denotes the mutual promise made to one another by the husband and wife at the time of the solemnization of marriage. The husband promises on his part "to love, comfort, honour, and keep his wife;" the wife on her's "to obey, serve, love, honour, and keep her husband;" in every variety of health, fortune, and condition; and both stipulate "to forfake all others, and to keep only to one another, so long as they shall live." This promise is witnessed before God and the congregation; accompanied with prayers to Almighty God for his blessing upon it; and attended, according to the form established in this country, with such circumstances of devotion and solemnity as place the obligation of it, and the guilt of violating it, nearly upon the same foundation with that of oaths. The Christian Scriptures enjoin upon the wife, that obedience which the husband promises, and in terms so peremptory and absolute, that it seems to extend to every thing not criminal, or not entirely inconsistent with the woman's happiness. "Let the wife," says St. Paul, "be subject to her own husband in every thing." "The ornament of a meek and quiet spirit (says the apostle, speaking of the duty of wives) is in the sight of God of great price." No words ever expressed the true merit of the female character so well as these. The man who does not duly regard the end of the institution, and who is conscious at the time of his marriage, of such a dislike to the woman he is about to marry, or of such a unhallowing attachment to some other woman, that he cannot reasonably ever hope to entertain an affection for his future wife, is guilty, when he pronounces the marriage vow, of a direct and deliberate prevarication; aggravated by those ideas of religion and of the supreme being, which the place, the ritual, and the solemnity of the occasion cannot fail of suggesting. The fame is true likewise with respect to the woman. The charge, says Paley, must be imputed to all, who, from mercenary motives, marry the objects of their aversion and disgust; and like wife to those who desert, from any motive whatever, the object of their affection, and, without being able to subdue that affection, marry another. The crime of falsehood is also incurred by the man who intends, at the time of his marriage, to commence, renew, or continue a personal amour with any other woman; and if a wife be capable of so much guilt, the parity of reason extends to her. The marriage vow is violated by adultery, and also by any behaviour which, knowingly, renders the life of the other miserable; as desertion, neglect, prodigality, drunkenness, peevishness, penuriousness, jealousy, or any levity of conduct, which admiresuits occasion of jealousy. Paley's Principles of Mor. and Pol. Philos. vol. i.

Marriage, Matrimonium, in Law, signifies not only the lawful joining of man and wife, but also the right of be- lowing a ward, or widow, in marriage; as well as the land given in marriage. See Maritagnim.

Marrica, Cafe, in Geography, a cape on the S.E. coast of Arabia. N. lat. 18° 36'. E. long. 56° 25'.

Marriona, a bay of the island of Antigua; two miles S. of Willoughby bay.

Marko, a river of Naples, which runs into the sea; eight miles S. of Nicotera.

Marrquinn vulgarly Morocco leather. See Morocco.

Marrrose, in Geography, an island in the East Indian seas, near Antongil bay, the Island of Madagascar. This island affords plenty of lemons and pine apples, with an ample supply of fruit, fowls, and fresh meat.

Mark, a self euloginous substance contained in the cavities of the bones. See Bone and Medulla.

Marrows, in Agriculture, a provincial word used to signify fellows in speaking of cattle, as oxen, &c.

Marrolliastrium, in Botany. See Ballota, Leonurus, and Stachys.

Marrollium is supposed to have been so called from the ancients in its having been originally found in the neighbourhood of Marrullum, a town of the Maryians in Calyce, at the mouth of the lake Frugius. Ambrosius records various other conjectures as to the origin of this name. Some authors have supposed it derived from marre, the sea, because a native of maritime situations; some have thought it was named from its bitter properties; anaurus, bitter; and others have imagined its name to have been suggested by the withered appearance of its leaves, which seem as if they were corroded with ruff, rubigo. These ideas afford rather a presumption that nothing is really known about the matter. —Horaeound. Lin. Gen. 204. Schreb. 301. Wild. Sp. Pl. v. 1. 100. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 636. Att. Hort. Kew. ed. 2 v. 37. 402. Tournef. t. 91. Jull. 114. Lamekchart. S. 508 (Pf-udodictamn). —Tournef. t. 89. Clas and order. Didynamia Gymnoperinia. Nat. Ord. Ferticillate, Linir. Labiate, Tournef. and Julli.

Gen. Ch. Cal. Perianth inferior, of one leaf, falver-shaped, rigid, ten-frecked; its mouth equal, spreading, mostly ten-toothed; the teeth alternately smaller. Cor. of one petal, ringent; tube cylindrical; limb gaping; throat long, tubular: upper lip erect, linear, cloven, acute. lower lip reflexed, broader, cloven half way down into three segments, of which the middle one is broader and emarginate, the others acute. Stem. Filaments four, shorter than the corolla, concealed under the upper lip, two of them longer; anthers simple. Pet. German superior, four-cleft; lyle thread-shaped, in length and position like the filaments; stigma cloven. Peric. none, except the calyx, which is contracted at the neck, expanded at the mouth, including the seeds. Seeds four, rather oblong.

Obl. The following variations in the generic character of Marrullium are noticed by Linnaeus and Schreber; these authors observe that the Marrullum of Tournouf and Pseudodictamus of the same author differ from each other in this respect, the former having the upper lip of its corolla erect, and the latter vauluted. Some species of this genus have only five calyx-teeth. M. crpyum has an entire upper lip, whilft M. hipoicum has the upper lip of its corolla three or four-cleft.

A very natural division of Marrullum into two sections is afforded from the number of calyx-teeth being either five or ten. Linnaeus deferred eleven species in the fourteenth edition of his Systema Vegetabilum, and Willdenow has added three more; namely, M. creticum, which Linnaeus considered a variety of pregrinum, M. catarifolium, and bifrutum. There is also a beautiful new species in the Flora Graeca called vulpinum.

Sect. 1. Calyx with five teeth.

branched, rigid. Leaves opposite, hoary, bluntly toothed. Flowers purple, in small, loose whorls. The segments of the calyx spreading, and ending in very stiff prickles.—Linnaeus says that there are three small purple flowers on each side, and that the calyx is acute, with spreading teeth. Willdenow quotes *M. plicatum* of Forskål as a synonym of *M. Afianum*, and Vahl says it scarcely differs from it, except that the former has ten-flowered whorls, which is sometimes the case with the latter—the herbage is white with wool, and the leaves less wedge-shaped and rounder.

2. *M. africanaum*. African White-Horehound. Linn. Syst. Veg. ed. 14. 537. Jacq. t. 1. 109.—Leaves ovate, crenate, downy, very rugose. Calyx-teethawl-shaped. Upper segments of the corolla lanceolate and acute. Found at Aïr and in the East. It flowers in May.—Primary *flos* perennial, numerous, half a foot in length, branched and decumbent; from these spring other *flos* annually, which are herbarious, erect, a foot high, woolly and hoary. Leaves on stalks, wrinkled on both sides, soft and bitter, the younger ones extremely woolly. Flowers scellate, in whorls, of a beautiful blue colour.

4. *M. Creteum*. Cretan White-Horehound. Willd. n. 4. Sm. Prod. Fl. Græc. p. 2. 412. Daelch. Hist. 662.—Leaves lanceolate, whitish, rugosely veined, toothed at the top. Calyx-leaves bristle-shaped. Stem branched, divaricated.—A native of the Levant, flowering from July to September.—Linnaeus considered this species most, as a variety of the last, calling it *M. percgrinum* 3, and professor Martyn has done the same. We are however inclined to follow Dr. Smith in considering it as a distinct species. Stems slender, hoary, near three feet high. Leaves very hoary, much longer and narrower than those of the preceding; the *flos* of flowers are smaller; and the bristles indument of the calyx longer and crenate. The whole plant has an agreeable flavour.

7. *M. catviufidum*. Cat-Mint White Horehound. Willd. Sp. Pl. v. 3. 110. Lamarck Dict. v. 3. 771. (M. orientale catariæ folio flore albo; Tourn. Cor. 12.)—Leaves...
14. *M. Pseudo-Diathamus*. Shrubby White Horehound. Linn. Sp. 817. (Pseudo-Diathamus; Dod. Pempt. 281.) — Calyx-border flat and hairy. Leaves heart-shaped, concave. Stem shrubby. A native of the island of Crete. Found also by Dr. Sibthorp in other islands of the Archipelago.—It flowers from June to August. —Stems two or three feet high, divided into many branches. Leaves small, growing very close to the flanks. Flowers whorled, of a white colour; whorls resembling those of *M. crispum*, but not so large. The whole plant very hoary, covered with a soft and dense compact cottony subfluence. —This species is the *Diathamus* of Dioscorides, and is called in English the false Dittany of Crete, from its general resemblance to *Origanum Diathamus*.

15. *M. acutabuliferum*. Saucer-like White Horehound. Linn. Sp. Pl. 817. (Diathamus falso verticillatus, petrcarpio conoide, heticus; Barrel. It. t. 129.) — Calyx-border longer than the tube, membranaceous, the greater angles rounded. —A native of Crete, introduced by Sir George Wheeler into this country in 1767. —Its time of flowering exactly coincides with the lark. —Stems about two feet high, hairy. Leaves heart-shaped, serrated, rough on their upper side, downy beneath. Flowers small, of a pale purple, in large whorls. —Dr. Sibthorp found this species in Crete, but not in any other of the Grecian islands. It was known to Dioscorides, who called it *Ethere ac to κρίνη διατάμους*.

The genus now described is composed of many curious and interesting species to the botanist, though only a few of them find a place in our gardens. Those which are cultivated as shrubs, especially the two last, from the hoariness of their foliage, make a pretty variety when intermixed with other plants. — *M. velutinum*, which is one day to appear in the *Flora Graeca*, is entirely new, and we have adopted it from the Prodromus to that work.

**Marrubium**, in *Gardening*, comprises plants of the shrubby kind, of which the species cultivated are, the shrubby white horehound (*M. Pseudo-Diathamus*); and the saucer-leaved white horehound (*M. acutabuliferum*).

**Method of Culture** — These sorts of plants are capable of being increased by planting cuttings of the young shoots or branches in a shady border in the early spring, as about April. When the plants are well rooted, they may be removed into the places where they are to grow; when they grow strongly, they should be fenced from hard frosts in winter.

They continue the longest in poor dry soils, from their having a less luxuriant growth in such cafes.

These plants afford variety in the borders, clumps, &c. of pleasure-grounds, and other situations.

**Marrubium**, in *Ancient Geography*, a town of Italy, and capital of the Maris; seated on the E. bank of the lake Fusinus. The inhabitants of this town, as well as the Marsi, in general, were famous for disdaining and healing the bites of serpents, and for being excellent swimmers. Its ruins at St. Benedetto, present to the investigation of the curious an arena, and traces of the circuit of a spacious amphitheatre.

**Marrucini**, in *Ancient Geography*, a people of Italy, in the Adriatic gulf, between the Veltini and the Frentani. Their country was watered by the Aternum. In their origin they were Sabines. Their principal town was T cape, seated on a mountain.

**Mars**, in *Astronomy*, one of the primary planets in our solar system; its orbit is situated between those of the Earth and Jupiter. It evidently owes its name to its fiery appearance, which is fupposed, with much probability, to be derived from its own atmosphere, the existence of which is indicated with more certainty than in any other planet.

Besides the reddish colour of Mars, we have another argument of his being encompassed with an atmosphere; and it is this: that, when any of the fixed stars are seen near his body, they appear extremely obscured, and almost extinct. This is the effect of the atmosphere. If this be the case, an eye placed in Mars would fearlessly see Mercury, unless, perhaps, in the sun at the time of conjunction, when Mercury passes over his disk, as he sometimes appears to us, in form of a spot. A spectator in Mars will see Venus about the same distance from the sun as Mercury appears to us; and the Earth as big as Venus appears to us, and never above 48 degrees from the sun: and when the Earth is found in conjunction with, and very near the sun, he will see the Earth appear hoary, or falcated, and its attendant the moon of the same figure, and, at its utmost distance from the Earth, not above 15 minutes of a degree, though they are really two hundred and forty thousand miles aunder. This planet being but a fifth part so big as the Earth, if any moon attends him, she must be very small, and has not yet been discovered by our best telescopes.

The telescopic appearance of Mars is very variable; but the predominant brightness of the polar regions leads to the supposition that its poles, like those of the Earth, are covered with perpetual snow; and Dr. Herschel imagines that the changes in brightness are connected with the summer and winter feasons on that planet. In the year 1784, he published in the Philosophical Transactions, vol. lxxiv., an account of a very laborious investigation of all the circumstances relating to the telescopic phenomena of this planet, and concludes by giving the following refult:

1. The axis of Mars is inclined to the ecliptic 59° 42'.
2. The node of its axis is in 17° 47' of Pices.
3. The obliquity of the ecliptic on the globe of Mars is 28° 42'.
4. The point Artes of the ecliptic of Mars answers to our 19° 28' of Sagittarius.
5. The figure of Mars is that of an oblate spheroid, whose equatorial diameter is to the polar one as 1355 to 1272, or as 16 to 15 nearly.
6. The equatorial diameter of Mars reduced to the mean distance of the earth from the sun, is 9° 8'.
M A R S.

grade, increasing in velocity till the moment of opposition of the planet with the sun.

This velocity then becomes a maximum, diminishes and again becomes nothing when Mars approaching the sun is distant from it 136° 48'. Its motion then becomes again direct, after having been retrograde during 73 days, and in this interval the planet describes an arc of retrogradation of about 16° 12'. Continuing to approach the sun, it finishes by immersing in the evening its rays. These singular phenomena are renewed at every opposition of Mars, but with a considerable difference as to the extent and duration of these retrogradations.

Mars does not move exactly in the plane of the ecliptic, but deviates occasionally several degrees. The variations in its apparent diameter are very great. It is about 10' in its mean latitude, and augments to 26' as the planet approaches its opposition. At this time the parallax of Mars becomes sensible, and is nearly double that of the sun. The fame law which exists between the parallaxes of the sun and Venus, exists likewise between the sun and Mars, and the observation of this last parallax had given a very near approximation of the solar parallax before the transit of Venus had ascertained it with greater precision.

The diff of Mars changes its form, and becomes sensibly oval according to the relative position of the sun. These phases shew that it is from the sun it receives its light. From the observation of spots distinctly seen on its surface, it is inferred that it moves on itself from west to east, in a period of 1° 44' 45". From observations made by Dr. Herchel in 1779, he concludes that the sidereal revolution of Mars cannot well be less than 24° 39' 5", nor more than 24° 39' 22".

The mean diameter of Mars is about 4000 miles, or nearly half that of the earth.

Its character is 5°. Its mean distance from the sun is 1,523,500 of those parts; whereas the distance of the sun from the earth is 1,000,000; and its eccentricity 14,418, and its real distance 145,044,148 miles; its mean distance from the sun in semi-diameters of the earth 36,162; the periodical time, in which it makes its revolutions round the sun, is 686 days 23' hours; which is the length of his year, and contains 667 1/4 of his days; every day and night together being 40 minutes longer than with us; and its revolution about its own axis is performed in 24 hours 40 minutes nearly. Its proportion of light, that of the earth being 1, is 7/4; proportion of bulk, that of the sun being 1,380,000, is 2 1/4; and of density, that of the sun being 2/3, is 1/4.

In the aconical rising of this planet, that is, when it is in opposition to the sun, it is found five times nearer to us than when in conjunction with him; and, therefore, he appears so much bigger and brighter at one time than another.

Mars, having his light from the sun, and revolving round it, has an increase and decrease like the moon: it may also be observed almost biflected, when its quadratures with the sun, or in his perigeeon; but never is seen corniculated, or falcated, as the inferior planets; which both shews that his orbit includes the earth's within it, and that he shines not by his own light. The phases of Mars were first discovered by Galileo.

This planet's distance from the sun is to the distance of the earth and sun, as 1 1/2 to 1; so that a man, placed in Mars, would see the sun's diameter less by one-third than it appears to us; and, consequently, the degree of light and heat, which Mars receives from the sun, is less than that received by the earth, in the proportion of 4 to 9. This proportion, however, will admit of a sensible variation, on account of the great eccentricity of this planet.

For the other elements of the orbit of this planet, the reader is referred to the article Planet.

Sig. XI. +  Sig. X. +  Sig. IX. +  Sig. V. +  Sig. IV. +  Sig. III. +  Sig. II. —  Diff.  Log.  Degrees.
Mars, among the Ancients, signifies iron; because imagined to be under the influence of that planet. See Iron.

Mars, Saccularis. See Iron.

Mars Sulphuratus. See Iron.

Mars, called Arès by the Greeks, in Mythology, the god of war, the son of Jupiter and Juno, according to Homer and the other Greek poets, or, as Ovid tells the story, of Jupitor alone; the being displeased that Jupiter should have a daughter Minerva, without female aid: being therefore a god of discontent, he was made the god of war and strife.

He had a father called Bellona, the goddess of war.

Among the ancients, there were several princes of this name. The first, to whom Diodorus attributes the invention of arms, and the art of marshalling troops in battle, was the Boles, whom the scripture calls Nimrod, the mighty hunter (Gen. v.), who, after having practised his skill upon wild beasts, turned it against men; and having subdued a great number of them, declared himself their king. The second Mars was an ancient king of Egypt. The third was king of Thrace, called Odin, distinguished by his valour and conquests, and promoted to the honour of god of war, and called the Hyperborean Mars. The fourth is called the Mars of Greece, named Arès. The fifth, and last, is the Mars of the Latins, who entered into the prison of Rhea Sylvia, and begat upon her Romulus and Remus. In fine, the name of Mars was given to most warlike princes, and every country valued itself on having one, as well as a Hercules. Accordingly we find one among the Gauls under the name of Hefus; and there, as in Lucian and Laërtius, that these ancient people sacrificed to him human victims. We find a Mars also among the Scythians. The Greeks threw into the history of their Mars the adventures of all that have been named. Arminius represents the Mars of Greece as merely a deified man.

Although Mars was worshipped in several places, yet he was not, where in such high veneration as at Rome, where he had several temples; among which, that dedicated to him by Augustus after the battle of Philippi, under the name of Mars the Avenger, was one of the most celebrated.

He had for his priests the fides and flamines, who from him were called Martiales. They sacrificed affes to him, on account of the larish diaphance of their voice. The vulture was a bird favored to him, from their always flying to the places where armies are going to engage, and bloodshed is to be expected. The usual at ributes of Mars are the helmet and spear, which he does not lay aside, even when he is going on his amours. Several of the old Roman poets of the fifth age speak of a wife of Mars, called Nerinea, signifying, according to some, mildness, and given to him in order to soften and humanize the roughness of his temper; but we find no traces of her in their later poets. The temples of Mars were of the Doric order, and usually placed without the walls; hereby denoting that this deity was to prefere the walls from the perils of war.

Mars, Games of, ludi Martiales, were combats instituted at Rome in honour of the old Mars.

They were held twice in the year; once in the Circus, on the fourth of the ides of May; and a second time on the fifth of August. These latter were established some time after the other, in memory of the dedication of the temple of Mars on that day. These games concluded in courtes of horses, and combats with wild beasts. Germanicus is said to have killed two hundred lions in the Circus, on these occasions. See Field of Mars.
the anthers upon the filaments in pairs, erect, flicking by
their base. *Phl.* Germain two, superior, ovate; styles
combined, very short; stigmas single, generally simple, at
sometimes beaked, the beard either simple or divided. *Peric.*
Follicles two, ovate-oblong, smooth. Seeds numerous, im-
bricated, confoe.

ECT. *Corolla* nearly wheel-shaped, five-crested. Crown
of the filaments of five compressed undivided leaves, without
teeth. Anthers terminated by a membrane; masses of pollen

The stem in this genus is rather shrubby, generally twing-
ing, round, scarcely angular. Leaves opposite, stalked,
broader, flat. Cymes or tufts lateral, between the foot-
stalks. It is very nearly related to *Pergularia* from which,
according to Mr. Brown himself, it differs merely in the
want of a tooth, or appendage, at the inside of each leaf
of the crown. There appears however to be more of a tube
in *Pergularia*, the corolla of which is truly salver-shaped.

Eight species are described by the author of the genus.

1. *M. violacea.* Soft-leaved Marfdenia. —Stem twining,
Leaves heart-shaped, broadly ovate, pointed, downy and
soft. Cymes umbel-shaped. Mouth of the flower naked.
—Gathered by Mr. Brown in the tropical part of New
Holland.

2. *M. timidaria.* Indigo Marfdenia. (Tarram akkar, ;
Mar. Smaragd 73.) —Stem twining. Leaves heart-shaped,
ove-oblong, pointed, nearly smooth, glandular in their foro-
part. Tufts lateral. Mouth of the flower bearded. —Native
of Sumatra. Seen by Mr. Brown in the Banyan herba-
nium. This plant is said to afford the best indigo in Suma-
tra, and as Mr. Marfden appears to be the first person who
has given any account of it, there is more propriety in
its bearing his name. For the indigo in general use, see IN-
DIGO and INDIGOBE.

3. *M. viridis.* Green-flowered Marfdenia. —Stem
twining. Leaves oblong-lanceolate, smooth, obtuse at the
base. Tube of the flower slightly hairy within.—
Gathered by Mr. Brown in New Holland, within the
 tropic.

Leaves lanceolate, acute at each end, smooth: slightly ru-
gose on the upper side. Mouth of the flower densely
bearded. —Gathered in Jamaica, by professor Swartz, who
gave it to Dr. Joseph Banks, but does not appear to have
mentioned it in any of his works. —Stem twining. Leaves
Heart-shaped. Marfdenia. —Stem nearly erect. Leaves ovate-lanceolate, smooth, velutine. Tube of the flower
celling; mouth bearded. —Native of New South Wales,
about Port Jackson, where it was gathered by
Mr. Brown, as well as by Dr. White. The character of the
tube in this species seems, in that respect, to invalidate
the above-mentioned distinction between Marfdenia and
Pergularia.

5. *M. crenascens.* All-coloured Marfdenia. —Stem eredt.
Leaves oval, bluish, veiny, slightly downy. Footstalks
half an inch long. Corolla nearly wheel-shaped. —Found
by Mr. Brown in the tropical part of New Holland.

All the above have a simple pointless stigma, and are con-
Cidered by the author just mentioned as the most true and
genuine Marfdenia. The two following have a beaked
stigma.

above. (Cynanchum ceraea; Lam. Sp. Pl. 311. Willd.
Apocynum primum latifolium; Cels. Flora Pl. x. 1. 124. Per-
plecton latifolium; Ger. Em. 602.) —Stem erect. Leaves
heart-shaped, ovate, acute. Cymes umbell-like. Segments
of the limb bearded, four times as long as the tube.—
Native of Syria. Gerarde had it in his garden, having re-
ceived it, as he informs us, from his loving friend John
Robin, herbarist in Paris. (See ROBINIA.) It is marked
by Mr. Aiton as a flower plant. Jacquin says it requires
the shelter of a greenhouse at Vienna in winter, but flowers
in the open ground in June and July, though without bearing fruit.
This is a smooth, upright, but weak, *frub,* irregularly
branched, five or six feet high, with plant leafy twigs,
nowadispofed to twine round their neighbours. When
wounded they are, according to Jacquin, not milky. Leaves
imperfectly opposite, heart-shaped, acute, entire, glaucous,
milky, an inch and half long, and an inch wide, on round
footstalks half an inch in length. Cymes lateral, of numerous,
white, fragrant flowers, smaller than Hawthorn blossoms.

8. *M. rostrata.* Beaked Twining Marfdenia. —Stem
twining. Leaves ovate, somewhat heart-shaped, pointed,
smooth. Umbels many-flowered. Limb bearded. —
Gathered by Mr. Brown in New South Wales. This species
is said in his *Prodras** to differ from its congener, in
having the masses of pollen kidney-shaped, and somewhat
transferc, flicking upon the extremity of the stigma, at
some distance from its glandular part. Hence the name
*Nephrendra* (from *nepheles,* the kidney, and *randa,* a man), al-
luding to the form of the impregnating substance, is sug-
ferred. It is that work, apparently with the other dominions
of the plant's possibly combining genus by itself.

MAKESVILLE, in Geography, a town of France, in the
department of the Oise, and chief place of a canton, in the
district of Beauvais, 11 miles N.W. of Beauvais. The
place contains 7000, and the canton 10,838 inhabitants,
on a territory of 155 kilometres, in 18 commune.

MARSEILLES, a city of France, and principal place of a
district, in the department of the Bouches du Rhone,
and near the coast of the Mediterranean. For an account
of its foundation and ancient flate, see MASSILLA. This ancient
city was for a long time an independent commercial republic,
till at length, in the progress of the Roman conquests in
Gaul, it was subdued by their arms; and under their govern-
ment, it flourished in commerce, arts, and elegant literature.
However, its opulence and glory perished in the common
ruin of the Roman empire. The advantages of its situa-
tion at the foot of a rocky mountain, near the sea, caused
it's trade to revive, even in the ages of Gothic barbarism;
nevertheless it languished under the government of the counts
of Provence. Since its union with the other dominions
of the kings of France, Marailles has enjoyed a distinct
municipal government and jurisdiction, under magistrates
elected by the citizens. The duties which it formerly paid
for the support of the French government were imposed by
the king's edicts, and amounted to nearly one-third of the whole
revenue paid by Provence. Marailles is divided into the
Old and New Town; the former lies on an eminence, confis-
t of narrow crooked streets with mean houses, and is inhabited
chiefly by fishermen and other poor people; the public
streets are apprisos and extensive, and the houses regularly
built, elegant and commodious, which are occupied by opu-
ulent families, and by thriving merchants, tradesmen, and
manufacturers. The port exhibits a noble spectacle of
commercial industry, and the quay, in its prospers flate,
crowded with a busy multitude, consisting of people of
all nations and languages; the neighbouring territory is
thickset with villas belonging to the wealthy inhabitants of
the city; its trade extended to various parts of the globe,
and its manufactures were various and extensive.

Before the revolution, this city was the residence of a
bailiwick, and the see of a bishop; it had also four parish
churches,
churches, including the cathedral, and two collegiate ones, with two abbeys, an academy of the fine arts, an observatory, and a mintage. Its arsenal was floored with all implements necessary for fitting out the galleys; its armoury, co-rolling of four walks intermixing another, was reckoned the smell in the kingdom, and contained arms for 40,000 men. In the arsenal is a dock for building the galleys, which, being roofed over, and communicating with the harbour, is of a parallelogrammic form, having public and private buildings on the two long sides, and on one of the shorter, the other side affording an opening into the Mediterranean, and being defended on each point by a strong fort. The entrance into the harbour is rendered difficult by a rocky cape that is contiguous, nor has it depth of water sufficient for men of war. This port was frequented, before the revolution, by upwards of 4500 vessels in the course of a year. The number of inhabitants in the city, is reckoned at 111,150, and in the canton 115,394, on a territory of 310,000, in two communes. N. lat. 43° 17′ 44″. E. long. 5° 22′ 12″.

MARSH, in Agriculture, a term applied to a tract of land lying on the borders of the sea, or any large river into which it flows. These tracts of land are mostly level, and converted to the purposes of grazing either with sheep or other animals. And in some districts, lands of this nature are subdivided or distinguished into two kinds, salt marshes and fresh marshes. The former are sometimes simply termed saltfats or saltings. They are the parts or portions of marsh grounds, which lie without the walls or embankments where such defences exit.

Marshes are for the most part of a rich deep alluvial nature in the qualities of their soils.

It is flated by the author of the Synopsis of Husbandry, in speaking of the marshes in the southern parts of the illand, that they are subject to be overflowed at every spring tide, or at other times, when, by the violence of the wind, or the impetuosity of the tide, the water flows beyond its usual limits. "The goodness of the falls is in a great measure analogous to the fertility of the adjoining marshes; and the extent of them differs according to the situation, as in some places the tide beats directly against the wall, whilst in others the falls or forelands are of a considerable breadth." It is likewise added, that "in some places the grass from falls is annually mown, and yields a short, delicate hay, that proves a very fabulous provender for sheep; but care must be taken to prevent its being carried off by the tide, for which reason it is often found necessary to bring it into the inclosures for making." It is added, that "these salt marshes are very efficacious in relieving many complaints incident to cattle, and are likewise useful in furnishing a considerable range for young sheep. In feeding them, however, some caution is to be used, and it will be necessary to remove the flock over the wall on the apprehension of a high tide, but more especially on the approach of spring tides, when the falls are usually overflowed. As the return of these latter is periodical, and a high tide may generally be before seen by those who are conversant in these matters, it rarely happens that any mischief ensues when there is no breach made in the wall; though there have been instances where sheep have been drowned on the falls, from a sudden and unexpected high tide, and others, where this misfortune has been the consequence of neglect, in not bringing the flock over the wall; or, as it is termed by the graziers, locking them on such occasions."

But the latter are those tracts of land that lie within the wall, and are very extensive in many parts of the kingdom. It is observed in the work just mentioned, that "Romney marsh is by far the most extensive, and withal the most fertile of any level which comes under this denomination, It contains near 25,000 acres; besides which are Walland marsh and Dingle marsh, which are comprised within the walls, the former 13,000, and the latter 6,000 acres." And it is stated, that "the internal regulations of these marshes are committed to the superintendence of expeditors. These are appointed by the Commissioners of Sewers, and are to take care that the repairs of the walls are maintained in due order, and that the coasts attending the same be levied on each tenant, according to the number of acres occupied by him; for which purpose they are to make advertisements to be made out, with the names of the occupiers, and the rateable proportions to be borne by them respectively; and these rates, which must be confirmed by the commissioners, are termed scotis; and that when any occupier refuses to pay his foot, the expeditors can obtain a warrant from the commissioners empowering him to drain the same, as for any other tax." These marshes are both appropriated to the purpoices of breeding and feeding. Besides these marshes, there are vast tracts of them in various other parts of the kingdom. See Grazing.

It is further suggested by the writer just noticed, that "the naked and exposed situations of marshes render them excessively cold in the winter, and no less sultry in the summer. The inconvenience of the parching heat of the sun in the summer months. To guard against these two extremes, it is granted, perhaps, be no unprofitable undertaking to form plantations of trees in different parts, which would operate as well for a shade against the sun's rays, as a defence to break off the winter blasts. Many trees might be fixed on for this purpose, which, delighting in a moist situation, seem to be peculiarly adapted to this use. Of this kind are the elder, the fycamore, the willow, and the poplar. Clumps of one or other of these trees being planted in different parts, would, it is supposed, be found very beneficial, and completely answer the purposes before mentioned. To every one who hath been conversant in husbandry, it is evident that the sway of cattle of every kind fly to the shade in the summer season; at which time they will even neglect their food to avoid the searing heat of the sun, and the more intolerable things of the insect tribe; so that in the middle of a summer's day, it is in vain to search for a flock of sheep in the uplands. At that time the hedges afford them a secure asylum; but in marshes, where this protection is wanting, it lurchly would be the trial to set about raising a shelter, which may answer in some respects the purpoises of hedges in inclosures. Besides, as these aquatics are all of them quick in forming their shoots, a few years, in a soil prepuptum to their growth, will furnish a constant supply of poles adapted to cutting into rails, for which there is always a perpetual demand, and which will be no inconsiderable saving, not only in the original purchase of these articles, but in the carriage or conveyance of them likewise."

And it is asserted that "great profit is made by the renters of marshes in the neighbourhood of London bordering on the Thames, from justing of horses, the pasture beinglickly accounted valuable to that useful animal; for which reason, such horses as have been worn down by hard travel, or long afflicted with the farcy, lamenesses, &c. have frequently been restored to their pristine health and vigour, by a few months run in the marshes, especially on the saltings; but as every piece of marsh land in some measure participates of this salient disposition, so do they all of them supply, in a comparative degree, the virtues above-mentioned; and for this reason the Londoners are happy to procure a
run for their horses, at four or five shillings per week." And "another method practised by the graziers in the vicinity of London is, to purchase sheep or bullocks in Smithfield at a hanging market, which being turned into the marshes, in the lapse of a few weeks, are not only much improved in flesh, but go off at a time when the markets, being less crowded, have considerably advanced in price; and thus a two-fold gain is made from this traffic; and as many of the wealthy butchers of the metropolis are possessed of a tract of such marsh land, they have, from their constant attendance at Smithfield, a perfect knowledge of the rise and fall in the markets, and consequently are enabled to judge with certainty, when will be the proper time to buy in their stock, and at what period to dispose of them." These advantageous modes of traffic are confined solely to those graziers who reside in the vicinity of London. "In the Isle of Sheppey, where they proceed on different principles, the graziers never wish to depasture any horses; this animal being thought by them to do much injury to the marshes, especially in wet seasons, by trampling with his feet, and is moreover very apt to wash through the ditches, and to break down the dry fences. These arguments sufficiently cogent to induce those graziers to reject the pasturing of horses; whilst those who reside in the vicinity of the metropolis, where the weekly pay is larger, and they depend greatly on this method, are justified in adhering to a custom which they find turns out so confiderably to their profit and advantage."

In many districts of the island that are situated on the borders of the sea, or near the mouths of large rivers, there are very extensive tracts of this description of land, which by proper drainage and inclosure may be rendered highly valuable and productive. This is particularly the case in Somersetshire and Lincolnshire, as well as that mentioned above, and others more to the north of the kingdom. In the former of these counties, vast improvements have, according to Mr. Billingley, as stated in his Survey, been effected by the cutting rhymes and ditches, for the purpose of dividing the property, and the deepening of the general outlets, to discharge the superfluous water. Many thousand acres which were formerly overflowed for months together, and consequently of little or no value, are now become fine grazing and dairy lands.

The quantity that has been thus improved under the authority of parliament on Brent marsh, within these twenty years, is thus stated:

<table>

17,400

And that of these 17,400 acres, six parts of seven are cleared of stagnant water, and rendered highly productive; while the turf-bogs have been little improved. It is likewise added, that in the parish of Mark alone, 10,000 sheep have been rolled in one year, before the inclosing and draining were attempted.

And the same writer states, that the probable expense and subsequent improvement of the complete drainage of the above-named marsh and the river Axe, would stand thus:

To balance of profit                              | 24,406|

§ 331,844

356,230

Cr.

By 9000 acres of turf-bog improved at the most moderate computation 15/- per acre, making £750l. per annum, twenty-five years purchase | 168,750|

By 15,000 acres of marsh flooded land 10/- per acre, or 750l. per annum, twenty-five years purchase | 187,500|

356,230

The view and statements which are here given fully shew the vast benefits that may be derived to individuals as well as the nation at large, by improving lands of the marsh kind by judicious draining, embanking, and other means. Yet, notwithstanding this, immense tracts of ground of this sort remain without improvement, and of course of very little value.

Marsh Land, a fort of rich pasture or grazing ground lying near the sea, or large rivers. In some places it is termed fen, but very improperly. See Fen.

Where marsh land lies flat, it is necessary for the owner to keep all the water he can from it. The sea-water in particular is to be kept from it as much as possibly; and this is usually done at a very great expense, by high banks and walls. There are two things greatly wanting in these lands, in general, which are good shelter for the cattle, and fresh water. The careful farmer may, however, in a great measure obviate these by digging, in proper places, large ponds to receive the water, and by planting trees and hedges in certain places towards the sea, where they may not only afford shelter for the cattle, but keep off the sea breezes, which will often cut off the tops of all the grass in these places, and make it look as if mown with a scythe.

Experience hath shewn, that these forts of lands fatten cattle the fooner of any, and that they preferve sheep from the rot. It would be of great advantage to them, if there were
were raised, in the middle of every large marsh, banks of earth in a crescent, or in the form of two semicircles, and these planted with trees; these would serve as a shelter for cattle, let the wind blow from what quarter it would, and would soon repay the expense of making the improvement.

In different parts of the kingdom there are very large quantities of land upon the sea-coasts that would be worth taking in, though little has yet been done in that way. The coasts about Bolton, Spalding, and many other parts of Lincolnshire, give frequent instances of this, where the sea falls from the land, so that on the outside of the sea walls, on the owest, where every tide the salt water comes, there grows a great deal of good grass, and the owest is firm to ride upon when the water is upon it. This owest, when taken, hardly links anything at all, and they dig the walls from the outside of it, all the earth they are made of being taken thence, the sea, in a few tides, filling it up again; and though the sea, at high water, comes only to the foot of the bank, yet once in a year or two, some extraordinary tide goes over the banks, though they are ten feet high. These banks are fifty feet broad at the bottom, and three feet at the top; the earth being all carried in wheelbarrows, and the face towards the sea, where the greatest slope is turfed.

In speaking of the Romney marsh lands, Mr. Bennell states, that "the natural situation of marsh land, so much beneath the surface of the uplands, renders it subject to be frequently covered with water in the winter time; and as this circumstance proves highly detrimental to the land, by protracting the growth of the grass, and in causing it to be four and ill-tailed, no pains should be spared to refit the calamity, as well by keeping the ditches sufficiently cleansed, as by cutting drains in different parts of the marsh to carry off the superfluous water."

And also, "as the gate-ways in the marshes are apt to be very miry in the winter season, care should be taken to heighten the ground with bones, gravel, or chalk, which will render these passages much more comfortable to the drivers, no less than to the flock, especially milch cows, which being brought twice a day into the yard, would, but for this precaution, cause the gate-ways to be impervious in wet weather."

Besides, "when the summer turns out moist and growing, the herbage often shoots faster than the flock can eat it down. In this case it is common to brush over the marshes at the mowing season, though they had not originally had in for that purpose; by which economy the farmer becomes possessed of a much larger portion of hay than he had before formed an expectation of, and which, in counties where this commodity fetches a good price, is an advantage whereof he has a right to avail himself; for these casual brushings may probably furnish him with a quantity of winter provender, sufficient to his own use; whilst those marshes which were primarily intended to be mown, and have been designedly laid in with that view, will produce a commodity of a better quality and more saleable, that may be disposed of at market. Thse graziers, on the contrary, who live at a distance from the market, and are on account of their local situation obliged to pay larger wages to their workmen, flight the opportunity of increasing their flock of hay; and in cafés where the humidity of the summer hath rendered it necessary to mow the bullock pastures, in order that the succeeding shoot of grass may be more sweet and toothsome, have made a free gift of the same to those who have engaged to clear it off the ground." On the removal of this old grass, the ground is left at liberty to send forth a more vigorous shoot in the autumn, so that these roues at that time produce a sweet and wholesome pasturage, which would otherwise have been choked up with the rotten tore of the last year; yet there are cafes where it may be necessary to suffer this old grass to remain on the ground, as where a portion of food is required for the cows or other horned beasts in the winter. Then this old tore, having been sweetened by the frosts, will be found exceedingly useful, and the cattle will at that time greedily devour, what in the summer months they turned from with disgust and indifferenence.

This fort of management is only required in particular cafes; in others the grass never becomes coarse and rank, but, on the contrary, remains close and fine in the marlhy pastures.

Marsh Malloy, in Botany. See Althea.
Marsh Trifolium. See Menthae.
Marsh Nicholas, in Biography, was born at Hambington, in Wiltshire, in the year 1638. He finished his education at Magdalen college, Oxford, where he took the degree of B. A. in 1657. In the following year he was elected fellow of Exeter college, and proceeded as a member of that college M. A. in 1658, D. D. in 1671. During these periods he was made chaplain to Dr. Ward, bishop of Exeter, and afterwards to the earl of Clarendon, lord chancellor. He obtained some other preferment, and in 1678 he was nominated to the vacant provostship of Dublin college, where he discharged the duties of his high trust with such fidelity and regularity, that his conduct has been held up as a pattern to all his successors. In 1682-3, he was promoted to the fees of Leighlin and Ferns, and in 1690 he was translated to the archbishopric of Cashel, from thence to Dublin, and from Dublin to Armagh. While he filled the fee of Dublin, he built a noble library, which he enlarged after he became primate, and furnished with a choice collection of books. He endowed an hospital at Drogheda for the reception of twelve widows of decayed clergymen, to each of whom he assigned an apartment, and twenty pounds a year for maintenance. He extended his bounty to the encouragement of the propagation of the Gospels, and to other munificent and charitable institutions; presenting a number of oriental MSS. to the Bodleian library at Oxford. After having lived many years in great honour and reputation, and been seven times appointed one of the lords-justices of Ireland, he died, in the 75th year of his age, in 1713. He was a man of extensive and deep learning; and in his personal character he was pious, amiable, and exemplary. As an author, his principal piece was "An introductory Essay to the Doctrine of Sounds," containing some proposals for the improvement of Acoustics, printed in the Philosophical Transactions of the Royal Society of London. Biog. Brit.

Marsh Cape, in Geography, a cape on the south coast of New Georgia. S. lat. 9° 21'. E. long. 150° 56'.

Marsh Creek, a river of North America, which runs through Malden township, in Upper Canada, and discharges itself into Lake Erie.

Marsh's Island, the largest of a group of 13 islands at the Great Falls in Penobscot river, all lying within seven miles of one another. Marsh's island is about five miles long and two and a half wide, and estimated to contain about 5000 acres. Round this island are five falls, one of which is distinguished by the name of "The Great Falls," or "Old Town Falls."

Marsh-Effluvia, or Miasma, in Medicine. See Effluvia and Miasma.
Marsh Fever, the fever occasioned by respiring the miasms, which exhale from swampy ground. This is various under the different circumstances which produce it; but it is always a fever of paroxysms, occurring at regular intervals. In temperate climates and cool seisons, it is an intermittent, or ague; in warm countries, in hot autumnal weather, it is a remittent, of tedious and difficult cure; and in the hot seasons of hot climates, it is the bilious remittent, or yellow fever, so fatal to strangers recently arrived from colder latitudes. In an able treatise on yellow fever, lately published by Dr. Bancroft, (in 1810,) it is satisfactorily shewn, that these different forms of fever are the offspring of the same caufe; and that in proportion to the heat of the climate and season, to the comparative cold of the climate from which the patient has come, or of the season which has preceded, to the concentrated state of the miasmata, and to the full exposure which has been undergone, in the same proportion will the fever commence more rapidly, be more violent in its attack, and more rapid and dangerous in its course, and from these circumstances alone, all the varieties of periodic fevers, from the yellow fever, which commences within twelve hours, to the mild avernal eagle, which lies dormant from autumn to the ensuing spring, are produced. See EEFUVIA, HEAT, MIASSA, REMITTENT.

MARSH LANDERS, in Rural Economy, a term provincially applied to neat cattle of the short-horned breed, or such as are bred on lands of the marsh kind, in different places.

MARSHAL, or MARSECHAL, MARESCALLUS, primarily denotes an officer, who has the care or the command of horses.

Nicer derives the word from polearnenus, master of the camp; Matthew Paris from Martis fennecalus. In the old Gaulish language, march signified herd; whence marsecal might signify him who commanded the cavalry. Specman, Skinner, and Menage, derive it from the German mar, marre, a mare, or even, borse, and schar, scharre, which makes some impropriety, the title being first given to barons, or those who had and bred horses; and that, in face of the time, it passed to those who commanded them. Palmer makes four several derivations for the four several kinds of marshals in use among the French; viz. marshals of France, marshals of camp, marshals of logs, or quarter-masters, and farriers, who are also called by the name of marshals. The third he derives from marche, or marchir, to mark, limit; and the last from mair, mazer, and chal, borse.

That the marshal was an officer of considerable note in Germany, France, and elsewhere, must incontrovertibly be acknowledged; but the exact time of the first institution of his office cannot now be so well ascertained. At first, the marshal or marsecallus was, probably, an officer of inferior rank, to whose direction and management sovereign princes committed the care of their horses. Some have supposed the marsecallus and the "Comes Stabuli" to have been the same officer under different titles; whilst others, allowing the functions of these officers to have been originally different, contend that they were united in, and for a long time after, their institution continued to be exercised by, one and the same person. This contrariety of opinion seems to have arisen from confounding the officers of the Western empire in its early state with those established in it at a subseuent period, as well as with those of France, Italy, and of the Eastern empire. In the early times of the Western empire, whilst the "Comes Stabuli" remained a mere officer of the household, and uninvited with a military employment, no mention of a marsecallus occurs among the officers of the crown. In those times the "Marecallus" were only ministerial to the "Comes Stabuli," and the same difference subsisted between them as between ordinary servants and their masters. The "Comes Stabuli" was a high officer of the emperor, who appointed him to that office, and committed to him the superintendence of the imperial stables and fluid; whereas the "Marecallus" were persons acting under him in a servile situation, and employed in dreesing, feeding, and training a limited number of the emperor's horses. Afterwards the promotion of the "Comes Stabuli" to the military dignity of commander-in-chief of the army, opened the way for the "Marecallus" to emerge out of their obscurity, and to rise to a more exalted station than they had before enjoyed; for on account of their skill in the several branches of horsemanship and the management of cavalry, the "Comes Stabuli" selected one of them to reconnoitre the position and to watch the motions of the enemy; to assign the quarters and lodging for the soldiers; to inflate the piquets, and direct the foragers. The office of "Marecallus," thus raised from servility, soon attained to great dignity and power; insomuch that the leading of the van of the army, the command of the cavalry, and the making of the first attack on the enemy, were annexed to it. After the decline, and upon the new-modelling of the empire, the office of the "Comes Stabuli" was funk into that of the "Marecallus," who from that time exercised the functions of each, and became the most considerable officer in the state. The French, from almost the earliest times of their monarchy, had both Conitable and Marshal. (See Constable.) The Marshal is mentioned in the "Leges Salicae," in the capitularies of Charlemagne, and by several of the contemporary writers of that age. The "Marecallus," from his first institution in France, was considered as subordinate to the Conitable, whose minister he was both in war and peace. His authority, however, was great, and in many respects scarcely equal to that of his principal, that his office was ever personal, and granted for life only. The French were so jealous of the power of their marshals, which became important from their prerogative of leading the van of the army, that they used every precaution for preventing the office from becoming hereditary in one family.

Among our Anglo-Saxon ancetors there was an officer, distinguished by the appellation of "Herêtoch," or "Heretoche," (derived from hore, exercitus, and zogon, decuriae,) who, according to the additions to the laws of King Edward the Confessor, was the same officer as the French styled either "Conitable," or "Marshall." The identity of these officers has, however, been questioned, and it has been alleged, that there were essential differences, as well in the constitution as in the functions of these officers. Each county or shire in England had its peculiar "Heretoche," but in that age the French had only one "Conitable," or "Marshall," in their kingdom in commendation at the same time. The "Heretoche" were military officers of the public, and each of them was annually elected by the common freemen of the people of his own country; whereas the "Conitable," and "Marecallus" of France were civil as well as military officers of the crown, appointed by the sovereign only, and generally for life. The power of the "Heretoche" extended no farther than to the leading of the forces of that particular county, by which he was chosen to be their military chief; but the authority of the "Conitable," and under him of the "Marshall," extended over the whole national army. The "Conitable" of France was the third person in the kingdom in point of rank, and next to him was the "Marshall," but the "Heretoche," even in his own county court, was placed next below the sherifl.
and immediately before the "Trithingrewe." When the
"Heretocle" had conducted the forces of his own country to
that part of the kingdom where the king thought proper
to assemble his army, and they had joined the main body, his com-
mand was superseded, and he himself became subject to the
orders of the commander-in-chief; whereas the "Contable"
and "Marshall" had the management and direction of the
campaign, and the various operations of the war, acknowled-
ging no superior in command except the king, when he
was personally present. In time, the "Heretocle" was
no other than a colonel of a county militia, acting under
the commander-in-chief of the king's forces. Duke
William, even before his invasion, and more especially after-
wards, must have known the great difference between the
officers of the Anglo-Saxons and those of the French and
Normans too well to have interpreted the "Heretocle" by
either "Contable" or "Marshall," and if he, cannot have
been author of the additions to the Confessor's laws.
These additions, it is supposed, were not formed till the
latter part at least of the reign of King Henry II., and pro-
ably not till after his death; and in that time the Germans
and Italians, confounding together the two offices of
"Contable" and "Marshall," not only used the words
"Contabularius" and "Marecallus" as synonymous, but
constantly gave the appellation "Contabillus" to the leader
of every party and detachment of the foildery.

We find the term "Marshall" used in the duchy of Nor-
mandy for an officer vested both with authority and jurisdic-
tion, and that officer grown up there to the meridian of his
dignity and power, before William's invasion of our island,
and therefore, if we had not any positive evidence of the
fact, yet it would be highly probable that he brought the
name and office into England at the time of the conquest,
in the same manner as the princes of the Norman lineage
carried both to Sicily and Naples; and of this we are assured
by the chronicle of Normandy, which expressly tells us, that
the Conqueror made Roger de Montgomery and William
Fitz-Oliver, "Marshall" in England. This office, next
to that of the "Contable," was conferred for several genera-
tions, in the family of the Clares, earls of Pembroke; after
which, reverting to the crown, it was held by different great
personages, till the 25th of Henry VIII., when it was
granted to Thomas Howard, duke of Norfolk, and his
heirs male for ever, with power to exercise it by deputy;
since which time, it hath, with some interruptions arising
from attainters, and other consequences of civil divisions,
continued in that family.

Mr. Madox (Hib. Excheq. c. 2.), describing the office
of the king's mareschal, or marshall of England, says it
was executed partly in the king's army, in time of war,
and partly in his court, in time of peace. Of the military func-
tions of this office he merely says, that he and the con-
table were to give certificates to the barons of their having duly
performed the service required of them in the king's armies;
which seems to have been a legal superin-
tendancy over those armies. But from other accounts, it
appears, that in the reign of Edward I., the mareschal's
police was in the vanguard, and that it was his duty, and
that of the constable, to muster the forces. (See Rymer,
vol. ii. p. 781.) His civil duties were (as Madox has col-
lected them from ancient records), to provide for the secu-
rit} of the king's person in his palace, to distribute the
lodgings there, to preserve peace and order in the king's
hnanle, and to assist in determining controversies
among them. He also performed certain acts, by him-
self or his substitutes, at the king's coronation, at the
marriage and interments of the royal family, at the cre-
tion of barons and knights, and at other great and cere-
nomous assemblies in the king's court. It is said in the
dialogue "De Scaccario," (already cited) that no business
of importance ought to be done without his being consulted.
See EARL MARSHALL.

Besides the earl-marshall, there were, during the reigns of our
Norman race of sovereigns, and also in subsequent and full
latter times, marshals, whose employments, or marshal-
ships, were different from, and subordinate to, those of
that great officer. Our ancient records take notice of some
officers by the name of marshals, who are mentioned only
in general to have been servants of the king's household;
and we find by the patent-rolls, that king Henry III. had
no less a number of marshals than seven continually attending
upon him in his court; for which service, each of them was
paid by the keeper of the wardrobe, the yearly wages of
twenty marks. This, indeed, will not seem extraordinary,
when it is considered, that the being "marchall," or having
the "marchallen" of a thing, meant no more than being the
director, or having the oversight, charge, or ordering of it.
Accordingly, Mr. Madox specifies several officers of the
king's household under the several denominations of marshals
of his horset, of his birds, and of his meares.

The marshal, as well as the Contable (see that article), in
consideration of the services which his office required, had
various fees and emoluments, as well as certain rights and
privileges; which belonged to him, partly as a military
officer, and partly on account of his attendance about the
king's court. They are specified by Grose in his "Mili-
tary Antiquities," vol. i. p. 104, &c. and by Edmandon
in his "Complete Body of Heraldry," vol. i. p. 66. It
is hardly necessary to add, that at present the earl-marshall
is not considered as a military officer.

MARSHAL OF ENGLAND, EARL. See EARL MARSHALL.

MARSHAL, KNIGHT, OR MARSHAL OF THE KING'S HOUSE, is an
officer, whose business, according to Pleta, is to execute
the commands and decrees of the lord steward, and to have
the custody of prisoners committed by the court of verge.
Under him are six marshal's men, who are properly the
king's bailiffs, and appear in the verge of the court, when a
warrant is backed by the board of green-cloth. The court
where causes of this kind between man and man are tried,
is called the MARSHAL'S FEAST, and is under the knight-marshall.
See COURT.

This is also the name of the prison in Southwark; the
reason of which may probably be, that the marshal of
the king's house was wont to sit there in judgment, or keep his
prison.

There are some other inferior officers of this name; as
MARSHAL of the jullices in cyre.

MARSHAL of the king's bench, who has custody of the
prison called the king's bench in Southwark.

This officer gives attendance upon the court, and takes
into his custody all prisoners committed by the court;
he is femaille for his absence, and non-attendance incurs a for-
feiture of his office. The power of appointing the marshal
of the king's bench is in the crown. 27 Geo. II. c. 17.

See COURT OF KING'S BENCH.

In Pleta, mention is also made of a MARSHAL OF THE EXCHEQUER,
to whom the court commits the custody of the king's
debtors, &c.

MARSHAL, or Marshall, of France, was, during the
monarchy, the highest dignity of preference in the French
armies. This dignity was for life, though, at its first
institution, it was otherwise. They were then only the
king's first ecuyers under the constable, but in time they
became the constable's lieutenants in the command of the
army,
army, the confible himself being then become captain-general. At first they were but two in number, and their allowance was but five hundred livres per annum in time of war, and nothing in time of peace; but in the reign of Francis I. a third was added; Henry II. created a fourth. Since it has been various; Lewis XIV. increased it to twenty. Their office at first was to marshall the army under the confible, and to command in his absence.

They did then what the marshals de camp did afterwards; to which last they transferred their title, and the least confiderable part of their authority.

The first marshal performed the office of confible in an assembly of the marshals.

**MARSHAL, Arch.** See Arch-Marshal.

**MARSHAL, Cler.** See Clerk-Marshal.

**MARSHAL, Field.** See Field-Marshal. This denomination is likewise given as an honorary rank to general officers who have no immediate command.

**MARSHAL, Provost.** See Provost.

**MARSHAL, Sub.** See Sub-Marshall.

**Marshals of Arms, in Heraldry,** have been ranged by some authors as a different order of officers of arms, and whilst some have attributed this title to Perfurants, others have denied that there are belonging to, and depending upon, the office and officers of arms, certain minions, whom they call marshals to heralds. The word "marshall" in this case however, signifies no other than a deputy to a king of arms, of a whole realm, or of any province or march within it, commissioned and appointed to perform the duties of such king of arms in his absence, or when he happens to be employed in other offices of the public; and to be a court of conditior, or afoit to him, when the thinks proper to use him in that capacity. The denomination of marshal is undoubtedly very ancient, in this country as well as in foreign parts; of which Edmondson mentions many instances. Complete Body of Heraldry, vol. i.

**MARSHALL, Thomas, in Biography,** was born at Barkby, in Leicestershire, about the year 1621. He was instructed in grammar-learning by the vicar of his native town, and was, in 1640, entered at Lincoln college, Oxford, where, in the following year, he was elected a scholar on Trapp's foundation. When the civil wars broke out, he bore arms in defence of the king at his own cost; and upon the defeat of the parliamentary visitors in 1647, he left the university, went to the continent, and became preacher to the company of English merchants at Rotterdam and Dort. While he was abroad, he was, without his knowledge, elected fellow of his college, and made doctor of divinity. These honours recalled him to his native country, and to Oxford, where he was elected rector of his college in the year 1672. He was afterwards appointed chaplain in ordinary to his majesty; in 1668, he was presented to the rectory of Bladon, near Woodstock, in Oxfordshire, and in the following year he was made dean of Gloucester. He died at Lincoln college in 1685; and left all his books and MSS. to the public library, which did not already form a part of it, and the remainder he gave to Lincoln college. He likewise founded three scholarships, supported by rent-charges on different estates. He was a very learned man, and deeply skilled in the Saxon and Eddern tongues, and was eminent for his thirtiety, profound learning, and other valuable qualifications. He was author of "Observations in Evangeliarum Verisimilium quae in Anglice-Saxonica, etc." 4to. 1665. "An Epistle prefixed to Dr. Hyde's Translation into the Malayan Language of the Four Gospels;" and other pieces.

**MARSHALLIA, in Botany,** is a species adopted by professor Martyn from Schreber, who named it in honour of Mr. Humphrey Marshall, author of Arbustum Americanum, the American grove, or an alphabetical catalogue of forest trees and shrubs, natives of the American United States. This work was published at Philadelphia, in 1808, and a French translation appeared at Paris in 1850. - Marshall is known of Macfiallina, but from Schreber, and according to his generic characters, it should be placed between Serratula and Pteronia. Schreb. 8to. Mart. Mill. Dict. v. 3. - Chaf and order, Sympomia Polygalia Equales. Nat. Ord. comp advises, Linn. Circumsepalia, Joff. Gen. Ch. Common calyx spreading, of numerous, linear-lanceolate, obtuse, concave, nearly equal, permanent scales. Cor. compound, uniform, longer than the calyx; the florets hermaphrodite, equal, numerous, of one petal, funnel-shaped, villoze; tube the length of the calyx; limb somewhat ven-tricose, divided into five, linear, rather erect segments, two of them more deeply separated. Stam. Filaments five, capillary; anthers cylindrical, tubular, as long as the limb. Ptl. German ovate; style thread-shaped, a little longer than the labes; stigma two, recurved. Peric. none except the permanent calyx. Seed solitary; ovate, five-fidged, with an oblong, broad, obtuse, caruncle, erect, numerous leaves. Recept. flat, claspy; styles linear, a little dilated, and obtuse at the top, green, the length of the calyx.

We are not aware that any species of this genus has been yet described. Willdenow has not enumerated any in his extensive work, so that the above character is all that is at present known relative to the matter.

**MARSHALLING a Coat of Arms, in Heraldry,** signifies the due and proper joining of several coats of arms belonging to distinct families in one and the same shield, or escutcheon; by impaling and quartering (which see); or, according to Nuper, marshalling of arms is when enligns of honour, or the entire arms of other families, are joined with the paternal ones of the bearer by partition lines, making distinct arms or compartments in one shield.

Marshalling is also to be extended to the disposition of the appurtenances of such arms, in proper places without the escutcheon.

**MARSHALLSVILLE, in Geography,** a place of America in Mahackony county, Virginia; in which is a post-office; 25 miles from Washington.

**MARSHALSEA.** See County of Marshallsea.

**MARSHAM, Sir John, in Biography,** a well known writer, born in 1602, at London, received his early education at Westminster School, from which place he was sent to St. John's college, Oxford, where he took his degree of M.A. in 1625. He now made a tour on the continent, and returning to London, entered at the Middle Temple for the study of the law. In 1629 he visited the Low Countries and Paris, in the suite of Sir Thomas Edmondes, embassador extraordinary to Lewis XIV. Refusing his legal studies after his return, he was appointed one of the six clerks in chancery in 1638. In the civil wars he adhered to the royal side, and was plundered of a considerable part of his estate, but on the restoration he was elected one of the representatives in parliament for the city of Rochester, was returned to his place in chancery, and received the honour of knighthood; and in the course of two or three years after this he was created a baronet. He died in 1639, leaving behind him a character for great learning in the languages, history, and chronology. The first fruit of his studies was "Dintriba Chronologica," in which he examines the principal difficulties occurring in the chronology of the Old Testament. He wrote the preface to the first volume of
of the "Monasticon Anglicanum," but his principal performance is entitled "Canon Chronicus Aegyptiacus, Ebraicus, Graecus, et Disquisitio." In this he proposed to the learned world the hypothesis of four collateral dynasties of Egyptian kings, reigning at the same time over different districts of that country, in order to reduce the chronology of the Egyptian records to a conformity with that of the Hebrew scriptures. Sir John sapphizes that the Jews derived their several rites from the Egyptians, and limits the prophecy of Daniel's weeks to the reign of Antiochus Epiphanes. He left at his death, in an unimpaired state, a fifth book of his "Canon Chronicus," containing the Persian empire. Biog. Brit.

MARSHFIELD, anciently Merefield, in Geography, a market-town and parish in the hundred of Thoraby, Gloucestershire, England, is situated on the borders of Somersetshire and Wiltshire, seven miles distant from Bath, 13 from Bristol, and 102 from London. The manor was anciently part of the demesnes of the crown, but soon after the conquest was given to the see of Wells to be held as one of the honour of Gloucester. It afterwards came to the earls of Gloucester; William, the second earl, gave it to the abbey of Keynsham, which he had founded for Black canons, in the reign of Henry II. In this abbey the manor continued till the dissolution; since which period it has paffed, by grants, defiant, and purloin, to various people, and is now the property of Chriftopher Codrington, esq. The parish of Marshfield is sixteen miles in circumference; the town, which flands in the centre, conflits principally of one street, of a mile in length. It is governed by a bailiff, annually elected at a court-baron, whose power, however, though he is attended by a jury, is limited, and extended but little farther than the examination of weights and measures. A weekly market is held on Thursdays, which, with the two annual fairs, were first granted to the abbot of Keynsham in the year 1262, renewed at various times, and finally confirmed by James I. In the population survey, under the act of 1801, Marshfield was rated to contain 265 houses, occupied by 1256 persons. The chief trade of the inhabitants is malt-making, which is carried on to a considerable extent. The parish church is a spacious structure, confiding of a lofty nave, two aisles, and a well finished tower. The whole building is in the style of the age of Henry IV., and was probably erected by the abbot of Tewksbury, to whom, at that period, the appropriation belonged. On the left hand of the high altar are three subfells, or stone flails, with light canopies and finials, where the officiating priests used to be feated.

Upon a great common, called the Downs, are the evident remains of ancient intrenchments; near which are five tumuli, or barrows; the largest is called Oifwald's tomb. The ancient tradition of this being the grave of Oifwald, king of the Northumbrians, is not supported by history.

At a place called the Rock's, near the town, are three stones set up to mark the limits of the three counties of Gloucester, Wilts, and Somerfet, which meet here in a point. Rudge thinks that from this circumstance originated the ancient name of the parish, meare being an Anglo-Saxon word for limit or boundary. Rudge's History of the County of Gloucecer, 2 vols 8vo. 1803.

MARSHFIELD, a port-town of America, in Plymouth county, Massachusetts, bounded S. by Duxbury, and 36 miles S.E. of Bolton; incorporated in 1640, and containing 1266 inhabitants.—Alto, a township in Caledonia county, Vermont, adjoining to Calais on the N.W., and Peacham on the N.E.; containing 170 inhabitants.

MARSHPY, or Marshpee, an ancient Indian town of America, in Barnstable county, Massachusetts, containing 155 inhabitants. In this town is an Indian church, but the number of Indians does not exceed 60 or 50 persons.

MARSHY HOPE, the N.W. branch of Nanticoke river, in Maryland.

MARSHY LANDS, in Agriculture. See Marsh-Land.

MARSICO NOVOL, in Geography, a town of Naples, in Principato Cita, the see of a bishop, suffragan of Salerno; 18 miles N. of Policastro.

MARSICO VETERE, a town of Naples, in the Basilicata; 14 miles S. of Potenza.

MARSIGLIA, Lewis-Ferdinand, Count, in Biography, a folder and philosopher, was born in 1658, of a good family, at Bologna. He was brought up from his earliest youth in manly exercises, but was, at the same time, extremely attentive to his studies, particularly in mathematics and natural history. In 1675, he accompanied a Venetian envoy to Conflantinople, where he employed himself in procuring information of all kinds relative to the Turkish empire. The result of his enquires, he published in "Observations concerning the Thracian Bosporus," which he added to Christiana Sweden: this work was published at Rome in 1681. The remarks which he collected respecting the civil and military state of the Ottoman empire, and the rife, progress, and decline of that power, did not appear till after his death. He remained at Constantinople eleven months; and after his return he went to Vienna, and offered his services to the emperor Leopold. They were accepted, and his skill in fortification was employed in constructing works for the defence of the river and island Raab. He was rewarded with a company of infantry, but in a short time he fell into the hands of the Tartars, who fold him a trilling fum to the governor of Temefwar, by whom he was carried as a slave to the siege of Vienna, where he was again fold, and endured incredible hardships, till his friends found means of redeeming him. He was soon after this employed to superintend the cannon foundry at Vienna; and in the course of the employment, he made many experiments on the strength and action of gunpowder, which he communicated to the celebrated Viviani. He was entrusted with important commands in the army, and had a large share in the capture of Buda, from the plunder of which he secured for his share several oriental manuscripts. He was raised to the rank of colonel in 1668, and was deputed by the emperor to the pope for some political negociations, which he conducted with great dexterity. During the remainder of the war he served in Hungary, where he was employed in constructing bridges over the Danube and other rivers, and in protecting the encampments. From the variety of his talents, civil and military, he was in great esteem with the imperial commanders, and was frequently consulted on important occasions, and was at length appointed the imperial commissioneer for fixing the boundaries between the two empires in Hungary and Dalmatia. When the sucession war between the emperor and his allies broke out in 1703, he accompanied the king of the Romans to the siege of Landau. He was afterwards sent with his regiment to garrison the important fortres of Briac, and acted as second in command under the count of Arco. Great diffentions prevailed between the two generals, and the place surrendered after a short resistance. The court of Vienna instituted a legal inquiry into the facts, in consequence of which Arco was beheaded, and Marfigi deprived of all his honours and employments. He attempted to procure a revision of the sentence from the emperor, but being unsuccessful in his efforts, he retired to Switzerland, and wrote a justification of his conduct, and then applied his
Marligli, referred to Marsilia by Linnaeus, is now by common consent separated from it. See Salvinia.

The species of Marsilia are,

1. M. quadrifolia. Linn. Sp. Pl. 1563. Brown n. 1. (Lenticula paludiris quadrifolia; Mapp. Alsat. 166. t. 166. Lens paludiris altera; Camer. Epit. 83).—Leaflets wedge-shaped, somewhat obovate, rounded, entire; smooth, as well as the footstalks. Fruit shorter than its falk. Native of various parts of the south of Europe, as well as in New South Wales, in watery places, creeping to a considerable extent. The footstalks are from two to five inches long. Leaves not unlike those of a Trefoil or Oxalis, except in confining of four leaflets, which are smooth, spiny, and entire, with numerous fine parallel nerves; their bafe brown or purplish. Fruit-stalks either axillary, or united with the bottom of the footstalks, solitary or in pairs, firm, rigid and fessile, half an inch to an inch long. Involucrum the fize of a small pea, ovate, oblong, with a small point, clothed with flabby deciduous hairs.

2. M. bifolia. Brown n. 2.—Leaflets wedge-shaped, somewhat obovate, rounded, nearly entire; hairy, as well as the footstalks. Fruit nearly fucculent.—Gathered by Mr. Brown in the tropical part of New Holland, as well as near Port Jackson. We have, from the ifles of Mauritius and Bourbon, specimens nearly answering to this definition, inasmuch as their leaflets are not quite entire, and are somewhat hairy, as well as their footstalks; but the fruit-stalks do not differ in proportion from the former, of which we rather suppute these specimens to be a variety.

MAR

Leaflets wedge-shaped, deeply toothed at the summit. Fruit roundish, with two teeth at the base. Fruit-talks rigid, scarcely longer than the fruit.—Native of Egypt. Very much smaller than M. quadrifolia, and remarkable for the deep incisions, or teeth of its exactly wedge-shaped leaflets, which resemble some Medicago or Trigoneina. These are paler beneath, and somewhat hairy, as well as their foot-talks. About four axillary rigid fruit-talks, very little longer than the fruit itself, and slightly hairy, grow together, more or less combined at their base. The fruit is lateral, or oblique, at the end of each flalk, roundish, compressed, corrugated and hairy, with two teeth at the outermost angle of its base, where the flalk terminates; rounded at the other end, and not pointed there as in the first species. M. Delile has supplied us with a wild specimen from Egypt, under the name of M. emarginata, by which this plant is defined to appear in the great work on that country, now publishing at Paris. We find no difference between this specimen and the authentic ones of Linnaeus, the native country of which is not marked upon them.

4. M. coronandiana. Burn. Ind. t. 62 f. 2. (M. minut / Linn. Mant. 308).—Leaflets wedge-shaped, somewhat obovate, nearly entire, smooth. Fruit elliptical, vertical, with two teeth at the base. Fruit-talks capillary, twice as long as the fruit. Native of Coromandel and Tranquebar, communicated by the Rev. Dr. Rutler. Nothing can be more difficult than this species from the preceding, with which it is confounded by Linnaeus. Possibly the mistake of the learned Seder, and the figure of Burmann, may have led M. Delile to suppose his emarginata different from the minut /.

5. M. angustifolia. Brown n. 3. —“Leaflets lanceolate, somewhat toothed at the extremity; smooth when full grown.” Found by Mr. Brown in New Holland, within the tropic. Of this we have seen no specimen.

MARSILLAC. In Geography, a town of France, in the department of Allier; 12 miles S. of Montluçon.

MARSILLY, a town of France, in the department of the Marne; 10 miles S. of Sceaux.

MARSOLLIER, James, in Biography, a writer of history, born at Paris in 1617, was brought up to the church, and took the habit of a canon-regular of St. Genevieve, and was sent with others to Ufze, to restore order in the chapter of that city. He fixed his abode there, and was elected provost of the cathedral, a dignity which he soon resigned in favour of Piconet, afterwards bishop of Angers, and was then made archdeacon. He died in Ufze, in the seventy-eighth year of his age. His principal works were “L’Histoire du Cardinal Ximenes,” two volumes; “L’Histoire de Henri VII Roi d’Angleterre;” “Histoire de l’inquisition et de son Origine;” this, which was first printed in one volume, 12mo., has been since reprinted with considerable additions in two volumes: “Histoire de l’Origine des dixmes et autres Biens temporaux de l’Eglise;” “La Vie de St. Francois de Sales;” “Entretiens pour plusieurs Devoirs de la vie;” “Apologie d’Erasmus;” this last is an attempt to prove the attachment of Erasmus to the Roman Catholic religion. The style of Malfioller is free and flow-

MARSOM’s Key, in Geography, a small island in the Spanish Main. N. lat. 12° 5’, W. long. 52° 58’.

MARSON, a town of France, in the department of the Marne, and chief place of a canton, in the district of Chalons-sur-Marne. The place contains 400, and the canton 768 inhabitants, on a territory of 2675 kilometres, in 18 communes.

MARSTA, a town of Sweden, in the province of Uppland; 16 miles S. of Uppl. —Alfo, a small island near the W. coast of Sweden, in the North Sea, N. lat. 56° 47’ E. long. 12° 31’.

MARSTON Moor, a place of England, in the county of York, memorable for a battle fought here in 1644, with which commenced the misfortunes of king Charles. The Scotch and parliamentary armies, having joined, laid siege to York, and prince Rupert, reinforced by the duke of Newcastle, determined to raise the siege. Both parties drew up on Marston Moor to the number of 50,000, and victory was long in a state of suspense. Rupert, who commanded the right wing of the royalists, was opposed to Oliver Cromwell, who now first presented himself to the head of a body of troops, disciplined by himself. After a sharp conflict the victory of the royalists gave way to those of the infantry who fled next to them were also put to flight. Cromwell having driven his opponent from the field, returned to a second engagement, which proved equally successful. The prince’s whole train of artillery was taken, and the royalists never afterwards recovered this defeat.

MARSTRAND, one of the most extreme among that cluster of islands, which extends from the coast of Sweden. Marstrand, from its strength called the “Gibraltar of Sweden,” is a rocky island in the Cattegate, about two miles in circumference. The town, which lies on the eastern side, contains 160 houses, and 1200 inhabitants. It was declared a free port in 1770, and was the great refor to the American vessels, which were not permitted to enter into any other port of Sweden. This traffic enriched the town, particularly in 1780 and 1781. Since the peace, the commerce has greatly diminished, and the inhabitants have derived their chief subsistence from the herring fishery, by means of the number of ships which, in bad weather, take refuge in the harbour, and by a contraband trade. Marstrand is called a free port, but the exemption is imaginary for although all goods are admitted into the town free of duty, yet they cannot be exported without paying the usual customs: and they are subject to a very strict search. The harbour is secure and commodious, but of difficult entrance, and in tempestuous weather dangerous without a pilot. Each of the two entrances is commanded by two new batteries. The place is still further fortified by the strong citadel of Carlstein, which stands on a eminence in the middle of the island. It was built, in 1682, by Charles XI., and taken by the Danes in 1719: but the fortifications have been since considerably strengthened; and it is now deemed impregnable. On the top of the highest tower is a light-house, which commands an extensive view of the Cattegate, sprinkled with an astonishing number of rocks and islands. It is said, that on account of the numerous rocks and shoals, that render this sea dangerous, above 300 vessels have been accustomed to take refuge annually in the harbour of Marstrand. This place has of late years much declined in the number of houses and of inhabitants; 18 miles N. W. of Gotholm. N. lat. 57° 54’ E. long. 11° 30’.

MARSUIN,
MAR

MARSUIN, in Ichthyology, a name by which many have called the phocaena, or porpoise, a fish too often confounded with the dolphin.

MARSUPIALE, in Natural History, a name given by Tyson to the creature commonly called the polemus, or opposum. The peculiar distinction of this creature from all others, is its having a pouch, or marsupium, under its belly, into which it receives its young in time of danger; whence the name.

MARSUPIALIS MUSCULUS, in Anatomy, a name given by Cowper, and some others, to a muscle on the thigh, called also by some, barbalis. It is that muscle, called by Albinius, Winflow, and the generality of modern authors, obturator internus.

MARSUPIUM CORNEUM, a name given by Spigelius, Cowper, and some other authors, to certain muscles of the thigh, called by the French writers, les petits jumeaux, and by Albinius, ventriferus. Vefalus does not esteem them separate muscles, but calls them only canalne portiones decimo femur motuum musculo attinat, feffy portions affixed to the tenth muscle of the thigh.

Riolan, who calls the pyriformis, or pyramidal muscle of the thigh, the quadrigereminus, or quadrigereminus prior, calls thee the quadrigermini secundu & tertii. They are sometimes distinct, sometimes they grow together.

MARSY, François-Marie de, in Biography, a modern Latin poet, was born at Paris, and entered at an early period into the society of the Jesuits, where he cultivated his literary talents so successfully, that at the age of twenty he had acquired considerable reputation by his Latin poetry. His chief work in this department was entitled "Pictura," published in 1736. In this poem he paffes over the mechanical part of the art of painting, and gives, as it were, a gallery of pictures, several of which are touched with much descriptive force. Some circumstances obliged him to quit the habit of the order, and he employed himself as a man of letters, and composed several useful works, among which were "L'Histoire de Marie Stuart," in three vols.: a translation of "Melville's Memoirs;" "Dictionnaire abrégé de peinture et d'Architecture;" "L'Histoire Moderne," being intended as a sequel to Rollin's Ancient History: of this he finished eleven volumes, and it was afterwards continued to twenty-six. In 1752 he published "Rabelais moderne, ou les Œuvres de Rabelais mis à la portée de la plupart des Lecteurs," eight vols. He has been much and deservedly blamed for not suppressing the indecencies and obscenities of the author, as he undertook to abridge him by omitting the obscene and lefs interesting passages of his works. He was liable to a heavier censure for publishing, in 1754, "L'Analyse de Bayle," in four vols. 12mo., since reprinted in Holland. On account of this Marly was, for a time, imprisoned in the Bastille. He died in 1763, while employed in writing the 12th vol. of his Modern History.

MARSY, GALPARD, an excellent sculptor, born at Cambridge in 1624, where he acquired the principles of his art under his father, and in 1648 he went to Paris to perfect himself in his profession. He was accompanied by his brother Balthasar; they worked together many years, till a length they attracted the notice of M. de la Vrilliere, secretary of state, who employed them in the decorations of the hotel de Toulouse. After this they were engaged in the works carrying on at Verailles; their most celebrated performance was a group of tritons watering the horses of the sun in the baths of Apollo. Their last work in conjunction, was the tomb of John Caimin, king of Poland. After this Balthasar laid aside his profession, but Galpard finished several other works that did honour to his reputation. In 1657 he was received into the Academy of Painting and Sculpture, was nominated professor in 1659, and chosen rector in 1675. He died in 1681, having survived his brother seven years. Gen. Biog.

MARSYAS, in Ancient Mythology, a native of Cænææ, a town in Phrygia, and son of Hyagnis, who flourished, according to the Oxford Marbles, 1556 years B.C. Marfias was a famous performer on the flute, of which his father was said to be the inventor. He is represented by Diodorus Siculus, (lib. iii. cap. 1.) as a man commendable for his wisdom and temperance. Having engaged in a musical contention with Apollo, he chose the people of Nysa, at that time the residence of Bacchus or Olibis, for judges. Apollo played at first a simple air upon his instrument; but Marfias taking up his pipe, struck the audience so much by the novelty of its tone, and the art of his performance, that he seemed to be heard with more pleasure than his rival. Having agreed upon a second trial of skill, it is said that the performance of Apollo, by accompanying the lyre with his voice, was allowed greatly to excel that of Marfias upon the flute alone. Marfias, with indignation, protefted against the decision of his judges, urging, that he had not been fairly vanquished according to the rules stipulated, because the dispute was concerning the excellence of their several instruments, not their voices; and that it was wholly unjust to employ two arts against one.

Apollo denied that he had taken any unfair advantage of his antagonist, since Marfias had employed both his mouth and fingers in performing upon his instrument; so that if he was denied the use of his mouth, he would be still more disqualified for the contention. The judges approved of Apollo's reasoning, and ordered a third trial. Marfias was again vanquished; and Apollo, inflamed by the violence of the dispute, fed him alive for his presumption.

Paulanis relates a circumstance concerning this contest, that had been omitted by Diodorus, which is, that Apollo accepted the challenge from Marfias, upon condition that the victor should use the vanquished as he pleased.

It is natural to suppose that great provocation had been given on both sides, previous to a trial of skill, big with such feroius confquences. And it appears from a paflage in Apuleius, that the champions had tried their strength at inventive and sarcasm, before the musical contest began. According to this writer, Marfias was so foolish as to irritate the god, by oppofing his own entangled hair, his frighten, and faggvy beard, to the flowing locks, the finical effeminy, and dainty cleanliness of his rival; for which he was hiffed by all the nuflers and company present.

It is difficult to acquire a true idea of the character of this musician, as some ancient writers, in speaking of him, tell us that he was a man of talents and wisdom, while others represent him as an ignorant clown; but as Polomus, in our Shakspere's Hamlet, is in some femes a wife man, and in others an idiot.

Plato tells us that we are indebted to Marfias and Olympus for wind-musick; and to these two musicians is likewise attributed the invention of the Phrygian and Lydian measure. Marfias is also said by some to have been the inventor of the double flute, though others give it to his father Hyagnis.

Antiquity has furnished us with several monuments of the punishment inflicted upon him by Apollo. He may be seen in Berger, in Mafle, and in De Chom. The Bury is like wise well and fully reproposed in one of the ancient pictures dug out of Herculanium. Here the vanquished musician is bound to a tree, the executioner holding by with a
knife in his hand, only waits for orders from the victor to flay him alive. Apollo is seated at a distance, with a lyre in one hand, and a pæan in the other, and a muse by his side, preparing a garland for him in token of victory. A young man, on his knees, appears to implore his mercy; this is thought to be Olympus, the scholar of Marlyas, asking pardon for his matter, or, perhaps permission to give him funeral obsequies, which, as we learn from Hyginus, he obtained.

And Diodorus informs us, that Apollo, soon repenting of the cruelty with which he had treated Marlyas, broke the strings of the lyre, and by that means put a stop, for a time, to any further progresses in the practice of that instrument.

MART, denotes a great fair or market, for selling of goods, holden every year. See Fair and Market.

MART, Letters of. See Letters and Marque.

MARTA, in Geography, a town in the duchy of Catalonia, on a river of the same name, which it issues from the lake of Bòlea; 11 miles E. of Castres.

MARTA, or Martina, a town of Hindostan, on the coast of Malabar; 10 miles S. of Coch-in-Can.

MARTA, Ste., a branch of the Andre; which see.

MARTA, Santa, or St. Martha, a province of South America, in the viceroyalty of New Granada, bounded on the N. by the Spanish Main, on the E. by Rio de la Hacha and Maracaban, on the S. by Santa Fé, and on the W. by Carthagena. This is a mountainous and very high country, extending in length about 350 miles, and in breadth about 200. The climate is hot and sultry, but the heat is mitigated by the winds which blow over the mountains covered with snow. The chief town is

MARTA, Santa, or St. Martha, which is a sea-port on the Spanish Main, founded in 1555; with a good haven defended by two forts, but of late considerably diminished; the houses being now mostly constructed of wood and covered with thatch. This was the place of arms of Quesada, the conqueror of New Granada, and was reduced to ashes in 1556, by Sir Francis Drake. It is now a bishop's seat. The port is large and convenient, protected by lofty ridges, and has in front a round hill, which defends the city on the side of the snowy mountains, at the distance of three leagues. These mountains may be regarded as the termination of the main chain of the Andes; which see. The climate is less hot and more healthy than that of Carthagena; and the city is supplied with excellent water from the river Goegaia, or Guaya, which passes near it: the banks of the river being covered with beautiful groves of trees, and among others, some which bear an enormous appearance, and are used as foap. The environs produce cotton, tobacco, some wine, cacao, Brazil wood, sugar, vanilla, and some wheat. Here is also abundance of cattle, and some mules are bred. The population of Santa Marta is not ascertained. At Caruina, on the S. of Cape Vela, 10 leagues E. of the city of Santa Marta, there is a pearl fisheries, which, under bad conduct, yields only about 50,000 dollars. At Ocana there are copper mines, and gold veins near the river Arigoana, 30 leagues from the city. Ornaments of tombac have been found in the tombs of the Indians. Etella, who has given a minute and interesting description of this province, says, that it only contains between 25 and 30,000 souls, the population of a mere European town; 100 miles N.E. of Carthagena. N. lat 10° 16' 2", W. long 74° 4' 30". See New Granada.

MARTABAN, a sea-port town in a province of the same name, in the Burman empire. It was formerly a port of considerable commerce; but it has lost its distinguishing importance by the plunder and devastation of the Peguans and Siamese, and by the obstruction of the navigation into its harbour, occasioned by ships that were sunk in the river by order of the Burman sovereigns. N. lat 16° 38'. E. long 98° 2'. See ARAKAN, AYA, BURMAN EMPIRE, Pegu, and Siam.

MARTAGO, a town of Spain, in the province of Leon; 10 miles S.S.E. of Ciudad Rodrigo.

MARTAGON, in Botany, a name given to several species of lily.

MARTANO, in Geography, a town of Naples, in the province of Otranto; 10 miles N.W. of Otranto.

MARTAWAN, a village of Syria, that lies on the road from Alexandria to Aleppo, celebrated among the Turks and Europeans, on account of an extraordinary practice of the inhabitants, who let out their wives and daughters for a trilling sum. "This prostitution, held in abhorrence by the Arabs, seems to me," says Volney, (Trav. in Egypt, &c. vol. ii.) "to have originated in some religious custom, which taught perhaps to be fought for in ancient worship, the goddes Venus, or to be attributed to the commonalty of women permitted by the Antarians, to which tribe the inhabitants of Martawan belong."

MARTAULE, in Conchology, the name given by French naturalists to a peculiar species of oyster, called allo mammium by others. It is one of the most curious shells in the world. Its figure is that of a hammer, with a very long head, or rather of a pick-axe. It has a body of moderate thickness, and two long arms. It is of a brownish colour, with a beautiful tinge of violet-blue. Notwithstanding the strange shape of these shells, they close very exactly.

MARTET, in Ichtyology. See Squalus Zygoma.

MARTEL, in Geography, a town of France, in the department of the Lot, and chief place of a canton, in the district of Gourdon; 29 miles N. of Cahors. The place contains 2711, and the canton 9953 inhabitants, on a territory of 1874 kilometres, in 14 communes.

MARTELLI, Lodovico, in Biography, was born at Florence in 1479, and became distinguished by his poetical genius, and, but for an early death, would have had a high rank among the literary characters of his age and country. He was author of many verses, as well in the burlesque as in the serious style; but is chiefly known for a tragedy, entitled "Tullia," which is much esteemed among the early productions of the Italian drama. He had a brother, Vincenzo, who was patronized by the prince of Salerno. On some account he was thrown into prison; on which occasion he made a vow to undertake a pilgrimage to Jerusalem, should he regain his liberty. This event took place; and he finally retired to a tranquil life, and died in 1556. A volume of his poems and letters was published in 1607; many of his letters also are to be met with in the collection of letters of illustrious men, published at Venice in 1564.

MARTELLI, Pietro-Jacopo, an eminent Italian poet, born at Bologna in 1605, was educated first at the Jesuits' school, and afterwards at the university of his native city. His father would willingly have brought him up to the profession of physic; but the young man could not endure the practice, and was permitted to devote himself to the study of classical literature. When he was about thirty-two years of age, he obtained the post of one of the secretaries to the senate of Bologna. He published a serious poem, entitled "Gli Occhi di Gena," the Eyes of Jesus. He next applied himself to tragedy, and having carefully perused the Greek and the French tragedians, he published "La Morte di Nerone." This and several of his other pieces were acted upon
upon different theatres, with great applause. In 1707 he was appointed professor of the belles letters in the university of Bologna, and soon after was made private secretary to Aldrovandini, who had been nominated delegate to pope Clement XI. At Rome he contracted an intimacy with many men of high literary reputation, and was the means of renewing the assemblies of the academy of Arcadia. He published about this period several tragedies, and a singular dialogue, "De Volta," On Flying, in which he endeavoured to prove that men and heavy bodies might be supported in the air, and in the same work he gave a description of a flying ship, which he projected. He also wrote several dialogues in verse concerning the art of poetry. He next went to Paris with Aldrovandini, who was appointed the pope's legate at the courts of France and Spain, and became acquainted with the most distinguished men of letters, at whose request he raised at length his opinions "On ancient and modern Tragedy," in the form of dialogues, which were published by his friends before he had revised them for the press. On his return to Rome, in the course of nine months, he published his tragedies in three volumes, and was reckoned to have conferred, by the work, a great benefit on Italian literature, by reviving a true taste for this species of composition. In 1716 he was diligently occupied at Rome with a dispute between the cities of Bologna and Ferrara, concerning the derivation of the waters of the Reno and Po. His zeal in this bufiness caused him, in 1718, to be promoted to the vacant place of first secretary to the senate. He wrote several other pieces besides those that have been referred to, and began a poem "On the Arrival of Charlemagne in Italy, and his Accession to the western Empire," which he never finished. He died in 1727, at the age of sixty-two. As a man, he was beloved for the suavity of his manners and his social qualities. As a poet, he was elevated and splendid rather than gay and natural, and a great admirer of his own productions. His principal works in prose and verse were printed in nine volumes, 8vo, in the year 1729. Gen. Biog.

MARTELIER, Peter de le, who rendered his name celebrated as an advocate at the French bar, was the son of a lieutenant-general. He came to London during the time that the parliament of Paris held its sittings there, and entered himself at the bar, followed the profession of a pleader during forty-five years, with a celebrity that placed him among the most eminent advocates of his time. In 1611 he pleaded the cause of the university of Paris against the defects, and pronounced a most bitter philippick on the society, which was much admired as well in print as on the delivery. It went through several editions, and was answered by some person on the part of the society. Martelli was afterwards created a counsellor of state. He died in 1631. He is buried, in his epitaph, "Princes Pa
tornorum, et Patronus Principum." Morei.

MARTELLO, Cape, in Geography, the south point of the island of Negropont. N. lat. 38° E. long. 29° 59'.

MARTENNE, Edmund, in Biography, a learned French Benedictine monk, was born in the year 1634. At the age of eighteen he took the vows in the abbey of St. Remi at Rheims, where he was greatly distinguished among his contemporaries by the diligence of his application, and the profound laborious researches. As an author he first appeared in 1690, with a work, entitled "Commentarius in Regulam sancti Benedicti literalis, moralis, historicus," which is a compilation of what the best writers have said on the subject, and contains dissertations on different questions, which display the erudition of the author. He published "De antiquis Monarchorum Ritus," in two volumes, 4to, which furnishes much curious matter, illustrative of ancient ecclesiastical and profane history. From this period he was frequently before the public by works of various merit; but his fame with posterity is chiefly secured by the part which he took in new-modelling the work, entitled "Gallia Christiana." To enable him to do this, it was determined that he should visit the public archives, and the libraries of the churches and monuments throughout the kingdom, to search for such documents as had escaped the knowledge and investigation of the original authors. On this literary mission he set out, and traversed, alone, Poitou, Berry, Nivernois, and part of Burgundy. He spent six years in these travels, the result of which was a rich harvest of materials, which, exclusive of more than two thousand pieces illustrative of the "Gallia Christiana," compose the greater part of five volumes in folio, published in 1717, under the title of "Th
erius novus Anecdotaier," &c. In the same year he published, conjointly with his fellow-labourer, D. Urfin Durand, a particular account of their journey, entitled "Literary Travels of two Monks of the Congregation of St. Maur." Two years after, they took another journey by order of their superiors, and published an account of it, under the same title with the preceding. The result of this second journey was an immense collection of documents, in nine volumes, folio, under the title of "Veterum Scriptorum et Monumentorum Historicorum, et Dogmaticorum amplissima Collecori," of these the first three appeared in 1724, and the six last in 1733. He was concerned in many other publications, particularly in father Mabillon's sixth volume of his "Annales Ordinis S. Benedicti," and in the new edition of father d'Abchery's "Spicilegium." He died in 1739, at the great age of eighty-five. He was respected and beloved by his literary contemporaries, as well on account of the simplicity of his manners as of the vast extent of his learning, and his indefatigable industry. Mo
eri.

MARTENS, Thierry, in Latin, Martinus, a native of Alost, in Flanders, celebrated as the peron who first introduced the art of printing into the Netherlands; having exercised this useful and noble art nearly sixty years at Alost, and later in Antwerp. He died at the last-named place in 1555, at the age of four-score. He was an author as well as a printer; but it is said his own productions were the least valuable of those that issued from his press. He was highly esteemed by the learned men of the period in which he lived, and enjoyed the friendship of Erasmus, who lodged in his house. He employed the double anchor as a sign of the books that were printed at his office. Gen. Biog.

MARTHA RAEB, in Geography, a harbour and village in Jamaica. N. lat. 18° 31'. W. long. 77° 32'. See FALMOUTH.

MARTHA, St. See Santa MARTA.

MARTHA, St., Bay, a bay on the W. coast of the island of Curacao.

MARTHA'S Vineyard, an island in the Atlantic, near the coast of New England, belonging to Duke's county, Massachussets, called by the Indians "Nope," or "Cape
cwok," lying between 40° 17' and 41° 29' N. lat., and between 70° 22' and 70° 50' W. long., W. of Nantucket; about 21 miles in length, and 6 miles in breadth.

MARTHA'S Vineyard, Chappaquiddick, Noman's island, and the Elizabeth islands, which contain about 16,500 acres of valuable land, constitute Duke's county, containing 3118 white inhabitants, and between 400 and 500 Indians and mulattoes; who subsist by agriculture and fishing. Cattle and sheep are raised here in great numbers; and 700, corn,
and oats are the chief produce of the island. White pipe-
chay and yellow and red ochre are found in Martha's Vine-
yard.

MARTIALON, a town of Switzerland, in the canton
of Zürich ; 5 miles S. of Schaffhausen. 

MARTIGAO, a town of Spain, in the province of
León ; 10 miles S. of Ciudad Rodrigo. 

MARTIAL, or Martialis. Marcus Valerius, in
Biography, a native of Bibilis, in Spain, where he was
educated, and remained till he had arrived at man's ciliate,
when he came to Rome. He was first bidden to study the
law, but he was too much addicted to poetry to settle to
a profession that requires great labour and severe study.
His fine talents and taste for polite literature ingratiated him
with the principal literary characters then in Rome, and even
procured for him imperial patronage. Flattered with the
notice taken of him, he became the panegyrist of the em-
perors, and in his turn gained the greatest honours, and was
rewarded in the most liberal manner. Domitian gave him
the tribunship, but the poet, unmindful of the favours
which he had received, after the death of his benefactor, ex-
pelled to vindicate the vices and crudities of a moniler, whom,
in his lifetime, he had extolled as the pattern of virtue, good-
ness, and excellence. Trajan treated the poet with coldness;
and Martial, after he had passed thirty-five years in the cap-
ital of the world, in the greatest splendour and affluence, re-
tired to his native country, where he had the mortification
to be the object of malevolence, satire, and ridicule. He
received some favours from his friends, and his poverty was
alleviated by the liberality of Pliny the younger, whom he
had immortalized in his poems. Martial died in the 104th
year of the Christian era, and in the 73rd year of his age.
He is unquestionably the most eminent of the epigrammatists,
and is looked to as the mode form of that species of com-
position. He wrote fourteen books of epigrams, which are
described by himself as 'some good, some middling, and
more bad.'

"Sunt bona, sunt quedam mediocria, sunt malà plura!"

this is thought by the best judges of compositions of the kind
as sufficiently needful. The invention of so many of his epig-
grams devolves the strongest confession: the poet has in many
influences flown himself a declared enemy to decency, and
the book is to be read by young persons with the utmost caution,
as its tendency is often to corrupt the purity of morals, and
initiate the votaries of virtue into the mysteries of vice.
The best editions of Martial are those of Paris 1617, folio ; Sciri-
vern. 12mo. Lug. Bat. 1619; Schreveli, 8vo. 1670. There
are, as there ought to be, several callugated editions and se-
flections for the use of schools.

MARTIAL, St., in Geography, a town of New Mexico, in
the province of Sonora; 48 miles S. of Pitiquin.

MARTIAL is sometimes used to express preparations of
iron, or such as are impregnated therewith; as the martial
regulus of antimony, &c.

MARTIAL, Court. See Court-Martial.

MARTIAL LAW, is the law of war, depending upon the
arbitrary, but just power and pleasure of the king, or his
lieutenants. The king, though in times of peace he makes
no laws but by the consent of his parliament; yet, in war,
uses absolute power over the foildiers; though even this
power hath been vested, of late years, in the king, or his
generals of the army, by act of parliament, and under par-
ticular restrictions too.

Martial law, says Sir Matthew Hale, is in reality no law,
but something indulged rather than allowed as law. The
secrecy of order and discipline in an army is the only thing
that can give it countenance; and therefore it ought not to
be permitted in time of peace, when the king's courts are
open for all persons to receive justice according to the laws
of the land. The petition of right (which fee) enacts that no fol-
dier shall be quartered on the subject without his own consent;
and that no commission shall issue to proceed within this land
according to martial law. See Martial Court.

MARTIALES FLORES. See FLORES Martiales.

MARTIANAY, John, in Biography, a learned French
Benedictine monk, was born at St. Sever, in Gascony,
in the year 1647. Having entered into the order at Tou-
louse, in 1668 he applied with great diligence to the study
of the Greek and Hebrew languages, with the view of ob-
taining a critical acquaintance with the sacred scriptures.
When he had attained to that degree of competency in the
pursuit which gave him confidence in his own powers, he
perceived himself by reading lectures in different monasteries
belonging to his order, and spent a considerable part of his life
in endeavouring to illustrate them by various and very erudite
publications. He was engaged jointly with father Pou-
get, in publishing a new edition of the works of St. Jerome,
in five vols. folio, after which he gave the world a life of the
faint. He was likewise author of "Historical Treatises on
the Truth of the Inspiration of the Sacred Books"; a treat-
ise "On the Canon of the Books of Scripture;" of one
"On the Manner of explaining the Sacred Scriptures;" he
published also the "New Testament, with Notes taken en-
tirely from the Scriptures," and of a "Commentary on the
Whole of the Scriptures." He died in 1717, about the age
of seventy. Moreni. 

MARTIANO, in Geography, a town of France, in the
department of the Tanaro; 12 miles S.E. of Aith.

MARTIANUS CAPELLA. See CAPELLA, MARTIA-
NUS.

MARTICHORA, in Natural History, the name given
by the ancient Greeks to the animal which we call the mantu-
chora, or man-tiger.

MARTICK, in Geography, a township of America, in
Lancaster county, Pennsylvania, having 1248 inhabitants.

MARTIGAO, a town of Portugal, in the province of
Beira; 21 miles N.E. of Coimbra.

MARTIGNANA, a town of France, in the depart-
ment of the Stura, near the Po; five miles W. of Saluzzo.

MARTIGNANO, a town of Italy, in the Trevisan;
seven miles N.W. of Treviglio.

MARTIGNE, a town of France, in the department
of the Ille and Vilaine; eight miles S.S. W. of La Garenne.—
Alfo, a town in the department of the Mayenne; seven miles
N.W. of Laval.

MARTIGNE BRIAND, a town of France, in the depart-
ment of the Mayne and Loire; 15 miles S. of Angers.

MARTIGNE la COMTE, a town of France, in the depart-
ment of the Sone and Loire; 6 miles N. of Charolles.

MARTIGNY, which, according to antiquaries, was the ancient
Oberham, a village of Switzerland, in the Valtelais,
situated on a small plain, encircled by high mountains, and
divided by the Drance, that falls into the Rhine. This is
a place much frequented by travellers; it leads to the Valley
of Cham-unity, to St. Maurice, and the lake of Geneva, and
is the passage of the merchandise which is conveyed over
the great St. Bernard into Italy. Near Martigny, are the ma-
jestic ruins of Le Bath, an old episcopal castle, crowning
the summit of a craggy rock, and impeding over the imple-
tious Drance.

MARTIGUES, Les, a town of France, in the depart-
ment of the Mouths of the Rhone, and chief place of a
canton, in the district of Aix; situated on an island at the
mouth
MARTIN, Bernard, in Biography, was born at Dijon, in 1574. He was educated for the profession of the law, and was admitted an advocate in the parliament of Burgundy, where he distinguished himself by the erudition and eloquence of his pleadings. In 1605 he was called to the capital on an affair of some consequence. Here he published the result of several years critical researches into different ancient authors, under the title of Bernardi Martini Vararum Lectorum, lib. iv. After this he applied himself solely to his professional studies, and made large collections for a commentary on the cumin of Burgundy, which he had just put to the press when he died in 1639. Moreni.

MARTIN, saint, was born at Sahara, in Pannonia, now denominated Hungary, about the year 316. He lived in the army some years, but being converted to Christianity he embraced a religious life, and was the means of converting his mother from the pagan doctrines. In 374 he obtained such a reputation in the church that he was appointed bishop of Tours, but his elevation to this high dignity did not lead him to basify the original simplicity, and even austerity of the monk. He erected the monastery of Marmonier, and is considered as the apostle of the Gauls. He died in the year 397. Under his name there is extant a confession of faith on the doctrine of the Trinity.

MARTIN I., pope, who obtained likewise the honour of saint and martyr in the Romish church, was a native of Todi in Umbria, became prebendary of the church of Rome, in 649, and was elected to the papal throne on the death of Theodore. It is not our business, in this place, to enter at large into the contests which agitated the church at this period; they relate chiefly to the number of wills and operations in Chiril, one party maintaining the doctrine of one will and one operation, and the other, that of two wills and two operations. See Monothelites.

As soon as Martin had taken possession of his see, he directed a council of bishops to be assembled at Rome, who met at Rome to the number of one hundred and five. The debates were violent and protracted through five sittings, when by the influence of the pope it was decreed that the doctrine of two wills was the true Catholic doctrine, and that, of one will, plainly heretical. Martin next endeavoured to conciliate the emperor, and by a most submissive and flattering letter, endeavoured to convince him that the doctrine of one will was repugnant to the decrees of the councils, to the doctrine of the fathers, and to the belief of the church; and that therefore it had been of necessity condemned. Conflians was not, however, so easily won over; he was enraged at the conduct of the pope, and determined to revenge the insult offered to the imperial laws, and without hesitation ordered the exarch of Italy, at all events, to seize and depose Martin, and to send him away prisoner. The officer performed the duty enjoined upon him with the utmost promptitude. The pope, notwithstanding the remonstrances of the clergy, who offered to vindicate his authority, and to stand by him at the last, surrendered to the civil power, and was carried privately, with a few domestics, on board a vessel in the Tyber, which was immediately dispatched to the East. During a tedious voyage of three months, they touched at different places, at which the pope was not permitted to go on shore, notwithstanding his sufferings from sea-sickness, the gout, and other distressing maladies. He was, moreover, cruelly deprived of such comforts and refreshments as were brought to him by the clergy and others, who were driven away, and sometimes grossly insulted as enemies of the state, and rebels to the emperor. When he had arrived at the island of Naxos, in the Archipelago, he was confined there a whole year, and then ordered to be brought to Constaninople, where he arrived in the autumn of 654. Here he was closely imprisoned and severely maltreated for more than three months. He was at length brought to trial on a charge of high treason, of which he was found guilty, without much regard to the nature of the evidence adduced; the verdict was however no sooner delivered than the high treasurer, who presided as judge, ordered the guards to strip him, and the people to anathematize him; he was then delivered to the governor of Constaninople, who directed an iron collar to be put about his neck, and to have him dragged through the streets of the city, loaded with chains, and then shut up in prison, till he should be led out to execution. Here he was treated with great barbarity, and probably would have died under his sufferings, had not the emperor been persuaded to spare his life. He accordingly banished him to the island Cheroneus, where he arrived in the spring of 655. In this inhospitable country, and in the midst of a pagan people, he had the mortification of finding himself entirely neglected by his friends in Italy, and suffered even to want the common necessaries of life. He died in the following September. There are still extant seventeen of his "Letters," in the fifteenth volume of the Collect. Conciliorum, which are said to exhibit superior talents and an enlarged mind. Bower.

MARTIN II., pope, sometimes called Marinus I., the son of a prebendary, and a native of Galleium in Tuscany, recommended himself to different popes by his great talents for business, and thus he rose to the dignity of archdeacon of the Roman church. In 866 he was deputed by pope Nicholas to Bulgaria and Constaninople, for the purpose of excommunicating the patriarch Photius; and again in 859 by pope Adrian II. to fit in the general council convened in opposition to that patriarch. Ten years afterwards he was sent legate to Constaninople, a third time, by pope John VIII. to renew the act of excommunication. By the last named pontiff he was probably ordained bishop, but without fee. Upon the death of John, in 882, he was elected his successor; and Photius says that he was indebted for his elevation to wicked practices, of which there is certainly no mention made by any of the more ancient writers. One of the first measures of his administration was to declare the acts of the late council of Constaninople null and void, and to anathematize all who should communicate with Photius, or acknowledge him as lawful patriarch. These proceedings gave great offence to the emperor Basilius, that he would not own him for lawful pope. Another measure of pope Martin's government, was his restoration of Formosus, bishop of Porto, to his see, though he had been repeatedly excommunicated by his predeceased, and even obliged to swear that he would never resume the episcopal functions. Martin absolved him from the obligation of his oath, declaring him innocent of the crimes laid to his charge, and replaced him in his bishoipry. Nothing more of moment is recorded of this pontiff. He died before he had reigned over the holy see eighteen months. We know nothing of his works - "A Constitution for the Benedictine Monastery in the Diocese of Limoges," which may be found in the ninth vol. of the Collect. Concil. Bower.

MARTIN III., pope, sometimes known by the name of Marinus II., probably a Roman by birth, succeeded to the papal dignity on the death of the eighth, or, as others affirm, the ninth Stephen, in the year 942. Little is known of this pope, except that he was too much attached to the system of monkery,
monastery, and granted very extraordinary privileges and exemptions to what were called religious men and houses. He died in 1426, after a pontificate of about three years and a half. He was a great friend to the poor, and was liberal in building, repairing, and adorning churches; and is deservedly praised for his endeavours to reconcile the Christian princes who were engaged in bloody wars.

**Martin IV.** pope, whose original name was Simon de Brie, or de Brion, was descended from an illustrious family, and born at Montpfiemer, in the Touraine. He many years held distinguished offices in the church, and in 1260 was appointed keeper of the seals to Lewis IX.; in the following year he was created cardinal by pope Urban IV., after which he sustained the character of papal legate in France, both under that pope, and under Gregory X. After the death of Nicholas III., and when the Roman see had been vacant more than six months, he was elected to fill it in February 1281, and upon his promotion to this high honour he assumed the name of Martin, avowedly in honour of St. Martin of Tours, of which church he had been canon. From the moment of his accession, his whole attention was directed to the promotion of the Roman hierarchy. With the design of favouring the views of Charles, king of Sicily, on the Greek empire, and the city of Constaninople, and with the view of rendering the influence of the papal see triumphant in the East, he excommunicated the emperor Michael Palaeologus, under a very slight and flimsy pretext, of his having broken the peace which had been concluded between the Greek and Latin churches, at the council of Lyons, in the pontificate of Gregory X. This design was entirely defeated by the famous conspiracy known by the name of the Sicilian Pef ters, (which see,) by which all the French in the island were butchered, and the revolution effected that feated Peter, king of Arragon, on the throne of Sicily. The pope immediately thundered out the most dreadful anathemas against all the persons concerned in this atrocious deed, and when Peter landed in the island, and was crowned king, he wrote several threatening letters to him, demanding that he should instantly reneg his pretensions, and withdraw from a country which belonged to the apollitical see, upon pain of excommunication, and the forfeiture of his own kingdom. The king set his holiness at defiance, and avowed his determination to keep possession of Sicily, as the inheritance of his wife, and he was readily obeyed by the clergy in both his kingdoms, whom he commanded to continue in the regular exercise of their functions, notwithstanding the interdict. Irritated at Peter's relish, the pope, by a bull, deprived him of the kingdom of Arragon, and his other dominions in Spain, which he declared to be forfeited, and that they should be the property of any prince who would seize them. In derision of the pope's pretended power to deprive him of the regal title, the king of Arragon styled himself "Peter, a gentleman of Arragon, the father of two kings, and lord of the sea." Martin, anxious for revenge, offered the dominions of Peter to Philip of France, and to afflict him in the furrow, his holiness granted him the tenth of the ecclesiastical revenues, and encouraged his subjects to flock to his banner, by granting indulgences to all who should engage in that holy war. While he was meditating other projects, as well for the humiliation of the rebellious monarch as for the glory of the Roman hierarchy, he was cut off by a sudden death in 1285, after a pontificate of four years. There are five of his "Letters," and the sentence which he pronounced against Peter of Arragon, in the 11th vol. of the Collect. Conciliorum. Besides these, there are thirteen of his letters in Wadding Annal., and in the appendix to this work. Moreri. Bower.

**Martin V.** pope, whose former name was Otho, or Eudes Columna or Colonna, was a descendant from a branch of an ancient and well-known family of that name. He studied canon law at Perugia, and was created protonotary and referendary by pope Urban VI. He was appointed nuncio to the Italian states by Boniface IX., and raised to the purple by Innocent VII. He adhered to the interests of Gregory XII. till he was deposed by the council of Pisa. He was appointed apollitical legate for the patrimony of St. Peter, and vicar general of the apollitical see in Umbria; in which employments he gave the most perfect satisfaction to his employers. Upon the deposition of pope John by the council of Constance, in 1417, he was elected to the papal dignity, and took the name of Martin V. On his coronation he was conducted on horseback through the city in pontifical attire, by the emperor on foot, holding his bridle, on the right hand, and the elector of Brandenburg on the left, and followed by a crowd of princes and the whole council. After dissolving the council of Constance, in the year 1418, Martin set out on his return to Italy, with the view of endeavouring to terminate the civil war in which the city of Rome and the whole patrimony of St. Peter had been some time involved. In his progress he spent some time at Geneva, where he received the ambassadors of the city of Avignon, and from that city he dispatched a legate into Bohemia, who made a fruitless effort to quell the disturbances in that kingdom, which had been excited by the denial of the cup in the sacrament to the laity, and the execution of Huf and Jerome of Prague. Martin next went to Milan, where he was received with extraordinary marks of honour. After this he visited Mantua, Ferrara, Rattana, and came to Florence in the beginning of the year 1419. Here he continued about two years, which were spent in reducing the tyrants who had feized the cities in the ecclesiastical state, or such places as had revolted against the papal authority. In a short time after, he had the satisfaction of seeing Balthasar Colle, formerly John XXIII., throwing himself on his mercy, and his submission was followed by a splendid embassy from Joan II., queen of Naples, to do him homage in her name, and to request that his holiness would send a legate to perform the ceremony of her coronation. Immediately after this ceremony, Joan caufed all the places which her predecessor Ladislaus had feized in the ecclesiastical state to be restored, and also sent James Sforza, a soldier of fortune, with the flower of her army, against Braccio of Perugia, who had made himself master of many cities belonging to the church, and of Rome itself, which he governed under the title of "Defender of the City of Rome." Sforza was defeated, and pursued with great slaughter to the borders of the kingdom of Naples. The pope instantly excommunicated the conqueror, who, to shew his contempt for such kind of hostility, in his turn excommunicated the pope and all who adhered to him. Through the mediation of the Florentines, an agreement was soon concluded between Braccio and the pope, the former confessing to deliver up Rome, and some other cities to the pope. Martin resolved to go to Rome, which he entered in September, 1420, and was received with the loudest acclamations of joy by the clergy, the senate, and the people, who hailed his approach as their deliverance from absolute destruction. At this period, the city was but little better than a heap of ruins, and the inhabitants almost starving. To remedy these evils, Martin applied himself with the utmost zeal and vigour, and in less than two years he acquired the title of Romulus II., by his exertions
to promote order and regularity, and to restore the city to its ancient splendour and beauty. In the mean time Peter de Luna, under the name of Benedict XIII., continued to act the part of sovereign pontiff, and at his death, in 1424, Giles de Munio was elected his successor, by the name of Clement VIII., who was supported by Alphonso of Naples. When Martin sent a legate to this prince, in 1426, to reconcile with him on his being the only Christian prince who upheld the schism in the church, Alphonso prohibited the legate from entering his dominions, and likewise forbade the bishops, and other ecclesiastics, to receive any letters from the pope on pain of forfeiting their dignities and revenues. Alphonso, after this, was glad to come to an accommodation with his holiness, which, after protracted negotiations, was effected in the year 1429. It was agreed that the anti-pope and his cardinals should resign their dignity, submit to Martin, receive abjuration from the legate, and be provided for with considerable benefices. Thus terminated the schism, known by the name of the "Great Western Schism," after it had lasted more than half a century. Martin was now left without a rival, and he immediately turned his attention to promote crusades against the Hussites of Bohemia. He died of a stroke of apoplexy in 1431, having been at the head of the church more than thirteen years. Martin was as decided as he was learned in the church, and despised, generally, of lucrative employments in his relations, in preference to all others, however lucrative. Fifteen of his "Letters," "Bulls," and "Constitutions," are to be met with in the seventeenth volume of father Labbe's Concil. Maxim. Others are also to be found in "Bozzi Anufal," and in the first volume of Laurentius Cherubini's "Magnus Bullarium," &c. Bower. 

Martin, a Catholic primate in the sixteenth century, was by birth a Pannonian, or Hungarian, who quitted his native country when he was very young, and travelled into the East, for the purpose of visiting Jerusalem and the holy places. From Palestine he went into Spain, where he converted great numbers of people to what was called the Christian faith, and founded many monasteries. He was present at the second council of Braga, in 563, and presided at the third council in the year 572. He died in 572, and left behind him many very learned works, of which the most important is entitled "Collectio Canonum Orientalium," confuting of eighty-five canons of the Greek church, translated into Latin by himself. He was the first to be met with in all the collections of the councils, and in them the pretended "Apostolical Constitutions" are never cited. Moreri. 

Martin, Benjamin, a celebrated optician and experimental philosopher, was born in the year 1704. He was the son of a farmer, and became in early life a school-master at Chichester, where he wrote some excellent books on mathematical subjects. The profits of his profession probably enabled him to procure, by degrees, a good apparatus of philosophical instruments, with which he commenced lecturer in experimental philosophy, and travelled for some time in that character through different parts of the kingdom. He next appeared in the same profession in London, and delivered his courses to crowded audiences for many years. He finally settled in Fleet-street, London, as an optician, and made several important improvements in mathematical and philosophical instruments. The growing infirmities of age, obliged him to quit the active part of his business, and, trading too much to others, his affairs became embarrassed, and he was made a bankrupt, though it was found his effects were more than sufficient to discharge all his debts. His mind was not equal to the shocks of adversity, and in the moment of dependancy he attempted to destroy himself. He did not succeed in the effort, but the wound which he inflicted hardened his death, which took place in 1732, when he had attained the age of seventy-eight. His works are numerous, and were exceedingly valuable at the time of their publication. Some of them retained a large share of popularity till within the last twenty years, particularly his "Philosophical Grammar," "The young Mathematician's Complete Guide," in two vols. octavo; "The Philosophy Britannica," or "System of the Newtonian Philosophy," in three vols. octavo. He had, during his long life, formed a capital collection of fossils and other curiosities, which were sold after his death. "As an artist," says his biographer, "he was industrious and ingenious; and, as a writer, he possessed the happy method of explaining his subject; he wrote with perspicuity and even elegance." 

Martin, David, a French Protestant divine in the 17th and the early part of the 18th centuries, was born at Revel, in the diocese of Lavaur, in the year 1639. Having paffed through his academic studies with credit and applause, he was admitted M. A. and doctor of philosophy in the year 1659. After this, he applied himself to the study of divinity; to that of the sacred scriptures, the oriental languages, ecclesiastical history, and the different branches of prose as well as verse literature. In 1669, he settled as pastor, and entered on the duties of the ministry in the ninth year of the revocation of the edict of Nantes in 1687. After this, and the demand of his place of worship, it being discovered that he still maintained a private connection with his church, he narrowly escaped an arrest, and withdrew to Holland. In 1686, he was invited to become professor of divinity, and pastor of the Walloon church in Deventer; but the regency of Utrecht, where he had taken up his residence, prevailed upon him to accept the office of pastor in their city. He afterwards received invitations from several other churches, both in the republic and abroad, and particularly from that of the Hague, which he declined. He now employed himself in giving lectures in philosophy and divinity, and acquired so high a reputation by his successful manner of instructing his pupils, that young persons of high rank, and even the sons of sovereign princes, were placed under his tuition. He had deeply studied the nature and genius of his own language, and when the French academy was about to publish the second edition of their Dictionary, he sent them remarks and observations, of which they availed themselves, with polite acknowledgments to the author. He died in 1751, having completed his eighty-second year. He was author of many learned works, among which is an edition of "The New Testament, according to the Geneva Version, with Corrections, Notes, New Vocabularies, &c.:" "A History of the Old and New Testament," in two vol. folio, embellished with upwards of 400 engravings; "A Treatise on Natural Religion;" and one on "Revealed Religion," in two volumes octavo. This was his last work, the second edition of which bears the date 1720. Moreri. 

Martin, Claude, an officer in the British military service in India, was by birth a Frenchman, of rather a mean defence. He had sufficient interest to get a good mathematical education at a public school, and at the age of 20 entered into the army. His regiment was sent to India with general Lally, and, in the year of 1756, he behaved with great gallantry, but being ill-treated, he enlisted into the English service, in which he rose to the rank of colonel. Being employed to make a map of the citates of the nabob of Oude, he recommended himself to his patronage. Martin was enabled, under the protection of the nabob, to open a profitable bank, and to embark in other commercial speculations, by which he gained a deal of wealth. At Lucknow
he built a curious mansion in a style of his own, in which he could enjoy all the mildness and coolness of an European climate with the favour of the Alsatian. He erected another of the same kind on the banks of the Ganges, which he fortified in the European manner. He formed a large museum of natural history; contrived an ornamental garden, which he stocked with a prodigious variety of plants; and built an observatory, which he furnished with the best astronomical instruments he could obtain. He died in the year 1799, bequeathing the great wealth which he had amassed principally in charity.

Martin, in Geography, a small island near the W. coast of Scotland, at the entrance of Loch Broom. N. lat. 57° 55'. W. long. 5° 3'.

Martin, a county of Halifax district, North Carolina, adjoining Tyrrell, Halifax, Bertie, and Pitt counties, containing 5312 inhabitants, of whom 1646 are slaves.

Martin, Cape, a cape of Spain, on the coast of Valencia. N. lat. 38° 47'. E. long. 3° 7'.

Martin, Cape, a cape on the N. coast of New Spain, in the North sea.

Martin, St., one of the northernmost of the Caribbean islands in the West Indies, situated between Anguilla on the N., at the distance of 12 league, and St. Bartholomew on the S.E., at the distance of 15 miles. This island is chiefly valuable for its salt-pits and salt-water lakes, which were held in such estimation by the Spaniards, that they erected a fort upon the island to protect them, and to prevent other nations from making a settlement. The salt-lakes abound in good fish and turtle; and the salt-water pools are the haunts of birds in great number. In this island there is no fresh water, except that which falls from the clouds and is preserved in cisterns. In the woods are wild hogs, turtles, doves, and an innumerable multitude of parrots. Here are also various trees producing gums, and plenty of the candle-tree, splinters of which, when dried and lighted, emit a very fragrant smell. Its tobacco, which is the chief commodity that is cultivated, is reckoned the best in the Caribbean islands.

In 1659 the Spaniards abandoned this island, blew up its fort, and destroyed all the houses and cisterns of the occupants. The French and Dutch afterwards shared the island between them; but in the year 1689 they were attacked and plundered by Sir Timothy Thornhill. And in 1714 the French were driven out by the British forces, and did not return till the peace of 1763. The two colonies breed poultry and sheep, which they sell to the other islands; and they also cultivate a little cotton and coffee. About forty years ago the French part contained 400 white families, and 10,000 slaves. The Dutch part comprised sixty families, and about 200 slaves. In March 1801, this island was taken by the British. On the N.W. side it has commodious harbours and bays. N. lat. 18° 5'. W. long. 62° 55'.

Martin, St., a town of Hungary, on a small river which runs into the Waag; 10 miles W. of Rofenburg.—Alfo, a town of Mexico, in the province of Zacatecas; 95 miles S.W. of Zacatecas.—Alfo, a town of Naples, in Capitanata; 10 miles S. of Termoli.—Alfo, a town of Spain, in Afturia; 44 miles W. of Oviedo.—Alfo, a town of Spain, in Old Castile, on the Duero; 42 miles S.S.W. of Burgos.—Alfo, one of the Seilty islands. N. lat. 50° W. long. 6° 14'. (See Scilly Islands)—Alfo, a town of the island of Cuba; 150 miles S.W. of Havana.—Alfo, a town of France, in the department of the Po; nine miles N.W. of Pinerola.—Alfo, a town of France, in the department of the Dora; 18 miles S.E. of Aosta.—Alfo, a town of France, in the department of the Maritime Alps; 19 miles N. Nice.—Alfo, a town of Sweden, in South Finland; 30 miles N.E. of Abo.—Alfo, a town of South America, in the government of Moxas; 180 miles N.W. of Trinidad.—Alfo, a small island in the Pacific ocean, near the coast of Peru; lat. 11°.

Martin d’Auvergne, St., a town of France, in the department of the Cher; six miles N. of Bourges.

Martin d’Avesy, St., a town of France, in the department of the Saône and Loire; 12 miles S.W. of Clamecy.

Martin le Beau, St., a town of France, in the department of the Indre and Loire, near the Cher; nine miles E.S.E. of Tours.

Martin le Chapelier, St., a town of France, in the department of the Lozere; 12 miles S.W. of Mende.

Martin de Cédes, St., a town of France, in the department of the Hérault; 21 miles S. of Grenoble.

Martin de Courtenay, St., a town of France, in the department of the Marne; six miles E.N.E. of Chalons sur Marne.

Martin d’Enringes, St., a town of France, in the department of the Hérault; five miles S.E. of Grenoble.

Martin de Fontoyne, St., a town of France, in the department of the Calvados; four miles S. of Caen.

Martin de Londres, St., a town of France, in the department of the Herault; 12 miles N.W. of Montpellier.

Martin de Paliéries, St., a town of France, in the department of the Var; nine miles N. of St. Maximin.

Martin de Ré, St., a town of France, in the department of the Lower Charente, on the N. coast of the island of Ré; nine miles W.N.W. of La Rochelle. N. lat. 46° 12'. W. long. 1° 38'.

Martin de Tournon, St., a town of France, in the department of the Indre; seven miles N.W. of Le Blanc en Berry.

Martin de Trebogo, St., a town of Spain, in the province of Leon; 41 miles S. of Ciudad Rodrigo.

Martin de Villamaus, St., a town of France, in the department of the Ardèche; 21 miles S.W. of Tournon.

Martin Felix, St., a town of Bavaria, in the principality of Kempten, on the Iller; five miles W.S.W. of Kempten. N. lat. 47° 58'. E. long. 10° 15'.

Martin Iar, Islands of, three small rocky islands, which, according to Perouse, are mere rocks in the Atlantic ocean; the largest being about a quarter of a league in circumference. At a distance they appear like five heads of land. S. lat. of the largest 20° 31'. W. long. 28° 8' from Paris.

Martin's, St., Bay, a bay on the S. coast of the island of Guernsey.

Martin's, St., Point, a cape on the S.E. coast of Guernsey, two miles S. of St. Peter.—Alfo, a cape on the W. coast of Africa. S. lat. 32° 40'.

Martin's, St., Islands, a chilter of small islands in lake Huron. N. lat. 45° 33'. W. long. 84° 20'.

Martin, Marit of, or Martinet, in Ornithology. See Hirundo Urbica.

Martin, or Martlets, in Zoology, the name of a creature of the weaflf kind, being the mystela martes of Lannzeus, with cloven feet, body of a deep yellow colour, approaching to black, and whitish throat. There are two species of this creature, the one called the martes abietum, or fir-martin; the other the martes fagarum, or beech-martin. The beech-martin is distinguished from the other by having a larger and blacker tail, and being all over of a darker colour, and by
by being white on the throat; whereas the others are yellow; but the species are scarcely kept up distinct, the creatures mixing with one another in the breed. When distinct, the bee-thorn is found to be a much tamer creature than the other, and may be kept about houses like a cat; and often lives of its own accord about houses, and among old walls. Their skins make a valuable fur; and that of the fir-thorn, or yellow kind, is much the most valuable; prodigious numbers of their skins being annually imported from Hudson's Bay and Canada.

The thorn is of the size of a cat, but long-bodied; its legs are also shorter, and its claws less sharp and shorter. Its whole body is covered with hair of a yellowish-black, except only the throat, which, in the bee-thorn, or tame kind, is white; and in the wild kind, or fir-thorn, yellow; its teeth are sharp and strong, and the dog-teeth, in particular, stand out a great way.

The bee-thorn, with all, inhabits woods, makes its lodge in the hollows of trees, and brings from four to five young at a time. It makes great havock among poultry, game, &c. and will eat mice, rats, and moles. The pine, or fir-thorn, inhabits the north of Europe, Asia, and America; and is found also in Great Britain, particularly in Scotland; where it lodges in the fir-forests, building its nest at the top of the trees.

The thorn leaves for a long season, that the hounds, when out in a morning, will often take it, and make a noble cry. The chase in this cafe is very good while it lasts, but it is very perplexed for the creature is not able to run long, and when she is tired, she gets up into a tree; the hounds often lose her occasion, but if she is spun up in the tree, she is to be hunted down, with hicks, &c. When killed, the hounds are not suffered to eat her flesh, for it is unwholesome.

Martin, Free, is a name given in this country to a cow-calf, call at the same time with a bull-calf, which is a kind of hermaphrodite; that is never known to breed, nor to discover the leaf inclination for the bull; nor does the bull ever take the leaf notice of this animal. It has all the external marks of a cow-calf, viz. the teats, and the external female parts, called by farmers the bearing. When these animals are preferred, it is not for propagation, but for all the purposed of an ox or spayed heifer, viz. to yoke with the oxen, and to fatten for the table. They are much larger than either the bull or the cow, and the horns grow larger, being very similar to the horns of an ox. The below of the free thorn is like that of an ox; and the meat resembles that of the ox or spayed heifer; being generally finer than that of the bull or cow; and is more susceptible of growing fat with good food. Mr. Hunter has anatomically described the ovaries of this kind, in the Phil. Trans. vol. lxxix. part i. p. 280, &c.

Martin, St., Cape, in Church History. See Cape.

Martinez, in Ornithology, the name of a species of water-fowl, of the larus or gull kind, the larus naturis of Linnaeus, and called by the Dutch, the burgomaster of Greenland; by the Cornish people, the waggell, or the great grey-gull. See Larus Naturis.

Martin, Adam, in Biography, refusing to conform to principles that he did not believe, was deprived of his living at Rothorn in Cheshire, in the year 1662, after which he acted as chaplain in the family of lord Delamere. He died about the year 1660, and is known as an author, by a useful tract on surveying, called the Land-meters Vade Mecum. He wrote likewise twelve problems on the subject of metre, and two almanacs. He kept a mathematical school at Warrington, and afterwards at Dunham, in Cheshire. In theology he was the author of "Divinity Knots unlooke," and "Truth and Peace restored."
with dissertations. The first is an enquiry what kind of melody mankind is inclined to by nature, untaught by rules or example. Here the ancient Greek syllons, tetra
cords, scales, and genera are considered, and their numerical
correlations given. Much musical erudition is manifested
in this dissertation concerning the music of the ancients.

Dissertation II. On what kind of concourse was used
by the ancients, or, in other words, whether they had simulta-
aneous harmony, or that kind of harmony, or music in parts,
which the moderns call counterpoint. This subject is well
discussed, the opinions pro and contra fairly given, with
specimens of early attempts at harmony, and progressive
improvements in counterpoint from the time of Guido.
Infmite pains have been taken in this profound enquiry.
No writer was ever more timid in assertion than the worthy
Padre Martini. Not a sentiment has escaped him on the
authority of his own opinion or conjecture, all is confirmed
by the most curious specimens and citations from the most
ancient and reputable writers on the subject.

Dissertation III. Of the melody and musical instru-
ments used by the Hebrews in the Temple. The sacred
writings and the fathers have been idly confuted and
quoted in this inquiry, as well as the ancients, and the service
of the synagogues, whence several Hebrew chants have been
drawn, as well as from the Psalms of the first reformers,
and the cantus-fermo of the Missal.

This volume, besides plates of ancient instruments, and
musical examples printed with type, has head and tail-pieces
in the form of vignettes to each chapter and dissertation,
on which are engraved canons by the author in every kind of
construction; which being only given in a single part, with
out bars, and often wrapped up in mystery, their solution
will be an excellent study for Tyros in the art of com-
position.

"Storia della Musica," tomo secondo da F. Giambatilla
Martini, in Bologna, 1770, 4to. Though thirteen years
had elapsed between the publication of the first volume and
this, the learned and laborious author has advanced but a
little way in the history of ancient music. The first
volume adheres more closely to the subject of his history than
this, which is more miscellaneous. Chronologically, the
author advances no further in this volume, which is wholly
confined to Greek music, than the invention of the Olympic
games. So that the period which he describes is limited to
fabulous times. Indeed he describes the customs, manners,
and uses to which music was applied by the most ancient
inhabitants of Greece, more than the music itself, of which
there are no remains to give evidence to the wonderful
powers ascribed to it. He has a chapter on the origin of
music in Greece, chiefly on the word of the poets; and
another chapter on the universal use of music among that
refined people. In this volume we have, likewise, learned
dissertations, one on the fugal qualities ascribed to music
by the Greeks; and another on the respect which they had
for this art, and the wonderful effects said to have been pro-
duced by it.

In this volume, besides a number of learned and elaborate
canons, placed in a similar manner to those of the first
volume, we have a map of ancient Greece and Asia Minor;
and in the preface a sketch of the history of the early
inhabitants of those countries, who first cultivated the fine
arts.

"Storia della Musica," tomo terzo da F. Giambatilla
Martini, in Bologna, 1781, 4to.

It is much to be lamented that this was the last volume
of his elaborate work, which the learned author lived to pub-
lish! It is the more to be lamented, as this indefatigable
ecclesiastic had, with incredible pains and considerable ex-
pense, collected materials sufficient for the completion of his
whole plan. And this third volume advances no fur-
ther in the history of ancient music, than the period between
the establishment of the Olympic games of Greece to the
time of Alexander the Great. The history of Roman
music only was to have occupied the fourth volume.

From the materials of which P. Martini was in posses-
sion, there is reason to believe that the history of music in Italy,
where the present stylem throughout Europe had its rise
during the middle ages, and from the time of Guido to the
present period, would have been the most valuable pre-
sent to all Europe which the good father could make; but
in writing the history of ancient Greek and Roman music,
he had no other means of information than those of
which others were in possession; the classical writers and their
commentators. Of the three, I. Martini has availed
himself, it will perhaps be said, to an excessive degree.
In the volume now before us, we have a long preface,
and canons, as before. And besides the history of music from
the first Olympiad, we have the history of every species of
poetry that was connected with music, with the history of
its professors, as well as of the stage, tragic and comic, and
of all the poets and philosophers who cultivated music,
and wrote upon the subject. The volume is terminated with
another dissertation on the miraculous effects ascribed to
music of the ancient Greeks, with new facts and reason-
ing. This volume will probably be thought tedious by
those who have read, or are able to read, the original authors
whence its materials are derived; to others it is a valuable
Thesaurus of all that can be extracted concerning music,
from the chief writers of high antiquity and authority, that
are come down to the present times.

It is but justice to extend the account of this important
work beyond the general limits of the short analysis given
of other literary musical articles. The style has been said
to be dry and prolix. It is indeed cultivated by no extrac-
tious matter, or ingenious reflections; but each page is
replete with information on the subject in question; and the
notes abound in curious passages from scarce books. The
road through which the good father leads us, is not shrewed
with flowers, is not barren, but frequently abounds a glimpse,
at least, of incipient cultivation, which excites a wish and
expressions to advance out of twilight, into regions where
the fun of science shines with more luster, to which, alas!
the author did not live to lead us.

Between the publication of the second and third volumes
of his "Storia Musica," P. Martini published a work, en-
titled "Effremare o sia Saggio di Contrappunto," Bologna,
two volumes, folio, 1774.

This excellent treatise, though written in defence of a
method of composing for the church upon cantus-fermo, now
on the decline, yet has given the learned author an oppor-
tunity of writing its history, explaining its rules, defending
the practice, and of inferring such a number of venerable
compositions for the church by the greatest masters of choral
harmony in Italy, from the beginning of the sixteenth cen-
tury to the middle of the last, that we know of no book so
full of information concerning learned counterpoint, so
rich in ancient and scarce compositions, nor so abundant in
instructive and critical remarks, as this.

The work is divided into two parts or volumes. In the
first, after a candid and fair explanation of his design, and a
wish to keep sacred music separate from secular, we have
"a short compendium of the elements and rules of coun-
terpoint." The laws of harmony are here comprised in ten
rules, which are extremely well explained and illustrated.

We
MARTINI.

We then have a fundamental and practical essay on counter-point constructed upon canto-fermo. This is followed by upwards of sixty admirable compositions in all the ecclesiastical tones by the greatest masters of the old school of counterpoint in Italy; such as Anninuccia, Cifra, Morales, Palestrina, Pontio, Porta, Willaert, his scholar Zarlino, and others.

The second part contains examples of composition; or a fundamental and practical essay on contrapunto fugato, implying the art of fugue. Here all the terms of this art are explained; as subject, answer, point, regular fugue, and imitation. Canon is defined, and indications and signs are given for the commencement of the several parts in Italian, Latin, and Greek, with explanations of other techniques placed at the beginning of canons, where several parts are to be.

There are prefixed to many ancient canons, certain mottoes and enigmas of very difficult solution. The author has collected and explained a series of these. Other technical terms occur, such as propo gia, risposta, antecedent, consequent, contrapunto, rotefi, &c. All these rules and terms are illustrated with examples of composition by P. Martini himself. After which we have near fifty compositions in fugue and canon of the most curious kind, from the works of Palestrina, Agostini, Benevoli, Bernabei, Luca Marenzio, Monteverde, Clari, Lotti, Marcello, Peri, Stradella, Stefani, Alessandro Scarlatti, &c. in 2, 3, 4, 5, 6, 7, and 8 parts.

The compositions of these masters are not more admirable than the historical and critical notes of the editor, which young students will find no less instructive than amusing.

In 1709 Padre Martini drew up and gave to his disciples a very short tract, entitled "Compendio della Teoria de numeri per Ugo del Musico di F. Giambattita Martini. Minore Convettuale." In this tract, the good father defines the three principal calculations, ratios, and proportions necessary for a musician to know in the division of the monochord and in temperament:

The arithmetical progression, in which the intervals are equidistant.

The geographical progression, or series of numbers in a duplicate ratio.

The harmonical progression, consisting of a series of numbers.

See PROGRESSION and PROPORTION, where the English reader will find the several progressions and proportions used in harmonics more clearly explained than in this small tract of Padre Martini, in Italian, or even in a translation of it.

But Padre Martini was attacked in a more rude and formidable manner by Eximeno, in a publication subsequent to his treatise "Dell' origine e delle Rigole della Musica," in a publication under the title of "Dubbio di D. Antonio Eximeno sopra il Saggio di Contrappunto del Giambattita Martini," printed at Rome 1775. In this work, as a defence of his own flimsy syllable, he tries to overturn all other syllables, particularly that which Padre Martini is endeavouring to explain and defend in his "Saggio di Contrapunto." It is the method of teaching counterpoint by writing upon canto fermo, which has been established in the conservatories of Naples more than a hundred years. And when we recollect the great composers, not only of church-music, but theatrical, which the Neapolitan school has produced, we cannot help regarding its method with reverence, particularly as far as regards ecclesiastical composition, alla Palestrina, which is that of our services and full anthems on the venerable models of Tallis and Bird; nor can that reverence be diminished by the writings of any of its foes, till a better method is discovered, which has not yet been done by signor Eximeno; who is a lively writer, an able logician, and seemingly better skilled in every other art and science than that of music, if we may be allowed to judge by the specimens which he has given in illustration of his own rules of composition, which were intended to supersede all former laws of harmony throughout Europe.

The Neapolitans, whole school and method of teaching counterpoint by writing upon canto fermo P. Martini had so well defended in his "Saggio di Contrapunto," published, without name or date, a pamphlet entitled "Giudizio di Apollo." A certain Andrea Manini, of Udine, having, in a work entitled "Trattato in Genere Teorico," published in 1761, treated with difference, not only P. Martini, but his excellent master, Jacopo Peri; all the venerable harmonists of the 16th and 17th centuries appear before Apollo in defence of the perfections truded; and Manini, the author of that libel, is sentenced, not only to perpetual banishment from Parma, and from all intercourse with the muses and their votaries, but prohibited, in future, from all further use of his pen. This pamphlet lifted from the Neapolitan press, was circulated all over Italy, no body knew by whom or by what means.

MARTINI, GIUSEPPE SAN, an exquisite performer on the hautbois, and an original and excellent composer, was a native of Milan; but best known in England by the title of Martini of London, where he arrived in 1723. His first public performance there was at a benefit concert, at the little theatre in the Hay-market, then called the French theatre, from a company of French comedians being allowed to act there in the French language, to which George I. frequently went, as his majesty was not sufficiently acquainted with our language to be much amused at our national theatres. The benefit concert at which Martini was first heard, was for a signor Piero; in the advertisement for which, Martini is called "an Italian master, just arrived." But in this performance the applause he received was such, that he was immediately engaged as principal hautbois at the Royal Academy of Music, or Opera, where he continued to perform during the whole time of Handel's regency.

His first publication in England was advertised October 6, 1730; consisting of "Twelve sonatas for two flutes and a basset, being exceeding fine harmony." Such previous praise is seldom given to compositions that deserve it; but the public soon found that a newspaper eulogium, for once, spoke the truth.

About the year 1740, he was taken into the service of his royal highness Frederic prince of Wales, was music-master to the princes, and gave lessons in finging to several ladies, who had the good taste to be sensible of his merit, and the good fortune to prevail on him to attend them; but he performed no more in public after he quitted the opera.

We never heard him play; but the concertos which Tommy Vincent, his scholar, used to perform on the hautbois, and which he had composed for himself, were admirable; full of fire, and new and elegant passages, in the true genius of the instrument; and the best judges who had often heard him at the opera and in private parties, would allow of no parallel in his tone and execution, with those of any other hautbois player upon earth.

He died about the year 1750. And as a proof of the high admiration with which the public was impressed by his performance, when his books and instruments were sold by auction after his decease, a hautbois on which he used to perform,
perform, which originally only cost five-and-twenty shillings, told for eighteen guineas, to somebody, who perhaps imagined, that an instrument on which Martini used to play delightedly, would almost play itself.

As a composer, Martini was possessed of all the learning of the old school, with infinitely more invention, taste, and grace than any other Italian of his time.

His twelve sonatas for two violins and a bafe, dedicated to the princes of Wales, were very long in high favour with the public; and his full concertos, when performed at the concert of ancient music, fill the attention and admiration of all true judges of instrumental music. Indeed San Martini was the only composer of whose productions the exclusive admirers of Corelli, Geminiani, and Handel ever spoke without the farcical epithet of new, or the more broad cenfure of modern flimsy stuff. But Martini still wrote fugues; in spite of which his music floor its ground among the moderns, better than any other instrumental compositions with which we are acquainted.

Martini, Giovanni Battista San, a younger brother of San Martini of London, in 1775, was organist and maestro di cappella to many churches at Milan, and wrote so faft, that his ecclesiastical compositions were too flight and flimsy. The late viscount Dudley and Ward, when on his travels, took lessons of him in music, and his lordship, then the honourable Mr. Ward, having collected all the curious compositions of the time, in his progress through Italy, Martini eagerly borrowed of his cleve all the new music which he could possibly spare, and honestly confessed that it was with a view to feed his own fancy, which, by writing so much and so faft, was a little exhausted. There was scarcely a clown in Italy who did not know good music from bad. And we ourselves, on a day of festivity, in a church, heard two penfants, after littering a little while to one of Martini's masses, cry out, "Quita musica e felicior-ante," and hallowed away to another church.

The violin music, however, of this Martini, particularly his symphonies, concertos, and sonatas, composed about the middle of the last century, was full of fire, invention, and beautiful melodies. He was one of Giardin's masters on the viola; and the first piece he played in public, after his arrival in England, was a solo at the benefit of Cuzzoni, composed by San Martini of Milan.

Some of his symphonies and full pieces were played at Vauxhall, Ranelagh, Mary-bone, and Cuper's gardens, with great applause, during many years.

Martini, Abate, a learned Venetian dilettante, and an excellent judge of every species of music, ancient and modern; was an able mathematician, composer, and performer. He had travelled into Greece, in order to make observations in geography, agriculture, and natural history, but being unable to satisfy himself as he expected, his pride was so hurt by the disappointment, that he would not publish any of his remarks or discoveries. Among other curious enquiries, he made many concerning the music of the modern Greeks, in hopes it would throw some light upon that of the ancient. He knew as much, we believe, as any one else, about the fycams of Pythagoras, Pindar, and the Greek writers collected by Medeburn, as well as of Rameau and Tartini. He was a great admirer of the works of Marcello, and fing, by heart, all his cantatas and poet melodies; and was the founder of an academy for the performance of his music, exclusively.

When he visited the Greek isles, besides enquiries after ancient music, his curiosity extended to the present state of music among the modern Greeks, of which we have spoken elsewhere. See Music of the Greek Church, and Russian Music.

Martini, of Madrid, a lively and spirited composer, who has furnished the theatre Italian, at Paris, with the music of several successful comic authors. We are not much acquainted with the vocal music of this author; but have sometimes thought his instrumental too turbulent and clamorous.

Martini, in Geography, a town of Naples, in the province of Otranto; 16 miles W. of Oultuni.

Martínico, one of the largest of the Caribbean islands in the West Indies, being about 60 miles in length, and 30 in breadth, and containing about 260 square miles. The interior part is hilly, abounding with hillocks or small eminences, above which are elevated three mountains of considerable height. The height of these, called Peles, exhibits appearances of an extinct volcano, and is covered with woods that attract the clouds, and occasion noxious damp, which render it in a great measure inaccessible. The other two mountains are in moist parts cultivated. These mountains, and particularly the first, furnish springs, from which issue the streams that water the island; these are naturally of gentle current, but, with the slightest storm, are changed into torrents. The chief river is called Galion, and waters the N.E. part of the island. The water which they supply, partaking of the nature of the foil over which they pass, is in some cafes excellent, and in others so bad, that the inhabitants are under a necessity of drinking the water which they have collected in the rainy season. The produce of the soil, fertilized by its rivers, is fugar, cotton, indigo, cocoa, ginger, and such other commodities as are found in the neighbouring islands; and as its bays and harbours are numerous, safe, commodious, and well fortified, it is favourably adapted for trade. The island is divided into twenty-eight parishes, which contain about the same number of towns and villages, and two principal towns, viz. Fort Royal and St. Pierre. The first Europeans, who formed a settlement in this island, were the French, under the conduct of M. Delahuze, accompanied by about 100 persons from St. Christopher's in the year 1635; and after having obtained land from the Caribs, they at length expelled the natives. The French being thus masters of the island, and living without molestation, erected themselves for some time to the cultivation of cotton, soon adding that of annatto and indigo. About the year 1650, they commenced the culture of sugar; and ten years afterwards, Benjamin Da Costa planted some cocoa-trees. His example was followed in 1664, when the demand for chocolate in France became more common. Cocoa continued for some time to be the principal object of cultivation till the year 1718, when all the cocoa-trees were destroyed. The coffee-tree was then introduced, as a kind of succedaneum to the cocoa which had failed. Martinico promised great advantages to the French; and accordingly it was made the seat of their government, and the object of their particular attention. Nevertheless, at the end of the 17th century, its progres had not been very considerable. In 1750, the whole population, reckoning white men, free negroes, and slaves, amounted to no more than 21,420 persons. The cattle consisted of 1,658 horses or mules, and 9,171 head of horned cattle. The inhabitants cultivated a great quantity of cocoa, tobacco, and cotton; they had nine indigo louises, and 183 small sugar plantations. In 1736, there were 447 sugar works; 11,953,322 coffee trees; 193,870 of cocoa; 2,668,450 of cotton; 39,400 of tobacco; and 6750 of annatto. The population amounted to 73,000 blacks, men, women, and children; and their supplies for provision con-
fitted of banana-trees, caffava, potatoes, and yams. At this time the annual exportation amounted to 700,000 lb. Herling. The export trade was very extensive. However, the war of 1744 checked this prosperity. By a series of misfortunes and losses, Martinico fell into the hands of the English in 1762; but in the following year, at the conclusion of the war, it was restored to its original proprietors. In the year 1775, this island contained 1,138,300 white people; 25,244 free people of colour; 71,142 slaves. It was then thought that the slaves were too numerous, and it was intended to exterminate this sort of sugar-cane; with some caico, indigo, cotton, and coffee. The noted snuff, called "Maconba," is made of tobacco raised in the parish of that name in the north of Martinico. About this time its products were computed at 23,000,000 lbs. of sugar, 5,000,000 lbs. of coffee, 6,000,000 lbs. of cocoa, and 42,000,000 lbs. of cocoa. In the statistical account of France, published by Herbin, the population of Martinico in 1788 is said to consist of 10,603 whites, 4851 free mulattoes, and 73,416 slaves. The exports at that time amounted to 25,634,000 francs; while the imports from France amounted to 151,123,000 francs of French produce, and 9,138,000 francs of foreign trade. Martinico is celebrated for a distillery of liquor. Quarries of free-stone are rare in this island, and blocks of lava are used. Lime is made with the madrepores and sea-shells. No mines have been discovered; but a ferruginous sand, after a volcanic production, had been observed on the shore near Mount Pelée. The inhabitants of Martinico are pale, and deficient in that bloom which is observable in the people of France. Most of the native quadrupeds have been destroyed; but rats and mice unhappily abound. In this island there is a bird called the whitter of the mountain, from the resemblance of his cry to that of a man whistling. The red ant was very destructive till it was destroyed by putting arsenic into its nests, or burning it over its path. The hurricanes in Martinico are very violent and destructive. The rain descends in large drops resembling the sound of hail. In the year 1794, Martinico was taken by the British under the command of sir John Jervis and sir Charles Grey; the attack commenced Feb. 3, and the island surrendered March 16. N. lat. 14° 24' to 14° 32'; W. long. 61° 2' to 61° 26'.

Martinico, Little, one of the Grenadine islands in the West Indies. N. lat. 13° 38'. W. long. 61° 18'. See Berla.

Martinius, Matthias, in Biography, a learned German Protestant divine and philologist, was born in the county of Waldeck in the year 1572. He was educated under the care of Degener, and at the age of twenty-three, was appointed preacher to the court of Nassau-Dillenburg, and in 1596 he was nominated one of the professors of the college of Hardom. He particularly excelled in his philological lectures, and in initiating his pupils in the oriental languages. About the year 1607 or 8, he became pastor of Embden, where he remained three years, much respected and esteemed as a minister and a man. He was now offered the rectoryship of the college of Bremen, which he accepted, to the great benefit of that institution. In 1618, Martinus was one of the deputies appointed by the city of Bremen to the synod of Dort, where he enlisted among the combatants against the supralaparians. He died at the age of 58, in the year 1635. His works are very numerous; but the most important, and that on which his fame is chiefly built, is "Lexicon Philologicum, præcipue Eymolgicum et Sacrum," in two large volumes, folio. Moore.

Martino, Sr., in Geography, a town of Italy, in the department of the Adda and Oggio; 8 miles W. of Bergamo.—Allo, a town of France, in the department of the Po, in the district of the Four Valleys, to which it gives name; 9 miles N.W. of Pinerolo.—Allo, a town of France, in the department of the Saja; 10 miles N. of Turin.—Allo, a town of France, in the department of the Maritime Alps; 12 miles W. of Tenda.—Allo, a town of Italy, in the Veronese; 15 miles N.W. of Verona.—Allo, a town of Italy, in the department of the Reno; 12 miles N.E. of Bologna.—Allo, a town of Italy, 13 miles N. of Modena.—Allo, a town of Naples, in Calabria Ultra; 5 miles N.W. of Oppido.—Allo, a town of Naples, in Basilicata; 24 miles S.S.E. of Potenza.—Allo, a town of Corfica; 4 miles N. of Biaia.—Allo, a town of Italy, in Friuli; 7 miles S.E. of Friuli.

Martino Pecatorius, in Ichthyology, a name given by Salvian, and some others, to the genera plicatrix of anhurn, and the lophius of Artedi.

Martinowa, in Geography, a town of Austrian Poland; 6 miles N. of Halicz.

Martsinsberg, Sr., a town of Hungary; 10 miles S.E. of Raab.

Martsinsborough, a town of America, in North Carolina, on the S. side of Tar river; 20 miles above Washington.

Martsinsburg, a port-town of Virginia, and capital of Berkeley county, about 8 miles S. of the Potomac, in the midst of a fertile and well cultivated country; 27 miles from the mineral springs at Bath. It contains more than 70 houses, a court-houfe, gaol, and episcopal church, and another near the town is appropriated to the Presbyterians; 22 miles N.E. of Winchester, and 58 N.N.W. of Alexandria.

Martsinsdyck, Sr., a town of Holland, in the island of Tolen; 5 miles W. of Tolen.

Martsinsperg, a town of Austria; 6 miles S.S.W. of Zwell.

Martsinvast, a town of France, in the department of the Channel; 3 miles S. of Cherbourg.

Martsinville, a port-town of America, and the capital of Guilford county, in North Carolina, pleasantly situated on the E. side of Buffalo creek, and containing about 40 houses, a court-houfe, and gaol.

Martiobarbuli, among the Romans, a designation given to orderers who carried leaden balls to annoy the enemy with.

Martiorda, or Marticona, in Natural History, the name which the ancient Greeks gave to the animal which the Romans called manticora.

Martzay, in Geography, a town of France, in the department of the Indre; 11 miles S. of Chartillon sur Indre.

Marlet, in Heraldry, a little bird represente without feet, and properly also without a beak. It is used as a difference, or mark of distinction, of a younger brother; some say, more peculiarly of the fourth brother, or family. See Differences.

Marten, in Ship, small lines fastened to the leech of a sail, being received through a block on the top-mast-head, and coming down by the mast to the deck. Those martas which belong to the top-masts are fastened in the same way to the heads of the top-gallant-masts, but their fall comes down no farther than the top, when it is hauled. The word is, top the martas, i. e. hale them up. Their design is, in furing the fall, to bring that part of the leech
leech which is next the yard-arm close to the yard, so that the sail may furl up the closer.

MARTO, in Geography, a town of European Turkey, in Romania; 20 miles S.E. of Gallipoli.

MARTOCK, a market town and parish in the hundred of that name, and county of Somerset, England. It chiefly deferves notice on account of its church, which is a large and elegant edifice, consisting of a nave, chancel, north and south aisles, and a porch. The interior is finely ornamented with carved work, and some paintings of the apotles. An altar-piece in flueco, erected by John Butler, esq. particularly attracts admiration. The market is held twice a week, on Wednesday and Saturday, and is usually well supplied with provisions of every description. Near the market-houfe, which is a neat modern building, erected at the junction of three turnpike roads, in the middle of the town, stands a very handsome fluted column, being a model of the famous pillar of Trajan. The parish is of great extent, and is divided into nine tythings, containing, according to the parliamentary returns of the year 1801, 376 houses, occupied by 2102 persons. The town is watered on the south-west by the river Parret, and on the north by the Yevo. The manor was possessed by Edith, queen of Edward the Confessor, at the time of the Norman conquest. The History of Somersetshire, 3 vols. 4to. 1791.

MARTON, Sr., a town of Hungary; 10 miles W. of Rosenburg.

MARTORANO, a town of Naples, in Calabria Cita, the fee of a bishop, suffragan of Cofenza; 13 miles S. of Cofenza. N. lat. 30° 8'. E. long. 16° 28'.

MARTOREL, a town of Spain, in Catalonia, situated on the Noya, at its confluence with the Llobregal. This is a small, dirty, close, and ill-built town; it has a parish church, a convent of monks, and some barracks; the inhabitants are laborious; the women make lace and blinds. Near this town is a triumphal arch, said to have been erected by Hannibal in honour of his father; it stood at the north end of a bridge originally built by his order when he crossed the river in his way to Italy, and repaired in 1768; 20 miles N.W. of Barcelona.

MARTRY, Sr., a town of France, in the department of the Upper Garonne, on the Garonne; 10 miles N.E. of St. Gaudens.

MARTOS, a town of Spain, in the province of Jaen, supposed to be the ancient *Trusc*, afterwards called *Auggula gemella*; situated on the side of a lofty mountain, on the top of which is a caftle. The town belongs to the order of Calatrava, by which a civil and military governor are kept there, and an alcalde mayor for the administration of justice. It was once an episcopal fea, which was destroyed under the Moors. Its present population amounts to 15,000 persons. The top of the rock on which the caftle stands is famous for the death of the two brothers of Carvajal, commanders of the order of Calatrava, who under an unfounded charge of murder were precipitated from the rock by order of Ferdinand, king of Castile; 10 miles W. of Jaen.

MARTIGNY, a town of France, in the department of the Valadoes; nine miles N.N.W. of Cen.

MARTRES, a town of France, in the department of the Upper Garonne; 15 miles N.E. of St. Gaudens.

MARTRES de Vevey, Lex., a town of France, in the department of the Pays de Dôme; seven miles S.E. of Clermont.

MARTYN, John, in Biography, late professor of botany at Cambridge, was born Sept. 12. 1659, in Queen street, London, where his father Thomas, a very worthy and respectable man, lived in a mercantile station. His mother, whose maiden name was Catharine Weeton, died Nov. 1, 1700. After being educated at a private school in the neighbourhood, he was taken, at the age of 16, into the counting-houfe of his father; nor does it appear that he neglected or despised the duties of the station to which he was then deHined, though he had already imbibed so frong a taffe for literature, that he confantly devoted much of the night to study, allowing himself, for many years, no more than four of the 24 hours for sleep. In the summer of 1718 he first acquired a taffe for botany, in conquence of his acquaintance with Mr. Wilmer, an apothecary, who afterwards became demonstrator in the Chelsea Garden. He was in the following year introduced to Dr. Patric Blair, and the justly celebrated Dr. William Sherard, the moft liberal and intelligent promoter of this science that his country could then boast. With such instructors and counsellors, his progres was rapid. He soon became defirous of commencing author, and it is fortunate that this was not prevented, by his imbibing the diffidence of Sherard along with a portion of his knowledge. Mr. Martyn translated Tournefort's history of the plants growing about Paris, from the French into English, in 1720; which however he did not print till twelve years afterwards, when it appeared, dedicated to lord Petre, and improved in many repects, being accommodated to this country by the addition of English names, and the mention of particular places of growth. Nor were his studies merely speculative, or confined to books. He underwent various botanical excursions, which were chiefly performed on foot, that he might observe plants in their natural situations, as well as insects, which had now likewise excited his attention. When at home, he busied himself in feeding seeds, that he might speculate upon their germination, and the structure of their cotyledons, and was eager in collecting, not only dried specimens of plants, but their seeds and fruits. His attention to these subjects, prove him to have been no superficial enquirer, and his letters to Blair flew that he studied both nature and Cefalpinus with advantage. The leading character of his mind seems to have been a taffe for enquiry, which prompted him to examine every thing for himself. His observation of the works of God directed his thoughts to the divine origin of all things, and his perusal of some of the most famous admirers of revealed religion, served but to confirm him in its truth. About the year 1721 he became acquainted with the celebrated Dilleniis, and in conjunction with him and several others, among whom we find the names of Deering, Thomas Dale, and Philip Miller, estabHished a botanical society, which met every Saturday evening. Dilleniis was president, and Martyn secretary. The latter, ever foremost in activity, read before this society a course of lectures, upon the technical terms of the science, the foundation, as it is premed, of what he afterwards published. These meetings were continued for about five years only.

We are not informed of the period at which Mr. Martyn changed his mercantile occupation for the medical profession, to which he was, doubtless, led by the general tenour of his pursuits. In 1723 he was offered admission into the Royal Society, which he declined, as it appears by one of his letters to Dr. Blair, from pure modesty. His objections however were overcome the next year; and he soon proved himself an active and worthy member, by his various communications, to be found in the transactions of that learned body; of which publication he subsequently took a part in the abridgment, though he was an unsuccessful candidate for the place of Secretary to the society, obtained by Dr. Cromwell Mortimer. In 1726 he published his tables of Officinal Plants, in 20 pages folio,
MARTYN.

folio, disposed according to Ray's system. He had given a public course of lectures in Botany the preceding year, and had, with the assistance of Dr. Blair, undertaken to make a collection of birds. His herborizing excursions were from time to time continued, notwithstanding his various labours and engagements in town. His second course of lectures there, in 1726, being much approved, he was recommended by Dr. Sherard and Sir Hans Sloane as fit to teach the science in which he excelled, to the University of Cambridge. He gave, in 1727, in the anatomy school, the first botanical course ever read in that University, though Ray had studied there, and done all that he could to excite a love of natural knowledge. For the use of his pupils he reduced the alphabetical catalogue of Cambridge Plants, printed by that great man, into a systematic form, according to the principles of its author. As he excelled in the knowledge of Cryptogamous vegetables, he improved the work in that department; and he now very judiciously laid aside the old systematic practice, of separating trees and shrubs from herbs, in his classification. When we consider what Mr. Martyn undertook, and what he accomplished, in the technical and systematic departments of Botany, he will be found to deserve a high rank amongst the philosophers, even of the age in which he lived; nor did he leave any walk of his beloved science unexplored. In 1728 he published the first Decade of a magnificent work, entitled 

_Illustration Plants._

in imperial folio, in which his merit in the descriptive line is conspicuous. The plates were drawn by that great artist Van Huyfum, engraved in mezzotinto by Kirkall, and printed in colours. In the latter part of their execution they fail very much, that mode of colouring plants having scarce ever been found to answer, though at present carried in France to a higher degree of perfection than here tofore. (See _Figures of Plants._) Four more Decades of this work appeared in the course of nine years, after which it ceased, on account of the great expense of the undertaking.

When this publication commenced, its author is said to have "sedulously applied himself to the practice of physic." We preface this must have been as an apothecary, for he was not, by any medical degree, authorized to practice as a physician.

In 1729 he had a design of reading botanical lectures at Oxford, and it is not known what prevented this scheme. Probably the recent establishment of the Sherardian professorship there, in favour of his friend Dillenius, might very justly deter Mr. Martyn from what could not but seem an unnecessary, if not an unfair, intrusion.

In the following year we find him projecting, in conjunction with Dr. Ruffel, the Herculean labour of a new edition of _Stephens's Latin Thesaurus_; but this design was dropped. Instead of it, he associated himself with the same friend, and some others, in a critical work, entitled the _Gruh-fleet Journal_, a periodical publication, which had a large sale. In what style or temper it was executed we have not had an opportunity to inquire; but the critical dissertations of our author, published by his son, display his critical learning and acuteness in no ordinary degree.

On the 20th of May, 1730, Mr. Martyn was admitted of Emanuel College, Cambridge, with an intention of taking his degrees in physic; but after keeping five terms in his marriage, and the necessary attendance to his profession, caused him to relinquish this design. He had resided for three years in Great St. Helen's, but the town air disengaging with his constitution, which was allmatic, he removed to Chelsea, where he married, on the 20th of August 1732, Eulalia, youngest daughter of John King, D.D.

rector of Chelsea and prebendary of York, by whom he had three sons and five daughters. Four of the latter died young, but the other children survived him.

At the close of this year the Professorship of Botany at Cambridge became vacant, by the death of Mr. Bradley, who had for some years, not very worthily, filled it. All eyes were directed towards Mr. Martyn as the properest person for this situation, and his opponents, who wished to obtain it for themselves or their friends, conscious of his superior merit, had no other resource than to represent him as a Nonjuror. Whatever effect this might have had was defeated, by his taking the requisite oaths, and his unanimous election took place on the 8th of February 1733. It is remarkable that in two or three years after obtaining the appointment, he finally ceased to lecture. This is attributed to the want of encouragement, and especially of a botanical garden, at Cambridge. There had been hopes of the latter being established in 1731, through the liberality and zeal of a Mr. Brownell of Willingham; but the scheme fell to the ground, nor was it revived with effect till many years afterwards.

Nevertheless, our indefatigable botanist and scholar was not idle. The work on which his literary fame chiefly and firmly reigned is his splendid quarto edition of Virgil's _Georgics_, which appeared in 1741, dedicated to Dr. Mead. Here his abilities and his acquisitions had their full scope. The text was accompanied by an English translation, and ample notes in the same language. In the preface the editor was enabled, by his peculiar line of study, to throw more light upon the natural history of his author, than any one before him had done, nor is it easy to improve upon his performance. He was affiliated in the aulteristical part by his friend the celebrated Halley, to whose worth he has given a just and feeling tribute in the preface. In 1749 he published the _Bucolics_ on the same plan, and intended to have gone through the whole of the Roman poet; but growing infirmities, and the loss of his wife, who died of a cancer in the breast this year, for a while damped his ardour. The labours of his profession, too, were becoming burdensome. He speedily indeed repaired his domestic losses, marrying, in July 1750, Mary Anne, daughter of Claude Fonmoreau, of Streatham, merchant. This lady bore him one son, and survived him.

In the spring of the year 1752 he retired from practice, and devoted himself to that rural seclusion, which his acquirements were so well calculated to render both profitable and delightful. He took a farm in a most beautiful situation at Streatham, and, but for occasional attacks of the gout, enjoyed several years of learned leisure united with scientific experience, in attention to the business of his farm, and the care of his family. On the 30th of January 1761, he resigned his professorship of botany in favour of his son the Rev. Thomas Martyn, who was elected in his stead, and who has ever since filled that station with honour to himself and to his parent. In gratitude for this election, so conformant to his own wishes, Mr. Martyn, some time afterwards, gave his botanical library, of above 200 volumes, with his drawings, herbarium, and collections of seeds and _Materia Medica_, to the university, for which the thanks of that body were very handsomely returned him in 1765.

This worthy man died at Chelsea, to which place his incurring invidious remarks had induced him, about a year previous, to return, on the 20th of January 1768, in the sixty-ninth year of his age, and was interred in the burying-ground there, near his first wife, where also the relics of Miller, Ehret, and, if we mistake not, of several other botanists, repose. Our account of him is chiefly taken from a small volume,

Gen. Ch. Cal. Perianth inferior, in five unequal segments, withering. Cor. of one petal, bell-shaped; tube inflated; spreading upwards, gibbous, and inering honey, on one side at the base; limb in five obtuse, nearly equal segments, the lowest more; the larger and more erect, slightly concave and crowded. Stain. Filaments four, thread-shaped, incurved, with the short pointed rudiment of a fifth between the upper pair; anthers two-lobed, converging, the two uppermost sometimes abortive. Pfl. German superior, oblong; style thread-shaped, simple, as long as the filaments; stigma two-lobed. Peric. Capsule woody, oblong, gibbous, quadrangular, with two furrows at each side, pointed and recurved at the summit, separating into two parts, enclosing an internal nucleus of four cells. Seeds several, ovate, tuberculated with a pulpy coat.

Eff. Calyx five-cleft, inferior: Corolla ringent. Capsule woody, coated, with a hooked point, two valves and four cells. Seeds several, ovate, pulpy.

Obf. The Martynia peregrina of Linnæus, having an inferior germen, and very different fruit, is now made a distinct genus. See Gloxinia.

1. M. diandra. Diandrous Martynia. Gloxin. Obs. 14. t. 1. Willd. n. 1. Jacq. Hort. Schoenbr. v. 3. 19. t. 295. (M. annua, villosa et vilcosa, folio subrotundum, flore magnò rubro; Houft. in Mart. Decad. 42. t. 42.)—Stem branched. Leaves heart-shaped, toothed. Two flaments abortive. Beak of the capsule very short. Discovered at Vera Cruz in South America, by Dr. Houfton, who sent fruits to Chelsea garden in 1731, which being found in a hot-bed, the plants flowered after midsummer. The root is annual. The whole plant downy, viscid, soft, juicy; branched and pubescent above. Leaves opposite, heart-shaped, acute, toothed, pliable, five to eight inches in diameter, on long, round, purplish, spreading stalks, without stipules. Clusters from the forks of the stem, of several pendulous hand-foot flowers, the fique and flavescently near the long podvalve, but their tube is nearly whole and downy, their limb of a rich crimson. Each flower has a pair of ovate purplish downy bratæas, at the base of its calyx, and equal to that part in length. Capsule ovate, about an inch long, with a very short recurved beak.

3. M. Probosidea. Long-stalked Martynia. Ait. Hort. Kew. n. 1. Gloxin. Obs. 14. (M. annua; Linn. Sp. Pl. 862. Swartz Obs. 230. Geitn. v. 2. 131 t. 110. M. caule ramoso, folis cordato-ovatis pilosis; Mill. l. c. 191. t. 286. Probosidea Jussieu; Schmidt. l. c. 49. t. 12, 13.)—Stem branched. Leaves heart-shaped, wavy. Beak longer than the capsule. Tube of the corolla scarcely longer than the limb. Native of the country about the Mississippi, from whence seeds were brought to the Paris gardens. Miller had some of the produce, and the plants flowered with him at Chelsea, before the year 1759, when he published his very excellent figure of this species, surpassed only by the elaborate and exquisite delineations of Schmidel. Linnæus had this plant also in the Upfal garden; and it is doubtless what he intended by M. annua, though he confounded the first species, if not the second also, with it. As the whole genus is annual, the above expressive name has been preferred. The leaves are heart-shaped, obtuse, undivided, and nearly entire, sometimes, but not invariably, alternate; their footstalks and ribs very hairy. Clusters terminal, many-flowered, lax, and hairy. Calyx bell-shaped, very unequally five-lobed. Bratæas at its base linear. Corolla pale flesh-coloured, internally dotted with purple; its tube declining, an inch long, and about half as much in diameter; limb in five broad, obtuse, wavy segments, almost as long as the tube, at least if their combined base be reckoned as a part of the limb; there are about five longitudinal orange stripes, within the tube, along its lower side. The capsule is remarkable for its long beak, and for a longitudinal crenell-like internal ridge, connecting the nucleus with the coat. The stigma consists of two flat ovate valves, which Turrera observed to be irritable, cloathing when touched.

4. M. longiflora. Long-flowered Cape Martynia. Linn. Syn. Veg. ed. 14. 559. Ait. Hort. Kew. n. 2. Meerburch l. c. 7. (M. capenis; Gloxin. Obs. 14.)—Stem nearly simple. Leaves roundish, wavy. Capsule with two teeth at the base, and a very short abrupt beak. Tube of the corolla three as long as the limb. Native of the Cape of Good Hope. Professor David van Royen sent its seeds to Linnæus, by the name of a new Pedalium. These vegetated and produced flowers in the Upfal garden. A sketch, which appears to be the prototype of Meerburgh's rude but expressive piece, was sent with the seeds. This is the lovely beautiful of the genus. It is annual like the rest, but more hardy, flowering in the greenhouse in July and August. The flum bears only short axillary branches. The flowers are rounded, and wavy, or bluntly toothed, nearly smooth. Flowers.
Flowers axillary, foliary, on shortish stalks, at whose base is a pair of glands. Calyx very small and short, with five teeth. Corolla white; tube declining, two inches long, slender, but less so than that of M. Craniolilia; limb in five irregular roundish lobes. Capsule oblong, with a pair of recurved teeth above, near the base, and an oblique, abrupt, scarcely hooked, very short beak. The stigma is linear and revolute. — There are considerable aberrations in various parts of the fructification in the different species, and yet the whole undoubtedly constitute a most natural genus, well defined by its fruit.

Martynia, in Gardening, contains plants of the tender, herbaceous, flower kind, of which the species mostly cultivated are, the two-flamed Martynia (M. diandra); the hairy Martynia (M. proboscidea); and the perennial Martynia (M. perennis). But there are other species which may be cultivated.

Method of Culture. — The two first sorts of these plants may be increased by sowing the seeds in pots filled with rich, fine soil, where they are watered frequently. When the plants have attained a little growth, they should be removed into separate pots of the same soil of earth, re-planting them in a bark-bed, giving due water and shade, till they become properly rooted, when they must have free air in fine weather: after they are a little advanced in their growth, they should be removed into larger pots, and be replaced in the bark-bed in the flower, due room being allowed them. They should constantly be kept in this situation, and be duly watered and supplied with fresh air in warm weather.

And the third sort may be raised by dividing the roots, and planting them in the spring, as about the middle of March, in pots of light rich earth, being plunged in the bark-bed of the flower. When the plants are up, they should be duly watered in a flight manner, and in warm weather fresh air be freely admitted, keeping them from being shaded by other plants. Even the cuttings of the shoots of the young plants planted in pots, and managed in the above manner, will also take root and form plants.

These afford ornament and variety among other flower plants.

MARTYR, Justin, in Biography, a Christian father, who flourished about the year 140 of the Christian era, was the son of Pricius, and born in Flavia Neapolis, anciently called Sichem, a city of Samaria, in Palestine. He was born, according to Tillemont, in 103, but, according to Fabricius and Grabe, in 89. In his youth, he was a lover of truth, and studied philosophy under several masters; first under a Stoic, next a Peripatetic, then a Pythagorean, and lastly, a Platonick, whose principles he preferred above all other, till he became acquainted with the Christian religion, which he embraced as the only certain and useful philosophy.

The time of his conversion to Christianity is uncertain: Cave and Tillemont conjecture, that it happened about the year 132 or 133. The first of these writers gives the following account of the course of his life, after his conversion.

In the beginning of the reign of Antoninus the Pious, he came to Rome; and in the year 140 prefented his First Apology to that emperor. Afterwards he went into Asia, where he had the celebrated conference with Trypho the Jew; and then retired again to Rome, where he wrote his Second Apology, ascribed to Marcus Antoninus, the philosopher, and suffered martyrdom about the year 164. Tillemont is inclined to place his death in 167 or 168. Fabricius supposes that he suffered martyrdom in the 74th year of his age, A.D. 163; but Grabe refers his martyrdom to the year 165 or 166, in the 74th or 76th year of his age.

Vol. XXII.

Justin is mentioned by many ancient Christian writers, who bear honourable testimony to his memory.

Eusebius, besides the accounts he had before given of Justin's books against Marcion, and all heresies, and his apologies, gives also this distinct enumeration of his works. He says, that Justin left behind him a great number of very useful works; as his Apology to Antoninus the Pious, and his sons, and the Roman senate, and another to his successor; a book against the Greeks (or Gentiles); another book against the Gentiles, called Elenchus (or a Confutation); another of the Monarchy of God; another, entitled Philo- ter; of the Soul; a Dialogue against the Jews, which he had at Ephesus with Trypho. There are also, says Eusebius, many other books of his, which are in the hands of the brethren. Jerome's account of Justin's works agrees with that of Eusebius.

However, the principal works of Justin are his two Apologies, and his Dialogue with Trypho the Jew, in two parts. According to Tillemont, with the context, and the Bene- dictine editors of Justin's works agree, the first and larger apology was not presented to the emperor before the year 170. Cave says that it was presented in 140; Pagi and Bnafage refer it to the year 139, and Maffuet about 145. The Dialogue with Trypho was written, according to Pagi and Bnafage, in the year 139; and according to Maffuet and the Benedictines, about the year 155. The Second Apology seems to have been presented to Marcus Antoninus in the beginning of his reign, about the year 162. The larger Apology is still extant entire; the beginning of the second apology is wanting; and is the conclusion of the first and beginning of the second part of the Dialogue with Trypho. Besides these, there are two Discourses to the Gentiles, generally allowed to be Justin's; one called an Oration to the Gentiles, the other the Piae, and an exhortation to the Gentiles, supposed to be the Elenchus mentioned by Eusebius. The piece now extant of the Monarchy of God, seems to be a fragment of that work of Justin. The epistle to Zeno and Serenus is at least doubtful, and thought by Lardner not to be Justin's. The epistle to Diognetus is generally supposed to be Justin's, though some have doubted the general account of the Epistle, which is more elegant than that of Justin's other pieces. The Questions et Reponses ad Orthodoxos, and other pieces usually joined with Justin's works, are allowed to bear the marks of a later time.

In Justin's works there are numerous quotations of our gospels, except that of St. Mark, which he has seldom quoted: and he quotes them, as containing authentic accounts of Jesus Christ and his doctrines. These gospels were read and expounded in the solemn assemblies of the Christians, as the books of the Old Testament were; and as they had been before in the Jewish synagogues. This reading of the gospels Justin mentions in his first apology to Antoninus the Pious. This general reading of the gospels, as a part of divine worship at that time, about the year 140, or not very long after, is not only a proof that they were well known, and allowed to be genuine, but also that they were in the highest esteem. Other passages alleged by Dr. Lardner, relate to the Acts of the Apostles, the Martyrs of the Romans, the first to the Corinthians, the Epistles to the Galatians, Ephesians, Philippians, and Colossians, the second to the Thessalonians, the Epistle to the Hebrews, the second of Peter, and the book of the Revelations.

Of Justin's works there have been numerous impressions; but that of Prudent Marand, a learned Benedictine, printed at Paris in 1542, fol. and Styan's Thrilly's edition of the two Apologies, and Dialogue with Trypho, printed at Lon-
M A R

MARTYR: or MARTIRE. Peter, a native of Anghiera, in the Milanese, was born in 1455. He is distinguiished in history as an able negotiator, and was employed by Fer-
dinand V., king of Castile and Aragon, in the education of his children. He obtained some ecclesiastical ben-
ces, and died in 1525. He wrote a history of the dif-
covery of America, under the title of "De Rebus Oceani-
est Orbe novo," an account of his epiphany, which he under-
took, at the desire of Ferdinand, with a description of the coun-
tries through which he passed, entitled "De Legatis 
Babylonica," and a work entitled "Epitome de Rebus 
Hispanicis," containing a history of the most memorable 
events in his time, from 1488 to 1525. After his return 
from Egypt, he was rewarded with ecclesiastical preferment, 
and received many favours from pope Adrian VI., who would 
have taken him to Rome, had he not excused himself on ac-
count of his advanced age. He died about the year 1526, 
and was buried in the cathedral of Grenada, of which he 
was canon and prior. Gen. Biog.

MARTYR, Peter, a distinguished reformer in the sixteenth 
century, was born at Florence in the year 1500. He was 
initiated into the principles of the Latin language by his mo-
ther, who was so well skilled in that tongue, as to be able to 
interpret the comedies of Terence from the original. He was 
afterwards placed under the tuition of a very able ma-
ter, who taught the children of the principal families in the re-
public, among whom Peter distinguished himself by the avid-
ity with which he discovered for learning, his excellant ap-
lication, and his rapid progress. When he was sixteen years of 
age, he conceived an inclination for the monastic life, and 
took the habit among the regular canons of St. Auguf
gine, at the monastery of Pifoli, near Florence. This step was 
taken without the consent or knowledge of his father, who on 
that account left the bulk of his property, at his death, 
to an hospital, reserving only a small annuity for his son. In 
the monastery he went through the different branches of 
science usually taught there, and acquired the character of 
the first scholar in his order, and he was as eloquent as he 
was learned. At the age of twenty-six he was appointed to 
the service of the pulpit. and preached to very crowded au-
torities, with universal applause, in several of the principal 
cities of Italy. Notwithstanding his great popularity, and 
his preferments in the church, particularly that of principal 
of the college of St. Peter at the altar in Naples, a public of 
great dignity, and supported by ample revenues, he cheer-
fully relinquished all, on account of the conviction which he felt 
upon the pernicious of the writings of Luther, Zuingly, 
and Bucer. His sentiments having undergone a complete 
change he did not repugn private to make converts to 
the new doctrines; at length his zeal carried him so far as 
to lead him to avow his sentiments in his public discourses. 
This kind of freedom quickly excited a host of enemies 
against him, and he was summoned to give an account of 
his conduct before a general meeting of the order at Ge-
nova. Peter, however, knew what sort of a tribunal it was 
before which he was commanded to appear, and accordingly 
withdrew privately to Pisa, where he wrote letters in jutifi-
cation of his sudden departure, and where he celebrated 
the Lord's supper according to the manner of the reformed. 
From Pisa he went to Florence, where he met with the ce-
lebrated Bernard Oehinus, who, like himself, had embraced 
the Protestant faith, and determined to renounce his coun-
try rather than shrink from the conscientious discharge of 
his duty. Quitting Florence, he passed through the nor-
thern parts of Italy without being discovered, and ar-
ived safe in Switzerland, where he was received with the 
greatest hospitality by the ministers of Zurich in the year 
1542. He was shortly after this invited to Straufburg, at 
which city he filled, for the space of five years, the theo-
logical chair, and maintained the utmost harmony with 
Bucer, who was his colleague in the ministerial office. In 
1546, he married a nun who had escaped from a convent and 
become a Protestant; and in the following year he was in-
vited by king Edward VI. into England, together with 
Bucer, Fagius, and other learned reformers. He gladly 
brought the offer thus made him, and was, in 1549, ap-
pointed professor of divinity at the university of Oxford. 
He was promoted by the king to a canonry of Chrift-
church, and admitted to the degree of doctor of divinity 
in this university. In this situation Peter Martyr continued 
faithfully and diligently occupied in differeniting scriptural 
knowledge, till the death of the king, and the accession of 
queen Mary, when the kingdom was once more brought 
under the yoke of Rome. On this event, Peter Martyr 
was obliged to leave the kingdom. He had the good for-
tune to arrive safely at Straburg, when he was very soon 
replaced in the divinity chair, from whence he removed to 
Zurich in 1550, to undertake the professorship of divi-

MARTYR, a person who suffers torments, and even death, 
in defence of the truth of the gospel: and thus they are 
distinguished from confessors. See CONFESSOR.

The word is Greek, μαρτυς, and properly signifies a wit-
ness. It is applied, by way of eminence, to those who suffer 
in testimony to the truth of the gospel.

Anciently thieves who were hunted for the faith, were 
called martyrs, and also those who perished in the holy 
war. In the time of St. Augustin, the title of martyr
MARTYR.

was given to confessors, or those who were tortured for the faith, without losing their lives. It is Tertullian's thought in his Apology: "Plures efficiumur, quoties metimur; fideum ecclesiae est fanguis Christianus."

St. Stephen is called the proto-martyr, or first martyr. — The first three or four ages of the church were stained with the blood of martyrs, who suffered for the name of Jesus. The greatest of their number is acknowledged by all who have a competent acquaintance with ancient history, and who have examined that matter with any degree of impartiality. Accordingly, 19,700 are computed to have suffered martyrdom with St. Irenæus at Lyons, under the empire of Severus; 6666 soldiers of the Teban legion are said to have been martyred in Gaul: father Papebroch reckons 16,000 Abissinian martyrs, and 150,000 others under Diocletian alone.

Mr. Dodwell, however, endeavours to invalidate the unanimous decisions of the ancient historians, and to prove in a dissertation (De Panecitate Martyrum), that the number of martyrs who suffered under the Roman emperors was very moderate; alleging, that those of whom we have accounts in the fathers, are comprehended within a very small compass; and that, excepting Nero and Domitian, the rest of the emperors made (carelessly any.

After Dodwell, several writers have maintained his opinion, and asserted, that whatever may have been the calamities which the Christians, in general, suffered for their attachment to the gospel, very few were put to death on that account. In this view, we may include Mr. Giffon, the celebrated historian of "The Decline and Fall of the Roman Empire," who, after observing that "the deaths of a few eminent martyrs have been recorded with care," professes "to separate (if it be possible) a few authentic as well as interesting facts from an insignificat mass of fiction and error, and to relate, in a clear and rational manner, the causes, the extent, the duration, and the most important circumstances of the persecutions to which the first Christians were exposed." Of these persecutions we propose to give an account under the article PERSECUTION; and we shall leave it to the attentive and candid readers of the 16th chapter of our author's second volume to judge, how far he has acquitted himself with impartiality, and with justice to the suffering Christians or their unrelenting persecutors. "History," the ingenious historian very properly observes, "which undertakes to record the transactions of the past, for the instruction of future ages, would ill deserve that honourable office, if the condenced to plead the cause of tyrants, or to justify the maxims of persecution." — "It must, however," he says, "be acknowledged, that the conduct of the emperors who appeared the least favourable to the primitive church, is by no means so criminal as that of modern sovereigns, who have employed the arm of violence and terror against the religious opinions of any part of their subjects. From these reflections, or even from their own feelings, a Charles V. or a Louis XIV. might have acquired a just knowledge of the rights of conscience, of the obligations of faith, and of the innocence of the ancients. But the princes and magistrates of ancient Rome were strangers to those principles which inspired and authorized the inflexible obliquity of the Christians in the cause of truth, nor could they themselves discover in their own breasts any motive which would have prompted them to refuse a legal, and as it were, a natural submission to the sacred institutions of their country. The same reason which contributes to alleviate the guilt, must have tended to abate the rigour, of their persecutions. As they were actuated, not by the furious zeal of bigots, but by the temperate policy of legislators, contempt must often have relaxed, and humanity must frequently have suspended, the execution of those laws, which they enacted against the humble and obscure followers of Christ." After this general apology for the ancient persecutors of the Christians, our author proceeds to deduce, from a general view of their character and motives, the following conclusions in their favour; 1. That a considerable time elapsed before they considered the new facts as an object deserving the attention of government. 2. That in the conviction of any of their subjects who were accused of so very singular a crime, they proceeded with caution and reluctance. 3. That they were moderate in the use of punishments; and 4. That the afflicted church enjoyed many intervals of peace and tranquility. How far these conclusions are justified by the facts which our author adduces, we leave for the present to the judgment of the reader, and refer him to the article PERSECUTION. To the humanity of the Roman magistrates he ascribes the inconsiderable number of Christian martyrs. "The martyrs," he says, "devoted to immediate execution by the Roman magistrates, appear to have been selected from the most opposite extremes. They were either bishops and prebysiers, the persons most distinguished among the Christians by their rank and influence, and whose example might strike terror into the whole sect; or else they were the meanest and most abject among them, particularly those of the fervile condition, whose lives were esteemed of little value, and whose sufferings were viewed by the ancients with too carelessly an indifference. The learned Origen, who, from his experience as well as reading, was intimately acquainted with the history of the Christians, declares, in the most express terms, that the number of martyrs was very inconsiderable. His authority alone would be sufficient to annihilate that formidable army of martyrs, whose relief, drawn from the most part from the catacombs of Rome, have replenished to many churches, and whose marvellous achievements have been the subject of so many volumes of Holy Romance." Our author adds, "that the general assertion of Origen may be explained and confirmed by the particular testimony of his friend Dionysius, who, in the immense city of Alexandria, and under the rigorous persecution of Decius, reckons only ten men and seven women, who suffered for the profession of the Christian name." The number of martyrs, according to our author, was owing in a great degree to the dillusions that were conferred on their remains and on their memory by survivours. "The sober disgregation of the present age, will more readily confute than admire, but can more easily admire than imitate, the fervour of the first Christians, who, according to the lively expression of Sulpicius Severus, demand martyrdom with more eagerness than his own contemporaries solicited a bispioric." "The Christians sometimes supplied by their voluntary declaration the want of an accuser, rudely disturbed the public service of Paganism, and rushing in crowds round the tribunal of the magistrates, called upon them to pronounce, and to inflict the sentence of the law." And it is added, that "the more prudent rulers of the church found themselves obliged to restrain the indecent ardour of their followers, and to disturb a conity which too often abandoned them in the hour of trial." In forming an estimate of those who suffered death in consequence of the edicts published by Diocletian, his associates, and successors, our author, deriving his data from the history of Eusebius, who enumerates the martyrs of Palestine at 92, considers Palestine as the 16th part of the eastern empire, and supposing that the country which had given birth to Christianity produced at least the 16th part of the martyrs, who suffered death.

R. 2
deth within the dominions of Galerius and Maximin; he inter-fered, that the whole might con-fuently amount to about 1500: a number which, if it be equally divided between the 10 years of the persecution, will allow an annual con-summation of 150 m. tyr ys. Allowing the same proportion to the provinces of Italy, Africa, and perhaps Spain, where, at the end of two or three years, the rigour of the penal laws was either suspended or abolished, the multitude of Christian martyrs in the Roman empire, on whom a capital punish-ment was inflicted by a judicial sentence, will be reduced to something left to 2000 persons, since it cannot be doubted that the Christians were more numerous, and their enemies more exasperated, in the time of Diocletian, than they had ever been in any former persecution. This probable and moderate computation may teach us to estimate the number of primitive saints and martyrs, who sacrificed their lives for the important purpose of introducing Christianity into the world.** Our author concludes his remarks upon this sub-ject, with suggesting a melancholy truth, which, whatever may be thought of his general reasoning, will be both al-lowed and lamented. ** Admitting,** he says, **all that history has recorded, or devotion has figured, on the subject of martyrdoms, it must still be acknowledged, that the Chris-tians, in the course of their intestine divisions, have inflicted far greater severities on each other, than they had ex-perienced from the zeal of infidels.** In the Netherlands alone, more than 100,000 of the subjects of Charles V. are said to have suffered by the hand of the executioner; and this extraordinary number is attested by Gratius.**(Annales de Rebus Belgicis, l. i. p. 12. fol. ed.) If this be admitted as true, it must follow, that the number of Protestant martyrs who were executed in a single province, and a single reign, far exceeded that of the primitive martyrs in the space of three centuries, and of the Roman empire.**

Whilst some have diminished the number of Christian martyrs far below the standard of truth; others have probably erred as much in the other extreme. F. Ruinart, (in the preface to his ** Selecta et Sincera Martyrum Aelia. Amst. 1713.) endeavours to prove, that the catalogue of martyrs is not at all swelled; that the car-nage was immense under the first emperors, and especially in the time of Diocletian. F. Papelbroch, in his ** Aelia Sanctorum,** also makes the number of martyrs immense. The truth lies probably between the extremes.

The martyrs were left in number than several of the ancient and modern writers have supposed them to be, but much more numerous than Dodwell and his followers are willing to believe; and this medium will be easily admitted by such as have learned from the ancient writers, that, in the darkest and most calamitous times of the church, all Christians were not equally or promiscuously disturbed, or called before the public tribunals. Those who were of the lowest rank of the people escaped the bell; their obscurity, in some measure, screened them from the fury of persecution. The learned and eloquent, the doctors and ministers, and chiefly the rich, for the confiscation of whose fortunes the rapacious magnates were perpetually gaping, were the persons most exposed to the dangers of the times. Mothesheim's Eccl. Hist. vol. I.

There is scarcely any faith or religion that does not pre-tend to its martyrs: Mahometans, heathens, idolaters, &c. all have their martyrs. In the ancient church, the acts, sayings, sufferings, and deaths of the martyrs, were preferred with great care, in order to be read on certain days, and thus proposed as models to future ages: and yet, notwithstanding all this diligence, we have but very little left of them: the greatest part of them having been destroyed, during that dreadful persecution, which Diocletian carried on for ten years, with fresh fury, against the Christians: for a most diligent search was then made after all their books and papers; and all of them that were found were committed to the flames. Eusebius, indeed, composed a martyrology, but it never reached down to us; and those since compiled are extremely suspected.

From the eighth century downwards, several Greek and Latin writers endeavoured to make up the loss, by comp-iling, with vast labour, accounts of the lives and actions of the ancient martyrs: but most of them have given us little else than a series of fables, adorned with profusion of rhetorical flowers, and striking images, as the writer, even among the Romish doctors, frankly acknowledges. Nor are those records, that pass under the name of Martyrology, worthy of superior credit, since they bear the most evident marks both of ignorance and falsehood.

MARTYR, Era. of, is an era followed in Egypt and Abyssinia, and which even the Mahometans, since their be-coming masters of Egypt, frequently observe. See EPOCHIA.

The era of martyrs is also called the era of Diocletian.

MARTYRS, Knights of the, in Palestine and Jerusalem, or of St. Cosmas and Damian, an order which, according to Giustiniani, was instituted in the 10th century, and afterwards approved and confirmed by pope Jean XX. in the year 1044. The badge of this order is said to have been a red cross, formed of four equal shafts, the centre thereof charged with the figures of the saints Cosma and Damian, placed within a circle. But Giustiniani is charged with having converted the religious order of canons regular of the Penitence of the Martyrs, who wear a red cross on their white habit, into an order of knighthood.

MARTYR'S REEF and SHOALS, in Geography, a rocky shoal between the gulf of Mexico, on the N. side of the Florida stream. N. lat. 24° 57'. W. long. 81°.

MARTYROLOGY, from μαρτυρία, witness; and λεγω, dicco, I speak, or λέγειν, colligo, I gather; a register or cata-logue of martyrs.

A martyrology, properly speaking, should contain no more than the name, place, and day of martyrdom of each saint; but the term is frequently extended to the histories of martyrs. The custom of collecting martyrologies is bor-rowed from the heathens, who inferred the names of their heroes in their Fæli, to preferre to posterity the memory and example of their noble actions. Baromius gives pope Clem-ent the credit of being the first who introduced the custom of collecting the acts of the martyrs. The martyrology of Eusebius of Caesarea was the most celebrated in the ancient church. It was translated into Latin by St. Jerome; but the learned agree that it is not now extant. That attributed to Beda, in the eighth century, is of very doubtful authority; the names of several saints being there found, who did not live till after the time of Beda. The ninth century was very fertile in martyro-logies; then appeared that of Florus, subdeacon of the church of Lyons; who, however, only filled up the chafers of Beda. This was published about the year 830, and was followed by that of Waldemarbutus, monk of the diocese of Treves, written in verbo about the year 848, and this by that of Usuard, a French monk, and written by the command of Charles the Bald, in 875, which last is the martyrology now ordinarily used in the Romish church. That of Ra-banus Maurus is an improvement on Beda and Florus, written about the year 845; that of Notker, monk of St. Gal, was written about the year 894. The martyrology of Audo, monk of Ferrières, in the dio-cese of Treves, afterwards archbishop of Vienne, is a de-scendant
feudant of the Roman, if we may so call it; for Du Solier gives its genealogy thus: the martyrology of St. Jerome is the great Roman martyrology; from this was made the little Roman one, printed by Rosweyd; of this little Roman martyrology was formed that of Beda, augmented by Florus. Ado compiled his in the year 838. The martyrology of Nevelon, monk of Corbie, written about the year 1089, is little more than an abridgment of that of Ado; father Kircher also makes mention of a Coptic martyrology, preferred by the Monarques at Rome. We have also several Protestant martyrologies, containing the sufferings of the Reformed under the Papists; viz. an English martyrology, by J. Fox; with others by Clark, Bray, &c.

**Martyrology** is also used, in the *Roman Church*, for a roll or register kept in the vault of each church, containing the names of all the saints and martyrs, both of the universal church, and of the particular ones of that city or monastery.

Martyrology is also applied to the printed or written catalogues in the *Roman* churches, containing the foundations, obits, prayers, and masses to be said each day.

**MARTZIAN**, in the *Materia Media*, a word formed by the modern Greek writers, to express a fest of episcopal, growing upon the rocks, and used in painting, dyeing, &c.

The word is formed of the Arabian name *margian*, by changing the g into t.

**MARU**, in *Botany*, a name by which *Dodonaeus*, and some others, have called the *cerinthe*, or *bouncy-root.*

**Maru, or Maru-Sub-Jen**, in *Geography*, a town of Persia, in the province of Khorasan, on the river Marga; formerly a magnificent city, and the residence of many huts; but defolated by the Turcomans in the twelfth century; 200 miles N. of Herat. N. lat. 38° 42'. E. long. 61° 12'.

**Maru-erud, or Maru el Roud**, a town of Persia, in the province of Khorasan, on the Marga, founded, as some say, by Alexander the Great; 125 miles N.E. of Herat. N. lat. 37° 36'. E. long. 61° 18'.

**Marvaglss**, a town of Italy, in the bailiwick of Bellinzana.

**Marva**, a town of Portugal, in Alentejo; six miles S.E. of Castello de Vide. N. lat. 39° 13'. W. long. 7° 2'.

**Marubiium**, in *Botany*, &c. See *Marubium* and *Hornehound.*

**Marudo**, in *Geography*, a country of the island of Bornoe, which advances towards the north between four great points, of which the first, called Sanfason, is at the distance of 11 Dutch miles from the second, denominated Tandjong Mater; after which follows the bay of Marudo, with a town of the same name situated at its bottom. At some distance from the shore are discovered four large islands, and some smaller. The two other points on the E. of the bay are Pulo Avigo and Punta Corpoan, between which there are some little islands. From this last point the coast bends to the east, and forms a large bay, called that of St. Ann. The country of Marudo is remarkable for forests and mountains; one of the latter, on the S. of the town of Marudo, called by the Portuguese and Dutch the mountain of St. Peter, is of prodigious height. In these wild countries monkeys are very numerous, besides the "orang-outang," and in the bodies of these monkeys are found the burl bazaar.

**Marvolos**, a town of France, and principal place of a district, in the department of the Lozère; nine miles W. of Mende. The place contains 3011, and the canton 8823 inhabitants, on a territory of 222 square kilometres, in ten communes. N. lat. 44° 33'. E. long. 3° 22'.

**Marvel** of Peru, or *Four-o'clock Flower*. See *Marshmallow*.

**Marvel, Andrew**, in *Biography*, a political writer of considerable eminence, was the son of a clergyman, and born at Kingston-upon-Hull, in the year 1620. He was sent to Cambridge at the expense of the corporation of Hull, and was entered a student of Trinity college in 1635. His fine talents rendered him an object for the tempting arts of the Jefuit emissaries, then perpetually looking about our universities, and they so far succeeded in their profligate attempts as to induce him to quit his college and go to London, where he was accidentally found by his father in a book-feller's shop. He was perfumed by his parent to return to Cambridge, and serious reflection upon the dangers which he had thus escaped, seems to have left upon his mind a rooted aversion from that systen of religion which could make use of such vile arts to extend its progres. His father was unfortunately drowned as he was crossing the Humber, in 1649, and Andrew took possession of his small inheritance. This might be the occasion of some inattention, on his part, to the duties of academical life, for it appears that in the following year he, with some other young men, were excluded from their college for non-attendance. Perhaps, however, he had then begun the course of travels which he pursued through Holland, France, and Italy. He had ever a great propensity to ridicule, and it was first publicly displayed by a satire upon Flecknoe, an English priest and poetaster at Rome; and next in a burlesque poem addressed to an abbot de Maniban, at Paris, a pretender to fortune-telling. Of the residence and pursuits of Andrew Marvell, for many full years, little is known. In 1653, he was engaged by the protector Oliver Cromwell, to superintend the education of a Mr. Dutton. It was not till four years after this, that he took any part in public affairs, when he essayed into an employment for which he was not altogether fitted, and which he considered to be the most honourable towards his majesty's constitution; that is the abridgment and irregular government. This al- lowed to the right of a seat in the house of Lords in the office of Latin secretary, which he held till the death of Cromwell. In the parliament of 1660, Marvell sat as one of the representatives of the borough of Hull, an honour which was conferred upon him to the end of his life. He is supposed to have been one of the last persons who received a pension from his constituents, which he earned by the diligence, firmness, and integrity with which he discharged his duty. At the beginning of the new reign he paid little or no attention to the duties of parliament, and in 1661, and the following years, he was absent in Holland and Germany, and upon his return he accompanied lord Carlisle, the ambassador-extraordinary to the northern courts, as his secretary. In 1665, he renewed a confidant and uniform attendance on parliament, and from this period to 1674, he made a regular report of the proceedings of both houses to the mayor and corporation of Hull. The whole efforts of Andrew Marvell, in and out of parliament, were directed to the preservation of civil and religious liberty. He was not a powerful or a frequent speaker, but his influence over the members of both houses was considerate. By his writings he obtained the character of the withest man of his time, and was of great service to the cause which he espoused. In 1672, Dr. Parker, afterwards bishop of Oxford, published a work of bishop Bramhall's, to which he prefixed a preface of his own, maintaining the most extravagant positions concerning the rights of sovereigns over the confi-
Marvell immediately attacked him in a work entitled "The Rehearsal Transposed," which, with a profusion of witty farce, contains much solid argument, and may be reckoned one of the ablest expositions of the maxims of religious tyranny. Marvell was author of several other works, of which we may notice "A Reasonable Argument to the Grand Juries of England to petition for a New Parliament." His last piece was entitled "An Account of the Growth of Popery and Arbitrary Power in England." This was so very offensive to the pertons in power, that an advertisement was issued in the Gazette, offering a reward for the discovery of the printer, publisher, and author of it. Notwithstanding the ceremony with which our patriot attacked the court and its plans, Charles II. delighted in his conversation, and his ministers took every means in their power either to gain him over to their party, or at least to silence him. A remarkable anecdote on this subject is related. One morning, after he had been the preceding evening familiarly entertained by his majesty, the door of his apartment, up two pair of stairs, in a court in the Strand, was suddenly opened by the lord-treasurer Danby. Marvell, who was writing, being surprized, asked his lordship if he had not mistaken his way. "No," replied the courtier, "now I have found Mr. Marvell;" and he proceeded to say he had been sent by his majesty to know in what manner he could serve him. Marvell rejected every offer, though his lordship was commissioned to present him with a thousand pounds. At the moment he nobly affixed his independence, he was to dictate as to be obliged to borrow a guinea of a friend to supply the necessary demands of life. Well might his biographer say, that "of all men in his station, he is the person who ought to be selected as an example of genuine independence produced by the philosophical limitation of wants and desires. He was not to be purchased, because he wanted nothing that money could buy, and held cheap all titular honours in comparison with the approbation of his confidence, and the esteem of the virtuous." He died in 1678, and was buried in the church of St. Giles's-in-the-Fields; and the corporation of Hull, in gratitude for his services, defrayed the expenses of his funeral, and raised a monument to his memory. His works were published in two volumes, 12mo, in 1726, and a more complete edition was given to the public in 1776, with a new life of the author, by Capt. Edward Thompson, in three volumes, quarto, to which our readers are referred.

Marvella in Geography, a town of Spain, situated in a bay on the sea-shore, three leagues from Malaga, at the foot of some high mountains, and containing 1100 inhabitants. From the number of houses fallen into ruins, and the extent of the walls, part of which still remain, and are more than a mile in circumference, we might infer that the population has been much greater. The sea is on the S., and on the N. the mountains of Marvella, on which a few vines are planted. This town has one parish-church, two monasteries, a hospital, two schools, a monastic-house, and a priory. On the shore a battery, mounted with two pieces of ordnance, is erected for the defence of the bay, where no large ship can anchor; on the E. and W. sides of the town are some kitchen-gardens. The inhabitants derive their subsistence from fishing, and the produce of a limited agriculture. They also employ twenty barks in conveying leather, charcoal, wood, wine, dried raisins, and black-いろんな, &c. to Cadiz, Malaga, and Ceuta. To these they may sometimes add the jujUPER-berries, which the mountains furnish in great profusion, and of which the English consume great quantities in their dyes.

Marugio, a town of Naples, in the province of Otranto; ten miles S.S.W. of Orta.

Marville, a town of France, in the department of the Meuse; six miles S.E. of Montmedy.

Marullus, Michael Tarchianotes, in Biography, a learned modern Greek, a native of Constantinople, which city he abandoned at its capture by the Turks in 1453, and retired to Italy. He was engaged in the military service, though a steady adherent to polite literature. He enjoyed the patronage of several princes of high rank, and was for a time liberally entertained by Lorenzo de Medici. He married the learned Alexandra Scala, of Florence, a circumstance that involved him in a bitter quarrel with Politian, who was her admirer. Marullus was engaged in several other controversies with men of learning, which he brought on himself by his confusions of the ancient Latin poets, and his high notions of his own merits. He left his life in the year 1590, while attempting to cross the little river Cecina, in Tuscany. His "Latin Poems," which have been frequently republished, consist of four books of Epigrams, and four of Epistles, with a fragment of a Poem on the education of princes. He was reckoned a good imitator of Lucanus, who was the principal object of his admiration among the ancients, and of whom he gave an edition. There was another poet of Calabria of this name, in the fifth century, who wrote a paraphrase on Atilio, king of the Huns, which the barbarian required by causing the poet and his poem to be burnt together. Moreri.

Marum, in Botany. See Originum, Salvia, Teucrum, and Thymus.

Marut, in Hindu Mythology, is a personification of the wind, more commonly called Pavana, under which article we shall more particularly describe this potent deity. The Maruts are frequently alluded to in Hindu books, as the genii or regents of the winds, of whom Pavana is the chief. Eight are usually spoken of, and they then seem to correspond with the guardians of the cardinal and intermediate points, into which the Brahmans have arranged the heavens; reminding us, under this division, of the octagonal temple of the winds at Athens. These eight guardians or regents are, (1.) Indra, being reckoned as the first of the infernal deities, and ruler of the east, that point being reckoned first; and proceeding: 2d. Pavaka, the god of fire, rules the south-east: 3d. Yama, king of death and judge of hell, over the south or lower region: 4d. Nirit or Nairit, south-west: 5d. Varuna, regent of waters, west: 6d. Pavana, otherwise called Vayu, north-west: 7d. Kuvera, the god of wealth, the north: and 8d. Ani, a name and form of Siva, rules the north-east. Some mention is made of these several deities and powers, under their respective names. Female divinities seem also to have dominion over the points of the heavens, as noticed under Marti.

It is not always, however, that we find this arrangement, although it be the most usual, followed by Hindu writers. Other deities are sometimes substitutted, and their guardianships altered. Sir William Jones has addressed a spirited hymn to Indra, in which a stanza is introduced descriptive of a poetical co-operation of these powers, in aid of their chief Indra, the god of flowers. (See Indra.) It is borrowed from the popular mythology of Nepal and Tibet, and we will extract the stanza, as descriptive of Hindu mythological poetics; premising that it relates to a freak of Indra, who is failed to have alluded the form of a shepherd's boy, that he might the easier steal from a garden some pomegranate blossoms, to deck the dark trellis of his virtuous conforT Indra; which fee.

"—— The
— The reckless peasant, who these glowing flowers, 
Hopeful of rabied fruit, had forlorn’d long, 
Seiz’d, and with cordage ftrong,
Shackle’d the god who gave him flowers.
Straight from even winds immortal genii flew—
Varuna green, whom foamy waves obey’d; 
Bright Valni, flaming like the lamp of day; 
Kuvera, fought by all, enjoy’d by few; 
Marut, who bids the winged breezes play; 
Stern Yama, ruthless judge! and I/a cold; 
With Nairit, mildly bold: 
Thy, with theuddy flash that points his thunder,
Rend his vain bands afunder.
'Th’ exulting god refumes his thousand eyes,
Four arms divine, and robes of changing dyes.”

MARUTY is a name of Hanuman, who, although an ape only in appearance, is yet, in the sacred romances of the poetical people of the East, a very important personage; and of whom almost if not fully as much is said and sung as of any deity in their malignant, although certainly curious, Pantheon.
In their theologienes he is called the son of Siva, who miraculously impregnated the mother in a manner corresponding with the usual whimsicality of these tales, if literally received; but popularly he is deemed the offspring of Pavana, the regent of the wind, otherwise called Maruti, which see, and hence his name, which means windy. Hanuman means with bloated cheeks.

This human hero was produced with a vast number of others by the celestials for the purpose of assisting Rama in his conquest of Lanka from the tyrant King of Lanka; which conquest is the subject of that singular poem the Ramayana, as noticed under those several articles.
Sir William Jones, hinting at the similarity of the Indian conquests of Dionysus and Rama, whose armies of Satyrs were respectively led by Pan, and the son of Pavan, finds farther coincidences of character, both in the principals and their general.
Pan improved the pipe by additional reeds; Hanuman was also a musical genius, and one of the four syllables of Hindoo music is named after him. In the peninsula of India, and on Ceylon, or Lanka, statues, pictures, legends and romances of Hanuman are very common. He is also seen on very ancient coins and medals, of which exact representations are given in plate 104 of Moore’s Hindoo Pantheon; and many, in other plates of the subject of this article, with fundry legends respecting him and his history, that however admissible in such a work, would be evidently misplaced in this.
His building of Rama’s bridge between the continent and Ceylon, and some other points concerning him, are noticed under LANKA. Maruti or Hanuman is represented sometimes wholly as a monkey; at others as a man with a monkey’s head, and perhaps tail; and with from one to four pair of arms, holding divers weapons, or as a respectfull attendant on Rama, who is seldom seen without him.

MARWICK HEAD, in Geography, a cape of Scotland, on the W. coast of the island of Pomona. N. lat. 52° 58’.
W. long. 5° 10’.

MARY, the mother of our Saviour Jesus Christ, in Scripture Biography, was the daughter of Joachim and Anna, and espoused to Joseph before the conception and birth of Christ; so that our blest Lord was by his mother the tribe of Levi, and by his legal and reputed father Joseph, of the tribe of Judah.

Of the parents of Mary, we have no information in Scripture, not so much as of their names, unless [name], mentioned by St. Luke iii. 23, be the same with Joachim; and, therefore, for the birth of Mary, and for an account of her parents, we are under a necessity of having recourse to some ancient apocryphal writings. It is of principal importance to know, that she was of the royal race of David, and she was also akin to the race of Aaron. Since Elizabeth, the wife of Zacharias, was her cousin. See Luke i. 27; 34, 35-36.

As the time of Mary’s delivery approached, Cæsar Augustus issued an edict, commanding the subjects of the empire to register their names, according to their families, in their respective cities. Joseph, though he was not rich, and though he lived in Galilee, might have some small inheritance in or near Bethlehem, and might be obliged to go thither upon that account. St. Luke gives us this reason of his going to Bethlehem, “because he was of the house and lineage of David;” (ch. ii. v. 4.) It is probable, says Lardner, that this journey was owing to the cullum of the Jews; who, whenever they were numbered, entered themselves according to their tribes and families. Mary accompanied him on this occasion, more perhaps from choice than from any legal necessity; or for some sufficient reason with which we are not acquainted.

While they remained at Bethlehem, our Saviour was born in the circumstances recited by the evangelists. (Luke ii Matt. ii.) Of her visit to Jerusalem, at the time of her purification and of her presentation of Jesus in the temple, and of other incidents that occurred in the early period of our Saviour’s life, it is sufficient to refer to the evangelical history. We find that Mary was present at the marriage of Cana, in Galilee, where our Lord performed his first public miracle (John ii. 1, 2, &c.), and that she accompanied her son to Capernaum, where she seems to have chiefly resided. Epiphanius, however, intimates, that she followed him every where during the whole course of his public ministry; but if that was the case, it is not recorded by the evangelists. We find her at Jerusalem at the last passover which our Saviour attended; and she followed him to Calvary, where she stood at the foot of his crofs, and where she was recommended by him, with an attention highly worthy of the dignity of his person, and excellence of his character, to the care of his beloved disciple, who from that hour took her to his own house. Our Saviour appeared to her after his resurrection, and she was one of the first to whom he vouchsafed this honour andconiunction; she was also with the apostles at the time of his ascension, and continued with them at Jerusalem. (Acts i. 14)

After this, she dwelt in the house of St. John the Evangelist, who took care of her as of his own mother. As St. John flaid for a considerable time in Palestine, it may be reasonably concluded, that Mary, our Lord’s mother, did not go with him to Ephesus, as Barnabius and some others have thought, but died before he went thither, according to the opinion of Cave and Bnafage; and was buried at Jerusalem.

Theophrastus says, that Joseph had by the widow of his brother Cleophas, who died without issue, five children, four sons and two daughters, named Mary, and he supposes Mary, mother of our Lord, to be the same as Mary the mother of James and Joses, who were Joseph’s children by a former wife; as was also Salome, the mother of Zebedee’s children. And whereas, in John xix. 25, mention is made of Mary wife or daughter of Cleophas, and sister to our Lord’s mother, he says, that by “ sister” must be there understood “ relation,” for that Mary is supposed to be daughter of Cleophas, brother of Joseph, whole widow he had married. He says, that there are four Maries mentioned in the gospels; viz. our Lord’s mother, Mary Magdalene, Mary daughter of Cleophas, and the sister of Lazarus. Gregory Nyffen says, that three Maries are mentioned as standing at the foot of the cross of Jesus, Mary our Lord’s...
Mary Magdalene has been supposed by many to be the person called a "Sinner" in the seventh chapter of St. Luke's gospel; but Dr. Lardner has adduced a variety of circumstances in his "Letter to Jonas Hanway, cifo," which make it very probable, that Mary Magdalene was not the person to whom the evangelist there refers and by therefore objects to the appellation Magdalen House, as appropriated to an asylum for penitent prostitutes. Mary Magdalene was so called, probably from Magdala, the place of her nativity, a town situated somewhere beside the lake, and mentioned Matt. xix. 29; whereas it appears from the history in Luke (ver. 27) that the woman there mentioned was of the city, in which our Lord then was; which city was Capernaum or Naïn; and there is no reason for believing that Mary Magdalene resided at either of those places. Another passage (Luke viii. 1, 2, 3.) affords additional reasons for supposing that Mary Magdalene is not the woman intended in the preceding chapter. This Mary appears to have been a woman of high flattery and opulent fortune, not likely to have been designated under the description of "a woman in the city which was a sinner;" she is mentioned by St. Luke before Joanna, the wife of Herod's steward; and, besides, when the other evangelists have occasion to speak of our Lord's female friends, they commonly assign the first place to Mary Magdalene. (See Matt. xxvii. 56. 61. xxviii. 2. Mark xv. 40-47. Luke xxiv. 10.) Grutius thinks it was at her expense the spices were bought for embalming the body of Jesus. This precedence, as Lardner supposes, might have been, partly, owing to her age. Mary Magdalene is mentioned as a person who belonged to those who were called dæmones. She is also mentioned with divers other honourable women, who attended our Lord in his journeys, and ministered to him of their substance. And it is justly questioned, whether our Lord would have allowed of that, if Mary's conduct had been discretable in the former part of her life; nor can we reasonably imagine, that any women of distinction and good credit would admit into their society one who had been under the reproach of a disorderly life. Among these women was our Lord's mother; and undoubtedly an exact decorum was observed, according to the Jewish custom. Moreover, Mary Magdalene seems to have prefigured in the direction of the affairs, which were under their care. On the other hand, the woman called a "Sinner," was absolutely excluded from having any part in that company. (Luke viii. 2. Mark xiv. 40-47.) "I conceive of her," says the judicious and candid Lardner, "as a woman of a fine understanding, and known virtue and discretion, with a dignity of behaviour becoming her age, her wisdom, and her high station; by all which she was a credit to him whom she followed as her master and benefactor. She showed our Lord great respect in his life, at his death, and after it; and she was one of those to whom he first shewed himself after his resurrection. See Matt. xxviii. 1-10. Mark xvi. 9. John xx. 1-18.

Some have supposed, that Mary, sister of Martha and Lazarus, was the same as Mary Magdalene. Dr. Lardner refutes this opinion, by alleging, that Mary Magdalene derived her name from a place in Galilee; whereas Lazarus and his sisters were inhabitants of Bethany near Jerusalem; Mary Magdalene is frequently named with other women who attended our Lord in his journeys, and came up with him from Galilee to Jerusalem, at the times of the great feasts; whereas Lazarus and his sisters resided at Bethany; and Mary Magdalene is particularly mentioned with others, whom our Lord had miraculously healed of infirmities; but nothing of a like kind is ever said, or hinted of Mary, sister of Lazarus. We shall here add, that Mary, sister of Lazarus, does not seem to have been the woman described by St. Luke as a "Sinner." Lardner's Works, vol. xi.

Mary I., queen of England, in Biography, daughter of Henry VIII., by Catharine of Arragon, was born in 1516. In her infancy she was betrothed to three different persons, first, to the dauphin of France; next, to the emperor Charles V., and afterwards, to the duke of Orleans. These alliances did not take place, and after her mother's death Mary was excluded from the succession to the crown, as illegitimate. In 1544 she was restored to her right, but her illegitimacy was not reversed; and Henry, though by this act he opened the way for the princes to mount the throne, would not allow the former acts to be reversed; he even obliged his parliament to confer upon him a power of still excluding the two sisters, Mary and Elizabeth, if they refused to submit to any conditions which he, at any time, should be pleased to impose: and he farther required them to enact, that, in default of his own issue, he might dispose of the crown as he pleased, either by will or letters patent. Mary, bred up by her mother in a zealous adherence to the Roman Catholic faith, reluctantly subscribed to her father's supremacy on his break with the papal see; and when, upon the accettion of her brother Edward VI., the reformation was introduced into the English church, she refused, though strongly urged and menaced, to comply with the new worship, and obtained a connivance through the interference of her, kinsman the emperor. "As intolerance," says one of this prince's biographers, "was no less the character of the new than it had been of the ancient religion, Mary was again molested; her chaplains were thrown into prison; urgent remonstrances were made to her without shaking her firmness; and finally, her brother was, with great difficulty, persuaded still to indulge her in her nonconformity."

On the death of Edward in 1553, we have already seen, in the several articles relating to this period of our history, that an attempt was made to exclude both Mary and Elizabeth from the crown, by setting up lady Jane Grey, the failure of which effort has been before noticed. Mary now, by the loyalty of her subjests, was, without a contest, placed upon the throne, and her title universally recognized. She soon displayed a passionate zeal for the reformation of the Catholic religion: her temper was four and fomn try, and she inherited too much of the wilfulness and despotical humour of her father. She almost immediately re-instituted those bishops who, in the late reign, had been deprived of their fees for their adherence to popery, while Cranmer was indicted for the crime of high-treason; and several Protestant bishops were thrown into prison. The next step that outraged the feelings, and call down the spirits of those who adhered to the Protestant faith, was her marriage to the archduke Philip, son of the emperor Charles V. Previously to this a complete reformation of the Catholic worship took place throughout the kingdom, and all the clergy who refused to comply with it were ejected from their living. These changes, which were regarded as preludes to still more arbitrary and cruel measures, occasioned a vast number of discontent, that broke out into insurrections in Devonshire and Kent. In the former, Carew was the leader, in the latter
latter Wyatt: these were soon suppressed, and they only served as pretexts for new severities. The princes Elizabeth, who was an object of peculiar hatred to her sister, on account of her attachment to the principles of the reformers, was thrown into the Tower, and lady Jane Grey, with her unfortunate husband, whose lives had hitherto been spared, were executed. Philip, who had long been expected by the queen, arrived in England in July 1554, and the .nuptials were conunitted. The ruling passion of this prince was ambition, which his conduct was devious of gratifying. She had, at this period, another object in view, in the purfance of which she was quite successful; this was that of reconciling the kingdom to the pope, which was effected in great form by means of the legate, cardinal Pole. The fanguinary laws againft heretics were renewed, and it was determined, in council, to put them into execution. The mercifles crimes of cruelty which followed this resolution, have fiercely flamed the peculiar character of this reign, and indelibly fixed upon the sove-reign, the hateful, but well-merited epithet, of bloody queen Mary. From various disappoinments which she met with, as in the want of a family, as in her husband's inattention, and in the discontents of her subjects, it has been questioned whether the period of her short reign was more afflicative to herself, or difastrous to the nation. It is to the honour of the legate Pole, that he totally disapproved of the severity of persecution, but the arguments of Gardiner and others in its favour convinced the queen of the futility of her proceedings. When the flames soon began to be kindled in the metropolis and other parts of the kingdom. Protestant, illusrious for their talents, and of the purest moral character, were called upon to seal their faith in the flake. For an account of the sufferings which this cruel woman inflicted, and of the martyrs which she sent to prifon, to exile, and death, we refer to the several articles in the work, which have been devoted, as far as the writers have been able, in a foul compafs, to keep them in "everlasting remembrance." In the space of less than four years, 277 persons were committed to the flames, including prelates and beneficed clergymen, laymen of all ranks, women, and even children. It is believed, that neither flame nor compassion, nor a regard to her future reputation, ever touched the heart of queen Mary. It might not, perhaps, occur to her that by her dark deeds she was raising a name, that should, to the last records of her country, be held in abhorrence by persons of all ranks and parties; and that the liping infant should, in almost their earliest lessons, learn to dread the sound of "the bloody queen." The fincerity of her zeal has been referred to as an extenuation of her crimes, and we would not withhold from her any trait that might tend to make her a lefs hateful object with pofficrity: she evidenced that fincerity by the sacrifices which she was ever ready to make of the revenues of the crown, in retribution of the goods of the church, and more than once, to the remonstrances on this head, she replied, in words to the following effect, "that she preferred the salvation of her soul, to ten such kingdoms." To gratify Philip, she warmly promoted a war with France, in conjunction with him, though contrary to the terms of the marriage articles, and the manifest interests of the English nation. War was declared in 1557, and the affilliance of the English troops contributed to the victory over the French at St. Quintin. In the following year, the lots of Calais more than overbalanced any succcizes that might be achieved in other parts. This town was taken by the duke of Guife in the winter of 1558, after it had been more than 200 years in the possession of England. The diligence of this circumstance sunk deep into the heart of the queen, who had been, some time before, in a declining state of health, occasioned by a drophical complaint: and she expired in the month of November 1558, in the fortieth year of her age, and the sixth of her reign. With her expired the dominion of popery in this kingdom, which could never overcome the horror and detestation which her cruelties had inspired. "It is not necessary," says the historian, "to employ many words in drawing the character of this prince. She possessed few qualities either estimable or amiable, and her person was as little engaging, as her behaviour and address. Obstinacy, bigotry, violence, cruelty, malignity, revenge, tyranny; every circumstance of her character took a tincture from her bad temper and narrow understanding. And amidst that complication of vices, which entered into her composition, we shall scarcely find any virtue but fincerity; a quality which she seems to have maintained throughout her whole life; except in the beginning of her reign, when the necessity of her affairs obliged her to make some promises to the Protestants which she certainly never intended to perform. But in these cases a weak bigotted woman, under the government of priests, easily finds cajufiry sufficient to justify to herself the violation of a promise. She appears also, as well as her father, to have been fulcetible of some attachments of friend-ship; and even without the caprice and inconstancy which were so remarkable in the conduct of that monarch. To which we may add, that in many circumstances of her life she gave indications of resolution and vigour of mind, a quality which seems to have been inherent in her family." Hume's Hist. 8vo, vol. iv.

MARY DE MEDICIS, daughter of Francis II., grand duke of Tuscany, and wife of Henry IV. of France, was born at Florence in 1573. On the death of her husband, in 1610, she was appointed regent of the kingdom, in which character she displayed great political intrigue, and planned projects of unbounded ambition. Differences arose between her and Lewis, who were compromised by means of Richelieu, whom she introduced to the favour of the monarch. But afterwards a violent breach occurred between her and the cardinal, who was supported by the king. By her intrigues, the nation lost all its influence abroad, and was torn to pieces at home by contending factions. After several vicissitudes of fortune, she was abandoned by her son, Lewis XITl., whose reign had been constantly disturbed by the civil motions that she had occasioned, was exiled to Bruffles, and all her favourites, even her physician, were either banifhed or sent to the Bastile. She died in poverty in the year 1642. She built the superb palace of Luxembourg at Paris, and embellished that city with aqueducts and other ornaments. Hist. of France, 8vo, 1792.

MARY, queen of Scotland, daughter of James V., was born in the royal palace of Linlithgow, on the 8th of December, 1542. Her mother was Mary, the eldest daughter of Claude, duke of Guife, and widow of Louis, duke of Longueville. Her father dying a few days after her birth, she scarcely existed before she was hailed queen. After the rejection of a proposal made by Henry VIII. of England to contract her to his son Edward, an offer was made by the Scots to marry her to Francis, the dauphin son of Henry II. of France, and in her sixth year she was sent into that country for education. She displayed, on advancing to maturity, a degree of personal beauty which was the admiration of a gay and galant court. The opening powers of her mind also, and her natural disposition, afforded early hopes of capacity and merit. After being taught to work with her needle, she was instructed in the Latin language; and is said to have read and spoake it with accuracy and fluency.
MARY.

In the several modern languages her proficiency was still greater, and the spoke the French, the Italian, and the Spanish tongues, with ease and propriety. She walked, danced, and rode with enchanting gracefulness, and she was qualified by nature, as well as by art, to attain to distinction in painting, poetry, and music. When she had completed her fifteenth year, the negotiations for her marriage were entered upon. It was the object of the French court to obtain by this union that ascendancy over Scotland which the prudent jealousy of the Scots attempted to guard against. Her nuptials with the dauphin were celebrated with great pomp in 1558, and her husband received the "crown matrimonial" of Scotland. On the accession of Elizabeth to the throne of England, Mary was obliged by her ministers to put in her claim to that dignity, on the plea of Elizabeth's illegitimacy, and the and the dauphin openly, and for a short time, assumed the title and arms of king and queen of England. This fatal step catalyzed upon her the perpetual hatred of her rival, queen Elizabeth, and was the principal cause of all her misfortunes. In 1559, the death of Henry II. raised his son, Francis II., to the throne of France, and conferred upon Mary the crown of a queen-confort of that powerful kingdom. Her mother, who had acted as regent, died in 1560, while that country was involved in a war between the Protestants, supported by queen Elizabeth, and the Catholics, aided by France. Peace between England and France succeeded her death, by an article of which Francis and Mary were bound to recognize Elizabeth's title to the English crown, and renounce their own. In a very few months Francis died, leaving his widow overwhelmed with sorrow for the loss of that influence which she possessed as his queen. Her humiliation, the disgrace of her uncles, the princes of Lorraine, which industriously followed, and the coldness of Catharine of Medici, the queen-mother, who governed her son Charles IX., plunged Mary into inexpressible sorrow. She was invited to return to her own kingdom, and the endeavoured to reconcile herself to her fate. She was now past from a situation of elegance and splendour to the very reign of uncivilization and turbulence, where most of her accomplishments would be lost, and none of them could be properly appreciated. Among the Scots of that period, elegance of taste was but little known: the generality of the people were sunk in ignorance and barbarism, and what was denominated religion, dictated to all a petulant rudeness of speech and conduct to which the queen of France was wholly unaccustomed. At length, however, though much against her inclination, the embarked, bidding farewell, with sighs and tears, to the beloved land which had so long fostered her, nor could she be prevailed on to quit the deck till its coats were quite out of view. She arrived in Scotland in August 1561, after an absence of almost thirteen years.

It cannot be expected, that in the limits to which this article must necessarily be kept, that we can enter into all the controversy to which the history of this queen has given rise. It will be sufficient for the readers of the Cyclopedia, if we give a concise narrative of undisputed and indubitable facts, following, in a great measure, Dr. Robertson as our guide.

When the queen arrived, the Protestant cause in Scotland was espoused by the majority of the people, but had not as yet obtained an establishment, and its adherents were full of suspicions of the machinations of the papal party, supported by the court of France, and by the secret attachment of Mary, who was zealously devoted to the Catholic religion. The Protestant leaders looked to Elizabeth as the great protectors of their principles, and she took every opportunity to undermine the influence of Mary, and involve her in difficulties; not only on account of her predilection for the French alliance with her country, but because Elizabeth regarded her as a personal rival and a claimant of her crown. On this and on various other accounts, though the reception of Mary was for the moment highly flattering, and seemed to denote an universal spirit of loyalty, abundant sources exalted of impending disturbances. The commencement of her administration was prudent and moderate. Although the zeal of the reformers inflamed her religion, she would not listen to the violent counsels of the papal faction, but gave her confidence entirely to the Protestants. She repressed the outrages of the banditti of the borders, and made a progress into the north, with the view of remedying the disorders there. Her appearance gave so much alarm to the powerful earl of Huntley, that he took up arms, and Mary, with her ministers who attended her, was brought into great danger, from which she was rescued by the loyalty of some Highland clans. The earl was afterwards defeated and slain by Mary's natural brother, the earl of Murray. Her people were now anxious that she should enter upon a second marriage, and various matches were proposed to her by foreign potentates. Her choice fell upon her kinsman Henry Stuart, lord Darnley, son of the earl of Lennox, a youth who, besides a fine person, did possess a single valuable quality. This match was opposed by many of her powerful nobles, but through the intercession of the queen, the consent of the nation in general was obtained, and the union took place in 1565. She proclaimed her husband king, and commanded that all writs should run in their joint names, and she began to devise means to revenge herself on those who had opposed her marriage. These were the chiefs of the Protestant party; in her own mind she would have exercised clemency towards them, but the solicitations of the French court, then engaged in a league with Spain to extortify these, induced her to change her intentions. She called a parliament, in which their attainder, and some measures in favour of the Catholic religion in Scotland, were to be proposed, when a circumstance occurred, which for a time took the whole possession of her mind. David Rizzio, the son of an Italian musician, had accompanied the Piedmontese ambassador to Scotland, and gained admission into the queen's family by his musical talents. He soon shared much of her favour, and was raised to the office of her French secretary. This good fortune rendered him so arrogant and insolent, that he was regarded by the nobles with all the ill-will usually attending a worthless favourite. Rizzio afflicted Darnley in engaging the affections of the queen; and very soon after the marriage he became her rival, and took such liberties with the queen, as passed all bounds of prudence and decorum, and Darnley resolved to get rid of him. At the same moment, some men of rank, who implored to Rizzio the queen's eminence to the exiled nobles, concurred in the project for his destruction. A conspiracy was formed for effecting the purpose, and a band of armed ruffians took possession of the gates of the palace of Holyrood house, while the king, with some other persons, and lord Ruthven in complete armour, entered the chamber where Mary was at supper with the countess of Argyle and Rizzio. The unhappy victim chung to the queen for protection; but her entreaties and supplications were of no avail; he was dragged from her presence, and murdered in the next apartment. This savage deed, aggravated by the queen's situation, who was far advanced in pregnancy, could not be forgiven. From this hour, Mary took no pains to conceal her hatred of her husband, whom she treated with every mark of aversion and contempt, nor
nor did the birth of a son, afterwards James VI. of Scotland, and the title of that name in England, produce a reconciliation. She, however, soon manifested her affection from Rizzio to Hepburn, earl of Bothwell, a potent nobleman, who had ever evinced an attachment to her cause, and had been a principal instrument of rescuing her from the power of the conspirators, who would willingly have sacrificed her as well as her paramour. He, neglected and defpised by every one, was glad to live in solitude; and in the beginning of 1567, he was feized with a disorder, which brought his life into danger, and which was attributed by some persons to poison. When he was getting better, Mary paid him a visit at Glasgow, in which she put on an appearance of the greatest kindness and affection, and he consented to accompany her to Edinburgh. Here she attended him with the affidavit of a tender wife, and slept two nights in the chamber under his apartment. But on the next day he left her to be present at a masque in her presence, and in two o'clock the following morning the house was blown up with gunpowder, and the king's dead body was found in an adjacent field. To Bothwell and the queen this foul deed was imputed, and feeling that the king's safety had been endangered, the conference which should be brought to trial, but no warrant was apprehended of his accuser on the day appointed, he was acquitted. Within a week from this acquittal, Bothwell, at a public entertainment, openly avowed his intention of marrying the queen; the perfidious people, the highest rank in the country, applauded his determination, and subscribed a paper expressing their conviction of his innocence with respect to the murder, and recommending him as husband to the queen. The sentiments of the nation by no means corresponded with the declaration of these most spirited nobles, and the projected union was generally looked upon with detestation. Bothwell resolved to bring it to effect with violence. As the queen was proceeding from Edinburgh to Stirling, to visit her infant son, he suddenly appeared on the road with a large body of horse, dispersed her tender train, and seizing her person with a few couriers, conveyed them to his castle at Dumbarton. That this was a preconcerted plan, done with the consent of the queen, there never was a doubt in any one's mind. On the 5th of May, and within a few weeks of her husband's murder, Bothwell married her, and from this period, Bothwell, without the title of king, polished the whole power of the crown; no access was permitted to the queen except through his creatures, and he made a desperate attempt to get the person of the young prince into his hands, but without success. These transactions excited a general indignation in foreign countries, and rendered the Scottish name odious, till at length the nobles of the land redeemed their credit by a determined and practical patriotism in defending the prince. They collected an army, and declared against Bothwell, who, with the queen, retired to Dumbarton, and also raised troops. To avoid the consequences of a battle, Mary was obliged to accept the condition of dismissing Bothwell from her presence, and surrendering herself to the confederates. Bothwell took his leave, and rode from the field, just one month after his marriage, and the never saw him afterwards. She was, after this, received with respect by the nobles; but the fudlers and common people could not be prevented from expressing their feelings in the most approbrious terms. A standard was held before her, on which was written the name of the late king, with the infant prince kneeling, and uttering the words "Judge and revenge my cause, O Lord." She was conducted to Edinburgh, as a spectacle of shame through the streets, and sympathy for her condition was lost, in horror of her real or imputed crimes. She was soon after obliged to resign the crown, which was placed on the head of the prince, Murray being appointed regent during the minority. Mary was now thrown into prison, from which she contrived to make her escape, and after an unsuccessful attempt to regain her power, she resolved to throw herself upon the generosity of her rival, Elizabeth, and hastily embarking in a sailing-boat, she landed at Workington in Cumberland, whence she was respectfully conducted to Carlile. The queen of England was at a loss to know how to treat a foreign princess expelled from her country, and acceded by her own sujets, who was likewise regarded by the Catholic party as the rightful claimant of the English crown. She determined, however, to take advantage of the incident, and at least to detain her as a sort of state prisoner. Mary proposed to submit her cause to the cognizance of her sister-queen; the offer was accepted, as implying a kind of judicial superiority in the latter, and affording the occasion of keeping Mary in a distant confinement for an indefinite period. By the requisition of Elizabeth, the regent Murray was induced to appoint commissioners to support his cause, Mary did the same on her part; and Elizabeth nominated three persons for distinction to hear both parties, the result of the proceedings, after a time, they were removed to Wellminster. The regent directly accused Mary of being accessory to the murder of her husband, of which, it was said, proofs were adduced in her own hand-writing; but after a variety of delays and subterfuges, by which both queens seemed inclined to stifle inquiry, the regent, who had come in person to England, was dismissed without either approbation or converse, while Elizabeth determined to support his party in Scotland, and Mary remained in custody. She hoped to regain her liberty by means of a marriage with the duke of Norfolk. Elizabeth was kept in ignorance of the design, while it was communicated to the courts of France and Spain, who highly approved it. When the fact was discovered by the vigilance of her ministers, she, without hesitation, committed the duke to the Tower. A rebellion in behalf of Mary's cause broke out in the north of England, which, though speedily suppressed, excited in the mind of Elizabeth such apprehensions, that in 1570 she had come to the determination of ending all connexion with her own country, under the custody of the regent. This plan was defeated by the murder of Bothwell, an event that revived the hopes of Mary's friends and adherents in Scotland, and caused great confusion in that country. The duke of Norfolk was liberated from confinement, and, carrying on a correspondence with Mary, was seduced, in 1571, into a conspiracy, which cost him his life. Mary, whole place of confinement had been the castle of Tutbury, was, on account of ill health, sufferd to go to Buxton. About this period the earl of Morton fell into the power of his enemies in Scotland, and was tried and convicted of having a share in the late king's death. By his dying confession, he admitted that he had been informed by Bothwell of the conspiracy, but that finding the queen was the author of it, he forebore to take any steps to reveal it. In 1584, there were other plots contrived to effect Mary's escape, by one of which the English nation was thrown into such alarms for the safety of the queen and the Protestant religion, that a measure was adopted which may be considered as the forerunner of Mary's late fate. The was rejected by princes were opened to her, by the most solemn oaths, to defend queen Elizabeth from all enemies, foreign and domestic. The unanimity with which the association was entered into by all ranks of people alarmed Mary, who submitted herself, with great apparent humility, to the queen's displeasure, though she was almost
MARY.

at the same instant detected in secret correspondence with the English Catholics. She had hitherto been under the care of the earl of Shrewsbury, who had discharged the trust reposed in him during fifteen years with respect and lenity towards the unfortunate captive, and with great integrity towards his employers. She was now committed to the custody of two keepers of inferior rank and harsh dispositions, viz. Sir Drake Drury, and Sir Amias Paulet. Elizabeth, in the mean time, obtained an ascendancy over the councils of the young king of Scotland, and engaged him in a league for the protection of the Protestant religion, now endangered by the power and bigotry of Philip II. of Spain.

A new conspiracy against the life of the queen of England afforded her ministers an opportunity of involving Mary as an accomplice in it, and letters alleged to be hers were produced, which proved, or which were thought to prove, her participation in the design of assassinating Elizabeth. The circumstances, if founded in fact, were no doubt greatly exaggerated, the zeal of the nation was inflamed to the highest degree, and the punishment of the great culprit was loudly called for. The court, being backed by the people at large, resolved to proceed to the extremity it had long meditated. The papers of the Scottich queen and her domestics were seized, and she herself was conveyed a close prisoner to Fotheringay-castle. Under the cover of that phrase, "close imprisonment," there is no treatment; however severe, that has not been practised by gaolers, and functioned by their employers. Preparations were made for trying her publicly, and in October, 1586, a commissio was opened for the purpose. At first she refused to plead, using the obvious and valid arguments, that she was a foreigner, and a sovereign in her own right; that she owed no allegiance to the laws of a kingdom in which she had been treated only as a captive, and from which she had received no protection. Her objections being overruled, she was persuaded or threatened into a consent to plead. She made her defence with great dignity of mind, and solemnly disclaimed the least concurrence in any design to take away the queen's life; she was, however, declared guilty of being an accessory to Babington's conspiracy. Though the trial was conducted in a manner which would have been illegal, even if she had been a subject of England, and though no certain proof could be made out against her, she was, to the alienation of Europe, condemned to suffer death. The fair heroine received her sentence with fortitude and composure, and when the ears of Shrewsbury and Kent were introduced to inform her that she must prepare for death next morning at eight o'clock, she seemed in no wise terrified, though somewhat surprised with the intelligence. She said with a cheerful and smiling countenance, that she did not think the queen would have conferred on her death, or have executed the sentence against a person not subject to the laws and jurisdiction of England: "But as such is her will," said she, "death, which puts an end to all my miseries, shall be to me most welcome; nor can I esteem that foul worth the felicities of heaven, which cannot support the body under the horrors of the last passage to these blissful mansions." On the evening before her execution on the succeeding morning, she prepared herself with religious solemnity and perfect repose. She called in all her servants and drank to them; they pledged her, in order, on their knees; and craved her pardon for any past neglect of their duty: she even deigned, in return, to ask pardon for her offences towards them, and a plentiful effusion of tears attended this last solemn farewell and exchange of mutual forgiveness. She then distributed among them her money, her jewels, and her clothes, according to their rank and merit. She wrote her will with her own hand, constituting the duke of Guise her principal executor, and to the king and queen of France she recommended her son, provided he should prove worthy of their esteem. At her usual time she went to bed, slept some hours, and then rising, spent the rest of the night in prayer. Having foreseen the difficulty of exerting the rites of her religion, she had taken the precaution to obtain a consecrated host from the hands of pope Pius, and she had referred the use of it for this last period of her life. By this expedient, she supplied, as much as she could, the want of a priest and confessor, which was refused her by the bigotry of the ears of Shrewsbury and Kent, who would have forced upon her the dean of Peterborough, rather to enter upon controvertial topics, than to afford her the consolation that her situation required. Towards the morning she dressed herself in very elegant attire, and met the awful ceremony with a dignity and mildness of disposition that affected every beholder, except, perhaps, the dean of Peterborough, who insulted her with his congratulations, and the two noble ears, who seemed devious of refusing every requisition, however reasonable for her to ask, and for them to grant. Her behaviour at this awful crisis has furnished matter for all the descriptive eloquence of history: it was indeed calm, magnificent, and pathetic, in a supreme degree. After due preparations, she laid her head on the block, and firmly received the fatal stroke. She died in her forty-fifth year, after a captivity of almost nineteen years. She was a woman of great accomplishments both of body and mind, natural as well as acquired, but unfortunate in her life, and, during one period, very unhappy in her conduct. An enumeration of her qualities might carry the appearance of panegyric; an account of her conduct, in some parts, wear the aspect of severe satire and invective. Her misfortunes, the solitude of her long and tedious captivity, and the persecutions to which she had been exposed on account of her religion, had wrought her up to a degree of bigotry during her later years, and such were the prevalent spirit and principles of the age, that it is the least wonder if her zeal, her renunciation, and her interest uniting, induced her to give content to a design which conspirators, actuated only by the first of these motives, had formed against the life of Elizabeth. Mary wrote "Poems on various occasions, in the Latin, French, and Scotch languages": "Confections of her long imprisonment, and royal advice to her son:" "A Copy of Verles, in French, sent with a diamond ring to queen Elizabeth:" "Genuine Letters of Mary, queen of Scots, to James, earl of Bothwell:" Besides these, there are many other tracts, epistles to queen Elizabeth, Cecil, and other distinguished characters preferred in the Cottonian and Ashmolean libraries. Robertson's Hist. of Scotland. Hume's Hist. of England.

MARY, St., in Geography, an island in the East Indian sea, near the N.W. coast of the island of Borneo. N lat. 6° 30'. E. long. 113° 40'.—Allo, one of the Scilly islands. N lat. 49° 57'. W. long. 6° 17'. See Scilly islands.—Allo, an island in the Indian sea, separated from the E. coast of Madagascar, by a strait about three leagues wide; the island is about 15 leagues long, and from two to three wide, amidst rocks, on which is found some beautiful white coral; on the E. coast is found ambergris, used by the inhabitants in their sacrifices to the memory of their ancestors. The interior abounds with gentle hills, innumerable brooks, and springs of fresh water. The inhabitants, who pretend to be the descendants of Abraham, call the island "Noffi Ibrahim." The soil is fertile, and produces rice, sugarcanes, legumes of different kinds, pine-apples, tobacco, &c. The air is inebriating, and rain frequently occurs and sometimes times.
times continues, without intermission, for a fortnight. S. lat. 16° 45'. E. long. 50° 30'.—Also, one of the Shiant islands, among the Western islands, near the S.E. coast of Lewis, in Scotland, about seven miles in circumference; 32 miles S. of Stornaway.—Also, one of the Azores islands. N. lat. 37°. W. long. 25° 6'.—Also, a county of Maryland, on the peninsula between Patowmac and Patuxent rivers, 39 miles long, and 15 broad, containing 13,690 inhabitants, of whom 6590 are slaves.—Also, a poit-town and port of entry of Georgia, situated on St. Mary river, a few miles from its mouth. The town is small, and its trade is inconsiderable; 129 miles S. of Savannah. N. lat. 30° 45'. W. long. 79° 12'.—Also, a river which forms part of the southern boundary line of the Upper States; and in part divides Georgia from East Florida. It rises in the great Okasooka or Ekatanoga swamp, which extends S. into E. Florida. It is thought to be that which is called Mary river, discovered by John Ribalt in 1562. Between this and Nassau river lies the low even coast of Amelia island. The harbours of both rivers are spacious, but Nassau is the better; it has nine feet of water at low spring tides, runs a course of 170 miles, enters the ocean between the points of Amelia and Talbott's islands, in N. lat. 39° 44', and is navigable for vessels of considerable burden for 90 miles. Its banks afford immense quantities of fine timber, suited to the West India market.—Also, a branch of the Miami, which runs into lake Erie.—Also, a river of Nova Scotia, which runs into the sea, N. lat. 47° 5'. W. long. 61'.—Also, a river of America, which runs from lake Superior to lake Huron; on which are two forts. N. lat. 46° 22'. W. long. 84° 24'.—Also, a port on the S. side of the bay of Fundy.—Also, a small island, called "Bates Island," in the German sea, near the coast of England, and county of Northumberland; six miles N.N.W. of Tyne-mouth. N. lat. 55° 6'. W. long. 1° 11'.

Mary's, St., Boy, a bay on the S. coast of Newfoundland. N. lat. 57°. W. long. 54° 20'.—Also, a bay of the Atlantic, on the coast of Africa. S. lat. 13° 12'.—Also, a bay on the W. coast of Nova Scotia, E. of the bay of Fundy.

Mary, St., Cape, the most southern promontory of Brazil.—Also, the point of land which forms the N. side of the mouth of La Plata river, in Paraguay, or La Plata, in South America. S. lat. 35° 14'. W. long. 55° 32'.—Also, the S.E. headland at the mouth of Placentia bay, Newfoundland.

Mary, St., Falls of, a cataract in St. Mary's river, between lake Superior and lake Huron, confisting not of a perpendicular defect of water, but of a rapid, which continues near three quarters of a mile, over which canoes, well-piloted, might pass. These falls supply immense quantities of fish, which are commodiously caught by dipping nets at the bottom of the falls.

Mary's, St., Inlet, a bay on the coast of Georgia, at the mouth of the river St. Mary. N. lat. 30° 56'. W. long. 81° 40'.

Mary's, St., Islands, a cluster of small islands in the gulf of St. Lawrence, near the S. coast of Labrador. N. lat. 50° 40'. W. long. 60°.

Mary's, St., Keys, rocks on the S. coast of Newfoundland. N. lat. 46° 47'. W. long. 53° 57'.

Mary's, St., Key, a small island in the gulf of Mexico, near the coast of Florida. N. lat. 30° 11'. W. long. 89° 12'.

MARYBONE, or St. Mary le Bone, a large parish at the north-western extremity of London, and now constituting a populous portion of this capital. It was anciently called Thiburn, from its situation near a small bourn or rivulet, which was formerly named Aye-brook or Eye-brook. When the feite of the church was altered to a place near the brook, it appears to have gained the appellation of St. Mary-at-the-Bourn, of which its present name is a corruption. The parish is situated in the hundred of Offulfon, and county of Middlesex; it is eight miles and a quarter in circumference; and contains about 2550 acres, whereof nearly half is occupied by buildings, and the remainder, extending westward to Kilbourn turnpike, and northward to Primrose-hill, is grazed except a few acres appropriated to market gardeners. The soil on the northern and eastern parts is clay, and on the south a fine gravel. The manor of Tybourn, was an ancient demeane of the crown; and the manor-house was used as a palace; this manse was pulled down in the year 1791, and Devonshire Mews built on the site. In the vicinity was a well known place of entertainment called Marybone-gardens, which were opened before the year 1737, for public balls, and evening concerts with exhibitions of fire-works, &c. The gardens were shut up in 1782, and the feite is now occupied by Beaumont-freet, and part of Devonshire-freet and Devonshire-place. Marybone-park, a part of the ancient royal demeane, and since called Marybone-park farm, contains 543 acres, according to an actual survey made in the year 1794, under the direction of John Fordeyce, esq., surveyor-general of the crown lands. About two-thirds of this district are in the parish of Marybone, and the remainder in that of Pancras. A new scheme has been recently proposed to lay it out for villas, roads, fire-works, &c. A canal, called the Regent's, from Paddington to the Thames, is to be built through it. An act of parliament for this purpose was obtained in the year 1812. It was also decided to erect extensive barracks here, but this scheme having been feverly and jrritably repudiated in some of the public journals, it is relinquished. Since Marybone has been in some degree incorporated with London, several splendid mansions have been erected by the nobility, and other persons of opulence within this parish. The most remarkable are, the seat of Aldborough's in Stratford place; Montague house, in Portman square; Manchester-house; Harcourt-house; Chandos-house; Foley-house, which might have been added to the list, is now taken down, and the ground let to build a wide street from Portland-place southward. In Duchess-freet, Thomas Hope, esq., has a splendid manse, containing a large and valuable collection of ancient vases, sculpture, paintings, &c. The late sir Francis Bourgeois had a handsome house in Charlotte-freet, which was filled with a large and choice collection of pictures by the most eminent masters. The whole of these are bequeathed to Dulwich college, in Kent, where a large and appropriate gallery is now building for their reception. Sir Francis was a man of the highest talents, esq., professor of architecture to the Royal Academy. Attached to which is a museum, to contain the remains of the late sir Francis, and also those of his friend Noel Defenans, esq. In the year 1400, bishop Braybrouke granted a licence to take down the old church of Tybourn, and to build a new church of stones or flints in a more eligible situation. This edifice, called Marybone church, being, through length
of time, in a ruinous condition, was taken down in the year 1741, when the present structure was erected on the site; but it is very small and ill suited to the present population. There are, however, eight private chapels in the parish, belonging to the establishment of the church of England; viz. Oxford chapel, built before 1730; Portland chapel, 1760; Bentinck chapel, 1772; Welbeck chapel, 1774; Portman chapel, 1779; Quebec chapel, 1788; Margaret-street chapel, first used as a place of worship of the established church in 1789; Brunswick chapel was built about 1795. The parish also contains several chapels appropriated to persons of different religious profession: among which are two for Roman Catholics; one belonging to the Greek church; and one for the Wesleyan Methodists.

At the beginning of the last century, Marybone was a small village, nearly a mile distant from any part of the metropolis. In the year 1715, a plan was formed for building Cavendish-square, and several streets on the north side of Tyburn road. In 1718, the ground was laid out, the circle for the centre inclosed, and surrounded with a parapet-wall and palisadoes. The duke of Chandos took the whole north side, intending to build a magnificent mansion, of which the houses belonging to the earls of Hopetown and Gainborough were to have been the wings. Lord Harcourt and Lord Bingley took some ground on the east and west sides, and the rest was let to builders; but the failures of the South-Sea year put a stop to the improvements, and the square was not completed for several years. As an inducement to the builders to persevere, a chapel and market were projected; and they were both finished in 1734, though the market was not opened till 1732. The houses on the north side of Tyburn road were completed in 1739, and it was then called Oxford-street. Maitland, whole work was published in 1739, says, there were in his time 577 houses in Marybone parish. Portman-square was begun about 1764, and Portland-place about 1770. Manchelifer-square, which had been begun in 1776, by the building of Manchellier-house, was finished in 1788. From that time to the commencement of the present war, the buildings rapidly increased. In the return under the population act of 1800, this parish is stated to contain 27,064 houses, occupied by 63,983 persons. The present number of houses must exceed 83,300. The progressive increase in the population appears in the registers of baptisms and burials, which were, on an average,

Among the many eminent persons buried in this parish, we specify the following names: Humphrey Wanley, antiquary; James Figg, the celebrated prize-fighter, rendered famous by being a subject for Hogarth's pencil; James Gibbs, architect; Archibald Bower, historian, &c.; Edmund Hoyle, author of the treatise on Whist; John Michael Kybrack, flutist; William Guthrie, historian and geographer; James Ferguson, astronomer; Allan Ramsay, portrait-painter; Mark Anthony Joseph Baretto, linguist; John Dominick Serres, marine-painter; Stephen Storace, an eminent musical composer; William Cramer, musician; Francis Wheatley, artist; George Stubbs, artist; admiral sir Richard King, baronet; Alexander Dalrymple, geographer, &c.; Thomas Holcroft, author of various works; William Henry Cavendish, duke of Portland. Very numerous entries occur in the registers of marriages, baptisms, and burials, relating to families of the first rank. A charity-school was instituted in this parish in 1750, for clothing, instructing, and apprenticing the children of the industrious poor. On the north side of Oxford-road, near Stratford-place, were some ancient conduits belonging to the city of London; near them stood the lord mayor's banqueting-houle, where the city officers were accommodated when they went to view the corduits; it was pulled down in 1737, and the springs were arched over.

This parish is governed by a select vestry, and is extremely well regulated, for which it is much indebted to the late bishop Harley, who was many years curate here, and exerted his interest in procuring the acts of parliament by which the regulations are confirmed.

The public place of execution for criminals convicted in the city of London and county of Middlesex, was formerly in this parish, at the end of Park-lane, near Tybourn-turnpike. For further particulars respecting this part of London, see Paddington and Pancras. Lysons' Environs of London, vol. iii. and Supplement to ditto, 1812, 410. Malcolm's "Londonium Redivivum," vol. iv. 410.

MARYBOROUGH, a post-town of Ireland, in the Queen's county and province of Leinster. It is situated on the river Barrow, and is the sittings town of the county. It is not large; but in its neighbourhood is manufactured a great quantity of stuffs, ferges, druggets, and other woollen goods. Maryborough received its name from queen Mary I. in whose reign the county was made fries ground: it had, before the Union, the privilege of being represented in parliament; and it still retains its peculiar magistrates. It is 40 miles S.W. from Dublin. Cariff. Beaforri.

MARYGOLD, in Búyó. See Calendula.

The leaves of this plant appear to be of greater virtue than the flowers, to which many exploded virtues have been ascribed: their expressed juice has been given in doses of two or three ounces, or more, as an aperient; and is said to loosen the belly, and promote the natural secretions in general. Lewis.

MARYGOLD, Com. See Chrysanthemum.
MARYGOLD, Fig. See MeSEMBRANThemum.
MARYGOLD, French. See Tagetes.
MARYGOLD, Marsh. See Caltha.
MARYGOLD, Zoophyes, in Natural History, the name of a species of sea-animal, of a very beautiful kind, and of the nature of those commonly called zoophyes, or plant-animals, by the old naturalists. In St. Lucy's parish, in Barbadoes, there is a cave, in which is a bafon of very clear salt water; and in the midst of this bason lies a flone, which has been for many years found to be the habitation of a great number of animals of this species.

The flone is always covered with water; and from small holes in its sides, in several parts, there appears at all times of the year a number of creatures representing the flowers of some of the radiated plants, and particularly of the common marygold: they are yellow, and seem composed of a very great number of petals. These, in their natural state, are all regularly and beautifully expanded; but as soon as any thing disturbs them, if it be only the motion of
of a stick, that comes within three or four inches of the whole body, leaves all the leaves up together, and the flower, stalk and all, is retracted back into the hole of the flower; but if the water be left a few minutes undisturbed again, they will appear, and expand themselves in the former manner.

When they are nicely observed, there is a yet farther resemblance of a flower in their structure; for there arise from the centre of the body certain oblong bodies, which very naturally resemble the stigma arising from the centre of a flower; but these have evidently the powers of animal limbs; for they no sooner appear, but they dart themselves out to the verge of the flower in several directions, and are plainly interlaced in search of prey. — They are composed of several joints, and the creature often makes them meet in the manner of a forceps, to lay hold of any thing it pleases. These parts, however, seldom appear except exerted any long time together, but are, after a time, received back into the body.

These arms may easily be conceived to be of use to draw in the prey within the compass of the body of the animal; and as soon as it is there, the same contraction of the several rays which serves them to escape danger, and bury themselves in the cavity of the flower, will also serve to hold fast the prey till the creature has fed on it.

Beneath these lager yellow radiated zoophytes, the top of the flower usually affords a number of others of a blue colour, which stand among a fort of vessels of water-bladders, diploated like clusters of grapes. Philos. Trans. N° 470. p. 591.

MARY-GREY, in Geography, the name of a tolerably high mountain in the county of Tyrone, Ireland, between Omagh and Strabane. The road passes between this mountain and Daffy Belf, another inflated mountain of considerable height,—Beaufort.

MARYKIRK, a town on the S. coast of the island of Sanday, N. lat. 55° 6'. W. long. 2° 27'.

MARYLAND, one of the United States of America, lying between 37° 56' and 39° 44' N. lat. and 7° and 43° W. long. 134 miles in length and 110 in breadth, or 14,000 square miles in superficial measure, one-fourth of which is water. This state is bounded N. by Pennsylvania, E. by Delaware and the Atlantic ocean, and S. and W. by Virginia. It is divided into 19 counties, 11 on the western, and eight on the eastern shore of Chesapeake bay, as in the following table.

Each of the counties sends four representatives to the house of delegates; besides which the city of Annapolis and town of Baltimore each two. Annapolis is the capital of the state; but Baltimore is more populous and of greater commercial importance. The number of inhabitants in this latter town, according to the census of 1800, was 26,714, of whom 28,423 were slaves. The bank established in Baltimore, with a capital of 500,000 dollars, is called "The Maryland Bank." There is, besides, a branch of the bank of the United States. In 1796 a new bank was established by law, with a capital of 2,000,000 dollars, called "The Bank of Baltimore." The other principal towns of this state are Georgetown, in which a bank has been lately established, called "The Bank of Columbia," and also a college for the accommodation of about 200 students, endowed chiefly by Roman Catholics of the several states, but as to education unlimited by any particular sect.—Fredericktown; Elizabethtown; and Elkton. See each place respectively. Chesapeake bay, which separates this state into the eastern and western divisions, receives a number of large rivers; from the eastern shore in Maryland, among other smaller ones, it receives Patowomeck, Nanicoke, Choptank, Chelif, and Elk rivers; from the north, the rapid Susquehanna; and from the west Pataposco, Severn, Patuxent, and Patomac, half of which is in Maryland, and half in Virginia. The Susquehanna and Patowmac excepted, there are small rivers. As to the face of the country, calmar of the blue ridge of mountains, which stretches across the western part of
MARYLAND.

of this state, the land is generally level and free from stones. The ground is uniformly level and low in most of the counties on the eastern shore, and consequently much covered with water, except where it is intercepted by numerous creeks. The large tracts of marsh render the clofs of the summer and fall seaons in this part of the state sickly; spring and summer are most healthy. The soil of the good land in Maryland produces from 15 to 16 bushels of wheat, or from 20 to 30 bushels of Indian corn, per acre. Ten bushels of wheat, and 15 bushels of corn per acre, are the annual average crops in the state at large. The staple commodities are wheat and tobacco. Some cotton of inferior quality is also raised in this state, and in the interior counties, as the uplands, considerable quantities of hemp and flax are cultivated. Two articles are paid to be peculiar to Maryland, viz. the genuine white wheat, which grows in Kent, Queen Ann's, and Talbot counties, on the eastern shore, and which degenerates in other places; and the bright kite's foot tobacco, which is produced at Elkridge, on the Patuxent, on the western shore. Among other kinds of timber are the oak, of several kinds, made into flaves for exportation, and the black walnut employed for furniture. The apples are large but mealy; the peaches plentiful and good. From these the inhabitants diffl cyder, brandy, and peach-brandy. The forests abound with various kinds of nuts, collectively called "Miff," and used for fattening hogs, which run wild in the woods. As to the manners of the inhabitants, Mr. Moree says that the farmers of Maryland affec
t many very much with each other; that their manners are as polished as those of the country gentlemen in England, their minds well informed, and their intercourse free and familiar; their sons generally receive a liberal education, and many of them engage in the study of the law, without purifying it as a profession. The inhabitants of Maryland, however, are not exempt from that pride, which is too general among those who are connected with and accustomed to flaves; but with their pride they blend a great degree of hospitality. Many of their women polishes all the amiable, and many of the elegant accomplishments of their sex. The mines of iron ore in this state abound, and it is of superior quality; furnaces and forges are also numerous. Coal has been lateiy found near Baltimore, and great quantities of eye-
wh. they are manufactured in this state; griffills are common. The trade of Maryland is principally carried on from Balti-
more, with the other states, with the West Indies, and with some parts of Europe. To these places the inhabitants fend annually about 30,000 logheads of tobacco, besides large quantities of wheat flour, pig-iron, lumber, and corn; beans, pork, and flax-feed in smaller quantities; and receive, in return, clothing for themselves and negroes, and other dry goods, wines, spirits, sugar, and other West Indian commodities. The balance is generally in their favour. The value of exports from this state in 1801 was 9,151,039 dollars. The first settlers in Maryland were Roman Catholics; besides these, there are many Protestant Episcopalians, English, Scotch, and Irish Presbyterians, German Calvinists, German Lutherans, Friends, Baptists, Methodists, Mennonists, and Niceties or New Quakers; all of whom enjoy liberty of con- fidence for the seminaries of learning in Maryland; see COLLEGE.

The revenue of Maryland arises chiefly from taxes on real and personal property; and the annual expenses of government are estimated at about 20,000l. currency. The legislature is composed of a senate and house of delegates, which are styled "The General Assembly of Maryland." The senators are elected in the following manner. On the 1st of September, every fifth year, the freemen choose two men in each county, to be electors of the senate, and one elector for the city of Annapolis, and one for the town of Baltimore. These electors, possessing the qualifications ne-
cessary for county delegates, meet at Annapolis, or any other appointed place, on the third Monday in September, every fifth year, and elect by ballot fifteen senators out of their own body, or from the people at large; nine of them repre-
sents on the western, and fix on the eastern shore; all more than twenty-five years of age; residents in the state more than three years before the election; and possessing a real and per-
sonal property above the value of 1,000l. The senate may origi-
nate any bills, except money bills, to which they can only give their assent or disaffent. The president of the senate is chosen by ballot. The house of delegates is composed of four members for each county, chosen annually the first Monday in October: the city of Annapolis and town of Baltimore, as we have already observed, send each of them two delegates. The qualifications of a delegate are, full age, one year's residence in the county where he is chosen, and real and personal property above the value of 500l. Both houses choose their own officers, and judge of the election of their members; a majority of each is a quorum. The election of senators and delegates is without vote, and there is the returning officers, except in Baltimore town, where the commissioners superintend the elections, and make returns. The ratified election of the legislature is on the first Monday in November. The qualifications for a freeman are, full age, a freehold estate of fifty acres of land, and actual residence for a year in the county where he votes, and property in any part of the state to the value of 30l. The governor is appointed on the second Monday in November, annually, by the joint ballot of both houses; but cannot continue in office longer than three years successively, nor be re-elected until the expiration of four years after he has been out of office. The qualifications for the chief magistracy are twenty-five years of age, five years' residence in the state, next pre-
ceding the election, and real and personal estate above the value of 5000l., 1000l. of which must be freehold estate. A council for assisting the governor in his office, consisting of five persons above twenty-five years of age, residents in the state three years next preceding the election, and possess-
ing a freehold of lands and tenements above the value of 1000l. is chosen, annually, on the second Tuesday of No-
vember by joint ballot of senators and delegates. The go-
vernor, with the advice of his council, appoints the chancel-
ellers, all judges and Justices, the attorney-general, naval and militia officers, and all others, except constables, auditors, and overseers of the roads. A court of appeals is established for the final determination of all causes, which may be brought from the general court of admiralty, or of chancery. This constitution was established by a convention of delegates at Annapolis, Aug. 14, 1776.

Maryland was granted by King Charles I. to George Calvert, baron of Baltimore, in Ireland, June 20, 1632. It was called Maryland in honour of the queen, Henrietta Maria, and was the first colony which was erected into a province of the English empire, and governed by laws enacted in a provincial legislature. The first emigration, consisting of about 200 gentlemen of considerable fortune and rank, with their adherents, chiefly Roman Catholics, failed from England in November 1632, and landed near the mouth of Patowmac river in the beginning of the fol-
lowing year. Calvert purchased the rights of the aborigines for a satisfactory consideration; and, with their free content, took possession in March, 1633, of the town, which
he called St. Mary's. The foundation of this province was laid by Lord Baltimore, on the broad balls of security to property and liberty in religion; Christianity being established without allowing pre-eminence to any particular sect. This wise measure soon converted a dreary wilderness into a prosperous colony. The transportation of people and of stores, during the first two years, cost Lord Baltimore upwards of 40,000/. The freemen of the province, as an expression of gratitude, granted him, at an early period, a subsidy of fifteen pounds of tobacco on every poll. The first assembly was convened in February, 1634-5. Successive assemblies were convened in January, 1637-8, and in February, 1638-9; at which latter meeting an act passed "for establishing the house of assembly." An attempt was made by the British parliament, in 1640, to annul the charter of Maryland; but the effort failed, and Maryland remained prosperous and happy, till the intrigues of one William Celyborne disturbed its tranquility. In 1645, a rebellion was raised in the province; nor were peace and order reëstablished till August 1646. The assembly at that time, though composed chiefly of Roman Catholics, passed an act, which indicates a spirit of liberality very uncommon at that period. It recited, that the enforcement of conscience had ever been of dangerous consequence in those countries in which it had been practised. And it was enacted, "that no persons professing to believe in Jesus Christ should be molested in respect of their religion, or in the free exercise thereof, or be compelled to the exercise of any other religion, against their consent; so that they be not unfaithful to the proprietors, or conspire against the civil government. That any person molesting another in respect of his religious tenets, should pay treble damages to the party aggrieved, and twenty shillings to the proprietary; that those reproaching any with opprobrious names of religious distinction, should forfeit ten shillings to the persons injured; that any one speaking reproachfully against the blessed virgin, or the apostles, should forfeit five pounds. But blasphemy against God should be punished with death." This act passed 1649, and was confirmed in 1676, among the perpetual laws of the province. The year 1650 is remarkable in the history of Maryland for the final establishment of that constitution, which continued, with some short interruption, till the present one was adopted in 1776. In 1692, the Protestant religion was established by law in this province. In 1716, the government was restored to Charles, lord Baltimore, the then proprietary, and continued in his hands, and those of his successors, till the late revolution; when, though a minor, the proprietary's property in the lands was confiscated and the government assumed by the freemen of the province, who framed the present constitution. Maryland was the last to sign the articles of confederation, published by congress after the declaration of independence. On the 11th of March, 1781, they signed these articles, and they were thus finally ratified. M'Ort's Geog. vol. i.

MARYLAND POINT, a point in the state of Maryland, formed by a bend in the Patowmac river, W. of Port Tobacco.

MARY-PORT', a market town in the parish of Crofton, county of Cumberland. It is situated six miles distant from Workington, and 350 from London, on the banks of the river Ellen, which divides it into two parts. It was first called Mary-port, in honour of the lady of the late Humphrey Senhouse, esq., whose family have long been proprietors of the manor: the small hamlet from which the town arose, was named Ellen-town. From this situation in the town, like many on the western coast of Cumberland, derives its origin and consequence from the coal trade: about the middle of the last century, the beach was occupied by only one house, called Valencia, and about half a score miserable huts, that served to shelter a few fishermen; but so great has been the increase of population and building, that in the year 1801 the houses amounted to 520, and the number of inhabitants was 2032. The streets are wide, and the houses neatly built. Wooden piers, with quays, have been erected on each side of the river, for the convenience of shipping. There are now belonging to the port between seventy and eighty vessels, from 30 to 250 tons burthen. They are chiefly employed in the exportation of coal to Ireland; and in the importing of timber, flax, and iron from the Baltic. An extensive cotton manufacture has been established here, which furnishes employment for nearly 500 people. A weekly market is held on Fridays. A chapel was erected in the year 1760, and consecrated in 1763, by bishop Lyttelton. On an eminence, called the Mote-hill, at the south end of the town, is an artificial mound, the base of which is one hundred yards in circumference. It is protected by a deep ditch, which almost surrounds it.

On the north side of the Ellen, near Maryport, are the remains of a considerable Roman station, generally called Ellenborough; though the village of that name stands on the opposite side of the river at some distance. This station, in the opinion of Horley and Warburton, was the Volantium of the Notitia. Camden supposed it to be the Valentinum; and other writers have flown it Olennacum. The fort is on a high bank, overlooking the sea, and commanding an extensive prospect of the Scotch coast. The area is a square, with four entrances, and defended by a double ditch and rampart. The numerous vestiges of antiquity and variety of inscriptions found at this station are supposed not to be equalled by those discovered at any other in Britain. The principal of these remains is a Roman altar, about five feet high, of curious workmanship, and ornamented on every side with sculptures and inscriptions.

Near the port stands Nether-hall, the seat of the Senhouse family, where the relics found at the station are chiefly preserved. This mansion was formerly called Alnecburgh-hall, and Ellenborough-hall. Hutchinson's Histry, &c. Cumberland. Beauties of England, vol. iii.

MARYSBURGH, a township of Upper Canada, in Prince Edward county, situated at the eastern end of the peninsula, which forms the bay of Quinto, and lies open to lake Ontario on the south.

MARYVILLE, a poll-town of America, in Knox county, Tenneffee; 516 miles from Washington.

MARYTOWN, a town of Scotland, in the county of Angus; 5 miles E.S.E. of Brechin.

MARYVILLE, the county-town of Blount county, in the state of Tennessee.

MARZA, a town of Sicily, in the valley of Noto, where they manufacture salt; eight miles S.S.E. of Noto. Also, a town of Africa, in the desert of Zanhaga, inhabited by Moors, who trade with Europeans for gum, of which there are three forests near.

MARZA BIIR, a town of Arabia; 10 miles W. of Hali.

MARZA Eran, a town of Arabia; 12 miles S. of Soc sia.

MARZA Ibrahin, a town of Arabia; five miles S. of Serrain.

MARZA Kaud, a town of Arabia; 35 miles S. of Mecca.

MARZA Sujia, a town of Africa, in the kingdom of Barca; 8 miles N. of Curen.

MARZAGLIA, a town of Italy, in the department of the Pannaro; four miles W. of Modena.
MARZANO, a town of Naples, in the province of Naples; 12 miles S. of Taranto.

MARZILLA, a town of Spain, in the kingdom of Navarre; 30 miles S. of Pamplona.

MARZOAN, a mountain of Egypt, near the coast of the Mediterranean sea, from Caffa to the town of Florence.

MAS BAY, a bay in the North sea, on the coast of Norway. N. lat. 60° 50' E. long. 5° 30'.

Mas d'Agenois, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Marmande, situated on the Garonne; six miles E. S. E. of Marmande. The place contains 1,600, and the canton 6,135 inhabitants, on a territory of 82.5 square miles, in seven communes.

Mas d'Auzé, a town of France, in the department of the Aude, and chief place of a canton, in the district of Carcassonne; one mile N. of Carcassonne. The place contains 670, and the canton 6,093 inhabitants, on a territory of 17.5 square miles, in 16 communes.

Masa, a town of the republic of Venice; 20 miles N. E. of St. Salvador.

MASACCO, or TOMASO DI SAN GIOVANNI, in Biography, was born at Castello di San Giovanni, nel Valdarni, in the duchy of Florence. Concerning the period of his birth there has been found considerable difference among the early biographers of artists; but Baldinucci, among other evidences, produces one most completely unanswerable, which proves that he was born in 1402. This decisive proof was found in the book of the fidal chamber of Florence, concerning the taxes or customs paid by the inhabitants of the commune of Castello di San Giovanni in 1437; in which our Tomaso gives his portion, and describes himself as being in his twenty-fifth year, and his brother Giovanni in his twenty-first.

Mafaccio (for by this name Tomaso is best known) appears to have attached himself very early to the art of painting; for, at the age of 19, he was matriculated at the city of Florence as a painter; which would hardly have occurred, if he had not been at that time advanced considerably in his profession. His parents were defended of a noble flock, and had the means of enabling their son to follow with advantage the chosen object of his mind; and happy was it for the art, and the world, that for a while nothing impeded the progress of a man, whose extraordinary powers enabled him to extend the regions of art, to animate its almost torpid spirit, and flew to future ages how far its aid, morally and intellectually, might be cultivated for the benefit of mankind.

His father's name was San Giovanni di None, of the family of the Ghiberti. He was by profession a notary of the city of Florence; an office which, at that time, entitled him to respect, and presupposed a qualification for filling higher stations in the magistracy of that place. Finding his son Tomaso intent upon the practice of painting, he placed him as a scholar under Mafolino di Panicle, who was at that time engaged in painting the chapel of the Brancacci in the Carmine. At the same time, the arts of sculpture and architecture began to revive; the former in the hands of Donatello and Ghiberti, and the latter also in those of Filippo Brunelleschi. With the works of these men Tomaso was captivated; and recognizing in them the revival of the true taste observable in the antique, he attempted to apply it in painting; the inseparable companion of the other art of sculpture. How well he succeeded his works fully testify, after a lapse of 400 years, or nearly. His is the glory of forming a new epoch in the art. One hundred and fifty years had passed from the time of Cimabue to Masaccio; that period was of such a change to every great improvement of art as was made by Giotto, who was a disciple of Cimabue; but still much was imperfect in design, in colour, in the imitation of the natural actions of the figure, of attitudes, reliefs, and the more subtle graces of the art. Most of these Masaccio filled up the want of, and gave a more perfect imitation, as well as a better choice of nature, than any of his predecessors; overcame many difficulties, which had been insuperable to them; and opened the way to those great men who succeeded him, particularly to Raphael, who seems to have been born with a soul congenial to his, and who frequently imitated, and sometimes borrowed figures from him, which he was not always able to improve. He is said to have been the first who attained that most essential point, foreshadowing the feet properly, so as to make them appear to rest flat upon the ground, and which, till his time, had not been done; probably owing to the painters taking too near a view of their figures, when looking down upon the feet, and drawing them as so seen, they would of necessity make them appear almost perpendicular. Masaccio discovered the evil of this, and taking a proper distance for his view, and a just point of light, gave their proper effect. For this he was indebted to perspective, the principles of which were imparted to him by Brunelleschi.

He attempted to compose and draw the nude or naked figure, in more varied actions than his predecessors had dared to attempt; and though his figures are frequently imperfect, and in a flying and inipid, yet he sometimes wonderfully succeeded, particularly in the actions of the limbs; and in his heads, and the foldings of drapery, he still upholds his imitation with the best.

So much skill, and so great a novelty in the art of design, soon drew him into notice; and the city of Florence wished to employ his talents. His industry keeping pace with his powers, the productions of his pencil were of course very numerous: but alas! few now remain to testify concerning him; and of these, the greater part disfigured by time, and by ignorance, which pretending to secure, has only hastened their destruction. Baldinucci, who wrote in 1680-90, says, that in his time, though much had been destroyed, yet sufficient remained in Florence of the works of our artist, to prove the vast extent of his study and his labour; to which he applied so fervently, that he neglected every thing which did not appertain to his art, not even collecting the money owing to him for his pictures, and being entirely negligent of his perfon; so that from thence he acquired the name of Mafaccio, and is by that so much better known than his own, that we have thought it proper to place our account of him under it, rather than that of Tomaso di San Giovanni. He was engaged to adorn the principal churches and convents in Florence; but, after having for some time employed himself there, he was stimulated by a desire either to live the works of the ancients, those of contemporary artists, or for the benefit of his health, to travel to Rome, where his high merit was also recognized, and was called into practice. Among other works he painted, in a chapel of the church of Santa Maria Maggiore, a picture of Santa Maria della Neve, with four saints; in which was the portrait of pope Martin, painted from life, with a spade in his hand, marking out the foundations of that church; and also that of the emperor Sigismund II. Valari says that Michael Angelo thought it worth while to study this pic-
tire, which he praised highly. Whilft he was thus honourably employed at Rome, he heard that his friend and protector Cosmo di Medici was again flattered at the head of affairs at Florence, and immediately returned there. Upon his arrival he found his master Mañolino dead, leaving incomplete several pictures in the chapel of the Brancacci, the finishing of which was immediately entrusted to Masaccio, who, to the designs already begun by Panicale, added many others, which still remain monuments of his superior ingenuity. While he was engaged in adorning the Chiefa del Carmine, a procession of the host occurred, which gave rise to a picture in fresco (in which style all his works are executed) of the peculiarities of that ceremony. This he painted over a door which led to the adjoining convent, and which is now destroyed. In it he represented a great number of citizens marching in procession, five or six abreast, with a propriety and variety of action, and in so just a perspective gradation of form and colour, as perfectly astonished the beholders. Among others, he introduced his friends Brunellefchi, Donatello, Mañolino, Antonio Brancacci, who endowed the chapel, &c.

Thus successfully and usefully ran the course of Masaccio's life till he arrived at the age of forty-one, when he was suddenly snatched from his honours and the world by the remorsefuls hand of death, not without suspicion of poison having been administered by some envious or malignant person. This unhappy event caused universal grief throughout the city of Florence; and Brunellefchi observed, that, in the death of Masaccio, the profeflors of the art had sustained the greatest loss which could possibly havebefallen them. The works, however, which he had so ingeniously wrought, remained for their instruction; and almost all the enlightened artists who then lived, and who immediately followed, to carry the art to its utmost pitch, failed not to study and benefit by the superior qualities of this extraordinary man. Amongst them were Lionardo da Vinci, Michael Angelo, and Raphael; and even such men as these three thought his labours worthy of their study, little more need be added in their praise.

MASAFFRAN, in Geography, a river of Algiers, which forms the boundary towards the north between the provinces of Tremercen and Tettric. It is formed by the union of several smaller streams, and runs into the Mediterranean. N. lat. 36° 40'. E. long. 3° 14'.

MASAFUERO, an island in the South Pacific ocean, first seen in 1363, and situated W. of Juan Fernandez, both being nearly in the same latitude, and distant, by the globe, about 31 leagues. It is very high and mountainous, and at a distance appears like one hill or rock; its form is triangular, and its circumference about seven or eight leagues. The fourth part, first seen by Capt. Carteret in May 1707, when he first made the island, at the distance of 23 leagues, is much the higheft; on the north end there are several spots of clear ground, which, perhaps, might admit of cultivation. In the account of lord Anfon's Voyage it is said, that only one part of this island affords anchorage, which is on the N. side, and in deep water; but Capt. Carteret found no part where there was not anchorage. On the W. side, in particular, there is anchorage at about a mile from the shore, in twenty fathom, and about two and a half miles, in forty and forty-five fathom, with a fine black sand at the bottom. In the same voyage it is also said, that there is a reef of rocks running off the easter point of the island about two miles in length, which may be seen by the sea breaking over them; but this, according to Capt. Carteret's account, is a mistake, as there is no reef of rocks or island running off the easter point, but there is a reef of rocks and sand running off the western side, near the S. end of it. The author of Anfon's Voyage is also mistaken as to the distance of this island from Juan Fernandez, and its direction, for, he says, the distance is twenty-two leagues, and the direction W. by S.; but Capt. Carteret found the distance nearly one-third more, and the direction is due W., the latitud of both islands being nearly the same. The goats formerly mentioned in Anfon's Voyage were found by our later navigators in great abundance, and equally easy to be caught. On the S.W. point of the island there is a remarkable rock with a hole in it, which affords a good mark to come to an anchor on the western side, where is the best bank of any about the place. About a mile and a half to the northward of this hole, there is a low point of land, and from this point runs the reef just mentioned, in the direction of W. by S. to the distance of about three quarters of a mile, where the sea continually breaks upon it. To anchor, run in till the hole in the rock is shut in, about a cable's length upon this low point of land then bearing S. by E. E., and anchor in twenty and twenty-two fathom, fine black sand and shells. There is anchorage also at several places on the other sides of the island, particularly off the N. point, in fourteen and fifteen fathom, with fine sand. All round the island there is plenty of wood and water, but they cannot be procured without difficulty; as a great quantity of stones, and large fragments of the rock have fallen from the high land every where round the island, and upon this the surf breaks to such a degree, that a boat cannot come with safety within a cable's length of the shore. Masfraero is a good place for refreshment, especially in the summer season. We have already mentioned the goats, and there is round the island plenty of fish, which may be easily caught; such as excellent coal-fish, cavallies, cod, holibut, and cray-fish. King-fishers, thraks, and seals are numerous. The latter animals yield excellent train-oil, and their hearts and plucks are good food, somewhat resembling in taste the hog; and their skins are covered with very fine fur. On this island are many birds, and some very large hawks. S. lat. 33° 45'. W. long. 86° 46'. Hawkeforward's Voyages, vol. 1.

MASAGRAN, or Masachran, a town of Alghiers, in the province of Tremercen, surrounded with mud walls, and seated on the declivity of a range of hills, within a fur-long of the Mediterranean; 20 miles N. of Arzew. Shaw's Travels, p. 15.

MASIBPET, a town of Hindoostan, in Golconda; 28 miles N.N.W. of Hyderabad.

MASAN, a town of Mocaumpour; 44 miles S.W. of Mocaumpour.

MASANET, a town of Spain, in Catalonia; 17 miles S. of Gerona.

MASANI, a town of Servia; 30 miles S. of Paffarowitz.

MASARA, a town of Alghiers; 12 miles N. of Conflantin.

MASARINO, in Ornithology, a name given by the Portuguese in the Brazil, to a large bird of the curlew kind, approaching to the goose in size; and more commonly known by its Brazilen name curaoa.

MASARUOLO, in Geography, a town of Italy, in Friuli; 3 miles N. of Friuli.

MASAYA, a town of Mexico, on the west side of the lake of Nicaragua; 10 miles N. of Granada.

MASBATE, one of the Philippin islands, about 90 miles in circumference, the inhabitants of which are, for the most part, 4 T 2
part, free and independent. Tribute is paid by about 350 families. The chief produce of this island is rice. It has some mines, but they are not wrought. N. lat. 15° 18'. E. long. 123° 20'.

MABOTHAI, or MAZOTHAI, the name of a feet, or rather of two feets: for Euebius, or rather Heggiepous, whom he cites, makes mention of two different feets of Mazbothzans. The first was one of the seven feets that arose out of Judifim, and proved very troublesome to the church; the other was one of the seven Jewish feets before the coming of Jesus Christ.

The word is derived from the Hebrew יִבְשָׁב, יִבְשָׁב, יִבְשָׁב, to rift, or separate, and signifies idle, lazy, indolent people. Euebius speaks of them, as if they had been so called from one Mazbothicus, their chief; but it is much more probable that their name is Hebrew, or at least Chaldaic, signifying the same thing with a Sabbatarian in our language, that is, one who makes profession of keeping Sabbath.

Valeius will not allow the two feets to be confounded together; the last being a feet of Jews before, or at least contemporary with Christ; and the former a feet of heretics defenced from them. Rufinus distinguishes them in their names; the Jewish feet he calls Maphutbai; and the heretics Maphutheani. The Mazbothzans were a branch of the Simonian.

MASCALAT, in Geography, a town of Arabia, in the province of Oman; 240 miles W.N.W. of Oman.

MASCALL, an island in the bay of Bengal, near the coast of Aracan, about 50 miles in circumference. N. lat. 21° 40'. E. long. 92°.

MASCAR, or MASCAR, formerly Vitoria, a town of Algiers, and capital of a province of the same name, sometimes called Trencen, from the most considerable town in it. This town is the residence of the bey, and the only place in the whole kingdom which, under the domination of the Turks, flourishes and perceptibly increases in prosperity. It is indeed smaller than Trencen and Sherriei; but furnishes them beauty, and the modern appearance of the houses, and it is daily enlarging in extent. Mascara is situated in the centre of a district abounding with corn-fields, and embellished with numerous small villages. So late as in the time of Shaw (1732) it was but an inconsiderable place; but at present it is a great number of good houses, newly erected mosques, and a strong castle, in which the bey resides; and is attended by a numerous and splendid retinue. The Bedouins in its vicinity are exempt from taxes, and merely serve as volunteers in cases of necessity; 40 miles E.S.E. of Oran.

MASCARIB, or MASEERIB, a town of Syria, belonging to a powerful Arabian prince; three days' journey S.S.E. from Damascus.

MASCARDI, Augustin, in Biography, an Italian, was born of a good family, at Sarzana, in the territory of Genoa, in the year 1591. In early life he entered himself among the Jesuits, which society he quitted upon the invitation from pope Urban VIII., who made him his chamberlain, and nominated him to the professorship of eloquence in the college of Sapienza at Rome. He died at the age of 49, and he is spoken of by cardinal Bentivoglio, who was his most intimate friend, as one of the most learned and eloquent persons of his time. He was author of many works, of which, the most valuable is on "The Art of writing History," first published in 1636, and reprinted with additions by Pirani in 1646. He published an account of the conspiracy of Fiesco in 1629, and the work of cardinal de Retz on the same subject is only a free translation of that of Mascardi. Moreri.

MASCARENHAS, in Geography, a town of Portugal, in the province of Tarso-Montes; 4 miles N. of Mirandola. See also "isle of Bourbon.

MASCARI, a town of Sicily, in the valley of Demona; 9 miles S.W. of Taormina.

MASCARIN, one of the Galapagos islands in the Pacific ocean. S. lat. 1° 12'.

MASCAT, or MASKAT, a town of Arabia, in the territories of the Imam of Oman. This is the most important and best known city in these territories; and hence the Imam is, by many travellers, called "king of Mascat." It stands at one end of a beautiful plain, near a small gulf, encompassed with steep rocks, forming an excellent harbour, in which the largest vessels may find shelter. This harbour is likewise protected by forts; so that the city is fortified both by art and nature. Arrian calls it "Moea," and speaks of it as being, even in his time, a great emporium of the trade of Arabia, Persia, and India. Mascat has ever enjoyed this advantage, and even at present possesses a considerable trade. The Portuguese made themselves masters of it in 1508. Two churches, one of which is now a magazine, and the other the house of the "wali," or governor, still remain to show that they were once established here. About 150 years after their conquest of Mascat, the Portuguese were expelled by the Arabs, through the treacherous aid of a Banian, who had been robbed of his daughter by the Portuguese governor. The Banians are more numerous at Maskat than in any other city; their number amounting to 1200. They are permitted to live according to their own laws, to bring their wives hither, to set up idols in their chambers, and to burn their dead. At Mascat, Europeans pay 5 per cent. upon imports; Mahometans, 64; and Jews and Banians 7 per cent. The Imam's natural subjucts pay 6 per cent. in kind, upon dates exported, and there are the principal article which the country affords. Mascat is distinguished by the strictness of its police; so that a stranger may walk in the streets any hour of the night without molestation. Theft is never pardoned: every peron caught in the act either suffers death, or the loss of a hand; and therefore the merchandise lies at all times safe in the street; 220 miles S.S.E. of Gambron. N. lat. 25° 22'. E. long. 74° 50'. Niebuhr.

MASCATLAN, a town of Mexico; 60 miles from Acapulco.

MASCAY, a town of the duchy of Stiřia; 8 miles S.E. of Windisch Weilritz.

MASCANTANS, an Indian nation, inhabiting near lake Michigan, and between that and the Mississippi. The number of warriors is 400.

MASCHARADA, in the Italian Mafio, is applied to music composed for the gestures of pantomimes, buffoons, mimics, and such grotesque characters.

MASCHARSKA, in Geography, an island of Russia, in the frozen sea, near the west coast of Nova Zembla. N. lat. 73°. E. long. 52° 14'.

MASCHERE Sceniche, Ital., dramatic masks of the ancients. So immenee was the size of the theatres of Greece and Italy, that we may naturally conclude a musical declamation for the stage to have been a necessary consequence of speaking loud; for whoever shouts, halloos, or bawls, with sufficient force to be heard further than common speech can penetrate, makes use of fixed tones, which, if softened, would become musical; and it is well known that the tones of speech are too transient and undetermined to be afor-
ascertained by those of music, or to be audible at a great distance, or in a wide space.

This want of natural power of voice sufficient to be heard in the open air, for the ancient theatres had no cover, and by a great multitude, gave rise not only to singing upon the stage, but perhaps to chanting in the church. The necessity of augmenting the force of a performer's voice by every possible means, first suggested the idea of dramatic marks, which were used by the actors upon the principle of speaking trumpets.

The mask was called by the Latins persona, from personae, to found through; and delineations of such masks as were used in each piece were generally prefixed to it, as appears from the Vatican Terence. Hence dramatis persona, masks of the drama; which words, after masks ceased to be used, were understood to mean persons of the drama.

Quintilian, lib. ii, gives a list of invariable masks appropriated to different characters, to which the public had for many ages been accustomed. And Julius Pollux is still more ample in his account of theatrical masks, used in tragedy, farce, and comedy. Niobe, weeping; Medea, furious; Ajax, astonihed; and Hercules, enraged. In comedy, the flave, the parasite, the clown, the captain, the old woman, the harlot, the auliere old man, the debauched young man, the prodigal, the prudent young woman, the matron, and the father of a family, were all distinctly characterized by particular masks. This custom is, in some measure, still preferred in the Italian comedy, and in our pantomime entertainments, which originated from it.

MASCHIGIKA, in Geography, a bay on the N.W. coast of Nova Zembla. N. lat. 76° 25'. E. long. 59° 14'.

MASCITI, Michele, in Biography, an Italian performer on the violin at the beginning of the last century, and a voluminous composer for that instrument. In Le Cene's catalogue at Amsterdam for 1729, there is a list of seven of his works, engraved on copper, consisting of folios, duets, sonatas, and concertos.

MASCLE, or MACLE, in Heraldry, a bearing which differs both from the lozenge and fuls in this respect, that according to the sentiments of all authors, it should be exactly square and voided.

According to Guillim, the macle represents the mask of a net, and is an honourable bearing. It only differs from a lozenge, by being voided.

When any coat, in which one or more masques are borne, is to be hazioned, it is necessary to mention their number, and how they are placed; and if they are conjointly, that circumstance must also be mentioned.

MASCLE, Francis, in Biography, a learned French priest and orientalist, was born at Amiens about the year 1672. He was educated for the church, and while he was very young, applied himself most diligently to the study of the sacred scriptures, and with this view he made himself master, not only of the Greek and Hebrew languages, but also of the Syriac, the Chaldee, and the Arabic. He obtained considerable preferment in the church, and to assist the young clergy in their pursuits, he drew up 'A Course of Philosophy,' and 'A Course of Divinity,' which he intended for publications, but was from various unforeseen circumstances obliged to relinquish his design. His application to study, and his able-minded manner of living, irreparably injured his health, and he died in 1728, at the age of sixty-six. He was the author of 'Ecclesiastical Conferences in the Diocese of Amiens, on the Duties and Obligations of the Ecclesiastical State, and on the principal Truths of Religion;' and some controversial pieces. But his celebrity with pouterity chiefly rests on his 'Grammar Hebraica,' which is a work of great merit, and does high honour to the author's erudition and his latinity. This was first printed at Paris in 1716, and the author's attack upon vowel points involved him in a controversy with M. Guarin, a learned Benedictine monk. In 1730, Maclef, in conjunction with the abbé de la Bletterie, one of the fathers of the oratory, published the second edition of his grammar in two volumes, 12mo.; the first containing the original work greatly enlarged; and the second containing three other grammars, viz. the Chaldee, the Syriac, and the Samaritan, together with a reply to the objections of M. Guarin, entitled 'Nova Grammaticae Argumenta ac Vin dicata.'

MASCOBU, in Geography, a town of New Mexico, in the province of Mayo; 110 miles N.E. of Santa Cruz.

MASCULINE, something belonging to the male; or the stronger of the two sexes.

MASCULINE is more ordinarily used, in Grammar, to signify the first and worst of the genders of nouns.

The masculine gender is that which belongs to the male kind, or something analogous to it.

Mott substantiae are ranged under the heads of masculine or feminine. This, in some cafes, is done with a skew of reason, but in others it is merely arbitrary; and on that account, is found to vary according to the languages, and even according to the words introduced from one language into another. Thus, the names of trees are generally feminine, in Latin, and masculine in the French.

Farther, the genders of the same word are sometimes varied in the same language. Thus auro, according to Prussian, was anciently masculine, but is now become feminine. And navire, a ship, in French, was anciently feminine, but is now masculine. See Gender.

MASCULINE Rime, in the French Poetry, is that made with a word which has a strong, open, and accent pronunciation; as all words have, excepting those which have an e feminine in their syllable.

For infinque, amour et jour, mort et fort, are masculine rimes; and père et mère, gloire et mémoire, are feminine. Hence allo verbes ending with a masculine rime, are called masculine verbes; and those ending with a feminine rime, feminine verbes.

It is now a rule established among the French poets, never to use above two masculine, or two feminine verbes successively, except in the looser kinds of poetry.

Marot was the first who introduced this mixture of masculine and feminine verbes; and Ronford was the first who practiced it with success. The masculine verbes in French, should always have a syllable less than the feminine ones.

MASCULINE Sign. Astrologers divide the signs, &c., into masculine and feminine; by reason of their qualities, which are either active, and hot, or cold, accouned masculine; or passive, dry, and moist, which are feminine.

On this principle they call the Sun, Jupiter, Saturn, and Mars, masculine; and Moon and Venus, feminine. Mercury, they suppose, partakes of the two. Among the signs, Aries, Libra, Gemini, Leo, Sagittarius, and Aquarius, are said to be masculine; Cancer, Capricornus, Taurus, Virgo, Scorpio, and Pisces, are feminine.

MASDEVALLIA, in Botany, a word of whose derivation we have no account, but it should seem to be formed of some proper name. Prod. Fl. Peruv. c't. Chil. tab. 26. Swartz Orchid in Schrad. N. Tourn. v. 1.
MAS

MASI'ELSON, in Geography, a town of Sweden, in the province of Gotland; 54 miles E.E. of Gothenburg.

MASELSJO, a town of Russia, in the government of Archangel; 20 miles S. of Kola.

MASENO, a village of the Valteline, celebrated for its baths; eight miles E.E. of Chavannes.—Alfo, a river which rises in the Alps, and runs into the Adda; four miles E. of Morbegno.

MASERA, a town of Arabia, in the province of Oman, on the coast; 70 miles S.S.E. of Kalhat. N. lat. 22°.

MASERATA, a town of the duchy of Piacezana; 18 miles S. of Piacezana.

MASHA, the name of a drink given to horses or cattle. It is made of half a peck of ground malt, put into a pail; on which is poured as much hot boiling water as will wet it well; then illuring it about half an hour, till it becomes lukewarm, and sweet like honey, it is to be given to the horse.

A mash is only given after a purge, to make it work better; after hard labour, or for drink in time of sickness.

MASHAM, in Geography, a market town and parish, partly within the liberty of St. Peter of York, and partly in the wapentake of Hang-East, in the North Riding of Yorkshire, England. It is situated on the river Ure, at the distance of nine miles from Rippon and 224 from London; and contained, according to the population return in the year 1801, 152 houses, occupied by 1022 persons. In the church, which is a handsome structure with a fine spire, is a monument for Sir Hiramudke Wylly; and in the church-yard the lower half of a croft, adorned with compartments of men and animals in relief. Leland mentions this town as "Mafreham, a praty quick market town and a fair church. Several of the Scorpes of Mafham were buried in York Minster. Wiville dweltith a little above Mafham on the further rie of Ure." A weekly market is held in this town on Tuesdays, and three fairs annually. In the vicinity of Mafham [old Jervaux abbey, founded in 1145 for Ciftertians: at the dissolution, the site was granted to the earl of Lennox. From the fragments of ruins which are scattered over a great extent of ground, the outward walls appear to have been a mile in circumference. At Swinton, near Mafham, is the seat of the Danby family. At Clifton, a short distance from the town, are the remains of a large building of ancient architecture, which was formerly the manor of the lords Scroop of Mafham. Camden's Britannia by Gough, vol. iii. Daye's Tour in Yorkshire, 8vo.

MASHANGUR, a town of Candahar, in the province of Cabul, on the river Swad; 48 miles N. of Attock. N. lat. 33° 54′; E. long. 71° 7′.

MASHIELSON, in Agriculture, a term used to signify a mixture of wheat and rye; or what is sometimes called medlin.

See MELLIS.

MASHUK, in Geography, a town of the Arabian Irak; 5 miles N.W. of Samara.

MASHAD, a town of Samogitia; 36 miles N.N.W. of Medniki.

MASHAN, a river of Persia, which runs into the Sihon, in the province of Khorsan.

MASHIS, a small town of Spain, in the province of Galicia; 12 miles N.W. of Orenfe.—Alfo, a small island in the East Indian sea. S. lat. 7° 25′; E. long. 130° 35′.

MASIN, a town of France, in the department of the Dora; five miles S.E. of Ivrea.

MASIMA, a kingdom of Africa, situated on the upper side of the river Niger, S.E. of Beero, N. of Bambarra, and adjoining to Tombutco, which lies to the N.E. This state belongs to the Foulah, who are chiefly occupied in pallingage, and who pay an annual tribute to the king of Bambarra. N. lat. 14° 50′ to 16°; W. long. 6° 4′ to 5°.

MASINGA, a town of Cacongo. S. lat. 5° 10′; E. long. 12° 8′.

MASIVAN, or Merzifon, a town of Asiatic Turkey, in the government of Sivas; 90 miles N.W. of Sivas.

MASHUS, Andrew, in Biography, was born in a small village near Brussels, but at what particular year is uncertain. He purfued his academical studies at the university of Louvain, where he carried away the first honours in the class of philosophy, in 1553, when he was still a boy. After this, he applied himself to the study of the civil and canon law, and was nominated counsellor to the duke of Cleves. He was a most extraordinary linguist, and was deeply learned in the ancient and oriental languages, as well as in all modern European tongues. He filled several considerable offices in the state, at Vienna and Constantinople. By order of Philip II., king of Spain, he was sent to Antwerp, and associated with Montanus and Fabresius, &c. in publishing the Bible Royal, or Antwerp Polyglot. He died in the territory of Cleves, in the year 1575. His works are numerous, chiefly grammatical and theological: of which we notice the "Grammatica Syriaca:" "Syrorum Peculum," or an explanation of peculiar words, which occur frequently in Syriac writers: "Lexicon Gracum, et Graeco-Lingua Inquisitiones." Moreiri.

MASK. See Masque and Maschere.

Mask-Lough, in Geography, the name of a large lake between the counties of Mayo and Galway, in Ireland. It has to the north a communication with lough Carrab; and there is supposed to be a subterraneous channel, by which the superfusious waters of both are discharged into lough Corrib, near the village of Cong. Beaufort.

MASKALWA, a town of Russia, in the government of Irkutsk, on the Angara; 24 miles N. of Balaganfok.

MASKE-
MASKELYNE, next, in Biography, an eminent astronomer and mathematician, who filled the important office of astronomer royal of England for the long period of 46 years, with the highest credit to himself, and with great advantage as well as honour to his country. He was descended from a good family long settled in Wiltshire, and was born in London in the year 1732. At nine years of age he was placed at Westminster school, where he continued until he was fifteen, and where he made a distinguished progress in classical learning. He also paid due attention to English literature; but manifested a particular desire to understand astronomy, and the construction of optical instruments. This predilection, it is said, was considerably increased on seeing the memorable solar eclipse of 1748, exhibited through a large telescope in a camera obscura. It is, indeed, highly probable that so unusual a phenomenon might have made a strong impression on his susceptible mind, and stimulated him to those exertions which led to his future eminence. From this period he applied himself with ardour to the study of astronomy and optics; but soon experienced the necessity of laying a proper mathematical foundation for those sciences; and he therefore turned his attention to the elements of geometry and algebra, of which he learned in a few months without the help of a master. Thus, like most other eminent mathematicians, he may be considered, in a great measure, as self-taught; but, contrary to the usual course of such studies, his early turn for astronomy led to his mathematical attainments.

In 1749, he was entered at the university of Cambridge: he was first placed at Catherine-hall, but soon after removed to Trinity-college, where he pursued his favourite studies with increased success; and, on taking his first degree, received distinguished honours from the university. He took his several degrees at the following periods, A. B. in 1754; A. M. in 1757; B. D. in 1768; and D. D. in 1777.

As soon as he was of age for holy orders, he was ordained to the curacy of Barnet, where he officiated for some time; and where he devoted most of his leisure hours to the study of practical astronomy.

In 1756, he became a fellow of his college, and though it was several years before he took his doctor's degree, we shall henceforward mention him under the title of doctor, as that by which he has been so long and so familiarly known to the scientific world.

In 1758, he was elected a fellow of the Royal Society, and he soon after became an important contributor to the Philosophical Transactions. This learned body, who at that time paid particular attention to astronomical and mathematical subjects, elected him to go to the island of St. Helena, to observe the transit of Venus over the sun's disk, which was to take place June 6, 1761. As this observation was to settle an important element in astronomy (the sun's parallax), it excited much attention, and preparations were made in different countries for observing it with accuracy. Two other astronomers, viz. Mr. Charles Mason, and Mr. Jeremiah Dixon, were sent for the same purpose to Bengoolen; and his majesty, George II., granted supplies for these expeditions. The French king likewise sent astronomers, to observe the transit, to Pondicherry, to the island of Roderigo, and to the north of Siberia.

Dr. Maskelyne sailed for St. Helena on board the Sea Horse frigate, captain Smith, and remained ten months on the island, making astronomical observations and philosophical experiments. His observation of the transit of Venus was not completely successful, owing to the cloudy state of the weather; but his voyage answered a more important purpose, and one far more useful to his country, than that originally intended; it afforded him an opportunity of taking lunar observations, which were now for the first time made with effect. This method of finding the longitude at sea had been long contemplated as a grand desideratum in navigation; and plans and preparations had been made for the purpose by Flamsteed, Newton, La Caille, Euler, Halley, Bradley, Mayer, and others: but the honour was reserved for Dr. Maskelyne to reduce their theories to successful practice. This he was enabled to do by means of Hadley's quadrant, recently invented; and also by professor Mayer's lunar tables, for which a parliamentary reward of 3000l. was afterwards given on Dr. Maskelyne's report of their correctness. See our articles GREENWICH, LONGITUDE, and LUNAR OBSERVATIONS.

During the voyage, both outward and homeward, he exercised the officers on board in taking lunar observations, and taught them to clear the distances from the effects of parallax and refraction, and thence to find the longitude within certain limits. While on the island he made accurate observations on the tides, the variation of the compass, and the comparative gravity of bodies there and at London. He also observed the annual parallax of Sirius, and the horary parallaxes of the moon. The chief results of these operations are inserted in the Philosophical Transactions of the above period.

Soon after his return from St. Helena, he published his well-known work, entitled "The British Mariner's Guide," which contained, among various new and practical illustrations and articles in nautical astronomy, rules and examples for working the lunar observations; but, in order to shorten and simplify these laborious operations, other tables and calculations were still wanted, which he afterwards supplied by his Nautical Almanac and Requisite Tables.

In 1763, he undertook another scientific voyage by appointment of the lords of the Admiralty and the Board of Longitude. He failed for Barbadoes, on board the Princeps Looins, admiral Tyrrell, for the following purposes:—To find the longitude of that island by astronomical observations; to determine the rate of going of Mr. Harrison's new time-keeper; and to try Mr. Irwin's marine-chronometer, which was intended for making fiducial observations at sea, but which did not answer. He was, besides, in the course of his voyage, to take lunar observations with a curious new Hadley's sextant, and to determine the longitude by the eclipses of Jupiter's satellites, and the occultations of fixed stars by the moon. All these objects of the expedition he executed to the entire satisfaction of his employers; and he likewise officiated as chaplain to the ship during the voyage.

In 1764, the office of astronomer royal became vacant by the death of Mr. Dilly, who had survived his appointment, as successor to Dr. Bradley, only two years. Dr. Maskelyne's celebrity immediately pointed him out as the most competent person to fill the situation. His reputation stood very high in the Royal Society, both as a profound mathematician, and an able astronomer; while his experience at sea, and, above all, his success in establishing the lunar observations, seemed to render him peculiarly well qualified to carry into effect the purpose for which the Royal Observatory had been established—that of preparing tables for finding the longitude at sea. Through want of this knowledge, it was said, that not only single ships, but whole fleets had been lost, which induced government to offer immense rewards for practical methods of determining the problem. When Mr. Flamsteed, the first astronomer royal, was appointed to the office
office in 1767, he was directed by king Charles II. "to apply himself with all diligence to the rectifying the tables of the motions of the heavens, and the places of the fixed stars, in order to find out the much desired longitude at sea, for the perfecting the art of navigation." These were the words of his commission, which have been since continued to his successors. Thus, the office of astronomer royal was justly considered of great national importance, and Dr. Maskelyne's appointment to it, which was announced in the London Gazette, Feb. 16, 1765, gave universal satisfaction. It should be noticed, that the office includes a seat at the Board of Longitude, i.e. a board formed of commissioners, who are appointed "for examining, trying, and judging all proposals, experiments, and improvements relating to the longitude."

During the long period of Dr. Maskelyne's official services, his time may be considered as chiefly occupied either at the Observatory, the Board of Longitude, or the Royal Society. His biography, therefore, like that of most other scientific men, conflits chiefly in a history of his labours; and as they are very numerous, and likewise well known to the astronomical world, we shall state them in a brief and summary manner, referring our readers occasionally to publications where they are more particularly detailed.

Soon after his appointment, he laid before the Board of Longitude the plan of an annual publication, to be entitled the "Nautical Almanac, and Astronomical Ephemeris." The first volume was for 1767, and it has been continued, under his direction, up to the year 1816, inclusive, making in the whole fifty volumes, a lasting monument of labour and profound learning. It is universally allowed to be the most useful work on practical astronomy ever published. In such high estimation has it been held by foreign astronomers, that they have generally and implicitly adopted its computations, and acknowledged its superior accuracy. M. Lalande, in giving an account of similar publications, says, "Le Nautical Almanac de Londres est l'Ephéméride la plus parfaite qu'il y ait jamais eu."

In 1767, he published an auxiliary work, entitled "Tables requisite to be used with the Nautical Almanac, in order to find the Latitude and Longitude at Sea." This performance, well known to seamen by the name of "The Requisite Tables," has passed through several editions, and has been successively enlarged, particularly by different methods of working the lunar observations, by Meffrs. Lyons, Dunthorne, Withell, Wales, and by Dr. Maskelyne himself; and it has been also improved by the latitudes and longitudes of places supplied by captain Cook, captain Huddart, Meffrs. Bailey, Wales, and other scientific navigators. Some time after this, he published Mayer's Tables, with both Latin and English explanations, to which he added several tracts and tables of his own, and prefixed to the whole a Latin preface, with the title "Tabulae motuum Solis et Lunae, &c." It was published, like the foregoing works, by order of the commissioners of longitude, and the various other publications issued by that Board during his time were also printed under his inspection, and are too numerous to be here stated.

Another important and laborious duty that devolved on him in consequence of his office was, to examine the pretensions of the various candidates, who claimed the parliamentary rewards for new or improved methods of finding the longitude.

It may be observed, that his appointment took place at a period peculiarly interesting in the history of astronomy. His successes in introducing and promoting the lunar observations greatly excited the public attention to the subject of the longitude, which was rendered still more interesting by the great rewards held out by parliament for further improvements in the problem, whether by astronomical or mechanical methods. These offers, united with the powerful motives of honour and emulation, called forth, during several years, many extraordinary efforts of genius, and produced useful inventions both in arts and sciences, and particularly in the contruction of time-keepers. See Chromometer.

The parliamentary offers likewise encouraged numerous candidates of very slight pretensions, and even visionary whoes applications became very troublesome. The claims of all were referred by the Board of Longitude to the astronomer royal, by whom scientific plans were examined, and the rates of chronometers ascertained. Thus by his office he was constituted arbiter of the fame and fortune of a great number of anxious projectors; and it is easy to conceive how arduous as well as unpleasant such a duty must have been. It was not indeed to be expected that the fangrene hopes and false-love of such a variety of candidates could be gratified, with justice to the high trust and confidence thus repose, in him; and hence complaints were frequently heard, and pamphlets published, expressive of discontent and disappointment.—Appeals even were made to parliament; but whatever difference of opinion might have then existed, time and experience have since fully proved the truth and impartiality of Dr. Maskelyne's decisions.

In giving a general view of his labours at the Royal Observatory, we shall begin with his publication of the Greenwich observations, which were printed in 1774, by command of his majesty. The first volume began with the observations of 1765, and they have been continued annually since. M. Lalande, in mentioning this performance in 1792, calls it "le recueil le plus précieux que nous ayons." Since that period they have been successively improved, and are universally allowed to possess an unrivalled degree of accuracy. His catalogue of the right ascensions and declinations of 36 principal fixed stars, with tables for their corrections, is a most useful and important performance, and is adopted in all observatories. It is mostly distinguished by the appellation of "Dr. Maskelyne's 36 Stars." His observations also of the sun, moon, and planets, are equally esteemed, and have been made the basis of the solar and lunar tables, lately computed in France according to the theory of M. Laplace; and which are republished in professor Vince's Astronomy, vol. iii. The solar tables were calculated by M. Delambre, and the lunar by M. Burg; copies of which have been tranmitted to Dr. Maskelyne, by order of the French Board of Longitude, with the following grateful acknowledgment of the important assistance derived from his Greenwich observations. The letter is worthy of being recorded, as highly honourable to all parties, and as an interesting article in the history of astronomy. The following is a copy.

"Monsieur, et respectable Confrère,

"Le Bureau des Longitudes me charge de vous offrir sept exemplaires des tables qu'il vient de publier. Cet hommage de la haute élite et de la reconnaissance est bien dû à l'auteur du plus grand et du plus précieux recueil d'observations qui existe. C'est à cette force que nous avons puifé Monsieur Burg et moi pour la plus exacte détermination des coefficients des équations lunaires et solaires, c'est
Masks—nor plus by lady accuracy. and making the celestial Almanac, suiting the appearance que nous en donne votre der-
ni~re preface.”—Delambre.

Such is the testimony to the superior accuracy of the Green-
wich observations given by the great astronomers of France; and it is truly gratifying to observe, that the hitherto flated of the two countries did not prevent friendly communications on astronomy. War should never extend to the sciences; and leaf of all to that sublime study which does the highest honoun to the human intellect, and which has rendered the most efficient services to mankind.

It would greatly exceed our limits to enumerate all the corrections and improvements effected by Dr. Maskelyne’s ob-
servations, many of which will be found in professor Vince’s Astronomical Letters, and the Philosophical Transactions.

His communications to the Royal Society are distin-
guished, like his other productions, for great attention to utility as well as accuracy. They conflict chiefly of astro-
nomical observations;—improvements of mathematical and optical instruments;—computations of the eclipses of the sun, moon, and Jupiter’s satellites;—articles on parallaxes, light, vision, refraction, weights, measures, gravitation, &c. with calculations and predictions of comets; making in the whole above thirty communications. It should be noticed that, in 1774, he went to Shehallen, in Perthshire, in order to ascertain the lateral attraction of that hill; by which the mean density of the earth was computed, and its central at-
traction according to the Newtonian theory first demonstrated. For this paper he was presented by the Council of the Royal Society with sir George Copley’s gold medal.

In the history of science, few persons can be men-
tioned who have contributed more essentially to the diffusion astrononinal knowledge than Dr. Maskelyne; and per-
haps no man has been so successful in promoting practical astronomy, both by land and sea. During his time private observatories became very general, though scarcely known before; nor could such be made useful without his Nautical Almanac, and other tables, except by men of great science, and by very laborious calculations. Belide the assistance thus derived from his publications, he was always ready to give advice concerning any plans that were likely to promote the science. Among the observatories that were erected through his encouragement, may be men-
tioned that of the late Alexander Aubert, eqg, whose excellent collection of instruments has been rarely equalled, even in na-
tional institutions. M. Lalande makes the following honour-
able mention of this gentleman and of his liberal pursuits.

"M. Alexandre Aubert, directeur des affaires, avoit
\[\text{franticmicrometer};\] but though profoundly skilled in opt-
tics, and ingenious in mechanical contrivances, he always paid great deference to the opinions of opticians, and other practical mechanists.

His plans were mostly directed to substantial objects, while a steady perseverance gave an efficacy to all his undertak-
\[\text{ings: and notwithstanding his profound knowledge of phy-
\[\text{cal astronomy, his attention was chiefly directed to reduce}
the scientific theories of his predecessors to the practical pur-
poses of life. In this he was eminently successful, particularly in his labours for the longitude, by which he essentially con-
tributed to the advancement of navigation, the prosperity of commerce, and the wealth, honour, and power of his country.

Thus, from Dr. Maskelyne’s important labours, his pub-
лиц character is well known, and his fame immovable estab-
lished: and, as to his private character, it was likewise truly estimable. He was, indeed, exemplary in the discharge of
every duty. In his manners he was modest, simple, and unaffected. To strangers he appeared dilletant, or rather diffident; but among his friends he was cheerful, unreserved, and occasion-
ally convivial. He was an epigrammatist, and his effulgent thoughts and classical allusions; and even sometimes indulged in his playful effusions of this kind, as appears by the following lines, which he composed on seeing Mr. Ruffell’s selenographia, or
map of the moon, executed with so much exactness.

He makes Luna thus speak;

"Me prope viderunt Actaeon, Endymionque; Has memini folos; ait ubi Ruffelius?"

which he thus translated,

"Actaeon and Endymion saw me near:

But when did I to Ruffell thus appear?"

This epigram was composed extemporaneously when he was about seventy years of age, and is therefore the more worthy of being remembered as an instance of his lively and pleasant disposition at that advanced period. It also shews his passion for astronomy, which displayed itself so early in life, and which seemed to increase with his years.

Notwithstanding the doctor’s numerous avocations he found time to maintain a regular correspondence with the principal astronomers of Europe; and he was visited alternately by many illu-
\[\text{trious foreigners, as well as eminent characters of his own country, but his warmest attachments were always manifested}
to the lovers of astronomy. Among his most intimate friends may be reckoned Dr. Herchel, Dr. Hutton, Meffrs. Wol-
lafons, Mr. Aubert, bishop Horley, sir George Shuckburgh,
\[\text{baron Malere, professor Robertson; and also professor}
Vince, whose publications so ably illustrate Dr. Maskelyne’s labours, and whom he appointed the depositary of his scientific papers.

Dr. Maskelyne had good church preferment from his col-
lege; and his paternal estates (of which he was the last male
\[\text{heir, were also considerable. He married, when rather advanced in life, a young lady of large fortune, the sister and co-heirest of lady Booth of Northamptonshire, by whom he had one daughter, whole education he superintended with the fondest care. These ladies survive him, and allo his sister Margaret, who was married to Robert, the late lord Clive.}

Dr. Maskelyne died on the ninth of February 1811, in the 75th year of his age. His health previously declined for many months; and he contemplated his approaching dif-
solution with pious resignation, and with a lively hope of being admitted into the presence of that Deity, whose works he had so long studied and so ardently admired. His favourite science tended the more strongly to confirm his religious principles, and he died, as he had lived, a sincere Christian.

Vol. xxii.
M A S

MASSELYNE's Islands, in Geography, so called after Dr. Massey, a cluster of small islands in the South Pacific ocean, lying off the south-east point of Malacollo Island.

N. lat. 16° 32'. E. long. 137° 56'.

MASKINGIE, a river of Canada, which runs into Lake Michigan, N. lat. 47° 25'. W. long. 86° 30'.

MASKO, a town of Sweden, in the government of Abo; 9 miles N.W. of Abo.

MASI, S.F., in the Mutria Medica of the Turks, the name of a medicine greatly in use among those people; and called also agnos or amphiun. It is prepared principally of opium. They take a dram of it at a time, and sometimes two or three; they always use it when going to battle, and very often as a provocative to venery, as they do the crude opium.

MASLAWSTANO, in Geography, a town of Poland, in the diocese of Kiev; 36 miles S.E. of Białowieża.

MASLEM, a town of Abhai, Turkey, in the province of Diarbekir; 28 miles N.N.E. of Racca.

MASLIN. See Bullisiy.

MASNED, in Geography, a small island of Denmark, near the S. coast of Zealand. N. lat. 54° 59'. E. long. 11° 54'.

MASOLINO DA PANICALE, in Biography, a painter, concerning the exact time of whole birth and death the biographers of the older artists differ exceedingly; one making him die at the age of 37, in the year 1445, another in 1448, and a third in 1450. It appears most probable, from a circumstance mentioned in the life of Masaccio, that the truth lies nearer the latter than the former periods; and that he must have lived somewhere longer than 37 years. In the first place, all agree that Masaccio, who was born in 1422, was taught the art of painting by Masolino, whom he saw executing his labours in the chapel of Brancaccio, in the church of St. Peter of Carmine at Florence, and again it is said by the same biographers, that Masaccio learnt for the first time the death of his master upon his return from Rome, at which time it is most probable he was 30 years of age, or thereabouts; and then was engaged to finish the pictures which Masolino had left incomplete, and not till then; which would hardly have been the case if Masolino had died in 1415, or 1418, since Masaccio was a reputed painter before he was 20 years old, and almost if not quite, at the height of the profession before he was 25.

Panicale was in his early life employed as a goldsmith, and afterwards learnt under Lorenzo Ghiberti the arts of modelling and encaustic painting; and became one of Ghiberti's best workmen, particularly in clearing out the figures after casting. At the age of 19, he chose to study painting, and for that purpose engaged himself with Starnina. Few of the works of Masolino are now known. The principal ones are the hall of the Orfini palace at Rome; and his Hillory of St. Peter in the church of St. Pietro, at Florence, above-mentioned. He seems to have greatly improved upon the style of the school of Giotto, and was probably led to it by having wrought with Ghiberti in sculpture. His style, though stiff and meagre, exhibited symptoms of a certain harmony and grandeur unknown before.

MASTER, John, an English nonconformist divine, was born at Dunmow, in Essex, in the year 1705-6. His father, who was a dissenting minister, lent him to pursue his academical studies under Mr. Jennings, of Chipworth, in Leicestershire. This was in the year 1722; and the first situation which Mr. Mason had after he had completed his academical course, was that of chaplain and private tutor in the family of Mr. Pecks, at his seat near Hatfield. In the year 1729 or 30, he accepted an invitation to become pastor to a congregation at Dereham, in Norfolk, which he continued about seventeen years, diligently discharging the duties of his function, highly esteemed both as a preacher and friend. In 1745 he published his treatise on "Self-Knowledge," which is unquestionably one of the most valuable works on practical religion in the English language. It is probable that not less than a hundred thousand copies of this work have been circulated in our own country; and it has been translated into almost all the European tongues. In the year 1746, Mr. Mason removed to Cheshunt, in Hertfordshire, where he spent the remainder of his days as a useful preacher, and continued to benefit, not only the village in which he lived by his public discourses and private exhortations, but to enlighten and improve the public by his writings. He died in February, 1763, in the fifty-eighth year of his age. As a divine, his most important publications are, 1. "The Lord's-day Evening Entertainment," in four volumes: 2. "The Student and Pastor; or Directions how to attain Eminence and Usefulness in those respective Characters?" 3. "Christian Morals," in two volumes, and Fifteen Discourses, Devotional and Practical." Mr. Mason published, likewise, in the year 1750, "An Essay on Elocution," which was exceedingly well received, and went through three editions in a very short space of time, and may be considered as the foundation of many of our popular treatises on the same subject. Not long afterwards he published "An Essay on the Power and Harmony of Prosaic Numbers;" and "An Essay on the Power of Numbers, and the Principles of Harmony in Poetical Compositions." In 1761, the author reprinted these and the "Essay on Elocution," in one volume, octavo. Besides the articles already mentioned, Mr. Mason published some single sermons preached on particular occasions. As a preacher his sermons were correct, periphrastic, nervous, always illustrative of the text and doctrine which he had undertaken to explain, and they were ever adapted to promote the purposes of piety and charity. In the pulpit he was grave and solemn, his voice was clear, his delivery deliberate, dignified, and void of all affectation, and his manner was easy and natural. His personal character was an exemplification of the duties and virtues which it was the business of his life to enforce; in his intercourse with the world, he was free, easy, communicative, and pleasant in conversation; and much of the gentleman appeared in all his behaviour. Although it is now nearly half a century since this excellent man was taken from our world, there is still a member of his church at Cheshunt living, who cherishes, and will ever cherish, the recollection of the virtues of his pastor, so long as her life and faculties are continued. Life prefixed to the fifteenth edition of the treatise "On Self-Knowledge."

MASON, William, an English poet of considerable celebrity, born in 1725, was the son of a clergyman who held the living of Hull. He was admitted of St. John's college, Cambridge, where he took his first degree in 1745. He removed to Pembroke college, and was elected a fellow in 1747; he obtained the degree of M.A. in 1749, and entered into holy orders in 1754. He obtained the patronage of the earl of Holderness, by whom he was presented to the rectory of Altby, in Yorkshire, and who procured for him the appointment of chaplain to his majesty. In 1749, he printed "An Ode on the Infallibility of the Duke of Newcastle," as chancellor of the university of Cambridge,
bridge, which gained him reputation. "A Monody to the Memory of Pope," and a poem, entitled "His, an Elegy," added to his fame, which was still farther increased, in 1752, by the dramatic poem of "Elfrida." In this, and in his "Caradocus," published in 1759, he attempted the restoration of the ancient Greek chorus in tragedy. Mr. Mason did not originally compose these pieces for the modern stage, which he considered as sunk beneath his level by the corrupt taste of the public; and though attempts were afterwards made to fit them for representation, and they were brought upon the theatre, they could obtain no permanent place there. In 1769, he published a small collection of new "Odes." He was in all his verses an imitator of Gray, but they have been thought to display more of the artificial mechanism of poetry than of its genuine spirit. His "Elegies," published in 1763, are in general marked by the simplicity of language proper to this species of composition, and they breathe noble sentiments of freedom and virtue.

In the year 1772, appeared the first book of his "English Garden," a descriptive poem in blank verse, of which the fourth and concluding book was printed in 1781. The main object of this work was to recommend, by the charms of poetry, the modern system of natural or landscape gardening.

In 1773, as a tribute to the memory of his friend Gray, he published the poems of that distinguished genius, to which are prefixed "Memoirs of his Life and Writings." Mason's observations on the character and genius of his friend did honour to his taste and feelings. This work was originally published in one quarto volume, but another edition was given to the public in four thin volumes, crown octavo. Mason, as has already been observed, was warmly attached to the principles of liberty: during the contest with America, he strongly expressed his disapprobation of the hostilities carrying on against the transatlantic part of the community. He was a zealous member of the Yorkshire Association, for procuring a reform in parliament, which, notwithstanding the exertions of the widows, husbands, and mothers of our countrymen, is still, apparently, at a great distance. Mr. Mason, in 1783, published in a quarto volume a translation of Ficicopy's Latin poem on the "Art of Painting," which unites great elegance of language and verification, with a correct representation of the original. As a clergyman, he obtained the preferments of precentor and canon-residentiary of the cathedral of York; and at that church he preached, in 1788, an "Occasional Discourse," on the subject of the flave-trade, which was an animated declamation against the inhumanity of that traffic. In the same year he published the poems of the poet-laureate, Whitehead, to which he prefixed a memoir. The centenary commemoration of the revolution in that year, called forth a new exertion of his lyric powers in a "Secular Ode," which breathed the spirit of his muse of freedom. Without referring to the other publications of Mr. Mason, we may observe that he lived to witness the French revolution, the horrors of which wrought a complete change in his political principles. He died in April, 1797, at the age of 72. His character in private life was that of a wise and benevolent and active man of the world, and a tablet has been placed to his memory in the Poet's Corner in Westminster Abbey. Gentleman's Magazine.

Mr. Mason was not only an excellent poet and able divider, but a dilettante painter and musician; and in these last capacities an acute critic. We did not, however, agree with him in his reforming schemes of church music. He had been himself a good performer on the harpsichord; had some knowledge of composition, a refined taste, and was a very good judge of modern music; but his ideas of reforming cathedral music would reduce it to Calvinistical psalmody. He wished for nothing but plain counterpoint in the services and full anthems, and dull and dry harmony in the voluntaries, without melody, accent, or measure; and he preferred the mechanical execution of a barrel organ in church music, to the most judicious accompaniment of a commissariat organ.

We think organ-playing, in the sublime style of Handel and Sebastian Bach, is so precious a faculty, that it should be cultivated and cherished as feculously for the sake of the art of music, as the innocent amusemment of the congregation.

Mr. Mason, as precentor of the cathedral of York, it is to be feared, has scripted music of all its ornaments, as Jack did religion, in the Tale of a Tub.

There are, however, many excellent reflections in his "Compendium of the History of our Church Music," and, in general, a just and discriminate character of our ecclesiastical composers, in his "Copious Collection of those Portions of the Psalms of David, Bible, and Liturgy, which have been set to Music, and sung as Anthems in the Cathedral and Collegiate Churches of England. To which is prefixed a critical and historical essay on Cathedral Music." Printed at York in 1782.

Though this excellent scholar, and charming poet, honoured us with his friendship, of which we were always ambitious; and though, from his knowledge of music, we regarded him as the most intelligent and refined of our lyric bards, we never could subscribe to his reform of cathedral music, farther than in the accentuation of the words, and distinction of long and short syllables, in which our old cathedral composers, as well as plaindunns, are egregiously defective; nor could we ever flatter him in his high opinion of Henry Lawes, as a musician of superior genius and learning, or for his perfect accuracy in expressing words; though Milton tells us that his

"—— tuneful and well measur'd long,
First taught our English music how to span
Words with just note and accent, not to scan
With Midas-casts, committy'd short and long.

And Waller joins in saying, that other composers admet the poet's frame but faintly and dimly, like the rays through a church-window of painted glass; while his favourite Lawes

"—— could truly boast
That not a syllable is lost.

See Henry Lawes, and Comus.

Mason, a person employed, usually under the direction of an architect, in the raising of a stone building.

The word comes from the French mason, which signifies the same. Some derive this farther from the barbarous Latin marcus, a mason, because these artisans are obliged to use machines for raising walls. Du Cange derives it from marica, a name given to the long hinge-walls which include vineyards, &c., in which masons are supposed to have been first employed: "Mason or marcarium contractor." M. Hunt derives it from mase, an old word signifying house; hence mason is a person who makes mases, that is, houses. In the corrupt Latin, a mason was called muggle comacius, which Lindenbroeck derives from Comacilla, an island in Romania, where, in the time of the Lombards, the best architects were found.

The chief business of a mason is to prepare the mortar, to rule
raise the walls from the foundation to the top, with the necessary retreats and perpendiculars, form the vaults, and employ the stones as delivered to him.

When the stones are large, the business of hewing or cutting them belongs to the stone-cutters; though these are frequently confounded with the masons. The flints or sculpture are performed by carvers in stone, or sculptors. The tools or implements principally used by masons are the square, level, plum-bob, bevel, combs, hammer, chisel, mallet, saw, trowel, &c.

Befide the common instruments used in the hand, they have likewise machines for the raising of great burdens, the conducting of large stones, &c. The principal of these are the lever, wheel, pulley, &c.

In the estimation of the value of masons' work, walls, columns, blocks of stone or marble, &c. are measured by the cubic foot; and pavements, slabs, chimney-pieces, &c. by the superfluous or square foot. Cubic or solid measure is used for the materials, and square measure for the workmanship. In the solid measure, the true length, breadth, and thickness, are taken and multiplied constantly together; in the superficial, there must be taken the length and breadth of every part of the projection, which is seen without the general upright face of the building.

Examples. 1. Required the solid content of a wall, 53 feet 6 inches long, 12 feet 3 inches high, and 9 feet 8 inches thick. The product of $53.5 \times 12.25 \times 2 = 1310.75$, or 1310 feet 9 inches.

2. Required the value of a marble slab, at 8s. per foot; the length being 5 feet 7 inches, and breadth 1 foot 10 inches. Ans. 4l. 1s. 10d.

3. In a chimney-piece, suppose the length of the mantle and slab each 4 ft. 6 inch. Breadth of both together 3 2

Length of each jamb 4 4

Breadth of both together 1 9

Masons, Free or Accepted, a very ancient society, or body of men; so called, either from some extraordinary knowledge of masonry or building, which they are supposed to be masters of, or because the first founders of the society were persons of that profession.

They are now very considerable both for numbers and character; being found not only in every country in Europe, but in other parts of the globe, and confining principally of persons of merit and consideration. As to antiquity, they lay claim to a standing of some thousand years; and, it is said, can trace up their original as early as the building of Solomon's temple. It is very doubtful when they were first introduced into this country; some have traced the origin of masonry in general to the year 674, when glass-making was introduced; and it is certain that, after this time, many of our public buildings, in the Gothic style, were erected by men in companies, who, as some say, called themselves free, because they were at liberty to work in any part of the kingdom. Others have derived the infiltration of free masons from a combination among the masons not to work without an advance of wages, when they were summoned from several counties, by writs of Edward III., directed to the sheriffs, to affit in rebuilding and enlarging the castle, together with the church and chapel of St. George, at Windsor; accordingly it is said, that the masons agreed on tokens, &c. by which they might know one another, and to affit one another against being imprest, and not to work unless free, and on their own terms.

Dr. Henry, in his "History," attributes the origin of the free-mason society in Britain to the difficulties found in former times, of procuring a sufficient number of workmen to build the multitude of churches, monasteries, and other religious edifices which the superfluity of that age prompted the people to raise. Hence the masons were greatly favoured by the popes, and many indulgences were granted in order to augment their number. In times like those we speak of, it may well be supposed that such encouragement from the supreme pastors of the church must have been productive of the most beneficial effects to the fraternity; and hence the increase of the society may naturally be deduced. The doctors quotes in confirmation of this, the words of an author who was well acquainted with their history and constitution. "The Italians," says he, "with some Greek refugees, and with them French, Ger- man, and Flemings, joined into a fraternity of architects, procuring papal bulls for their encouragement and their particular privileges; they built themselves free-masons, and ranged from one nation to another, as they found churches to be built; their government was regular; and where they fixed near the building in hand, they made a camp of tents. A surveyor governed in chief; every tenth man was called a ward, and overtook each nine. The gentlemen in the neighbourhood, either out of charity or commutation of penance, gave the materials and carriages. Those who have seen the accounts in records of the charge of the fabrics of some of our cathedrals near 400 years old, cannot but have a great esteem for their economy, and admire how soon they erected such lofty structures."

Mr. W. Pilton, pail-maker of the Lodge of Antiquity, in a treatise on Masonry, published in 1792, tracing its origin from the creation, supposes its introduction into England to have been prior to the Roman invasion. Accordingly he appeals to those remains of stupendous works executed by the Britons, still existing, and which must have been executed at a much earlier period than the time of the Romans; and it is said, that the Druids had among them several customs similar to those of the masons, and that they derived their government from Pythagoras: but it is difficult to ascertain the resemblance for which the advocates of the early origin of the society of free-masons contend. Although masonry is said to have been encouraged by Cæsar, and by many Roman generals, who were governors in Britain, and the fraternity of masons was actually employed in the construction of many magnificent fabrics, we have no existing records of their lodges and conventions; and of the customs that prevailed in their assemblies the accounts transmitted to us are very imperfect. In the time of Caracallus the art of masonry revived; and among other artisans, he collected a number of ingenious masons from many different countries, and appointed his steward Albanus as the superintendant of their assemblies. At this time, lodges, or conventions of the fraternity, began to be introduced. Albannus obtained from Caracallus a charter to hold a general council, of which he was president, and in which many new members were admitted. This Albanus is said to have been the famous St. Alban, who suffered martyrdom in Britain for the Christian faith. In proof of this fact, Mr. Pilton refers to some ancient manuscripts. By the departure of the Romans from Britain, the progress of masonry was checked, and it was afterwards wholly neglected. After the introduction of Christianity, however, masonry, together with other arts, revived, and lodges were formed; but being under the direction of foreigners, they gained no permanent reputation. After the year 557, when St. Aulphian
Masons.

Austin with his companions arrived in England, masonry was taken under his protection; and the Gothic style of building was introduced by those foreigners, who about this time returned to the kingdom. Austin, it is said, distin-
guished himself by being the head of the fraternity, who founded the old cathedral of Canterbury in 601; that of Rochester in 602; St. Paul's in London in 604; St. Peter's in Westminster in 605; as well as many others. The num-
ber of masons in England was thus greatly increased, as well as by his other buildings of castles, &c. throughout the kingdom. In 640 some ingenious artificers arrived from France, and formed themselves into a lodge under the di-
rection of Bennet, abbot of Wirral, whom Kenred, king of Mercia, soon after appointed inspector of the lodges, and general superintendant of the masons. Masonry, however, during the heptarchy, was in a low state; but it began to revive under the patronage of St. Witswin, who was em-
ployed by Ethelwulf in repairing some religious houses; and from that time the art was gradually improved till the year 872, when it found a zealous protector in Alfred the Great, who appropriated a seventh part of his revenue in employing a number of workmen for rebuilding the cities, castles, &c.
ruined by the Danes. During the reign of his successor Edward, the masons continued to hold their lodges under the fumption of Ethred, husband to the king's sister, and Ethelward his brother, to whose care the fraternity was intrusted. The true re-establishment of masonry in England, however, is dated from the reign of king Athelstan; and there is still existing an ancient lodge of masons in York, which traces its origin to this period. This lodge, laid to be the most ancient in England, was founded in 926, under the patronage of Edwin, the king's brother, who obtained for it a charter from Athelstan, and became himself grand-
master. By virtue of this charter all the masons in the kingdom were assembled, and in their assembly, as it is reported, they established a general or grand lodge for their future government. Under the patronage and jurisdiction of this lodge it is alleged, that the fraternity very con-
siderably increased; and kings, princes, and other eminent persons, who had been initiated into the mysteries, paid due allegiance to the assembly.

On the decease of prince Edwin and king Athelstan, the ma-
sons were dispersed, and remained in an unsettled state till the reign of Edgar, in 960. They were then collected by St. Dunstan, and employed in works to which they had been ac-
customed; but for want of permanent encouragement, their lodges declined, and masonry remained in a low state for more than fifty years. It revived under Edward the Confes-
fessor, in 1041; and by the assistance of Leofrith, earl of Coventry, he rebuilt Westminster Abbey, the earl being super-
tintendent of the masons. After the conquest, in 1066, Gundulph, bishop of Rochester, and Roger de Montgomery,
earl of Shrewsbury, both of them excellent architects, became joint patrons of the masons; and under their auspices the Tower of London was begun, though finished only in the reign of William Rufus, who likewise rebuilt London bridge with wood, and in 1067 first constructed the palace and hall of Westminster. During the reigns of Henry I. and of Stephen, the masonic lodges assembled; and the society was employed in building a chapel at Westminster, near the House of Commons, and other works; the president of the lodges being Gilbert de Clare, the marquis of Pembroke. Under the reign of Henry II., the lodges were superintended by the grand-master of the Knights Templars, who employed them in building their temple in Fleet-street, in the year 1155. Masonry continued under the patronage of this or-
der till the year 1199, when John succeeded Richard I. in the throne of England, and Peter de Colechurch was then appointed grand-maister. He began to rebuild London bridge with stone, which was afterwards finished by William Alcmain, in 1209. Peter de Rupibus succeeded Peter de Colechurch in the office of grand-maister, and Geoffrey Fitz-
Peter, chief surveyor of the king's works, acted as deputy under him; masonry continued also to flourish under the auspices of these two artificers during this and the following reign. On the accession of Edward I, in 1272, the superin-
tendence of the masons was intrusted to Walter Giffard, archi-
bishop of York, Gilbert de Clare, earl of Gloucester, and Ralph, lord of Mount Hermer, the progenitor of the fa-
mily of the Montagues; and by these architects the abbey of Westminster was finished, after having been begun in 1226, during the minority of Henry II. During the reign of Ed-
ward II., the fraternity were employed in building Exeter and Oriel colleges in Oxford, Clarc-hall in Cambridge, &c.
under the auspices of Walter Stapleton, bishop of Exeter, who had been appointed grand-maister of the masons in
1257.

In the reign of Edward III., the lodges under his patron-
age were numerous; and the fraternity held communications under the protection of the civil magistrates. William a Wykeham continued grand-maister on the accession of Richard II., and by him both the New college in Oxford, and Winchelsea college, were founded at his own expense. After the accession of Henry IV., Thomas Fitz-Allan, earl of Surrey, was appointed grand-maister, who, after the en-
gagement at Shrewsbury, founded Battle-abbey and Frotheringay; the Guildhall at London being also built in this reign. On the accession of Henry V., the fraternity were directed by Henry Chichely, archbishop of Canterbury, under whom the lodges and communications of the fraternity were frequent. In 1425, however, during the reign of Henry VI. an act was made against the meetings of the chapters and congregations of masons, because it was said, that by such meetings "the good course and effect of the statutes of labourers were openly violated, and broken, in subversion of the law, and to the great damage of all the commons." But this act was not put in force, and the fraternity ceased to meet as usual under the protection of archi-
bishop Chichely, who still continued to preside over them.

Notwithstanding a charge alleged at this time against the masons, the duke of Gloucester, protector and guardian of the kingdom, apprised of their innocence, took them under his protection, and transferred the charge of sedition against Henry, bishop of Winchelsea, and his followers. Although the duke was afterwards impeached, imprisoned, and murdered, the masons were not only permitted to meet without molestation, but were joined by the king himself. In that year (1442) he was initiated into masonry, and from that time was affiduous in making himself complete master of the art. He revised the constitutions of the body, and honour-
ced them with his sanction; and his example was followed by many of the nobility. The king presided over the lodges in person, nominating William Waneleft, bishop of Win-
chelsea, grand-maister. The bishop, at his own expense, built Magdalen college, Oxford, and several religious houses. Eton college, near Windsor, and King's college, at Cam-
bridge, were also founded during this reign. Henry him-
self founded Chrift's college, Cambridge, as his queen, Mar-
get of Anjou, did Queen's college in the same university. About this time, the masons were protected and encouraged by James I. of Scotland, who honoured the lodges with his
preference,
MASON.

preference, and settled an annual revenue of four pounds Scots (an English noble) to be paid by every master-mason in Scotland, to a grand-master, chosen by the grand lodge, and approved of by the crown.

The flourishing state of masonry was interrupted by the civil wars between the houses of York and Lancaster, which brought it almost totally into neglect. About 1471, however, it revived under the auspices of Robert Beauchamp, bishop of Sarum, who had been appointed grand-master by Edward IV. and honoured with the title of Chancellor of the Garter, for repairing the castle and chapel of Windsor. It again declined during the reigns of Edward V. and Richard III.; but came once more into repute on the accession of Henry VII. in 1485. It was now patronized by the masons and fellowes of the order of St. John at Rhodes (now Malta) who assembled their grand lodge in 1520, and chose Henry for their protector. On the 24th of June, 1502, a lodge of masons was formed in the palace, at which the king professed as grand-mason; and having appointed John Tywhill, abbot of Waltham Abbey, and Sir Reginald Bray, knight of the Garter, his wardens for the occasion, proceeded in great state to the east end of Waltham Abbey, where he laid the first stone of that excellent piece of Gothic architecture, called Henry the Seventh's chapel. The capel-stone of this building was celebrated in 1507. The palace of Richmond, as well as many other noble edifices, were raised under the direction of Sir Reginald Bray; and the colleges of Brazen-Nose, in Oxford, and Jesus and St. John's in Cambridge, were all finished in this reign.

On the accession of Henry VIII. cardinal Wolsey was appointed grand-mason; who built Hampton-court, Whitehall, Christ-church college, Oxford, with several other noble edifices; all of which, upon the divorce of that princess, were forfeited to the crown in 1530. Wolsey was succeeded as grand-mason in 1534 by Thomas Cromwell, earl of Essex, who employed the fraternity in building St. James's palace, Christ's hospital, and Greenwich castle. Cromwell being beheaded in 1540, John Touchet, lord Audley, succeeded to the office of grand-mason, and built Magdalen college, in Cambridge, and many other structures. In 1547, the duke of Somerset, guardian of the king, and regent of the kingdom, became superintendent of the masons, and built Somerset-houfe in the Strand; which, on his being beheaded, was forfeited to the crown in 1552.

After the death of the duke of Somerset, John Poyntz, bishop of Winchester, presided over the lodges till the death of the king, in 1553. From this time they continued without any patron till the reign of Elizabeth, when Sir Thomas Sackville accepted the office of grandmaster. Lodges, however, had been held during this period in different parts of England; but the general or grand lodge assembled in the city of York, where it is said the fraternity were numerous and respectable. Of the queen we have the following curious anecdote with regard to the masons: hearing that they were in poetiers of many secrets, which they refused to disclose, and being naturally jealous of all secret assemblies, the sent an armed force to York, to break up their annual grand-lodge. The queen, however, being afterwards thoroughly convinced that the fraternity of masons did not interfere in state affairs, became quite reconciled to their assemblies, and from that time masonry made a considerable progress; lodges were held in different parts of the kingdom, particularly in London and its neighbourhood, where the number of the brethren increased considerably. Several great works were carried on there under the auspices of Sir Thomas Gresham, from whom the fraternity received every encouragement.

Sir Thomas was succeeded in the office of grand-master by Charles Howard, earl of Effingham, who continued to preside over the lodges in the fourth till the year 1588, when George Halings, earl of Huntingdon, was chosen grand-master, and remained in the office till the decease of the queen in 1603.

On the accession of James I. to the crown of England, masonry flourished, and lodges were held, in both kingdoms. A number of gentlemen returned from their travels, with curious drawings of the old Greek and Roman architecture, as well as strong inclination to revive a knowledge of it. Among these was the celebrated Inigo Jones, who was appointed general surveyor to the king. He was named grand-mason of England, and was deputed by the king to preside over the lodges. Several learned men were now initiated into the mysteries of masonry, and the society increased considerably in reputation and confluence. Ingenious artists returned to England in great numbers; lodges were constituted as seminaries of instruction in the sciences and polite arts, after the model of the Italian schools; the communications of the fraternity were established, and the annual festivals regularly observed. Under the direction of this accomplished architect, many magnificent structures were raised; and among the rest, he was employed, by command of the sovereign, to plan a new palace at Whitehall, worthy of the residence of the kings of England. This was executed; but for want of a parliamentary fund, no more of the plan was ever finished than the banqueting-house. Inigo Jones continued in the office of grand-mason till the year 1648, when he was succeeded by the earl of Pembroke; under whose auspices many eminent and wealthy men were initiated, and the mysteries of the order held in high estimation.

After Charles I. ascended the throne, earl Pembroke was continued in his office till the year 1649, when he resigned in favour of Henry Danvers, earl of Danby. This nobleman was succeeded, in 1652, by Thomas Howard, earl of Arundel, the ancestor of the Norfolk family. In 1652, Francis Russell, earl of Bedford, accepted the government of the society; but Inigo Jones having continued to patronize the lodges during his lordship's administration, he was re-elected the following year, and continued in office till the year of his death, 1646. The progress of masonry, however, was for some time obstructed by the breaking out of the civil wars; but it began to revive under the patronage of Charles II., who had been received into the order during his exile. Some lodges during this reign were constituted by leave of the several noble grand-masters, and many gentlemen and famous scholars requested at that time to be admitted into the fraternity. On the 27th of December, 1663, a general assembly was held, where Henry Jemmy, earl of St. Albans, was elected grand-mason; who appointed for John Denham his deputy, and Mr. Christopher Wren, afterwards the celebrated Sir Christopher Wren, and John Webb, his wardens. At this assembly several useful regulations were made, for the better government of the lodges; and the greatest harmony prevailed among the whole fraternity. The earl of St. Albans was succeeded in his office of grand-mason by earl Rivers, in the year 1666, when Sir Christopher Wren was appointed deputy, and distinguished himself beyond any of his predecessors in promoting the prosperity of the lodges which remained at that time, particularly that of St. Paul's, now the Lodge of Antiquity, which he patronized upwards of eighteen years. At this time he attended
Masons.

attended the meetings regularly; and during his presidency made a present to the lodge of three mahogany candlesticks, which at that time were very valuable. They are still preserved, and highly valued as a testimony of the esteem of the donor.

Whilst the city, after its destruction by fire in 1666, was in building, lodges were held by the fraternity in different places, and many new ones constituted, to which the best architects referred. In 1674, Sir Rivers resigned the office of grand-master in favour of George Villiers, Duke of Buckingham, who left the care of the fraternity to his wardens, and Sir Christopher Wren, who still continued to act as deputy. In 1679, the Duke resigned in favour of Henry Bennet, Earl of Arlington; but this nobleman was too deeply engaged in state-affairs to attend to his duty as a mason, though the lodges continued to meet under his sanction, and many respectable gentlemen joined the fraternity. During the short reign of James II., the masons were much neglected.

In 1685, Sir Christopher Wren was elected to the office of grand-master, who appointed Gabriel Cibber and Mr. Edward Strong his wardens; yet notwithstanding the great reputation and abilities of this celebrated architect, masonry continued in a declining way for many years, and only a few lodges were held occasionally in different parts of the kingdom.

At the Revolution, the society was in such a low state in the south of England, that only four regular lodges were held in London and its suburbs; and of these only two, viz. that of St. Paul's and one at St. Thomas's Hospital, Southwark, were of any consequence. But in 1693, King William, having been initiated into the mysteries, honoured the lodges with his presence, particularly one at Hampton-court, at which he is said to have frequently presided during the time that the new part of his palace was building. Many of the nobility also were present at a general assembly and feast held in 1697; particularly Charles, Duke of Richmond and Lenox, who was elected grand-master for that year; but in 1698, resigned his office to Sir Christopher Wren, who continued at the head of the fraternity till King William's death in 1702.

During the reign of Queen Anne, masonry made no considerable progress. Sir Christopher's age and infirmities drew off his attention from the duties of his office, the annual festivals were entirely neglected, and the number of masons considerably diminished. It was therefore determined that the privileges of masonry should not be confined to operative masons, but that people of all professions should be admitted to participate in them, provided they were regularly approved and initiated into the order.

Thus the society once more rose into esteem; and on the accession of George I., the masons, now deprived of Sir Christopher Wren, resolved to unite again under a grand-master, and revive the annual festival. With this view, the members of the only four lodges at that time existing in London, met at the Apple-tree tavern in Charles-street, Covent-Garden; and having voted the old lodges mason then present into the chair, constituted themselves a grand lodge pro tempore. It was now resolved to renew the quarterly communications among the brethren; and at an annual meeting held on the 24th of June the same year, Mr. Anthony Sayler was elected grand-master, invested by the oldest mason there present, initiated by the master of the old lodge, and had due homage paid him by the fraternity. Before this time a sufficient number of masons, met together within a certain district, had ample power to make masons without a warrant of constitution; but it was now determined, that the privilege of assembling as masons should be vested in certain lodges or assemblies of masons convened in certain places, and that every lodge to be afterwards convened, excepting the four old lodges then existing, should be authorized to act by a warrant from the grand-master for the time, granted by petition from certain individuals, with the consent and approbation of the grand lodge in communication; and that without such warrant, no lodge should hereafter be deemed regular or constitutional. The former privileges, however, were still allowed to remain to the four old lodges then extant. In consequence of this, the old masons in the metropolis vailed all their inherent privileges, as individuals, in the four old lodges, in trust that they never would suffer the ancient charges and land-marks to be infringed. The four old lodges, on their part, agreed to extend their patronage to every new lodge which should hereafter be constituted according to the new regulations of the society; and while they acted in conformity to the ancient constitutions of the order, to admit their masters and wardens to share with them all the privileges of the grand lodge, that of precedence only excepted.

Masons being thus settled, the brethren of the four old lodges considered their attendance on the future communications of the society as unnecessary; and therefore truanted implicitly to their masters and wardens, satisfied that no measure of importance would be adopted without their approbation. It was, however, soon discovered, that the new lodges being equally represented with the old ones at the communications, would at length far outnumber them, that by a majority they might subvert the privileges of the original masons of England, which had been centred in the four old lodges; and on which account a code of laws was, with the consent of the brethren at large, drawn up for the future government of the society. To this the following was annexed, binding the grand-master for the time being, his successors, and the master of every lodge to be hereafter constituted, to preserve it inviolably: "Every annual grand lodge has an inherent power and authority to make new regulations, or to alter there for the real benefit of this ancient fraternity, provided always that the old land-marks be carefully preserved; and that such alterations and new regulations be proposed and agreed to at the third quarterly communication preceding the annual grand feast; and that they be offered alio to the perusal of all the brethren before dinner, in writing, even of the youngest apprentice; the approbation and consent of the majority of all the brethren present being absolutely necessary to make that binding and obligatory." To commemorate this circumstance, it has been customary, ever since that time, for the master of the oldest lodge to attend every grand initiation; and, taking precedence of all present, the grand-master only excepted, to deliver the book of the original constitutions to the new invested grand-master, on his promising obedience to the ancient charges and general regulations.

By this precaution, the original constitutions were established as the basis of all succeeding masonic jurisdiction in the south of England; and the ancient land-marks, as they are called, or the boundaries set up as checks against innovation, were carefully guarded from the attacks of any future invaders.

In 1720 the fraternity sustained an irreparable loss by the burning of several valuable manuscripts, concerning the lodges, regulations, charges, secrets, &c. (particularly one written by Mr. Nicholas Stone, the warden under Inigo Jones.) This was done by some furious brethren, who were alarmed at the publication of the masonic constitutions. At a quarterly communication it was this year agreed, that for
for the future, the new grand-mafler shall be named and pro-
pofed to the grand lodge some tine before the feast: and if
approved and prefent, he shall be fubstituted as grand-mafler
elect: and that every grand-mafler, when he is installed,
shall have the power of appointing his deputy and war-
dens, according to ancient custom.

In the mean time, mafonry continued to spread in the
north as well as the south of England. The general af-
fembly, or grand lodge at York, continued to meet as usual.
Several lodges met in 1705, under the direction of Sir John
Tempeft, bart. then grand-mafler: and many perfons of
worth and character were initiated into the mysteries of the
fraternity. The greatfe vaults harmonized between the two
grand lodges, and private lodges were formed in both parts
of the kingdom, under their separate jurisdiction. The only
diftinftion which the grand lodge in the north appears to
have retained is in the title of the Grand Lodge of all England:
while the other was only called the Grand Lodge of England.
The latter, however, being encouraged by some of the
principal nobility, fon acquired confegence and reputation,
while the other foon gradually to decline: hut, till within
these few years, the authority of the grand lodge at York
was never challenged: on the other hand, every mafon in
the kingdom held that affembly in the highest veneration, and
confidered himfelf bound by the charges which originated
from that affembly. It was the glory and boaft of the
brethren in all parts of the country where mafonry was stabili-
ed, to be accounted defendants of the original York mafons;
and from the univerfity of the idea that mafonry was ftabili-
ized at York by charter, the mafons of England have
received tribute from the firit flates in Europe. At prefent,
however, this focial intercourse is abolished, and the lodges in
the north and fouth are almost entirely unknown to one
another; and neither the lodges of Scotland nor Ireland court
the correfpondence of the grand lodge at London. This
is faid to have been owing to the introduction of fome inno-
ciations among the lodges in the fouth; but for the coolnefs
which fubsists between the two grand lodges, another reafon
is alined. A few brethren at York having, on fome trivial
occasion, feceded from their ancient lodge, they applied to
London for a warrant of conflation. Their application was
honoured without any inquiry into the merits of the cafe;
and thus, instead of being recommended to the mother lodge
to be reforted to favour, thefe brethren were encouraged to
revolt, and permitted, under the faneion of the grand
lodge in London, to open a new lodge in the city of York
itfelf. This illegal extension of power juftly offended the
grand lodge at York, and occafioned a breach which has
never yet been made up.

The duke of Bucleugh, who in 1723 fnceeded the duke
of Wharton as grand-mafler, firft propofed the scheme of
raifing a general fund for diftrefled mafons. The duke's mo-
tion was fupported by Lord Paisley, colonel Houghton, and
a few other brethren; and the grand lodge appointed a com-
mittee to confider of the moft effectual means of carrying
the fcheme into execution. The difpofal of the charity was
firft vifted in seven brethren; but this number being found
too fmall, nine more were added. It was afterwards resolved
that twelve mafons of contributing lodges, in rotation with
the grand officers, fhould form the committee; and by an-
other regulation fince made, it has been determined that all
pall and prefent grand officers, with the mafons of all regu-
lar lodges which fhall have contributed within twelve months
to the charity, fhall be members of the committee. This
committee meets four times in the year by virtue of a fum-
mons from the grand-mafler or his deputy. The petitions of
the diftrefled brethren are confidered at these meetings; and
if the petitioner be confidered as a diftrefled object, he is
immediately relieved with five pounds. If the circumftances
of the cafe are of a pecufiar nature, his petition is referred to
the next communication, where he is relieved with any fund
the committee may have fpecified, not exceeding twenty
guineas at one time. Thus the diftrefled have always found
ready relief from this general charity, which is fupported by the
voluntary contributions of different lodges out of their
private funds, without being burdenfome to any member in
the fociety. Thus has the committee of charity for free-
mufons been ftabilized; and fo liberal have the contribu-
tions been, that though the funds annually expended for the
relief of the diftrefled brethren have for feveral years past
amounted to many f Thoufand pounds, there still remains a
considerable surplus.

What the end of the institution of mafonry is, feeems ill,
in fome measure, a secret; though so much of it as is known
appears laudable enough, as it tends to promote friendfhip,
society, mutual affifiance, and good fellowfhip.

The members of this fociety, among whom we may
reckon a great number of illuftrious perfons in various parts
of the world, allege, that in the admiration of members, and
the management of its concerns, a particular regard is
paid to the principles of religion and morality; they fay
also, that in proportion as mafonry has prevailed, focieties
and even nations have been civilized. However this be, it is,
certain, that its figns feeve as a kind of univerfal language, fo
that by means of them people of the moft diftant nations may
become acquainted, and enter into friendfhip with one another.
This must be allowed to be a circumstance of no small im-
portance and utility, to thofe who travel in diftant regions,
and wifh to find affociates and friends even among strangers.

The brethren of this family are faid to be polished of a
great number of fecrets, which have been religioufly ob-
erved from age to age.

The unintimated, however, ridicule the notion that mafons
poifeft any peculiar fecrets, apprehending, that in fome un-
guarded and convivial moment or other, they would be di-
vulged; and that it would be dangerous to repofe confi-
dence in the number, as well as in the various difpofitions,
of thofe who are admitted into the fociety. Secrecy and
filenle are undoubtedly on many occasions defirable and
laudable attainments; and we find that among many of the
philofophers of antiquity, they were ftrictly enjoined and
fedulously cultivated. If the laws, charges, and regulations
of the free and accepted mafons, as they are detailed in a
work, entitled "The Confitution of Free-Mafonry, &c."
by the late Laurence Dermott, Esq., and refored and cor-
rected with confiderable additions by Thomas Harper,
D. G. M. 1807, are faithfully recorded, which we have no
reason to queftion, they are not only irreproachable, but
defering of commendation.

The abbe Barruel, however, who in his "Memoirs
illuflrating the Hiftry of Jacobinism," translated into
English by the Hon. Robert Chifferd, F. R. S. and A. S.,
and published in 1798, afcribes the French revolution, and
the fubfquent convulfions on the continent of Europe, to the
principles and operations of the freemafons, pro-
nounces a pangenic on the English mafons, and repre-
sents them as diilguifhed from the others by ficks which
only appear to unite them more closely in the bonds of
charity and fraternal affection. At the time, he fays,
when the Illuminates of Germany, the moft detestable of the
Jacobin crew, were seeking to ftrengthen their party by that
of mafonry, they affected a contempt for the English lodges.

This
This zealous writer also allows, that for a considerable length of time the generality of lodges both in France and Germany, might have been excepted from the charge which he adduces against the objects of his censure and condemnation. The grand objects of the masonry, which he criminations, were equality and liberty. The very name of free-masonry carries with it the idea of liberty; and as to equality, it was disfigured under the name of \textit{fraternity}, which has nearly a similar figurination. The author seems to have been enrolled as a member of this society against his own inclination; and he describes the manner in which he was admitted to the several degrees of \textit{apprentice}, \textit{fellow-craft}, and \textit{master}, in one evening. The grand object which he proposed to himself was to learn the famous secret of masonry. When the moment arrived that was destined for this purpose, he was ordered to approach nearer to the Venerable. Then the brethren who had been armed with swords for the occasion, drawing up in two lines, held their swords elevated, leaving the points toward each other, and formed what in masonry is called the \textit{arch of steel}. The candidate passes under this arch to a fort of altar elevated on two pedestals, and near the farthest end of the lodge. The master, seated in an arm chair, or a fort of throne, behind this altar, pronounced a long discourse on the inviolability of the secret which was to be imparted, and on the danger of breaking the oath which the candidate was going to take. He pointed to the naked swords which were always ready to pierce the breast of the traitor, and declared to him that it was impossible to escape their vengeance. The candidate then swears, that rather than betray the secret, he contents to have his head cut off, his heart and entrails torn out, and his ashes cast before the winds. Having taken the oath, the master said the following words to him, which the reader (as he says) may easily conceive have not escaped my memory, as I had expected them with so much impatience. ‘My dear brother, the secret of masonry confounds in these words, \textit{equality and Liberty; all men are equal and free; all men are brethren.’ The master did not utter another syllable, and every body embraced the new \textit{brother equal and free}. The lodge broke up, and we daily adjourned to a masonic repast.

Under the designation of occult lodges, or the higher degrees of masonry, some authors comprehend all the three degrees of apprentices, fellow-craft, and master, are sufficiently zealous to be admitted into the higher degrees, where, as he says, the veil is rent asunder, where emblematical and allegorical figures are thrown aside, and where the twofold principle of equality and liberty is unequivocally explained ‘by war against Chiril and his allies, war against kings and their thrones!!!’ Such is the result of the grand mysteries of the craft is what he undertakes to demonstrate; and we refer those who are desirous of knowing or examining his proofs to his own statement of them.

Masonic writers in general, says M. Barruel, divide free-masonry into three classes, the Hermetic, the Cabalistic, (comprehending the Martinists), and the Eclectic masonry; all of which agree in one point, viz. their hatred to Christianity and revelation. The Hermetic masonry, or the Scotch degrees, who work in chemistry, have adopted Pantheism or the true Spoomozim. With those who belong to this class ‘every thing is God, and God is every thing.’ This is in their grand mystery, engraved in one word ‘Jehovah,’ on the crown brought by the Knights Templars from the Holy Land. The Cabalistic masonry was found in the Prussian lodges of the Rosicruccians, at least before their union with the Illuminée; and it was adopted, we are told, by certain lodges of Rosicruccians in France, a few years before the revolution, and particularly at Bourdeaux. The Jehovah of this sect is no longer the God \textit{sokak}; but he is, at once the God ‘Silamor,’ and the God ‘Sokak.’ The first is joined by the genius ‘Sallab,’ and the second by the genius ‘Sokak.’ If these famous Cabalistic words are inverted, we have ‘Oromas,’ or the God \textit{good}, and ‘Arinmeshes,’ the God \textit{evil}, and the genius will become ‘Kallas’ and ‘Kakos,’ good and bad. Thus in attributing to Oromas a multitude of good genie or spirits like himself, and to Arinames evil genie participating of his own wickedness, we have the ‘Jehovah’ of Cabalistic masonry; that is, the \textit{word} to be recovered in their lodges, or the tenets to be sublimated to those of Christiannity. According to the Martinist system, the God \textit{good}, the God \textit{evil}, and every thinking being, or, in other words, God, man, and the devil, are of the same nature, the same essence, and the same species. The enlightened Martinist cranies the pains of hell from his moral code, and the tendency of his political system is to reduce all society, all legitimate authority, to that of a father governing his children; to overturn every throne, and annihilate every law but that of the ancient patriarchs. This fict is said to have influenced the revolutions in France and Germany, and to have excited England; and every where their grand object is to represent the French revolution as the fire which is to purify the world.

The Eclectic masons are represented as much more numerous than the Martinist masons. Thence, after having passed through the different degrees of masonry, attach themselves to no particular system, either political or religious, into which they have been initiated, but adopt from them whatever may be fitted to their political or religious views. They are what they please, Deists, Atheists, Sceptics, an aggregate of all the errors of the philosophy of the day: with respect to religion, they admit that equality and liberty which deny every authority but their own reason, and reject all revealed religion; and as to governments, they admit of no kings, unless subjevtient to the will of the people in right of its sovereignty. Those who belong to a fort of Eclectic masonry, hitherto established in Germany, assert that all are independent, and have a right of making their own laws. For this reason, they have abolished the names of Grand Lodge and Scotch Lodge. This fict is said to have improved upon masonic equality and liberty.

Each Eclectic masons could not have been very numerous in France, as the major part of them was under the inspection of the Grand Parisian Lodge, called the ‘Grand Orient.’ The sentiment introduced into all the Eclectic lodges, is that of hating Chiril and his religion, and detesting all sovereignty and legislative power, except that of the people. All classes, and every code of masonry, Hermetic, Cabalistic or Martinist, and Eclectic, have concurred in forwarding the revolution; and it little imported to the feck which struck the blow, provided that ruin ensued.

In tracing the origin of free-masonry, M. Barruel rejects the opinion of those who ascribe it to the Perlian, Egyptian, Grecian, Roman, or Druid fages; but he attributes its commencement to the Knights Templars, who were either the authors of it, or borrowed it by tradition from the ancient mysteries of Paganism, and of its fages. According to our author’s statement, the depoitions of the Knights Templars declare, that on their reception into the order they denied Chiril, trampled on the cross, and spat upon it; that Good Friday was a day particularly consecrated to such outrages; that they promised to prostitute themselves to each other for the most unnatural crimes; that every child begotten by a Templar was cast into the fire; that they bound themselves by oath to obey, without exception, every order from the grand-
M A S

...maister, to spare neither sacred nor profane; to look upon every thing as lawful when the good of the order was in question; and, above all, never to violate the horrible secrets of their nocturnal mysteries, under pain of the most terrible chastishments. After having traced, in various particulars, the resemblance of the free-masons to these ancient knights, our author, as if he did not think this parentage sufficiently disgraceful, traces them farther back by several centuries to Manes and the Manichees; adopting several unfounded opinions, reflecting on the Albigenians, Waldensce, &c. in the south of France. It would lead us far beyond our limits to pursue our author's declamatory reasoning, and to detail those points of resemblance which he discovers between the free-masons of the continent and those ancient heretics. If the reader has curiosity, he may consult Barruel himself.

Our author clohes his account of the free-masons, as to their origin, principles, and practices, with diverting the attention of his reader to a body of men, or rather, as he calls them, a band of conspirators, who had coalesced, under the name of "Illuminés," with the Encyclopédists and masons, far more dangerous in their tenets, more artful in their plots, and more extensive in their plans of devolatation. They more felenly prepared the explosions of the revolutionary volcano, not merely swearing hatred to the altar of Christ and the throne of kings, but swearing at once hatred to every god, to every law, to every government, to all society and social compact; and in order to destroy every plea, and every foundation of the social contract, they proscribed the terms unite and disunite, acknowledging neither equality nor liberty, but in the "entire, absolute, and universal overthrow of all property whatever."

MASONS, in Geography, a county of Kentucky, on the S. side of Ohio river, watered by a number of creeks, which fall into Sandy river and the Ohio, and containing 11,405 inhabitants, of whom 1063 are free.—Also, a township in Hillborough county, New Hampshire, on the Mahafuctetts line, about 70 miles W. of Portsmouth, and 50 N. W. of Boston, containing 1779 inhabitants.

MASON'S ILEAND, a small island in the Patowmac. N. lat. 39°, W. long. 77° 33′.

MASONRY is the art of preparing and combining stones, so as to tooth or indent them into each other, and form regular surfaces, either for shelter, convenience, or defence; as the habitations of men, animals, the protection and shelter of goods, &c.

The tools employed by the mason are different in different countries, according to the quality of the stone.

In London, the value of stone occasions it to be cut into fentailings by a law, and the operation is done by the labourer: in different parts of the country where stone abounds, it is divided into smaller fentailings by means of wedges. Hard stone and marble are reduced to a surface by a mallet and chippel.

The principal implements used in London for hewing stones are the mallet and tools. The form of masons' tools, which are used by the perscive blow of the mallet, is that of a wedge; the cutting edge is the vertical angle. The material out of which such tools are made is iron, except the end which enters the stone, which is of steel. The end of the tool which is struck by the mallet is a small portion of a spherical surface, and projects on all sides beyond the adjoining part or hand hold, which increases in magnitude towards the middle of the tool, and thence tapers forward, in the form of a wedge or pyramid, to the entering or cutting edge. The other tools used by the mason are, a level, a plumb rule, a square, a bevel, and rules both straight and circular, of various descriptions, for trying the surfaces in the progressive state of the work.

The tools used in London, in succession, to work the face of a stone, are, the point, the inch tool, the boaster, then the broad tool. The operation of working with the point is called pointing, and that with the boaster is called boassing. The operation of the point leaves the surface in narrow furrows, with rough ridges between them. The inch tool is used in cutting away the ridges, and the boaster in making the surface of the work nearly smooth. The point is in breadth, at the entering part, from 2/16 to 1/16 of an inch, the boaster 2 inches wide, and the broad tool 3/4 inches at the cutting edge. In the use of the tool, the cutting edge is always perpendicular to the same side of the stone. There are two kinds of operations performed by it: supposing the impression made by the whole breadth of the tool, at the cutting edge, to be called a cavity. In one operation, the successive cavities follow one another in the same straight line, until the breadth or length of the stone is exhausted; then successive equidistant parallel lines are repeated in the same manner, until the whole surface of the stone has been gone over by the tool. This manner of hewing is called striking, which is a kind of fluted surface. In the other operation, every successive cavity is repeated in new equidistant lines throughout the length or breadth of the stone, then a new series of cavities is again repeated throughout the length or breadth of the stone, and thus until the whole breadth or length of the stone is exhausted. This mode is called tooling.

Tools for working cylindrical and conical parts of mouldings are of all sizes, from 4th part of an inch upwards; but those for working convex mouldings are generally half an inch broad, unless in confined spaces, where such breadth cannot be admitted.

A stone is taken, for the greater part, out of winding with points, and entirely with the inch tool.

In London, the facings of buildings made with squared stone, are either froked, tooled, or rubbed.

In the country, where the faving of stone by the use of the saw is not a compensation for the loss of time taken up in sawing, the operation is entirely performed by the mallet and chippel.

When stones are very unhapely previous to the operation of hewing, a stone ax, jedding ax, scabbling hammer, or cavi, is used in order to bring the stone nearly to a shape: one end of the jedding ax is flat, and it is used for knocking off the very protuberant angular parts when less than right angles, the other end is pointed for reducing the different surfaces nearly to the intended form.

In some parts of the country, different fancies of hewn surfaces are indulged, as herring-bone work: this is forming the surfaces of the stones by zig-zag lines parallel to each other.

In Scotland, besides what has already been noticed in hewn work, are other kinds denominated droved, broched, and striped. Droving is the same as that called random tooling in England, or boasing in London; and the chippel for broaching is called a punch, and is the same as that called a point in England. Broached work is first droved and then broached, as the work cannot be done regularly at once with the punch. Stripped work must also be froked droved and then stripped. Hence, of these three kinds of surfaces, the droved is the cheapest. Though broaching is sometimes performed without droving, it is never fo regular; and besides, the surface is generally full of inequalities. It must be observed, however, that workmen in general do not take the same pains to drove the face of a stone which is to be afterwards broached, as in that of which the droving is to remain the final
MASSONY.

A chief stone used in London is Portland, which comes from the island of Portland in Dorsetshire. It is used for public edifices, not only in ornamentals, moldings, and pilasters, but in all the exterior parts. In private buildings, where brickwork predominates, it is used for lintels, window fills, balusters, flaps, copings, etc. It must be observed, however, that under a great pressure it is apt to splinter or flake at the joints, and for this reason the joints cannot be made so close as many other kinds of stone will admit of. When it is recently quarried it is soft, and works easily, but acquires great hardness in length of time. The cathedral of St. Paul, Westminster bridge, and almost every public edifice in London, are constructed wholly, or in part, of Portland stone.

Purbeck stone comes from the island of Purbeck, in Dorsetshire also. It is mostly employed in rough work, as flaps and paving.

Yorkshire stone is used where strength and durability are requisite, as in paving and coping.

Rye gate stone is used for hearths, flaps, and copings.

In Edinburgh a very fine stone called Craigleith, brought from a village of the same name in the neighborhood of this city, is most commonly used in the construction of their edifices. They have also very good stone from the Halls quarry, but rather inferior in point of colour.

This Craigleith quarry produces two kinds of rock, one of a fine cream or buff colour, called the liver rock, which is almost unchangeable, even though exposed in a building to the weather.

The city of Glasgow is built of various kinds of stone, the beet of which are the Posis and the Lord President's quarry; most other kinds are not only perishable, but liable to change their colour.

In the north of England, stone fit for hewn work is chiefly of a reddish colour. There is a very good white stone, however, in the vicinity of Liverpool, of which several of the public buildings are constructed.

All the stone fit to be squared, or squared and rubbed smooth, for the use of building, is mostly composed of sand. The stone used for the same purpose in the south of England is, in some parts, entirely chalk, and in other parts limestone. The Bath and Oxfordshire stone has so little grit in its texture, as to be wrought into mouldings with planes, as in joinery, and the surfaces are finished with an instrument called a drag.

Marbles, with regard to their contexture and variegation of colour, are almost of infinite variety; some are black, some white, some of a dove colour, and others beautifully variegated with every kind of rich colour. The best kind of white marble is that called statuary, and when cut into thin slices becomes almost transparent, which property the others do not possess. The texture of marble, with regard to working, is not generally understood even by the best workmen, though upon sight they frequently know whether it will receive a polish or not. Some marbles are easily wrought, some are very hard, and other kinds resists the tools altogether.

Mortar is another principal material used in cementing the stones of a building. The reader who wishes to obtain a full knowledge in this department of masonry, may consult the article CEMENT, where he will receive satisfactory information.

Wherever it is intended to build upon, the ground must be tried with an iron crow or with a rammer; if found to shake it must be pierced with a borers, such as is used by well diggers; and if the ground proves to be generally firm, the loofe or soft parts, if not very deep, must be excavated until a solid bed appears.

If the ground proves soft in several places to a great depth under apertures, and firm upon the face of the piers, turn inverted arches under the apertures, so that the foundation wall, the arcades will rest on the face of the ground, then the whole wall will sink uniformly or deflect in one body. Should the ground be even of an uniform texture, it is always eligible to turn inverted arches under apertures, wherever there is a part of a wall carried up from the foundation to the fill of that aperture; it is from neglecting this circumstance that the fills of windows in the ground stories of buildings are frequently broken; indeed it is seldom or never otherwise.

Arches adequate to this purpose should rather be of a parabolic form than circular, the figure of the parabola being better adapted to preserve an equilibrium than the arc of a circle, which is of uniform curvature. If unfortunately the soft parts of the ground prove to be the face of the piers, and, consequently, the hard places under the apertures, build piers under the apertures, and supend arches between the piers with their concave side towards the trench as usual.

For more information upon this subject, the reader will refer to the article Foundation.

In laying the bedding joints, the masons commonly have a horizontal position in the face of the work, and this disposition ought always to take place when the top of the wall terminates in a horizontal plane or line. In bridge building, and in the masonry of fence walls upon inclined surfaces, the bedding joints on the face sometimes follow the upper surface of the wall or terminating line.

The footings of stone walls ought to be constructed of large stones, which, if not naturally nearly square, should be reduced by the hammer to that form, and to an equal thickness in the same course; for if the beds of the stones in the foundation taper, the superstructure will be apt to give way, by resting upon mere angles or points with inclined beds instead of horizontal. All the vertical joints of any upper course should break joint, that is, they should fall upon the solid part of the stones in the lower course, and not upon the joints.

When the walls of the superstructure are thin, the stones which compose the foundation may be so disposed that their length may reach across each course, from one side of the wall to the other. In thicker walls, where the difficulty is greater in procuring stones of sufficient length to reach across the foundation, every second stone in the course may be a whole stone in the breadth, and each interval may consist of two stones of equal breadth, that is, placing header and stretcher alternately. But when these stones cannot be had conveniently,
conveniently, from one side of the wall lay a header and stretcher alternately, and from the other side lay another series of stones in the same manner, so that the length of each header may be two-thirds, and the breadth of each stretcher one-third of the breadth of the wall, and so that the back of each header may come in contact with the back of an opposite stretcher, and the side of that header to come in contact with the side of the header adjoining the said stretcher. In broad foundations, where stones cannot be procured for a length equal to two-thirds of the breadth of the foundation, build the work so that the upright joints of any course may fall on the middle of the length of the stones in the course below, and so that the backs of each stone in any course may fall upon the solid of a stone or stones in the course below.

The foundation should consist of several courses, of which each superior course should be of less breadth than the inferior one, say four inches on each side in ordinary cafes, and the upper course project four inches on each side of the wall. The number of courses must be regulated by the weight of the wall, and by the size of the stones of which the foundation consists.

A wall which is built of unhewn stone is called a rubble wall, whether with or without mortar. Rubble work is of two kinds, coursed and uncoursed. Coursed rubble is that of which the stones are guaged and dressed by the hammer, and thrown into different heaps, each heap containing stones of the same thickness; then the masonry is laid in courses or horizontal rows, which may be of different thicknesses. The uncoursed rubble is that where the stones are laid promiscuously in the wall, without any attention to placing them in rows. The only preparation which the stones undergo is that of knocking off the sharp angles with the thick end of the scabbling hammer.

Walls are most commonly built with an ashlar facing and backed with brick or rubble work. Brick backings are common in London where brick is cheaper, and stone backing in the north of England and in Scotland where stone is cheaper. Walls faced with ashlar, and backed with brick or uncoursed rubble, are liable to become convex on the outside from the greater number of joints, and from the greater quantity of mortar placed in each joint, as the shrinking of the mortar will be in proportion to the quantity, and therefore a wall of this description is much inferior to one of which the facing and backing are of the same kind, and built with equal care, even though both sides were uncoursed rubble, which is the worst of all walling. Where the outside of a wall is an ashlar facing and the inside coursed rubble, the courses of the backing should be as high as possible, and set with thin beds of mortar. In Scotland, where stone abounds, and where perhaps as good ashlar facings are constructed as any in Great Britain, the backing of their walls must commonly consist of uncoursed rubble, built with very little care. In the north of England, where the ashlar facings of walls are done with less neatness, they are much more particular in couring of their backings. Coursed rubble and brick backings are favourable for the infestation of bond timbers; but in good masonry wooden bonds should never be in continued lengths, as in cafe of fire or rot the wood will perish, and the masonry, being reduced by the breadth of the timber, will be liable to bend at the place where it was infected. When it is necessary to have wall timber for the stiffening of battens for lath and plaster, the pieces of timber ought to be built with the fibers of the wood perpendicular to the surface of the wall, or otherwise in unconnected short pieces not exceeding nine inches in length.

In an ashlar facing the stones generally run from twenty-eight to thirty inches in length, twelve inches in height, and eight or nine inches in thickness. Although both the upper and lower beds of an ashlar, as well as the vertical joints, should be at right angles to the face of the stone, and the face bed and vertical joints at right angles to the beds in an ashlar facing, where the stones run nearly of the same thickness, it is of some advantage, in respect of bond, that the back of the stone be inclined to the face, and that all the bonds thus inclined should run in the same direction, as this gives a small degree of lap in the setting of the next course; whereas if the backs were parallel to the front, there could be no lap where the stones run of an equal depth in the thickness of the wall. It is of some advantage likewise to effect the stone, so that a thicker one and a thinner one may follow each other alternately. The disposition of the stones in the next superior course, should follow the same order as in the inferior course, and every vertical joint should fall as nearly as possible in the middle of the stone below.

In every course of ashlar facing, with brick or rubble backing, through stones (as they are technically termed) should be introduced, and their number should be proportioned to the length of the course, and every such stone of a superior course should fall in the middle of every two like stones in the course below; this disposition of bonds should be strictly attended to in all long courses. Some wallers, in order to shew or demonstrate that they have introduced sufficient bonds in their work, choose their bond stones of greater length than the thickness of the wall, and knock or cut off their ends afterwards. This method is far from being eligible, as the wall is not only liable to be shaken by the force applied to break the end of the stone, but the stone itself is apt to be split.

In every pier where the jams are coursed with the ashlar in front, every alternate stone ought to go through the wall with its beds perfectly level. If the jam stones are of one entire height, as is frequently the case when architraves are wrought upon them, and upon the lintel crowning them, in the stones at the ends of the courses of the pier which are to admit the architrave jam, every alternate stone ought to be a through stone; and if the piers between the apertures be very narrow, no other bond stones will be necessary in such short courses. But where the piers are wide, the number of bond stones must be proportioned to the space; through stones must be particularly attended to in the long courses below and above windows.

Bond stones should have their sides parallel and of course perpendicular to each other, and their horizontal dimension in the face of the work should never be less than the vertical one. All the vertical joints, after receding about three quarters of an inch from the face with a close joint, should widen gradually to the back, and thereby form hollow wedge-like figures for the reception of mortar and packing. The adjoining stones should have their beds and vertical joints filled with oil putty from the face to about three quarters of an inch inwards, and the remaining part, of the beds with well prepared mortar. Putty cement will stand longer than moll stones, and will even remain prominent, when the stone itself is in a state of dilapidation, by the influence of the corroding power of the atmosphere. It is true that in all newly built walls cemented with oil putty, the first appearance of the ashlar work is rather unsightly, owing to the oil of the putty disseminating itself into the adjoining stones, which makes the joints appear dirty and irregular; but this disagreeable effect is removed in a year, or less; and if care has been taken to make the colour of the putty suitable to that of the stone, the joints will hardly appear.
MASONRY.

appear, and the whole work will seem as if one piece. This is the practice of Glasgow. In London and Edin-
burgh fine water putty is used instead of it.

All the stones of an ashlar facing should be laid on their natural beds. From a neglect of this circumstance the stones frequently fall at the joints, and this disposition of the lamina sooner admits the corroding power of the at-
mosphere to take place.

In building walls or solidified pillars of very small hori-
izontal dimensions, every stone should have its beds level and
without any concavity in the middle; because if the beds are concave, when the pillars begin to fail in weight of the fabric the joints will in all probability fail. It ought
likewise to be observed that every course of masonry of such piers ought to consist of one stone.

Vitrivius has left us an account of the construction of the walls of the ancients, as follows, "The forts of walls are the reticulated, Plate L. fig. 1, and the ancient, which is called the uncertain. fig. 2. Of these the reticulated is the hand-
somest, but the joints are so ordered that all the parts of the courses have an uniform position; whereas in the uncertain, the materials rest firmly one upon the other, and are inter-
 woven together; so that they are much stronger than the reticulated, though not so handsome. Both forts are formed of very small pieces, that the walls, being saturated with mortar, may endure the longer: for the stones, being of a porous and spongy nature, absorb the moisture from the mortar; and when there is an abundance of mortar, the wall, having more humidity, will not so soon decay, but will on
that account be rendered more durable; for as soon as the
humidity is extracted from the mortar by the suction of the stones, then the line and sand separating the cement is dissolved, and the mortar no longer uniting the materials, the walls soon become ruinous. This may be observed in
some tombs near the city, which are built with marble or
heaven stone, and the internal parts crammed with rubble stones; the mortar being by length of time drained of its humidity by the suction of the stones, and the union of the joints being dissolved, they separate and fall to ruin.

To avoid this error, the middle space (fig. 2.) must
be strengthened with abutments of the red heizen stone or
bricks, or common flints, built in walls two feet thick, and
bound to the front with cramps of iron fixed with lead; for
the work being thus built in a regular manner, and not laid in
promiscuous heaps, will remain without defect; and being
by the orderly arrangement of the courses and joints firmly
united and bound together, it will not be liable to fractures,
or will the abutments suffer it to fall to decay. For this reason the walls of the Greeks are not to be de-
scribed; for though they do not use smooth or polished ma-
terials, yet where they discontinue the square stones, they
lay the flints, or common hard stones, that they use, in the
same manner as bricks are generally laid, bending the cour-
ses together with alternate joints, and thus make their works durable.

These walls they build in two manners: one is called
Ipidodion (fig. 3.), and the other Pseudipidodion (fig. 4.).
Ipidodion is when all the courses are of an equal thickness; and Pseudipidodion when they are unequal. Both these
forts are firm; stiff, because the stones themselves are of a
compact and solid nature, and do not absorb the moisture
from the mortar, but preserve its humidity to a great age;
and, secondly, being situated in regular and level courses, the
mortar is prevented from falling, and the whole thickness of
the wall being united, it endures perpetually.

Another fort is that which they call Emplecton, fig. 5
and 6.) which is also used by our villagers. The faces of the
stones in this kind are smooth; the rest is left as it grows in
the quarry, being secured with alternate joints and mortar; but
our artificers, quickly raising a shell, which serves for the faces
of the wall, fill the middle with rubble and mortar: the walls, therefore, consist of three coats, two being the faces, and
one the rubble core in the middle, figs. 5 and 6. But the
Greeks do not build in that manner; they not only build
the facing courses regularly, but also use alternate joints
throughout the whole thickness, not ramaining the middle
with rubble, but building it as the face, and of one united coat construct the wall: besides this, they dif-
pole fragile pieces (A), which they call diatonos, in the
thickness of the wall, extending from one face to the other,
which bind and exceedingly strengthen the walls. Thefe,
therefore, who would build works of long duration, must
attend to these rules, and make use of such methods of build-
ning; for the smooth polish, and beautiful appearance of the
stones, will not prevent the wall from being ruined by age.

An arch, in masonry, is a part of a building suspended
over a given plan, supported only at the extremities, and
covec towards the plan.

The supports of an arch are called the spring walls.
The whole of the under surface of the arch opposite to
the plan is called the intrados of the arch, and the upper
surface is called the extrados.

The boundary line, or lines of the intrados, or those common to the supports and the intrados, are called the springing
lines of the arch.

A line extending from any point in the springing line on one side of the arch, to the springing line on the op-
posite side of the arch, is called the chord or span of the arch.

If a vertical plane be suppos’d to be contained by the
span and the intrados of the arch, it is called the section of the
hollow of the arch.

The vertical line drawn on the section from the middle of the
spanning line to the intrados, is called the height of the arch, as also the middle line of the arch, and the part of the
arch at the upper extremity of this line is called the crown of
the arch.

Each of the curved parts on the top of the section, be-
tween the crown and each extremity of the spanning line, is
called the haunches or flanks of the arch.

The section of almost every given arch used in building
has the following properties: the upper part is one con-
tinued curve, concave towards the span, or two curves form-
ing an interior angle at the crown, both concave towards the
spanning line.

Every two vertical lines on the section equidistant from
each extremity, and parallel to the middle line, are equal.

The above definitions and propositions not only apply to
arches with level bales, but also to arches which stand on
inclined bases.

When the base of the section or spanning line is parallel
to the horizon, the section will consist of two equal and
similar parts, so that if one were conceived to be folded
upon the other, the boundaries of both would coincide.
Archs, the intrados of which is the surface of a geo-
mctrical solid that would fill the void, are variously named,
according to the figure of the section of that solid perpen-
dicular to the axis, as circular, elliptical, cycloidal, catenarian,
parabolical, &c.

Archs of the circular kind have two distinctions, viz.
the femicircle, and those of segments less than a femicircle,
are called semicircular or skew arches.

There
MASONRY.

There are also pointed, composite, lances, or Gothic arches, which are formed in the face of the wall, or in sections parallel thereto, with the intrados of the arch.

When the extremities of an arch rise from supports at unequal heights, such an arch is called a rampart arch.

When a vertical line is drawn upwards, through each extremity of the spanning line, so as to cut off equal and similar parts of the intrados, the arch is called a horse-shoe arch, or Moretian arch. Hence, in this kind of arch, the spanning line is less than any other line, or chord drawn parallel to the span, but under the top of each said vertical line.

When the upper line or side of an arch is parallel to the underline or side, the arch is called an extradosed arch.

A simple vault is an interior concavity extended over two parallel opposite walls, or over all the diametrically opposite parts of one circular wall. An arch or vault are frequently understood as synonymous; but the distinction which we shall here observe is, that an arch, though it may be extended over any space, has a very narrow intrados, not exceeding four or five feet; whereas a vault may be extended to any limit more than four or five feet. Thus, we frequently lay an arch in a wall, but we never lay a vault in a wall; though nothing is more common than to lay a vaulted apartment, a vaulted room, a vaulted cellar, &c. So that a vault, as Sir Henry Wotton has observed, is an extended arch; we shall therefore apply the term to the head of the aperture in a wall which flows curvilinear interjunctions with the faces of the wall, and the word vault to arches of apartments. We frequently, however, call the stone-work suspended over an apartment an arch as well as a vault, so that every vault is an arch, but every arch is not a vault.

The intrados of a simple vault is generally formed of the portion of a cylinder, cylindrical, sphere, or spheroïd, never greater than the half of the solid; and the springing lines which terminate the walls, or where the vault begins to rise, are generally straight lines parallel to the axis of the cylinder or spheroïd, or the circumference of a circle or ellipse.

A circular wall is generally terminated with a spherical vault, which is either hemispherical, or a portion of the sphere less than a hemisphere.

A vaulted apartment, surrounded by an elliptic wall, is generally covered with a spheroïdal vault, which is either a hemispherical, or a portion less than a hemispherical.

A conic surface is seldom employed in vaulting; but when the vault is to have this kind of intrados, the intrados should be the half of a cone with its axis in a horizontal position, or a whole cone with its axis in a vertical position.

All vaults which have a horizontal straight axis are called straight vaults.

Besides what we have already denominated an arch, the concavities which two solids form at an angle are called an arch.

If one cylinder pierce another of a greater diameter, the arch is called a cylindro-cylindrical arch; the cylinder being applied to the cylindric part which has the greater diameter, and the cylindric to that which has the less.

If a cylinder pierce a sphere of greater diameter than the cylinder, the arch is called a sphero-cylindrical arch; and on the contrary, if a sphere pierce a cylinder of greater diameter than the sphere, the arch is denominated a cylindro-spheroïdal arch.

If a cylinder pierce a cone so as to make a complete perforation through the cone, two complete arches will be formed, called cono-cylindrical arches; and on the contrary, if a cone pierce a cylinder so as to make the interior concavity through the cylinder a complete conic surface, the arch is called a cylindro-conic arch.

If a straight wall be pierced with a cylindric aperture quite through, two arches will be formed, called plano-cylindrical arches.

Every species of arches is thus denoted by two preceding words; the former ending in a, signifying the principal vault or surface cut through, and the latter in e, signifying the kind of aperture which pierces the wall or vault.

When two cylindrical vaults, or two cylindroïdial vaults, or a cylindric and cylindroïdial vault pierce each other, and also their axes, so that the diameter of each hollow may be the same when measured perpendicular to a plane passing through the axis of both surfaces, the figure so formed is called a groin: but for more particular information on this point, see the article Groin.

The formation of stone arches, in various cases, has always been looked upon as a most curious and useful acquisition to the operative mason, or to the architect, or other person who is appointed to superintend the work. In order to remove the difficulties experienced in the construction of cylindric or cylindroïdial arches, both in straight and circular walls, we shall here give an example of each:

First, let it be required to construct a semi-cylindrical arch cutting a straight wall with its axis oblique to the surface of the wall, but parallel to the horizon.

Let A B C D (Plate II. fig. 1.) be the plan of the aperture, A D and B C the plan of the jamb; and A B and D C the plan of the sides of the wall; produce D A and C B to G and F; draw the straight line I G M F E at right angles with A G and C F; bisect G F at M; draw M H K perpendicular to G F: make M H equal to the height of the intrados of the arch, and describe the semi-ellipsis G H F, which is the section of the intrados of the arch: make G I, H K, and F E equal to the breadth of the beds of the arch stone, and describe the semi-ellipsis I K E, which is the section of the extrados of the arch.

Now suppose the distances between the joints around the intrados of the arch to be all equal, and all the joints to tend to the centre M; divide the semi-ellipses into such an odd number of equal parts, that each part may be in breadth equal to what is intended for the thicknesses of the stones at that part; produce E I to S, and extend the whole number of these parts from G to S; and through the points of division draw lines perpendicular to G S, or parallel to A G. Through all the points of division of the ellipsis G H F, draw lines parallel to G A to meet A B; then take the lengths of all the parts of the lines so drawn that are terminated by G F and A B as follows: viz. make the first line on the left of G A equal to the first on the right of G A, and the point b will be obtained; and the second on the left of G A equal to the second on the right of G A, and the point c will be obtained; proceed in this manner until all the other points are obtained; then a curve being drawn through all the points A, B, C, D, &c. to T, will give the one edge of the envelope of the intrados of the arch; and by producing the perpendiculars erected upon G S to the points c, f, g, &c. and making the several distances b c, c f, d g, &c. equal to A D or B C, the points D, e, f, g, &c. to U, will give the other edge of the envelope by tracing a curve through them; then A b c d, b c f e, c d g f, &c. are the isloits of the stones.
To find any bevel which the joints on the face of the arch make with that on the intrados of the same. Let \( pq \) be one of the joints tending to the centre \( M \) of the section of the arch: with the radius \( MG \) describe an arc \( GNO \), cutting \( pq \) at \( N \); draw \( NP \) parallel to \( GA \), cutting \( AB \) at \( P \); draw \( PQ \) parallel to \( FG \), cutting \( GA \) at \( Q \); draw \( ML \) parallel to \( GA \), cutting \( AB \) at \( L \), and join \( LQ \). Then \( LQM \) is the bevel required: in the same manner may all the remaining bevels be found.

Again, let \( pqr \) be the section of an arch stone, then making two bevels, one to \( qr \) and the other to \( rs \), will be all the bevels that are necessary for that stone. Having obtained the several bevels, we shall now proceed to work the arch stone, whose section is \( pqr \): first work the lower bed of the stone corresponding to the joint \( pq \); then draw a line for the soffit, which work also by means of the bevel \( qps \); then gauge the soffit to its breadth, and work the upper bed of the stone by means of the bevel \( rs \); then take the soffit mould from the envelope, and draw the ends of the stone which coincides with the faces of the wall; then with the face bevels \( QLM \), and \( VLM \), work the face of the stone.

Note, that finding the bevels for half the arch will be sufficient by reverting them.

The other arch standing upon \( DC \) shows the ends of the stones in the face of the wall; its boundaries are two ellipses of equal height to those of the section.

To construct a cylinder-cylindrical, or a cylindrical arch in a cylindrical wall, the axis of the aperture being at right angles with the axis of the cylindrical wall. Let \( ABCD \) be the half plan of the wall, \( BC \) being half of the convex curve, \( AD \) half of the concave curve, \( CD \) the middle line of the aperture tending to the centre of the concentric circles which form the plan, and \( AB \) parallel to \( CD \), being the joint. Through \( C \) draw \( EF \) perpendicular to \( CD \): make \( CE \) and \( CF \) half the breadth of the aperture: from the centre \( C \), with the radius \( CE \) or \( CF \), describe the semicircle \( EFG \), which will be the section of the intrados: produce \( CE \) and \( CF \) to \( H \) and \( I \), making \( EH \) and \( FI \) each equal to the breadth of the beds, and describe the semicircle \( KIK \): divide the intradosal curve \( EFG \) into the number of parts answering to the number of arch stones, and proceed to find the envelope, as described, for the straight wall, which will give the moulds for the soffits of the stones as before.

To find the curves of the ends of the stones upon the face of the arch. Let \( LM \) represent a joint: draw \( LN \) and \( MO \) perpendicular to \( HI \), cutting the plan of the wall at \( N \) and \( O \); draw \( NP \) parallel to \( CI \), cutting \( MO \) at \( P \). In \( LM \) take any number of points \( t \) and \( y \), and draw \( ts \) and \( yz \) parallel to \( LN \), cutting the plan at \( s \) and \( z \), and \( NP \). Then by \( Dr \) draw \( MQ \), \( tu \), \( yx \), perpendicular to \( LN \): make \( M, Q, \) \( tu, \) \( yx \), respectively equal to \( P, \) \( r, \) \( s, \) \( u, \) \( v, \) and \( x \) \( w \). Then \( K \) and \( Q \) will be the curve of the joint required, which gives the face line of the upper bed of the lower stone, and the face line of the lower bed of the upper stone. In the same manner all the other face lines of the beds are to be found. The temple must be cut in the shape of \( LMQ \).

To form an arch stone. First make one of the beds, then make the soffit, then form the other bed, then form the face lines of each bed, then run a draught round the three face lines, then between these work the face of the stone in lines perpendicular to the horizon. This will be easily found by drawing a vertical line upon the section of each stone.

It is only necessary to draw the moulds for one half of the arch, as the reverting of them in their application gives the stones of the other half.

The joints of any arch whatever may be found in the same manner, provided that the planes of the beds intersect a vertical plane perpendicular to the curve in the middle of the aperture.

It is obvious, on finding the face lines of the beds, that the lowest face line is the quickest, and part of the plan of the wall itself; the next face line is flatter, or has less curvature, and thus each successive face line of curvature as it comes nearer to the top, and if there were a joint in the top, the face line of the beds would be quite a straight line. Indeed, the face lines of two or three courses might be wrought with straight edges, as the difference could hardly be perceived.

**MASORA**, a term in the Jewish Theology, signifying a work on the bible, performed by several learned rabbins, to secure it from alterations which might otherwise happen.

Their work regards merely the letter of the Hebrew text; in which they have, first, fixed the true reading, as well as the right method of writing and pronouncing, by vowels, pata, and accents: they have, secondly, numbered not only the chapters and fections, but the verses, words, and letters of the text: and they find in the Pentateuch 5245 verses, and in the whole bible 23,206. The mafora is called, by the Jews, the hedge or fence of the law, because this enumeration of the verses, &c. is a means of preferring it from being corrupted and altered. They have, thirdly, marked whatever irregularities occur in any of the letters of the Hebrew text; such as the different size of the letters, their various positions and inversions, &c. and they have been fruitful in finding out reasons for these irregularities and mysteries in them. (See **CABBALISTS**). They are, fourthly, supposed to be the authors of the Keri and Chetibib, or the marginal corrections of the text in our Hebrew bibles. See **KEFI-CHETIB**.

The text of the facered books, it is to be observed, was originally written without any breaks, or divisions into chapters or verses, or even into words; so that a whole book, in the ancient manner, was but one continued word; of this kind we have still several ancient manuscripts, both Greek and Latin. In regard, therefore, the facered writings had undergone an infinite number of alterations, whence various readings had arisen, and the original was become much mangled and disfigured, the Jews had recourse to a canon, which they judged infallible, to fix and aferent the reading of the Hebrew text; and this rule they call **MAFORA, TRADITION, from **MORAD, tradidit**, as if this critique were nothing but a tradition which they had received from their fore-fathers. Accordingly they say, that when God gave the law to Moses, at Mount Sinai, he taught him, first, the true reading of it, and, secondly, its true interpretation; and that both these were handed down by oral tradition, from generation to generation, till at length they were committed to writing. The former of these, viz. the true reading, is the subject of the mafora; the latter, or true interpretation, that of the **MIFNAH AND GENARA**; which fee.

According to Elias Levita, they were the Jews of a famous school at Tiberias, about 500 years after Chirill, who composed, or at least began, the mafora; whence they are called **MAFORTAE, and **MAFORTAE DOCTORS. Aben Ezra makes them the authors of the points and accents in the Hebrew text, as we now find it; and which serve for vowels.

It is pretended by those who lay a great stress on the points, that the same word, being written with confonants only, as most of the Hebrew words are, has various significations, according to the vowels with which you read or pronounce. **MIFNAH AND GENARA**
nounce it; e.g. the three letters ג"כז, dbr, have at least five different significations, viz. he lpace, speaking, a word, a participle, furnish, which Bible. 25. macratai and their significates signify one thing and when another. When it signifies "he lpace," they affix the points which denote a short and e, long, and say ג'כז, daber. When it is a participle, and signifies "speaking," they read by the points ג"כז, dober; when it is a noun, and signifies a "word," they put under it two a's short, and read ג'כז, dabar, when it signifies a participle, they put two o's under, and read ג'כז, deber, when it signifies a fold, they put the points which denote a and e, and read ג'כז; and so they have done with other words.

What has been done, in this cafe, by the Maforites, would certainly be of great use for understanding the Hebrew text, if they had lived while the Hebrew was a living language, and those points had been then us'd, and we could have been assured of their knowledge of the true pronunciation of all words, according to their different significations; but as the Hebrew was a dead language many hundred years before this time, the true ancient pronunciation was as much unknown then as now. We have St. Jerome's testimony, that different vowels were us'd in the pronunciation of the same word in different countries; and this was at least 100 years before the Maforites began the invention of their points, either for vowel, pause, or accent; and they were improving for some centuries. It is also manifest, from the LXX, that the ancient Jews read with different vowels from those which the Maforites have affixed. This is amply evinced by Maclef in his "Grammar." But if nothing more than the bare pronunciation of Hebrew words was concerned in the cafe, the matter would not be worth the laft dispute. We know not how the ancient Greeks and Romans pronounced the Latin and Greek tongues. Every nation gives the famous bind to the Latin and Greek letters, which they give to those of their own language, which occasions those languages to be differently pronounced by different people. However, all write and interpret them in the same manner; which difference in pronouncing or speaking is of little consequence, but the cafe is different with regard to the Hebrew; molt of the words in that language are written without vowels; and the question is, what vowels the words require to make the sense understood; not how the words are to be pronounced in speaking, when vowels are affixed to them. Therefore we say, that as it appears from the LXX, that the Jews, before our Saviour's time, used other vowels, by which they spake their words, than those which the Maforites have us'd; the consequence is, that the points which the Maforites have now affixed to every Hebrew letter, whether for vowel, pause, or accent, are of little or no authority, and deserve not to be regarded by us; and that the true sense of an Hebrew word, written only with conno- nants, is not to be fetched from the points of the Mafora, and the rules given concerning them, but from the context and construction, and the affinity of the LXX, and other ancient translations. Although we cannot charge the Jews with wilful falsification of the Hebrew text, that is, they have not designedly changed the letters of their biblest, yet we cannot say that they have not in some places wilfully falsi- fied the sense by their points, of which Maclef gives us an instance in his arguments for his "New Grammar," with regard to the famous prophecy in Gen. xxxi. The learned Mr. Johnstone of Cranbrook, in a pitholous discourse on Daniel's 70 weeks, has also observed how the Maforites have endeavoured to mar that prophecy also, by their points; putting a frop, which they call an "athmachi," which answers to our femicolon, in the place where there ought to have been only a comma. And, as Mr. Johnstone observes, our English translators took the prevalent Hebrew text as it is printed by the Maforites, to be the only sense and meaning of the Old Testament. In Dan. ix. 25. they put their "athmachi" or femicolon after the seven weeks, and thus cutting off the seven weeks from the three score and two weeks, make the prophecy wholly uninterpretable to Christians; but if they had placed a comma after seven weeks, and their "athmachi" or femicolon after three score and two weeks, the number of years, viz. 483 (69 weeks) would exactly point out the time when the Chriftian Messiah came. See Points, under which article this subject is farther dif- cussed.

The age of the Maforites has been much disputed. Arch- bishop Usher places them before Jerome: Capel, at the end of the fifth century; father Morin in the tenth century; Dr. Kennicott about the year 800: Baffage says, that they were not a society, but a succession of men; and that the mafora is the work of many grammarians, who, without af- sociating and communicating their notions, composed this collection of criticism's on the Hebrew text. It is urged, that there were Maforites from the time of Ezra and the men of the great Synagogue, to about the year 1030; and that Ben Afcher of Tiberias, and Ben Naph- tali at Babylon, who were the bell of the profeflion, and who, according to Baffage, were the inventors of the mafora, flourished at this time. Each of these published a copy of the whole Hebrew text, as correct, says Dr. Pri- deaux, as they could make it. The callens Jews have followed that of Ben Naphtali, and the western that of Ben Afcher; and all that has been done since is to copy after them, without making any more corrections or maforatical criticisms.

The learned Walton, in the appendix to his Polyglott, has given us all the various readings of Ben Afcher and Ben Naphtali and the Oriental and Occidental Jews, and also of the Keri and Chethil; but we are still farther indebted to Dr. Kennicott for his admirable Hebrew bible and the Diff- errato Generalis annexed to it. See Bible.

The Arabs have done the same thing by their Koran, that the Maforites have done by the bible: nor do the Jews deny their having borrowed this expedient from the Arabs, who first put it in practice in the seventh century.

There is a great and a little mafora, printed at Venice, and at Bâil, with the Hebrew text, in a different character. Buxtorf has written a maforatical commentary, which he calls Tiberias. See on this subject, Dr. Brett's Differration on the ancient Versions of the Bible, &c. Lond. 1760, or Eddon Watson's Collection of Theological Tradis. vol. iii. Kennicott, ubi supra, and Differrations; and Jennings's Jewish Anti. vol. i. p. 400, &c. and the various authors there cited.

MASORITES, Jewish doctors, authors of the mafora.

MASOVIAS, or Masunens, in Geography, a late pa- latinate of Poland, being one of the most ancient and one of the laft that remained annexed to the crown. Masovia pro- perly confifted of two palatinates, viz. Czerk or Malovia Proper, and Polotsk. This palatinate was feized by Prufia in the general division; but at the peace of Thifis, it was taken
MAS

taken from Prussia, and given to Saxony, forming a part of the duchy of Warfaw.

MASPA, a town of South America, in the audience of Quito; 45 miles N.W. of Archidona.

MASPALOMA, a town on the S.E. coast of Canary island; 12 miles S. of Palmas.

MASPHA, or MASPHE, in Scripture Geography, a country at the foot of mount Hermon, towards the springs of Jordan. Joshua says it was inhabited by the Hivites.

MASPHE, or MASPAT, a town of Judea, which belonged to the tribe of Gad, situated in the N. and E. part of the tribe of Gad. This town was taken and destroyed by Judas Maccabaeus.

MASPHIE, or MASPHT, a town of Judea, in the tribe of Benjamin. In this town were sometimes held the general assemblies of the Irazeites. It was rebuilt by Afa king of Judah. Here Judas Maccabaeus and his brethren assembled, in order to fight with Lybias, general of the army of Antiochus.

MASQUE, or MASK, a cover for the face, contrived with apertures for the eyes and mouth; originally worn chiefly by women of condition, either to preferve their complexion from the weather, or out of modesty to prevent their being known.

Poppea, wife of Nero, is said to be the first inventor of the mask, which the continued to guard her complexion from the sun and weather, as being the most delicate woman, with regard to her person, that has been known. Theatrical masques were in common use, both among the Greeks and Romans; Suidas and Athenaeus ascribe the invention of them to the poet Choricius, a contemporary of Theseus; Horace attributes them to Echylus; but Aristotle informs us, that the real inventor, and, consequently, the time of their first introduction and use, were unknown. Brantome oberves, that the common use of modern masques was not introduced till towards the end of the sixteenth century.

Masque is also used to signify any thing used to cover the face, and prevent a person’s being known.

The penitents of Lyons and Avignon hide their faces with large white veils, which serve them for masques.

Masques, or MASK, a theatrical drama, much in favour in the court of princes during the sixteenth and seventeenth centuries, and latterly particularly in England.

According to Hall’s Chronicle, the first masque performed in England was at Greenwich, 1513, “after the manner of Italy”; and Hollinghed says, that “there was not only a masque, but a good comedy of Plautus performed in 1520.” In 1530, a masque was performed at Whitehall, “consisting of music, dancing, and a banquet, with a display of grotesque personages and fantastic dresses.” This piece seems only to have wanted machinery to fulfill the idea of a complete masque, such as were afterwards written by Ben Jonson and others, which, with a consequent musical declamation in recitative mixed with air, would have formed an opera exactly similar to the musical drama of Italy, in the ensuing century.

Shakespeare and Beaumont and Fletcher, have frequently introduced masques into their plays. Of the fourteen comedies of Shakespeare, there are but two or three in which he has not introduced masques; even in most of his tragedies, this wonderful and exquisite dramatist has manifested the same predilection for masques.

The French and German writers on our musical dramas, confused masque with masquerade, and masquerade and interlude with the Italian intermezzi; but we had interludes long before the Italians had intermezzi, and our poems, or dramas,

called masques, bear no resemblance to an Italian mascherata. M. de Melfi, who in the Bib. Brit. 1749, has given a regular series of our masques, more especially those of the seventeenth century, is constantly mistaken in these particulars.

Masques were certainly the precursors of opera in England, and belong to the chain of dramas which completed the union of poetry and music on our stage; and it does not appear, on examination, that the Italian Mascherata, published by Lacta, which have been thought their prototypes, were dialogued or performed on any stage. They seem to have been only proceffional songs, sung through the street by the representatives of different professions and trades, masques, during carnival time. And the interludes which de Melfi and Riccoboni, and their translators, think we had from the Italian intermezzi, seem to want analogy: as interludes, with us, was a general name for every species of stage representation, out of the church.

Masques in England certainly bear some resemblance to operas: as they are in dialogue; performed on a stage; ornamented with machinery, dances, and decorations; and have always music, vocal and instrumental. But then the effontial and characteristic criterion, recitative, is wanting; without which the resemblance is imperfect. One musical pieces, which are sometimes found with the name of opera, differ in this particular so much, that they more resemble masques than the dramas which are entitled to that appellation: for, in English musical dramas, the dialogue is all declaimed or spoken in the same manner as in our old masques; and in Italy, whence we have both name and thing, an opera consists of both recitatives and airs, and is sung from the beginning to the end.

Riccoboni says, that James I., on coming to the crown in 1603, granted a licence to a company of players, in which patent interludes are included; but an interlude then was another word for a play, whether comedy, tragedy, or farce. Masques are not mentioned in this patent; but as masques, at this time, were court entertainments, or performed in the houses of the nobility, on particular occasions of festivity, the necessary machinery and decorations rendered such exhibitions too expensive for the ordinary public theatres. Indeed, the several parts of the masques of the sixteenth and seventeenth centuries were usually represented by the first personages in the kingdom; if at court, the king, queen, and princes of the blood often performed in them.

Masques appear to have been still more the favourite amusements of the court during the early and tranquil part of Charles I.’s reign than in that of James; and the queen, who seems to have brought her from France at least as great a love for dramatic exhibitions as she found here, frequently represented the principal character in the piece herself. Most of the court masques were written by Ben Jonson, who, in his 8th of poet-laureat, seems to have furnished more of these dramas, than birthday or new-years odes. And though the masques of this reign are frequently said, in the title-page, and dranatis perfonas, to have been performed by the king, queen, and nobles of their court, yet it does not appear that these great personages often took part in the dialogue or songs of the piece; but generally appeared on the stage in the splendid ballets only, as dancers, representing mythological or allegorical characters. Indeed, the queen, at the time of the first masques of this reign, can hardly be supposed sufficiently exercised in our language to undertake a part in which declamation was necessary.

In 1633, there were no less than five masques performed at different places before the king and queen, and peri-
fonsages of the court. A very circumstantial account of one of these has been left in a MS. by lord commissioner Whitelock, written by himself. It was acted at Whitehall, and the whole expense defrayed by the gentlemen of the four inns of court. The whole narrative of this masque is curious, and may be seen in Burney's General History of Music, vol. iii.

Masque, in Architecture, is applied to certain pieces of sculpture, representing human hideous forms, grotesque, or faty's faces, &c. used to fill up and adorn vacant places, as in friezes, the pannels of doors, keys of arches, &c. but particularly in grottoes.

Masques and Chilquers. See Chilquers.

Masquelonge, or Kennonchesque, in Geography, a river of America, which runs into lake Michigan. N. lat. 43° 10'. W. long. 87° 4'.

Masque-Pocona, a jurisdiction of Peru, in the audience of Chares, extending about 30 leagues. The temperature is hot, but not in a degree too great for vineyards. The valley in which the city stands is above eight leagues in circumference, and produces all kinds of grain and fruit; and the woods and uncultivated mountains afford great quantities of honey and wax, which constitute a principal branch of its commerce. The city of the same name, which is the usual residence of the bishop, is 80 leagues from Santa Cruz de la Sierra; it is very thinly inhabited, though in other parts of the jurisdiction there are several populous towns. Juan and Ulloa's Voyages to S. America, vol. ii.

Masquerade, or Mascarada, an assembly of perfons masked or disguised, meeting to dance or divert themselves. This was much in use with us, and has been long a very common practice abroad, especially in carnival times.

The word comes from the Italian mascarata, and that from the Arabic maskara, which signifies raiIlery, buffoonery. Granacci, who died in 1543, is said to have been the first inventor of masquerades. Encyclopædia.

Masquinonge, in Geography, a lake of Canada; nine miles N.W. of Montreal. N. lat. 47° 10'. W. long. 74° 10'.—Also, a river which runs into this lake.

Masrakitha, a pneumatic instrument of music among the ancient Hebrews, composed of pipes of various sizes, fitted into a kind of wooden chett, open at the top, and flapped at the bottom with wood covered with a skin. Wind was conveyed to it from the lips, by means of a pipe fixed to the chett; the pipes were of lengths musically proportioned to each other, and the melody was varied at pleasure, by flapping and unflapping with the fingers the apertures at the upper extremity.

Masri, in Geography, a town of Peru, in the province of Kerman; 160 miles E.N.E. of Sirgian.

Mass, Massa, in Mechanics, the matter of any body cohering with it; i.e. moving and gravitating along with it. In this sense, mass is disinguished from bulk or volume, which is the expansion of a body in length, breadth, and thickness.

The mass of any body is rightly estimated by its weight. And the masses of two bodies of the same weight are in a reciprocal ratio of their bulks.

Mass, or Maffe, Miffa, in a religious sense, denotes the office, or public prayers made in the Romish church, at the celebration of the eucharist.

Nicod, after Baronius, observes, that the word comes from the Hebrew, mifchab, oblatum; or from the Latin, missa, missarium; because, in former times, the catechumens and excommunicated were sent out of the church, when the deacon said, ite, mifsa off, after sermon, and the reading of the epistle and gospel; they not being allowed to assist at the confection. Menage derives the word from mifsa, deificating; others from mifsa, mission, sending; because, in the maüs, the prayers of men on earth are sent up to heaven.

Romish divines define the mass, an oblation made to God, wherein, by the change of a sensible object by virtue of a divine institution, the sovereign dominion of God over all things is acknowledged.

This they esteem the greatest and most august ceremony in use in the church; as being the sacrifice of the new law, wherein the body and blood of Jesus Christ are offered up to God.

They are divided about the question, whether or no it be proper or allowable for the same perfon to celebrate masses several times in one day? Having the authority of pope Leo, in his letter to Dioscorus, for the affirmative side of the question, and that of several of the councils for the negative.

There is a great variety of masses in the Romish church; the thing acquiring new titles and appellations, according to the different rites, intentions, and manners, in which it is performed, as well as other circumstances. Thus they have a

Mass, Ambrosian, celebrated according to the rite of St. Ambrose; particularly used in Milan. See Ambrosian.

Mass, English, was the form which anciently obtained in England.

Mass, Gallican, is the rite that formerly obtained in the churches of France.

Mass, Greek, is that rechaed according to the Greek rites, in the Greek language, and by Greek priests.

Mass, Latin, is that used in the Latin church, in the Latin tongue, and according to the rites of the Latin church.

Mass, Mozarabic or Gothic, is that which was formerly celebrated in Spain, the rites of which are still practised in the churches of Toledo and Salamanca.

Mass, High, called also grand mass, is that sung by the choristers and celebrated with the assistance of a deacon and subdeacon.

Mass, Low, is that wherein the prayers are all barely rehearsed, without any singing, and performed without much ceremony, or the assistance of any deacon or subdeacon.

Mass of the Beata, or our Lady, is that offered to God, by the means and through the intercession of the Virgin.

Mass, Beata, is a mass rehearsed every day, at which the ladies and confreres of the place attend. This is also called the perfomed mass.

Mass, Common, or mass of the community, in a monastery, is celebrated at certain hours, at which the whole body assist.

Masses, Solitary, or Private, were those that were celebrated by the priest alone, in behalf of the souls detained in purgatory, as well as upon some other particular occasions. These masses were prohibited by the laws of the church in the eighth century, but they were a rich source of profit to the clergy. They were condemned by the canons of a synod, assembled at Mentz, under Charlemagne, as criminal innovations, and as the fruits of avarice and flight.

Mass of the Holy Ghost, is that celebrated at the beginning of any solemnity or church assembly, commencing with an invocation of the Holy Ghost.

Mass,
Mass, **Holiday**, is that wherein certain prayers, or lessons, are read, suitable to the day.

Mass of **judgment**, was that wherein a person cleared himself of any calumny, by some proof agreed upon.

Mass for the **death of our enemies**, was a form that obtained a long time in Spain; but it was at length abolished, as inconsistent with Christian charity.

Mass of the **dead**, or *requiem*, is that performed at the request of the deceased; the introit whereof begins with Requiem. In the thirteenth century it was the custom before criminals were carried out to execution, to make them attend at a mass of the dead, rehearsed for the repose of their souls.

Mass, **Parish**, or great mass, is that which the parson is obliged to rehearse to his parishioners on Sundays and holidays.

Mass, **Little**, is that said at private altars, with less ceremony. The first mass is that said at break of day.

Mass of a faint, is that wherein God is invoked by the intercession of some saint.

Thus there are also masses of apostles, martyrs, pontiffs, virgins, &c.

Mass of **fermuty**, was formerly rehearsed at the examination of catechumens, when inquiry was made as to their disposition for baptism.

Mass, **Silent.** See Massa **Bassa.**

Mass, **Dry,** is that where there is no consecration; as that, according to Durandus, where the priest cannot consecrate, by reason of his having said masses before on the same day: or it is that used by the candidates of the priesthood, in order to become acquainted with the ceremonies; as Eckius will have it.

Mass, **Votive,** is an extraordinary mass, besides that of the day, rehearsed on some extraordinary occasion.

Mass of the **pope,** is, that in which there is no consecration of the elements; but after singing some hymns, the bread and wine which were before consecrated are received. This mass is performed among the Greeks, who consecrate the eucharist in Lent only on Saturdays and Sundays. Among the Latins, it is used only on Good Friday.

Mass-books, importing or selling of, and other popish books, incurs a penalty of 40s. by 3 Jac. I. cap. 5, sec. 25.

Mass, **Candle.** See Candle-mass.

Mass, **Childer.** See Childer-mass.

Mass, **Christ.** See Christ-mass.

Mass of pope Julius is a very celebrated picture of Raphael representing the ceremony of the mass in the Vatican, and disdained by its rich and excellent colouring.

Mass, in **Painting**, a technical term of the art, which implies an union of a variety of parts, so as to convey to the eye one undivided impression. It likewise signifies, in its ordinary sense, a large portion of one colour.

Massa, **Anatomy**, a name applied to one of the muscles of the foot, the flexor accessorius digitiun pedis; which is called mappa carnea Sylvii. See Flexor.

Massa, **Duchy of**, in Geography, a small principality, situated near the Mediterranean, between Genoa and Tuscany. This principality, and that of Carrara, were, before the French revolution, annexed to Modena, and were transferred with it to the Cispaline republic. On a subsequent change in 1806, they were given to Lucena.

Massa, a town of the republic of Lucena, and lately the capital of a duchy of the same name; situated on the river Frigida, near the sea. The see of a bishop was driven by a bull of Pius; 53 miles S.S.W. of Modena. N. lat. 44° 2'. E. long. 10° 1', —Alfo, a town of Etruria, in the flat of Sienna, the see of a bishop, suffragan of Populonia. Borsa and lapis lazuli are found in its vicinity; 24 miles S.W. of Sienna. N. lat. 43° 45'. E. long. 10° 53'.

Massa di Sorento, a sea-port town of Naples, in the province of Lavora, having a harbour for small vessels. On the sea-shore is an ancient temple adorned with marble columns, and a Molea pavement. It is now dedicated to St. Peter. It has a high watch-tower, like those along the coast. A little farther is the cape or promontory of Minerva, deriving its name from a temple in honour of that goddess, on an eminence facing Sorento. Seneca calls this temple "Athenaum," as it had been built or consecrated to Pallas, goddess of Athens. On the site of its ruins is a watch-tower: from which medals and vases have been occasionally dug. This cape was fatal to most of the ships of L. Junius's fleet, who, falling to join those of P. Claudius Pulcher, his colleague, which had been defeated by Aedobral, admiral of the Carthaginians, a form against this promontory; and the losses sustained by the two confounded were so great, that the Carthaginians, in consequence of them, became masters of the sea for five or six years; or, till the battle won by C. Lutatius over them, which terminated the first Punic war; six miles S.W. of Sorento.

Massa, a town of Italy, in the department of the Lower Po; 24 miles S.S.E. of Ferrara.

Massa, a town of Fenz; eight miles S. of Salee.

Massac Creek, a river of America, in Kentucky, which runs into the Ohio, N. lat. 36° 47'. W. lat. 89° 25'.

Massac Fort, a fort built by the French on the W. bank of the Ohio, near its mouth in N. lat. 37° 15', 11 miles below the mouth of Tenessee river. A considerable quantity of land above and below the fort is annually inundated.

Massaccio, a town of Italy, in the marquisate of Ancona; 18 miles S.W. of Ancona.

Massachusetts Proper, constituting with the district of Maine (which see), one of the United States of America, is situated between 41° 15' and 43° 52' N. lat. and between 69° 50' and 73° 10' W. long. Its greatest length is 190 miles, and its greatest breadth 90 miles; in its whole extent it contains 6250 square miles. On the N. it is bounded by Vermont and New Hampshire; E. by the Atlantic ocean; S. by the Atlantic, Rhode island, and Connecticut; and W. by New York. This part of Massachusetts is divided into twelve counties, which, with the number of houfes, inhabitants, and chief towns in each, are exhibited in the following table.
The capital of this state is Boston, which fee; its population is about sixty persons for every square mile, and this is the only state in the union in which there are no slaves. The western part of this state is somewhat mountainous and hilly, and its climate resembles that of New England, to which we refer. By an admeasurement made by the barometer at Princeton, in this state, about 45 miles N.W. from Boston, and at Cambridge, in the year 1775, it appears that Princeton is 133 feet higher than the level of the sea. The summit of Wachusett mountain in Princeton was found to be 2989 feet above the same level, and may be seen at the distance of 60 miles.

In Massachusetts are to be found all the varieties of soil, from very good to very bad, capable of yielding all the different productions common to the climate, such as Indian corn, rye, wheat, barley, oats, hemp, flax, hops, potatoes, field beans and peas, apples, pears, peaches, plums, cherries, grapes, &c. That part of the state which is distinguished by the name of 0 or Plymouth Colony, including the counties of Barnstable, Duke's, Nantucket, Bristol, and Plymouth, in point of soil, is the poorest part of the state, being generally sandy and light, imperfectly, however, with many excellent tracts of land. The northern, middle, and western parts of the state, have, generally speaking, a strong good soil, adapted to grazing and grain; very similar to the soil of New Hampshire and Vermont on one side, and to that of Rhode Island and Connecticut on the other. It has been observed that the effects of the east winds extend farther inland than formerly, and injure the tender fruits, particularly the peach, and even the more hardy apple. The average produce of the good lands, well cultivated, has been estimated as follows: 50 bushels of corn on an acre, 30 of barley, 2 of wheat, 15 of rye, 200 of potatoes. The best cultivated and most productive part of the state lies in the vicinity of Boston. Cambridge, Newton, Roxbury, Dorchester, and Dedham, are laid to be literally gardens, from which the inhabitants of the capital are principally supplied with the finer fruits, roots, and vegetables. The staple commodities of this state are fish, beets, lumber, &c. The chief towns of this state, besides Boston the metropolis, are Salem, Newburyport, Charlestown, Wobcester, Northampton, Springfield, Plymouth, Ipswich, &c. The country is well watered by a number of small rivers, some of which fall into Connecticut river, which passes farther through the W. part of the state; others run northward to Merrimack river, which enters from New Hampshire, and waters the N.E. corner of the state; others pass into Connecticut and Rhode island; Myklick and Charles rivers fall into Boston bay; and others fall into the Atlantic ocean in different parts of the sea-coast. The only capes of considerate note on the coast of this state, are cape Ann, on the N. side of Massachusetts bay, and cape Cod on the south. Besides these, there are cape Malabar, or Sandy point, extending ten miles S. from Chatham towards Nantucket, cape Poge, the N. point of Chucksquidick, and Gay Head, the west point of Martha's Vineyard. The chief bays on the coast are Ipswich, Boston, Plymouth, cape Cod or Barnstable, and Buzzards. The islands scattered along the coast are numerous; the principal of which are Plum island, Nantucket, Martha's Vineyard, Elizabeth island, and Edgartown, which includes the fertile island of Chucksquidick; besides which there are many small islands in Boston bay. Within the state are several light-houses. Locks and canals in various parts of the state have been objects of contemplation; such as one between Barnstable bay and Buzzards' bay, another between Boston and some part of Connecticut river; and some others, all of which remain to be completed. The locks and canals in Connecticut river were projected for the purpose of rendering this river passable for boats and rafts from the mouth of Chickapee river, northward, throughout the commonwealth. By a subsequent law, two separate corporations have been formed; the one called the Upper Canals for improving the navigation of the river between the mouth of Deerfield river, and the head of the Miller's falls; the other, called the Lower Canals, for improving the navigation of the river between the head of the falls at South Hadley and the mouth of Chickapee river.

Iron ore, in immense quantities, has been found in various parts of this state, particularly in the old colony of Plymouth, which has become the seat of the iron manufactures. In the towns of Taunton, Bridgewater, Middleborough, &c., nails have been made in such quantities as to prevent a great measure, the importation of them from Great Britain. The
Copper in the 17th, literary, life, France, cents. There was a ditto 1795, the false entitled reported market 1804.

1790; the Value distinguishing lands, 1799, these dwelling-houses besides schools, and the produce of the whole that belongs to the United States. Upwards of 29,000 tons are employed in carrying on the fisheries; 46,000 in the coaling business, and 95,000 in trading with almost all parts of the world.

Pot and pearl ash, flax, flaxseed, bees-wax, &c. are carried chiefly to Great Britain, in remittance for their manufactures; mails and provisions to the East Indies; fish, oil, beef, pork, lumber, candles, &c. are carried to the West Indies, for their produce, and the two first articles, fish and oil, to France, Spain, and Portugal; roots, vegetables, fruits, and small meats, to Nova Scotia and New Brunswick; hats, saddlery, cabinet work, men's and women's shoes, nails, tow-cloth, barleys, hops, butter, cheese, &c. to the southern ilates. The Negro trade was prohibited by law in 1788, and there is not a single slave belonging to the commonwealth.

The principal sources of revenue are land and poll taxes, and the sales of new lands. Taxes are levied on all males upwards of fifteen, except such as are exempted by law; also on the number of acres of improved and unimproved land, on dwelling-houses and barns, ware-houses, stores, &c. These are all valued, and upon this valuation taxes are laid, at the rate of so many pounds for every 1000.

In January 1805, the funds and expenditures of the commonwealth, as received from the treasurer, were as follows, viz:—

| Amount of public debt, funded and un- | 1,000,000  |
| funded, nearest | 00 |

Funds of the commonwealth, as estimated January, 1805—

| In United States Stocks, 6 per cents. | 701,225  |
| 3 per cents. | 6 per cents. | 701,225  |
| deferred, at par value, | 701,225  |
| dols. | 618,421  |
| Value at market prices, January 1805; as reported to the legislature | 618,421  |
| Amount of bonds and notes due, for sale of lands, | 100,000  |
| (good for not more than) | 100,000  |
| $1 capital stock of the Union Bank | 400,000  |
| $5 ditto of the Bank of Boston | 600,000  |
| Dividends 7 to 8 per cent. per annum | 1,718,421  |

Annual expense for the support of government, estimated January, 1805, nearly 175,000 dols.

The constitution of the commonwealth of Massachusetts established in 1780, contains a declaration of rights and a frame of government. The declaration affords the natural freedom and equality of men;—Liberty of conscience;—Freedom of the press;—Trial by jury;—Sovereignty and independence—that all power is in the people—that hereditary honors and emoluments are inadmissible—that every subject is entitled to protection of life, liberty and property—and, in return, must obey the laws and pay his proportion of the common expense—that he shall not be obliged to accuse himself; but may be heard in his own defense—that he may keep arms; but standing armies shall not be maintained in time of peace—that no tax shall be levied without the consent.
content of the people by their representatives—that no ex post facto law shall be made—that the martial law shall ex-
tend only to men in actual military service—that the legisla-
tive, executive, and judiciary powers shall be kept distinct, 
&c. By the frame of government, the power of legislation is lodged in a general court, consisting of two branches, 
viz. a senate and a house of representatives, each having a 
negative upon the other. They meet annually on the last 
Wednesday in May. No act can be passed without the ap-
probation of the governor, unless two-thirds of both branches 
are in favour of it after a revision. Either branch, or the 
governor and council, may require the opinion of the ju-
tices of the supreme judicial court, upon important ques-
tions. Senators are chosen by districts, of which there 
cannot be less than thirteen. The number of council-
ors and senators for the whole commonwealth is forty; 
the number in each district is in proportion to their 
public taxes; but no district shall be so large, as to have 
more than six. 
Sixteen senators make a quorum. The 
representatives are chosen by the several towns, accord-
ing to their numbers of rateable polls. For 150 polls one 
is elected; and for every addition of 225, an additional one. 
Their travelling expenses, to and from the general 
court, are defrayed by the public, but their wages for 
attendance are paid by their own towns. Impeachments, 
for misconduct in office, are made by the representatives, 
and tried by the senate; but the judgment can go only to 
removal from office and future disqualification. Money 
bills originate in the house of representatives, but may be 
altered by the senate. Representatives are privileged from 
arrests on mfeine proced. Sixty members make a quo-
rum. The supreme executive authority is vested in a go-

vernor, who is elected annually by the people, and has a 
council consisting of the lieutenant-governor, and nine gen-
tlemen chosen out of the forty, who are returned for 
councillors and senators. Five councillors make a quo-
rum. The governor is commander of all the military 
force of the commonwealth. He may convene the gene-
ral court, may adjourn them, when the two branches may 
disagree about the time, and in their recess, may prorogue 
them from time to time, not exceeding ninety days—may 
pardon convicts, but the legislature alone can grant par-
don before conviction. He commissions all officers, and 
with the advice of the council, appoints all judicial offi-
cers. Military officers are their appointees; the respective 
companies choose their captain and subalterns, who choose 
their regimental officers, who choose their drillers. The 
major-generals are appointed by the general court. 

Justices of the peace are commissioned for seven years; all other 
judicial, and all executive and military officers continue 
during good behaviour, yet are removable by the governor 
on address of the legislature. The salaries of the go-

vernor and justices of the supreme court cannot be dimi-
nished, although they may be enlarged. Official qualifica-
tions are as follows: for a voter, twenty-one years of age, 
one year's residence, a freehold of three pounds an-
nual value, or sixty pounds of any other estate—for a re-
presentative, 100l. freehold, or 200l. other estate, and one 
year's residence in the town—for a senator, 300l. free-
hold, or 600l. other estate in the commonwealth, and five 
years residence in the district—for governor, or lieutenant-
governor, 1000l. freehold, and seven years residence. Every 
governor, lieutenant-governor, councilor, senator, or repre-

sentative, must declare that he believes the Christian religion, 
and has the legal qualifications. A governor, lieutenant-
governor, or justice of the supreme court, can hold no other office. No man shall hold two of these offices, judge 
of probates, sheriff, regifter. No justices of the supreme 
court, secretary, attorney-general, treasurer, judge of 
probate, instructor of Harvard college, clerk, regifter, 
sheriff or custom officer, can have a seat in the legislature. 
The privilege of habeas corpus cannot be suspended more 
than a year at one time. In 1795; if two-thirds of the 
qualified voters desire it, a convention shall be called to 
revise the constitution. This period is now past; a vote 
for a revision could not be obtained; a convincing proof 
that the people feel themselves happy under their present 
government. 

The militia of Massachusetts is composed of all the able-

bodied white male citizens from 18 to 45 years of age, 
excepting from the enrolment, within those ages, clergy, 
school-masters, civil officers of importance, either under the 
state or federal government, and also those who have held 
any military commission whatever. The whole is formed 
to eleven divisions, which, in January 1805, comprised 58,879 infantry, 2679 cavalry, and 2581 artillery. These 
divisions are subdivided into 22 brigades, 90 regiments of 
infantry, 59 troops composing 18 squadrons or battalions of 
cavalry; and 54 companies of artillery: the latter are 
armed each with two light brahs pieces attached to the 
brigades, with tumbrills and apparatus complete; and have 
charge of various other heavy field-pieces, stationed all 
along the sea-coast. There is an annual return made of 
the whole militia to the adjutant-general, who makes out 
duplicate abstracts for the governor, and for the president 
of the United States. 

The religion of this state is established by their constitu-
tion on a liberal and tolerant plan. All persons, of what-
ever religious profession or sentiments, may worship God 
agreeably to the dictates of their own consciences, unmo-
elled, provided they do not disturb the peace. The great 
body of the people are Congregationalists, professing Cal-
vinistic doctrines; but some are avowedly Armenians, and 
some Unitarians; and, as Morfe says, the latter it is fuppofed 
are increasing. Morfe's Geog. vol. i. 

Massachusetts Fort, a fort of America, on the bor-
ders of Vermont and New York; nine miles S. of Ben-
ning-ton. 

Massachusetts Sound, on the N.W. coast of America, 
is situated on the southern side of the Quadrant ile. 

Massaciolic!, a town of the republic of Lucca; nine miles S.W. of Lucca. 

Massacre Island. See Maona. 

Massacre River, a river of Hifpaniola, which runs into 
the sea on the N. side of the island, N. lat. 19° 45'. W. 
long. 72° 3'. 

Massada, in Ancient Geography, a fortrefs of Palestine, 
in the tribe of Judah, situated on the mountain Achelis, N. of 
the town of Ziph, was built by one of the Maccabees. 
At the time of the reduction of Judea, A. D. 73, Flavius 
Silva, governor of Judea, made an expedition against ths 
fortress. It was in the possession of Eleazar, a commander 
of the Sicarii. He was a descendant of Judas, who had 
perfidiously many of the Jews not to submit to the affliction 
made by Cyrenius, when he came into Judea, after the re-
moval of Archelaus. When there was no method of 
ecapeing, Eleazar called together the principal persons, 
and consulted with them what might be best to be done; 
at which time he addressed them with an oration, in order to in-
duce them to kill themselves rather than to fall into the hands 
of the Romans. This oration had great effect on many; 

fome
fame, however, hesitated; but in the progress of his address, all were persuaded. They then chose ten men of the number, by lot, to play the rest. When these ten men had executed their commission, and slain men, women, and children, they cast lots upon themselves, and he who had the lot killed the other nine, and then himself. There remained, however, one ancient woman, and another woman related to Eleazar, who exceeded most women in knowledge and prudence, and five children, who had had themselves in a cave under ground: they had carried water with them for their drink, and lay quiet there, while the rest were intent upon the slaughter of each other. The whole number of these people, the women and children julit mentioned, was 960. This slaughter was made on the 15th day of April, A.D. 73. Josephus.

MASSAFRA, in Geography, a town of Naples, in the province of Otranto; 19 miles N.W. of Otranto.

MASSAGANO, a town of Angola, and capital of a province, to which it gives name, on the Coanza; 106 miles E.S.E. was, latitude 1° 53' S.; longitude 17° 44' W.; distance 14° 40' W.; ancient province, inhabited by a people of Asia, who inhabited the country on the west of the Caspian sea, and who imitated the free Scythians in their habit, manner of living, arms, and warlike genius; but they used, besides bows and arrows, javelins and cymetars. Brars freed them instead of feel for making their offensive weapons, and their defensive armour was ornamented with gold. Their horses were likewise fenced with a brest-plate of brafs, whilft their bridles and other furniture were adorned with gold; for silver and iron were not used by them, because their country did not produce these metals. Although every man was obviousto marry a wife, yet they held them all in common; so that when a man met with a woman to his liking, he took her into his chariot or waggon, and cohabited with her without any further ceremony, than hanging up his quiver at the head of it. This custom, Herodotus tells us, was unjustly attributed to all the Scythians by the Greeks, whereas it was peculiar to the Massagetes only. A more inhuman custom than this was adopted by them, according to this author, when a man had once attained the old age, which was not so much limited by law as inferred by occurring symptoms, all his relations met, and sacrifice him, together with a number of cattle of several kinds, and having boiled the flesh altogether, they fit down to it as a feast. This kind of death was accounted by them the most happy, as that of dying by sickness was reckoned unfortunate, because those who died in this way were buried, instead of acquiring the honour of being sacrificed to their gods, and feasted upon by their nearest relations, and intimate friends. The fun was the only deity they worshipped, and to him they sacrificed horses, which, being reckoned the noblest and swiftest of all creatures, they thought most proper to be offered to the noblest and swiftest of all the gods. They neither fowed nor planted; but contented themselves with the milk and flesh of their cattle, and with fish, of which the Iaxartes afforded a very great plenty. Herodotus, book i. cap. ult. and lib. iv. cap. 172. Anc. Hist. vol. iv.

MASSAGONG, in Geography, a small island in the East Indian sea, near the east coast of Naffan. S. lat. 3° 8'. E. long. 100° 5'.

MASSALAGEM, Nef, a sea-port town of Madagascar; on the coast. S. lat. 16° 30'. E. long. 63° 10'.

MASSALAFON, Old, a sea-port town of Madagascar, on the coast; 60 miles N. of New Massalagem.

MASSALIANS, MASSALIANI, in Ecclesiastical History, certain sectaries, so called from a Hebrew word, signifying prayer; it being their distinguishing tenet, that a man is to be continually in prayer.

St. Epiphanius distinguishes two kinds of Massalians, the ancient and the later.

The ancient, according to him, were neither Jews, Christians, Samaritans, but pure Gentiles; who, owning several gods, adored only one, whom they called Almighty.

As to the later Massalians, who were by profession Christians, their rite was not till about the time of St. Epiphanius. Their doctrine was, that prayer alone was sufficient to salvation. Many monks, who loved a life of laziness, and were averse from labour, at times, joined these Massalians. See Euchites.

MASSANDRA, in Geography, an island of Africa, on the river Coanza; 24 miles from its mouth.

MASSANI, in Ancient Geography, a people of India, who, among others, were subdued by Alexander, according to Quintus Curtius. They inhabited a territory near the mouth of the river Indus.

MASSANIELLO, or ANELLO Thomas, in Biography, a fisherman of Naples, a remarkable leader of revolt, which was caused on account of some unreasonable impositions in the shape of taxes. His father was a fisherman, and he was brought up to the same business, and was at a very early period distinguished among his companions by his courage, his activity, and integrity. From his person and manners he obtained the esteem and love of all who knew him. At the time when this obnoxious tax was introduced, viz. in the year 1647, Massaniello was twenty-four years of age, and had a wife and several children. His wife had been detected in smuggling a small quantity of meal for the support of her infant offspring, and had not only been imprisoned for the offence, but condemned to pay a large fine, for the discharge of which they were obliged to sell their furniture. Exasperated both on his own, and the public account, Massaniello excited his friends to afflict him in driving away the officers: they were soon joined by the populace, who demolished all the tax-offices throughout the city, and then demanded the abolition of the tax itself. They not only carried their point, but obtained the offer to their leader, Massaniello, of a large pension, which he nobly refused. These concessions, instead of restoring order in the city, left it at the mercy of the mob; and at the instigation of some of the malecontents, Massaniello was induced to issue a command for burning the houses of all persons concerned in levying the tax, which was very readily executed. He then required the viceroy to abolish all taxes of every kind. This, and other concessions being allowed, Massaniello soon found himself at the head of a vast body of men, and exercised uncontrolled sway. He spent little time in refreshment or repose, gave his orders with precision and judgment, and appeared free from all personal views of interest or ambition; he began, however, to govern with more severity, and put to death several persons upon mere surmises. The viceroy, apprehending left the French should take advantage of this confusion, entered into a treaty with Massaniello, granting everything that had been demanded, and agreeing that he should retain his power, and the people their arms. This success was his ruin; intoxicated with power, and deterred by the constant agitation of his mind, he became frantic, and performed all sorts of extravagant actions, to which an end was put by his assassination, on the 18th of July, only ten days after his extraordinary elevation. Every indignity was shown to his body; but in the course of a few days, the very rabble who had joined in throwing it into the common sewer, upon a temporary rise of provisions, exclaimed.
it, and carried it through the streets in solemn procession, and gave it a magnificent burial. Mod. Vienn. Hill.

MASSAPA, in Geography, a town of Africa, in the country of Mocaranga; 230 miles N.W. of Sofia. S. lat. 18° 10'. E. long. 32° 10'.

MASSARIA, Alexander, in Biography, a physician of celebrity in the sixteenth century, was born at Vicenza, and graduated at Padua, where he studied under Fallopio, and the other eminent professors of that school. He then returned to his native place, where he practiced his profession, with considerable reputation, for the space of twenty-five years; when his fame had recommended him to the magnificence of Venice, whether he was invited; and he settled there in the year 1578. Nine years afterwards, when Hieron. Mercurialis quitted his professorial chair, and removed to Bologna, Massaria was immediately appointed his successor. He performed the functions of his new office with considerable eclat, and attracted a large concourse of pupils; and at the same time was consulted by the first people of the state. He died suddenly in the year 1598, when upwards of seventy years of age. He was the author of several works; especially a treatise on the plague, on the abuse of blisters, on the proper use of blood-letting and purging in fevers, (in which he opposed the indeterminate recommendation of that practice into which Bo- talius had fallen); and also on the diseases of women, and on typhus. The work, which has been most frequently reprinted, was his "Practica Medica, seu Predictiones Academica;" a systematic treatise on the diseases of the whole body; first published at Francfort, in 1694. Eloy Dill. Hist. de la Médecine.

MASSAYLIANS, in Ancient Geography, a people who inhabited the interior of Mauritania Cafariensis, on the mountains called Durus.

MASSAT, in Geography, a town of France, in the department of the Arriéres, and chief place of a canton, in the district of St. Girons; nine miles W. of Tarascon. The place contains 7,456, and the canton 12,157 inhabitants, on a territory of 177½ kilometres, in four communes.

MASSEYDAY, a bay on the W. coast of Mexico, between Acapulco and Aquacara, a port near the cape of California, where Sir Thomas Cavendish lay after he had passed the straits of Magellan.

MASSEL, a town of Sileia, in the principality of Oels; three miles N.E. of Tschiritz, having near it an eminence called Tappelberg, which was once a famous pagan burying ground.

MASSERANO, a town of France, in the department of the Siena; lately the capital of a papal state, infalted in Piedmont; 49 miles N.N.E. of Turin. N. lat. 45° 39'. E. long. 8° 19'.

MASSETER, in Anatomy, a powerful muscle belonging to the lower jaw: it is described in the article Disloca- tion.

MASSUEBE, in Geography, a town of France, in the department of the Gers, and chief place of a canton, in the district of Mirande; nine miles S.E. of Mirande. The place contains 1,850, and the canton 11,215 inhabitants, on a territory of 220 kilometres, in 36 communes. N. lat. 43° 25'. E. long. 0° 39'.

MASSEY'S ISLAND, a small island in the Pacific ocean, discovered in 1790 by lieut. Ball; S.S.W. of Sirius island.

MASSEY'S TOWN lies on the northern bank of Ohio river in America, between Little Miami and Scioto rivers.

MASSI, a people of Africa, on the banks of the lake Meravi.

MASSIA, a river of Mexico, which runs into the Pacific ocean. N. lat. 16° 30'.

MASSAC, a town of France, in the department of the Cantal, and chief place of a canton, in the district of St. Flour; 14 miles N. of St. Flour. The place contains 2,722, and the canton 9,870 inhabitants, on a territory of 2534 kilometres, in 15 communes.

MASSIANAC, a town on the E. coast of Madagascar. S. lat. 22° 52'. E. long. 47° 55'.

MASSICOT. See Massicourt.

MASSIESBURG, in Geography, a town of America, in the state of Ohio, and county of Adams, situated on the northern bank of the Ohio, 38 miles below the Scioto, or fix miles above Limetown, in Kentucky, settled in 1790. About 10 miles above it is a thriving town, built on the N. bank of the Ohio, incorporated in 1802.

MASSIEU, William, in Biography, a man of letters, was born at Caen in 1665. When he had finished his school studies, he was entered among the Jesuits, but in a short time he disengaged himself from the trammels of the society, and became a distinguished member of the French Academy and the Academy of Inscriptions and Belles-Lettres. In 1740 he was nominated Greek professor in the college royal, a post which he retained till his death in 1772. He was profoundly skilled in the ancient languages, of which he gave proof by his various publications: of these the chief were "Memoirs of the Academy of Inscriptions," and "Histoire de la Poésie Françoise," which ranks very high, on account of its curious researches. Moretti.

MASSILARGUES, in Geography, a town of France, in the department of the Hérault; 12 miles E.N.E. of Montpellier.

MASSILLA, Portus Hispalensis (Marseille), in Ancient Geography, a celebrated city of Gaul, in Gallia Narbonensis, and denominated by Cicero the Athens of the Gauls. Livy says that it was as much poliished as if it had been in the midst of Greece. It was as much distinguished for its sciences and arts as for its commerce, and also for the variety and eminence of its colonies. Caesar says that it was almost surrounded on three sides by the sea, and on the other land side very strong, partly by its situation, and partly by a deep ditch, which guarded its ramparts. Strabo says that it was large, encompassed by good walls, and situated on a hill in the form of an amphitheatre above its harbour. This town was founded by a colony from Phocæa, a celebrated city of Ionia. Two perfons were deputed for this purpose, who carried with them a number of persons of both sexes, together with various instruments adapted to the mechanic arts and to agriculture, and also the laws according to which the colony was to be governed. They were directed by the oracle to touch at Ephesus, and to put themselves under the conduct of the person whom Diana should point out to them. A female was warned by Diana of their arrival in a dream, and ordered to take with her one of her statues, and to accompany these strangers. She also took from the temple some of the sacred fire, which was to be perpetuated in the new temple that was to be erected at Marseille in honour of the goddess by whom she was deputed. The first object of their attention to the Phocæans, when they entered the gulf where they were to build this city, was to gain the protection and favour of the prince who reigned in this country. On the day of their arrival the daughter of the prince was to be married; and, according to the custom of the Gauls, the presented a cup of water to the object of her choice. One of the Phocæans engaged her affection and attachment, and to him she presented the figuliative cup. Her father approved.
proved her choice, and assigned to the Phocaeans a portion of land, where they established themselves in the first year of the 45th Olympiad, or the 600th year B.C. Allowing for the mixture of fable and truth in this relation, we may deduce from it the time when the city of Marseille was founded, and the country from which its founders emigrated. Having compassed the new city with walls, and constructed a citadel for its defence, they established a government upon the basis of those laws which they had brought with them, and decreed to Diana of Ephesus, who became the tutelar divinity of Marseille, a particular worship in the temple which they built for her, and of which the female who conducted them thither was the first priestess. Agriculture and fishery were the objects of their attention and the sources of their subsistence; they cultivated the vine and the olive, which were probably the first productions which they transplanted into Gaul. Our limits will not allow our tracing the particulars of their history through the vicissitudes of subseuent centuries. For many ages they were left to have maintained their original simplicity and frugality, and to have distinguished themselves by their hospitality to strangers, and their compassion to the indigent. About 320 years B.C., Pytheas, an ingenious astronomer of this city, undertook to perfect navigation, and to discover the shores of the regions whither his gaze was fixed. With this view he navigated northwards, and on his return, entered into the Baltic sea. About the same time another citizen of similar talents and pursuits, called Euthymenes, examined the western coasts of Africa, and reconnoitred the mouth of the Senegal. These two voyages were undertaken at the expense of the republic. These voyages, and other circumstances, served to extend their commerce and to improve their maritime power. Before the siege of this city by Caesar, it had sent its ships to the Levant, Africa, Spain, and England; and it held a principal rank among republics. During the disputes between Pompey and Caesar, Marseille took part with the former, and refused to open its gates to the latter, though he appeared before it at the head of three legions. Caesar profected the siege of the city, which, after long resistance, and much internal disaffection, was obliged to surrender at discretion. The victor, in consideration of the antiquity of the city, and the celebrity which it had acquired by its culture and the sciences, declared it free and equal for all the Romans. In the year 1717, he was nominated to the bishopric of Clermont, but before his consecration he was called on to preach a course of Lent sermons before the young king, Lewis XV. Believing him to be a faithful prelate, and having obtained the consent of the clergy, he was appointed to succeed him in the see of Aix, which he filled with great success, and with much zeal and learning. His works were collected and published by his nephew, in the years 1745 and 1746, in 14 vols. 12mo. They contain a complete "Course of Sermons for Advent and Lent." "The Petit Carême." "Funeral Orations," &c. Moreri.

MASSIMA, Ital. Maxima, Lat. Magna, the longest note in the first time-table of the early consuls. Its form is an oblong square, with a tail to it, thus: It is equal in duration to two longs, four breves, and eight semibreves.

MASSINA, in Geography. See MASINA.

MASSING, in Painting, the art of producing an union of effect in the various parts of a picture.
Upon the ingenuity with which the smaller parts are united together, either by blending their edges or merely approximating them, and thus forming the larger masses of light, shade, or colour, depends all the beauty of chiaro-fumo, and it can only be agreeably effected by the hand of taste. It has been generally agreed among artists and connoisseurs, that in order to make a picture agreeable it should have three distinct masses of light, one larger, and two smaller ones. The arrangement and scale of them are arbitrary.

The manner employed by Sir Joshua Reynolds to inform himself of the mode in which the great artists of Italy had regulated their works with regard to the general masses, is simple, and so completely effective that nothing farther than a transcript of it need be added for the benefit of those who are pursuing the art. In note 39 to Malou's translation of Fresnay's poem on painting, he says, "When I was at Venice, the method I took to avail myself of their principles was this. When I observed any extraordinary effect of light and shade in any picture, I took a leaf of my pocket-book, and darkened every part of it, in the same gradation of light and shade as the picture, leaving the white paper untouched to represent the light; and this without any attention to the figures. A few trials of this kind will be sufficient to give the method of their conduct in the management of their lights. After a few experiments I found the paper blotted nearly alike. Their general practice appeared to be, to allow not above a quarter of the picture for the light, including in this portion both the principal and secondary lights, another quarter to be as dark as possible, and the remaining half kept in mezzotint, or half-shadow."—"By this means you may also remark the various forms and shapes of those lights; what portion is strongly relieved, and how much united with the ground."—And in note 41 he adds, "the same method may be used to acquire that harmonious effect of colours, by adding colours to the darkened paper, to ascertain the quantity of warm and the quantity of cold colours."—"The predominant colours of a picture ought to be of a warm mellow kind, as red or yellow, and no more cold colour introduced than will be just enough to serve as a ground, or foil to set off, and give value to the mellow colours; and never should itself be a principal. For this purpose a quarter of the picture will be sufficient; those cold colours, whether blue, grey, or green, are to be diffused about the ground, or surrounding parts of the picture, wherever it has the appearance of wanting such a foil; but sparingly employed in the masses of light." For further information on this point, see the articles Clair-obscur, and Effect.

MASSINGALES, in Geography, a place of America, in Sullivan's country, Teneffice, in which is a post-office; 427 miles from Wallingham.

MASSINGER, Philip, in Biography, an English poet and dramatic writer, was born in 1584 at Salisbury. His father, Arthur, was in the service of Henry, second earl of Pembroke, in whose family Philip was probably educated. His college studies: he pursued at St. Albans's hall, Oxford; but it is asserted by Anthony Wood, that in the university he gave his mind more to poetry and romance, than to the studies of the place. He left his college without a degree, and his father being dead, he found no other means of support than the employment of his talents as a writer for the stage. From 1660 to 1662, a space of 16 years, he was fiercely known to the public in the profession he had embraced: he was during that period probably employed in giving assistance to other writers of more celebrity, and there is good reason for believing that he was a conductor to Fletcher in some pieces that bore his name, though he was in such em-harrassed circumstances, as to suplicate the loan of almost the smallest sum to prevent him from being sent to gaol. In the last of the years above-mentioned, his first printed play made its appearance under the title of the "Virgin-Martyr." There are few facts on record respecting the life of Maffinger: it appears, however, that, in his circumstances, he never rose above indigence, and that from his own dedications he would have found it difficult to subsist, had he not received the aid of liberal benefactors. He died of a feverish indisposition in the month of March 1646, and was buried by the side of Fletcher, in the church-yard of St. Saviour's, Southwark. The list given of plays composed either wholly or in part by Maffinger amounts to thirty-eight, of which seventeen only are printed in the most complete edition. They are but little known, nor have any of them the present polishing of the stage, excepting his comedy of "A New Way to pay old Debts," which is sometimes acted. His chief excellence is in tragedy, and according to an approved critic, "it would not be easy to name one of the early English dramatists who has surpassed him in harmony of verse and beauty of language, or in strength of character. His popularity was never equal to that of Shakespeare, Jonson, Beaumont, and Fletcher: his pieces have the irregularity of plot common at that period, with a mixture of low and grofs scenes; the portraits are drawn more from general ideas of his own conception, than from the observation of real nature; and his knowledge of the human heart is much inferior to that of Shakspere, to whom, in some respects, there is a great similarity. His morality is generally pure, though his language is often gross and inde-licite." The best edition of his works is that of Mr. Gifford, in four volumes, 8vo. 1805, to which the reader is referred for a more full account of the author.

MASSINISSA was an African prince of great fame; he was the son of Gala, king of the Maffyis, one of the tribes composing the Numidian nation. In the year 213, B. C. Maffiniss, then about 17 years of age, was sent by his father, who had made a treaty with the Carthaginians, against Syphax, king of another tribe of the Numidians, whom he twice defeated. After this he served at the head of the Numidian auxiliaries of the Carthaginians in Spain, and had a large share in the defeat and death of the two Scipios. When young Scipio had restored the Roman superiority in that country, Maffiniss privately entered into a negotiation with him and became an ally of the Romans; and to his exertions they owed many of their victories in Africa. After the death of his father, his eldest brother, and his nephew, Maffiniss, who had been deprived of his inheritance, obtained succours from Bocchoris, king of Mau-ritania, expelled his competitors, and placed himself on the Maffyian throne. Syphax, dreading his ambition and martial talents, attacked him with a numerous army, and, gaining a signal victory over Maffiniss, obliged him to take refuge on mount Balbus. From this place he made frequent incursions on the adjacent Carthaginian territory, and proved so troublesome, that Syphax sent against him one of his most active commanders, with orders to bring him either dead or alive. He was now under the necessity of conciliating, and actually lived for a time in a cave, supported by the plunder of his two attendants. At length he resolved to make an attempt at recovering his kingdom, and being joined by a number of partisans, he not only recovered the throne of the Maffyis, but was able to make incursions on the dominions of Syphax. In the battle of Zama, Maffiniss greatly contributed to the defeat of the great Hannibal, and the Romans, who had been frequently the spectators of his courage and valour, rewarded his fidelity with
with the kingdom of Syphax, and some of the Carthaginian territories. At his death, Maslinias showed the confidence he had in the Romans, and the high estimation in which he held the Roman and Egyptian talents of Scipio Emilianus, by entrusting him with the care of his kingdom, and empowering him to divide it among his sons. He was more than ninety years of age when he died, and had reigned about sixty years. He experienced adversity as well as prosperity, and in the early periods of his reign he was exalted to the greatest danger, and was, as we have seen, often obliged to save his life by seeking a retreat among his savage neighbours. His alliance with the Romans was the beginning of his greatness, and after this he lived in the highest state of affluence. He is remarkable for the large share of health he enjoyed to the last. "Toward the close of his life he was seen at the head of armies, exerting himself with the most indefatigable activity and ardour, and he often remained for many succasive days on horseback without a saddle under him, or a covering for his head. He aligned the strength of his mind and the vigour of his body, chiefly to the great temperature which he observed. He was often eating brown bread at the door of his tent, like a private soldier, the day after he had defeated Roman armies over the arid plains of Carthage. He left fifty-four sons, of whom three only were legitimate, viz. Micipula, Gallufa, and Marabetal. At his death he was the most powerful prince in Africa, his territories extending from Mauritania, to the western borders of Cyrenaica. His army at this time was numerous and well disciplined, and his treasury was full; he was undoubtedly one of the ablest sovereigns of his age, though little scrupulous in the means which he resorted to for his aggrandizement. Univer. Hiit.

Massisa, in Geography, a town of Attic Turkey, in Aladulla; 12 miles E. of Adana.

Massive, something heavy and solid; a term used in opposition to tenderness and delicacy.

Thus we say, a building is too massive, that is, its walls are too thick; a wall is massive, that is, the lights and openings are too small in proportion.

Massive Column. See Column.

Masson, M. in Biography, author of "A Treatise on Composition" in French, published in 1705, and much esteemed by the learned. He was born at Chalon, in Champagne. This work is divided into two parts; of which the first treat of melody, the second of harmony. The first part contains seven chapters, and the second ten; proceeding from two parts to four, and ending with instructions for composing a fugue.

Masson, John, a learned writer of the reformed church, was born in France, from which, on account of his religious opinions, he was obliged to make his escape, and became a refugee in England. From thence he passed into Holland. In 1708 he published, at Leyden, the lives of Horace and Ovid, in Latin; after this he wrote the life of Pliny the younger, prefixed to a splendid edition of his Epistles, printed at Amsterdam in 1734. In the year 1712 he commenced a work, entitled "Histoire critique de la Republique des Lettres," which he carried to sixteen volumes, 12mo. Masson is, likewise, supposed to be the author of the "History of Peter Bayle, and his Works."

Masson, Francis. " Works," which ranks very high among those who pay by encountering personal difficulties and hardships, with the most indefatigable and disinterested zeal, have promoted botanical knowledge, was born at Aberdeen in August 1741. Whether he was originally educated as a gardener, or at what time he found his way to London, we are not informed. It appears that, having been for some time known to the late excellent superintend- ent of the Royal Garden at Kew, Mr. Aiton, and probably employed under him there, he was fixed upon as a fit person to undertake some botanical expedition, for the purpose of enriching that collection, when the return of the celebrated Banks and Solander from their voyage round the world, gave a popularity and a stimulus to every exertion in favour of natural science. We believe the establishment of a travelling botanist in the king's service, if not suggested by the first-mentioned of these eminent men, was planned entirely under his advice and direction. In 1771 or 1772, Mr. Maffon was dispatched to the Cape of Good Hope. That country had been, for near a century, celebrated as a mine of botanical riches, which had scarcely reached our gardens but through the medium of those of Holland. The works of Hermann, Commelin, Burnmann, Breynius, and others, had sufficiently evinced the abundance of these treasures; but comparatively few of them had been procured in a living state, or cultivated with success, even by the Dutch themselves; and of those but a very small portion had, from the time of the first earl of Portland, when he came over with king William, to our days, come into general cultivation in England. The writer of this work recollects the pleasure which the novel sight of an African Geranium, in Yorkshire and Norfolk, gave him about forty years ago. Now every garret and cottage-window is filled with numerous species of that beautiful tribe, and every greenhouse glows with the innumerable bulbous plants and splendid heaths of the Cape. For all these we are principally indebted to Mr. Maffon, besides a multitude of rarities, more difficult of preservation or propagation, confined to the more curious collections. Many of these perhaps have only survived to bloom once or twice within the walls to which they were first configned; to be defined and named by the skill of a Solander, a Dryander, or of the younger Linnaeus in his transient visit among us, and have then disappeared. Such has unavoidably been the fate with many of the Orchis tribe, for want of our knowledge of their requisite treatment; while many of the Liliaceae have flowered on their arrival, but though their bulbs have continued for many years, they have nothing to do with that which is the object of the gardener, for want of their native acid soil and burning sun. Such deficiencies and disappointments indeed were fiercely felt while Mr. Maffon continued at the Cape, so abundant and replete were his supplies. The Dutch appear not to have restrained his inquiries or acquisitions. He was allowed to travel many hundred miles up the country, and we have often heard him recount his adventures. At length, his harvet having been judged, for the present, sufficiently abundant, he was, in 1776, ordered to explore the Canary islands, the Azores, Madeira, and part of the West Indies, especially the island of St. Christophor. In this mission he employed about five years more, and returned to England in 1781.

During his stay at the Cape, he entered into correspondence with the great Linnaeus. Having discovered a bulbous plant of a new genus, he was not only landfully ambitious of botanical commemoration in its name, but he was particularly anxious, as appears by one of his letters, to receive this honour from no less a hand than that of his illustrious and venerable correspondent. This indeed was the "universal passion," the only reward by which he aspired for all his labours. That he sought no pecuniary advancement, the extreme flenderness of the fipend which could be obtained for him, and his disregard of such objects at all times, abundantly evinced. He obtained the honour to which he aspired. The specimen of Maffon is in the herbarium of Linnaeus.
named by his own trembling hand near the close of his life, proves that the name had his function, though it appears from the *Supplementum Plantarum*, p. 27, to have been originally suggested by Thunberg, in whose company Maffon botanized for two years at the Cape. This justice rendered to the merits of our botanical traveller, was finally crowned by the publication of plates of two species of *Maffoni*, in the *Hortus Kewensis* of his friend Aiton, a book which he had so eminently contributed to enrich, by his discoveries in various parts of the world. Before that book appeared however in 1789, he had, in 1783, visited Portugal and Madeira, and had returned to the Cape of Good Hope in 1786. He now combined experience and foresight with zeal and activity. He was prepared to take advantage of different feasons; in some to collect specimens, in others roots or seeds; so as best to make up for former deficiencies or losses; and he had already made himself acquainted with the various situations, or tracts of country, most promising for every purpose. In consequence of this knowledge, it was settled, in consultation with his able adviser, Sir Joseph Banks, that his travels should now be restrained to within forty miles of the Cape town. That space of country was found to be as yet inexhausted, and almost perhaps inexhaustible, as to what it might afford for our gardens, and the expense as well as labour of the undertaking was, by this plan, greatly lessened.

Mr. Maffon returned to England again in 1795, and spent two years there among his botanical friends, seeing the produce of his exertions every day blooming around him, at Kew and at Hamnermith, his residence at Kennington, placing him within reach of the principal botanic gardens, as well as at a moderate distance from the great theatre of scientific and literary information in Soho square. A life of so much labour soon became irksome, to a man who had been used to so much bodily exertion, and mental recreation, amid the wild and novel scenes of nature, and he solicited another mission. This was obtained from his royal master, at the recommendation of his former friend and patron; and he was sent to explore such parts of North America, under the British government, as appeared most likely to produce new and valuable plants. This was truly a national project, worthy of those who planned it; the vegetable productions of that country, from the hardiness of their constitution, being not merely objects of curiosity, taste, or luxury, but capable of being naturalized among us, for the probable benefit of our arts, our domestic and rural economy, our kitchen gardens and farms, as well as of our shrubberies and parterres. The success of our traveller was equal to the expectations that had been formed. New plants, of interesting characters and properties, sprang up under his lips, and it seemed probable that much practical knowledge was likely to result from his discoveries, even through the experience and converse of the wild inhabitants of those little explored regions. So others have found who have followed Mr. Maffon; for he surived not to reap or to communicate more than a foretaste of these advantages. He died about Christmas, 1805, in the sixty-fifth year of his age, at Montreal, in Canada. What little property he left, fell into the hands of two of his nephews, and confided chiefly of the journals of his various travels, drawings, and collections of dried plants or other natural productions. Some of these relics have been purchased by the present Mr. Lee of Hamnermith, a worthy friend of their original possessor. From him, or from our own personal knowledge, most of the above particulars are derived; the dates only being taken from the short mention of our deceased friend, communicated by the present Mr.

Aiton, to Sims and Konig's Annals of Botany, v. 2. 534. We cannot conclude better than in Mr. Lee's own words. "Maffon was of a mild temper, persevering in his pursuits, even to a great enthusiasm. O. great industry; which his specimens and drawings of fish, animals, insects, plants, and views of the countries he passed through, evince. And though he passed a solitary life, in countries distant from society, his love of natural history never forsook him. Characters like him seem for the present dwindling in the world, but I trust they will revive. If a selection of his *memoranda* would be acceptable to the world, there is matter enough to carry it to a great extent."

Mr. Maffon published, in 1795, a splendid work on the *Sponsor Stereae* consisting of a thin folio volume, with forty-one coloured plates of as many species, almost entirely nondescript, accompanied by descriptions. This volume is dedicated to the king, in the same respectful and feeling style as the first edition of Mr. Aiton's *Hortus Kewensis*; and we think we perceive traces of the same able and judicious pen in both.

**MASSONIA, in Botany, so called in honour of the late Mr. Francis Maffon; see the preceding article.** The younger Linnaeus observes in his *Supplementum*, where the present genus was first published, that he was indebted to Mr. Maffon for all the Canary plants described in that work.—Linn. Suppl. 27. Thum. Gen. 59. Schreb. 416. Willd. 55. Pl. v. 2. 28. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 209. Jull. 52. Lamarck Hist. t. 223. —Clas. and order. *Heraclia* *Monogynia*. Nat. Ord. *Spacents*. Linn. *Afrobbotii*. Jull.

Gen. Ch. Cal. none. Cor. Petals six, inferted on the outside of the nectar, lanceolate, straight, spreading. Nectary inferior, cylindrical, membranous, of one leaf, with six stamens, and as many teeth. Stam. Filaments six, awl-shaped, incurred, equal, rather longer than the petals, inserted into the teeth of the nectar; anthers ovate, incumbent. Pifl. German superior, three-lobed; ilyle thread-shaped, curved; stigma nearly simple. Peric. Capsule trianul, smooth, of three cells and three valves, burling at the angles, which are extended upwards into three short, rounded, erect wings. Seeds numerous, globe-shaped, somewhat angular, smooth.

Eff. Ch. Nectary inferior, tubular. Petal's six, equal, inferted on the outside of the nectar. Capsule with three wings, three cells, and many seeds.

1. *M. latifolia*. Broad-leaved Massonia. Linn. Suppl. 193. Ait. Hort. Kew. ed. 1. v. 1. 403. t. 3. Thum. Nov. Gen. 4. Curt. Mag. t. 946. —Leaves nearly orbicular, depressed, perfectly smooth.—Native of the district of Ruggefeld, at the Cape of Good Hope, where it blooms in September and October. In our greenhouse the flowers are produced in March and April. It was sent to Kew in 1775. The root is a round bulb. Stem none. Leaves two, radical, depressed, spreading widely on the ground in opposite directions, each from three to six inches long, nearly orbicular but somewhat pointed, entire, oblongely ribbed, fleshy, quite smooth; dark green above, with several purple spots towards the extremity; paler and spotless beneath. Flowers numerous, in a sessile radical head or tuft, between the leaves, each flower accompanied by an ovate leafy bractae, about equal to the nectar, or longer. The whole *corolla* is greenish, its petals deflexed. *Stamen* much longer than the petals, fleshy, purple, with yellow anthers.

2. *M. muricata*. Prickly leaved Massonia. Ker in Curt. Mag. t. 559. —Leaves nearly orbicular, depressed, prickly on the upper side towards the point.—Native of the Cape; introduced by Mr. Maffon to Kew garden in 1792. It differs
fers from the soil essentially in the prickles of the leaves. The flowers moreover are white in every part; except the anthers before they burst, and the very timid rim of the nectary, which are of a bluish green. The nectary itself is described by Mr. Ker as brimful of honey, which surely justifies its Linnaean and Thunbergian appellation, though the ingenious author we have quoted, prefers calling it merely the tube of a monocotalous corolla. To us the petals in this genus, as in Narcissus, appear totally distinct in nature and substance, as they often are in colour, from the nectariferous tube.

3. M. seabra. Shagreen-leaved Maffonia. Andr. Repof. t. 220. (M. phyllitia; Jacq. Coll. v. 4 177. Ker in Curt. Mag. t. 642. Redout. Liliac. t. 183.)—Leaves nearly orbicular, depressed, their upper side covered with prominent tubercles.—Sent by Mr. Maffon from the Cape in 1790. It flowers here from January to April, and is said in the Bot. Mag. to be easy of culture as any other Cape bulb. This species has the habit and size of the two preceding, but differs in having in the whole upper surface of the leaves besprinkled with innumerable, small, prominent protuberances, or tubercles. The flowers are of a greenish-white, the rim of the nectary being of a deeper green than the rest. The anthers are broad, and closely laid over each other. Stamens and style tall, slender and white; the stigma minutely three-lobed.

4. M. echinata. Rough-leaved Maffonia. Linn. Suppl. 193. Thumb. Nov. Gen. 41. Ait. n. 4.—Leaves ovate or lanceolate, depressed, their upper side covered with hairy tubercles. Petals very narrow.—Sent from the Cape by Mr. Maffon in 1790. It seems not yet to have found its way, even once, into our periodical publications. It is said in the Hortus Kewensis to flower in May. Thunberg describes the bulb as scarcely five or six as a hazel-nut. Leaves two, ovate, blunt with a point, smaller than any of the former, covered with prominent tubercles and white hairs.

5. M. praecox. Few-flowered Maffonia. Ait. n. 5.—Leaves lanceolate or elliptical, veined, covered with naked tubercles. Petals ovate.—Sent with the three last from the Cape, by Mr. Maffon, in 1790. It is said to flower in May.

6. M. anguiptifolia. Narrow-upright-leaved Maffonia. Linn. Suppl. 193. Ait. Hort. Kew. ed. 1. v. 1. 465. t. 4; Ker in Curt. Mag. t. 736. M. lanceolata; Thumb. Nov. Gen. 40.—Leaves elongate-lanceolate, ascending, smooth. Tube of the nectary long and cylindrical; mouth closed. Found by Thunberg on the summit of the Ooderec Ruggefeld mountain at the Cape, flowering in August, it being there a winter plant. This was sent over with the first species, by Mr. Maffon, in 1775, and flowers here from January to April, increasing by offsets and seeds without difficulty. The leaves differ in their upright position from all the foregoing. They are smooth like \textit{M. latifolia}, but much narrower, and not spotted. The flowers are fragrant like a hyacinth, white, with purple anthers, and a slender tube, twice or thrice as long as the petals, closely cloathed at its mouth by the timid bales of the filaments.

7. M. undulata. Waved-leaved Maffonia. Thumb. Nov. Gen. 41. Ait. n. 7. Wild. n. 3.—Leaves upright, lanceolate, waved, smooth.—Found by Thunberg in the island country above the Cape of Good Hope, and sent by Mr. Maffon, in 1791, to Kew, where it flowers in April. Bulb the size of a hazel-nut. Leaves radical, three, four or five, very narrow in their lower part, lanceolate, waved, erect, about a finger's length. Flowers in a dense umbel, raised upon a common stalk, rather shorter than the foliage.

8. M. resifolia. Trumpet-flowered Maffonia. Ker in Curt. Mag. t. 554. Ait. n. 8. (M. violacea; Andr. Repof. t. 49. Manila enifolia; Thumb. Prod. 60. t. 3. Agapanthus enifolius; Willd. Sp. Pl. v. 2. 48. Polyanthus pygmea; ibid. 105. Jacq. 1c. Or. t. 380.)—Leaves lanceolate, spreading, smooth. Tube of the nectary five times longer than the recurved petals, swelling gradually upward, open-mouthed. Three filaments shorter than the bell. Native of the Cape, where it was gathered by Thunberg and Maffon, but introduced into this country by Mr. Williams of Turnham-Green, who is recorded to have raised it from Cape seeds in 1790 or 1791. It flowers from September to February. The leaves are two only, and most remembrance theofe of \textit{M. anguiptifolia}. The flowers grow in a rather dense, short-stalked cluster, and are of a pale lilac hue, very remarkable for their long, slender, gently-swelling tube or nectary, their minute \textit{braha}, and unequal \textit{flaments}. These circumstances, and the habit of the plant, have caused much difference of opinion respecting its proper genus, and Cavalières, it seems, has made it a \textit{Hyacinthus}, to which the good Senr. of Dr. Sims appears to have devoted him to allent, and we confide ourselves much of the fame opinion. But Mr. Ker has thought otherwise, and he is followed by the editors of the Hort. Kew. Jacquin's excellent figure shows the calyptra to be deficient in the dilatations or wings proper to \textit{Hyacinthus}, nor is there any line of distinction to be drawn between the nectary and petals; which Mr. Ker uses as an argument for considering the nectary and petals as one in the real \textit{Maffonia}, where they appear to us to be very distinct.

We propose our doubts merely for the sake of truth, and by no means for controversy.

\textbf{Massonia}, in \textit{Gardening}, comprises plants of the herbaceous bulbous-rooted flowery perennial kind, of which the species cultivated are, the broad-leaved \textit{Massonia} (\textit{M. latifolia}); and the narrow-leaved \textit{Massonia} (\textit{M. anguiptifolia}).

\textbf{Method of Culture.}—Thee plants may be increased by planting the offsets from the roots, when the leaves drop off, in pots of sandy earth, plunging them in a hot-bed in the flower. And they are likewise capable of being raised from seeds, sown in pots of the same sort of earth, plunging them in a hot-bed in the house.

Afterwards the plants should have a free air in the green house, where they must be kept.

They are capable of affording variety in the collections.

\textbf{Massorah}, in \textit{Geography}, a town of Hindoo-kan, in Bahar; 23 miles E.S.E. of Bahar. N. lat. 53° 37'. E. long. 15° 5'.

\textbf{Massoudi}, in \textit{Biography}, the surname of Aboul Hassen Ali, a celebrated Arabian geographer and historian, descended from Maffon Ebn Maffon, one of the most confidential friends of Mahomet, flourished in the tenth century. He was an author of a work, entitled, according to our translation, "Golden Meadows and Mines of precious Stones," which he wrote in the year 336 of the Hegira. It is an historical and geographical treatise, comprised in two volumes: the first of which commences with the creation of the world, and comes down to the birth of Mahomet; and the second continues the history from that date to the author's time. He is author of another history, entitled "A Register of the Lands of Egypt." Other works are attributed to him, and, among those, the following is the principal: "A History of Infidels at various Times against Lawful Authority, and particularly that of the Chaliphs." He died at Grand Cairo in Egypt, in the year 345 of the Hegira. There was another person of this name, who wrote a history of Syria and Damascus, entitled, according to the English version of it, "The Garden of Syria,"
Syria," and a treatise "On the Conjugation of the Arabic Verbs."

MASSOW, in Geography, a town of Hinder Pomerania; 9 miles N. of Stargard.

MASSOWAH, Mafuah, or Mafuah, meaning, says Bruce, the port or harbour of the shepherds, a small island of the Red sea, near the coast of Abyssinia, in a bay, with an excellent harbour, governed by a chief called the Naybe of Arkeko; which fee. The water in the harbour is deep enough for ships of any size, which may ride in it secure from any wind. It was called by the Greeks "Sebaicum Ox," from the capacity of its port, which is distributed into three divisions. The island itself is very small, nearly three-quarters of a mile in length, and about half that in breadth; one-third occupied by houses; one by cellars or tanks, of which there are about thirty, to receive the rain-water; and the half reserved for burying the dead. When Arabim Felix was conquered by the arms of Selim, emperor of Constantinople, Mafuah was a place of great commerce, possessing a share of the Indian trade, in common with the other ports of the Red sea near the mouth of the Indian ocean. Its exports were brought to it from an inhopecful and almost inaccessible mountainous country behind it: thee consisted of gold and ivory, elephants' and buffaloes' hides, and, above all, slaves. Along its coast were found pearls, considerable for size, water, or colour. As long as commerce flourished, Mafuah continued to be a place of much resort; but it fell into obscurity very suddenly under the oppression of the Turks, who completed the ruin of the Indian trade in the Red sea, which had commenced some years before by the discovery of the Cape of Good Hope, and the settlements made by the Portuguese on the continent of India. The first government of Mafuah under the Turks was by a baahaw sent from Constantinople; but when it ceased to be a place of trade, it was not thought worth while to keep up the expensive establishment of a baahah. In reward for the assistance given to the Turks, when they conquered this place, by a tribe of Mahometans called Belowe, shepherds inhabiting the coast of the Red sea, under the mountains of the Habab, about lat. 14°, the Turks gave their chief the civil government of Mafuah and its territory, under the title of Naybe of Mafuah; who held it, after the baahaw was withdrawn, of the grand signior, for an annual tribute, upon receiving a firman from the Ottoman Porte. The janizaries, established there as a garrison, intermarried with the women of the country; and in consequence of these intermarriages, Moors and natives of Mafuah became mutually related, and always subject to the influence of the Naybe. From motives of policy, it was agreed that one-half of the customs should be paid by the naybe to the king of Abyssinia. Having thus secured the friendship of Abyssinia, the naybe declined paying tribute to the baahaw of Jidda, to whose government he had been subjected by the porte; and he afterwards declined paying a share of the customs to the king of Abyssinia.

Mafuah was found by Mr. Bruce and his companions, as the result of various observations of the sun and stars, to be in N. lat. 15° 35' 5"; and by an observation of the second satellite of Jupiter, September 22, 1769, its longitude was fixed at 39° 36' 20". E. of Greenwich; the variation of the compass being 12° 48' W. As Loheca is nearly opposite, (N. lat. 15° 40' 52'";) the breadth of the Red sea between Mafuah and Loheca is 4° 10' 22'"; and supposing a degree to be equal to 66 statute miles, this breadth, in round numbers, will be 276 miles. The height of the barometer, on the 4th of October, at 6 in the morning, was 25° 8' 2"; at 2 P.M., 25° 3' 9"; and half past 6 P.M., 25° 3' 7"; and the greatest height of Fahrenheit's thermometer, viz. October 22, at 2 P.M., was 93°. Mafuah is very infalubrious, as is the whole coast of the Red sea from Suez to Babelmandeb, but more especially between the tropics, and subject to violent fevers, generally terminating in death on the third day. Fevers generally end in intermitents, and dyfenteries, always tedious and often mortal. Another disease, endemic in this country, is called "banzeer," the hogs or the swine, and is a swelling of the glands of the throat, and under the arms; and another complaint consists of small swellings all over the body, but thickest in the thighs, arms, and legs. Another disorder, common in these countries, is called "Farentett," signifying the worm of Pharaoh, which afflicts those who are in the confuant habit of drinking flagrant water. This plague appears indiscriminately in every part of the body, and most frequently in the legs and arms. This worm is feared by the natives gently by the head, and then wrapped round a thin piece of silk, or small bird's feather. Every day, or several times a day, they try to wind it upon the quill as far as it comes readily; and, upon the smallest resistance, they defit for fear of breaking it. When this operation, which sometimes lasts for three weeks, terminates, the hole or puncture discharges, by prefire, a small quantity of lymph; and in about three days it is healed without a fear. The elephants is also one of the endemic diseases of the country.

At Mafuah it is a general custom for people to burn myrrh and incense in their houses, before they open the doors in the morning; and when they go out at night, or early in the day, they have always a small piece of rag highly fumigated with these two perfumes, which they stuff into each nostril, to keep them from the wholesome air.

The houses in Mafuah are, in general, built of poles and bent grafts, as in the towns of Arabia; but, besides these, there are about twenty of stone, fixed or eight of which are two stories each. At Mafuah all the necessaries of life are scarce and dear, and in quality indifferent. The fame sort of money is in use at Mafuah and the opposite coast of Arabia. It is valued by the Venetian fequin: but glafs beads, called "contaria," of all kinds and colours, perfect and broken, pass for small money, and are called, in their language, "Borjooke."

The harf is likewise called dahab, meaning in Arabia gold, and frequently a fequin. The harf is 120 grains of beads. The trade carried on at Mafuah is considerable, though the island is narrow and confined, and the government unjust and violent. The goods imported from the Arabian side are blue cotton, Surat cloths, and cochineal ditto, called Kermis, fine cloth from different markets in India; cotton unspun from ditto in bales; Venetian beads, crystal, drinking and looking-glasses, and kokhol, or crude antimony. The three last articles come in great quantities from Cairo, first in the coffee-ships to Jidda, and then in small barks to this port. Old copper is also an article by which the gain is great, and a large quantity is imported. The Banians were once the principal merchants of Mafuah; but in Bruce's time they were reduced to fix. They are silver-smiths, that make ear-rings and other ornaments for the women on the continent, and are aflayers of gold; but they make only a poor livelihood. As there is no water in Mafuah, the num-
her of animals belonging to it can be but small. Bruce's Travels, vol. iii.

MASSOWBA, a town of Congo; 10 miles N. of Bombi.

MASSUET RENÉ, in Biography, a learned French Benedictine of the congregation of St. Maur, was born at St. Owen de Mancelles, in the diocese of Evreux, in 1665; he became distinguished for his proficiency in ancient literature, particularly in the writings of the fathers and ecclesiastical antiquities. In 1716 he published a new edition of the works of St. Irenæus, in folio, more correct than any preceding edition, and accompanied with notes and prefaces; he also added to it fragments of each piece of Irenæus, as are no longer extant; and prefixed to the whole are three dissertations, which reflect credit on his erudition, industry, and judgment. The first contains an account of the heresies against whom Irenæus wrote, and of their opinions; the second, a history of his own life, actions, and writings; and the third of his opinions. He was engaged after this, by his superiors, on a continuation of "The Lives of the Saints," and "The Annals of the Benedictine Order." He died in 1716, at the age of fifty. Moreci.

MASSURA, in Geography, a town of Hindooftan, in Bahar; 45 miles S.S.W. of Bahar.

MAST of a Forrest, the fruit of that genus of trees called glandiferous, or mast-bearing; as beech, oak, chestnut, &c.

MAST, in Ship Building, a large pole, or long piece of round timber, laced in vessels, to which are attached the yards, falls, and rigging, in order to receiving the wind necessary for navigation.

The word mast signifies the same thing in French, High Dutch, Flemish, and English; the Italians use the word albero, and the Spaniards maño.

Masts are long fir trees, or several fir trees coaxed or doubled and bolted together, and cylindrically rounded a great part of their length, and, arching sideways, are similar to truncated cones.

Their number depends upon the size and nature of the vessel, some having three lower masts, which are called ships; some have two lower masts, such are brigs and fnoos; others only one mast, such are cutters, floops, and other small trading-vessels. Besides the lower mast, each vessel has a bowspirt; and to complete the necessary heights of the masts, and convenience in many respects, there is attached to the head of the lower-mast, the top-mast, and to the head of the top-mast, the top-gallant-mast, and sometimes to the head of the top-gallant-mast, a small one, called a royal-mast. To these several masts are confined their respective yards and falls, and consequently the rigging for their support.

An attempt has been lately made to introduce four or more masts in vessels; but, upon a very liberal trial, it was found not to answer the purpouses intended; for when the number of masts are multiplied, the yards must be shortened, or they would entangle each other in working. By this, too, the falls would be narrowed, and would receive too small a portion of wind for the force required. If, on the contrary, there is not a sufficient number of masts, the yards would be unmanageable, from their length. Experience, therefore, has proved, that, in large vessels, three lower-masts and a bowspirt, in smaller vessels, two lower-masts and a bowspirt, and in the smallest, one mast and a bowspirt, are the most advantageous number for nautical purpouses.

All large masts, previous to the American war, were made of New England white pine, having been found the highest, and in all respects best suited to the purpose; but since then masts from Riga have been procured. As the largest trees from that country seldom exceed twenty-four inches in diameter, and more frequently from nineteen to twenty-one, a much larger number of pieces was of course used in constructing main-masts. From this circumstance, and the nature of the wood being considerably heavier than white pine, the masts now in use exceed the former ones by nearly one quarter in weight; but Riga masts are considerably stronger than those of New England.

The choice of trees for making masts, yards, &c. to the bell advantage, is of great importance; otherwise much unnecessary waste and expense must occur; and the greater number of trees any mast is composed of, the more judgment is required to fast each tree to the nearest face. The bell method to attain this, is to draw upon a board or piece the several pieces the mast is composed of, similar to the Plate of Masts, &c. Every tree should be carefully examined whether it be found, and should it be not quite straight, if sufficiently large, it might be made straight, in putting the mast together.

The belt position, and indeed the heights of the masts, should be duly considered and ascertained by the constructor or ship-builder, as it is only the business of the mast-maker to make them agreeable to the length or heights belt suitable for the veil to bear, of which the former is the best judge.

The lengths and diameter of the masts, &c. being given, the present method of making a main-mast is as follows. For a ship of 74 guns:

From the butt set up the heights of the decks upon a straight line drawn along the middle, and the given length, which is one hundred and eleven feet; from which set back fix inches for every yard in the length, for the heading and flrop, or reef for the treble trees; and then divide the height of the main-mast, which is the upper part of the hounds; from these set back fix thirty-three inches of the length of the head for the length of the hounds; and from thence, to produce the curve sideways, set off the following diameters: and, first, the given diameter, which is thirty-seven inches, must be set off at the partners, which is at the middle-deck of three-deck ships, and the main-deck of all others, and thirty-eight inches at the upper deck, in order to give the hoop a quicker drift; and this equally from a straight line along the middle: then divide the distance from the upper part of the hounds to the partners into four quarters or equal distances, terming that next the partners the first quarter, the next the second, and so on.

Then set off, as before, at the first quarter, thirty-fix inches and three-eighths, or sixty-sixty-one parts of the given diameter; and at the second quarter thirty-four inches and three-quarters, or fifteen-sixteenths; at the third quarter thirty-two inches and a half, or seven-eighths; and at the lower part of the head, the heartfelt way, thirty-two inches and a half, or seven-eighths; and the fore and aft-way twenty-fix inches and three-fourths, or five-eighths, and at the upper part of the head twenty-three inches and an eighth each way, or five-eighths of the given diameter. The interval between the lower deck to the heel is divided into two quarters, and the fame dimensions set off at the first and second quarters above; lastly, the heel is thirty-one inches and three-quarters, or fix-fixteenths of the given diameter.

Thus a curve passing through these several diameters could give the shape of the mast; and supposing it a single tree, it would only be made circular to those diameters. But large masts now, as before observed, are made of various smaller trees, united strongly together by dovets, &c. and consist of a spindle, side-trees, blees, &c. The spindle is made of one or two trees, doubled and bolted together. (See Plate of Masts.) Its length is five-fixteenths the given length of
of the mast; its breadth or siding two-thirds of the given diameters of the mast, if the trees designed will admit, if not three-fifths, and so continued to the hance of the side-fibres, which is at the middle of the hounds, and above that to the size of the mast at the head. The thwart-ship size of the spindle tapers from a middle line to half the diameter at the flop of the hounds, and is to hance in about three inches on each side, four feet below the butt of the side-fibres, and from thence line straight to half the diameters of the mast at the second quarter, and tapers to half the size of the flop at the butt, and above the butt of the side-trees, the upper part tapers to one-fifth of the diameter at the head.

Side-trees.—Each side-tree is made of a single-tree, or two trees douelled and bolted together; they are sided to the size of the spindle the fore and aft-way. Their breadth athwart-ships, from the heel of the mast to the butt of the spindle, is one-half the diameter of the mast, and continues the fame to the second quarter, deducting the sublance of the spindle. At the third-quarter spindle included, the breadth is three-fourths of the given diameter, and at the hance one-fourth of the breadth of the spindle at the flop of the hounds. Sometimes side-trees are affiled in their length by working heel-pieces, larded underneath at their lower ends. The scars of the heel-pieces should be one-half, or not less than one-third of their length. The side-trees are douelled and bolted to the spindle. The mast, thus far completed, is hewn square to its several diameters before-mentioned, and then eight-squared the thwart-ship way.

The Side-fibres are fawn from one tree cut down the middle, and one-fourth of the diameter of the mast set off on each side for their thickeness. The breadth of the fibres is two-thirds the diameter at the partners, and forty forty-one parts of that breadth at the first quarter, eleven-twelfths at the second, five-sixths at the third, and two-thirds at the upper end, and a parallel breadth from the partners to the heel, they are douelled, and fastened with dumps to the side-trees and spindle. All the surfaces being fir one half payed with tar, they are fet close together.

When the spindle, side-trees, and side-fibres are douelled and bolted together, which is easier comprehended by frequently referring to the Plate of Masts, it is hewn square to its several diameters the fore and aft-way, then eight-squared, and any deficiencies in the angles made good by cant-pieces fayed therein; it is then sixteen-squared, and rounded and planed smooth from the heel to the hounds, except the surface left for douelling on the cheeks, where its flattened for one-third their length. The mast, completed thus far, is hooped with iron, as shewn in the Plate.

The iron hoops are four inches and a half broad, and five-eighths of an inch thick, and the inner edges chamfered to prevent their bruising the mast.

Masts thus far finished are sent to foreign ports, and hence called transportation masts.

Masts of a leffer size may be contructed of two trees, called the upper and lower tree, douelled together in the middle, and bolted: these trees give the diameter, fore and aft, and the upper part, for the reception of the cheeks, is formed as the one above; then, with the addition of the side-fibres, this mast may be so far completed as the former. Then to complete the mast, the

Cheeks must be added; they fashion the head of the mast, and leave a flop for the support of the treble-trees. The length of the cheeks for a main-mast is nine-twentieths of the whole length of the mast; for the fore-mast three-fourths, and for a mizen-mast two-fifths. The length for the head and hounds is agreeable to that first mentioned for the mast. The breadth of the cheeks at the head is two-thirds of the given diameter of the mast, and three-fourths at the flop; and the lower part of the hounds, in the middle between the hounds and lower end, eleven-twelfths of the breadth at the hounds, and at the lower end one-half of the given diameter. The thicknefs of the cheeks is set off from the sides; thus the upper part above the flop to be one-fourth of the given diameter, and a flop left at the upper part of the hounds to project half that thicknefs; the lower part of the hounds to be one inch more than the thicknefs at the upper part of the head, and from thence to line straight to five-ninths of the head at the lower end.

The cheeks are each made of a single tree, or two trees douelled together at the middle, and bolted; the inside of the cheeks is next fayed to the upper part of the spindle, to which they are douelled and bolted, and further secured by iron hoops; the upper hoop to be its breadth below the under side of the cap, another just clear of the treble-trees, and four more equally between; and another hoop its breadth below the flop. Two bolts are to be driven under every hoop, fix bolts in the hounds, and four more below; and the lower parts of the cheeks to be fastened with dumps and nails.

On the fore-side of the mast next below the ch-ck at the heel of the top-mast is a front fish fayed and fastened to the mast. (See the fictions in the plate.) The whole is then firmly woolland together with twelve or thirteen turns of rope between every hoop. And to make a fair surface, flligs of fir are fayed under the woollings next the edges of the front fish.

The Treble-trees for sustaining the top, and confining the heel of the top-mast, are made of oak, in length one-fourth the length of their respective top-mast, deep half the given diameter of the lower-mast, and in thicknefs two-thirds of the depth, fayed and bolted to the lower part of the mast head, refting on the flop, as fhewn in the plate.

The Crofts-trees are oak, in length one-third the length of the top-mast deducting fix inches, breadth what the treble-trees are thick, and their depth two-thirds their breadth; the under lides are tapered from the ends one-fourth their length, and are framed together at right angles, as shewn in the plate.

Bits or Brackets are made of elm, three to five inches in thickness; in length five-sixths the length of the hounds; and in breadth two-fifths of their length, fayed and bolted to the mast, under the treble-trees for their support, as in the plate.

Bellets are pieces of fir fayed on the treble-trees, and again the lides of the mast, between the ful-hole and after-crofts, to project the treble-trees one inch and a half, and the fame in depth. The outer-lides are rounded for the throunds to lay cayf thereon.

The Cap is made of elm, in one or two pieces, douelled together in the middle: the length of the main-cap is four times the diameter of its top-mast, and three inches more; the breadth is half the length, and the depth half the breadth. Fore and mizen-caps are the fame of their respective top-masts, adding two inches to the fore, and one inch only to the mizen. The cap is fixed on the mast-head by a squire tenon; the mortise or squire hole in the cap is made rather less than the tenon, to allow for its shrinking. Four eye-bolts are driven through the cap from the under-side, and well chocked on plates of one inch and three-quarters diameter, or less in proportion to the size of the cap, one on each side the squire hole, and the other by the side of the round hole which is before the squire hole, two-fifths of the diameter of the round hold, and half the tapering of the mast-head.
head in its length. The size of the hole is the given diameter of its top-mast, and three-quarters of an inch more, as it is lined with leather.

Lastly, a tenon is made at the heel of the mast, by which it is fixed in the hole: its size fore and aft is one-half the given diameter, and athwart-masts two-thirds, and of sufficient depth, as in the plate.

Masts made of single trees are finished in a similar manner, but having to check the flop for the root of the trellise-tree is made by the bobs or brackets. Merchant ship's masts are sometimes treed, but heaved only. Top-masts have their several sizes or diameters cut equally from a straight line along the middle of their length, which is for the 74-gun ships 66 feet. From the butt end set up once and a half the diameter, which is 20 inches, for the block below the heel, and twice and a half the diameters above that: for the heel, and from the lower part of the said heel, the length of the lower mast-head, or place of the cap, where the given diameter, 20 inches, is set off. Then from the whole length set back five inches for every yard in the length, for the length of the head and flop of the hounds, for main and fore-top-mast, and four inches for mizen-top-masts, and three-fifths that length below it for the hounds; these are divided from the lower part of the head to the cap into four quarters: that next the cap is the first quarter; then set off, as before, 10 inches and five-eighths, or sixty-five-thousandths of its given diameter; at the second quarter, 13 inches and five-eighths, or fourteen-fifteenth; at the third quarter, 17 inches and one-eighth, or six-fifteenths; at the lower part of the hounds, 16 inches and one-quarter, or three four-fifths; at the head, 18 inches, or nine-tenths; at the lower part of the head, 14 inches square, or seven-tenths; and at the upper part, 11 inches square, or five ninths.

The aft-sides of top-masts are lined straight, the heel to be square, and large enough, if the tree will admit, to fill up the trellise-trees at the lower mast-head, and to hance from the upper part to the diameter of the cap, and to be eight-square, or nearly so. The block below the heel to be eight-square, and of the same size as the diameter at the cap, with an iron hoop driven on the heel. The flop above the hounds on the fore and after-sides: to come up to the under-sides of the cross-trees; the hounds are left eight-square, and all below the hounds to the under-side of the main-cap is to be smoothly rounded. Sheave-holes for the top-rope are mortised through, one in the heel, and one in the block below it; their length rather more than the depth, and their thickness two inches for every foot in length. A groove to bury the top-rope is made in each angle, in the direction of the lower heave-hole.

The side-heave is a square mortise, cut through the middle of the heel; the size of the side-hole, which is in length once and a half the given diameter of the lower-mast, its depth one-third the given diameter of the top-mast, and its thickness two-thirds its depth, made of iron; but when made of wood, the depth is half the given diameter of its top-mast. A hole is made through one end for a laniard, and the other is framed.

Top-mast trellise-trees: their length is three inches and a half to every yard in the length of their top-mast, in depth one inch and one-eighth to every foot in their length, and two-thirds their depth in thickness. Each cross-tree is cut shorter than the trellise-tree, their depth seven-eighths the depth of the trellise-tree, and are framed and bolted together as in the plate; with a sheave-hole mortised through the fore-end of the main, and two sheave-holes in each end of the fore-top-mast trellise-trees.

Vol. XXII.

The top-mast cap is so similar to its topmast as the lower cap to its respective main, that it needs only a reference to the plate.

Mizen-top-masts differ but little from the former: they have no block, but the heel is set up from the butt, and, instead of a square head, have a long pole head about four times the length of the square head. They have a fixed hole mortised through the hounds, fore and aft, for the top-lalt-tree, and one a little above the flop, for the layfall-handles, and one a little below the track, for the mizen-gallant-trees.

Top-gallant-masts are made similar to mizen-top-masts: if to carry royal masts, the heads are square like a main-top-mast, but mostly made with pole-heads; if a gallow pole-head, the fame as a square head; if a common pole-head, its length is two-thirds the given length; and if a long pole-head, it is two-thirds the given length.

Royal masts are made similar to gallow-head top-gallant-masts.

Bowsprits are rarely made of one tree, but are made of many, similar to made-masts: if made of two trees, they are fixed to two-thirds the diameter of the bow-sprit the thwart-ship way, and each tree is one-half the diameter fore and aft, and doubled together in the middle, and bolted, and the deficiency made good athwart-masts by side-fiddles: consequently each side-fiddle must be in thickness one-fourth the diameter, and are doubled and bolted to the sides, as may be readily seen in the mast-plate. Bow-sprits made of single trees have a line straight along the middle, upon which is set up the length from the butt, which is 68 for a 74-gun ship; next set off the bed, which is three-tenths of the length set up from the butt, and fix inches added. Set back from the length four inches for every yard in the given length for the long square on the upper side, and one-third that for the short square on the under side; then from the bed to the outer end divide it equally into four parts, and that next the bed is the first quarter, and so on. At the bed set off equally from the middle line the given diameter, which is 35 inches; and at the first quarter, 34 inches and one-quarter, or sixty-fifth ones of the given diameter; at the second quarter, 32 inches and one-eighth, or seventwelfths; at the third quarter, 28 inches or four-fifths; at the outer end, 19 inches and a half, or from the; and at the heel, 35 inches or six-fifteenths. It is then fixed these diameters with a fair curve, and sawn square, then eight-squared, next sixteen-squared, and, finally, rounded from the heel to the square at the outer end. At the heel is a ten-inch, three-fifths the given diameter athwart-sprit, and two-thirds up and down, tapering one inch in the length, which is onethird the given diameter.

The bow-sprit-cap is made of elm, in length the diameters of the jib-boom, the breadth twice the diameter of the jib-boom, and half the diameter of the jack-raft, and the thickness four-fourths the breadth. In the lower part of the cap is a mortise to fix on the tenon at the outer end of the bowsprit, and a hole at two-eighths the diameter of the bowsprit above it, for the jib-boom to slide through, leaving half the diameter of the jack-raft on the forward side, where a groove is made to receive the same; bolts are then driven through the cap, as in the plate.

Beams are made of elm, about four inches thick, to breadth three-fifths of the given diameter of the bowsprit, and in length from the aft-side of the cap to the athwart-part of the long square. They are let in, one on each side, one-third into the trellis into the bowsprit; their upper sides are kept flush with the upper side of the bowsprit, and the outer edges raised above the level three inches to every foot in breadth,
MAST.

Breadth, and are bolted through the bowsprit with four bolts. A block is fitted with a heave-hole in each end, under each eye, as in the plate.

Saddles are pieces of elm fastened on the upper side of the bowsprit; that for the jib-boom is half the given diameter in length, and one-twelfth in thicknefs, and nails on the bowsprit at one-fifth the length within the outer end. A faddle to lead in the running-rigging is similar to the latter, having holes the size of the ropes bored through it, and nails on the bowsprit just before the gammoning.

Bowsprits of small vessels have an iron hoop with an eye on each side, and one on the upper side; it is let on and fastened at the outer end. A heave-hole is cut through at the heel, and one at the outer end.

The Jib-boom is prolonged from the bowsprit, has a straight line struck along the middle of its length, which is 50 feet 6 inches for a 74-gun ship: one-third of that length is set up from the butt, and at that place set off 14 inches and a half, the given diameter; and from thence to the outward end divide into four equal parts, and at the first quarter set off 14 inches and one-eighth, or forty-four of the given diameter; at the second quarter, 12 inches and one-quarter, or eleven-twelfths; at the third quarter, 12 inches and one-eighth, or five-sixths; and at the outer end, nine inches and three quarters, or two-thirds the given diameter. It is first squared to those diameters, then eight-squared; then set up from the heel three times and a half the given diameter, and from thence it is to be round to the outer end. Make a stop at once and a half the diameter within the outer end, and cut a heave-hole through from the upper side half its length within the stop, and another heave-hole at once and a half the diameter from the heel, and through the middle of the flatboard square, and a hole bored through between that and the heel, as in the plate.

Masts of wrought-iron have lately been proposed thus: the cylinder to be half an inch thick, and the fame height and diameter as the fir mast, will not be so heavy, will be considerably stronger, much more durable, less liable to be injured by shot, and be easily repaired even at sea. It will weigh only 12 tons, and, at 45£ per ton, will not cost more than 540; while its strength will be nearly 50 per cent. above that of a fir mast, that weighs 23 tons, and costs nearly 1200. This mast is made to strike nearly as low as the deck; to ease the ship in a heavy sea. Ships furnished with fir masts are, in such circumstances, obliged to cut them away. Ships furnished with iron masts will not, like others, be exposed to the risk of receiving damage from lightning; the iron mast of itself being an excellent conductor. By using an iron bolt from the heel of the mast, through the keelson and keel, the electric matter will be conducted through the bottom of the ship into the water, without injury to the ship. Bowsprits and yards may also be made of wrought-iron, at the same proportion of strength and expense as the mast.

Masts and yards, particularly the latter, by a patent of Mr. Smart's were proposed to be made hollow, of wood somewhat similar to the flaves of a cafe.

Gordon, in his Naval Architecture, has recommended masts to be made in a curious manner of several small trees to be united together by a sort of brackets at certain distances. The former have been actually tried, but their not coming more into practice seems to make against their utility.

By the above tables of lengths and diameters of masts, yards, &c. may be easily ascertained the relative lengths they bear to each other, and their diameter in inches to their respective yards in length.

The length of the main-mast, in most ships, is governed by the length and breadth of the ship. Thus: let the length at the load-water line from the rabbit of the flenn to the rabbit of the flenn-post be added to the extreme breadth, and half that sum is the length of the main-mast. But for very sharp-bodied ships take seventeen-twentieths of the above sum for the length of the main-mast. Then for the length of the fore-mast take nine-tenths of the main-mast, and in some ships more. For the bowprit take three-fifths of the main-mast, and in some ships more, and so on of the others, as may be seen by inspecting the table.

Mast, Armad, one that is made of more than one tree.
Mast Carlings, are large square pieces of oak timber placed into the beams at the sides of the mast rooms, for the purpose of framing the partners.
Mast, Heel of. See Heel.
Mast, Jury. See Jury.
Mast Rooms, the spaces between those beams where the masts are fixed.
Mast, Spreading a, at Sea, is when it is broke by foul weather.
Mast, Springing a, is when it is cracked in any place.
Mast Bay, in Geography, a bay on the N. side of the island of Jamaica; E. of Montego bay and near Catlin’s cliffs.
Mast Island, a small island in the Indian sea, near the coast of Africa. S. lat. 1° 28'.
Masts, in Rural Economy, a provincial term applied to acorns in some districts, but improperly. It is sometimes pronounced mofs.
Masta, in Geography, a small island in the Adriatic. N. lat. 44° 7'. E. long. 17° 23'.
Mastai, a town of Japan, on the S. coast of Nippon; 20 miles S.W. of Meaco. N. lat. 34° 46'. E. long. 134° 30'.
Mastasa, a town of Fez; 40 miles W.N.W. of Velez de Gomera.
Mastassin Lake, a lake of North America, at the head of Rupert’s river, which falls into James’s bay; it is about 200 miles in circuit, and intersected by projections of land.

Masted. A ship is said to be masted, when she has all her masts complete.
Masted, Over, or Tausta-masted, is said of a ship whose masts are either too long or too big; which makes her lie too much down by the wind, and labour too much a-hull.

Masted, Under, or low-masted ships, such whose masts are either too small, or too short; in which case the cannot bear fo great a fail as should give her true way.

Masted, a title given to several officers and persons of authority and command; particularly to the chief of the orders of knighthood, &c.

Thus we say, the grand-masted of Malta; of St. Lazarus; of the Golden Fleece; of the Free Masons, &c.
Masted, Magister, was a title frequent among the Romans; they had their matter of the people, magister populi, who was the dictator. Matter of the cavalry, magister equestrium, who held the second post in an army, after the dictator. Under the later emperors there were also matters of the infantry, magister pedum. A matter of the cenusa, magister cenusa, who had nothing of the charge of a cenfor, or subcenfor, as the names seem to intimate; but was the same with the praefectus frumentariorum.
Masted of the Military, magister militum, was an officer in the lower empire; created, as it is said, by Dioclesian, who had the inspection and government of all the forces, with power to punish, &c. somewhat like a constable of France.
At first there were two of these officers instituted, the one for the infantry, and the other for the cavalry; but the two were united into one under Constantine. Afterwards, as their power was increased, so was their number also; and there was one appointed for the court, another for Thrace, another for the East, and another for Illyria. They were afterwards called comites, comites, and clarissimi. Their power was only a branch of that of the praefectus praetorio, who by that means became a civil officer.
Masted of Arms, magister armorum, was an officer, or comptroller under the matter of the militia.
Masted of the Officers, magister officorum, had the superintendence of all the officers of the court; he was also called magister officii peditum; simply magister; and his post magisteria. This officer was the same in the western empire, with the eunuchates in the calender.
Masted, in the Roman history and laws, is used for every officer who is the chief of his kind; and has others of the same species, or that have the same functions, under him. In Latin, magister, and oftentimes praefectus, or praetorius.
Masted of the Armory, is an officer who has the care and oversight of his majesty’s arms and armory.
Masted at Arms, is an officer appointed to teach the
officers and crew of a ship of war the exercise of small arms; to confine and plant centinels over the prisoners, and superintend whatever relates to them during their confinement. He is also to observe that the fire and lights are all extinguished as soon as the evening-gun is fired, except those which are permitted by proper authority, or under the inspection of the centinels. It is likewise his duty to attend the gangway, when any boats arrive aboard, and search them carefully, together with their rowers, that no spirituous liquor may be conveyed into the ship, unless by permission of the commanding officer. In these several duties he is assisted by proper attendants, called his corporals, who also relieve the centinels, and another, at certain periods. Falconer.

**Master of Arts**, the first degree taken up in foreign universities, but the second in ours; candidates not being admitted to it till they have studied in the university seven years. See Degree.

**Master-Attendant**, is an officer in the royal dock-yards, appointed to hail, and assist at, the fitting out or dismasting of vessels or securing vessels of war, &c., at the port where he resides. It is particularly to observe that his majesty's ships are securely moored, and for this purpose he is expected frequently to review the mornings, which are sunk in the harbour, and observe that they are kept in proper repair. It is also his duty to visit all the ships in the ordinary, and see that they are frequently cleaned and kept in order; and to attend at all the general matters in the dock-yards, taking care that all the officers, artificers, and labourers, registered at the navy-books, are present at their duty. Falconer.

Master, Barrack. See Barrack.

**Master of the Ceremonies**, an officer instituted by king James I., for the more solemn and honourable reception of ambassadors, and strangers of quality, whom he introduces into the presence.

The badge of this office is a gold chain and medal, having on one side an emblem of peace, with king James's motto; and on the reverse the emblem of war, with *Dies & mon dolce*. He is always supposed to be a person of good address, and matter of languages, and has an appointment of 300l. a-year; he is constantly attending at court, and hath under him an assistant master or deputy, at 6l. 8s. 4d. a day; who holds his place during the king's pleasure.

There is also a third officer, called *warder of the ceremonies*, with 100l. a-year, whose business is to receive and distribute the master's orders, or the deputy's, for the service: but, without their order, he can do nothing. This is the king's gift.

**Masters of Chancery** are usually chosen out of the bar- risters of the common law; and sit in chancery, or at the rolls, as assistants to the lord chancellor, and master of the rolls. All these, too late as the reign of queen Elizabeth, were commonly doctors of the civil law. To them are also committed interlocutory reports, examination of bills in chancery, listing of accounts, taking oaths, &c., and sometimes, by way of reference, they are empowered to make a final determination of causes. They have, time out of mind, had the honour to sit in the lords' house, though they have neither writ, nor patent to empower them; but they are received as assistants to the lord chancellor, and master of the rolls. They had anciently the care of inspecting all writs of summons, which is now performed by the clerk of the petty-bag. When any meilage is sent from the lords to the commons, it is carried by the masters of chancery. Before them also affidavits are made, and deeds and recognizances acknowledged. See CHANCELLOR and COURT of CHANCERY.

Besides these, who may be called masters of chancery ordi- nary (being twelve in number, whereas the master of the rolls is reputed the chief), there are also masters of chancery extra ordinary, appointed to act in the several counties of England beyond ten miles distance from London, by taking affidavits, recognizances, &c. for the ease of the suitors of the court.

**Master of the Faculties**, an officer under the archbishop of Canterbury, who grants licences and dispensations: he is mentioned in the statute 22 & 23 Car. II. See Court of Faculties.

**Master-Gunner of England.** See Gunner.

**Master of the Horses**, a great officer of the crown, to whom is committed the charge of ordering and disposing all matters relating to the king's stables, races, and breed of horses, with a salary of 1200l. 13l. 4d. a-year. He hath a power of commanding the equestrians, and all the other officers and tradesmen employed in the king's stables; to all which he gives by his warrant to the avenor, the oath of allegiance, &c. for the faithful discharge of their duty. He has the peculiar privilege of making use of any horses, pages, or footmen, belonging to the king's stables; so that his coaches, horses, and attendants are the king's, and have the king's arms and livery.

There is also a master of the horses in the establishment of her majesty's household, with a salary of 500l. a-year. See Master of the Household.

Anciently the lord steward himself was called grand-master of the household.

**Master of the Jewel Office**, is an officer of the king's household, who has the charge of the gold and silver plate used at the king's table, or at that of any officer attending the court, and of all plate remaining in the Tower of London; as also of chains and lordly jewels not fixed to any garment. See Jewel-Office.

**Master of the Mint.** was anciently the title of him who is now called *warden of the mint*; whose office is to receive the silver and bullion which comes to the mint to be coined, and to take care thereof. The office of master and worker is now distinct; and this officer is allowed for himself 500l. a-year, and for three clerks 205l. each. There is also the king's assay-master, allowed for himself and clerk 35l. a-year; and the master's assayer-master, with a salary for himself and foreman of 125l. a-year.

**Master of the Ordnance.** See Ordnance.

**Master of the Revels** is an officer with an appointment of 200l. a-year; who has the care of all things relating to the performance of plays, masques, balls, &c. at court. Formerly he had also a jurisdiction of granting licences to all who travel to act plays, puppet-shows, or the like diversions; neither could any new play be acted at either of the two houses till they had paid his perusal and licence; but these powers were afterwards much abridged, not to be annulled, by a statute for regulating playhouses, till the licentiate plays by the lord chamberlain was established. This officer was a yeoman, with 40l. 11s. 4d. per annum.

**Master of the Robes.** See Robes.

**Master of the Rolls**, a patent officer for life; who has the custody of the rolls and patents which pass the great seal; and of the records of the chancery. In the absence of the lord chancellor, or keeper, he also sits as judge in the court of chancery; and is, by sir Edward Coke, called his assistant.

At other times he hears causes in the rolls-chapel, and makes orders and decrees. He is also the first of the masters
of chancery, and hath their assent at the rolls: but all
hearings before him are appealable to the lord chancellor.

He hath also his writ of summons to parliament, and, like
next to the lord chief justice of England, on the second
wool-pack: he hath the keeping of the parliament-rolls, and
has the rolls-house for his habitation; as also the custody
of all charters, patents, commissions, deeds, and recognizances,
which being made of rolls of parchment, gave rise to the
name. Anciently he was called clerk of the rolls.

Concerning the authority of the master of the rolls to
hear and determine causes, and his general power in the
court of chancery, there were (not many years since) divers
questions and disputes very warmly agitated; to quiet
which, it was declared by Stat. 3 Geo. II. cap. 30, that
all orders and decrees by him made, except such as by the
course of the court were appropriated to the great final
alone, should be deemed to be valid; subject nevertheless
to be discharged or altered by the lord chancellor, and so
as they shall prove involved, till the same are signed by his
lordship.

Blackit. Com. vol. iii.

In his gift are the six clerks in chancery, the examiners,
three clerks of the petty-bag, and the six clerks of the
rolls-chapel, where the rolls are kept. See Rolls,
CLERK, &c.

Master of a Ship, an officer to whom is committed the
direction of a merchant vessel, who commands it in chief,
and is charged with the merchandizes abroad.

In the Mediterranean the master is frequently called
patron, and in long voyages captain.

It is the proprietor of the vessel that appoints the master,
and it is the master who provides the equipage, hires the
pilots, sailors, &c. The master is obliged to keep a re-
gister of the seamen and officers, the terms of their con-
tract, the receipts and payments, and, in general, of every
thing relating to his commission.

Master of a Ship of War, is an officer appointed by the
commissioners of the navy, to take charge of navigating a
ship from port to port, under the direction of the cap-
tain. The management and disposition of the sails, the
working of a ship into her station in the order of battle,
and the direction of her movements in the time of action,
and in other circumstances of danger, are also more par-
ticularly under his inspection. It is likewise his duty to
examine the provisions, and accordingly to admit none
into the ship but such as are found sweet, and wholesome.
He is moreover charged with the flowage; and for the
performance of these services, he is allowed several assistants,
who are properly termed mates and quarter-masters.

Master of the Temple. The founder of the order of
the Templars, and all his succedors, were called magni
templi magistri; and ever since the dissolution of the order,
the spiritual guide and director of the house is called by
that name. See TEMPLE and TEMPLAR.

Master or Keeper of the Wardrobe, an officer in the lord
chamberlain's department, who has the direction of all the
royal robes, as those of the coronation, St. George's sacal,
and the parliament-robe; as well as of the wearing apparel,
collar of SS's, George and Garter, &c.

He has also the charge and custody of all former kings' and
queens' robes, remaining in the Tower; all hangings,
bedding, &c. for the king's house; and the charge and
delivery of velvet and feather allowed for liveries.
He has under him a groom and two clerks, a yeoman,
&c. See WARDROBE.

There are also several other officers under this denomina-
tion, as the master and conductor of the band of music,
whose salary is 300l. a-year; master of mechanics, with a
salary of 200l. a-year; master of the tennis-court, with a
salary of 120l. a-year; master of the barges, with 100l.
a-year; master of the barrows, with 2000l. a-year; master
of the buck-hounds, with 234l. a-year; master of the
flag-hounds, with 2000l. a-year; master-falconer, with 210l.
a-year, &c.

MASTER, Burgier. See BEUGHER.

Masters, Burgier. See BEUGHERMASTERS.

Masters, Fire. See FIRE.

Masters, Quarter. See QUARTER.

Masters-arch. See ARCH.

Master Load, in Mining, a term used to express the
larger vein of a metal, in places where there are several
veins in the same hill. See LOAD.

Master-pieces, an exquisite, or extraordinary work, or
performance, in any art or science.

Master-pieces, chef d'œuvre, is particularly used among
the French, for a work which those who aspire to be ad-
mitted master of any art or trade, are to perform in pre-
ence of the masters, or jurands, of that company, by way
of specimen of their capacity.

Master-vault. See VAULT.

Master-court, in Botany. See IMPERATORIA.

Master-court, Black. See ASTRANTIA.

Master-warm, a large yawn, sometimes remaining after
salivation. See YAWS.

MASTICA de Saba, in the Materia Medica, the name given
by the Indians to the stone commonly known among authors
by the name of Pedro del porco, a sort of bezoar taken out of
the gall-bladder of an Indian boar. The Indians, and
many of the European nations, esteem this one of the
greatest medicines in the world in peatisfical diseases, and
the small-pox.

MASTICATION, in Physiology, is the operation of
chewing, in which, by the motion of the jaws and teeth, the
food is brought into, a flat in which it can be swallowed.
The action of the teeth comminutes the harder kinds of
food, and the fluids, poured into the mouth from the falli-
vary glands, by their admixture, soften the food thus
communized. This proceeds, and the instriments con-
cerned in its performance, are described in the article De-
glutition.

MASTICATORIES. Masticatoria, in Medicinae,
are such remedies as are taken in at the mouth, and
chewed in order to promote the evacuation of the falsal
humor: as tobacco, ginger, pepper, sage, rosemery,
thyme, maltich, &c.

MASTIC. See Coleoarous CEMENT.

Mastic-tree, Turpentine-tree, or Pistachia-nut-tree, in Bo-
tany. See Pistachia lentiscus.

Mastich, in the Materia Medica, a resinous substance
that is obtained from the Pistachia lentiscus, which is a na-
tive of the south of Europe and the Levant, and which
appears by Evelyn's Calendarium Hortense to have been
cultivated in Britain in 1666. It is obtained, most abun-
dantly, according to Tournefort, by making transverse inci-
sions in the bark of the tree about the beginning of Augut,
from which the mastic resin, or gum, exudes in drops,
which running down and concreting on the ground, are
then collected for use. The time choosen for making
these incisions is the first of August, when the weather is
very dry: in the following day the mastic begins to appear
in drops, which continue to exude till the latter end of
September. The tree is rated also in several parts of
Europe; but no resin has been observed to issue from it in
these climates. It has its name mastic, from magistari, to
cheew, because it is thus used in Seio, and by the Turks, es-
pecially the women, for sweetening the breath, and strengthen-
ing the gums and teeth; and by producing a copious ex-
cretion
ertion of salvia, it proves serviceable in cachectic dis-

orders.

According to Olivier, (Travels in the Ottoman Empire,) mastic is gathered in 21 villages of the island of Scio; and the incisions, he says, are made from the 15th to the 20th of July, according to the Greek calendar. Cloths are frequently placed under the tree, so that the mastic which trickles from it may not be impregnated with earth and filth. By the regu-
lations made in the island, the first gathering cannot take place before the 27th of August. It lasts eight successive days, after which fresh incisions are made in the trees till the 25th of September, and then the second gathering is made, which likewise lasts eight days. After this time the trees are cut no more, but the mastic which continues to run is gathered till the 15th of November on the Monday and Tuesday of every week. It is afterwards forbidden to gather this production. This production in the 21 villages of Scio, amounts, one year with another, to 50,000 oke, and even more. Twenty-one thousand belong to the aga who farms this commodity, and are delivered by the cultiva-
tors in payment of their personal impost. They are paid for the surplus at the rate of 30 para per oke (nearly 16 fous the pound), and they are prohibited, under very severe penalties, from selling or disposing of it to any other than the aga who farms it. That of the belt and flint quality is sent to Constantinople, for the palace of the grand vizier. That of the second quality is intended for Cairo, and paffes into the harem of the Mamalukes. The merchants generally obtain a mixture of the second and third quality.

This resinous substance is brought to us in small yellowish transparent brittle grains or tears. A piece recently broken is quite transparent, but by exposure to the air it becomes superfluously somewhat pulverulent, and hence femintra-

tent. Its specific gravity is 1.074. By digestion with alcohol it is separated into two portions; the one soluble in this fluid, and the other insoluble: the former composes about 7ths of the whole, and is pure res; the latter in most of its properties closely resembles caoutchouc. The presence of this sub-
stance in mastic was first remarked by Kunde, an apothecary of Berlin, whose observations have since been confirmed by Mr. Matthews. After solution of the resin in alcohol an inflammable residue is left behind of a white colour, considerably elastic and adhesive; when heated it becomes brown, emitting an inflammable gas, and in this state greatly resembles common caoutchouc, except in being slightly glutinous. It is perfectly soluble in washed sulphuric ether, from which it is precipitable by alcohol in the form of a white curd. It is wholly insoluble in water. By digestion with nitric acid it is converted into a yellow brittle porous mass, nitrous gas being at the same time given out; it is charred by sulphuric acid, to which it communicates a deep (homewhat muddy) crimson colour, with the evolution of sulphurous acid. Neither the muriatic nor oxynitratic acids, nor the alkalies, whether caustic or carbonated, have any action on it: in all which particulars it agrees with caoutchouc.

It has a light agreeable smell, especially when rubbed or heated. It is almost totally soluble in spirit of wine, yielding a solution of a pale yellow colour, but not at all in water. Diluted with water, it yields a small proportion of a hing essental oil, in fumel very fragrant, and in taste moder-
ately pungent. Rectified spirit also brings over in dilution the more volatile odorous matter of the mastic. It becomes soft and tough like wax, being chewed. Mastic is recommended in doses from half a scruple to half a drachm, as a mild corroboreant and astringent, in old coughs, haemoptyes, diarrhœa, weak spots of the stomatch, &c. It is given either in fulness, divided by other mate-
rials; or diffused in spirit and mixed with syrups; or dissolved in water into an emulsion, by the intervention of gum arabic or almonds. It is also an ingredient in var-
ishes. See VARNISH.

The jewellers mix mastic with turpentine and ivory-
black, and lay it under their diamonds, to give them a lu-

The Lentisci lignum, or wood of this tree, is received into the Materia Medica of some of the foreign phar-

macopists, and is highly esteemed in dyspeptic, gouty, hemorrhagic, and dysenteric affections. Lewis, Wood-

to.

The Arabian writers, Avicenna and Serapion, in their chapters of the turpentine-tree, often mention the lentisc and its resin, which they lay was very much like the resin of the common turpentine-tree. But besides this, Avicenna has a peculiar chapter on mastic; whence it should seem, that by the name lentisk they do not mean the tree which produces mastic, but some peculiar species of the turpen-
tine-tree.

Avicenna distinguishes two kinds of mastic, the one called rumi, and the other capti: the rumi came from the island of Scio, and was white; the capti was of a blackish colour, and

Mastic, Indian. See SCHINUS.

A decoction of the bark of this tree makes a fomenta-
tion of extraordinary efficacy in pains of the legs, and in-
fiammations. Of the small branches are made efficacious tooth-
picks. Of the fruit boiled in water, according to the mea-
ure of the decoction, they prepare either a wine, a very good sort of drink, vinegar, or honey. A decoction of the leaves gives relief in pains proceeding from cold caules. See Chin. Herb. Plant.

Mastic, Syrian herb, warum Syriacum, is a species of

Teucrium; which see. See GERMANBERG.

Mastiche TURKA, maffich earth, a name given by some of the old writers on the materia medica to the Chio or Scio earth, or terra Chia. The reason of this strange appellation seems to have been, that the finest mastic coming from the island of Chio, had obtained the name of Kir, or Chat, and mastiche and Chia being thus become, in one sense, syn-

onymous words, the use of them was, in this manner, car-
ried much farther, and the earth of that island called by the name of the guma.

The Arabiansem mean to explain this very well, in their name of this earth; they not calling it maffich earth, but ibis belis mastiche, that is, terra regionis maffichis, the earth of the country where mastic is produced.

Masticot, Massicot, or Yellow Lead, is the yellow oxiey of lead. (See LEAD.) It is sometimes used by pain-
ters, and it serves medicinally as a drier in the composition of ointments or plasters.

The mastic which is used by the Dutch as the ground of their glazing, is prepared by calcining a mixture of one hundred weight of clean sand, forty-four pounds of soda,
fold with us under the name of barilla, and thirty pounds of pearl-onions.

**MASTIFF-Dog**, or **Badz-dog, villaticus, or catenaerus**, is a species of great size and strength, and a very loud Barker. Mr. Wood says, that it derives its name from maff thefis, being fuppofed to frighten away robbers by its tremendous voice. Great Britain was formerly fo noted for its maffifs, that the Roman emperors appointed an officer in this ifland with the title of **Procurator Cynicus**, whose fole buifnefs was to breed and tranfmit from hence to the amphitheatref, ufe as would prove equal to the combats of the place. Strabo, lib. iv. tells us, that the maffifs of Britain were trained for war, and ufed by the Gauls in their battles. See Dog.

**MASTIGADOUR**, or **Slabbering-bit**, in the **Magne**, is a fnaifle of iron, all smooth, and of a piece, guarded with pater noders, and comphofed of three halves of great rings, made into demi-ovals of unequal bifegs, the lefter being included within the greateft, which ought to be about half a foot high. A maftigadour is mounted with a headflall and two reins. A horse by chafing upon the maftigadour, keeps his mouth ftreth and mollified.

To put a horse to the maftigadour, to fet his group to the manege, and his head between two pillars in the fable. Hores that ufe to hang out their tongues cannot do it when the maftigadour is on; for that keeps their tongue too much in fubjeftion, that they cannot put it out.

**MASTIGON**, in Geography, a river of North America, which runs wellward into lake Michigan, about 11 miles N. of La Grande Riviere. At its mouth it is 150 yards wide.

**MASTIGOPHORI**, M. *gazogogo*, among the Greeks, certain officers appointed to preferve the peace, and correct such as were disorderly at the Olympic games.

**MASTIH**, in Geography, a town of Persia, in the province of Kerman; 140 miles E.N.E. of Sigirian. N. lat. 29° 16’. E. long. 59 40’.

**MASTOIDES**, *Mastoideus*, *Msoifoid*, in Anatomy, epithets applied to a certain procefs of the temporal bone, and to parts situated near, or connected with, it. In old writers, the bone altogether is fometimes called os mafoides. The large nipple-like procefs of the bone, behind the ear, is always diftinguished by that name, and the portion of the bone including it is called the mafoid portion. (See **Cranium**.) The cells by which it is excavated, are the mafoid cells. Mafoides is the name given by Albinous and others to part of the mafele defcribed in this work under the article **Sterco-cleido-siantoidea**.

**MASTRE, L.**, in Geography, a town of France, in the department of the Ardche, and chief place of a canton, in the district of Tournon; 15 miles N. of Privas. The place contains 2090, and the canton 11,873 inhabitants, on a territory of 170 kilometres, in nine communes.

**MASTUR.**, a town of Arabia Petraea, on the borders of the Red Sea; 92 miles S.W. of Medina. N. lat. 23° 54’.

**MASVAUX.** a town of France, in the department of the Upper Rhone, and chief place of a canton, in the district of Belfort; nine miles N. of Belfort. The place contains 2181, and the canton 9404 inhabitants, on a territory of 1934 kilometres, in 18 communes.

**MASUCO, or Mascon.** a town of Portugal, in the province of Tras los Montes; 27 miles S.S.W. of Miranda de Duero.

**MASULIA.** a town of Perlia, in the province of Guilan; 40 miles N.W. of Attara.

**MASULIPATAM.** a city and sea-port of Hindooban, in the circuit of Condapilly, near the mouth of the Kafha river, within the district named "MFolia" by Ptolemy.

**MAT**

This is a place of considerable trade for chintzes and printed linens. The air is deemed unhealthy; 65 miles S.S.W. of Rasjamanary. N. lat. 16° 8’ 30”. E. long. 81° 12’.

**MASURIEH**, a town of the Arabian Irak, on the Euphrates; 50 miles W. of Korna.

**MASZOW.** a town of Hungary; six miles W. of Rohenburg.

**MAT**, in Agriculture, a fort of covering material, prepared by weaving bafs or other substances of the fame fort together. They are mostly brought into this country with different forts of packages. Mats about Sandwich and Dover are flated by Mr. Young to be made ufe of for covering the flocks of wheat; by which practice, Mr. Boys affures him, the fample of wheat is improved, so as that the Dover bakers give a decided preference to it. The mats cost about seven-pence each. They are too expensive for general ufe.

**MAT. Garden,** a kind of coarse mat or covering formed of bafs, which is much ufed in gardening, for sheltering various forts of plants in winter and spring, in frothy and other cold weather; and in summer for fudding many forts of young or tender kinds occasionally from the fun; and for many other purpofes. They are found to differ greatly in regard to fize and fubflance, there being small, middling, and large fizes; but for general ufe, thofe called Ruffia mats are fuperior, both in dimensions, fubflance, and durability. It may also be proper to have fome of the smaller or middling fizes for particular occasions, and small gardens, in which, for fome purpofes, they may be more convenient than large ones. They were formerly fold by molt of the principal nurfery and feedmen, at from about fix to eight to twelve or fifteen shillings the dozen, according to fize and fhrength, but for fome years past the prices have been much higher.

These mats are alfo of effential ufe in all hot-bed works, for covering or fpreading over the lights or glafies of the frames in the nights, in winter and spring, to exclude the external night cold; alfo occasionally in the day time in very severe weather, and heavy falls of snow or rain. And likewife for occasionally covering feveral forts of fmall young efculent plants in the full ground in beds and borders, in the fecond fort as young lettuces, cauliflowers, small fallad herbs, early radifhes, &c. in the open beds, and under frames and hand-glafies, to defend them from cutting froft, snow, and other inclement weather; and sometimes in raising, transplanting, or pricking out small or moderate portions of particular forts of plants, both of the hardy and tender kinds, whether of the efculent or annual flowery kinds in the fpring, on beds or borders of natural earth, or in hot-beds, without frames, by being arched over with hoops or rods. They are likewife extremely ufeful in the fpring and summer, in hot, dry, funny weather, in shielding feveral forts both in feed-beds before and after the young plants are come up, and in beds of pricked-out fmall young plants, to thafe them from the fun till they take fresh root; as alfo for shielding the glafies of hot-beds occasionally, when the fun is too powerful for particular forts of plants in the heat of the day, as in cucumbers, melons, and various other kinds.

For kitchen and other garden districts furnifhcd with wall-trees, they are of great ufe in fpring to cover the trees of particular forts when in bloom, and when the young fruit is forming and advancing in its early growth after the decay and fall of the bloom; by which abftinance, in cold winters and fprings, when sharp frosts fometimes prevail, a tolerable good crop is often faved, while in trees fully efposed, the whole is cut off by the severity of the weather.

In the flower garden and pleafure-ground, they are also found
found useful on different occasions; in the former, in sheltering beds of curious sorts of flower-plants, both in their advancing growth, and to protect them from cold in winter and spring; and when in full bloom, to shade and screen the flowers from the sun and rain, to preserve their beauty more effectually, and to continue them longer in blow of a fine lively appearance; as well as to cover beds, &c. in raising various tender annual plants from seed in the spring; and in the latter occasionally in winter to defend some kinds of curious tender evergreens, &c., such as some of the magnolias, broad-leaved myrtle, olive, tea tree, &c., when shedding detached and trained against walls, and other places.

And besides in nursery, they are of considerable utility in the propagation and culture of numerous sorts of tender curious exotics, in defending them from cold, and shading from fourscore sun, while they are in their minor growth, &c. They are necessary also for matting round bundles of hedges or curious plants, when conveyed to a distance.

They are also occasionally of great use in severe winters on such gay's works as green-houses, hot-houses, foregrounds, &c., in covering the glass externally in the nights, and occasionally in the day time.

In using them, when the ends are open or loose, they should be secured by tying the end-thread or slings of the bags close and firm, otherwise they soon ravel out loose in that part, and are spoiled. Where made use of in the work of covering and shading, &c., they should generally in uncovering, if rendered wet by rain or snow, be pressed across some rail, hedge, or fence, &c. to dry, before folding them together, that they may be preferred from rotting, otherwise they will not last long.

These mats should never have any bags drawn out of them for tying up plants with, as is too commonly the practice, as by that means they soon become spoiled.

Mat-graft, a term applied to a particular sort of thick close grafts.

Mat, in Sea Language. See Mats.

MAT, in Sea Language. See Mats.

MATA, LA, in Geography, a sea-port town of Spain, in the province of Valencia; 22 miles S.S.W. of Alcántar.

MATA, a lake of Spain, in the province of Valencia, near the sea-side; which naturally produces an immense quantity of salt, that is the property of the king. The exports have amounted in some years to 100,000 tons weight, chiefly for Holland and the Baltic, as well as for New-land and New England, in order to cure fish.—Alto, a river of Africa, which crosses the country of Saba, and runs into the East India sea, S. lat. 10° 30′.

MATADON, a small island in the Sooloo Archipelago, N. lat. 2° 11′. E. long. 120° 11′.

MATACA, a bay on the N. coast of the island of Cuba; 30 miles from the Havana.

MATAFunda, in Antiquity, a machine for throwing flumes, probably by means of a fling. Some derive its name from the words fundo and matader, sometimes written natura, i.e. a murdering fling.

MATAGARA, in Geography, a town of Africa, in Su'tulmeff.

MATAGOLA, a small island in the Pacific ocean, near the coast of Chili. S. lat. 31°.

MATAGUA, a town of the island of Cuba; 92 miles S.E. of Havana.

MATAI'A, a province of South America, towards the river Amazon, between the mouths of Madeira and Tapajos rivers.

MATAJA, a river of Peru, which runs into the Pacific ocean, N. lat. 15° 20′.

MATALBA, in Botany, Anbl. Guian. t. 1. 128. Fig. 249. See Ephelis.

MATAIChI, in Geography, a town of New Mexico, in the province of Mayo; 150 miles E.N.E. of Santa Cruz.

MATAI'A, a town of the island of Candy, anciently called "Metallos," or "Metallum," on the S. coast; which was one of the harbours of Gortynia; 30 miles S. of Candy. N. lat. 44° 36′. E. long. 24° 10′.

MATALLI, in Hindu Mythology, is the name given to the peron who drives Iravit, the elephant of India, and is usually called his charioteer; but we do not recollect any other vehicle usually allotted to India than Iravit; see those articles.

MATAROE, in Geography, a small island in the Indian sea, near the coast of Africa. S. lat. 11° 45′.

MATALON, a town of Naples, in Lataura; 15 miles N.N.E. of Naples.

MATAMAN, or CAMBLA, a large country of Africa, near the Atlantic, S. of Bengalua, extending from S. lat. 16 to 24°, and from E. long. 13 to 18°.

MATANBA, an extensive country in the interior part of Africa, bounded on the N. by Congo, on the E. by an unknown country, on the S. by Malamba and Benguela, and on the W. by Angola; about 150 miles from N. W. to S.E., and about the same from N.E. to S.W.; it is divided into five provinces, viz. Upper and Lower Umlith, Upper and Little Ganghelli, and Bondo. The capital is St. Maria de Matamba.

MATAMBO, a town of Peru, in the district of Abanças; 12 miles N.W. of Cuzco.

MATAN, a town of the island of Borneo, near the W. coast, a little S. of the equinocial line.—Allo, a small island among the Philippines, near the port of Sibu, where the celebrated Magellan was killed in 1521, in an engagement with the natives.

MATANA, a town of Hindoostan, in Oude; 10 miles N.W. of Kairabad.

MATANCHEL, a sea-port on the W. coast of New Mexico, about 20 leagues to the N.E. of the rocks of Ponteque, over which may be seen, in clear weather, a very high hill, with a break on the top, called the hill of Xalisco, eight or nine leagues from the port.

MATANE, Great and Little, rivers in Lower Canada, which fall from the S. into the St. Lawrence near its mouth. The mouth of the Matane rivers is capable of admitting vessels of 200 tons burthen; and the coast near them for 20 leagues abounds in fine cod, fit for exportation. Great numbers of whales have also been seen floating on the water, which might prove a valuable fishery.

MATANZAS BAY, a bay on the N. coast of Cuba, N. lat. 23° 15′. W. long. 81° 2′.

MATAPÉ, a town of New Mexico, in the province of Sonora 24 miles S.E. of Patacón.

MATARAM, a town of the island of Java, and capital of a kingdom on the S. side, near the centre of the island. S. lat. 6° 20′. E. long. 110°. See JAVA.

MATAREA, or MATARIA, a town of Egypt, on the site of the ancient On, or Heliopolis, celebrated for its excellent water, and famous for a bloody battle fought between the French and the Turks, March 26, 1800, in which the Turks had 2000 men killed and wounded, besides those who perished in the defect; five miles N.E. of Cairo.

MATARIEH, a cluster of small islands in lake Menzaleh.

MATARO, an ancient town of Spain, in the province of
MAT

of Catalonia; it existed under the Romans, more within land on a spot where velvets of its buildings are still found, and was rebuilt by the Moors on its present site. It is supposed to be the ancient Illur of Ptolemy and Mela. Under the Moors it took its present name. It is pleasantly situated on the sea-side, at the extremity of a small fertile plain, which terminates at the foot of a chain of woody mountains. The old town, built on an eminence, retains its inclosure, its walls, and its gates. Its streets are narrow, but the largest, called "La Riera," which runs through the middle, is broad, straight, tolerably well built, and watered by a small stream, with a row of trees by the side of it. The new town, probably a faubourg to the preceding, is much larger, more open, and better constructed. It has been lately built, and runs towards the east as far as the sea-side; the streets are broad, long, and straight; the houses are mostly ornamented with paintings in friezo. It is daily increasing in extent; the surrounding country is fertile and well cultivated, and the town has many fountains of excellent water. Mataro is become a considerable town by its industry and commerce; its population, which, about the year 1775, was from 4 to 5000 persons, is now upwards of 25,000. It has a parish-church, three convents of monks, two of nuns, and an hospital. The administration consists of a military and civil governor, an alcalde-major, a port-captain, a minister, an auditor of the navy, and a garrison of two squadrons of cavalry. In the town are four manufactories of printed calicoes, two of calico, seven of lace, 17 of blinds, two of soap, 52 looms for flax—flockings, 116 for cotton—flockings, 48 for silk fluffs and velvets, 86 for ribbons and silk gauzes, fix dilleniers for brandy, five manufactories of fail—cloth, eight ten—yards, and 18 manufactories of silk, which, yearly make, on an average, about 20,000 pounds weight; 17 miles N.E. of Barcelona. N. lat. 41° 33'. E. long. 2° 19'.

MATATANA, a river of Africa, which runs into the India sea, S. lat. 22° 20'.

MATATANES, a town on the E. coast of Madagascar. S. lat. 22° 20'. E. long. 48°.

MATAVAI BAY, or Port Royal Bay, a bay near the N. part of the island of Otaheite, but opens to the N.W. and in the South Pacific ocean. The infide of the bay has good anchorage. S. lat. 17° 30'. W. long. 149° 13'.

MATAVAI Point, a cape of the island of Otaheite. S. lat. 17° 20'. E. long. 210° 22'.

MATCH, from the Saxon maco, a companion, because, says Johnson, the match is companion to the gun; a kind of rope, slightly twisted, and prepared to retain fire, for the uses of artillery, mines, fireworkes, &c.

It is made of hempen tow, spun on the wheel like cord, but very slack; and it is composed of three twits, which are afterwards again covered with tow, so that the twits do not appear; lastly, it is boiled in lees of old wines; whence its colour. This, when once lighted at the end, burns on gradually and regularly, without ever going out, till the whole is consumed.

It is necessary, says Walhuyzen (L'Art Militaire pour l'Infanterie, &c. p. 136, printed in 1653), that every musketier knows how to carry his match dry, in moist and rainy weather, that is, in his pocket; or in his hat, by putting the lighted match between his head and hat; or by some other means to guard it from the weather. The musketier should also have a little tin—tube about a foot long, wide enough to admit a match, and pierced full of little holes, that he may not be discovered by his match, when he stands cantined, or goes on any expedition. This was the origin of the match—boxes, worn, till of late, by our grenadiers.

Since fusées have been introduced in lieu of match—lock muskets, the consumption of matches has been much less considerale than before. See Musket.

MATCHADOH BAY, in Geography, a bay on the E. coast of lake Huron. N. lat. 44° 48'. W. long. 80° 10'.

MATCHAPUNGO, a small island near the coast of Virginia. N. lat. 37° 28'. W. long. 75° 44'.

MATCHIE, a small island near the coast of China. N. lat. 26° 30'. E. long. 119° 54'.

MATCHGONG, a town of Bengal; 25 miles N. of Burdwan.

MATCHING, in the Wine Trade, the preparing vessels to preserve wines and other liquors, without their growing sour or vapid. See Wine.

The method of doing it is this: melt brimstone in an iron ladle, and, when thoroughly melted, dip into it slips of coarse linen cloth, take these out, and let them cool. This is what the wine—coopers call match. Take one of these matches, let one end of it on fire, and put it into the bung—hole of a cask; flop it loosely, and thus suffer the match to burn nearly out; then drive in the bung tight and set the cask aside for an hour or two. At the end of this time examine the casks, and you will find that the sulphur has communicated a violently pungent and suffocating scent to the cask, with a considerable degree of acidity, which is the gas, and acid spirit of the sulphur. The cask may, after this, be filled with a small wine, which has scarcely done its fermentation, and bunging it down tight, it will be kept good, and will soon clarify. This is a common and a very useful method; for poor wines would scarcely be kept potable, even a few months, without it. Nor could it be prepared in large quantities without this help. Shaw's Lectures, p. 191.

MATCHOU, in Geography, a mountain of Thibet. N. lat. 31° 40'. E. long. 86° 29'.

MATCHTYGONG, a town of Hindoostan; 37 miles N.W. of Benares.

MATCUS, St., a town of Brazil, in the government of Minas Geraes; 40 miles N.N.E. of Villa Rica.

MATE of a Merchant Ship, is an officer who commands in the absence of the master, and shares the duty with him at sea; being charged with everything that regards the intended management of the ship, the direction of her course, and the government of her crew.

MATE of a Ship of War, is an officer under the direction of the master, by whose choice he is generally appointed, to affinit him in the several branches of his duty.

Accordingly, he is to be particularly attentive to the navigation in his watch, &c. to keep the log regularly, and examine the line and glasses by which the ship's course is measured, and to adjuit the sails to the wind in the fore—part of the ship. He is also to attend diligently to the cables, seeing that they are well coiled and kept clean, when laid in the tier, and sufficiently served, when employed to ride the ship. Finally, he is to superintend and affinit at the drawage of the hold, taking especial care that all the ballast and provisions are properly stowed therein. The number of mates allowed to ships of war and merchantmen, is always in proportion to the size of the vessel. Thus a first—rate man of war has five mates, and an East Indiaman the same number; a frigate of twenty guns and a small merchant—ship have only one in each; and the intermediate ships have a greater or smaller number, according to their

5 B several
several sizes, or to the services on which they are employed. Falconer.

Other officers have also assistants, called mates; as the surgeon, gunner, carpenter, boatman, cook, and corporal.

**MATE Creek, in Geography, a river of Kentucky, which runs into the Licking, N. lat. 38° 4'. W. long. 83° 41'**

**MATEGRIFFON, in the Military Art, a machine anciently used for throwing both darts and stones. It was both the destroyer and terror of the Greeks.**

**MATELEA, in Botany, apparently a barbarous name, for the toleration of which we have offered some apology under the article Hostea. We shall not attempt to legitimate it, as Linnaeus in some inferences has done, by any Greek pun, or forced derivation; which in this case might easily be done, though it would still have no reference to the plant. Aubl. Guian. 277. Just. 144. Lamarck Dict. v. 3. 726. Illust. t. 179. Brown Asclep. in Mem. of the Wernerian Society, v. i. 36. (Höetta; Willdl. Sp. Pl. v. 1. 174.) Clads and order, Pentamidia Dignynia. Nat. Ord. Contortae, Linn. Apocineae, Just. Asclepiadaceae, Brown.

Gen. Ch. Cal. Perianth of one leaf, turbinate, inferior, in five deep, ovate, acute, equal segments. Cor. of one petal, wheel-shaped; tube very short; limb in five deep, roundifh, equal segments, folding obliquely over each other. Stam. Filaments five, very short, inserted into the base of the tube; anthers united into a pentagonal head, each of two cells, burrfing tranfverfly, and terminated by a membrane; stamens of pollen affixed to the outer extremity, with respect to the cells, and covered with the fligmas; crown of the fligmas shield-like, lobed. Preis. Germans ovate, two, one of them abortive; fyles two, short; fligmas defacred, flattifh, recurved. Perc. Follicle lanceolate-oblong, acute, ribbed. Seeds numerous, imbricated, elliptical, crenate, without wings.

1. M. palustris. Aubl. Guian. t. 109. Native of marshes in Guiana. An upright shrub, two feet high, or more, with opposite, lanceolate, acute, entire, smooth leaves, marked with two glands at their base, and supported by short ifh footfalks. Flowers green, rather small, in short, simple, solitary, axillary clusters. Follicles pendulous, three or four inches long. Aublet describes a variety with broader, rather elliptical, leaves. Every part, when wounded, discharges a milky juice.

**MATELICA, in Geography, a town of Italy, in the marquisate of Ancona; 16 miles W. of Ancona.**

**M. TAILLES, Les, a town of France, in the department of the Herald, and chief place of a canton, in the district of Montpelier; seven miles N. of Montpelier. The town contains 325, and the canton 2703 inhabitants, on a territory of 215, kilometres, in 14 communes.**

**MATEMBO, one of Quebrima islands, near the coast of Africa. S. lat. 14°.**

**MATEO, St., a town of Mexico, in the province of New Bifycy; 120 miles S.W. of Parral. —Alfo, a town of New Navarre; 130 miles S.W. of Cafa Grande. —Alfo, a town of East Florida, on a river which runs into the gulf of Mexico; 120 miles W. of S. Auguilina.**

**MATER Dara et Pia, in Anatomy, two membranous coverings of the brain and medulla spinalis. See Brain.**

**MATER Metallorum, in Natural History, a name given by the Saxons mineralogists, and of one of other places, to a peculiar kind of martaste or mundic, which they suppose, according to the expression, to be the mother or parent of metals.**

The martaste they call by this name is the common yellow kind, but in a foul flate, it being usually mixed with some poor ore of iron, or with some ltony matter, which has made it concrete loosely and irregularly, and it is found sometimes formed into thin undulated plates, and sometimes into complex mafies; but is always cavernous or fpngy, or full of smaller or larger holes. There are often empty; but in some pieces they contain parcels either of the pure native metals, or of rich ores. Pieces of native copper are found in some, and ores of iron and tin in others. And it is said in Saxony, that native fire, in thin plates, is found in some few.

**MATERA, in Geography, a city of Naples, in Bafilia; the fee of an archbishop; 27 miles S.S.W. of Bari. N. lat. 40° 59'. E. long. 10' 35'.**

**MATERATA, a town of 1itra; six miles E.S.E. of Umago.**

**MATERFILON, in Botany, a name given by some authors to the jaca nigra, or common knapweed. Our English name mastellen seems a corruption of this. See CENTAUREA.**

**MATERIA CHEMICA, a term used by authors to express such bodies as are the peculiar objects of chemical experiments. The materia chemica, in a large sense, takes in all the bodies of the globe, all these being the subj ects of chemistry in its extensive sense; but the curious in chemical researches may be more, knowing, in general, what bodies they sought to procure, and have in readiness for them. Dr. Shaw has given a hint of these for his Portable Laboratory; and the reader will find a list according to more modern arrangement and nomenclature under our article LABORATORY.**

Becher long ago advised the young operator in chemistry to procure to himself a sort of artificial alphabet of nature; and this will serve the purpose very well, where no more is meant than a mere materia chemica, to be put in such order, that it may be readily had recourse to in all its parts. With this the young operator is to proceed regularly, as he would do in learning a language. Forming first syllables out of the joining of two or more letters of this alphabet; and then words, by combining these first sets together; and finally, whole discourses; this is forming these various simple bodies into mixtures, compounds, and decompounds. Becher's Phyl. Subrer. p. 179.

To avoid miscarriages, and prevent being imposed upon, it will be very proper to cultivate a knowledge of the productions of nature in their crude state, and peculiar places of growth, where being first viewed and examined before they are gathered or dug up, an exact knowledge of them, as nature furnishes them, may be procured. For want of this previous qualification, men, otherwise of great sagacity, have erred in their operations, and perhaps blamed the original author of a procès, in which they misconceived; while they are all the while using a wrong subject, or an adulterated or imperfect one, instead of the true. From this mistake alone, numberless complaints have arisen of failure and uncertain success in the processes and experiments recorded even by the best authors.

The person who would work in chemistry with pleasure and success, should make a sufficiently copious collection of a materia chemica of this kind, all the particulars of which he is well assured of, as to the genuineness and perfection of their kinds. These being always ready, will prevent the necessity
necessity of fending to the druggist at every turn, where the things lent for are often either not to be had, or only in a sophisticated state; when this alphabet of nature, composed of the several materials of chemical researches, is like the letters in a printing-house, distributed and lodged in proper cells, it may readily be drawn out for use as occasion requires. It is impossible to express with how little expense and trouble, yet with how great profit and pleasure, numerous experiments, and those of the most difficult kind, may be made, when the operator has, in this manner, all his materials about him. Becher tells us, that he has, in this manner, gone through fifty experiments in a day; and, while writing on chemical subjects, if any difficulty or uncertainty occurred, he immediately got up from his desk, made the necessary experiment, and fat down again to write the certain fact; so that he affirms, there was very little more trouble in making the experiment at the fire, than in describing the process by the pen.

Materia Medica, comprehends those substances, which, from disorders that occurred, vegetable or mineral kingdom, and employed either in a simple or combined state, are adapted to heal disorders; or, in other words, it is a collection of remedies. Among the ancients, this collection was very limited and imperfect, and yet formed in a fanciful and arbitrary manner, and frequently with a view to imaginary or superstitious virtues annexed to the substances which it contained. This is not to be wondered at, when we consider that all arts and sciences have been progressive in their improvement, and that the urgency of disease would lead those who studied medicine for their own relief, or for the benefit of others, to seek and to multiply remedies. The number of these remedies would naturally be augmented from views of interest; and as the priests of Eileclusius were the first and chief practitioners of phytic in Greece, whence the science originated, we may suppose, that superfluity would invent new remedies, or annex some mysterious efficacy to those that had been already discovered. Whilk the priests of Eileclusius, thus circumstantial, would endeavour to enlarge their knowledge of remedies adapted to the various disorders that occurred, the temples of their deity afforded peculiar means of preferring the knowledge of the Materia Medica, which they acquired for it was then common for persons, who had been cured of their diseases by remedies preferred to them in the temple, to hang up their revtive tablets, on which was inscribed some account of their disorders, and of the remedies by which they had been relieved. The celebrated Hippocrates was one of the first clinical practitioners, who disseminated the knowledge acquired in these temples; but though his writings are numerous, they are intermixed with too many additions by different persons, and in different ages, that it is not possible, with any satisfaction, to determine what was the true state of the Materia Medica in his time. Although Aricoilotle and Theophratus, soon after the age of Hippocrates, by laying the foundation of natural history, paved the way for a great improvement in the knowledge of the Materia Medica; yet for want of the means of accurately distinguishing substances from one another, this branch of phytic remained in much uncertainty and confusion. The writings of the ancient physicians of Greece, now extant, are few; and of course we obtain little information of the progress of the Materia Medica among them. We may presume, however, that they were diligent in exploring more efficacious medicines, and that, upon the whole, they were increasing their number. Erasistratus, it is said, simplified the practice of medicine, and thus retarded the progress of the Materia Medica, which was promoted by Hierophilus, and by Philinus and Serapijun, belonging to the sect of empirics. At Rome the knowledge of the Materia Medica was extended and improved, by the Greek physicians who practiced at Rome. Among these we may reckon Aseyipiaed, who, indeed, like Erasistratus, employed only a small number of medicines, Cellius, Scribonius Largus, and Andromachus the elder. Dioscorides, who lived in the time of the emperor Ves- palian, is commended by Galen as one of the best and most complete writers on the Materia Medica. He has given a long list of medicines, with some opinion respecting each; but Dr. Colini thinks, that, in several respects, his judgment in general may be suspected. About the same time with Dioscorides lived the elder Pliny, who, though eminently learned, was merely a compiler, and often injudicious, particularly with respect to the Materia Medica. Pliny, however, discovered more judgment than many of his contemporaries, in condemning the very luxuriant compositions which at that time were so much affected. Soon after Pliny appeared the celebrated Galen, who, on the subject of the Materia Medica, prepared a new system; making the virtues or power of medicines depend chiefly upon their general qualities of heat and cold, dryness and moisture. This doctrine, however unfounded and erroneous, was implicitly followed by all the physicians of Greece who succeeded Galen, as well as by all the physicians of Asia, Africa, and Europe, for at least 1500 years. When the knowledge of phytic had very much declined among the Greeks, it was transferred to the Saracens, who, at this time, not only preserved in Asia and Africa that cultivated science. Several productions of their own climate were added to the Materia Medica of the Greeks; but though they made some improvements, as, e. g. by substituting, in place of the more violent and drastic purgatives of the Greeks, several of a milder kind; they made no discovery of any medicines of peculiar power; and as they had derived almost the whole of their knowledge of phytic from Greece, to every part of it they had adopted nearly entirely the system of Galen. Upon the whole, it must appear that they made no improvement, either in the general plan of the Materia Medica, or in the virtues of particular medicines. One important innovation, indeed, they introduced, which laid the foundation of a considerable change at a subsequent period; and this was the application of chemical operations to the substances appropriated to medicine. As long as the physicians of Europe continued to be the fervile followers of the Saracens or Arabs, nothing new occurred among them; but when Constantinople was taken by the Turks, about the middle of the fifteenth century, many learned Greeks were driven into Italy, and thus the literature of the Greeks was transported to the western parts of Europe. The system of Galen, however, was adopted by the contending parties both of the Greeks and Arabs: and the Materia Medica, with a few additions by the Arabians, remained as it had been transmitted from Galen; being everywhere explained by the cardinal qualities and their different degrees, with very little reference to any thing acquired by experience.

We have already observed that chemistry first appeared among the Arabs, and there is reason for believing, that metallic substances were the objects of some of their first operations. These substances were principally mercury, and afterwards antimony; and of these substances we find a great variety of preparations in the "Curris Triumphalis Antimoni," published under the name of Basil Valentine, and supposed to have been written about the end of the fifteenth, or beginning of the sixteenth century. When the chemists directed the employment of their art to the preparation...
preparation of medicines, they were soon misled by the fanatical spirit which prevailed among them, and indulged the idea of preparing an universal medicine, and one which should protract life to 1000 years. In the prosecution of these visionary schemes they persisted, when in the beginning of the sixteenth century Paracelsus appeared. From the chemical practitioners of these times he learned the use of mercury and antimony; and from some empirics the use of opium. By the use of these remedies, he cured many diseases which had baffled the inert remedies of the Galenists; and thus establishing his fame, he formed a school of physicians, who appeared in opposition to the establisihed schools, then entirely followers of Galen. Hence the physicians of Europe were divided into the two sects of chemists and Galenists.

Early in the seventeenth century, Sir Theodore Mayerne, a chemical physician, was called over into England, and distinguished himself as a great favourite of chemical medicines, and particularly of antimony. His fame seems to have terminated in England all dilution between the Galenic and chemical practitioners. Hence it merits particular attention, that in the course of the sixteenth century, the introduction of the more frequent use of chemical medicines, and of the more frequent application of chemistry to the preparation of them, produced a very great change in the state of the Materia Medica. Fluid medicines, some of which were entirely unknown to the ancients, formed a much greater part of it than formerly; and not only those of the metallic, but many of the same kind, little known before, were now introduced. Distilled waters also, essential oils, quintessences, and extracts, were admitted by those who allowed of chemical remedies at all, to constitute almost the whole of the Materia Medica. While chemistry was thus employed to modify the Materia Medica, it was accompanied by every species of fanaticism, by the doctrines of astral influences, animal magnetism; by pretensions to alchemy, to panaceas, and to medicines capable of prolonging life. All these had some influence on the Materia Medica; but none were more generally received than the doctrines of signatures, which has retained its influence till very lately. The doctrines of chemistry, though attended with many absurdities, were, however, the most promising towards explaining that quality in medicines upon which their virtues depended; and accordingly have ever since been more or less applied to that purpose. It was about this time that certain physicians, who professed to judge of the constituent parts of medicines, partly from their chemical analysis, partly from their feasible qualities, formed plans of the Materia Medica. After all the schemes that were formed for investigating the virtues of medicines, it must be acknowledged, that the conclusions formed from any of them can hardly be trusted till they are confirmed by experience; and here it will be proper to take notice of two attempts which were made in England to confut experience with regard to the Materia Medica. The first was that of Mr. John Ray, who, in his "History of Plants," thought proper to enumerate the virtues of those which were used in medicine. About the same time Mr. Boyle endeavoured to engage the practitioners of phytic in the study of specific medicines, that is, of medicines whose virtues are learned only from experience. Nevertheless, from various circumstances, his collection has contributed very little towards the improvement of the knowledge of the Materia Medica. After this time physicians and chemists began to treat many vegetable substances, either by infusion and distillation in water, or by infusion in spirituous menstruums, and obtaining extracts in consequence of these operations; and labours of this kind have been since prosecuted with diligence. By such labours the doctrines of the Materia Medica have been often corrected, and we have been frequently taught not only to distinguish the different degrees of the same quality in different bodies, but they have been particularly useful in directing the most proper pharmaceutical treatment of medicines, and have sometimes afforded an analogy for judging of the virtues of untried substances. At a period, which soon followed, a number of different theories prevailed in the schools of physic; which variously affected the state of the Materia Medica. The Stahlians introduced archæal remedies, and many of a superstitious and inert kind; and, on the other hand, the mechanical physicians, by introducing the Corpuscularian philosophy, or the notion that the small parts of bodies acted upon one another by their figure, fire, and density, endeavoured to explain the operation of medicines upon the fluids and folds of the human body, in a manner that countenanced many erroneous opinions concerning their virtues. Dr. Boerhaave, adopting this system, contributed to extend its influence. Another circumstance that served to injure the writings on the Materia Medica was that of referring the operation of medicines to certain general indications; most of which have arisen from defects both of physiology and pathology, and are neither sufficiently explained nor well understood. Notwithstanding the imperfections that have been discovered in the writers on the Materia Medica, and that have been suggested by Dr. Cullen, to whom we are indebted for the preceding hints on this subject, he acknowledges, that, in modern times, and more especially during the course of the last century and towards the close of it, the Materia Medica has received much correction and improvement. "The progress of philosophy has corrected many superstitious fables that were formerly intermixed with the doctrines of the Materia Medica. Chemistry has given us many new medicines, entirely unknown in ancient times; and this science, in its progress, has not only gradually corrected its own errors, but has taught us to reject many inert medicines, which formerly made a part of the Materia Medica. It has taught us a greater accuracy in preparing all its peculiar productions, and to lay aside many of those operations with which it had amused the physician, and had imposed much useless labour upon the apothecary. In particular, it has instructed us how to make the combinations of medicines with greater correctness and propriety; and in all these respects has rendered the whole of the pharmaceutical treatment of medicines more simple and accurate than it was before. Chemistry has thus greatly improved the state of the Materia Medica, and has led physicians to a discrimination that should reject that luxuriance of composition formerly so frequent; and which, even at present, in most parts of Europe, is far from being sufficiently corrected. The reformation in this respect has not yet taken place to any remarkable degree, excepting in the northern countries of Europe, in Britain, Sweden, Denmark, and Russia."

Of the writers on the subject of the Materia Medica, whose names and works are enumerated by Dr. Cullen, the first we shall mention is John Schroeder, of the 17th century, an edition of whose work in the German language was published in 1746, and which has been literally quoted by Ray, Dale, and Allen. The next writer is John Bauhin, who, in his "Historia Plantarum," has written on the virtues of those plants which make a part of the Materia Medica. Of this author Dr. Cullen says, that, exclusively of his botanical merit, "he did not deserve to be followed as he has been by Ray and others after him; and by no means deserves to be read now." Simon Pauli succeeded Bauhin, and was himself followed by Georgius Wolfgangus Wedelius,
Wedelius, who was an abettor of the doctrine of signatures, as well as a believer in the power of amulets. Emanuel Koenig, towards the end of the 17th and soon after the beginning of the next century, published all the parts of the Materia Medica, in a manner which Cullen speaks of in degrading terms. John Baptif Chomel published his "Abrégé de l'histoire de Plantes utiles," in 1712, and has chosen, says Cullen, a proper plan of arranging the subjects of the Materia Medica, according to the similarity of their virtues in answering the general indications of cure, but he has executed it very imperfectly. Stephen Francis Geoffroy, though a man of genius, and in many respects of good judgment, has not always manifested it in his writings on the Materia Medica. Mr. Lienaud, in his "Synopsis Universæ Præsever Medicæ," has distributed the subjects of the Materia Medica according to the general qualities by which they are adapted to the several indications arising in the practice of physic; but the indications make no further distinction made, so general as well as too complicated to convey any instruction to young practitioners. M. Ferrein has, since the time of M. Lienaud, published at Paris a "Traité de Materia Medicæ," &c., which Dr. Cullen pronounces to be superficial and incorrect, and unworthy of the author, who was a man of learning and judgment. The "Precis de Materia Medicæ" of M. Venel, published by M. Carrère, is, as Cullen thinks, the most judicious writing that had appeared in France on the subject before his time. Of the writers of Germany Dr. Cullen mentions Zorn, G. Henry Bahr, Buchner, Loehefe, and J. Fred. Carthenier. The latter is author of the "Fundamenta Materæ Medicæ," a work of deferred reputation, in which the several subjects are distributed according to their sensible qualities, or to their more obvious chemical constitution, and many substances are very properly associated by their natural affinities. But this author, says Cullen, often attempts to explain the virtues of medicines by their chemical constitution in a manner that is not satisfactory. He has also employed general terms, which are not only ill defined, but also very often complicated, and sometimes altogether improper. In 1758, the learned and industrious Rud. Aug. Vogel published his "History Materæ Medicæ," of which Dr. Cullen does not speak in very high terms. Another German professor, H. Jo. Nepam. Crantz, published a treatise of the "Materia Medica et Chirurgica," which has not contributed to advance the knowledge of the Materia Medica. Professor Stichmen of Straffburg, in his "Institutiones Materæ Medicæ," has distributed medicines according to their indications, but with a brevity that often renders him obscure. He has also published a "Pharmacopœia Generalis," which Dr. Cullen censures partly for its superficialities, and partly on account of its being superficial and incorrect. But the errors and defects of preceding writers have been corrected and supplied by the "Apparatus Medicamini" of the very learned and ingenious professor Murray of Gottingen, the most complete and perfect work, in Cullen's estimation, that has ever appeared on the subject. This treatise, with great judgment and medical discernment, from former writers, and more especially from those of late date, collected every thing which deserved to be repeated. He everywhere discovers an intimate acquaintance with all the writers on the subject, and always makes a judicious selection of what they afford. By distributing the vegetable substances according as they belong to the several natural orders marked by the botanists, he has associated the substances of similar qualities and virtues, in a manner that may be of great advantage to students. An improved edition of this work was published by Althof at Gottingen, in 1793; &c. in six volumes, 8vo. To the Apparatus, &c. by Murray, was added a work of the same kind, with the same title, comprehending the mineral kingdom, by professor Gemein, in two volumes, published at Gottingen in 1795.

In Sweden the celebrated Linnaeus takes the lead of all who we here need say nothing, but may content ourselves with referring to his biographical article. According to Dr. Cullen, our attention, with respect to the whole that Linnaeus has delivered on the Materia Medica from vegetables, is very much superceded by the work given us on the same subject by his scholar Bergius. The "Materia Medica ex Vegetabilibus," by Petrus Jonas Bergius, is a work of great value and deserving peculiar notice.

Of British writers on the subject of the Materia Medica Dr. Cullen mentions Mr. Ray, Dr. Dale, Dr. Alkton, and Dr. Hiu, who published a compilation without felection or judgment. He speaks with deference commendation of the "Materia Medica" of Dr. Lewis, more especially as published and judiciously enlarged by Dr. Aikin. Dr. Rutty, of Dublin, after forty years labour in preparing it, has published his "Materia Medica Antiqua et Nova," which Dr. Cullen appreciates at a low rate. Dr. Cullen's "Treatise of the Materia Medica," in two volumes 4to, was published in 1780. Dr. Woodville's "Medical Botany," of which a second edition was published in 1810, with his last corrections, is well known, and highly valued; and we may here add that in this year (1812) Dr. Stokes, well known for his botanical and medical attainments, has published a work of similar title and design to that of Dr. Woodville.

Having given a compendious abstract of the history of the Materia Medica, and an enumeration of some of the chief writers on the subject, we shall now proceed to detail, as briefly as possible, the different methods of classification or arrangement which have been adopted by various writers; premising in general that the means by which the various or medicinal characters of different substances are determined is the principal and first object, that is, the natural qualities, their botanical affinity, their chemical analysis, and general experience. Of all the different modes of arrangement which have been adopted, the most simple is that of the alphabetical form, from this we can derive no information with regard to the specific virtues of various substances admitted into our catalogue of the Materia Medica. Another mode of arrangement is founded on the classes of bodies, or kingdom, to which the different substances belong; and thus we obtain three general divisions of animal, vegetable, and mineral substances. But this method of classification is liable to the same objection with the former, as it is too general, indiscriminating, and un instructive. A more eligible and useful arrangement is that to which we are led by the investigation of the sensible and most obvious qualities of medicinal substances; and accordingly we consider them as acid, alkaline, acrid, astrin gent, aromatic, gluttonous, neutral, bitter, emetic or cathartic. This mode of distribution was suggested by Car thcur, though he was under a necessity of deviating from it in his actual arrangement of various substances; and indeed, it is too vague and inappropriate to admit of general application; for some substances have no discriminating sensible quality; others possess several qualities so nearly similar, that it is difficult to refer them to one class in preference to another; and others again resemble one another in their sensible qualities, and yet are extremely different in their effects on the animal frame. Another mode of arrangement was adopted by Vogel, who classed his medical materials according to their effects on the human body.
MATERIA MEDICA.

These are the general divisions (says an anonymous writer in "Nicholson's British Cyclopaedia," of whose article we shall here avail ourselves as far as it is appropriate to our purpose) or classes into which simple medicines are partitioned under this system; but when we begin to consider their virtues more particularly, a variety of inferior divisions must necessarily enue. Thus, of the relaxing medicines, some, when externally applied, are supposéd merely to soften the part; and in such case are called emollients; while others which are supposéd to have a power of augmenting the disposition of the secerements of an inflamed part to the secretion of pus, are called maturants or suppuratives. Sedative medicines, that have the power of allaying pain, are denominated p Erdogan; if they altogether remove or defroy pain, they are called anodynes; if they take off fpaem, antispasticmodics; if they produce quiet sleep, hypnotics; if a very deep and unnatural sleep, together with considerable stupefaction of the senses, narcotics. Tonic medicines, in like manner, obtain the name of corroboratives, analeptics, or nerves, when they slightly increase the contractile power of the solids; but of allrings or adstringents, if they do this in a great degree. Some of this order of medicines have been supposéd to promote the growth of flesh, to consolidate wounds, and restrain hemorrhages, and hence the names of farciotics and traumatics, or vulneraries, names, however, which may well be dispensed with, as the quality is very questionable, and perhaps altogether erroneously ascribed. Other adstringents, again, are denominated repellant, disstiant, stimulant, or attractive, according to the respective modes by which they are conceived to promote one common effect. Medicines of the inflammatory tribe, are, in like manner, divided into vulneraries or blisters, by their application raise watery bladders on the skin; catheters, alterations, or corrosives, if they eat into and defroy the substance of the solid parts themselves; and rubefactive urubefault, if possest of lefs power than the vulneraries, they merely produce a redness on the part to which they are applied, by increasing the action of a part, and dilating the red particles of the blood, into vesseals which do not naturally possess them. The alterant tribe is divided into absorbents, antispastics, coagulants, refolvents, caleants, and refirerants, according to the peculiar mode by which the different individuals of this tribe are supposéd to operate. The evacuants are generally subdivided from the nature of the humour they are supposéd to discharge: emetics, if they evacuate the contents of the stomack by vomiting; cathartics, if they induce purging; laxatives, if they produce a moderate discharge of feces without pain or difficulty; emmocotics, if the discharge be greater, but still confined to the common nature of the feces themselves. Thus again they are named diaphoretics, if they promote the expulsion of humours through the pores of the skin with a small increas of action; sudorifics, if the increas of action be greater, and the discharge more copious. Such as excite urine are called diuretics; such as produce evacuation from the glands of the palate, mouth, and falvary ducts, salivating medicines; those that promote the discharge of mucus from the throat, apophlegmatics; those that evacuate by the nose, purges, erthines, irroratives; and those which promote the menstrual discharge, emmenagogues. To this order also, some writers reduce those medicines which expel any preternatural bodies, as worms, flusses, and slatus or confined air: of these the first are called anthelmintics; the secound, and especially when directed to the bladder, lithoeritics; and the third, carminatives. This fystem admits of various modifications; and authors have differed in the number and in the denominations of the classes which they have adopted. Thus, Dr. Cullen has distributed the various medicinal substances which he has introduced into the following twenty-three classes:

<table>
<thead>
<tr>
<th>Class</th>
<th>Subclass</th>
</tr>
</thead>
<tbody>
<tr>
<td>Astringents</td>
<td>Antacids</td>
</tr>
<tr>
<td>Tonics</td>
<td>Antalkalines</td>

</tbody>
</table>

Dr. Darwin comprehends all medical substances under seven classes:

<table>
<thead>
<tr>
<th>Class</th>
<th>Subclass</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nutrients</td>
<td>Invertents</td>
</tr>
<tr>
<td>Incitants</td>
<td>Revertents</td>

<tr>
<td>Sècements</td>
<td>Torpents</td>
</tr>
<tr>
<td>Absorberts</td>
<td></td>
</tr>
</tbody>
</table>

While Dr. Cullen's classification has been thought too diffuse, and Dr. Darwin's much too contracted, and adapted merely to his own exceptionable system of nosology, Dr. Kirby, in his small treatise, entitled "Tables of the Materia Medica," has adopted eighteen classes, which are, upon the whole, judiciously felected, though his arrangement is not altogether unobjectionable. Independently of the general arrangement of medical substances, there is another circumstance which deserves attention, and that is the nomenclature by which they ought to be distinguished. As the new nomenclature of Lavoisier is now generally adopted in the Pharmacopoeias of different colleges of medicine, it will be followed in the annexed table. The compiler of the table has also been anxious to exhibit, in every instance, a glance at the common doce for adult age, as well as to specify in terms as abbreviated as possible, the name of the country in which the different articles exist originally; the part or organ of the substance employed; and the distance in which it is supposed to be efficacious. The classification is as follows, and every class is subdivided, as far as possible, into an animal, a vegetable, and a fossil, fection.

Humulus Lupulus *.

* We have inserted the hop among the articles of the Materia Medica, as it probably would have been received by the Edinburgh college, had their Pharmacopæa been published some months later. Within the last year it has been frequently employed in the Edinburgh infirmary as a substitute for opium with great success, as it was found to produce sleep in cafes where opium was inoffensive or inadmissible. It is usually administered in the form of a saturated tincture.—Vid. De Roches” “Differt. Inaug. de Humulo Lupulo. Edin. 1803.”
Dr. Spens has adopted it in his edition of the Infirmary Pharmacopæa, and has given a formula of it under the title of “Pibulæ Humuli lupuli.”

For an account of the medical properties and use of the several classes, in the preceding table, see Emetics, Expectorants, &c.

Materia Subtilis. denotes a fine subtile matter, which the Cartesians suppose to pervade and penetrate freely the pores of all bodies, and to fill up all the pores so as not to leave the least vacuity, or interstice, between them. See Cartsians.

This machine they have recourse to, to support the doctrine of an absolute plenum, and to make it consistent with the phenomena of motion, &c. and, accordingly, they make it act and move at pleasure, but in vain: for were there any such matter, in order for it to be able to fill up the vacuities of other bodies, it must, itself, be entirely void of anything; i.e. it must be perfectly solid, vallly more solid than gold, and, therefore, more ponderous, and resist vallly more, which is inconsistent with phenomena. See Vacuum, and Plenum.

Yet Sir Isaac Newton allows of the existence of a subtile matter, or medium, much finer than air, penetrating the clofet bodies, and contributing to the production of many of the phenomena of nature. The existence of such a matter he argues from the experiment of two thermometers, which being inclosed in glafs vessels, one of them, exhausted of its air, and both carried from a cold to a warm place, the thermometer in vacuum grows warm, and rises, almost as soon as that in the air; and, if returned into the cold place, both cool and fall about the fame. Hence, says he, is not the heat of the warm room conveyed through the vacuum by the vibrations of a much subtler medium than air, which remained in vacuum after the exhaustion of the air? And is not this medium the fame whereby light is refracted, reflected, &c.? See Ether.

Material denotes something composted of matter. In which sense the word flands opposed to immaterial. The Epicurean, Spinofts, &c. own no other but material substances. (See Substance.) Among caufes, fome are material, others are formal. See Cause.

Material caufes, having no understanding or liberty, muft always act in the fame manner, when under the fame circumstances. Philosophers and divines dispute, whether or no there be any material forms really distinct from matter? (See

MAT

Form.) The Valentinians formerly applied the term materia to all people but those of their own fet; afferting that their souls were united with their bodies. Thus also the Stoics maintained, that none but the souls of their own men survived the body.

Material Circle. See Circle.

Material Object. See Object.

Materialists, a fect in the ancient church, composed of perfons, who, being preposified with that maxim in the ancient philosophy, Ex nihilo nihil fit, Out of nothing nothing can arise, had recourse to an internal matter, on which they suppos'd God wrought in the creation; instead of admitting God alone as the sole cause of the existence of all things.

Tertullian vigorously opposes the doctrine of the Materialists, in his treatise against Hermogenes, who was one of their number.

Materialists is also a name given to those who maintain that the soul of man is material; or that the principle of perception and thought is not a substance distinct from the body, but the result of corporeal organization. (See Soul.) There are others, called by this name, who have maintained that there is nothing but matter in the universe; and that the Deity himself is material. See Spinozsism.

M A T E S H O L M, in Geography, a small island in the North sea, near the coaft of Lapland. N. lat. 68° 39'.

MATGAR, a town of Hindooian, in the circt of Kot-ta; 15 miles S.S.W. of Kotta.

MATGA, a town of France, in the department of the Lower Charante, and chief place of a canton, in the district of St. Jean d'Angely; 14 miles N.W. of Saintes. The place contains 714, and the canton 14,940 inhabitants, on a territory of 205 kilometres, in 26 communes.

MATHAN, a town of Africa, in the kingdom of Bornou, called a royal city. N. lat. 18° 30'. E. long. 21° 40'.

MATHANON PORT, a port in the S.E. part of the ifland of Cuba, between Cape Cruz and Cape Maizi, which affords good anchorage for ships.

M A T H E M A T I C A L Point. See Point.

Mathematical Sect, in the History of Learning, is one of the two leading philosophical sects, which appeared towards the beginning of the seventeenth century; this sect directed its researches by the principles of Galiendi, and sought after truth by observation and experience. The disciples of this sect denied the possibility of erecting on the basis of metaphysical and abstract truths, a regular and solid system of philosophy, without the aid of affiduous observation and repeated experiments, which are the most natural and effectual means of philosophical progress and improvement. The advancement and reputation of this sect, and of natural knowledge in general, were much owing to the plan of philosophizing, proposed by lord Bacon, to the establishment of the Royal Society in London, to the genius and industry of Mr. Boyle, and to the unparalleled researches and discoveries of Sir Isaac Newton. Brown, Wallis, Locke, and many others, were of this sect. See Coniculch, Experimental, and Newtonian Philosophy.

The other sect of philosophers was the metaphysical.

Mathematics is that science which treats of the ratio and comparison of quantities, and is therefore defined the science of ratios; some writers call it the science of quantities, but this is inaccurate, since it is not quantities themselves which are the subject of mathematical investigation, but the ratios that such quantities bear to each other.

The
MATHEMATICS.

The term mathematics is derived from μαθηματική, mathēmatikē, discipline, science, representing with justification and precision the high idea that we ought to form of this branch of human knowledge. In fact, mathematics are a methodical combination of principles, reasonings, and conclusions, always accompanied by certainty, as the truth is always evident, an advantage that particularly characterizes accurate knowledge and the true sciences, with which we must be careful not to associate metaphysical notions, conjectures, nor even the strongest probabilities.

The subjects of mathematics are the comparisons of magnitude, as numbers, velocity, distance, &c. Thus, geometry considers the relative magnitude and extension of bodies; astronomy, the relative velocities and distances of the planets; mechanics, the relative powers and force of different machines, &c. &c. Some determinant quantity being fixed upon in all cases as a standard of measure.

Mathematics are naturally divided into two classes; the one comprehending what we call pure and abstract; and the other the compound or mixed. Pure mathematics relate to magnitudes generally, simply, and abstractedly, and are therefore founded on the elementary ideas of quantity. Under this class are included arithmetic, or the art of computation; geometry, or the science of magnitude and comparison of extensions of every kind; analysis, or the comparison of magnitudes in general; to which we may add geometrical analysis, which is a combination of the two latter. Mixed mathematics are certain parts of physics, which are, by their nature, susceptible of being submitted to mathematical investigation.

We here borrow from incontestable experiments, or otherwise suppose bodies to possess some principal and necessary quality, and then, by a methodical and demonstrative chain of reasonings, deduce from the principles established conclusions as evident and certain as those which pure mathematics draw immediately from axioms and definitions, observing, that these results are always given with reference to the experiments on which they are founded; or the hypotheses which furnished the first datum. Let us illustrate this by an example. Numberless experiments have been shewn us, that all bodies near the earth's surface fall with an accelerated velocity, and that the spaces passed through are as the squares of the times they have been in falling. This, then, the mathematician considers as a necessary and essential quantity, and from this datum he proceeds to examine what will be the velocity of a body after any given time, in what time it will have acquired a given velocity, what time is necessary for it to have generated a given space, &c. and in all these investigations his conclusions are as certain and indisputable as any of those which geometry deduces from self-evident truths and definitions. Again in optics, having established it as a principle of light, that it is transmitted in right lines while no obstacle is opposed to the passage of the rays; that when they become reflected, the angle of incidence is equal to the angle of reflection; that in passing from one medium to another, of different density, they fly off from their direct direction, but still follow a certain geometrical law; these principles, or qualities of light, being once admitted, whatever may be its nature, be it material, or be it immaterial, or whatever may be the medium through which it passes, or the surface by which it is reflected, are totally matters of indifference to the mathematician; he considers the rays only as right lines, the surfaces on which they impinge as geometrical planes, of which the former only enters into his investigation; and from this point all his enquiries are purely geometrical, his investigation clear and perspicuous, his deduction evident and satisfactory. To this class of mathematics belong mechanics, or the science of equilibrium and motion of solid bodies; hydrodynamics, in which the equilibrium and motion of fluids are considered; astronomy, which relates to the motion, masses, distance, and densities, of the heavenly bodies; optics, or the theory and effects of light; and, lastly, acoustics, or theory of sounds.

Such are the subjects that fall under the contemplation of the mathematician, and as far as a knowledge of these may be considered beneficial to mankind, so far, at least, the utility of the science on which they depend must be admitted. It is not, however, the application of mathematics to the various purposes of society, that constitutes their particular excellency; it is their operation upon the mind, the vigour they impart to our intellectual faculties, and the discipline which they impose upon our wandering reason.

"The mathematics," says Dr. Barrow, "effectually excite, not vainly delude, nor vexatiously torment fludious minds, with obscure subtleties, but plainly demonstrate everything within their reach, draw certain conclusions, infallibly by profitable rules, and unfold pleasantr questions. These disciplines also inure and corroborate the mind to a constant diligence in study; they wholly deliver us from a credulous simplicity, and most strongly fortify us against the vanity of scepticism; they effectually restrain the rash presumption, most easily incline us to a due affiavit, and perfectly subject us to the government of right reason. While the mind is abstractive and elevated from sensible matter, it distinctly views pure forms, conceives the beauty of ideas, and investigates the harmony of proportions; the manners themselves are sensibly corrected and improved, the affections composed and rectified, the fancy calmed and settled, and the understanding raised and excited to more divine contemplations."

Many of our readers will probably not be disposed to admit, to the full extent, the juifshefs of Dr. Barrow's panegyric; they may think he has over-rated the value of mathematical acquisition, and that some of his assertions are founded in self-sufficiency and pride. But those who form the latter opinion, must be unacquainted with the true character of this celebrated author; and those who entertain the former, are not probably initiated into the mysteries of those sciences; and, therefore, are not competent judges of their value. We are assured, that the mathematicians have had calamities, as well as eloquences; it has even been represented as a science which blunts all the tender feelings of our nature; that it renders its professors vain, arrogant, and preposterous; as destroying all relish for works of taste and imagination; hardening the heart against every truth, but those of the demonstrative kind; and, consequently, as having a tendency to lead us into infidelity and atheism.

The celebrated author of the Rambler indulged some of these notions. It was, he observed, "the great praise of Socrates, that he drew the wits of Greece, by his instruction and example, from the vain pursuits of natural philosophy to moral enquiries; and turned their thoughts from stars and tides, and matter and motion, to the various modifications of virtue, and relations of life." He pursues this thought still farther, and illustrates it by a story which he tells of one Geidus, a mathematician, who was so absorbed in his speculations, that when his servants came to acquaint him that a house was on fire, and the whole neighbourhood in danger of being burnt, he only replied, that it was very likely, for it was the nature of fire to act in a circle. He even diverts this pseudo-philosopher of the common feelings of humanity, and makes him as insensible to the wants of
his family, as to the distresses of his neighbours. But such illiberal notions are a disgrace to their author, and flew a narrowness of mind, that one would not expect to have found associated with so much talent. "A great and comprehensive genius excludes none of the sciences, they all contribute, by various means, to adorn and embellish life; and for this reason ought to be cultivated and improved. Happy is the mind that is not contracted by the study of philosophy, nor enervated by the charms of the belles lettres; that can be strengthened by Locke, infcribed by Clarke and Newton; impeached by Cicero and Demotethes; and elevated by the powers of Homer and Virgil." Bonnycastle's Astronomy.

That some mathematicians may have been vain and presumptuous, perhaps cannot be denied; but many, and these amongst the most eminent, have been equally distinguished for their modesty and unassuming manners, of which our Newton furnishes an illustrious example. Admitting, therefore, that the charge is just with respect to certain individuals, unless it can be shown (and which we believe it cannot) that it applies to a greater proportion of the professors of this science than of any other, the injustice of the accusation, as applied to the science itself, is evident. What science, or what subject can be named, in which the same charge will not apply to individuals; even that which above all might be supposed to have the greatest influence in check- ing these passions, the great founder of which was a pattern of humility, meekness, and peace; even this saucy fault has been but too frequently disgraced by the bigotry and intolerance of its professors. The next object to these pursuits is, that they destroy all relish for works of taste, and that genius is unnecessary, and only great labour required, in order to attain the first rank in the sciences. To this we will let Buffet reply: "Is it," says the philosopher, "at all affonishing, that the ignorant and superficial many should confound the fruits of that knowledge, which is acquired by study, with those new and original truths to which genius alone can give birth? To be just, we must weigh the great mathematicians of well established reputation against the great poets and great orators. Thus on the one side, let us place Homer, Virgil, Racine, Pope, Demotethes, Cicero, and Buffet; and on the other, Archimedes, Hipparchus, Galileo, Descartes, Huygins, Leibnitz, and Newton; and it will not then be so easily determined to which side the balance, in point of genius, ought to incline." We might pursue this subject to a much greater length, and enter into a formal defence of the other charges brought against mathematics and mathematicians; but they may be all answered in a word. Their greatest calumniators, amongst whom we place Joseph Scaliger, the äbe Desfontaines, and our countryman Hobbes, were men who coveted fame, and thought themselves competent to acquire it in every branch of human knowledge; they, therefore, attempted the most difficult problems, and their little knowledge of the subject led them into errors which made them the ridicule of all scientific men; thus exasperated and disappointed, they became the enemies of that science in which they had before so vainly defined to shine; and reproached it merely to gratify their pride and revenge.

The history, illustration, and application of the several branches of mathematics, have been treated of under their respective heads in the present work; and it therefore only remains for us, in the present article, to give a brief sketch of the most prominent parts of the history of the whole, in order to trace their progress and mutual dependence, which are lost in the detached accounts. With this view of the subject, we shall nowhere enter into particulars, but where these are required, reference will be made to the several articles in which such information may be obtained. Neither shall we offer any speculations concerning the origin of these sciences, which is rather calculated to amuse than to instruct; but proceed at once to real historical facts, observing only, with regard to the Egyptians, that they undoubtedly possessed some knowledge of geometry and astronomy before these sciences were transplanted into Greece; but as we are totally unequainted with the extent of their knowledge, all records of it having been lost or destroyed, it will be false to advance nothing on this head, and to begin our sketch with the earliest authentic traces of it amongst the ancient Greeks.

It is generally supposed, that the Greeks derived their first knowledge of the sciences from the magi of Egypt, and it was probably known in the known country long before the time of Thales, who is commonly held the father of Grecian philosophy, only because he is the first of whom any decided account has been transmitted to us. Herodotus informs us, that Thales predicted a total eclipse of the sun, and though no date is mentioned by this celebrated historian, yet astronomers have now ascertained that the only total eclipse, (and it could be no other than total, from the circumstances attending it,) happened in the year 610 before Chrilt. See Phil. Trans. for 1810, in which is given an elaborate paper on this subject, by F. Bailly, etc. At this period, therefore, it is obvious that astronomy was considerably advanced in Greece, as the prediction of an eclipse is far from being an elementary problem; it necessarily requires a vast number of delicate observations, which could only be obtained after a long series of years. Pythagoras, who is supposed to have been a pupil of Thales, and who flourished about the year 590 B.C., is the next of those celebrated Grecians whose names are rendered immortal by their great and important discoveries. This philosopher, it appears, made considerable improvements in arithmetic, astronomy, and geometry; in arithmetic he is said to have invented the multiplication table, or the abacus Pythagoricus; in astronomy, he suggested the idea of the true syllem, placing the sun in the centre, and making the planets revolve about him; and in geometry he discovered the 47th proposition of Euclid's first book, which alone would have been sufficient to have ranked him with the first of geometers. At this period flourished Anaximander, and soon after Anaximenes, Anaxagoras, and Cleofratus; these were all eminent in astronomy and philosophy. Eudoxus, 480 B.C., was a learned geometer, author of several problems, and his contemporary Zenodorus is the first of the ancients whose works have been handed down to us; all before his time having been lost or destroyed. About this time also flourished Hippocrates of Chios, who distinguished himself by the celebrated quadrature of the lunes which bear his name, as well as by his discoveries connected with the problem of doubling the cube, which excited great interest amongst the ancient mathematicians of this period. (See Duplication of the Cube.) This discovery revived some hopes of obtaining the required solution, but it soon appeared that the difficulty was merely changed, and not in the least diminished, and that it still presented obstacles that were insurmountable. This did not, however, discourage other mathematicians from following up the pursuit; and several curious geometrical properties were the result of these investigations; the conicoids of Nicomedes, the eisffod of Diocles, and the quadrarius of Diocletian, owe their origin to the same source.

Passing over some mathematicians and astronomers of less note,
note, we come to Plato, who cultivated both astronomy and geometry with great affinity, about 390 years B.C. The celebrated infirmer that he caused to be placed over the door of his school, "Let no one enter here who is ignorant of geometry," is a proof of the high estimation in which he held the latter science. To this philosopher we owe the introduction of the conic sections into geometry, and his disciple Aristeus is said to have composed five books on these curves, of which the ancient have spoken with the greatest commendations, but unfortunately they have not been transmitted down to our time. Besides Aristeus, Plato numbered amongst his friends, or scholars, Eudoxus, Menechmus, and Dinostratus; the former of whom was very celebrated for his extensive knowledge in astronomy and geometry; Menechmus, for his application of the conic sections to various problems; and the latter for the invention of the quadratrix, as applicable to the problem of doubling the cube, which seems to have been the germ of what is now termed the geometrical analysis.

It was about 90 years from the time of Plato to that of Euclid, during which period all the sciences were considerably advanced and extended, and treatises on particular subjects appeared from time to time, in which all the new knowledge was collected and arranged in systematic order. Thus was the object of Euclid in his celebrated Elements, a work which has met with such success incomparably surpassing that of any other book of science that ever was published, having been taught exclusively for several centuries in every place of mathematical instruction, and is therefore too well known to need any particular description. We are now arrived at that period when the Greek sciences were in their meridian splendour; Archimedes, one of the greatest geometers that ever appeared in any age or country, followed soon after the time of Euclid. His universal genius led him to the contemplation of almost every species of human knowledge, and nearly every branch of mathematical science is indebted to him for his numerous and important discoveries. Arithmetic, geometry, mechanics, optics, hydrodynamics, were alike the objects of his investigation, and experienced alike the powerful effects of his superior talents. We cannot in this place enter into a particular description of these discoveries, and must therefore refer our readers to the article ARCHIMEDES, in which an abstract of the most important of them will be found. After Archimedes, at the distance of about fifty years, another celebrated mathematician, Apollonius, cultivated the mathematical sciences with the greatest possible success, for the particulars of whose discoveries and writings we must refer to the article APOLLONIUS. This period, as before observed, (B.C. 250) was the most brilliant era of ancient geometry, for after the great men we meet with no other mathematician of the first order, yet there were several who cultivated both geometry and astronomy, and which nothing but the confined limits of this article would justify us in passing over in silence; such, for instance, as Eratosthenes, who first attempted to measure the circumference of the earth; Ctesibius, to whom we are indebted for the useful invention of water pumps; Hero of Alexandria, who was much celebrated for his application of geometry to the practical purposes of mechanics, and to whom we are indebted for the invention of the clepsydra, or water clocks. We might also enumerate many other eminent mathematicians and astronomers, but as we are under the necessity of limiting our observations to those who are most pre-eminently distinguished, we shall pass at once to Hipparchus, the prince and father of astronomy, who flourished about 142 B.C. To him we are indebted for the first systematic classification of the stars; for ascertaining nearly the duration of the year; the discovery of what he called the eccentricity of the solar orbit; the precession of the equinoxes; and various other important discoveries and observations; besides which Hipparchus had the merit of applying this science to the purposes of geography; he reduced to certain and invariable principles the method of determining the situation of places on the earth, by means of their latitudes and longitudes, of which, however, some notions were entertained as early as the time of Alexander. The next mathematician of eminence was Theodorus, who wrote an excellent work on the sphere, which may be considered as an introduction to spherical trigonometry; and though many of the author's propositions are almost self-evident, yet faithful to the views of the ancients, he has submitted them all to the most rigorous demonstrations, a task which he has performed with the greatest elegance. After this author, we proceed for three or four hundred years without meeting with any geometer who is much distinguished for his discoveries or improvements. The sciences had been for a long time in a declining state, in the school of Alexandria, where the celebrated Ptolemy began, in some measure, to revive them, at least the parts of them, by reducing all the parts of it into more order and conformity. His principal work, the "Almagest," (a word derived from the Greek, signifying the great collection) contains all the ancient observations and theories, to which his own researches being added, he may be said to have formed the whole the most complete collection of ancient astronomy that ever appeared; a work which supplies, in some measure, the place of those that preceded it, and for the compilation of which its author will be ever entitled to the gratitude of astronomers. It was some years after this period, (though the exact time has never yet been ascertained,) that Diophantus, a celebrated mathematician also of the Alexandrian school, made a new and remarkable step in arithmetic, by the invention of the indeterminate analysis; a species of algebra, and which is the first trace we have of this extensive branch of mathematics. The work consisted of 13 books, of which however only five have ever reached us, unless a seventh, which is found in some editions of Diophantus, be his work, which is considered as doubtful. This treatise displays great talents and originality, and has been admired in the greatest esteem by analysts of all ages, and has accordingly been commented upon and explained by various writers, both ancient and modern, but most of those of the former are lost. Of these we regret the commentary of the celebrated Hypatia, daughter of Theon, who flourished about the year 410 of the Christian era. The talents, virtues, and misfortunes, of this illustrious victim of fanaticism, have caused their homage of piety, while the remembrance of the deed, and the perpetrators of it, will as deservedly be execrated and abhorred by every friend of science and admirer of female virtue. (See HYPATHIA.) What was the distance of time between Diophantus and Theon is not distinctly known, it was however barren of any distinguished authors. About this period we meet with Pappus and Diocles, the latter of whom has been already mentioned in speaking of the duplication of the cube, and the former also made some ingenious advances, both with regard to this problem, and that of the trisection of an angle; but what he is more particularly distinguished for, is his collections of the various works of his predecessors; these collections contain one of the most valuable monuments of ancient geometry: in them he has assembled together a number of excellent works, almost all of which are now lost, and to them he has added several new, curious, and learned propositions.
MATHEMATICS.

propositions of his own; an interesting account of which is given under the article Pappus in Dr. Hutton's "Mathematical Dictionary;" see also the same article in the present work. After Pappus we meet with Eutocius, A.D. 520, who was himself a great mathematician; and whose commentaries on the works of Archimedes and Apollonius in particular are much esteemed. To the names already mentioned may be added those of Proclus, Marinius, and Hero the younger; to the former we are indebted for his commentary on some of the books of Euclid, but more for the kindness, attention, and protection, which he afforded to those who pursued those studies in his time. Marinius and Florus, his contemporaries, are celebrated for their architectural skill, and to them it is said we are indebted for the invention of domes; and Hero, who is supposed the younger, to dilmargin him from the learned author of the name of Alexandria, is equally celebrated as an engineer, and for his rule for finding the area of a triangle when the three sides only are given.

We are now arrived at that period so fatal to the sciences. These had for a long time taken refuge in the museums of Alexandria; where, destitute of support and encouragement, they could not fail to degenerate. Still, however, they preferred, at least by tradition, or imitation, that ancient and strict character which had been impressed upon them by the Greeks; but about the middle of the seventh century, a tremendous storm arose, which threatened their total destruction. Filled with all the enthusiasm a militant religion inspires, the successors of Mohammed ravaged that vast extent of country which stretches from the eait to the southern confines of Europe. All the cultivators of the arts and sciences, who from every nation had assembled in Alexandria, were driven away with ignominy; some fell beneath the swords of the conquerors; others fled into remote countries, to drag out the remainder of their lives in obscurity and distress. The places and the instruments which had been so useful in making an immense number of astronomical observations, were involved with the records in one common ruin. The whole of that precious library which contained the works of so many eminent authors, and was the common depository of every species of human knowledge, was entirely devoted to the flames by the Arabs; the caliph Omar observing, that if they agreed with the Koran they were useless, and if they did not, they ought to be destroyed; a sentiment worthy of such a leader, and of the cause in which he was engaged.

Here followed several ages of the most wretched barbarism and ignorance, so that it is even wonderful that the sciences should ever again have recovered this deadly blow; but as we before observed, some of the philosophers of Alexandria escaped the vengeance of their barbarous conquerors, and were carried with them some remnants of that general learning, for which this school was so deservedly celebrated. Still, however, destitute of books, of instruments, and probably also of the means of existence without manual labour, very little farther knowledge could be accumulated, and still less propagated, so that in a few years every species of knowledge connected with philosophy and mathematics must have become extinct, had not the Arabs themselves, within less than two centuries from this fatal catastrophe, become the admirers and supports of those very sciences which they had before so nearly annihilated. They studied the works of the Greeks with the greatest avidity, and if they added little to the stock of knowledge which those works contained, they became sufficient masters of many of the subjects to enable them to comment upon them, and to fet a due value upon these precious relics of ancient science; by which means they have been preserved, and handed down to the moderns. Of all the branches of mathematics, astronomy was that which the Arabs held in the greatest estimation, at the same time however they did not totally neglect the other branches. Our present system of arithmetic is derived from these people, though it does not appear that they were the inventors, but had acquired their knowledge of it from the Indians. Geometry also, and particularly trigonometry, owe much to the improvements of the Arabs. Mohammed Ben Musa, and Geber Ben Alpha, who lived about the eleventh century, are both well known for their scientific works. Amongst the Arabian princes and astronomers, the most celebrated are, Almanor, who flourished about the year 754; Al Naimon, who reigned from 815 to 833, in whole time, in consequence of the great support and assistance which he afforded to the sciences, we find them making very considerable progress; Alfragan, the Bishop Choras, and Albategni, were particularly distinguished about this period. This was an algebraist, geometer, and astronomer; Alfragan composed elements of the latter sciences, of which several editions have been published since the invention of printing; and Albategni, in consequence of his numerous and important observations, and accurate knowledge, was surnamed the astronomer of the Turks. The works of this author have been collected in one quarto volume, entitled "De Scientia Stellarum," of which there are two editions, one published in 1537, and the other in 1646. We cannot here enumerate all the Arabian astronomers and mathematicians who distinguished themselves for several centuries, an extensive list of whom, with their respective works, is given by Montucla in his valuable History of Mathematics; we must not however pass over Alhazen, a very celebrated Arab, who settled in Spain about the year 1050, and to whom we are indebted for a treatise on optics, and for the first theory of refraction and twilight.

About this time the mathematical science began to be propagated in several European countries. So early as the year 1202, an Italian merchant, Leonardus de Pisa, had composed a treatise on algebra, in which he succeeded in the solution of equations of the third degree, and those of higher dimensions, in certain cases, where they would allow of reduction. Jordanus Nemorarius was another eminent author in his time (A.D. 1250); he wrote on arithmetic, geometry, and the planisphere; but his contemporary, John of Halifax, commonly Sacrobosco, was much better known. This latter author was an Englishman, but went and resided as professor of mathematics at Paris. We have a treatise of his on the sphere; which has been commented on by Clavius, the Jesuit, and reprinted a great number of times; he likewise left us a treatise on the astrolabe, on the calendar, and on the arithmetic of the Arabs. In 1250, Campanus Novara translated and commented on Euclid's Elements, and wrote a treatise on the sphere, and another on the theory of the planets, the object of which was to explain the ancient almanacs, and the corrections introduced by the Arabs. We have another work of the same period on optics, by Thomas Pecam, who from a simple obversation monk became archbishop of Canterbury; this treatise has been several times reprinted, and was long considered as a classical work. The sciences at this time found a zealous patron in the great emperor Frederic II., even amid the continual wars he had to sustain against the pope. This prince ascended the throne in 1219, and died in 1250 during which period he founded the university of Naples.
Another celebrated philosopher of this period was Roger Bacon, an Englishman, who was born in 1214, and whose numerous works have been repeatedly reprinted. His treatise on optics is considered a very masterly performance for the time in which it was written. It has even been affirmed, that he understood the use of spectacles, and was the inventor of gunpowder; but in fact neither of these discoveries can be properly attributed to him, though, with regard to the latter, he was certainly upon the verge of it, but he did not thoroughly explain it, nor was this done for many years after. Bacon was persecuted by the monks, being accused of them of magic, and was on this charge thrown into a dungeon, from which he was not liberated, till he had fully convinced his superiors, and the pope, that he was no magician, nor ever had held any correspondence with the devil. With regard to the invention of spectacles, it was not made till after the death of Bacon, by Alexander Spina, a Jacobin friar, who died in 1332.

The 14th century produced few scientific men of eminence; but some of those who, though they did not advance this subject, prevented it from being lost, deserve to be mentioned. Of these we may enumerate Peter of Albano, who wrote a treatise on the artificial; and Cecchi Acoloi, professor of mathematics at Bologna, who composed a commentary on the figures of Socrates, which was several times reprinted. Both these men acquired the reputation of forcers and heretics, in consequence of which the former was burnt in effigy, and the latter in person, in the year 1328, at the age of seventy. In Germany, John of Saxony, an Augustinian friar, wrote on the Alphonsine tables, and on eclipses, and Henry of Heife, professor at the newly founded university of Vienna, treated on the theory of the planets; but these works were never printed. We might mention some other names, as John de Muris, author of a system of music, and an astronomical work; John de Lignières, also an astronomer at Amiens, and a few others; but their works being now wholly forgotten, it would answer no purpose to lengthen this article, and fatigue the reader with uninteresting details. Some progress, however, was made in mechanics during this century; wheeled clocks were constructed, which exhibited, besides the hours, several of the planetary motions; paper-mills were invented or improved, and the useful article paper began to get into common use, to which we are now arrived, was much more fruitful in men of science and genius than any we have met with since the time of the ancient Greeks. Amongst those who cultivated geometry and algebra at this time, is principally to be distinguished Lucas Pacioli, or Lucas de Burgo, who was a Franciscan monk, and flourished towards the end of this century. He composed several works, translated Euclid into Latin, to which he added some learned annotations; he also published a work entitled "Summa de Arithmetica Geometria," in which we find the common rules in arithmetic, the rule of false position, and the resolution of simple and quadratic equations; we are likewise indebted to him for two other works, one entitled "De Divina," and the other on the regular bodies.

Astronomy also made considerable progress in this age. Its first benefactor was John Gauenden of Vienna, and Peter Daitii, who, in 1412, proposed to the council of Constance a reformation of the calendar, which was become very incorrect. The cardinal Nicholas de Cusa ought also to be particularly distinguished for his persevering through fruitless attempts to revive the Pythagorean syllem. To these may be added Purbach, and his pupil Regiomontanus, who were two of the greatest promoters of astronomy at this period. They observed the heavens together at Vienna for ten years, and after the death of Purbach, his pupil took a journey to Rome to learn the Greek language with more facility, in order that he might read the other Greek works; Ptolemy having been before his principal recourse. Here his progress was very rapid; for in a short time he translated into Latin the Cosmics of Apollonius, the Cylinders of Serenus, the mechanical questions of Aristotle, the Pneumatics of Hero, all the works of Ptolemy, &c. Besides these labours, he was author of several excellent works of his own, particularly one on trigonometry; he was also employed by pope Sixtus IV. in the reformation of the calendar, but died before it was completed, in 1456. In France, James Lefèvre cultivated the mathematics with success, rendering them considerable service by his translations and other performances. In Italy, John Bianchini constructed astronomical tables, much perfected in their time; James Angelo, a Florentine, translated Ptolemy's geography; and Dominie Maria Noever of Bologna initiated Copernicus into astronomy. In Germany, John Engel, a Bavarian, published ephemerides of celestial motions, and proposed a scheme for reforming the calendar. In Spain, Ferdinand of Cordova commented upon Ptolemy's Almagest, and Bernard de Granolucli published also ephemerides in 1488, which calculated as far as 1550. In this century also, the properties of the magnet began to be better understood; some considerable voyages were undertaken and successfully performed; sea-charts were invented by Henry duke of Vitco; new lands and continents were discovered; in short, every thing seemed to promise a rapid progress in the cultivation of the sciences.

Early in the 16th century, we meet with several distinguished analysts and geometers. Of these Cardan is perhaps the best known, though some of his contemporaries equally distinguished themselves: such was Tartaglia, the author of the solution of cubic equations, which is commonly, though falsely, ascribed to Cardan. (See INDIFFERENT CAFFE.) A pupil of Cardan, Lewis Ferrari, also distinguished himself by his solution of biquadratic equations; the same was also done by Bombelli of Bologna, who likewise made several other important improvements and discoveries; amongst the rest, shewing that the two solutions of the common expression for the root of a cubic equation of the irreducible case was a real quantity, and thus removing what had been before considered as an unaccountable paradox. We ought also to mention Mauvilius, a Sicilian abbot, who discovered a method of summimg several series, as for instance series of squares, cubes, &c., as also the triangular and other figurate numbers. But during this century, no one has greater claim for his analytical discoveries than Vieti; to whom we owe a very important improvement in the algebraical notation. Before his time no solution of any but munerical equations had ever been attempted; the unknown quantity was represented by some letter or symbol, and all the other quantities were absolute numbers, and all particular rules were expressed in words at length as in arithmetic: but Vieti, by introducing letters as representatives of quantities, whether known or unknown, gave a generalization to the algorithm of this science, which is now one of its most important characterisies. To the fame celebrated author we are indebted for the theory of angular sections, a branch of analytical trigonometry, which has been so fruitful in the hands of the Bernoullis and Euler; as we are also for the first general
idea of applying algebra to the solution of geometrical problems, an invention which is falsely ascribed to Descartes. What is given above relates principally to analysis, but geometry also made some progress during the same period, through no very important discoveries were made in this science, except so far as that which relates to the angular sections of Vieta above-mentioned; however, Tartaglia, Maurolico, Commandino, and Ramus may be considered as possessing a respectable knowledge of this subject, and as having by their works and translations rendered it considerable service: besides these, we may mention Peter Metius, Hadrianus Romanus, and Ludolphus van Ceulen, each of them authors of different methods of approximation with regard to the ratio of the circumference to the diameter of the circle; the latter of whom, in particular, carried it to 36 places of decimals. Astronomy also was considerably advanced during this century; Copernicus very early in it made, or at least attempted to make, that important reformation of placing the fun in the centre of the system, according to the ancient or Pythagorean doctrine, though his work "De Revolutionibus," in which it is contained, was not completely finished till the year 1543, the author dying on the very day on which he received the first complete copy. This system, which is now so universally confided in, so simple in its mechanism, so conformable to all celestial appearances, and so worthy of the great and omnipotent architect, was, through the ignorance and superflition of a few contemptible bigots, declared to be heretical. To afford the mobility of the earth, or the fallibility of the pope, were considered as crimes of the blackest dye, and were accordingly visited with the most ingenious torture of the Inquisition; fortunately, however, for the cause of truth, and the sciences, this infatiation has long since been disarmed of its terror, and the true system of astronomy is now supported upon a basis, which no inquisitorial power will ever be able to destroy. Of those who most contributed to support the Copernican system, must be particularly distinguished the celebrated Galileo, whose important discoveries in various branches of astronomy, mechanics, and philosophy, are too numerous to admit of a minute detail in this place; we must therefore refer the reader for particulars to the article GALILEO. We shall, however, for the sake of connection, mention his discovery of the law of falling bodies, and his invention, or at least important improvement in the use of the telescope; whereby he first discovered the satellites of Jupiter. Tycho Brahe, the Danish astronomer, also flourished about this time, and is deservedly celebrated for his numerous and accurate celestial observations, which, aided by those made by himself, furnished Kepler with sufficient data to investigate the planetary motions, and finally led to the establishment of those laws that bear his name; and which may be considered as the first step towards the true theory of physical astronomy. See KEPLER'S LEXICON.

Such was the state of the sciences at the commencement of the 17th century, when a most important discovery was made by baron Napier, of Merchiston, in Scotland, who in 1614 published his "Logarithmorum Canonis Descriptio, &c." a work which entitles its author to a rank amongst the first-rate mathematicians. Previously to the invention of logarithms, all trigonometrical and astronomical calculations were attended with immense labour, in consequence of the numerous operations in multiplication and division which entered into them, at the same time that the results were necessarily attended with lefs certainty. But by this happy invention, all the most tedious cafes were rendered extremely easy, and consequently great facility given to astronomical and trigonometrical computations. It was not, however, in the first instance, so well calculated for general practice as the system in present use; for which we are indebted to Henry Briggs, professor of mathematics in the university of Oxford, who laboured with the greatest possible zeal to bring them into their present state. We shall not in this place enter into any description of the nature of these numbers, as this is already done under the article LOGARITHMS: it will therefore be sufficient for our purpose to name those who, at this time, most distinguished themselves in the advancement of this department of science; such were Gelibrand, Gunther, and Vlacq, all friends or pupils of Briggs; and to these we may add Julius Byrge, a German, who printed a table constructed according to the inverse order of our common tables of logarithms. Instead of conferring the numbers relative to the geometrical progression as the principal numbers, to which the logarithms ought to be subordinate, he, on the contrary, considered the logarithms as the principals, to which he made those depending on the geometrical progression correspond. But this system met with very little success, being in no respect calculated for common use, in consequence of the immense tables which it required.

About this period, 1620, Harriot, a well-known English analyst, enriched algebra by several important improvements, who first substituted small letters instead of the capital letters used by Vieta; and proved that every equation has as many roots as there are units in the index of the highest power, and that all equations may be considered as produced by the multiplication of equations of the first order. Descartes also shewed the method of expressing curve lines by means of equations, and of distributing them into different classes, according to the different order of these equations. We are also indebted to the same author for a method of drawing tangents, maximum and minimum, the theory of curves of double curvature, &c. problems which do their author more sublimarion than his more lofty, but hypothetrical theory of vortices, and other of his philosopbical speculations, which latter, however, are not materially connected with the present subject. Fermat also contributed largely at this period to the improvement of analysis, particularly in what relates to the Diophantine problems, and the theory of numbers; the latter of which branches may be said to date its origin from this time; many elegant numerical theorems were discovered by this author, most of which were left without demonstration, and some of them still remain to excite the talents of the ablest analysts of the present day. Several other mathematicians might here also be mentioned, who contributed to the advancement of the sciences at this period, but the limits of our article will not admit of such an enumeration; we must not, however, pass over Cavalieri, who first left the beaten path of the ancients, and treated geometry in a manner totally different from what they had done, and thus facilitated the operations in a variety of difficult problems; but at the same time it must not be denied, that it wanted the accuracy and certainty which characterized the ancient method. His work, which contained the doctrine of Indivisibles, was published in 1635, and may be considered the first link in the modern geometry. Mechanics and hydrodynamics were cultivated with equal success during this period. Torricelli, a pupil of Galileo, following the path of his master, made several important improvements; the most celebrated of which was his determination of the gravitating power of the atmosphere. This discovery led to that of the barometer, or rather perhaps the latter led to the
the former; for it was by an instrument of this kind that he was enabled to determine the weight of this fluid.

The results obtained by this means was opposed by various arguments, till the well-known experiment of the Puy-de-
Dome put the question at rest for ever. This experiment was projected by the celebrated Pascal, to whom we are indebted for many important discoveries in various branches of the mathematical sciences, particularly for the first ideas of the doctrine of probabilities, which has become in latter times an extremely useful science, being that on which are founded all calculations connected with life-insurances and annuities. The subject was but slightly touched upon by Pascal, but was afterwards considerably enlarged by Montmort, and finally completed by De Moivre.

At this period almost every branch of science was cultivated with the happiest effect; problems were proposed by the mathematicians of one country as challenges to those of another; a lively emulation was excited between the contending parties; and each supported the honour of his country with all the power he possessed. This was the means of producing many curious propositions and interesting theories, but the limits of our article will not allow of entering upon this subject, and we must therefore reluctantly pass over in silence many eminent writers of this time, whose names would otherwise deserve to be recorded. We must not, however, omit Dr. Wallis, who, in 1665, published his Arithmetica Infinitas, a work abounding with genius, and of which the object was to determine the sums of various series of numbers, the quadrature of certain curves, and many other subjects, in which this author discovered a profound knowledge of geometry and analysis; to him owe we the methods of denoting radical by fractional indices, as we do also the use of negative indices; Descartes having employed exponents in positive and integral powers only. The theory of continued fractions also date their origin from this period, having been first discovered by lord Boumker, of Caile Lyons, in Ireland, who was born in 1626, and died in 1634. Another eminent mathematician of this date defers particular attention, the celebrated Huygens, a Dutchman, whose extensive and persevering genius led him to the cultivation of every department of science; geometry, astronomy, analysis, and mechanics, are indebted to him for important improvements; in the former his theory of vortices displays the powers of his mind; in astronomy his name will ever be remembered for his discovery of what is now termed the fourth satellite of Saturn, and the ring by which that planet is encompassed; which discoveries were made by means of a powerful telescope which he had himself constructed; the theory of pendulums, their vibrations, the centres of oscillation, percussion, and various other interesting and useful mechanical problems are due to this distinguished author. (See Huygens.) It was also towards the conclusion of this century, at which we are now arrived, that the progressive motion of light was discovered by Roemer, a Danish mathematician and astronomer; before his time the propagation of light was supposed to be instantaneous, but by observations of the eclipses of Jupiter's satellites, this was found to be erroneous, and not only its progressive motion became obvious, but the velocity with which it moves was pretty accurately ascertained. Dr. Hooke, another celebrated English philosopher of the same date, here also claims our attention. To this distinguished author we owe a variety of discoveries and improvements in various branches of mechanics and astronomy, but of all these, perhaps his ideas of universal gravitation, though they were not complete, are the most deserving of notice. On this head he made the following suppositions:

all the celestial bodies have not only an attraction or gravitation towards their own centre, but they mutually attract each other in the sphere of their activity. All bodies which have a simple and direct motion, would continue to move in a right line, if some force were not incessantly turning them out of it, and compelling them to describe a circle, ellipse, or other curve. Attraction is so much the more powerful, as the attracting body is more near. These cases all enter into the Newtonian system, and only the law of attraction was wanting to render the theory complete.

We have not hitherto mentioned the name of Newton, though most of his discoveries were made prior to the beginning of the 18th century; because we wished to consider this important epoch unconnected with any extraneous matter, and to bring together in this place only those distinguished authors who contended with each other that crown of glory, which by universal consent has been placed upon the brow of the English philosopher. Under this class are included Leibnitz, and the brothers John and James Bernouilli, to whom we also add the marquis de L'Hopital, a French nobleman, as much distinguished for his amiable and upright disposition as for his profound knowledge in analysis and geometry. It does not enter into our plan to give a minute description of the labours of each of these authors, as that would far exceed the limits of this article; we must therefore confine our observations to what may be considered real discoveries, and in these our illustrous countryman will necessarily form the most prominent object; the Bernouilli undoubtedly possessed a most powerful genius, and gave the solution of problems the most refined that ever exercised the mental faculties of man; still their works are not of that description which can properly form a part of a brief abstrac of mathematical history, though in a more extended account they would form a very considerable part; the fame observation has place with regard to de L'Hopital. To Leibnitz we are indebted for the discovery of the differential calculus, at least it was he who first published it in the Latin Transact. for 1684, though his real claim to the original invention has been always a matter of dispute between the English and foreign mathematicians; the former contending that he had derived his method from hints which he had received, and from letters that passed between him and Newton and other English analysts. It is impossible in this place to enter upon the merits of Leibnitz's claims to the priority of invention, we must therefore refer the reader who wishes to see the matter fully investigated, to the "Commerciium epilicum de Analyt. promota," published by order of the Royal Society, in which the whole of this subject is minutely investigated. Montela has also given in his "Histoire des Mathematiques," an impartial investigation of these claims, but Boffist is evidently biased, and not only on this subject, but in others relating to Newton is tardy in his acknowledgment of his shining merit. With regard to Leibnitz and Newton, they were both rich in genius and invention, and it is not improbable that both arrived at the same calculus by different routes. One is unwilling to attribute to Leibnitz a claim to the discovery of analytic geometry, which is essentially that of Descartes. This discovery is not so important as that of plagiarists, and with regard to Newton it never was infamated by any of his opponents that any charge of this kind attached to his doctrine of fluxions. In fact, when we consider the methods of maxima et minima, of Fermat, Roberval, and Hudde, and the differential triangle of Barrow, each of which were so many advances towards the perfection of the new analysis, it will not be at all surprising that the same general results should be deduced by two such men as Leibnitz and Newton; where so much had been already
ready prepared for their use, and which only wanted a great
and comprehensive genius to generalize and bring it to perfe-
tion. The invention of fluxions, though it will ever form a
most important era in the history of the exact sciences, is
still by no means the greatest of Newton's discoveries.
Physical astronomy, chronology, and optics, are equally in-
debted to him, and shew the power and extent of his uni-
veral genius. It would be useless to attempt to enumerate
in this place his discoveries in these sciences, we must there-
fore refer the reader to the articles Attraction, Gravita-
tion, Fluxions, Optics, &c. as also the biographical article
Newton, where he will find a more ample detail of partic-
ulars than could with propriety be given in this general
sketch, the subject of which is not to enter into the mi-
ute of the history, but merely to trace the general
outline of the progress of the sciences, and the connection
and dependence of the several parts upon each other, which
view of the subject is lost in the detached histories of
the separate branches. We must now pass rapidly over the
history of the last century, not that it is less prolific in
events than the preceding, but because the events are more
recent, and many eminent authors of this period still exist,
and are still enriching the sciences with their discoveries.
Others that are no more, we ought particularly to distingui-
sh Halley, Bradley, Taylor, d'Alembert, and Euler. Of
these Halley will ever be remembered for his numerous
and accurate astronomical observations, and particularly for his
being the first and only astronomer that ever truly predicted
the return of a comet. The theory of the aberration of
light will immortalize the name of Bradley; and the doctrine of in-
crements will claim for its author, Dr. Taylor, a distinguished
place among modern geometers. D'Alembert is deservedly
celebrated for his extensive knowledge in elegant literature;
while his theory of partial differences, and various other ma-
thematical researches, cannot fail of placing him in the first
rank of modern mathematicians. Euler's voluminous writ-
ings display in every part a superior and comprehensive
genius, and the clearness and perspicuity with which he
treated the various branches of analysis and geometry, shew
the solidity and accuracy of his judgment: in fact, if we
consider Euler as an analyst and geometer, we cannot
deny him the honour which has been bestowed upon him
by a celebrated author of the present day, viz. that he was
one of the most extraordinary men that any age or country
ever produced. To these names we might add those of
Cotes, Maclaurin, Simpson, Cramer, Waring, and various
others, but the limits of this article require us to desist
from any farther enumeration.

In the preceding pages, we have endeavoured to follow, as
nearly as possible, the order of time in which the several dis-
coversies and improvements were made, and, as far as we were
able, to introduce all the most prominent parts of the history
of mathematics, and the most celebrated of its professors;
but in the short space that this article occupies, it must ne-
cessarily have happened that many distinguished names are
omitted. To compensate for this, in some measure, we have
framed the following biographical chart, which exhi-
bits, under one point of view, the dates, names, and dis-
covers of all the most eminent mathematicians from the ear-
liest period. Those who are more particularly celebrated are
printed in Roman capitals, with the country in which they
flourished, and that particular branch of mathematics in
which they most excelled, or which they have invented or
improved. Where there is nothing of a particular nature
whereby an author is distinguished, his country only is given,
and some general term, as astronomy, philosophy, mathe-
ematics, &c. to indicate to which branch of the sciences he
more particularly directed his attention. But in the last
four centuries, in order to make more room, such remarks
are omitted, and the name only retained. This table might
have been much more extended had our limits admitted of
it; but it is presumed that few authors are omitted, who
have contributed, in any considerable degree, to the advance-
ment of those sciences.
### MATHEMATICS.

Chronological Table of the most eminent Mathematicians from the earlist Period to the present Time.

MATHEO, Sr., in Geography, a town of Spain, in the province of Valencia; 27 miles S.S.W. of Tortosa.

MATHEPOUR, a town of Hindustan, in Guzerat; 30 miles N.W. of Poonam-Summat.

MATHER, Increase, in Biography, an eminent American divine, who flourished in the 17th and 18th centuries, was born at Dorchester, in New England, in the year 1635. He pursued his academical course of studies at Harvard college, in Cambridge, where he took his degree of B.A. in 1656. In the following year he made a voyage to England, and from thence he went to Ireland, and having a brother, minister to a congregation at Dublin, he entered himself of Trinity college, in which he proceeded M.A. in 1658, having performed the necessary exercises with great applause. He was not more distinguished for his talents than respected for the piety of his manners and the rectitude of his deportment, and was offered a fellowship in that institution; but finding the climate of the island unfavourable to his health, he returned to England, and officiated for some time as minister, in the place of Mr. Howe, at Great Stretton, in Warwickshire. Upon the return of the pastor to his flock, in 1659, Mr. Mather accepted an invitation to become chaplain to Colonel Bingham, governor of the island of Greenly, and preached every Sunday, as well before the garrison, as in the town of Peter le Port. When the time came that he was obliged to conform to the established religion, or quit his situation, he readily submitted to the latter, and returned to England. Here he might have had valuable church preferment, but he chose a clear conscience to any thing that the world could offer, and failed for New England, where he was chosen minister to the New Church at Bolton. Shortly after this, he married the daughter of Mr. John Cotton, a gentleman of considerable eminence in England, from whence he had been driven on account of his non-conformity. He had formerly been vicar of Bolton in Lincolnshire, in England, and was now settled as minister at Bolton in America. In 1664, Mr. Mather was ordained to the pastoral office, the duties of which he performed through life with credit to himself, and highly esteemed by his people. In the year 1663, when the Indians were driven out of the country by the Spaniards, Mr. Mather was chosen the representative of the inhabitants of the American provinces, to censure the actions of the Spaniards. Mr. Mather attended at a meeting of the freemen of Bolton, and by his zealous persuasion determined them to reject a motion for that purpose unanimously, and to leave the issue to Providence, rather than become the degraded instruments of voluntarily alienating their liberties. This firme measure had considerable influence in prevailing on the country in general to imitate the example set by the Boltonians. Upon the publication of the king's second declaration for liberty of conscience, some of the ministers of New England, and their churches, drew up addresses of thanks to him for the benefits which they enjoyed in consequence of it, and Mr. Mather proceeded to England for the purpose of presenting them. He was favourably received at court, and laid before the king the state of the country. While he continued in England, the revolution took place, and he was consulted by the new administration on many political topics, particularly on an attempt to obtain the reestablishment of the Massachusetts colony, upon their charter lost by being an act of parliament, which was frustrated by its dissolution. He at length obtained from his majesty a new charter, containing the whole of the old one, with the addition of new and more ample privileges. Having rendered this important service to his fellow citizens, he set sail for America in 1692, and on his return he received the public thanks of the house of representatives for his faithful and zealous endeavours to benefit his country. He now returned to his labours in the church, and at Harvard college, of which he was chosen president in 1684, and also created doctor of divinity. He died in 1723, at the age of 84. He was author of many theological tracts: of "A brief History of the War with the Indians in New England;" of "An Essay for the recording of illustrious Providences, wherein an account is given of many remarkable and memorable events which have happened in this late age, especially in New England;" of "A Discourse on Comets;" "A Discourse concerning Earthquakes, &c."

MATHER, Cotton, son of the preceding, was born at Boston in 1662-3, and was, while very young, distinguished by his great proficiency in the learned languages. At twelve years of age he was thought to be well qualified, by his previous knowledge, for entering on academical studies, and was accordingly admitted to Harvard college, where, in a very short time, he surpassed his contemporaries in the different branches of literature and science. Before he was twenty years of age he had taken his degrees of B.A. and M.A. He now undertook the office of pastor at Providence, and was ordained with great reputation for the space of about seven years, and he had, afterwards, the satisfaction of seeing several of his pupils become eminent characters in the church and the world. In early life he was afflicted with a rambling, or impediment in his speech; but by great attention and care he overcame the defect, and engaged in the services of the pulpit in the year 1680. He was first elected as assistant to his father in the church at Boston; and in 1683, he was ordained as co-pastor. He was indefatigable in every duty in which he engaged; and to render himself more extensively useful, he applied to the study of the modern languages, and made himself master of the Iroquois Indian tongue, so that he was able to write and publish treatises in each of these languages. He was frequently consulted on matters of state by the magistrates, and more than once succeeded in quelling dangerous riots by the force of his persuasion. In one thing, however, he was strangely misguided by the prejudices of the times in which he lived; he believed in the powers of witchcraft, and joined in the persecutions against those accused of witchcraft. He avoided the inhabitants of the small-pox, who had incurred the displeasure of their neighbours on this head. He contributed to promote the prevalence of the time by publishing the trials of the accused, and by some other writings in support of the absurd and pernicious doctrine of witchcraft. In every other respect he was uniformly influenced by a most disinterested regard for the public good; he planned and promoted several useful institutions, and he was an active member of a society whose professed business was to compose differences and prevent law-suits. He was a commissioner for Indian affairs, and exerted all his powers to promote the instruction and happiness of the native inhabitants. He was the first person that introduced the practice of inoculation for the small-pox into America. His fame was not confined to his own country; but his merit was known and acknowledged in distant parts. In 1710, the university of Glasgow conferred on him the degree of doctor in divinity, and in 1714 the Royal Society of London elected him one of their body. He died in 1728, when he had completed his fifty-fifth year, leaving behind him a character for great piety and benevolence; he was as a man and a member of society, polite, friendly, and a most entertaining as well as instructive companion. He published nearly four hundred distinct pieces, many of which were, of course, very small, such as single sermons, essays, &c. Among these, we may notice "Magnalia Christi Americana; or, An Ecclesiastical History of New
New England from its first planting in 1620 to 1693;" "The Wonders of the Invisible World; being an account of the trials of several witches lately executed in New England, and of several remarkable curiosities therein occurring;" "Johnes in Eremo; or, The Lives of several famous Divines;" and "India Christiana; or, An Account of the Propagation of Christianity in the East and West Indies." Our author, during a great part of his life, was honoured by an epistolary correspondence with several persons of eminent character for piety and learning, and among others with that of lord chancellor Lord Barington, Mr. Whitton, M. Defaguille, and the celebrated doctor Franke, professor of divinity in the university of Halle in Saxony. Biog. Brit.

**MATHIEU, Sr., in Geography, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Rochechouart; 12 miles N.S.W. of St. Junien. The place contains 1946, and the canton 9699 inhabitants, on a territory of 2252 square kilometres, in 10 communes.**

**MATILDA, or MAUD, in Biography, empress of Germany, and queen of England, daughter of Henry I. king of England, and Matilda of Scotland, was born in 1102. At eight years of age she was betrothed to Henry V., emperor of Germany, and was sent over to that country for education. The emperor dying, without issue, in the year 1125, Matilda returned to the court of her father, who, having lost his only son, caufed all the nobles, prelates, &c. to swear fealty to her as his successor, in case he should die without male issue; and in 1127 he married her to Geoffrey, eldest son of Fulk, count of Anjou. She now went to reside in Normandy, and in 1132 she was delivered of a son, afterwards Henry II.; and by the death of her father, in 1135, she became heiress of all his dominions in England and France. She was then residing at Anjou with her husband, of which circumstance Stephen, earl of Blois, took advantage, and feized upon the crown of England. The barons of Normandy followed the example of the English in submitting to Stephen, so that Matilda was almost instantly deprived of the inheritance which her father had attempted to secure for her. The government of Stephen was soon hated, and Matilda, in 1139, landed in England, and a number of the most powerful barons, without hesitation, declared in her favour. A civil war ensued, and, in 1141, Stephen was taken prisoner, and Matilda was crowned queen of England in the cathedral of Winchester. She was naturally of a haughty disposition, and, overfed with her good fortune, she refused to listen to the requests of her nobles, and insolently rejected the petition of the Londoners for the restoration of the laws of Edward the Confessor. Conspiracies were formed to seize her person, but she escaped the machinations of her subjects, and withdrew to Normandy in the year 1148, where she spent the remainder of her days. She died in 1167. Hume.**

**MATILDA, countess of Tuscany, the daughter of Boniface, marquis of Tuscany, celebrated for her attachment to the papal see, was born, according to some accounts, in 1039, and, according to others, in 1046. She first married Godfrey le Biffa, son of the duke of Lorraine, but lived almost entirely apart from him, not choosing to follow him from Italy to a colder climate. Godfrey died in 1076, and in the same year, by the death of her mother Beatrix, she succeeded to vast possessions in Italy. She now put herself entirely under the direction of Gregory VII., espoused his cause with all the zeal of a partizan, and in the year 1077 she made a reverent grant of all she possessed to the church, to the prejudice of the emperor. Henry IV., to whom they would have devolved on her death. She affidned the pope with all the forces she could raise, and several times appeared in person at his head. After the death of Gregory, in 1085, Matilda still continued to give her support to the Roman see under his successors, Victor III. and Urban II. In 1089, she married, a second time, Guelph, son of the duke of Bavaria, a distinguished leader in the party adverse to the emperor. Matilda died in 1115, leaving solemnly confirmed her dominions to the holy see. The popes, however, were not able quietly to take possession of those vast estates; and the contest for them was the source of long continued wars between them and the emperors. A part only of the donation finally took effect; nevertheless, Matilda is justly regarded by the votaries of the holy see as the most powerful temporary advocate of the papal interest, and as having rendered her a subject for extravagant panegyric with one party, and far very scandalous imputations with the opposite. Unver Hill.**

**MATILDA, in Geography, a township of Upper Canada, in the county of Dundas, being the sixth township in ascending the river St. Lawrence; a few miles N.W. of Oswego, et cetera.**

**MATILDA, a town of Spain, in the province of Leon; 20 miles S.S.W. of Salamanca.**

**MATIN, a river of Canada, which runs into the St. Lawrence; 150 miles below Quebec.**

**MATINS. See MATINS.**

**MATINA, in Geography, a town of Mexico, in the province of Colua Rica; 65 miles N.N.E. of Carthag.**

**MATINATA, Italy; a lover's morning song, under the window of his mistress. The Crusca dictionary defines it, "Composizione da cantare e sonare, ch'e fanno gli amanti in full matino davanti alla cafa dell' amata; come fcrania quel che fanno la notte al fen: *a composition sung and played by a lover in the morning, under the window of his mistress; as a serenata is performed in a similar manner in the evening. See SERENATA.**

**MATINICUS ISLANDS, in Geography, islands of America, on the coast of Maine. Matinicus lies in N. lat. 45° 56'. W. long. 68° 20'.**

**MATINO,**
MATINO, a town of Naples, in the province of Otranto; 10 miles E. of Gallipoli.

MATISPOLVA, a town of Transylvania; seven miles E.S.E. of Samosvmar.

MATITES, in Natural History, the name of a fHONE described by several authors. The characters they give of it are, that it is of a pale greyish colour, and of the form of the nipples of a woman's breasts, several of these nipples appearing upon one stone.

It is plain, that there needs no more to the formation of one of these matite than the petrifaction of a piece of the shell of one of the CEPLINI MAVII, or sea-eggs, which have large papillae, such as those of the Red fern, with some of its populin upon it. As to the colour, it is not to be limited to grey alone, but may be various as the colours of stones, since any species of stone may have gone to the formation of it; and whatever colour the stone matter was, of that will the matites be.

MATKNETZEL, in Ornithology, the name of a bird approaching to the snipe kind, and called by Gefner galinula curvirostra; and by the common people of Germany, matkern. It is common in watery places in many parts of Germany and Italy. See Fulica maculata.

MATLOCK, in Geography, a village and parish in the wapentake of Wirksworth, Derbyshire, England, is situated on the eastern banks of the river Derwent, 17 miles distant from Derby, and 143 from London. At the time of compiling the Domeflay book, it was a hamlet of the maro of Matlocks, which was part of the demesne of the crown. It was afterwards held by William de Ferrers, earl of Derby, but on the attainder of his son Robert reverted to the crown; and being granted by Edward I. to Edmund earl of Lancaster, continued a part of that earldom and duchy till the reign of Charles I., when it was sold to the copyholders of the manor, and is now divided into small shares. According to the return made under the population act of 1801, this parish contained 492 houses, occupied by 2334 persons. The inhabitants are chiefly employed in the neighbouring lead mines, and in the manufacture of cotton. The houses are principally of stone, and at the entrance of the village is a neat stone bridge. The church, which stands on the verge of a romantic rock, consists of a nave, side aisles, and a small chancel. On the eminence called Riber, are the remains of a Druidical altar, or cromlech, called the High Stone. It is composed of four marls of grit-stone, one of which, apparently the smallest, is placed on the others, and is computed to weigh about two tons. On this upper stone is a circular hole, six inches deep, and nine in diameter, wherein, till about the middle of the last century, floated a stone pillar. About a mile and a half from the village is Matlock-bath; which, though few situations can be more beautiful, was only occupied by some rude cottages inhabited by miners, till its warm springs began to attract notice, for their medicinal qualities, about the year 1698. At that period the original bath was built, and a house also built for the accommodation of visitors. A second spring having been discovered, a new bath and lodging-house were erected. At a later period, a third spring was found; another bath and house were consequently built; the latter, by various alterations, is become one of the most commodious hotels in England. These buildings are of stone, and are respectively named, the Old Bath, the New Bath, and the Hotel. In these, and two private lodging-houses, five hundred persons may at the same time be accommodated. The Matlock feaons commences at the end of April, and continues till November.

The scenery of Matlock dale is peculiarly romantic and picturesque; being diversified with rugged rocks contrasted with the finest verdure. Two of these rocks, the High Tor, and Maffon hill, are worthy of notice. The former is upwards of 350 feet in height; the lower part is covered with small trees and underwood of various foliage; but the upper part, for fifty or sixty yards, is one broad mass of naked perpendicular rock. The fragments that have fallen from it form the bed of the river which flows immediately below. After heavy rains, the impetuosity of the current is greatly increased, and the sublimity of the view proportionally augmented. Opposite to the High Tor, but rising with a gentler ascent, though to a greater elevation, is Maffon hill, which appears like a pile of immense jagges. The summit of this mountain has been named the Heights of Abraham, and overlooks the country to a vast extent, besides commanding a beautiful bird's-eye view of nearly the whole dale. The height of this stupendous eminence is about 250 yards; the path to its summit has been carried in a winding or rather zigzag direction, and in various places has been planted with rows of firs, which opening at convenient distances, admit the eye to range over the scenery beneath, from different points of view. Near the upper end of the dale is a spacious building, erected for the manufacture of cotton, by the late Sir Richard Arkwright, and now the property of his son Richard Arkwright, esq., whose elegant mansion, Willerley castle, stands on the south side of a commanding eminence, which terminates the extensive range of rocks that forms the external boundary of the Derwent, in its course through Matlock dale. The castle consists of a body, in the form of an oblong square, having a circular tower rising from the centre of the roof, and a semicircular tower projecting from the front on each side of the entrance, and two wings with a round tower at each angle; the whole structure is embattled, and the walls are of freestone. Beauties of England and Wales, vol. iii.

MATLOCK WATERS. See Matlock Waters.

MATMAI, one of the Kurile or Kurilko islands, the southermost and largest, subject to the Japanee, and fortified and garrisoned on the side toward the continent. The channel between this island and Japan is said to be no more than 60 veris wide, and full of rocks. The current is very rapid. On the southern promontory stands the Japanese town Matmai, where the supreme commander resides. The hairy Kurils are in possession of the island parts of the island. The Japanee and Chinese resort thither in trading vessels for the purchase of commerce, which consists in bartering with the Kurile for sea-otters, seals, and various sorts of furs; also fat, oil, and blubber of whales, and other marine animals; eagles' feathers for their darts and arrows, and other articles, in exchange for silk and cotton pieces for garments, Japaned veiiffs, rice, brandy, tobacco, fabrics, knives, pots, and kettles, hatchets, and the like. In the region of the bay Aikis, the land extends northward in a great headland, where lofty mountains rise on all parts, tending eastward in ridges; within land are spacious vales between the mountains, and large rivers roll in currents to the sea. The coast abounds in bays and bights, which might be made to serve for harbours. The forests consist of oaks, beech, elm, birch, willow, and other trees of unknown species. The fields produce a multitude of unknown vegetables, among which are strawberries, cranberries, bilberries, and a large port of hips and haws. Of animals, the forests afford haunts to black bears, elkS, roebucks, deer, fables, foxes, hares, and river-otters. The bays and inland lakes swarm with all kinds of ducks and water-fowl; nor is the country deficient in frogs and snakes.
MATOGROSO. or MATO-GROSSO is the most inland, and the most celebrated province of Brazil. According to Alcedo, the Portuguese first took possession of it in 1561, having discovered the riches of its gold mines, by means of the Missionaries, to whose pious and benevolent labours we are chiefly indebted for the discovery of the interior parts of Cabralia, or as it is called by the Portuguese, Land of the Amazons, though widely remote from the river idly so called. A town was erected, and a governor appointed. As in mining stations in general, the land is barren, and provides scarce and dear. The climate is hot and moist. It was in vain attacked in 1766, by orders of the viceroy of Peru, the Spaniards being obliged to retreat by the difficulty of the route, and the valour of the Portuguese. S. lat. 10° to 23°. W. long. 72° to 64°.

MATOLINEN, GREAT AND LITTLE, two small islands in the Atlantic, near the coast of Virginia; the former in N. lat. 37° 32', W. long. 75° 36', and the latter in N. lat. 37° 38', W. long. 75° 32'.

MATONBACKRAPETTA, a town of Hindooftan, in the circuit of Cuddapah; 32 miles S.S.E. of Cuddapah.

MATOON HARBOUR, a harbour on the southern coast of Nova Scotia. N. lat. 44°. W. long 64° 45'.

MATOUR, a town of France, in the department of the Saône and Loire, and chief place of a canton, in the district of Macon; 13 miles W. of Macon. The place contains 2062, and the canton 6373 inhabitants, on a territory of 7521 kilometres, in nine communes.

MATOURA, in Botany, a plant so called by Asbeck, and figured in his Guian. t. 259, appears to be properly referred by Schreber to VANDELLIA. It is known to the Creoles by the name of Boifile sauvage, or Wild Bafl, having the foliage of an Oxymum, with a bitterish, somewhat aromatic, flavour, and is used, either bruised or in decoction, as a vesicare, being considered very efficacious in that respect. It is a native of meadows in Cayenne and Guiana, flowering all the year round. The root is annual. Stem two feet high, much branched, square, leafy, slightly downy. Leaves opposite, an inch long, ovate, serrated, downy, paler beneath; elongated and entire at the base. Flowers axilllary, blueish, generally foitary. We are not informed of the derivation of the above name, nor whether the French Matouri be the original or the translation. —This plant is the VANDELLEA progenitis of Vahl, as well as of Willd. Sp. Pl. v. 3. p. 583, and is said to be extremely common in South America, by road finds, from the island of Trinidad to the Brails. See VANDELIA.

MATRA, in Geography, a chain of mountains in Hungary, S.W. of Erbun.

MATRAMODO, a town of Hindooftan, in the Carnatic; 27 miles W. of Vellore.

MATRASS, MATRACHUM, or BOLT-BEAD, a glass vessel, used by chemists in digestions, and other operations. The matras is made in form of a bottle somewhat bellied in the middle, with a long narrow neck; it is coated with earth, when it is to be placed on a very hot fire. And when it is required it should be dropped very close, they seal it hermetically.

The matras, used in alloying, is a vessel of very pure and transparent glafs, not too thick at the bottom, which would make it apt to burst in the fire. It is, for this use, to be about eight or ten inches high, and to have an orifice fearfully so much as half an inch wide, lest the matters contained in it, being in a violent state of ebullition, should either rise over the mouth of the vesfel, or at least be partly thrown out in form of small drops, like a thin rain, which drops always carry some of the metal with them. The bottom is spacious enough when it will hold an ounce or two of aqua fortis, and the height of the vesfel is of a farther use in making a greater repercussion of the flames. The mouth ought also to be turned backwards, in form of a broad lip, that the solutions, when poured out, may not run down the sides of the vessel. Cramer, Art. of Aff. p. 68.

Matrasies are also used as receivers: as to their form, some are spherical, others flattened at the bottom, and others in the shape of an egg, called phialophyllic. The most convenient of all, when only a small quantity of matter is used, are bottles of thin glass, called medical phials; because they are cheap, made of good glass, and may be quickly heated, so that the liquor contained in them shall boil without danger of being broken. See LABORATORY.

MATRAY, in Geography, a town of the Tyrolese; r. prox. 8.

MATRI, among Hindu Mythology, is a term applied to several of their female divinities, or divise mothers, the meaning of the word. It seems nearly the same as Sakti, which, however, is generally plaited to mean the active energy of a power, rather than a mother. (See SAKTI.) In the eighth volume of the Asiatic Researches, Mr. Pater- son enumerates eight of these Saktis, as follows:

1. Maheshwari, the Sakti of Mahela or Siva. 2. Sarasvati; in this character, indeed, more correctly called Brahmii or Brahmania, Sakti of Brama. 3. Narayana of Narayana. 4. Indrani, or Aindr, of Indra. 5. Kau- mari of Kartikya. 6. Varahi of Vihun, in the Varavhata. 7. Narasini of Vihun, in the Varavhavata. (Of all these the specific mention is made under their several names.) 8. Aparajita, a form of Bhavani, the female principle. The last, Mr. Paterison remarks, may be the Aphrodite of the Greeks; and Maheshwari, or a female Siva, riding on a white bull, may have given rise to the story of Europa's rape, while Brahmii, or the female Brahma, with the swan, may, is like manner, have occasioned the fable of Jupiter and Leda. These explanations were, perhaps, invented by the Greeks, to account for symbols, of the meaning of which they were ignorant. On the foregoing passage, Mr. Colebrooke, the worthy successor of Sir William Jones in the chair of the Asiatic Society, gives, in a note, the following information. "The eight Saktis, or energies of as many deities, are also called Matris, or mothers. They are called Brahmi, &c., because they sprang from the bodies of Brama, and the other gods respectively. In some places they are thus enumerated: Brahmi, Maheshwari, Aindr, Varahi, Vaihimavi, Kumar, Chamunda, and Charchika. Some reduce the number to seven; omitting the two latter, and adding Kauvery (which see.) Prayers are addressed to the Matra on various occasions, especially in the Cavauchs, or defensive incantations. (See Matra.) Two are cited by way of example, and an extract from the Mancandeya Parana, descriptive of these godfiees. "May Brahman, conferring the benefit of all benedictions, protect me on the
MAT

Ch. Comm. "The calf hemispherical, composed of linear, imbricated, nearly equal, membranous scales. Cor. compound, radiated; florets of the disk all perfect; tubular, funnel-shaped, five-cleft, spreading; those of the radius female, oblong and three-toothed. St. (in the tubular florets) Filaments five, capillary, very short; anthers cylindrical, tubular. P. (in the tubular florets) German oblong, naked; style thread-shaped; the length of the filaments: stigma cloven, spreading; the female or ligulate florets differ in having a rather shorter style, and two revolute fligmas. Peric. none, except the permanent calyx. Seeds in all the florets solitary, oblong. Down none. Recep. naked, cylindrical or conical.

Obl. This genus differs from *Pyrethrum* in having no crown or pappus attached to the seed.

1. *M. aurea.* Sweet Feverfew. Linn. Sp. Pl. 1256. (M. recutita; Linn. Sp. Pl. ed. 1. 891. Fl. n. 701.; Fl. Suec. ed. 1. 254. without the synonym*) Receptacle. Florets of the radius deflexed. Calyx-cells equal at the margin."—Native of Sweden, but of what country besides is uncertain, this being a very obscure species, much mislaid by authors. The Linnaean herbarium throws no certain light upon it. What Ehrhart has given in his *Plantae Officinalis* 58, as *Matricaria Chamomilla,* seems rather to answer to the description of the species in question.

Hudson and Lightfoot were of opinion that *M. flavescens* of Linnaeus was only a variety of this species, but Dr. Smith in his *Flora Britannica* says they are distinct, the former being never found in Britain, and having its flowers not more than half as large as in the latter.—Professor Martyn observes that "according to the Swedish observations, kine, goats and sheep eat this plant, horses are not fond of it, and swine refuse it. It seems to be rejected in general by all quadrupeds with us. It is supposed to posse..."
the same qualities with *Anthemis nobilis*, but in an inferior degree.'

Willdenow has adopted a third species, *M. caprifolium*, on the authority of Thunberg's *Prodrorus* and Linnæus's *Manifilis*; but on referring to the Linnæan Herbarium, we find its seeds furnished with a crown, so that it must of course be removed to *Pyrethrum*. For the same reason *M. Partbenium*, and *maritimum* have been placed under that genus.

**Matricaria**, in Gardening, comprehends plants of the hardy, herbaceous, perennial kind, of which the species cultivated is the common feverfew (*M. parthenium*).

It has several varieties, as with full double flowers, with double flowers, having the florets of the ray plane, of the disk tihular; with very small rays; with very short tubular florets; with naked heads, having no rays; with naked sulphur-coloured heads, and with elegant curled leaves.

**Method of Culture**—The plants of this species may be raised from seeds, by parting the roots, and by cuttings.

In the first mode the seeds should be sown in the spring, as about March, upon a bed of light earth, and when they are come up, planted out into nursery-beds, at about eight inches asunder, where they may remain till the middle of May; when they should be taken up, with a ball of earth to their roots, and planted in the middle of large borders, or other parts for flowering. But they should not be permitted to feed, as it often weakens and decays the roots; therefore, when their flowers are past, their stems should be cut down, which will cause them to pull out fresh heads, whereby the roots may be better preferred.

**Matrice, or Matrix.** See Matrix.

**Matrice, or Matrix**, in Dyeing, is applied to the five simple colours, whence all the rest are derived or composed.

These are the black, white, blue, red, and yellow or root-colour. See Dyeing.

**Matrix, or Matrices**, used by the letter-founders, are those little pieces of copper or brass, at one end whereby are engraved, dent-wife, or *en cres*, the several characters used in the composing of books.

Each character, virgula, and even each point, in a dis- course, has its several matrix; and, of consequence, its several punchen in to strike it. They are the engravers on metal that cut or grave the matrices.

When types are to be call, the matrix is fastened to the end of a mould, so disposed, that as the metal is poured on it, it may fall into the creux or cavity of the matrix, and take the figure and impression thereof. See Letter-Founders.

**Matrices**, used in Coining, are pieces of steel, in form of dyes, wherein are engraved the several figures, arms, characters, legends, &c. wherein the species are to be stamped.

The engraving is performed with several punchen, which being formed in relieved, or prominent, when struck on the metal, make an indented impression, which the French call *en cres*. See the manner hereof under Engraving on steel. See also Coining.

**Matricula**, a register kept of the admission of officers, and persons entered into any body or society whereof a list is made. Hence those who are admitted into our universities are said to be matriculated.

A mong ecclesiastical authors, we find mention made of two kinds of matricula; the one containing a list of the ecclesiastics, called matricula clericorum; the other of the poor subsisted at the expense of the church, called matricula paupercularum.

**Matricula** was also applied to a kind of almshouse, where the poor were provided for. It had certain revenues appropriated to it, and was usually built near the church; whence the name was also frequently given to the church itself.

**Matrimony.** See Espousals, and Marriage.

**Matrix, in Anatomy**, the womb, or that part of the female of any kind, wherein the fetus is conceived, and nourished till the time of its delivery. See Woman, Uterus, Fetus, &c.

**Matrix, Bearing down of, in Surgery.** See Prolap-sus.

**Matrix, Polyp of.** See Polypos.

**Matrix, Retrusion of.** See Retroversion.

**Matrix, Suffocation of the.** See Suffocation.

**Speculum Matricis.** See Speculum.

**Matrix** is also applied to places proper for the generation of vegetables, minerals, and metals.

Thus, the earth is the matrix wherein seeds sprout; and marcasites are by many considered as the matrices of metals.

The matrix of ores is the earthy and fanny substances in which these metallic metals are enveloped: these are very various, frequently fcar, quartz, floors, or hornblende.

**Matrix Sessilis, in Natural History**, a name given by Hartman, and some other authors, to a sort of fuffiance resembling fossil wood, or the backs of trees, common in the cliffs of the shores of the Baltic, and found in digging all over Prussia. This is the bed in which the fossil amber of that kingdom is lodged, and it is supposed to have no small share in the production or formation of that fossil. The workmen who dig for amber always make this their guide, and follow the veins of it, never searching any where else for the amber.

The fossil wood, which is truly fuch, and has been once vegetable matter, whatever part of the world it is found in, agrees in the fame general marks of distinction; and, knots, and other evident proofs of its having been once vegetable, are found in all of it; but this matrix of amber, whether found in Prussia, Denmark, or elsewhere, is flill of the fame kind, and shews none of these characteristic marks of wood. However, notwithstanding all this, it is fast, that on opening the fitches for the fortifications at Copenhagen, several large flakes of amber were found, all of them adhering to the fides of large bodies of trees, which were black as ebony. The pieces are preferred in the cabinet of the king of Denmark, in that place, and some of them weigh forty or fifty ounces. This is an additional circumstance to the common observation of something resembling wood being always found where amber is, and deferves to be considered, as it tends to overthrow the present received fystem of amber being originally a mineral production.

Dr. Fothergill, in his Essay upon the Origin of Amber, maintains, that it is a vegetable resin, the product, perhaps, of the fir or pine kind; and that it is changed into its present form by a mineral acid. In proof of its refulous nature, he alleges its aspect, texture, and form: besides, the bodies included in it are mothly animals of the flying kind, few reptiles, except such as ants, spiders, &c. which are found in trees, and scarcely ever any aquatics; and this could not happen in the sea, nor in the earth, but upon its surface.

He apprehends, likewise, that this resin, with the trees which afforded it, were buried in the earth by the deluge, or some violent convulsion of the same kind; to which purpose he observes, that the substance of which the proper veins of amber consist, hath several genuine characteristics of wood still remaining: the texture of amber, which is fibrous, and, when dried,
dried, capable of swimming in water, and burning like other
wood, sows, he says, what it hath been. Nor is the amber
dipped in these veins is one continued frutatus; but lumps
of it are irregularly differentiated through the whole of the
supposed woody masts. The change which this wood under-
goes, is produced partly by time, and completed by the vi-
trioic mineral acid of the earth. Such an acid, it is argued,
is present wherever amber occurs in its proper matrix, and
is sometimes found in the amber itself. The acid of the fall
of amber is vitriolic; and common turpentine affords, by
proper management with a vitriolic acid, a considerable por-
tion of the same chemical principles that amber does; and
those pieces of amber which have been found soft and im-
perfect, are nearly related to a vegetable resin. Phil. Trans.

Matrix is also applied figuratively to several things
wherein there appears a kind of generation, and where cer-
tain things seem to acquire a new being, or at least a new
manner of being. Of which kind are the moulds wherein
the printers' types, or letters, are call'd, and those used in
striking money and medals, in coming. See Matrix.

Matron, Matriona, among the Romans, signified
a married women, and sometimes also the mother of a
family. There was, however, some difference between matro-
nae and mater-familias. Servius says, that some imagined the
difference to lie in this, that matrona was a woman who had
one child, and mater-familias one that had several. But
others, particularly Aulius Gellius, take the name matrona
to belong to a married woman, whether she had any children
or not; the hope and expectation of having them being
enough to warrant the title of mother, matrona, and for this
reason it is, that marriage is called matrimony. This opinion
is supported by Narsus.

Matrons of an Hospital. See Hospital.

Matrons, Jury of, is a jury of twelve free women,
directed by the judge to enquire into the fact when a woman
is capitally convicted, and pleads her pregnancy. This plea,
though it cannot be made inlay of judgment, may be ur-
gered in repitie of excusio. If the jury bring in their
verdâl quick with child, execution shall be stayed generally
to the next session; and from session to session, till either
the woman is delivered, or proves, by the course of nature,
that she has been with child at all. But if the once hath had
the benefit of this reprieve, and been delivered, and afterwards
becomes pregnant again, she shall not be entitled to the ben-
efit of farther repitie for that cause; for the may now be executed
before the child is quick in the womb, and shall not, by her own
continence, evade the sentence of justice.

If a widow feigns herself with child, in order to excludethe
next heir, and a supposititious birth be suspected to be in-
tended, then upon the avit de ventre infelicitatis, a jury of
women is to be impanelled to try the question; Whether
with child or not?

Matronalia, feasts of the Roman ladies, or ra-
ther matrons, celebrated on the calends of March, in honour
of the god Mars.

Ovid mentions many reasons for the institution of this
feast; but the principal seems to have been the peace con-
cluded between the Romans and Sabines, by the mediation
of the women. The women granted to their servants
on this occasion the same privileges which were granted to
the slaves by their masters in the Saturnalia.

No men living in celibacy were allowed to assist at the
feast.

Matrosses, soldiers, in the train of artillery, next
below the gunners, and properly apprentices or assistants to
them: their duty is to assist the gunner in traversing, spung-
ing, loading, and firing of guns, &c. They carry fire-locks,
and march along with the guns and Borne-waggons, both as
a guard, and to help in case of emergency.

Matunga, in Geography, a town of Hindoostan; 37
miles N.E. of Rutnapour.

Matschach, a town of the duchy of Carinthia;
10 miles S. of Luxemburg.

Matschex, a town of Saxony, in the circle of
Leipzig; 6 miles N. of Leifelnich.

Matscheviz, a town of the duchy of Warsaw,
memorable for a battle fought in 1794, between the con-
fererat Poles, under Kochuko, and the Russians, under ge-
eral Ferfan, in which the latter were victorious: 600 Poles
fell, and 16,000 were made prisoners. All the artillery fell
into the hands of the Russians, and only 1,500 men escaped.
Kochuko, who was taken prisoner, was severely wounded,
and was nearly lost his life. 32 miles E. of Warsaw.

Matsima, or Schilpas, an island of Japan, E. of
Nippon, N. lat. 38 

Matsinglo, a town on the W. coast of the island of
London. N. lat 15 38 E. long. 120 121.

Matsukaw. See Masowia.

Matsunay, a sea-port of the island of Jelfo, tri-
batory to Japan. N. lat 40 40 E. long. 138 44.

Matsyavatara, in Hindo Mythology, is the first
of the ten chief incarnations of the god Vishnu. This avatara
was in the form of a fih, which is the meaning of the words,
and it has been proved to have immediate reference to the
deluge, and to be the fame history, digrified in oriental fic-
tion, of that event, as related in our scriptures. Sir W. Jones
(Asiatic Researches, vol. i.) affords to the opinion of
Bochart, that the table of Saturn was raid ed on the true history
of Noah; he shews that the seventh Menu of the Hindoos,
named Satayavata, in whose days this avatar is related to
have taken place, corresponds in fiction and character with
our patriarch. (See Menu and Satayavata.) In his
reign the Hindoos believe the whole earth to have been
destroyed by a flood, including all mankind, who had become
corrupt, except the pious prince himself, the seven Rishis,
and their several wives, who, by command of Vishnu, en-
tered a fowling vessel, accompanied by pairs of all animals.
(See Rishis.) Vishnu, assuming the form of a fih, com-
manded the ark to be fastened by a cable, formed of a vast
terp, to his stupendous horn; secured thereby till the
flood subsided; when he and Brahma flew a monster named
Hyagriva, or the horse-headed, who, while Brahma was re-
poling at the end of a kalpa (see Kalpa), stole the Vedas,
and mankind had consequently fallen into the depths of
ignorance and impiety. The Vedas having been recovered,
(see Veda, the world was progressively re-peopled by
ious inhabilants, descendants of the devout Satayavata and
his favoured companions. As Nuh, the true name of our
patriarch Noah, may be eall'd deduced from Menu, fo Adam-
may from adjn, meaning, in the Sanskrit language, first;
tending, as is evident in W. Jones's opinion, to the con-
clusion that the first and last of the seven Menu can be no
other than the great progenitor and restorer of our species.
The history of the avatar under discussion is the subject of
the first Purana, or sacred poem, consisting of 14,000
lines, (see Purana,) and is concisely told in the eighth
book of the Sri Bhagavata, or life of Krishna. See those
articles, also Kurmavatara, for a brief account of the
second incarnation of Vishnu.

Matsys, Quintus, in Biography, known by the name
of the blacksmith of Antwerp, because he followed that
employment till he was 20 years old, when he became a
painter.
painter, and arrived at great perfection in the dry style of
the time in which he lived.
He was born in 1460, and is said to have been excited by
love to exchange his heavy iron labours for the softer and
more engaging charms of the pencil. Whatever were his
motives, it was fortunate that he did devote his mind to that
pursuit, as he possessed uncommon talents, and exerted them
with great industry. His exertions were confined to subjects
of common and vulgar life, to which he gave considerable
interest, by his attention to expression, and his skill in re-
ndering it. The best instance we have in this country is his
excellent picture of the two mifers in Windfor cafe, of
which there is a duplicate by him in possession of lord Lyt-
telton at Hagley in Worcestershire. He died in 1529, aged
69.
MAT. The produce the first fusion of a sulphur-
retorted ore is called a mat, a term probably adopted from
the German miners; for the word was in that language signifies
dull without lustre, a character that is applicable with great
judicious to most of the half sulphurized regnis when compared
to the same metals in their pure state.
MATTA DE BRAZIL, in Geography, a populous town
of Brazil, in the government of Pernambuco: 25 miles W.
of Olinda: from its vicinity great quantities of Brazil wood are
fet in Europe.
MATTADEQUON CREEK, a river of Virginia, which
runs into York river, N. lat. 37° 40'. W. long. 77° 20'.
MATTADORE. See Oوبر.
MATTAGESS, in Ornithology, the English name of the
largest species of the kimis, or butcher-bird.
The word magges is borrowed from the Savoyards, and
signifies the murdering pye; and has been given from its
favour disposition, and its resemblance to the magpie in the
shape of its tail. See LAMUS ExcuBiER.
MATTAPONY, in Geography, a river of Virginia, na-
vigable 70 miles above 1 a month; it rises in Spotsylvania
county, and pursuing a S.E. course, joins Pamunkey below
the town of Dewon, and forms with it York river.
MATTARELLA, a town of Italy, in the duchy of
Spoleto; eight miles N.E. of Terni.
MATTATHIAS, in Biography, a Jewish priest, scion
of the family of Macabees, was defended from one of the
twenty-four appointed by David to officiate in the temple, and
was of the branch of the Almoneans. The perdition of
his countrymen, and profanation of their religion by An-
tiochus Epiphanes, were so grievous to him, that he retired
from Jerusalen to his native place, to avoid the fight. One
of the king's officers, named Apelles, coming thither to en-
force his master's commands, assembled the people, with
Mattathias and his five sons, and endeavoured to persuade
them to compliance, but the zealous and patriotic priest
louder declared, that although the whole nation abandoned
the religion of their fathers, he and his house would continue
faithful to their God. His zeal carried him much farther
than a mere affriction of his pious confance; he put in prac-
tice an injunction of the Mosaic law, by actually killing on
the spot a Jew who presented himself to sacrifice at the altar
of an idol. At the same instant, he fell upon, and slew the
king's officer, and his attendants, overthrew the idol, and
ran through the city, calling upon all who were attached to
their laws to follow them. They quickly found themselves at
the head of a considerable body of men; and having con-
quered together as to the lawfulness of fighting on the sab-
bath-day, it was agreed not only to be lawful but obli-
gatory to refiit an attack from their enemies, and the ene-
emies of their religion on the Sabbath. They instantly became ag-
gressors, and marched from city to city; overthrew the altars
of idolatry, and restored the worship of the true God,
Mattathias caufed all the prisoners taken from the apostates
to be put to death without mercy or compunction. Thus
successfully did he commence that revolt which was pro-
ductive of so many great events under his sons Simon, Judas,
and Jonathan, and perceiving their own end approaching, he
gave a most solemn exhortation to his sons to live in unity,
and pursuc with zeal and courage the course they had entered
upon. He died in 166 B.C., leaving behind him the char-
acter of a valiant and faithful adherent of the religion and
MATTEI, SAVERIO, a Neapolitan lyric poet, and mu-
cical critic; long in correspondence with Metastasio, an emi-
nent Hebraist, and translator of the psalms into Italian verse;
for the reception of music in every form of can-
tata, duet, trio, and chorus. He was in close friendship
with Jomelli, whole famous Mirfcrere, for two voices, was
composed to his version. He manifested his great reard
for the admirable musician Jomelli, by affilling Gimaro
Manna in the arrangement and execution of a plan for his
public funeral in 1754: furnishing an example to poledity
the gratitude due to great talents, and a bululus to young
artists to merit equal honours. The learned Mattei has
given an account of this public funeral, and of the works of
the great musician, in his "Saggio di Poesie Latine ed Ita-
liane," published at Naples, immediately after the melanch-
ol event.
MATTEUS, NICOLA, a Neapolitan performer on the
violin, who arrived in England in the latter end of Charles II.'s
reign, and was one of the first great players upon that in-
strument, who settled in London.
A general passion for the violin, and for pieces expressly
composed for it, as well as a taste for Italian music, seem
to have been excited in our country about this time, when French
music and French politics became equally odious to a great
d part of the nation.
In MS. memoirs of music, by the Hon. Roger North,
brother of the lord Keeper Norsh, to which we have had ac-
cess, there is a curious and characteristic account of this
musician; in which we are told "that the decay of French
music to which Charles was so partial, in favour of the
Italian, came on by degrees its beginning was accidental,
and occasioned by the arrival of Nicola Matteis. He was an
excellent musician, and performed wonderfully on the violin.
His manner was singular; but he excelled, in one respect,
all that had been heard in England before: his arca, or
manner of bowing, his shakcs, divisions, and, indeed, his
whole tytle of performance, were surprizing, and every stroke
of his bow was a mouthful.
"All that he played was of his own composition, which
manned him to be a very exquisite harmonist, and of a
boundless fancy and invention. And by all that I have been
able to observe of his abilities, or to hear concerning those
of other performers on the violin, none but Corelli seems to
to have surpassed him.
"When he first came hither he was very poor, but not
so poor as proud; which prevented his being heard, or
making useful acquaintance for a long time, except among a
few merchants in the city, who patronized him. And setting
a high value on his condeffention, he made them indemnify
him for the want of more general favour.
"By degrees, however, he was more noticed, and was
introduced to perform at court. But his demeanour did not
please, and he was thought capricious and troublesome; as
he took offence if any one whiffered while he played, which
was a kind of attention that had not been much in fashion
at our court. It was said that the duke of Richmond would
have
MAT

have settled a pension upon him, though he wished him to change his manner of playing, and would needs have one of his pages-few him a better. Matteis, for the sake of the jest, condescended to take lessons of the page, but learned so fast, that he soon out-ran him in his own way. But he continued so outrageous in his demands, particularly for his folsos, that few would comply with them, and he remained in narrow circumstances and obscurity a long while.

"Nor would his superior talents ever have contributed to better his fortune, had it not been for the zeal and friendly offices of two or three dilettanti, his admirers. These were Dr. Walgrave, a prodigy on the arch-lute; Sir Roger L'Éttrange, an expert violin; and Mr. Bridgman, the under-secretary, who accompanied well on the harpsichord. These becoming acquainted with him, and courting him in his own way, had an opportunity of describing to him the temper of the English, who, if humourous, would be liberal; but if uncivilly treated, would be fulkly and despise him and his talents. Assuring him that by this little complaisance he would neither want employment nor money.

"By advice so reasonable, they at length brought him into such good temper, that he became generally efficacized and sought after; and having many scholars, though on moderate terms, his purse filled apace, which confirmed his conversion.

"After this, he discovered a way of acquiring money, which was then perfectly new in this country. For observing how much his scholars admired the lessons he composed for them, which were all duos, and that most musical gentlemen who heard them, wished to have copies of them, he was at the expense of having them neatly engraved on copper-plates, in oblong octavo, which was the beginning of engraving music in England; and these he prefixed, well bound, to lovers of the art and admirers of his talent, for which he often received three, four, and five guines. And so great were his encouragement and profits in this species of traffic, that he printed four several books of 'Ayres for the Violin,' in the same form and size."

He printed lessons likewise for the guitar, of which instrument he was a concomitant master, and had so much force upon it, as to be able to contend with the harpsichord, in concert.

Another book of his writing was designed to teach composition, ayre, and thorough base. Of this work, though it was printed, but few copies are subsisting. His full pieces, concertos, and solos, were never published, and are very scarce, if at all to be found.

The two first of the four books mentioned above, of which many copies were dispersed, consist of preludes, canons, round dances, and double compositions fitted to all hands and capacities. The third book has for title, Ayres for the Violin, to wit: preludes, fugues, allemands, farands, courants, gigue, divisions on grounds, and double compositions fitted to all hands and capacities. The fourth book is entitled, Other Ayres and Pieces, for the violin, bafe-viol, and harpsichord, somewhat more difficult and artificial than the former; composed for the practice and service of greater masters upon those instruments.

Mr. North observes, that while the lovers of music were becoming acquainted with his manner of playing from his own books, which often happened in large assemblies, no one pretended to do the like; for none could command that fulness, grace, and truth, of which he was master. So that, in his own time, his compositions were thought impracticable from their difficulty; and since, as they were never thrown into the shops, they have been but little known. So that at present, now the instrument is so much advanced, no one can have the least idea of these pieces having ever been difficult, who was not a witness of his own manner of playing them. Indeed, his books, well studied, are sufficient rudiment of artful composition.

Another observation of this speculative dilettante is, that 'in a numerous assembly, when Matteis alone was to entertain the company, having his friends Walgrave, L'Éttrange, and Bridgman about him, and aiming with great humour and enthusiasm, he has set on the attention of the whole audience with much force and variety, as to prevent even a whisper for more than an hour together, however crowded the room.'

After this, it is easy to imagine that his reputation and abilities would enable him to accumulate wealth, or to live in splendour: he chose the latter, took a great house, and indulging appetite, lived so luxuriously, that he brought on disabilities which soon put an end to his existence.

He left a son, Nicola Matteis, whom he taught on the violin from his cradle. "I have seen the boy in coats," says Mr. North, "play to his father's guitar. When he grew up he became a celebrated master on the violin, in London, for several years. Being invited into Germany, he went to Vienna, and has continued there ever since, in full payment for all the masters we have received from those countries.'

The younger Matteis must have returned to England soon after Mr. North's Memoirs of Music were written; as we remember to have seen him at Shrewsbury, where he was settled as a language-master as well as performer on the violin in 1737. We afterwards learned French and violin of this master, who continued at Shrewsbury till his decease, about the year 1749. He played the solos of Corelli with more simplicity and elegance than any performer we ever heard.

According to Walther, his name appeared in the Vienna calendar, as one of the emperor's band of violinists in 1721 and 1727. In Roger's Catal. of Music, five different works appear under the title of "Arie cantabile a Violino solio Violoncello e baso continuo." This seems to have been the younger Matteis, of whom the Hon. Mr. North speaks.

MATTELOY, in Geography, a town of Hindoostan, in Canara; two miles from Nehuram.

MATTER, a town of Tunis, anciently called "Oppidum Matterensici;" 27 miles N.W. of Tunis.

Matter, materia, body, or an extended, solid, divisible, moveable, and passive substance, the first principle of all natural things, from the various arrangements, and combinations whereof all bodies are formed.

Aristotle makes three principles, matter, form, and privation: which last the Cartesians throw out of the number, and others the two last.

The properties of matter we are pretty well acquainted with, and can reason about its divisibility, solidity, &c. but the subject in which these properties reside, or their substratum, is still a mystery. Aristotele speaks very darkly on the subject, defining matter to be nec quid nec quantum, nec quale, nor any certain determinate thing at all; which many of his followers interpret so as to believe, that matter does not at all exist. The Cartesians make the essence of matter to consist in extension; arguing, that since the properties above-mentioned are all that are essential to matter, some of them must constitute its essence; and, since extension is conceived prior to all the rest, and is that without which none of the rest can be conceived, extension is that which con-

VOL. XXII.
Matter.

It constitutes the essence of matter. But the conclusion here is unjust; for, on his principle, the essence of matter, according to Dr. Clarke, would have the fairest title to constitute its essence, the existence being conceived prior to all properties, and even to extension. Since, then, the word extension appears to go farther, and to be more general, than matter, that impenetrable solidity, which is essential to all matter, and to matter alone, and from which all its properties manifestly flow, may, with more propriety, be called the essence of matter.

Again, if extension were the essence of matter, and so matter and space the same thing, it would follow, that matter is infinite and eternal, that it is a necessary being, and could neither be created nor annihilated; which is absurd. Besides, it appears, both from the nature of gravity, the motions of comets, the vibrations of pendulums, &c. that space is not matter; and therefore it is not extension, but solid, impenetrable extension, which has a power of refilling, that constitutes matter.

Many among the old philosophers maintained the eternity of matter; out of which they supposed all things to be formed by the hands of nature; as being unable to conceive how any thing should be formed out of nothing. Plato maintained, that matter had existed eternally, and concurred with God in the production of all things, as a passive principle, or a kind of collateral cause.

Matter and form, the two simple and original principles of all things, according to the ancients, composed some simple natures, which they called elements; out of the various combinations whereof all natural things were afterwards composed.

Dr. Woodward seems of an opinion not very unlike this, viz. that matter is originally and really very different, being at its first creation divided into several ranks, sorts, or kinds, of corpuses, differing in subtilty, gravity, hardnefs, flexibility, figure, fize, &c. from the various compounds and combinations of which, he thinks, arise all the various bodies in nature, as to colour, hardnefs, gravity, tallowes, &c. But for Isaac Newton takes all those differences to result from the various arrangements of the same matter; which he judges to be homogeneous and uniform in all bodies.

Besides the properties of matter formerly known, Sir Isaac Newton has discovered a new one; viz. "That of attraction, or that every particle of matter has an attractive power, or a tendency towards every other particle: which power is strongest in the point of contact, and suddenly decreases, in fomuch that it acts no more at the least sensible distance; and, at a greater distance, is converted into a repelling force, whereby the parts fly from each other." On this principle of attraction, he accounts for the cohesion of the particles of bodies, which is otherwise inexplicable.

For he takes occasion to observe, "That all bodies seem to be compounded of hard particles, even light itself, and all other the most volatile of fluids; insomuch that hardnefs may be esteemed a property of all uncompounded matter; at least, the hardnefs of matter faints on as good a footing as that of its impenetrability; all the bodies we know of being either hard themselves, or capable of being hardened. Now, if compound bodies be so hard, as we find some of them, and yet if they are very porous, and consist of parts which are only laid together, the simple particles, which are void of pores, and were never yet divided, must be much harder. Now, such hard particles being heaped together, can scarce touch one another in more than a few points; and therefore they must be separable with much less force than is requisite to break a solid particle, whole parts touch in all the space, without any pores or interlices to weaken their cohesion. How then should such very hard particles, only laid together, and touching only in a few points, stick together, and that so firmly as they do, without the assistance of something that causes them to be attracted or pressed towards each other?"

The same great author observes farther, "That the smallest particles may cohere by the strongest attractions, and compose bigger particles of weaker virtue; and many of these may cohere, and compose still bigger particles, whose virtue is still weaker, and so on for divers successions, until the progressions end in the biggest particles; on which the operations in chemistry, and the colours of natural bodies depend, and which, by cohering, compose bodies of a sensible magnitude. If the body is compact, and bends or yields inward to preffion, without any flowing of its parts, it is hard and elastic, returning to its figure with a force arising from the mutual attraction of its parts. If the parts slide from one another, the body is malleable or soft. If they slip easily, and are of a fit size to be agitated by heat, and the natural heat is great enough to keep them in agitation, the body is fluid; and, if it be apt to stick to things, it is humous. And the drops of every fluid affect a round figure by the mutual attraction of their parts, as the globe of the earth and sea affects a round figure, by the mutual attraction of the gravity of its parts."

Again, "Since metals, dissolved in acids, attract but a small quantity of the acid, their attractive force reaches but to a small distance. Now, as in algebra, where affirmative quantities cease, there negative ones begin; so in mechanics, where attraction ceases, there a repulsive virtue must succeed. That there really is such a virtue, seems to follow from the reflections and inflections of the rays of light; the rays being repelled by bodies in both those cases, without the immediate contact of the reflecting or inflecting body. The same thing seems also to follow from the emission of light; a ray, as soon as shaken off from a shining body by the vibrating motion of the parts of the body, and got beyond the reach of attraction, being driven away with exceeding great velocity; for that force, which is sufficient to turn it back in reflection, may be sufficient to emit it. It seems also to follow, from the production of air and vapour; the particles, when they are shaken off from the body by heat or fermentation, so soon as they are beyond the reach of the attraction of the body, receding from it, and also from one another, with great strength, and keeping at a distance, so as sometimes to take up above a million of times more space than they did before in the form of a dense body; which by contraction and expansion seems unintelligible, by reigning the particles of air to be frugivorous and ravenous, or rolled up like hoops, or by any other means than a repulsive power. The particles of fluids, which do not cohere too strongly, and are of such a smallness, as renders them molc susceptible of those agitations which keep liquors in a floror, are more easily separated and raredied into vapours, i. e. in the language of the chemists, they are volatile; rarefying with an easy heat, and condensing again with cold. But those which are groffer, and so are less susceptible of agitation, or which cohere by a stronger attraction, are not separated without a stronger heat, or perhaps not without fermentation. And these last are the bodies which chemists called fixed; and yet these, being rarefied by fermentation, become true permanent air; those particles receding with the greatest force, and being most difficulty brought together, which, upon contact, cohere the most strongly. And because the particles of permanent air are groffer, and arise from denser substances than those of vapours; thence it is, that true air is more ponderous.
powderous than vapour; and that a moist atmosphere is lighter than a dry one, quantity for quantity. From the same repelling power it seems to be, that flies walk upon the water without wetting their feet; and that the object-galluses of long telescopes lie upon one another without touching; and that dry powders are sufficiently made to touch one another to as flick together, unless by making them, or wetting them with water, which, by exhalation, may bring them together; and that two polished marbles, which by immediate contact stick together, are yet differently brought to clothe together as to flick."

He farther observes, "That, all things considered, it seems probable, God, in the beginning, formed matter in solid, stuffy, hard, indenumerable, moveable particles, of such sizes, figures, and with such other properties, and in such proportion to space, as most conduced to the end for which he formed them; and that these primitive particles, being solid, are incomparably harder than any porous bodies compounded of them; even so very hard as never to wear, and break in pieces: no ordinary power being able to divide what God himself made one in the first creation. While the particles constitute entire, they may compose bodies of one and the same nature and texture in all ages; but, should they wear away, or break in pieces, the nature of things depending on them would be changed. Water and earth, composed of old worn particles, and fragments of particles, would not be of the same nature and texture now with water and earth composed of entire particles in the beginning. And, therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations and new associations and motions, of these permanent particles: compound bodies being apt to break not in the midst of solid particles, but where those particles are laid together, and which is in few points."

It seems farther, "That these particles have not only a vis inerere, accompanied with such passive laws of motion as naturally result from that force, but also that they are moved by certain active principles, such as that of gravity, and that which causeth fermentation, and the cohesion of bodies. These principles are to be considered not as occult qualities, suppos'd to result from the specific forms of things, but as general laws of nature, by which the things themselves are formed; their truth appearing to us by phenomena, though their causes are not yet discovered."

Hobbes, Spinoza, &c. maintain all the beings in the universe to be material, and their differences to arise from their different modifications, motions, &c. Thus matter, extremely subtle, and in a brisk motion, they conceive, may think; and so they exclude all spirits out of the world. See Hobbesism and Spinozaism.

Dr. Berkeley, on the contrary, argues against the existence of matter itself; and endeavour to prove, that it is a mere substratum, and has no existence out of the mind. See Abstraction, Body, and Existence.

Some late philosophers have advanced a new hypothesis concerning the nature and essential properties of matter. The first person who suggested, or at least published an account of this hypothesis, was M. Bovechov, in his "Theoria Philosophias Naturali," printed at Vienna in the year 1758. He supposes that the whole mass of matter constituting the various bodies of the universe, consists of a very large, but finite number of simple, indivisible, unextended atoms. These atoms, which may be considered as physical points, are endowed with repulsive and attractive powers, which operate variously at different distances. In other words, they are surrounded with various spheres of repulsion and retraction, in the same manner as solid matter is generally supposed to be. At the least and innermost distances they repel one another, and by diminishing the distances, these repulsive powers are augmented beyond all limits, so as to be sufficient for annihilating the greatest velocity, and for preventing the actual contact of the primary atoms of matter. At sensible distances the force, which was repulsive, becomes attractive, and decreases sensibly, as the squares of the distances increase, so as to constitute universal gravity, and to extend beyond the sphere of the most distant limits. But between the supposed innermost repulsive force and the outermost attractive force, at sensible distances, many changes or varieties of force, and consequent determination to motion, occur; the repulsive force being diminished as the distance is augmented. The repulsive force becomes wholly extinct at a certain distance: but on increasing this distance, attraction begins, increases, becomes felt, and vanishes; and when the distance is still greater, the force becomes repulsive, increases, and vanishes as before. Changes of the kind now mentioned occur at sensible distances, sometimes more rapidly, sometimes more slowly; and sometimes one kind of force may become extinct and recover its appropriate state without passing to the other kind. For all these variations the different distances, though sensible to us, afford sufficient scope, as the least part of space is divisible in infinitum. Our author's assumed atoms policies, besides these repulsive and attractive forces, that vis ineratia which is admitted to belong to matter by almost all modern philosophers. Our author has illustrated his theory of repulsive and attractive forces by a geometrical curve, varying with a change of distances, which, at first view, appears to be a complicated irregular line; but which Bovechov shews to be regular and uniform, and capable of being expressed by an uniform algebraical equation. But finally, out of the subject, the detail of which he does not render it intelligible, would far exceed our prescribed limits, we must refer to his own work. Nor can we explain at large that law of continuity, by which variable quantities, passing from one magnitude to another, pass through all the intermediate magnitudes, without ever abruptly passing over any of them, and which our author first proves from induction, and then applies to the illustration and establishment of his system. From this law our author infers the impossibility of contact between bodies, and by means of it he explains the interior repulsive forces of his system. Again, from these repulsive forces he deduces the incutiention of his atoms; for as this repulsion is common to all matter, it must cause a perfect simplicity in the first elements of body. If these elements were extended, and consequently compounded of particles of an inferior order, these particles might possibly be separated, and then they might meet, and thus an abrupt passage from one velocity to another might take place, which is inconsistent with the law of continuity, previously established. Besides, our author, by rejecting the extension of the first elements of matter, and reducing them, as we have before observed, to mere physical points of attraction and repulsion, precludes all the difficulties that result from continual extention in body, and which have never been satisfactorily obviated. If the elements of matter are extended, each of them may be divided in infinitum, and each part may full be divided in infinitum. Can this division, it may be questioned, be actually made by the power of God or not? Can there be one infinit in number greater than another? Can there be a compound without a simple of the same kind? These difficulties, it is alleged, do not regard space, which is no real being; but they would regard matter, if it had continued extention. All these perplexities are laid to be removed by
MATTER.

maintaining, with Bofficovich, that the first elements of bodies are perfectly simple, and therefore inextensible. But if a particle of matter is not extended, in what respect does it differ from a point of space? M. Bofficovich says, it is extended with attractive and repulsive forces. But what is it before it is thus extended? Does it then differ from a point of space? It is next to impossible to form any satisfactory notion of such difference. A point of space, considered as an individual, is distinguished from another individual merely by its situation; it is, therefore, immovable, but matter is moveable. Have these forces, it is very properly asked, which make matter an object of sense, any substratum, any thing in which they are inherent as qualities? What are the things which these qualities distinguish from each other as individuals?

With regard to the exterior attractive forces of this system, there can be no question; because they constitute universal gravity, the effects of which are constantly perceptible. But between the interior repulsive and exterior attractive forces, we must admit many transitions from repulsion to attraction, and vice versa, at insensible distances, which are indicated to us by cohesion, fermentation, evaporation, and other phenomena of nature. Against this system, however ingeniously devised and ably supported by the celebrated author, many objections have been urged. That there should be no contact between bodies, is an assumption which will not be readily admitted by those who have long entertained different ideas on the subject; and yet Bofficovich himself allows, that bodies approach so near to one another as to leave no sensible distance between them, and our senses, it must be acknowledged, are impressed in the same manner by his repulsive forces as they would have been by solid bodies themselves. It has been said that M. Bofficovich, by denying the extension of atoms, annihilates matter; and to this objection we have met with no satisfactory answer. It has been also said, that upon this part of his system, there would be no difference between body and spirit. By others it has been alleged, that M. Bofficovich's repulsive and attractive forces are like the occult qualities of the Paracritics; but a similar objection has been urged against Newton's attraction; and it is equally groundless, because powers of this kind are sufficiently ascertained by their effects. Some have been indisposed to admit motion and collision without immediate impulse; and it must be confessed, that they are not easily explained and clearly understood upon his system.

For our author's mode of explaining them, and of applying his system to mechanics, &c. we must refer to the second part of the work already cited. His next object, in the third part, is to account on his system for the general properties of matter. Upon his theory matter is not impenetrable. Provided that any body move with a sufficient degree of velocity, or have sufficient momentum to overcome any power of repulsion that it may meet with, it will find no difficulty in making its way through any body whatever; for nothing will interstice, or penetrate another, but powers, such as we know do in fact exist in the same place, and counterbalance and over-rule one another; a circumstance which never had the appearance of a contradiction, or even of a difficulty. If the momentum of such a body in motion be sufficiently great, M. Bofficovich demonstrates that the particles of any body through which it passes, will not even be moved out of their place by it. With a degree of velocity something less than this, they will be considerably agitated, and ignition might, perhaps, be the consequence; though the progress of the body in motion would not be feebly interrupted; and with a still less momentum it might not pass at all. This theory M. Bofficovich has taken great pains to illustrate and confirm; shewing, that it is by no means inconsistent with any thing that we know concerning the laws of mechanics, or our discoveries in natural philosophy; and that a great variety of phenomena, particularly those which relate to light, admit of a much easier solution upon this hypothesis than upon any other. The most obvious difficulty, says Dr. Priestley, and, indeed, the only one that attends this hypothesis, as it supposes the mutual penetrability of matter, arises from the difficulty we meet with in attempting to force two bodies into the same place. But it is demonftrable, that the first obftruction arises from no actual contact of matter, but from mere powers of repulsion. This difficulty we can overcome; and having got within one sphere of repulsion, we fancy that we are now impeded by the solid matter itself. But the very fame is the apprehension of the generality of mankind with respect to the first obstruction. Why, therefore, says he, may not the next resistance be only another sphere of repulsion, which may only require a greater force than we can apply to overcome it, without disordering the arrangement of the confolent particles; but which may be overcome by a body moving with the amazing velocity of light?

This scheme of the mutual penetration of matter first occurred to Mr. Michell, independently of any communication with M. Bofficovich, on reading Baxter on the "Immateriality of the Soul." He found that this author's idea of matter was, that it was confituted, as it were, of bricks cemented together by an immaterial mortar. These bricks, if he would be confident in his reasoning, were again composed of less bricks, cemented likewise by an immaterial mortar, and so on ad infinitum. This putting Mr. Michell upon the confideration of the appearances of nature, he began to perceive that the bricks were so covered with this immaterial mortar, that, if they had any existence at all, it could not possibly be perceived; every effect being produced at least in visible infinities in ten certain, and probably in the tenth also, by this immaterial, spiritual, and penetrable matter. Mr. Michell, finding it necessary, in order to solve the appearances of nature, to admit of extended and penetrable immaterial substance, if he maintained the impenetrability of matter; and observing farther, that all we perceive by contact, &c. is this penetrable immaterial substance, and not the impenetrable one, began to think, that he might as well admit of penetrable material, as penetrable immaterial substance; especially as we know nothing more of the nature of substance than that it is something which supports properties; which properties may be whatever we please, provided they be not inconsistent with each other, that is, do not imply the absence of each other. This by no means seemed to be the case, in supposing two substances to be in the same place at the same time, without excluding each other; the objection to which is only derived from the repulsion we meet with to the touch, and is a prejudice that has taken its rise from that circumstance. Dr. Priestley observes, that if he were to make any alteration in this hypothesis, it would be to suppose the force of the sphere of repulsion next to any of the indivisible points, which constitute what we call solid bodies, not to be absolutely infinite, but such as may be overcome by the momentum of light. If, however, we consider that Mr. Bofficovich makes this nearly power of repulsion not to extend to any real space, but to be confined to the indivisible point itself, it may appear to be sufficient for the purpose.

The theory of M. Bofficovich is easily applicable to the cohesion of atoms, of more compounded particles, and of solid bodies. From the cohesion of particles he deduces the extension of bodies; because there must always be space between
MATTER.

between the particles. Extension, however, according to his sytem, does not suppose the continuity of matter; though we cannot perceive the small interval that subsists between the constituent parts of some bodies, and much less the distance between the simple elements that compose them. Figurability results from extension; and density from the various different quantities of matter that may be contained under the same figure and bulk; that body being the most dense, which contains in the same space the greatest number of atoms, and vice versa. But if these atoms are mere unextended points, it is not easy to conceive how any aggregate or combination of them can constitute a body of any supposed density. However, our author supposes that density may be augmented by the nearer approach of the atoms to one another; and of course a body of any given magnitude may be divisible beyond any assigned limits. An essential part of mobility in this system consists in forces, which, at certain distances, are determinations to motion. Universal gravity, which takes place in sensible distances, is perfectly intelligible in this system; though our author seems to suppose that, when it has extended to the sphere of the limits most distant from the sun, it may pass to repulsion, and again revert to attraction, and form limits of cohesion at the time the sun may be within such a limit with regard to the fixed stars, and our planetary system form only a small part of the whole universe.

But we are now advanced to the regions of mere conjecture and hypothesis. Our author has further extended his theory to the properties pertaining to different classes of bodies, such as fluidity, solidity, softness and hardness, flexibility, elasticity, viscosity; to the operations of chemistry; and to the explication of the phenomena of light, electricity and magnetism, and animal fermentation. Of his ample and various observations on these subjects, we can only select a few particulars. The parts of fluids are easily separated, and moved among one another, because they are spherical and very homogeneous, so that their forces are directed more to their centre, than to one another, and, of course, less obstructed in their motions. Some particles are mutually attracted in a very small degree, and others more sensibly, such as those of water and mercury. The particles of air are separated by a strong force of repulsion, which accounts for the great rarefaction of this fluid. Solid bodies are formed of substances of such figures, which occasion a greater cohesion than those of fluids, so that they are prevented from moving separately or round one another: of these forms are harder, as their constituent particles are placed in limits which have strong repulsive arches within them, and others, whose particles have their arches of repulsion weaker, are softer. Some are flexible, because their particles are placed in limits that have weak arches of repulsion and attraction on each side: and if these arches are short, the particles gain more limits of cohesion, and remain bent; but if the arches are longer, the former repulsion and attraction will continue to act and restore the body to its former position; and in doing this with an accelerated velocity, the parts will pass their former limits, and vibrate backwards and forwards, as is the case in a bowed spring: and thus our author accounts for elasticity. Viscous bodies, having less cohesion than solid, and more than fluids, adhere to others in consequence of an attraction which their particles acquire from their composition. Thus water itself adheres to some bodies, and is repelled by others; which variety is ascribed to the various respective forces derived from the different composition of their constituent particles. In explaining the composition of organic bodies, the author considers that particles may be so formed as to repel some and attract others, and thus accounts for vegetation, nutrition, and feculation: and as one particle may attract another in one part only, and repel it in every other situation, we may hence infer the orderly situation of the particles in many crystallizations. The process of various chemical operations and their effects are also explained by Boscovich, agreeably to his general system. Light he considers as an effluxion, emitted with great velocity from luminous bodies by a strong repulsion; and he attributes the phenomena of electricity and magnetism to various attractions and repulsions. Fire he supposes to differ from the electrical fluid merely in this circumstance, that fire is an actual fermentation, which is not the case with the electrical fluid. In explaining our bodily sensations, he ascribes what other philosophers attribute to the immediate contact of bodies to attractions and repulsions, which are adapted to cause that motion in our nerves, that is supposed to take place in the organs of sensation, and to be thence communicated to the brain.

We are happy to be able to close this concise and imperfect account of Boscovich's system with announcing to the philosophers, who may admit or reject it, that he was fully convinced of the necessity of admitting a self-existent, all-powerful, and intelligent Being, to whom he ascribes the creation of those materials that compose the universe, and the arrangements of them in their present beautiful form. Indeed, he expresses his astonishment, that any person who pretends to the name of a philosopher should refuse the evidence which the several parts of the visible universe afforded in proof of the existence of God, as the first cause of all. Chance, to which some have absurdly attributed the origin of the universe, he very justly considers as a word without a meaning; nor can he allow that the world has existed of itself in any form like its present from all eternity: God alone being eternal and actually infinite. He is also a strenuous advocate, not only for the principles and duties of natural religion, but for the excellence and benefits of that revelation which God has been pleased, in great goodnes, to communicate to mankind.

In conformity to the hypothesis of Boscovich and Michell, Dr. Priestley repudiates, that matter is not that inert substance that it has been suppose to be; that powers of attraction or repulsion are necessary to its very being, and that as part of it appears to be impenetrable to other parts. Accordingly, he defines matter to be a substance, polished of the property of extension, and of powers of attraction or repulsion, which are not distinct from matter, and foreign to it, as it has been generally imagined, but absolutely essential to its very nature and being: so that when bodies are divided of these powers, they become nothing at all. However, though he supposes that these powers are essential to the being of matter, insomuch that it cannot exist without them as a material substance at all, he by no means maintains that they are self-existent in it; but that from whatever source these powers are derived, or by whatever being they are communicated, matter cannot exist without them; and if that superior power or being withdraws its influence, the substance itself necessarily ceases to exist, or is annihilated. Whatever solidity any body has, it is polished of only in consequence of being endued with certain powers, and together with this caufe, solidity, being no more than an effect, must cease. Dr. Priestley, in another place, has given a somewhat different account of matter; according to which it is only a number of centres of attraction and repulsion; or more properly of centres, not divisible,
to which divine agency is directed: and as sensation and thought are not incompatible with these powers, solidity, or impenetrability, and consequently a *vitia inertiae*, only, having been thought repugnant to them, he maintains, that we have no reason to suppose that there are in man two substances absolutely distinct from each other. Disquisitions on Matter and Spirit, 1777, paffim. See SOUL.

Dr. Price, in a correspondence with Dr. Priestly, published under the title of a *Free Disquifition of the Doctrines of Materialism and Philosophical Necessity,* 1778, has suggested a variety of objections, in our opinion unanswerable, against this hypothesis of the penetrability of matter, and against the conclusions which are drawn from it. The *vitia inertiae* of matter, he says, is the foundation of all that is demonstrated by natural philosophers concerning the laws of the collifion of bodies. This, in particular, is the foundation of Sir Isaac Newton's philosophy, and especially of his three laws of motion. Solid matter has the power of acting on other matter by impulfe; but unfold matter cannot act at all by impulfe: and this is the only way in which it is capable of acting, by any action that is properly its own. If it be said, that one particle of matter can act upon another without contact and impulfe, or that matter, by its own proper agencies, repel or repel other matter which is at a distance from it, then a maxim hitherto universally received must be fals, that "nothing can act where it is not." Sir Isaac Newton, in his letters to Dr. Bentley, calls the notion, that matter possessles an innate power of attraction, or that it can act upon matter at a distance, and attract and repel by its own agency, an affurdity into which, he thought, no one could possibly fall. And in another place he expressly disclaims the notion of innate gravity, and has taken pains to shew that he did not take it to be an effential property of bodies. By the fame kind of reasoning purled, it must appear, that matter has not the power of attracting and repelling; that this power is the power of some foreign cause, acting upon matter according to flated laws; and that, confequently, attraction and repulfion; not being actions, much les inherent qualities of matter, as fuch, it ought not to be defined by them. And if matter has no other property, as Dr. Priestly afferts, than the power of attracting and repelling, it must be a non-unity; becaufe this is a property that cannot belong to it. Besides, all power is the power of fomethings: and yet if matter is nothing but this power, it must be the power of nothing; and the very idea of it is a contradiction. If matter is not folid extension, what can it be more than mere extension? Further, matter that is not folid is the fame with pore; it cannot, therefore, possess what natural philosophers mean by the momentum or force of bodies, which is always in proportion to the quantity of matter in bodies, void of pore. Momentum is the caufe of reftance, and not *vice versa.* Moreover, within the sphere of repulfion, the attraction of cofion takes place; and this is the power which, according to Dr. Priestley, unites the parts of matter, and gives it reftance. But, fince matter is penetrable, will not this attraction drive all the parts of it into one another, and confide them to coalesce into nothing? This effeet muft follow, unless there exifts, beyond the sphere of attraction, and nearer to matter, a second sphere of repulfion, which again prevents contact. Thus it appears evident, that if a power of attracting acts, it must contract itself into nothing; and that if a power of repulfion acts, it must diffipate itself into nothing. For a farther account of the arguments *pro and con* on this subjed, we must refer to the work already cited.

MATTUCCI, IL CAVALIERE, in Biography, a Neapolitan finger, poifled of a voice fo extraordinary, and a manner of finging fo perfect, that he was regarded at the head of his profession. After having been long in the service of the court of Spain, he returned to Naples, where he ftill lived in 1730. At fourfocre years of age he had fill a voice as firm, fweet, and flexible, as in his youth.

MATHIEU, ST., in Geography, a small ifland in the North Pacific ocean, about 140 miles from the south-eaft coast of Ruflia. N. lat. 60° 20'. E. long. 175° 10'.

MATTHESON, JOHN, in Biography, a native of Hamburg, was born in 1681. He was the fon of a Lutheran clergyman, and seems to have been educated with great care. Among his early studies, at seven years old he was allowed a music-mafter, under whom he profefled fo rapidly, that at the age of nine he was able to fing to the organ, in the church at Hamburg, anfems of his own compofition.

But while he was fo eagerly pursuing the study of music, he made himself mafter of modern languages, and applied part of his time to the study of the civil law, attending the public lectures by turns of two doéors learned in that faculty. But we fhall chiefly confine ourselves to his prografs in music, and the use he made of his attainments in that art; as his connection and conflict with Handel, early in their feveral lives, have rendered him an interefling perfonage to our readers of musical history.

At the age of eighteen he composed an opera in the German language, called the "Pleidias," and performed a principal part in it himfelf.

Handel, in 1703, at the age of nineteen, on the death of his father, in order to avoid being burthenfome to his mother, went to Hamburg, and engaged himself in the opera band of that city, as a fecond ripieno violin. He and Matthefon foon became acquainted, by accidentally meeting each other in an organ-loft, where Handel was prafticing at the time that Matthefon went thither for the fame purpofe. After this they fumbled and visited churches together, in order to exercife themselves on the organ.

As their young fudents lived much together, in great intimacy, they had frequent trials of skill, and, in friendly emulation, had frequent contentions in musical knowledge and talents: in the latter, it appearing that they excelled on different instruments, Handel on the organ and Matthefon on the harpsichord, they mutually agreed not to invade each other's province, and faithfully obferved this compact during five or fix years.

Matthefon tells us, that no one except himfelf knew that Handel could play on any other instrument than the violin; "but his superior abilities were foon discovered, when,
upon occasion of the harpsichord-player at the opera being absent, he was persuaded to take his place; for he then showed himself to be a great master, to the astonishment of every one except myself, who had frequently heard him before upon keyd-instrument.

About this time an opera, called "Cleopatra," composed by Mattheson, was performed on the Hamburg stage, in which he acted the part of Antony himself, and Handel played the harpsichord; but Mattheson being accustomed, at the death of Antony, which happens early in the piece, to take the harpsichord in the character of the composer, Handel refused to indulge his vanity by relinquishing to him that part, which occasioned so violent a quarrel between them, that, at going out of the theatre, Mattheson gave him a flap on the face; upon which, both immediately drew their swords, and a duel ensued in the market-place, before the door of the opera-houfe: luckily the sword of Mattheson was broken against a metal button upon Handel's coat, which put an end to the combat; and they were soon after reconciled.

This rencontre happened on the 5th of December 1704; and as a proof of their speedy reconciliation, Mattheson tells us that, on the 30th of the same month, he accompanied the young composer to the rehearsal of his first opera of "Almira," at the theatre, and performed in it the principal part; and that afterwards they became better friends than ever.

On the 25th of February, in the next year, Handel produced his second opera, called "Nero," which had likewise a very favourable reception. It was at the end of the run of these two dramas that Mattheson, who performed the principal man's part in both, quitted the stage, on being appointed secretary of legation to Sir Cyril Wych, resident at Hamburg from the English court.

Mattheson, with all his failings, was certainly a man of quick parts, diligent cultivation, and talents of various kinds; but as a musician, he had more knowledge than taste. Many stories were long in circulation at Hamburg, concerning his pedantry, vanity, and eccentricities. Long after he had ceased to play and compose, he continued to write musical treatises, of which the names are now hardly to be found. All the music we have seen by Mattheson is sterile of ideas and uninteresting. It has been said, that he was a great performer on the harpsichord, and that Handel often amused himself in playing his pieces; in doing which, if ever he regarded Mattheson as a formidable rival, his triumph must have been very complete in comparing them with his own, or with the inherent powers which he must have felt of producing better whenever he pleased. We are in possession of twelve Leffons by Mattheson, engraved on copper by Fletcher, in tall folio of 16-lined paper, London, 1714, who, in a preface, speaks of them as "pieces which claim precedence to all others of this nature, as being composed by one of the greatest masters of the age, in a style altogether pleasing and sublime."

They cooal, like other sets of leflons of that period, of overtures, preludes, fugues, allemandes, courants, gigue, and airies; but notwithstanding the editor's eloquence, they resemble all the harpsichord music which we ever saw, anterior to Handel's admirable "Suites de Pieces," first set in 1720; though, in good harmony, they imprefs the mind with no better idea of accent, grace, or passion, than the jingling of triangles, or bells of a pack-horse; and, indeed, are such as degrade the instrument to the level of "founding brafs, and a tinkling cymbal."

There is a lift of Mattheson's works in Walther's Musical Lexicon, as far as the year 1732, amounting to forty; but as he continued writing to the left, and lived till 1764, it is probable that he kept his promise of printing as many works on the subject of music as he had lived years, and still leaving to his executors as many more in manuscript for the use of posterity.

Mattheson bequeathed at his decease all his possessions to the republic of Hamburg, on condition that such an organ should be built for the great church as he described in his will. It had not been long finished when we saw and heard it, in 1772; but we believe it to be the largest and most complete in Europe. It cost upwards of 4000. sterling, was built by Hildebrand, is of 32 feet, has four sets of keys, long compass, up to F in altifimo, and, with the pedals, goes down to double C. The keys are covered with mother-of-pearl and tortoise-shell; the front is curiously inlaid, and the case richly ornamented. There are 64 stops in this organ; and a swell attempted, but with little effect; only three stops had been allowed to it, and the power of crescendo and diminuendo was so small, that if we had not been told there was a swell, we should not have discovered it.

Mattheson's picture is placed in the front of the organ gallery, and there is a Latin inscription under it recording the benefaction. This good man had more pedantry and non sense about him than true genius. In one of his vocal compositions for the church, in which the word rainbow occurred, he gave himself infinite trouble to make the notes of his score form an arch. What pity this arch was not repreented in the front of his instrument, where, upon the principle of Pere Cailef's Clavecin Oculaire, his arch might have had all the colours as well as the curvature of the rainbow! See Pere Cailef, and Clavecin Oculaire.

The rainbow story may serve as a specimen of Mattheson's taste and judgment with respect to the propriety of musical expression and imitation.

By his last will and testament, an anthem was performed at his funeral, which he had himself composed for the occasion; but it excited more laughter than sorrow, when heard in its old-fashioned grace. Yet, in spite of ridicule, he was certainly poffessed of a great share of musical erudition, and was of great use to his countrymen in his younger days, by bringing them acquainted with music of other parts of the world, and by introducing a better style among them than their own. He was left fond of fugues than his contemporaries; but in his latter days he became a mere theorist, without taste or feeling.
